These were but floating exceptions, for there were others who were admirable dispensers, and in all other respects to be commended. They could scarcely attain the dexterity acquired by what might justly be called the permanent staff, amongst whom I am bound to mention William Henry Baigent, from whom I learned more practical pharmacy than from any other source.

He spread plasters which would compete with the best machine work, the rapidity of the execution being only equalled by the beauty of the finish ; no dispenser I have yet seen could surpass him in the art of making an emulsion. His career was marked by strange contrasts ; curiously parsimonious during his long stay at Godfrey's, he subsequently became generous and open-handed, of which his gift of £100 to the Benevolent Fund is proof, and after years of an utterly secluded life, he took so keen an interest in the affairs of the city as to become Master of the Haberdashers' Company.

One great wave of business swept over the house and strained its resources to the utmost ; other establishments can refer to a similar experience. This was the dire invasion of cholera to which all England was exposed in 1848-49. In one year 53,293 persons are reported to have died in England and Wales of the epidemic. Never since the plague had there been so terrible a scourge. The laboratory was closed, except for the distillation of aromatic waters, chiefly aqua cinnamomi, and the preparation of remedies recommended by the Board of Health.

Essence of Mixed Spices.

[Used during the cholera epidemic.]

Ol. Myristicæ	ʒij.

The porters had to become assistants and help as best they could ; no one who went through that appalling visitation would wish for any purposes of gain to repeat that experience ; even the old laboratory porter was pressed into the service. His name was Leader, and as a specimen of bygone pharmacy he may be described. When I saw him first he was an antique in keeping with his surroundings, one on whom succeeding years seemed to make no impression. The date of his introduction to the firm was a mystery to the younger assistants, whom as young men he cordially despised. Sometimes he would enumerate former assistants, but he invariably left one out, as he had only stayed five years. Leader could write his name so that those skilled in autographs could read, he would talk of ingredients, and for some reason call unburnt furnace coal "green meat," but no one better knew how to light a laboratory fire or how to work a still, or how to guess a temperature by instinct. Alas ! the day when he went for a week to Greenwich and I tried single-handed to finish the carmine. It would not come, but Leader fortunately did, and all was peace. From that time it was only by compulsion that he would take his holiday, being thoroughly convinced that Godfrey and all his works would perish were he not at hand to avert the ruin.

When the firm went westward, Leader was no more a power ; new environment he could not understand, but nothing would persuade him to accept full salary for his past services and retire.

Constantly the old man dozed in the new laboratory, which he held in supreme contempt, till one morning he was found in his Covent Garden lodgings, quietly asleep, to rise in this world no more.

Two more extracts must end the record.

The Docteur Noir comes upon the scene. He was a West-Indian creole, tall and handsome, dressed in a faultless manner, a striking personality, so closely resembling Dumas the elder that when he made his appearance in Southampton Street I thought it was Alexandre in person. The Docteur was furnished with the highest testimonials and recommendations ; almost immediately he gained the confidence of some of our leading surgeons, and had an extensive and most lucrative practice among the best London circles. He professed to cure cancer, relying on a strong astringent ointment, the basis of which was krameria with chloride of zinc. The subsequent treatment, as far as we could judge, consisted in prescribing ounce packets of Radix Sarsæ, with directions for making the decoction ; also—he had a Vinum Ferri of his own, and once he compelled Leader to make it strictly to order, which was to plunge a red-hot iron into Malaga wine. (The method is sanctioned by mediæval authority.) The expected happened for the vessel was shattered, and its contents violently projected over the laboratory. The success of the Black Doctor was phenomenal, he lived in luxurious style, and kept his carriage ; he was honourable in all his financial relations, contracting no debts whatever.

In an evil hour he went to Paris and undertook to perform his cures under the watchful superintendence of the hospital authorities. Paris proved his downfall, for he was charged with empirical practice, and his career came to an ignominious conclusion.

After a long reign, King George III. was gathered to his fathers, and George IV. was crowned. The old firm had long enjoyed the privilege of sending twelve smelling bottles to the State Drawing Rooms for the use of the ladies of the Court ; they now applied to be permitted to supply the anointing oil, and they presented, on June 7, 1821, the following petition :—

"To the Lords Commissioners of the Court of Claims,

"May it please your Lordships,

"We, the undersigned, successors of the late Ambrose Godfrey, chemist, beg leave very respectfully to lay before your most honourable Court, the statement of his having had the honour of preparing the Oil used in anointing his late most gracious Majesty at his coronation ; and we have reason to believe that the same privilege had been enjoyed by his predecessors on similar occasions since their first establishment in the year 1680, but in consequence of those records having been accidentally destroyed, we presume not to urge any positive claim, though with due submission to your most honourable court, we offer ourselves to your consideration and favour, desiring to be appointed to perform the like service at the ensuing coronation of His present most gracious Majesty George the Fourth, whom may God preserve. Signed."

We learn from the *Times* (June 8, 1821) that the petition was returned to the applicants on the ground that the Court had no jurisdiction : so George the Fourth was not anointed with Godfrey's oil, which may account, and I think does, for the subsequent badness of his career.

OREXINE IN ANOREXIA.—Penzoldt finds that the base orexine is preferable to the hydrochloride in the treatment of anorexia, since it is less likely to produce vomiting than the salt. It should be given in 5-grain doses in a lozenge capsule, followed by a draught of about half a pint of fluid. Experiments on a wide range of cases, including many different diseases which were accompanied by loss of appetite have been treated with with marked success. The dose was generally given at about 10 in the morning. It frequently requires to be repeated for five days before the full and permanent effect is observed (*Therapist*, v., 100).

THE PRESERVATION OF CHLOROFORM.

BY D. B. DOTT.

The subject of the decomposition and preservation of chloroform has been ably investigated and discussed by D. Brown and D. Rainy Brown (*Ph. J.* [3], xxiii., 792, and xxv., 836), also by Schacht and Biltz (*Ph. J.* [3], xxiii., 1005). More recently, L. Allain (*Journ. de Pharm.* [6], xv., 252; *Ph. J.*, lv., 261) drew attention to the fact that sulphur, added in the proportion of one to a thousand of chloroform, acted as a preservative, preventing decomposition in chloroform exposed to diffuse daylight for an indefinite period. Allain does not explain the action of the sulphur. As it was shown in the papers above referred to, particularly by the Messrs. Brown, that oxygen is essential to the decomposition of chloroform by light, and that chlorine is always present at the earlier stages of alteration, it seemed probable that the sulphur acted as a reducing agent, and that any substance slightly soluble in chloroform and readily oxidisable would likewise act as a preservative. I therefore divided some pure absolute chloroform in four bottles. To the first was added a minute portion of morphine, to the second gallotannic acid, to the third hypophosphorous acid, and the fourth was left pure and simple. These were all exposed in a glass case to diffuse daylight, but where occasionally rays of direct sunlight reach. After a few weeks the pure chloroform showed signs of decomposition, distinctly evident to the nose and to silver nitrate. None of the others had decomposed, and even after a month's further exposure are still apparently unaltered. It therefore appears probable that any substance which is prone to oxidation and soluble, however slightly, in chloroform will prevent or greatly retard decomposition. If that is correct, one would infer that the preservative action of alcohol is partly due to its capacity for oxidation, whatever secondary part it may also play.

COCAINE IN OINTMENTS—A CAUTION.

BY WILLIAM JOHNSTON.

An illustration of the proneness of cocaine to decomposition recently came within my ken. A dispenser received the following prescription one evening when busy with other duties, and was told the ointment must be made up that night:—"Creolin, 80 minims; cocaine hydrochlorate, 132 grains; lanoline, 2 ounces." He had previously dispensed it for the same patient. Then he used boiling water to warm the mortar. This time boiling water was not available at the moment, but the hob was hot and handy, so the latter source of heat was resorted to. It was noticed that the mortar was pretty hot when used. The ointment was sent out in due course, and no more was thought of it till a day or two after, when it was returned with the complaint that there must be something wrong with it. The previous lots it was stated, had soothed the irritation of eczema like magic, but this had no effect at all. The dispenser scratched his head. He knew he had put the full quantum of cocaine in, and why shouldn't it minister comfort as before? Suddenly the thought of the warm mortar flashed across his mind, and the reason was clear. The alkaloid had decomposed in the hot fat and become useless. That such was the case was afterwards proved by a return to hot water as a warming medium. Another batch of ointment, made from the same lot of cocaine as before, yielded the original amount of satisfaction. Said satisfaction was somewhat one-sided, for the transaction left the chemist a poorer man by several shillings. However, the loss in cash was counterbalanced by the gain in experience, both to himself and perhaps to some readers of the Journal.

REVIEWS AND NOTICES OF BOOKS.

THE MEDICAL ANNUAL AND PRACTITIONERS' INDEX, 1896. By Various Authors. Pp. 732. Price 7s. 6d. net. (Bristol: John Wright and Co. London: Simpkin, Marshall and Co. 1896.)

The issue of this annual for the present year fully maintains the reputation established by the thirteen previous volumes. It is of the highest service to medical practitioners who wish to keep abreast with the rapid progress of their many-sided profession. The names of the contributors sufficiently attest the authoritative character of the work, and after a careful perusal of the present volume, it may be added that the alphabetical arrangement of the sections and the lucid style of the writers, together with the numerous and admirable illustrations, render the task of obtaining information a light one. In every department of medicine and pharmacy the past year's progress is clearly indicated and brought into relation with the previously established facts of medical science. As might have been anticipated in this Listerian age, the sections dealing with surgical subjects are particularly well done. The article on abdominal surgery by Mayo Robson, that on club-foot by Jones and Ridlon, and that on diseases of the ear by Dundas Grant may be especially mentioned. The article on the sensory distribution of spinal nerve-roots by Thorburn is of equal importance to both physicians and surgeons. Whilst, however, the surgical subjects are especially striking the medical and pharmaceutical sections are thoroughly well done, and full references are given to the original articles for those who require to consult them. A perusal of the section on the "Progress of Pharmacy" shows that the Germans are still in advance of other nations in scientific pharmacy. Among the useful preparations of German origin argentamine (ethylene-diamine silver phosphate), a non-coagulable silver phosphate, and formalin, a 40 per cent. solution of formic aldehyde, may be mentioned. Another German preparation, loretin (meta-iodo-ortho-oxyquinoline-ana-sulphonic acid) recommended by Schinzinger as a substitute for iodoform has yet to be tried by surgeons. It is to be hoped it may prove a successful substitute. In the chapter on new remedies it is noted that two cases of nephritis have been observed to follow the administration of β -naphthol. One of these cases proved fatal—a sufficient indication for caution in the employment of new drugs. It is hardly necessary to give further examples, and this notice may be concluded by stating that to pharmacists, as well as to doctors, the book is a reliable guide to the direction of progress in the medical world.

THE CHEMIST'S COMPENDIUM. Compiled by C. J. S. THOMPSON. Pp. 230. Price 2s. 6d. net. (London: Whittaker and Co., 2, White Hart Street, Paternoster Square. 1896.)

In the preface to this compilation it is suggested that, with the constant and increasing growth of pharmaceutical and kindred literature, pharmacists have doubtless felt the want of a book of convenient size, embodying the essential points of the many subjects of use to them in the daily exercise of their craft. Continuing, the compiler states that "this work is designed to supply this deficiency, and simply act as a handy-book of reference. It is also intended to serve as an introduction and guide to the standard text-books on the subjects included." Without entering upon a detailed criticism of the book, it is sufficient to remark that considerable revision will be required before it can fairly claim to serve the desired end. The pages on "Organic Materia Medica," in particular, require extensive emendation, and numerous discrepancies are apparent elsewhere on even a cursory examination. This is certainly not consistent with what is expected in "a handy-book of reference." The article on "Media for Mounting Sections," by the way, which is copied verbatim from the *Pharmaceutical Journal* (ser. 3, xxiii., 649), is wrongly attributed to Squire.

NOTES AND QUERIES.

FORMALDEHYDE FOR HARDENING SPECIMENS.

By the use of a four per cent. solution of formaldehyde, Mr. Thelwall Thomas has been able to harden in a few hours any piece of tissue placed in it. The specimens of tumour, etc., so hardened, readily froze on an ether microtome, and the sections could be stained with hæmatoxylin after immersion in methylated spirit.

PREPARATION OF RED MARROW.

In order to obtain red marrow in the most perfect state and liberal supply, the Liquor Carnis Company recommends in the *British Medical Journal* that the breast-bones of calves and other young animals should be broken, and the semi-fluid marrow poured out. What remains can be extracted by covering the bones with glycerin, and allowing them to remain for three days, turning each day. The marrow can afterwards be separated from the glycerin in a variety of ways.

SILVERING GLASS.

The following method has been recommended by B. J. Edwards, at a meeting of the Liverpool section of the Society of Chemical Industry:—Dissolve silver nitrate, 15 grains, in water, 6 fluid drachms, and add strong ammonia drop by drop until the precipitate first formed is re-dissolved. Next, dissolve caustic potash, 15 grains, in water, *q.s.*, and then add enough ammonia to not quite dissolve the precipitate formed. Filter this solution, and add the silver nitrate solution until the mixture is of the colour of weak tea. Then make up to 3 fluid ounces with distilled water, and add commercial grape sugar, $7\frac{1}{2}$ grains, dissolved in water, *q.s.* On pouring the finished liquid into a glass vessel, it is said to deposit a good film of silver in 15 or 20 minutes. If a thin, transparent film is required, so that the mirror can be looked through as well as into, the silver may be protected by a coating of celluloid varnish.

PALATABLE CASTOR OIL.

☞ Dissolve pure saccharin, 30 grains, in hot alcohol, $\frac{1}{2}$ fluid ounce, then add to castor oil (up to 1 pint) and mix thoroughly, after which add peppermint oil, 5 or 6 drops, to flavour. According to Edell (*Spatula*) this mixture has a more pleasant taste than any other combination of the oil.

LOTION FOR CHAPPED HANDS AND FACE.

According to *Meyers Bros'. Druggist*, a second application of the following lotion is rarely required:—Mix compound tincture of benzoin, 10 minims; alcohol, 2 fluid drachms; rose water, 30 minims; and glycerin, 1 fluid drachm. Apply to the chapped surfaces at night, after they have been washed with warm water and soap and thoroughly dried.

LABEL VARNISH.

A limpid, colourless varnish, which dries readily, and is not too brittle or easily affected by liquids, is prepared as follows (*National Druggist*):—Macerate together sandarac, 60 parts; mastic, 25; camphor, 1; lavender oil, 8; Venice turpentine, 4; ether, 6; alcohol, 44. Shake occasionally until the solids are dissolved.

APPLICATION FOR NEURALGIA.

Sabbatani paints the following solution on the painful parts:—Menthol and guaiacol of each 15 grains; absolute alcohol, 5 drachms. Rather less than a drachm is applied with a brush two or three times in twenty-four hours, the surface being afterwards covered with cotton wool (*Practitioner*).

ATROPINE SULPHATE AS AN ANTIDOTE IN OPIUM POISONING.

The value of the hypodermic injection of atropine sulphate in opium poisoning is illustrated by Dr. Paton's successful treatment of a case of attempted suicide, in which a female Chinese patient swallowed an infusion of 2 ounces of smoking opium. The solution of atropine sulphate was administered at intervals in 20-minim doses of 2 grains to the ounce solution, afterwards increased to 4 grains to the ounce. The total amount of sulphate injected amounted to $1\frac{1}{3}$ rd grain. Complete recovery resulted in a short time (*Lancet*).

SOLDER FOR ALUMINIUM FOR DENTAL WORK.

☞ Richards recommends the following:—Aluminium, 1 part; 10 per cent. phosphor-tin, 1 part; zinc, 11 parts; and tin, 29 parts (*Brit Journ. Dental Science*).

PARLIAMENTARY INTELLIGENCE.

METRIC SYSTEM OF WEIGHTS AND MEASURES.—A petition has been presented to the House by Mr. Boulnois (E. Marylebone) from the London Association for Protection of Trade—an Association said to comprise 4000 members, who are mostly retailers. The petitioners urge the adoption of the report of the Select Committee of 1895. This action of the London traders will probably be followed by pharmaceutical associations in various parts of the country.

THE STANDING COMMITTEE ON TRADE, under the vigorous chairmanship of Mr. J. E. Ellis, is making rapid progress through the forest of amendments which blocks the way of the Shops Bill. Clauses 1 to 4 have now been disposed of. Clause 1 was published in last week's issue of the Journal (p. 232). Clauses 2, 3, and 4 are now given as amended, and it may be possible in the next issue of the Journal to give the whole Bill in its altered form. New matter is indicated by the square brackets, and attention is called to deleted words. Unimportant verbal alterations are not noticed.

2. With respect to an order of a local authority under this Act the following provisions shall have effect; that is to say,—

- (1.) The order shall take effect at a date named therein, being not less than one month ("or two months" deleted) after the making thereof, and shall before that date be published in such manner as to the local authority making the order may appear best fitted to insure publicity for the same.
- (2.) The order may, if the local authority see fit, be expressed to have effect only during any specified part or parts of the year, and shall have effect accordingly, but, unless so limited, shall have effect throughout the year until amended or revoked.
- (3.) The central authority shall make regulations as to the form of such orders and of applications for the same, and [respecting the making of lists of persons whose consent is required for the purpose of putting the Act in force, and] as to the evidence to be produced respecting the proportion of persons signing such applications, and any such regulations shall be published in such manner as the authority making the same may direct, and shall have effect as if they were enacted in this Act.
- (4.) [For the purposes of this Act the local authority shall have power to frame such classification of shops according to trades as they may deem necessary having regard to the circumstances of the locality.]

3.—(1.) An order of a local authority under this Act may be amended by a subsequent order made upon the like application, and subject to the like provisions, and having the like effect as if it were an original order.

- (2.) If at any time it is made to appear to the satisfaction of the local authority that the occupiers of more than one-third in number of the shops to which an order for the time being in force under this Act relates, or of any class of such shops, are opposed to the continuance of the order, the local authority shall (formerly "may") revoke the said order, or revoke the same in so far as it affects such class of shops as aforesaid, and thereupon the order, in so far as it is so revoked, shall cease to have effect, but the revocation of an order shall be without prejudice to the making of another order under this Act.

4. If any question arises as to the class or classes of shops to which any particular shop belongs [or as to whether any particular place is a shop within the meaning of this Act, or as to whether a shop is or is not within the limits of the part of a district to which the order relates], such question may be referred to [any] court of summary jurisdiction [having jurisdiction within the district] which may hear and determine the question.

SHOPS (EARLY CLOSING) BILL.—It has been ordered that the Standing Committee on Trade shall have leave, until it has concluded the consideration of the Shops Bill, to continue to sit notwithstanding the sitting of the House. This would seem to point to a determination to accelerate the passage of the measure through the remaining stages of its parliamentary ordeal.

COMPANIES BILL.—This Bill was read a second time in the House of Lords, on Thursday, March 19, on the motion of the Earl of Dudley. No further progress with the Bill is possible till after April 21, to which date the House of Lords has adjourned for the Easter Vacation. It will, however, be taken in Committee on the first sitting day after the recess.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, MARCH 28, 1896.

POOR LAW DISPENSERS.

IN the proceedings of the July meeting of the Council, reported on page 13 of the last volume of this Journal, reference is made to the then recently promulgated order of the Local Government Board permitting the appointment of army compounders as Poor Law Dispensers. The Council thought that so retrograde a movement on the part of a Public Department called for some action, and the PRESIDENT was, therefore, authorised to approach the Local Government Board on the subject in the interest of persons registered under the Pharmacy Acts. As a result of the oral representations made by the PRESIDENT to the proper officials, it is understood that the Department is willing to consider any arguments that may be advanced against the General Order above referred to. A *précis* of the statement which has just been officially transmitted to the Board by the Secretary of the Pharmaceutical Society has been placed at our disposal, and we are enabled to briefly epitomise the principal items in the document.

It is first pointed out that the training of an army compounder comprises a six months' course of instruction in a military hospital under the supervision of an officer, (presumably a medical officer) and a duly qualified compounder. The duly qualified compounder is thus constituted pharmacy instructor after his own six months' course, and is not likely to be in a position to convey a very high quality of technical knowledge to the mind of his pupil. Further it is shown that the course itself is meagre, and does not include translation from Latin to English of instructions as to the use and dose of medicines. Moreover, there is no guarantee that even the course prescribed is conscientiously enforced in every case, nor is it clear whether the qualification is obtained at the end of the course by examination or by adjutant's order. At any rate, evidence is given that the process of converting a private soldier into a compounder is not a difficult one. On behalf of persons who have passed through an adequate period of training in pharmacy and the allied sciences, and who possess a legally recognised certificate of competency under the Pharmacy Act, 1868, it is therefore urged that the General Order of June 7, 1895, be modified.

The Society's statement proceeds to press home the fact that the qualification of an army compounder is not an adequate guarantee that the holder has had the special

practical training, or acquired that special technical knowledge requisite to properly (*i.e.*, safely) perform the duties of a dispenser, as set forth in the instructions issued by the Local Government Board. These instructions are published at page 212 of the Society's Calendar for 1896, and need not be particularised here. But two examples may be given. Under Section 5 of the instructions it is the duty of the dispenser "to make such pharmaceutical preparations for use in dispensing prescriptions as he may be required to make from time to time." How could an Army compounder be expected to personally make such preparations on the experience obtained during six months in a military hospital, where it would be almost impossible to get the necessary practical knowledge, and where whatever teaching was imparted would be given by a person possibly as ignorant of practical pharmaceutical operations as the pupil? Again, the dispenser to a Poor Law Union has "to prepare and dispense skilfully and cautiously all prescriptions," etc., etc., and to "express in writing" the proper directions. As medical officers to Poor Law Guardians do use Latin in their directions to dispensers, and, in fact, rarely use anything else, an army compounder, who is officially allowed to be ignorant of Latin, cannot efficiently or safely fulfil that duty. In the words of the Society's statement, "apart from the danger likely to arise from a haphazard rule-of-thumb manner of translating medical prescriptions, it is difficult to imagine why a class of individuals unable to fulfil the duties appertaining to a public appointment should be declared, on authority, to be eligible to hold that appointment." It is finally argued that as an army compounder is not permitted by law to keep open shop for retailing, dispensing, or compounding, it is manifestly unjust that the inmates of public infirmaries should have a smaller measure of protection accorded them than that provided by the Legislature for the general public.

COLLEGE COURSES IN PHARMACY.

CONSIDERABLE interest is at present being taken in the United States in regard to the length of college courses for pharmaceutical students. The American Pharmaceutical Association unanimously adopted a resolution declaring that at least six months' regular attendance at a school of pharmacy, with not less than one hundred hours of school work monthly, ought to be required by law as a necessary condition of registration as a pharmacist. In Wisconsin, partial effect has been given to this resolution by an amendment of the pharmacy law, which provides that all candidates for registration as pharmacists shall be given substantial credit for the courses of education pursued at pharmaceutical schools or colleges. That is to say the time spent at a recognised school is to be reckoned as the equivalent of a certain amount of experience in a pharmacy, or recognised in some other way by the boards of pharmacy.

The *Bulletin of Pharmacy* thinks it would probably be found practicable at the present time and under existing conditions, to count a satisfactory completed college course of any number of months as at least equal to the same number of months' employment in a pharmacy, with the limitation that no one shall be registered as a pharmacist without having had two years' experience in a pharmacy, exclusive of any college courses. The same journal recommends the non-recognition by boards of pharmacy of any titles or degrees (?) conferred by colleges or schools, except in so far as may be

convenient for systematising and facilitating the work of registration. The distinction made in Great Britain between the Major and Minor examinations and certificates is commended, and just as several American States now also recognise two classes of pharmacists, it is suggested that two definite standards should be recognised for special pharmaceutical college courses, one designated as the Minor course and the other as the Major course. It does not appear to be understood, however, across the Atlantic that neither of the British certificates carries with it any proof of college training. They simply indicate that the holder has passed examinations—the first compulsory, the second voluntary—in certain subjects. It is our chief lack in this country that these certificates are not evidence of systematic training, and the proposal to allow a college course to count as equivalent to part of the period of pupilage in the pharmacy may be worth consideration here, as leading the way towards a better system.

The proposal to recognise two definite standards, if implying the existence of two classes of pharmacists, is not one that should be endorsed. The trend of opinion in this country is almost entirely in favour of the same conditions being imposed upon all candidates for registration, as is, indeed, the case now. The term "Minor," as applied to the qualifying examination, is a complete misnomer, and must sooner or later be replaced by some more accurately descriptive term. The chief needs of pharmacy in Great Britain, and probably in the United States also, are power to enforce—before apprenticeship or pupilage—the passing of a suitable scholastic examination, also to insist upon at least two years' experience in a retail pharmacy, and a special school course of not less than one year. The holder of the legal qualification ought to be eligible for all the privileges now reserved by law for those who pass the highest examination, and the opinion is very general that some other distinctive title should be reserved for those who choose to devote more time to study and to pass another examination of a higher standard. It may be found advisable to have a lower qualification for mere retailers of drugs, etc., but there ought not to be more than one class of pharmacists, and there should be a strict line of demarcation between titles acquired by registration and those conferred for special work.

THE COST OF TECHNICAL EDUCATION.

THE return made to the Department of Science and Art, and just published, shows that the total amount expended on technical education during the year 1893-94 in England, Wales, Scotland, and Ireland was £647,631 18s. 7d., and that the estimated total expenditure for 1894-95 was £737,420 15s. 1d. This is in addition to the sum of £42,861, which is to be devoted annually to intermediate and technical education, in accordance with the Welsh Intermediate Education Act. The total amount of the residue paid to the Councils of Counties and County Boroughs in England and Wales, in respect of the financial year 1893-94, was £786,768 12s. 3d., of which £634,837 5s. 8d. was appropriated to educational purposes. Scotland received £54,430 13s. 8d., of which £35,111 10s. 1d. was appropriated to technical education, whilst the total amount expended on technical education by nine local authorities in Ireland was £4339 9s. 11d. in 1893-94, and the estimated total expenditure during 1894-95 was £4748 16s. 6d.

PHARMACEUTICAL SOCIETY

SCHOOL OF PHARMACY PRIZE EXAMINATION QUESTIONS.

Session 1895-96.

MATERIA MEDICA.

PROFESSOR HENRY G. GREENISH.

Monday, March 23, 1896.—11 a.m. to 2 p.m.

1. Carefully describe the characters which would enable you to recognise the following drugs:—Sassy bark, Indian pink, sandarac, pellitory root, quilla bark, Peruvian coca, Curaçoa aloes, scammony, belladonna root.
2. State the botanical source, natural order, habitat, and principal constituent of the following drugs:—Jaborandi, elemi, frankincense, Indian pink, mezereon bark, logwood.
3. Write a short account of storax.
4. In what tissue or tissues are the following drugs formed:—Aloes, lactucarium, guaiacum resin, scammony, myrrh, goa powder?

THEORY AND PRACTICE OF PHARMACY.

MR. INCE.

Monday, March 23, 1896.—3 to 6 p.m.

1. Describe in full, Adeps Præparatus and Adeps Lanae; their mode of preparation and employment in pharmacy.
2. Suggest methods for the emulsification of Lard, Spermaceti, Castor oil, Balsam of Copaiba and Phosphorated oil.
3. Note Suppositoria, pharmacopœial or otherwise, in the dispensing of which special precautions are required.
4. Show that ten grains of Extractum Nucis Vomicae should yield one grain and a half of total alkaloid.
5. Write in technical Latin: Macerate in a covered vessel, with frequent agitation for four days, then decant and filter. Let it be kept in a well-stoppered glass bottle.

BOTANY.

PROFESSOR GREEN.

Wednesday, March 25, 1896.—11 a.m. to 2 p.m.

[Four Questions only to be answered.]

1. What is a sporangium? Describe its development in any plant you please. Compare the sporangia of a fern with those of a Phanerogam.
2. Describe the structure and mode of development of the seed. Explain how it is that this structure is only found in the Phanerogams.
3. What is chlorophyll? Give some account of its functions, and the conditions under which they are performed.
4. Draw a diagram of one of the steles of the fern, and point out the tissues of which it is composed.
5. Give a short sketch of the different kinds of branching found among flowering plants. Compare the branching of the leaf with that of the stem.

PRACTICAL BOTANY.

PROFESSOR GREEN.

Wednesday, March 25, 1896.—3 to 6 p.m.

1. Make a delicate transverse section of the tissue provided. Sketch the appearances it presents, and identify all the structures it contains, pointing them out in your sketch.
2. Identify and briefly describe the microscopic preparations A, B, and C.

PRACTICAL CHEMISTRY.

PROFESSOR ATTFIELD.

March 26, 1896.—11 a.m. to 1 p.m., and 2 to 5 p.m.

1. State, qualitatively, the character of "The Mineral Water."
2. How much bicarbonate of potassium is present in one fluid ounce of "The Medicine"?
3. Is there any lead in the sample of "Vinegar"?
4. Analyse "The Powder," and state what substances are present.

ANNOTATIONS.

THE DISCOVERY OF ARGON.—It is announced that Messrs. Macmillan and Co. will shortly publish a volume by Professor William Ramsay on the recent discovery by himself and Lord Rayleigh of argon in atmospheric air. The intention is to supply such an account as may meet the requirements of educated men with no special knowledge of the recent developments of physics and chemistry, and, where necessary, the reasoning employed in drawing conclusions relative to argon will be stated in popular language. The book will also contain a prefatory account of all the progress made in connection with the chemistry of the atmosphere by Cavendish, Boyle, Lavoisier, and other early discoverers, portraits of whom will be included in the volume.

SCHOOL OF PHARMACY.—We are requested to state that this school will close on Saturday, March 28, for the Easter vacation. The laboratory of practical chemistry will reopen on Monday, April 13, and the lectures will recommence on the following Monday.

LORD KELVIN'S PROFESSORIAL JUBILEE.—It is proposed to recognise the completion of Lord Kelvin's fiftieth year as professor of natural philosophy in the University of Glasgow during the present year. A joint committee, including representatives of both the University and municipality, is therefore taking measures to secure the participation of other universities and scientific and learned societies, at home and abroad, in celebrating the prospective jubilee. The different bodies are being invited to send representatives to a celebration to be held in Glasgow on June 15 and 16 next. On the first day a *conversazione* will be held in the University, and on the second there will be a banquet in the City Chambers. An exhibition of mechanical, electrical, and other scientific apparatus illustrating Lord Kelvin's inventive and constructive genius will form a special feature of the celebration.

LIEBIG'S CONDENSER.—According to Kahlbaum, the condenser, with which Liebig's name is invariably associated, was really invented by Christian Weigel, and described by him in his dissertation of March 25, 1771. Liebig was not born until 1803. Weigel's condenser was described in Goettling's 'Manual of Chemistry,' published 1794, and Liebig, when he first referred to the use of this condenser, mentioned that work as the source from which he had obtained the description of the apparatus.

THE PRODUCTION OF LIQUID OXYGEN COMMERCIALY.—According to the *Daily Telegraph*, Dr. Linde, who was recently announced as having discovered how to make liquid oxygen easily and cheaply as compared with the methods at the time in use, appears to have been anticipated by an Englishman, Dr. W. Hampson, an Oxford graduate. The latter is said to have explained the principle of his method to several scientific men in 1894, but he was only able to patent his invention in May, 1895, just five weeks before his German rival applied for an English patent. Dr. Hampson gave a demonstration of his process at Brin's Oxygen Works, on Saturday last. Beginning with oxygen at a pressure of 1800 lb. to the square inch, he allowed a portion of this to expand and thus cool the rest of the gas, the operation being repeated until a temperature of -180°C . was reached and the oxygen liquefied, as much as seven cubic centimetres being obtained in four minutes. In practice, freezing mixtures will be used to expedite the process and render it more economical.

PHARMACEUTICAL CONGRESS AT BRUSSELS.—The official report of the proceedings at the national congress of pharmacy held at Brussels last August, to celebrate the jubilee of the Société royale de Pharmacie de Bruxelles, has just been published, and constitutes a large volume of more than four hundred pages. All the papers read before the Congress are published in full, together with the discussions to which they gave rise, and reports of the banquet and other proceedings.

IDENTIFICATION OF NARCOTIC EXTRACTS.—In a circular issued by G. Hell and Co., they give simple instructions for identifying various extracts official in the Austrian Pharmacopœia. *Aconite extract* should produce a sharp and burning taste on the tip of the tongue, followed by long-continued local anæsthesia. *Belladonna extract* is distinguished from that of *hyoscyamus* by the intense green fluorescence produced by shaking out an aqueous solution with chloroform or ether, evaporating, adding a little warm water to the residue, and then a few drops of ammonia solution. *Cannabis indica extract* should yield to ether a soft resinous substance, soluble in alcohol, ether, chloroform, benzol, and carbon disulphide, and not capable of saponification by potash. *Conium extract* is easily detected by the mouse-like odour given off on adding to an aqueous solution a little soda or potash solution. It should also yield a residue of minute double refracting needle-shaped or columnar crystals, on dissolving in warm water, shaking out with ether, adding soda solution, again shaking out with ether, evaporating, dissolving residue in semi-normal hydrochloric acid, and evaporating a drop on a glass slide. *Opium extract*, when dissolved in water and acidified with hydrochloric acid, gives an intense blood-red coloration with ferric chloride solution. *Nux vomica extract*, if dissolved in 70 per cent. alcohol and the solution evaporated on a water bath after adding one or two drops of diluted sulphuric acid, is indicated by a residue, the edges of which are violet tending to red. An aqueous solution, acidulated with diluted sulphuric acid and filtered, should give a curdy white precipitate with ammonia, orange red with potassium chromate, and is also precipitated by yellow or red potassium prussiate.

"THE SCOTTISH ALPS."—Mr. W. Lamond Howie gave his illustrated lecture on "The Scottish Alps" before a crowded audience at the rooms of the Lantern Society, Hanover Square, London, on Monday evening last. The lantern slides exhibited well merit the description—"marvels of technical merit"—that has been applied to them. Beautiful snow scenes, picturesque cloud effects, and delightful views of mountain, river, glen, and loch scenery, were all calculated to inspire enthusiasm, both with regard to photography and mountain climbing. Mr. Howie is also to be congratulated on his manner of presentation, no less than on the matter presented.

THE RÖNTGEN RAYS.—Mr. A. Campbell Swinton is announced to deliver a lecture in the Governors' Hall of St. Thomas's Hospital on Tuesday next, March 31, on the discovery by Professor Röntgen of the x -rays and their application to practical surgical use. Tickets can be obtained at the hospital, and the proceeds of their sale will be devoted to the Special Appeal Fund. Professor Oliver Lodge, of University College, Liverpool, is reported to have been able to observe the effect of rays which penetrated a 12-inch balk of timber and the palm of his own hand. In addition, he has been able to "see," in the same sense, through the head of a boy at the laboratory connected with the college, and also through every part of his body.

PROCEEDINGS OF SOCIETIES.

Chemical Society.—An ordinary meeting of the Society was held on March 19, Mr. A. G. Vernon Harcourt, President, in the chair. After the usual formal business had been transacted, Mr. H. J. H. Fenton, M.A., read a paper on "The Constitution of a New Acid Resulting from the Oxidation of Tartaric Acid." By oxidation a ketone acid had been obtained from tartaric acid having a composition expressed by one of the two following formulæ:—

Crystalline compounds were obtained with phenyl-hydrazine and hydroxylamine, one definite compound with each, and these were the only ones to be obtained. With acetyl chloride and acetic anhydride, compounds	COOH CHOH CO COOH	COOH COH COH COOH
---	----------------------------	----------------------------

stable in cold water had been produced. A solution of the second form and alkaline permanganate was decolorised at once. Racemic acid was isolated from this with hydrogen iodide. Dioxy-tartaric is first produced. With hydrogen bromide and acetic acid as solvent there is no change whatever, even after several weeks. With hydrogen bromide and ether as solvent the result is a body having the composition $C_4H_8(C_2H_5)_2$. It has no acid properties, and is a diethyl ester. It is quite unusual for such a body to be obtained from ether. When this body is placed in a dessicator over sulphuric acid it becomes liquid, and this question of liquefaction offers some difficulty in explaining. It first gains weight and then loses. When sealed up with hydrogen, however, it is perfectly stable. The second form easily gives anhydrides, and it is possible that this acid may belong to the maleic series. Intermediate products are formed (the acetic acid solvent) on heating— $C_4H_4O_6 + 2CH_3COOH - H_2O$.

Very little discussion followed the reading of this paper, Professor Armstrong merely saying that the subject was a difficult one to deal with. Professor Dunstan asked Mr. Fenton if he had tried solvents other than water in the dioxy-tartaric acid experiments, to which Mr. Fenton replied that other solvents had no action whatever. Too much or too little water would not do.

Specimens of the various substances Mr. Fenton had prepared were exhibited on the table.

Although three gentlemen contributed papers at this meeting, Mr. A. E. Tutton, of the Royal College of Science, practically monopolised the evening. His first paper was on "The Volume and Optical Relationships of the Potassium, Rubidium, and Caesium Salts of the Monoclinic Series of Double Sulphates, $R_2M(SO_4)_2 \cdot 6H_2O$," and this was immediately followed by two others intimately connected with the same subject, viz., "A Comparison of the Results of the Investigation of the Simple and Double Sulphates Containing Potassium, Rubidium, and Caesium," and "The Bearing of the Results of the Investigation of the Simple and Double Sulphates upon the Nature of the Crystal Element." This last paper was of a speculative nature. Mr. Tutton, it could easily be seen, is a thorough master of his subject. His clear delivery and lucidity of expression kept his audience at close attention to a subject which less ably handled must have bored unmercifully. He first of all explained the difficulty that had to be encountered in cutting section-plates, and took occasion to refer to the two instruments he had devised, which he had described to the Royal Society, one for grinding section-plates and prisms of crystals in any desired direction, and the other for producing monochromatic light of any desired wave length for investigating the optical properties of crystals. With the former of these two instruments he had cut hundreds of sections and not broken more than three or four. The author has for a number of years been working on the relationship of these crystalline salts from various points of view, and in the present instance, as in former investigations, he finds that the rubidium salts always, without exception, occupy a position between potassium and caesium, and invariably nearer the former than the latter; and one of his final conclusions is that the alkali metal R has a dominating influence in these results.

Mr. Barlow, whom Mr. Tutton mentioned as having contributed a paper to the British Association on the relationship of structure with optical properties, regretted his inability to join in the discussion, but expressed himself as highly pleased that the present papers went far to obliterate the supposed boundary line between chemistry and physics.

The President mentioned that some time ago he had been examining the double crystalline compounds of ferrous and ammonium chloride, and that his results had continually varied, although the crystals obtained were, so far as he could discover, perfect. He asked if Mr. Tutton could explain this.

Mr. W. J. Pope, on being asked to speak, said that no one who had not some practical acquaintance with the subject could realise the amount of work entailed in these investigations, and remarked that the selenates, $R_2M(SeO_4)_2 \cdot 6H_2O$, were not nearly so constant in their relationship as the salts under consideration.

Mr. Tutton briefly replied, and said his great endeavour had been to obtain irreproachable compounds for this work, and that it had even taken twelve months to get some of the crystals. Rubidium and caesium had a different molecular refraction from what had generally been supposed. The selenates and double selenates, he said, would be investigated next.

The last paper was on "The Hydriodides of Hydroxylamine," by Professor Dunstan, F.R.S., and Mr. Ernest Goulding. It was read by Professor Dunstan—a little too hurriedly, perhaps. By the action of methyl iodide on hydroxylamine a substance $(NH_2)OCH_3I$, was formed, a trimethyl compound of the base having the composition $N(CH_3)_3O \cdot HI$. There was also formed a hydriodide of hydroxylamine itself, represented by $NH_3O \cdot HI$. $(NH_3O)_2HI$ had also been obtained by the indirect method, and the authors had endeavoured to obtain them by the direct method (hydrogen iodide in water), but had not succeeded in getting the normal substance.

Among the following papers which were taken as read are one or two which would have been listened to with interest by pharmacists:—"An Analysis of the Water from the Dripping Well at Knaresborough, in Yorkshire," by B. A. Burrell. "Contributions to the Knowledge of Ethylic Aceto-Acetate, Part 1—Acetonilmalic Acid," by S. Ruhemann, M.A., Ph.D., and E. A. Tyler. "The Action of Lead Thiocyanate on the Chlorocarbonic Esters, Part 1—Carboxyethyl-thiocarbimide and its Derivatives," by R. E. Doran. "An Auxiliary Assay Balance," by R. Law. "Charas: the Resin of Indian Hemp," by J. B. Wood, M.A.; W. J. N. Spirey, M.A.; T. H. Easterfield, M.A.

Midland Chemists' Assistants' Association.—This Association met on Wednesday, March 18, Mr. H. Jessop in the chair, to hear a paper on—

"COD-LIVER OIL AND ITS EMULSIFICATION," BY P. C. ARBLASTER.

The cod-fish appears at Bergen, Norway, and farther north in the months of January and February, and is then caught in quantities of six to eight millions or more. Later, about March, the fish appears at Lofoden, where sometimes over eight millions are caught, yet later the fish go farther north to Finmark, where the catch is quite as large. About sixteen thousand fishermen congregate annually at Lofoden. The fecundity of the cod-fish is such that it has been estimated that if only one female fish escaped annually, and her eggs safely hatched, the species would be effectually preserved. This fact is less surprising when we recollect that the ovary of each female fish contains no less than nine million eggs.

As soon as possible after capture the fish are brought alive in a specially constructed tank to the shore, where they are sold to the tradesmen and manufacturers; or, what happens very seldom, the oil is extracted by the fishermen themselves on board.

There are five varieties of cod-liver oil, namely—

1. That extracted by means of steam or steam oil.
2. The ordinary medicinal oil, of a light yellow colour.
3. The oil of a dark yellow colour.
4. The brown medicinal oil.
5. The dark brown oil used by tanners and curriers to soften and preserve leather and skins.

1. *Steam Oil.*—In the preparation of this the livers are subjected to the action of steam in pans, pressed and transferred to closed lead cisterns, where the oil is left to deposit stearin and other impurities. After one or two months the clarified oil is bottled. Merchants draw off the oil at as low a temperature as possible to avoid stearin being afterwards deposited. This oil is almost water-white, and has very little taste or smell.

2. *The Light Yellow Oil* is prepared by allowing the livers to remain in heaps, and the oil runs out by itself. It is evident that through this exposure to the air, lasting some weeks, the oil gets somewhat rancid, and of course stronger to the taste and smell than the steam oil. Here as elsewhere the difference in the light yellow oils is due to the cleanliness observed and the casks used. Being prepared without heat, this oil contains very little stearin, and will stand a cold temperature better than the steam oil. Makers of high class oils always keep the oil for some time in ice houses to allow the olein, stearin, and palmitin to deposit.

3 and 4. These are the darker yellow and brown medicinal oils, and

are prepared by pressing the livers and subjecting them to a low heat. Dr. De Jongh's oil is of the fourth class.

5. *Curriers' Oil* is obtained by letting the livers ferment, heating and then subjecting to strong pressure.

Cod-liver oil contains, besides several glycerides, oleic, palmitic, and stearic acids, and free acetic and butyric acids. It also contains a number of inorganic substances, such as bromine, iodine, and sulphur, also combinations of phosphorus, besides sulphates and phosphates of lime, magnesia, and soda, with traces of ammonia. The attention of chemists has been called to the extremely small amount of iodine present. It forms at the utmost .01 per cent.

With regard to the emulsification of cod-liver oil, there are two methods in general use—the Continental and the English. The Continental method has the great merit of never failing to produce a good result if the proper proportions are used for forming the nucleus or base. The most satisfactory proportions are half as much water as of oil, and half as much gum as water. One part of finely powdered gum is placed in a dry mortar and 4 parts of oil are added and well stirred; when uniform, 2 parts of water are added, all at once, and upon stirring an emulsion is quickly made. Additional water may be added without risk of separation occurring.

When an emulsion begins to "crack" or separate it should not be thrown away. It may be restored by placing an additional quantity of gum in a mortar and gradually adding the cracked emulsion to it, triturating well after each addition, when the dispenser will generally have the satisfaction of seeing the uncombined oil disappear.

The principal qualities that a cod-liver oil emulsion should possess are: 1st, fine division of the oil globules; 2nd, non-separability, and, 3rd, palatability. The author said he should like to point out the many virtues of Irish moss, which contains about 70 per cent. of pectin or vegetable jelly and has extraordinary powers of emulsification. The only disadvantage in its use is the liability of its solution to ferment under certain conditions. This may be got over by the addition of 5 per cent. of alcohol to the bulk, or a small quantity of elixir saccharini, which acts as a powerful anti-ferment as well as a sweetening agent.

The formula he has found most satisfactory is:—

Irish Moss (picked)	1 drachm.
Cold Distilled Water.....	5 ounces.

Allow the water to stand on the moss for one hour, then boil for ten minutes, and strain through muslin, and make up to 5 ounces. To this in a bottle when nearly cold add:—

Cod-liver Oil	8 ounces.
Alcohol.....	1 ounce.
Water to make	16 ounces.
Flavouring	℥ss.

Use a quart bottle, shake the mucilage well round the sides, and then add the whole of the oil and agitate to form a nucleus; then add half the water and lastly the alcohol, flavouring, and as much water as required to make up the quantity.

Three samples were placed before the meeting, one made as above, one an acacia emulsion, and the third a so-called emulsion (in reality a soap) made by shaking together equal parts of cod-liver oil, freshly prepared, and lime water.

The author could not see why such a preparation as the third, properly flavoured, should not come into general use. The two drugs are separately prescribed largely for rickets and spinal diseases in children, also the presence of lime water would certainly help a delicate stomach to bear the oil.

To completely mask the odour and taste of cod-liver oil would be worth much gold to any man. The author had found oil of wintergreen very useful, though it is not much used in this country. He gave three formulæ, each of which is sufficient for one pint of the finished product:—

1.	Oil of wintergreen	} Of each 15 minims.
	Oil of sassafras	
2.	Oil of wintergreen	} Of each 20 minims.
	Oil of bitter almonds.....	
3.	Oil of neroli	} Of each 12 minims.
	Oil of bitter almonds.....	
	Oil of clove	

Oil of lemon appears to be of little use. Elixir of saccharin has been found very useful in bringing out the taste of the flavourings used.

After a good discussion on the paper, a note was read by the Chairman (Mr. H. Jessop), in which he stated that liniments of aconite and belladonna of one-twelfth the strength had as powerful an action as the official preparations, if the affected part was first well bathed with hot water.

Chemists' Assistants' Association.—At the meeting held on the 19th inst., when Mr. E. W. Hill, the President, occupied the chair, a paper was read by Mr. C. Morley on "The Rational Pharmacist." At the outset the author remarked that the various suggestions that had at various times been advanced for the betterment of the pharmacist's lot had been, as a rule, wide of the mark, inasmuch as the position and claims of the rank and file of the craft had been ignored. He then went on to mention the attributes which, in his opinion, the rational pharmacist ought to possess, and the faults which retarded the possession of these. Obviously the foremost was manipulative skill as a dispenser, accompanied by a good scientific training, so that an absolute guarantee could be given to the public of the excellence of every article offered for sale, over the quality of which direct control can be levied. It is only by this means that the extreme competition of outside traders can be combatted, since those who buoyed themselves up with the hope that "anti-company" legislation would prove a panacea for all their ills would probably find that they had been clutching at a straw, and that the readjustment of the Companies Act would not be of very material benefit. The personal element was undoubtedly of paramount importance in the direction of an abstract acknowledgment by the public of the pharmacist's right to a higher scale of remuneration in his own particular branch, towards which there seems fortunately to be some leaning in spite of keen competition, and everyone should, in his own interest, submit to tests every drug and chemical which passes through his hands, of which he can be the guarantor. If everyone did this, an improved prospect would be opened out to apprentices who are often imperfectly trained, with a resulting changed complexion of the examination returns. At the present time it is altogether lamentable to notice the deficiency which is frequently apparent in the term-completed apprentice, who frequently has never packed a percolator or drawn sweet nitre or sal volatile. This state of things is of course frequently entirely the fault of the pupil himself, who neglects to avail himself of the opportunities presented to him, but should it happen that he is left to his own devices instead of being familiarised with the processes which he will be called upon to understand at the qualifying examination, he has at any rate the consolation of knowing that there is probably no calling where the perceptive faculties are more calculated to be developed and self-reliance thus engendered than in that of the pharmacist.

Mr. Morley proceeded to remark that the predominance of the professional over the commercial instinct has given rise to what may be called a racial fault, since chemists have not hitherto been enterprising enough to appreciate the need which exists for emancipating themselves from old ideas and views of conducting business, and meeting the demand which exists for general attractiveness of their shops and wares, accompanied by a reduction in the charges for ordinary business transactions in which little or no skill is involved. The pharmacist's present position seems to be that he cannot relinquish the professional feature of the calling, since that would constitute a retrograde act which must not be entertained. On the other hand, the commercial side must be cultivated if he wishes to exist. To this end the two instincts which are naturally inimical should be made to serve one another by securing the greatest amount of respect from clients by proving the possession of an all-round knowledge, which is the essence of personality and on which alone can be fixed any hope of remuneration higher than that of the ordinary trader.

In regard to the sale of poisons, Mr. Morley said his experience was that the regulations were not followed with the faithfulness they should be, and this state of things was obviously unfair to the man who implicitly obeys the law, since the public are somewhat impatient of restrictions. Another unsatisfactory feature was for the pharmacist to be charged ninepence for a proprietary medicine containing a poison in the first schedule, and having a retail price of one shilling as fixed by the maker on the label, thus assessing threepence as the sum of recompense for the trouble and formality of registering, to say nothing of the consideration of qualification. In spite of these annoyances there must be no infraction of the law in any detail if the pharmacist is to compare favourably with the unqualified man. In conclusion, reference was made to the lack of

cohesion existing amongst the craft, the opinion being expressed that no individual sacrifice was too great which could conduce to the perfect union which was desirable on every social, political, and ethical ground.

Liverpool Pharmaceutical Students' Society.—At the usual meeting of this Society, held under the presidency of Mr. T. S. Wokes in the University College, on Thursday evening, the 19th inst., the following gentlemen were elected members:—Messrs. H. G. Saunders and W. H. Saunders.

A dispensing difficulty was brought forward under "Miscellaneous Communications" by Mr. Pickering, who had come across it in making the following mixture:—

R Quininae Sulph.	gr. 40.
Acid. Nit. Mur. Dil.	ʒiiss.
Sp. Chlorof.	ʒii.
Sp. Ætheris Nit.	ʒvi.
Mist. Creosoti ad	ʒviii.

The addition of the spirit of nitrous ether caused the creosote to separate and to become a deep brown colour, though, as Mr. Pickering said, he had taken the trouble to neutralise the spirit with sodium bicarbonate previously.

Mr. H. Wyatt, jun., said the coloration was caused by the action of nitrous acid on the creosote, which, in common with most bodies of a phenolic origin, gave coloured nitro derivatives. It was a needless precaution using sodium bicarbonate to neutralise the spirit of nitrous ether before adding it to the other ingredients, as the diluted nitro-hydrochloric acid and the glacial acetic acid present would still cause evolution of nitrous acid.

The Secretary exhibited some balances and a sound containing a small electric light used for illuminating the bladder during surgical operations or examinations, sent by Messrs. Maw, of London, as an exhibit at the recently postponed conversazione of the Society.

Mr. H. Peirson then read a paper on—

"SOME WEAK POINTS IN OUR TRADE MORALITY."

Mr. Peirson said the weak points he wished to touch upon were those in chemists' dealings with customers, apprentices, and other chemists and manufacturers. It was perfectly honest to charge more for booking goods, and to charge less in proportion for larger quantities, but not to charge Mrs. A a lower price than Mrs. B simply because the first lady asks for the reduction and the other does not. Still, it is too true unfortunately that people who grumble most get best served. Business can only be conducted on thoroughly straight-forward lines when fixed prices are maintained, and in order to keep the business together those fixed lines must be reasonable ones. The charges for prescriptions should be arranged to scale, and this scale, when fixed upon, ought to be adhered to. Poverty of the customer or the purchase of large quantities of medicine at a time should alone justify a reduced rate. Advertisements and labels are a fruitful source of immorality. If the seller abstained from recommending his preparations in extravagant terms his customers would be more likely to believe what he said, and would hold him in considerably more respect.

One of the weakest points of the trade is the treatment of apprentices. In the "good old days" apprentices, from all accounts, seem to have had a harder time of it than their modern prototypes, but there is little doubt that they were really taught their business, and thus properly equipped for the battle of life. Nowadays the greater part of an apprentice's knowledge is picked up in his first situation as an assistant, at the expense of the chemist who engages him, and that individual, instead of getting a premium for teaching him, has to pay him a salary. No one has a right to take an apprentice unless he is in a position to impart to him practically the details of the business, and yet apprentices are taken by numbers of chemists who never even make a tincture, buy all their ointments from a wholesale house, their ready-made pills from a "pill builder," and in the same manner with liniments and compound powders. In Wales there are many businesses of this stamp where the chemist's business is associated with that of a grocer, a tobacconist and a confectioner, the day's takings averaging about one chemist's article in three, and about one prescription to every three hundred transactions. Such chemists have no right to take apprentices and pretend to teach them the business, and yet how often is that done! The reason is that an apprentice is a cheap assistant, enabling the chemist to do without a paid one, and possibly with one errand boy less. Even in the larger and better businesses how often do we

find that the major part of an apprentice's time instead of being spent in the laboratory assisting in the various operations is taken up in packing and putting up for stock proprietaries, so that he only learns one side of his business, and cannot become a good all-round man. If a chemist takes an apprentice he should do so with the firm intention of teaching him his business, and not simply leave the boy to pick up his knowledge in a haphazard fashion. A sharp boy will pick up a good deal of information, useful and otherwise, but everyone is not sharp, so that an apprentice should not be left to himself, but an effort be made on the part of the chemist to turn him into a good assistant. This can only be done in a chemist's business of the kind likely to give a youth a proper insight into varied pharmacy, therefore it lies with the chemist to say whether he can honestly and with justice to the boy and himself teach the business in his establishment or not. If he takes a youth when not in a position to provide him with the experience required, he does that youth a grave injustice.

The last point touched on by Mr. Peirson was chemists' conduct to one another and to manufacturers. There was, in his opinion, a lack of fellow feeling, professional honour, *esprit de corps*, or whatever one may like to term it, amongst chemists. In this respect they have much to learn from their medical friends, who are very careful to maintain each other's reputation and that of their profession, seldom being heard to say anything depreciatory of their brother practitioners, at any rate to their clients. It would be good if the same could be said of chemists. With reference to the conduct of chemists towards manufacturers, the question of imitation was touched upon. If a man has a new idea, brings it out, works it up by spending much time and trouble on it, and creates a demand by advertising it, is it right for anyone to imitate that article? The Patent Law recognises the principle that an inventor is entitled to the sole benefit of his invention for a certain space of time; but when this period has elapsed the idea becomes common property. The majority of special preparations sold are not patented, but, in a broad sense, the same principle applies. A new preparation is brought out, nothing but the genuine article is sold for some time until the demand is created, becomes general and permanent. Then, to use the simile, the patent expires and the article becomes public property. Mr. Peirson said he thought in such a case others were quite justified in making a similar preparation, provided they did not slavishly copy the original, so as to mislead customers into thinking they were buying the original article. They should try to improve upon such articles, not to imitate them, and, above all, they should not run down and decry another man's preparation so as to sell their own, for it is easy to point out the good points of one's own articles without making unfair reflections on those of other makers.

This was followed by a paper on—

"SOLUTION," BY R. C. COWLEY, PH. CH.

The author began by discussing the effect upon the development of chemistry exerted by Avogadro's enunciation of his famous law that equal volumes of different gases under similar conditions of temperature and pressure contain the same number of molecules. Thus in the case of water as steam we find that the formula is H_2O , two volumes of hydrogen and one of oxygen having united to form two volumes of gaseous water or steam, and that it is not simply equal parts of H and O. In the state of vapour water exists as simple molecules of H_2O , but in its liquid form at lower temperatures we are unable to say of how many atoms these molecules consist, the general view among chemists and physicists being that the formula is at least $8H_2O$, possibly greater. The number of atoms in the molecule of a solid may be more numerous than those in a liquid, and that probably accounts for the allotropic forms of many elements, such as carbon, sulphur, phosphorus, etc., which exhibit no difference in their densities when in a state of vapour. Sulphur, when heated to its boiling point, shows its molecule to consist of six atoms, when heated still higher this six-atom molecule dissociates, and a vapour density is obtained corresponding to a two-atom molecule. At low temperatures acetic acid has the formula for its vapour density $2(CH_3COOH)$; when the temperature is raised, dissociation results, and a formula, CH_3COOH , is obtained. From this we may conclude that simple molecules can only exist in a state of vapour at a high temperature or in dilute solutions.

In determining vapour densities we sometimes get substances only yielding a fractional part of the figure expected, $NH_4Cl, POCl_5, I_2$ for example. This is accounted for by the molecules splitting up or becoming dissociated into simpler ones. The V.D. of NH_4Cl should be compared with air 1.85, but really it is only 1.01, this being due to

the molecule on heating dissociating into molecules of $\text{NH}_3 + \text{HCl}$. This can be proved by the atmolysis of NH_4Cl vapour through a porous clay tube, the NH_3 being lighter than the HCl passes to the outer surface of the tube first, and will change the colour of red litmus paper to blue. The solution of solids in liquids and their crystallisation therefrom show a striking similarity to vaporisation. A solid introduced into a liquid in which it is soluble will diffuse itself evenly throughout the whole of the liquid, and the quantity so dissolved will depend on the nature of the salt or solid, the solvent and the temperature.

Just as vapours or gases exert an equal pressure on all sides of the containing vessel, so salts exert an equal pressure upon all parts of the liquid in which they are dissolved, the pressure being termed the osmotic pressure of the salt. This agrees entirely with the kinetic theory of gases and the teachings of Boyle and Charles' laws, so that we may really say that if the solvent were removed from a dilute solution of a salt, this salt would be left filling the same space in the state of gas at the same temperature and pressure as when the liquid solvent was there, and that the osmotic pressure will conform to the laws of Boyle and Charles. Applying Avogadro's law to dilute solutions Van t'Hoff lays down that "Isosmotic solutions at the same temperature and pressure will contain the same number of molecules." Liquids vary in their power of dissociation; those so far studied are water, benzene and acetic acid—the latter being especially active, whilst hydrocarbon liquids are only slightly so.

The measurement of the osmotic pressure of salts in solution presented serious difficulties which were finally overcome by Traube and Pfeffer, who employed precipitated membranes to separate the solution from the solvent. These "membranes" were made of porous clay saturated with cupric ferrocyanide, silicic acid, tannate of gelatin, and other bodies which have the power of preventing the solids diffusing from the solution into the solvent. To the end of a long glass tube is attached by the stem a thistle funnel with its mouth tied over with bladder or other membrane, and filled with a dilute solution, this funnel being kept immersed in the solvent. A current of the solvent passes into the funnel and rises in the tube until the osmotic pressure is equal to the hydrostatic pressure, which may be ascertained by means of a manometer.

A simple experiment may be performed showing the effect of osmotic pressure very well. Allow one drop of solution of $\text{K}_4\text{FeC}_6\text{N}_6$ to fall into a solution of CuSO_4 , a membrane of $\text{Cu}_2\text{FeC}_6\text{N}_6$ is formed round the drop, and as the water passes into the globule from the surrounding solution this globule becomes larger and finally bursts. This phenomenon plays an important part in the physiology of the plant, the cell-walls with their protoplasmic lining prevent the solids in solution in the cell-sap from passing outwards, but readily permit the passage of water. When plant-cells are treated with dilute solution of NaCl , water is absorbed from the cells by the salt solution, and plasmolysis or separation of the protoplasmic cell-lining is the result.

Pfeffer, by observing the osmotic pressure of solutions of cane sugar of various strengths, obtained figures proving that Boyle's law relating to gases applied equally to solids in dilute solutions, and that as the temperature increased the osmotic pressure became greater.

The law of Avogadro, as modified by Van t'Hoff from these experiments with solutions, now runs as follows: "Isosmotic solutions at the same temperature and pressure contain the same number of molecules, and this is the same as would be contained in the same volume of a true gas at the same temperature and pressure." From this one may deduce that isosmotic solutions will have the same freezing-point. As long as a hundred years ago Blagden observed that the strength of a solution bears a simple ratio to the freezing-point, a fact re-discovered by Rudolf in 1861, who showed that if various salts were made into solutions with the same solvent, in strengths equal to their molecular weights, they depressed the freezing-point to the same extent. This work was further confirmed by Raoult, who determined molecular weights by noticing the depression of the freezing-point caused by solution of a known weight of a solid in a liquid, of which the molecular depression was known. This in the case of water is 19; acetic acid, 39; and benzene, 49.

Aqueous solutions were thought to disagree with Avogadro's law, for substances in such solution exert a greater osmotic pressure than that calculated from their molecular weight, and the depression of the freezing-point is about twice as great. However, Arrhenius by his theory of electrolytic dissociation cleared up the matter, stating that the water dissociates a salt, a base, or an acid into its

electrolytic ions, which roam about the solution in a free state, keeping up the equilibrium, the aqueous solvent acting on solids so that their condition is analogous to that of bodies such as NH_4Cl , which in a state of vapour are dissociated and have abnormal vapour densities in consequence.

The electrical conductivity of solutions agrees with the above and is in direct ratio to the dissociation. An electrolyte, or body conducting electricity, in an aqueous solution is the body exhibiting irregularities both in osmotic pressure and in depression of the freezing-point, and if in any other solution it will not conduct it loses its abnormal behaviour.

Cane sugar in aqueous solution will not conduct electricity, and is therefore perfectly normal. As soon as an electrical current passes through a solution of an electrolyte, polarisation results, but the electrolyte is not decomposed, the respective ions merely rearrange themselves, the anions going towards the anode, the cations towards the cathode. The weakest electrical current can polarise an aqueous solution of an electrolyte, effectually showing that the ions are already dissociated. It certainly seems strange that in a solution of NaCl , the Na and Cl are roaming about in a free state, and yet there is no evidence of either free Na or free Cl . Clausius considered them not permanently at liberty, but continually combining and decomposing, but Ostwald proved that the ions in a solution are charged with a high degree of electricity, altering the chemical behaviour of the elements.

The ordinary analytical reactions of salts are directly affected by this electrolytic dissociation in aqueous solutions. AgNO_3 will precipitate chlorine from KCl , but not from chlorates, for the ions in the first case are K and Cl , but in the second K and ClO_3 . FeSO_4 gives a black precipitate with AmHS , but K_4Fcy does not, for the ions in the last case are K_4 and Fcy . These and other examples go a long way towards proving that dissociation is a necessary condition to chemical change.

Recapitulating these remarks the author summed up as follows:

- 1st. In the state of vapour, simple molecules may exist, and in many cases these simple molecules may, with further heat, dissociate into simpler particles.
- 2nd. In the solid and liquid states the molecules are complex, and these may be simplified by solution in various solvents.
- 3rd. Water as a solvent assumes an anomalous position, splitting up salts into still simpler particles analogous to molecules dissociated at high temperatures.
- 4th. It is only these dissociated molecules which are capable of conducting electricity, or are, in other words, electrolytes.
- 5th. All ordinary reactions in chemistry depend on this peculiar condition of the molecules concerned.

A discussion upon the two papers followed, in which the President, Mr. J. Smith, and others took part.

Western Chemists' Association (of London).—At a meeting of this Association, held on March 18, a discussion took place on the subject of prescribing proprietary medicines. The discussion was opened by Mr. Parker, and taken part in by Messrs. Martindale, Taplin, McEwan, Andrews, and the President. The following resolution was subsequently put and agreed to unanimously:—

That this meeting is of opinion that the practice of prescribing proprietary medicines is becoming so extensive as to be seriously injurious to the progress of pharmacy, and detrimental to the best interests of the medical profession, and considers it to be most desirable that all prescribers should adopt the practice of writing prescriptions without the name of any particular maker attached, so that they may be dispensed by any pharmacist from recognised and published formulæ.

It was also agreed to send copies of the resolution to the General Medical Council, the Council of the Pharmaceutical Society, and the medical and pharmaceutical press.

SNUFFS FOR HAY FEVER, COLD IN THE HEAD, ETC.—The following formulæ are taken from the *Amer. Med. Chir. Bulletin*:—

1. Cocaine hydrochlorate.....	1.8 gramme.
Morphine sulphate	83 "
Bismuth subnitrate	30.0 "
2. Cocaine hydrochlorate.....	1.8 "
Camphor	4.0 "
Bismuth subnitrate	30.0 "
3. Boric acid	20.0 "
Salol	6.0 "
Menthol	0.25 "
Cocaine hydrochlorate.....	0.06 "

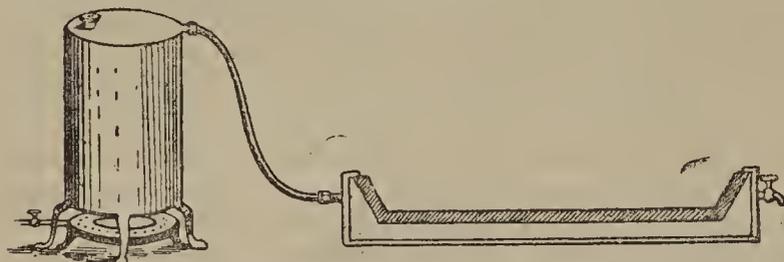

SCOTTISH NEWS.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—At a meeting held on Friday, March 20, Mr. J. Mackintosh Cameron, President, in the chair, an interesting lecture was given on—

“GRANULAR EFFERVESCING PREPARATIONS,” BY GEORGE LUNAN.

There are now four official granular effervescent preparations in the British Pharmacopœia, namely, citro-tartrate, phosphate and sulphate of sodium, and the sulphate of magnesium. Three of these are in the Addendum, 1890, and the growing popularity of these preparations assures further additions in the new B.P. It is not too much to say that caffeine and lithium preparations are most likely. We find the demand for granular effervescent preparations by prescription largely on the increase, and pharmacists must be prepared at short notice to dispense, if possible, variously medicated effervescent granules.

The apparatus which I use in my business consists of an ordinary photographic developing bath, jacketed with tin so as to form a hot plate. The cavity of the tin jacket is filled with steam generated in a small copper boiler heated by an ordinary bunsen gas stove. A metal pipe conveys the steam from the boiler to the cavity and there is an escape pipe at the other end of the steam jacket. By this means a suitable temperature is easily maintained, and the arrangement of a separate boiler works better than a water bath, or than directly applying the heat to the jacketed developing bath.

This is not offered as the acme of apparatus, nor is it put before you as an original idea, as, I believe, similar instruments for the same purpose are used all over the country. [A quantity of the mixed powders for granular effervescent citro-tartrate of sodium was then placed on the heated developing bath, and when the powders had become coherent into a mass, one half was rubbed through a sieve of one diameter of mesh, and the other half through a sieve of another diameter of mesh so as to have two quantities of granules of different sizes. The still moist granules were then returned to the hot bath and allowed to dry, the drying process being facilitated by turning the granules over occasionally.]

The demonstration induces various remarks. A necessary constituent is, of course, the citric acid, the water of crystallisation being liberated when heat is applied, and if the formula is properly adjusted this binds the powders into a suitably coherent mass, that can be granulated by pressing through a sieve of the desired size. As the medication varies so must the relative amount of citric and tartaric acid, so as to suit the medicament; thus a hydrous or deliquescent substance requires less of the former and more of the latter, and *vice versa* with an anhydrous hygroscopic ingredient. Yet the citric acid is not a *sine quid non*, for the U.S. Pharmacopœia has a semi-granular preparation made by damping the ingredients with alcohol, and so making a coherent mass suitable for granulating, actually dried and powdered. This, their caffeine preparation, has no citric acid for granulating purposes, yet it proves that where you have a medicament soluble in alcohol you can granulate without citric acid.

Heat.—The heat applied to a granule at any time should not exceed 100° C., otherwise you discolour the granule and drive off much of the carbonic acid gas. At the same time, for purposes of economy, a strong heat obviates the use of the official proportion of citric acid. Samples of cheap so-called citrate of magnesia contain a large percentage of sugar and tartaric acid, with a small percentage of citric acid. This was my experience when the prices of the two acids were not so nearly identical as to-day. It is a mistake to bake to the detriment of the medicament and the briskness of the effervescent draught.

Neutrality.—The theoretical usually slight acidity of the B.P. types of granules generally agrees with the practical. With substances such as citric and tartaric acids and bicarbonate of sodium

the variability is small, and a slight deficiency in the former is counterbalanced by the same in the latter. Theoretically the effervescent citro-tartrate of sodium contains about a half per cent. excess acidity, while the sulphate and phosphate of sodium preparations contain 1½ per cent., doubtless to give a pleasant sharpness to the draught, and in the latter instance to cover the mawkish saline taste. The effervescent magnesium sulphate contains one-tenth per cent. excess of acid. In granule-making the question of neutrality is important. In some cases it is necessary to make an exactly neutral granule if the therapeutic action is to be maintained. Take, for example, piperazine, which only acts in alkaline solution. It must be retained in its initial condition in the finished granule, not only by adjusting the basis of the formula so as to give, if anything, an alkaline reaction when decomposed, but the order of mixing must be strictly maintained to prevent it becoming neutralised by the acids. In this instance the piperazine must be first thoroughly mixed with the bicarbonate, and any predecomposition in the granule will take place between the acids and the latter, for which they have greater affinity. Pharmaceutically, too, the order of mixing has a great deal to do with the product. We invariably granulate piperazine without heat at all, having our formula so adjusted as to yield a coherent mass when simply mixed in the proper order. In this and in other instances of a similar type, with a little adjustment it is quite easy to avoid detrimental decomposition by heat.

Types of Granules.—The effervescent citro-tartrate of sodium affords a basis—not invariably as I have shown, however—suitable for medication where the quantity of medicament is small, such as citrate of caffeine, 2 grains to the drachm; antipyrin, 5 grains; iron carbonate, 5 grains; iron and arsenic, iron and quinine, and so on. Another type is the sulphate and phosphate of sodium and the sulphate of magnesium granules where the medicament forms 50 per cent., although ultimately, when dried, about 25 per cent. of the two former and 40 per cent. of the latter. These are naturally much less effervescent than the former type, although the sugar is entirely left out of the sodium salt preparations for this and physiological reasons. In the magnesium preparation the granule is overburdened with medicament and sugar, leaving only about 50 per cent. of available effervescent materials. I have something to remark regarding the size of granules of this type. There is, unfortunately, a demand for granules medicated with insoluble substances, such as euonymin, phenacetin, sulphonal, salicin, quinine salicylate and bismuth salts. Of course, these are neither elegant nor palatable, and in all cases should be pointed out to the prescriber as unsuitable modes of exhibition, excepting, perhaps, the bismuth salts, where the nascent carbonic acid would increase the effect. Even if permissible, in that case you have still to reckon on loss of medicament adhering to the glass or settling to the bottom. Non-volatile evaporable liquids can be mixed with the sugar, or, if not present, the bi-carbonate, and dried before being incorporated with the acids. I have in view such substances as lysidine. Powerful poisons, such as strychnine and arsenic can only be evenly diffused by adding to the sugar or bi-carbonate in solution and drying at a low temperature before mixing with acids. Two of the pharmacopœial granules—the sodium preparations—are without sugar for reasons already noted, and in many others not official in frequent demand, its presence is contra-indicated. True, a granule without sugar will always be less uniform unless sifted and made with a fine sieve, because the binding power of the sugar is absent, but against that I place the greater briskness which is always noticeable, the whole granule consisting of effervescent material. Saccharin has been used as a substitute for sugar in some cases.

There are cases where the use of sugar is prohibitive, and, from my own experience, I should say that far too much is used in granule making. In ordinary medicated granules it is not required either for palatability or to aid the granulating. It is impossible, however, to suggest a standard formula, as almost every substance requires a variation in the quantities of acids and bicarbonate to give the best result. The sugar in the official magnesium granule keeps it from readily disintegrating in water.

It is often more economical and gives a more effervescent draught to prepare the medicament with the decomposition of the granule, or if the carbonate from which the salt is produced is only slowly decomposed the reaction can be got over on the slab, and the product dried before incorporating with the granule mass. I have in view in the latter case such examples as the production of true citro-tartrate of magnesium, and in the former citro-tartrate of potassium and of lithium.

Size of Granules.—I use two sieves, a No. 12 and a No. 6, and find that, as far as I can understand, the former is most suitable

for granules with a large percentage of medicament or sugar, either or both, and a consequent small proportion of effervescing material and solubility. The small granule is more quickly decomposed in water, but it is also prone to caking and loss of carbonic acid in the stock bottle, unless dried until it is pulverulent. I do not think a No. 12 sieve suitable for many kinds, but no doubt it is the most suitable size for the types I have mentioned. It is, I think, a mistake, to sacrifice to uniformity or size of granule either the effervescence or colour of granules. Consequently, for all practical purposes, so that they may keep under varied weather and other conditions, a No. 6 or No. 9 sieve is the most suitable. These give an appreciable sized granule, which will keep for a longer period without change, protect oxidisable substances such as iron carbonate, retain the solubility of scale iron preparations, and mix and decompose easily in water without stirring. These are considerations which weigh with makers of granules, but they are not so important but that if desired by the prescriber the size can be made as he may wish without seriously interfering with the effect.

I have recommended principles which I believe are sound. It has not seemed to me necessary to give the minutiae of working details. That will come with little difficulty where there is a desire to make granules in an intelligent manner. The apparatus is simple, the means to your hands, the construction of formulæ contained in very simple equations; and to those who have not yet in their shops undertaken this manufacture I commend it as essentially a thing which ought to be done in the dispensing department, and not left in the hands of wholesale or special manufacturers.

The lecture gave rise to a discussion, taken part in by Messrs. Boa, Cameron, Cowie, Hill, McBain, and Sinclair, and on the motion of the Chairman a hearty vote of thanks was awarded to Mr. Lunan.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.—The usual fortnightly meeting of this Association, the last ordinary meeting of the session, was held on the evening of Thursday, March 19. Mr. W. L. Currie presided, and there was a large attendance of members. "Coal and Coal Gas" was the subject of an exceedingly interesting paper read by Mr. Robert Tocher, M.P.S., Maybole. The author sketched in a lucid manner the natural history of coal, and gave information regarding the principal gold fields of the world. He calculates that our coal supply will last for two or three hundred years at the most, and that then the inhabitants of this country will have to import their coal from China or North America, where the coal area, almost untouched, is seventy times greater than ours. On the motion of Mr. Laing, a hearty vote of thanks was given to Mr. Tocher for his lecture, which was rendered all the more interesting from the experiments he made, and the coal specimens and beautiful fossils which he exhibited.

ABERDEEN AND NORTH OF SCOTLAND SOCIETY OF CHEMISTS AND DRUGGISTS.—A special meeting of this Society was held in the Adelphi Hotel on Monday evening, the 23rd inst. The President, Mr. Johnston, occupied the chair. In the course of the evening the Chairman presented Mr. A. Strachan, in the name of the Society, with a gold Albert and appendage, on the occasion of his retiring from the Secretaryship, and also a silver toast fork for Mrs. Strachan. He referred to the many years Mr. Strachan had been Secretary of this, the oldest Society of Chemists and Druggists in the country, to the great services he had rendered during that time to the Society and to pharmacy in the North, and more especially to the great amount of efficient work done during the Pharmaceutical Conference visit in 1885.—Mr. Strachan feelingly replied, and thanked the members for the gifts to himself and Mrs. Strachan. He noted the changes that had occurred in the Society since he became Secretary, dwelling more particularly on the facilities the young men enjoyed of preparing themselves for examinations since the opening of the rooms in Bridge Street. He complained of the conduct of those chemists outside the Society who were always ready to run it down. In some instances those men, when preparing for their examinations, were the most exacting as to their rights to the rooms, but so soon as they passed they turned their backs on the Society.—Toasts followed, and the company spent a very pleasant evening. The following is the inscription on the appendage:

"Presented to Alexander Strachan in appreciation of his services as Secretary to the Chemists and Druggists for nineteen years. Aberdeen, March, 1896."

Mr. John Cruickshank has been elected Honorary Secretary in succession to Mr. Strachan.

IRISH NEWS.

ACETYLENE GAS.—Mr. John R. Wigham, M.R.I.A., of Dublin, has devised and patented a very simple apparatus for the production of this gas, and also a burner for its combustion. The gas was at first supposed to be of a poisonous nature, but Dr. Walter Smith and others have shown that it is not so. Two important points in its favour are:—First. The simplicity of production from the calcium carbide—namely, the mere application of cold water. Second. Its great illuminating power, which is thirty times that of sixteen candle gas. These are points which will render it of great importance as a lighthouse illuminant, although the present price of the calcium carbide may retard its use in other directions.

A NEW PHARMACY has been opened at Callan, Co. Kilkenny, by Mr. Hugh Montgomery, L.P.S.I., lately with Mr. D'Arcy, M.P.S.I., The Medical Hall, Tipperary.

NOT MEDICINES.—The Local Government Board has objected to a large number of items in the tender form of the South Dublin Union, some being for medicines which might be compounded by the resident medical officer, while others were for stimulants under disguise.—Sir George Owens, M.D., M.P.S.I., one of the guardians, said he approved of the action of the Local Government Board.

PHARMACEUTICAL SOCIETY OF IRELAND.—A pharmaceutical assistants' examination will be held at Dublin on Monday, the 13th prox., and a registered druggist examination on Tuesday, the 14th idem. The 30th and 31st inst. will be the last days for lodging applications. If sufficient numbers apply, examinations will be held for above qualifications at Belfast on the same dates as in Dublin.

THE ANALYST to the Richmond Lunatic Asylum, Dublin, Dr. McWeeney, has resigned, finding the small salary of £30 per annum insufficient.

LEGAL REPORTS.

"PINK PILLS FOR PALE PEOPLE."

On Friday, March 13, Mr. Justice Chitty in the Chancery Division, made an order by consent in the action of Fulford *v.* Gratte and Son, restraining the defendants from selling pills as and for Dr. Williams's pink pills for pale people, which were manufactured and sold by the plaintiff. Mr. John Cutler, who appeared for the plaintiff, said the origin of the action was that an order for Dr. Williams's pills had been sent to the defendants in mistake. Mr. Stewart Smith, who appeared for the defendants, said his clients did manufacture pink pills for pale people, but did not represent them to be of the plaintiff's manufacture. Under the circumstances of the case he could not resist the granting of an injunction.

THE CHEMISTS' ASSOCIATION, LIMITED.

On Friday, March 13, application was made to Mr. Justice North, in the action of Fry *v.* The Chemists' Association, Limited, for the appointment of a receiver and manager. The plaintiff and his wife are holders of 80 debentures of £50 each out of a total issue of 120 of a certain series, which were a charge upon the whole of the Company's property, including uncalled capital, and interest being in arrear, it was asked that Mr. Walter Howard, an accountant, might be appointed receiver and manager. His Lordship made the order as asked, and directed that if the parties consented, the usual decree in a debenture-holder's action should be drawn up. The Company did not oppose the application, Mr. C. E. E. Jenkins appeared for the plaintiff, Mr. Pattulls for the Company.

OBITUARY.

MORRIS.—On March 5, Caleb G. Morris, Chemist and Druggist, Llanfyrnach. (Aged 45.)

CORRESPONDENCE.

Several communications are unavoidably held over on account of want of space. Correspondents are requested to write as briefly as possible.

CASH CHEMISTS, EARLY CLOSING, ETC.

Sir,—There is no doubt that the dangerous rock ahead in the matter of the business of a chemist and druggist is the spread of these limited companies trading as cash chemists, stores, etc., and ruthlessly cutting down prices and profits. It is quite time the individual retail chemists of the country stood up as one man and tried by every means in their power to get the law altered. I have been contending for some years now with cutting grocers and stores, and every week have had to lower prices, and therefore profits, of something or other. I see that one drug company is opening a cutting retail branch in a manufacturing town a few miles from Liverpool, and advertising single articles at wholesale prices, etc., etc. Really, sir, wholesale prices won't keep the retail chemist; one can manage to get a living if patents only are cut, but when it comes to drugs and dispensing, the game is not worth the candle.

In the matter of early closing, I consider those chemists who are opposing it are very foolish. It is quite certain that if the public knew that the shops close at a certain time they would get what they want before that time. In the case of many chemists it may be necessary to have some arrangement whereby urgent cases occurring after closing may be dealt with, but this is a detail which could easily be arranged. I am often vexed and disgusted somewhat to find that after giving some thirteen or fourteen hours' attendance to business I have at the end of that time some £2 or £3 only, and often largely made up of cut patents. This business could just as easily have been done in two-thirds of the time, and would have been if the public knew that shops would close at such an hour. Why oppose early closing? I say support it by all the means in our power, we shall be all the better for the relief, and may have a chance of giving a little attention to some other pursuit, which shall be a change and perhaps a means of making a little more of the needful. I hope the Shops (Early Closing) Bill will soon become law, and that it will be promptly adopted throughout the country.

March 14, 1896.

HARASSED.

THE DECAY OF PRESCRIBING.

Sir,—Dr. Murrell's fear that prescribing is becoming a lost art is well founded. We have just dispensed the following prescriptions, written by consulting M.D.'s, which serve to show what may be expected in the future:—

- | | |
|---|----------|
| (1) ℞ Sanmetto (Od. Chem. Co.) | ʒij. |
| Aletus cordial (Rio Chem. Co.)..... | ʒij. |
| ℞ Hyoscyami | ʒss. |
| Aque ad. | ʒviij. |
| M. ʒss. three times a day in an equal quantity of water. | |
| (2) ℞ Liq. ext. coca (Squire) | ʒss. |
| Syr. cinch., alcoholic (Schacht) | ʒj. |
| Ft. guttæ. | |
| Take 40 drops twice a day in a wineglassful of water at 11 and 4. | |
| (3) ℞ Liq. Pepsin c. Eucalyptin (Schacht) | ʒi. |
| ℞ Nuc. Vom. | ʒviij. |
| Bismuth Salicylat. | gr. iij. |
| Menthol | gr. ʒ. |
| Ess. de Calisaya | ʒss. |
| Aque ad. | ʒviij. |
| M. ʒj. ter die ant. cibos. Mitte dos., viij. | |
| (4) ℞ Peptenzyme | gr. x. |
- One powder to be taken in a wineglassful of warm water directly after lunch and dinner.

Doubtless these are the production of much thought and profound judgment, but it is a pity these gentlemen should ignore the British Pharmacopœia. It will be observed that the writer of the last two prescriptions has an open mind, and selects his specialties from Great Britain, France, and America.

March 14, 1896.

PHARMACIST.

EARLY FLOWERS.

Sir,—It may be of interest to your readers to add a few notes on early flowers. *Petasites fragrans* and *Ruscus aculeatus* may be seen on any Christmas Day, but they were in flower as early as November 17. *Daphne laureola*, *Viola hirta* and *Vinca major* were noticed on December 22, while *Salix cinerea* (male) was out on January 2. Amongst a host of others, *Stellaria holostea* may be mentioned, on January 19; *Caltha palustris*, February 23; and *Adoxa moschatellina*, on March 9. *Lamium purpureum* and *Geranium robertianum* have been with us throughout the winter.

Ryde, March 20, 1896.

E. W. POLLARD.

UNDUE CUTTING IN THE RETAIL TRADE.

Sir,—The growing evil of under-cutting is a question which must deeply concern chemists of to-day, and any scheme formulated for its amelioration should have the deepest consideration. Your correspondent of the 29th inst. would do much to bias the public mind by the exposure of the constituents of patents, but the question of merit and demerit would be a delicate point for chemists to decide, for the efficacy of a medicine does not lie in its pecuniary value, but rather in its therapeutic effect. But there remains another point of action which is not often suggested, and I think could deal a death-blow to the invading army of quackery (so aptly termed the decoy duck of the cutter) into this country. Such a power can do infinitely more for us than legislation. I refer to the "profession." Could not a deputation from the Pharmaceutical Society appeal to the British Medical Association to consider the distressing effect quackery has on medicine and pharmacy? and if, as a result, the profession were to issue a manifesto to the country, declaring that such wholesale consumption of patent nostrums was undermining the constitutions of its subjects, people would be sacred and rely more on the legitimate sources for the alleviation of their ailments? Conversely, will our relationship there justify such an action? We have been taught that Pharmacy is Medicine's handmaid, but it seems as though we have the sack, since doctors supply their own drugs, surgical appliances, etc., etc., and even permit secret patent remedies to poach among the ingredients of their prescriptions.

Winchester, March 10, 1896.

S. G. BARTLETT.

SHOPS (EARLY CLOSING) BILL.

Sir,—The onslaught upon this Bill by "M.P.S." was certainly amusing, if not instructive. His principles seem to be entirely opposed to all legislation, since legislation, when really required, must prove detrimental to some, or it could not better others. His theory seems to be that two-thirds have no moral right to interfere with what concerns the proprietor, and the proprietor only. Then what right has a government to interfere with suicides, lotteries, etc.? Is it not equally for the individual welfare that legislation should be employed in this case? Would not the Act be a just and proper thing for the proprietors themselves?

What "M.P.S." calls the stale argument, "because others keep open," is no bogey, as thousands can testify. Two cases flash to my mind at once, where competing chemists are almost next door to each other. In such cases how can one close before the other closes? Individuality, however manly and moral, is a luxury that innumerable chemists cannot afford to carry out to the full. In such cases as I have cited, the correct thing to do, of course, is for the two to make friends and arrange a time of closing between them. But the Shops (Early Closing) Bill is the same principle fitted into shape for universal adoption, the one difference being that when the bulk of the inhabitants have found it advisable to arrange a certain hour for closing, their object shall not be frustrated by the dog-in-the-manger-like action of a few.

Let us look at the matter broadly and work for the general good—not for our own selfish ends. "M.P.S." acknowledges that the assistant ought to be protected, therefore I need not enter into that phase of the question. I have dealt with practically the only reasonable objection, and can but believe that the harm the Bill would do would be but a drop in the bucket as compared with the vast and unlimited blessing it would be to thousands upon thousands of our pale-faced and consumptive shop-keeping classes.

Rochester, March 17, 1896.

H. S. YOUNG.

ANSWERS.

"K."—See short note in Journal for August 17 last, page 149. We have a special article on the subject in hand, and hope to publish it shortly.

"SUBSCRIBER."—Your "coal gas" is peculiar in containing a constituent having the formula C_4H_2 . Please say what you mean by this, and we will endeavour to supply the information you require.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Beeny, Bennett, Boyd, Christy, Clarke, Cocks, Cope, Cracknell, Dott, Ellinor, Fennell, Forrett, Gerrard, Grace, Grimble, Hardy, Hill, Ince, Jackson, James, Jones, Junor, Kent, Knight, Maiden, Netting, Pollard, Porter, Pretty, Rideal, Ross, Russell, Sawyer, Tame, Tanner, Thompson, Whitehead, Wretts.

ALCHEMY AND PHARMACY. THEIR MYSTERY AND ROMANCE.

BY C. J. S. THOMPSON.

[All rights reserved.]

(Continued from page 43.)

CHAPTER VII.

The Art of Foretelling.

The theory of the art of foretelling by means of the stars, and casting horoscopes, was as follows:—The seven planets then known, including the sun, with the twelve figures of the Zodiac, comprised the astrological system. Each unit, or body, or nation was supposed to be governed or influenced by a certain star or constellation, and this power extended to all things connected with the person or nation. Thus, Saturn was supposed to influence life, sciences, and buildings; Jupiter—honour, wishes, and wealth; Mars—wars, persons, marriages, and quarrels; the Sun—hope, gain, and happiness; Venus—love and friendship; Mercury—fear, disease, debts, and commerce; the Moon—robberies, wounds, and dreams. The intrinsic quality was denoted by the planet. The Sun was regarded as favourable; Saturn, cold; Jupiter, temperate; Mars, ardent; Venus, fruitful; Mercury, inconstant; the Moon, melancholy. The days, colours, and metals also came under the same influences.

In casting a horoscope the astrologer had first to observe if the time was propitious, and what planet was dominant in the heavens. Then by means of calculations and diagrams, he would deduce the consequences from the position and bearing of the stars. The day was divided into four equal parts; the ascendant of the Sun, the middle of the sky, the descending of the Sun, and the lower part of the sky. These four parts of the day were sub-divided into twelve distinct parts, which were called the twelve houses of the Sun. It was of the greatest importance in drawing a horoscope to tell exactly in which "house" the star appeared. One can easily trace the connection of the influence attributed to the planets with the old Greek mythology, and it can hardly be wondered at, that the same system should have been brought to bear on medicine.

A favourite method of divination, especially with the sorcerers, was that of gazing into a beryl or crystal. For the proper performance of this ceremony a pure virgin or equally pure youth should be the gazer. The sorcerer having

repeated the necessary charms and adjurations with the invocation suitable to the spirits he wished to consult, the seer then looked into a large beryl or crystal, wherein he saw the answer represented either by types or by figures, and sometimes it is said he might hear the spirit speak to him.

Vallancey states, that in the Highlands of Scotland large crystals of somewhat oval shape were kept by the priests to work charms with, and that water poured on them was given to cattle as a preventive of disease. Dr. Dee was a famous conjuror with the crystal in the time of Queen Elizabeth.

Lilly describes these crystals as being the size of an orange, set in silver, surmounted with a cross, and engraved all round with the names of the angels Raphael, Gabriel, and Uriel.

Among other charms practised was Dactylomancy, which was performed by means of a ring suspended by a thread in the centre of an earthenware or metal pitcher. The ring which was supposed to have been made under the influence of a certain constellation, was swung from side to side of the vessel, and the sounds it made on touching, were taken as predictions and oracles.

The art of divination by fire was called Pyromancy, and was performed by allowing a certain body to burn, the smoke from which, by its density and colour, forecast the future. A favourite medium for consulting this oracle was by roasting a donkey's head on hot coals.

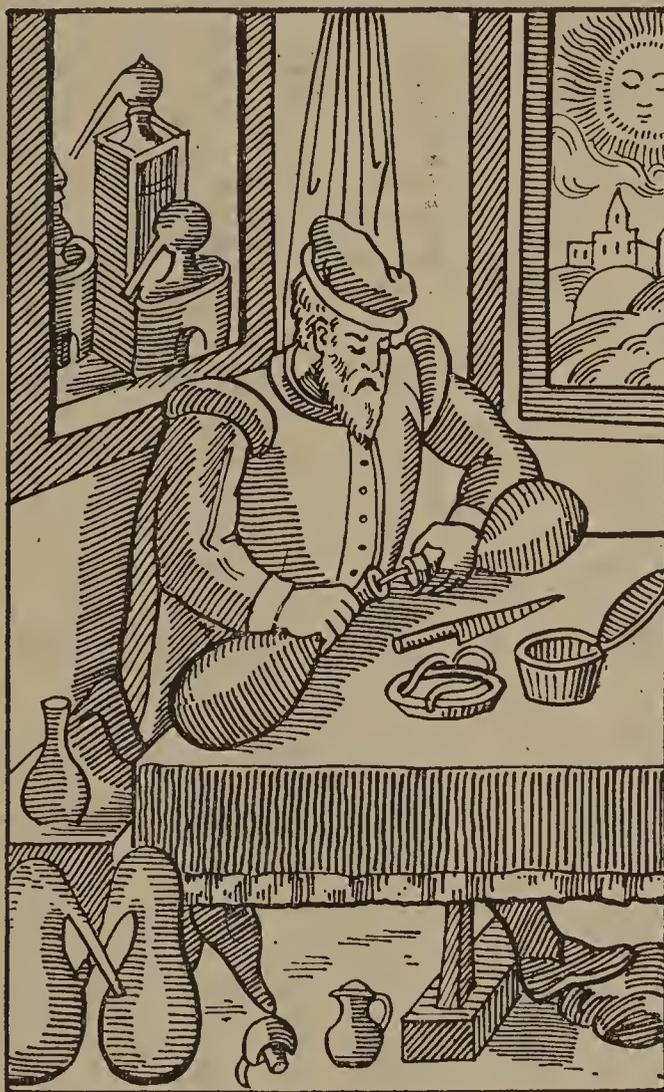

Popular belief in mediæval times attributed anything unusual, or beyond its understanding, to magic, so most of the early alchemists were believed to be magicians. Both Albertus Magnus and Roger Bacon were accused of dealing in the black arts, one having to resign his bishopric of Cologne and retire to a monastery, and the other to the Franciscan cells in Paris, to free

themselves from charges of their accusers.

The illustration represents an alchemist of the sixteenth century in an ante-room of his laboratory engaged in fixing a portion of his apparatus. On the table is his luting box and knife. Through one window a view of the laboratory with stills of varied size is obtained, while through the other the sun looks with becoming gravity on the operation.

The Symbols of the Alchemists.

In modern science chemists write their formulæ and work out their processes by means of symbols, so the alchemists used signs and hieroglyphics to represent the then known elements, metals, and other articles in common use. The

AN ALCHEMIST.

From an old engraving, dated 1576.

so-called elements—fire, air, water, earth—were represented by special symbols, here represented. The metals were supposed to be influenced by the planets to a certain degree, and were represented by the corresponding signs of the zodiac. Various other articles also had their symbols which served as a means of shorthand at a period when caligraphy was little known or employed.

Black Magic.

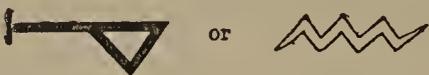

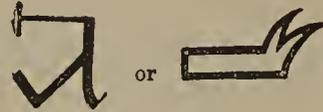

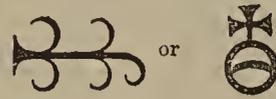

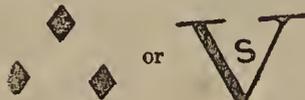

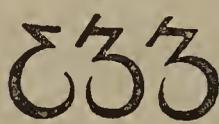

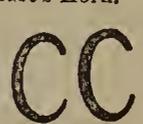

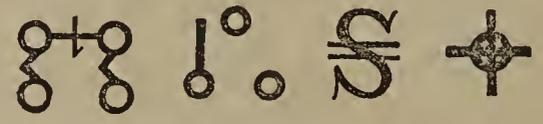

Geber, an alchemist of great repute in Arabia, was believed to possess the power of creating gold by magic. He was a man of undoubted learning and a skilful practitioner of his time, yet he was dubbed a sorcerer. He was said to possess all kinds of extraordinary implements, and, among others, a book of black magic which gave him full power over demons, and a brass idol which spoke oracles. On the day of his death, in 1003, the Evil One is supposed to have carried him off. James Iodoc, an Englishman, achieved considerable notoriety by claiming that he had succeeded in setting the demon in a magic ring. These men should not be confounded with the host of impostors and charlatans who simply preyed on the credulity of the people, but in those days all were judged alike. Most of the great mediæval alchemists dabbled in magic, and all agreed that to

obtain the intervention of Satan in human affairs, it was necessary to enter into a pact with him. Those who went to this length and became exponents of demonology or the black art, were initiated with much solemnity.

Taking the Oath.

The oath to the demon had to be pronounced in the centre of a circle traced upon the ground, accompanied by the offer of some pledge such as a garment of the novice. The edge of the circle was supposed to establish a mark which the demon could not cross. Heavy perfumes such as vervain, with burning incense and lighted tapers, always formed part of the ceremonial. The smoking brazier, which entered largely into the ritual, was believed to act upon the demons, and was constantly fed with all kinds of mysterious vegetable and animal substances, such as would produce most smoke being preferred. It is said that belladonna and opium were always used as ingredients of the incense, in order to produce a state of semi-stupor and influence the imagination.

The perfumes employed by the professors of the art had each a special significance, and were offered to some planet to form a link with the earth. A mixture of saffron, amber, musk, cloves, and

incense, together with the brain of an eagle and the blood of a cock was offered to the Sun.

The white poppy and camphor burnt in the head of a frog, with the eyes of a bull, and the blood of a goose, were dedicated to the Moon; while to Mars, sulphur was mixed with hellebore and euphorbium, together with the blood of a black cat and the brain of a crow, and then burnt.

One can imagine the terrible odour that would be caused by burning such articles as these, and as the column of smoke ascended, the half-stupefied and scared spectator fancied he saw the forms of writhing demons in the air.

Very curious properties were attributed to certain articles when thrown on live coals. Thus, if thunder and rain were required, the liver of a chameleon was said to produce it; while the gall of a cuttlefish burnt with roses and aloe wood, was all that was necessary to induce an earthquake.

By burning coriander, parsley, hemlock, liquor of black poppy, giant fennel, red santal wood, and henbane, almost any number of demons could be raised. Sorcerers of this class were called tempest raisers.

With the witchcraft practised largely by women in mediæval times we have not much to do, although belief in its influence was widespread during the middle ages. To bewitch an individual was to cause him gradually to die a mysterious death.

The process commenced at first with great secrecy, by modelling a figure of the intended victim in wax or clay. This having been done a swallow was killed, and the heart placed under the right arm of the figure, and the liver under the left. The effigy was next pricked all over with new needles, each prick being accompanied by the most terrible imprecations against the victim.

Another method was to make the figure of earth taken from a graveyard and mixed with dead bones. Certain mystic signs were then inscribed on it, which were said eventually to cause the death of the victim. So general did the practice of witchcraft become, that no class of society was safe from accusation and suspicion, thousands perishing by the faggot and torture.

From the fourteenth to the sixteenth century supernatural beliefs exerted a great influence on the people. One of the most celebrated trials of the time was that of the Duchess of Gloucester, who was accused of bewitching Henry VI. It transpired at the trial that she had instructed a priest named

Bolingbroke, who practised necromancy, to bewitch the King, a sorceress named Marie Gardimain being also implicated. An effigy of the King in wax was discovered half melted in front of a fire of dry plants, which had been gathered by moonlight in a graveyard.

Bolingbroke, the necromancer, was hung, Gardimain burnt, and the Duchess of Gloucester condemned to imprisonment for life. The "evil eye" was another form of witchcraft, mostly practised by women. Visions or apparitions in the sky, foretelling some war or disaster, were firmly believed in by the Church, and caused great consternation. Fiery dragons appearing in the heavens were said to predict civil

war, and we also read of pigs bearing royal crowns, and gory stars, all of which were doubtless caused by ordinary phenomena not understood at that time.

In the accompanying illustration, the alchemist with uplifted torch, is repeating the specified incantation over the still, under which he has just kindled a fire, having commenced the preparation of the "Elixir of Life."

The appearance of the devil presiding at a sabbath or meeting of sorcerers is thus described by De Lancre: "He is seated in a black chair with a crown of black horns, two horns in his neck, and one on the forehead, which sheds light on the assembly, the hair bristling, the face pale and exhibiting signs of uneasiness, the eyes round, large and fully opened, inflamed and hideous, with a goat's beard. The neck and the rest of the body deformed, and in the shape of a man and a goat, the hands and the feet of a human being." The word witch is thought by some authorities to be derived from *chausaph*,

which means a user of pharmaceutic enchantments, or an applier of drugs to magical purposes.

Witches sent storms and barrenness, drowned children, brought on ague, could kill with evil eye, slay with lightning, pass through key-holes, ride through the air on broom-sticks, and perform many other weird and wondrous things.

"They were generally old blear-eyed wrinkled dames," says Scott, "ugly and crippled, frequently papists and sometimes atheists; of cross-grained tempers and cynical dispositions." They were often poisoners, and generally monomaniacs. Epilepsy and all diseases not understood by the physicians were set down to the influence of witches. They were said to make two covenants with the devil, one public and one private. Then the novices were

AN ALCHEMIST.

From an old engraving, dated 1576.

presented to the devil in person, and instructed to renounce the Christian faith, tread on the Cross, break the fasts, joining hands with Satan, paying him homage, and yielding him body and soul. Some witches sold themselves for a term of years, and some for ever; then they kissed the devil, and signed their bond with blood, and a banquet ended the meeting; their dances being accompanied with shouts of "Ha, ha! devil, devil! Dance here, dance here! Play here, play here! Sabbath, sabbath!" Before they departed the devil was said to give them philters and amulets. These women were usually hypochondriacs, often driven by despair and fortune to confess any charge made against them.

PHARMACEUTICAL SOCIETY

MEETING OF THE COUNCIL.

WEDNESDAY, APRIL 1, 1896.

Present:

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. JOHN HARRISON, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Corder, Cross, Gostling, Grose, Hampson, Hills, Johnston, Martin, Martindale, Newsholme, Savory, Southall, and Warren.

The minutes of the last meeting were read and confirmed.

LETTER FROM MR. SCHACHT.

The SECRETARY then read the following letter:—

" March 26, 1896.

" 1, Windsor Terrace, Clifton.

" The President and Council of the Pharmaceutical Society of Great Britain.

" Gentlemen,—I beg to acknowledge the receipt of the resolution so kindly proposed by the President and supported by the Vice-President and the other members of the Council at its meeting in March.

" I esteem it the greatest compliment I have ever received, and though conscious that the terms therein employed are far too laudatory, I accept them gratefully as a measure of the feeling of personal attachment entertained for me by my late colleagues.

" Though no longer aspiring to the honour of membership of your Council, I beg to say I shall continue to feel a very deep interest in its proceedings and in all that concerns the interests of pharmacy.

" I have the honour to be,

" Gentlemen,

" Your very obedient servant,

" (Signed) G. F. SCHACHT."

NOMINATIONS FOR COUNCIL.

The Secretary reported that he had received twenty-four nominations to fill the fourteen vacant seats on the Council, and that the following eighteen nominees had declared their willingness to accept office if elected:—

Armitage, Nathaniel Newborn, 114, Tong Road, Armley, Leeds.

Bateson, Thomas, Stricklandgate, Kendal.

Campkin, Algernon Sidney, 11, Rose Crescent, Cambridge.

Carteighe, Michael, 180, New Bond Street, W.

Corder, Octavius, 31, London Street, Norwich.

Cross, William Gowen, Mardol, Shrewsbury.

Gostling, Thomas Preston, Linden House, Diss.

Harrison, John, 33, Bridge Street, Sunderland.

Hills, Walter, 225, Oxford Street, W.

Johnston, John, 45, Union Street, Aberdeen.

Martindale, William, 10, New Cavendish Street, W.

Newsholme, G. T. Wilkinson, 27, High Street, Sheffield.

Park, Charles James, 1, Mutley Plain, Plymouth.

Savory, Arthur Ledsam, 143, New Bond Street, W.

Storrar, David, 228, High Street, Kirkcaldy.

Symes, Charles, 14, Hardman Street, Liverpool.

Warren, William, 24, Russell Street, Covent Garden, W.C.

Wills, George Sampson V., 92, Croham Road, South Croydon.

The following six nominees had not expressed their willingness to accept office:—

Gravill, Edward Day, Jesmond House, Park Grove, Hull.

King, Horatio Alfred, Exchange Street, Norwich.

Martin, Nicholas Henry, Northumberland Road, Newcastle-on-Tyne.

Nichol, Anthony, 29, Bank Street, Carlisle.

Potter, Henry Arthur, 7, Raven Row, E.C.

Wilson, Harry, 146, High Street, Southampton.

NOMINATIONS FOR AUDITORS.

The Secretary also reported that he had received the following five nominations to fill the office of auditor, and that all the nominees had expressed their willingness to accept office if elected:—

Butt, Edward Northway, 77, Hamilton Terrace, N.W.

Lescher, Frank Harwood, 60, Bartholomew Close, E.C.

Stacey, Samuel Lloyd, 22, Great St. Helen's, E.C.

Umney, Charles, 50, Southwark Street, S.E.

Yates, Francis, 64, Park Street, Southwark, S.E.

FINANCE COMMITTEE.

The SECRETARY read the report of the Finance Committee, which recommended sundry accounts for payment, and stated that certain suggestions made by the auditors would receive attention.

The PRESIDENT (as Chairman of the Committee) moved the adoption of the report and recommendations. He said there was nothing special to refer to in the receipts, which mainly consisted of subscriptions and examination fees. The payments also were of the usual character. With regard to the Benevolent Fund, the receipts had been satisfactory, many members sending subscriptions with their subscription to the Society, and the local secretaries also having sent in a good many.

The report and recommendations were unanimously adopted.

ELECTION OF MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Lucas, Harry, Llandough. | Stoddart, James Geo. Young, Edinburgh.

Chemists and Druggists.

The following who were in business before August 1, 1868, having tendered their subscriptions for the current year, were also elected "Members" of the Society:—

Allen, Henry, London.

Cuthbert, Ralph, Huddersfield.

Ferrier, David Hynd, Dundee.

Glass, William Stephen, Edinburgh.

Lawson, Andrew, Dundee.

McKinnon, Daniel John, Dundee.

Marley, William, Newcastle-on-Tyne.

Troake, Robert James, Bristol.

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Abbott, James, Glasgow.

Barnett, Charles, Cleethorpes.

Bartlett, Samuel George, Winchester.

Cran, Newell Burnett, Aberdeen.

Cruickshank, John, Aberdeen.

Cummings, Charles, Dundee.

Davidson, Robert, Hawick.

Doig, John Lyall, Dundee.

Duncan, Adam, Leith.

Duncan, Charles Tocher, Dundee.

Forsyth, John, Dundee.

Fraser, Charles, Edinburgh.

Good, John Thomas, Bristol.

Green, Alfred, Wakefield.

Griffiths, Henry Thomas, Bristol.

Hearnshaw, John William, Spalding.

Houston, Fred. J., New Whittington.

Irving, James, Newton Stewart.

Joseph, Leopold, Cardiff.

Lindsay, Robert McIntosh, Dundee.

Peebles, Thomas Smith, Lochee.

Robertson, John Wright, Dundee.

Spencer, Frederick, Stratford-on-Avon.

Taylor, Walter, Child's Hill.

Waddington, Alfred Henry, Bradford.

Young, James, Torquay.

The PRESIDENT drew attention to the fact that this list included no less than twelve members or associates in Dundee, who had been introduced to the Society by the exertions of Mr. Harvey, the Local Secretary.

ELECTION OF ASSOCIATES.

The following, having passed their respective examinations and tendered or paid as "Students" their subscriptions for the current year, were elected "Associates" of the Society:—

Minor Examination.

Bagnall, Percy, Ashton-under-Lyne.	Patrick, Christopher, Bradford.
Bowden, Harold, Patricroft.	Rollett, Harry, Lincoln.
Mitchell, David, Broxburn.	Smith, Walter, Fyvie.
Veitch, George Hutcheson, Glasgow.	

Modified Examination.

Llewellyn, Richard, Merthyr Tydfil.

ELECTION OF STUDENTS.

The following, having passed the First examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Flood, William Hall, Lec.	Pilcher, Daniel Garnett, Margate.
Gittins, Samuel Ernest, Oswestry.	Roberts, William Henry, Chester.
Jeffery, John A. Paynter, Gateshead.	Rogers, F. E., Bury St. Edmunds.
Lloyd, Hugh William, Bala.	Stephenson, James, Newark.
McHattie, James Reith, Edinburgh.	Underwood, Albert Henry, Ipswich.
Mason, Hugh, Bexley Heath.	Walton, Thomas Robert, Cardiff.
Neal, David Thomas, Waddon.	Williams, David, Carmarthen.
Nicholls, Theophilus Henry, London.	Wrather, Thomas Edward, Bewdley.

RESTORATION TO THE REGISTER.

The name of the following person, who had made the required declarations, and paid the restoration fee, was restored to the Register of Chemists and Druggists:—

Abington, Leonard Yates, High Street, Staplo Hill, near Bristol.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and the nominal restoration fee of one shilling.

BENEVOLENT FUND COMMITTEE.

The report of this Committee included the recommendation of grants amounting to £57 in the following cases:—

The widow of a chemist and druggist, and former subscriber to the Fund. Is unable to support herself, and has no friends able to assist her. (Morecambe.)

The widow of a member. Has had previous grants amounting to £100. Is a hopeless invalid, and has no means. (Harrogate.)

The widow of an associate who died last year in an insolvent condition. She suffers from the effects of operation for cancer. (Wales.)

The widow of a chemist and druggist. Has had previous grants amounting to £60. Has been supporting herself in a situation, but has had to leave on account of ill-health. (London.)

The widow of chemist and druggist who had assistance from the Fund previous to his death. Applicant has also had a former grant. She is in feeble health, and her friends can only help her slightly. (Birmingham.)

The VICE-PRESIDENT, in moving the adoption of this report and its recommendations, said the Committee had before them eight cases for investigation yesterday. Of these they granted assistance to five, two were declined, and one deferred for further information. At first sight it might appear that the Committee had a partiality towards widows, but he could assure the Council that all the cases were dealt with on their merits, and the Committee were fully satisfied before arriving at their conclusions. In several cases where previous grants had been made the position of the applicants remained as acute as when they were formerly assisted, and he thought in one or two instances the aid they had been able to recommend was likely to prove exceptionally beneficial. In one of these, the applicant had got into a small business and was doing fairly well; but the premises she occupied being required for a bank, she had to leave. She had, however, thrown herself into the battle of life with much vigour, and she was now seeking to obtain a livelihood in another direction, and it was hoped good would result from the action of the Committee in helping her. Another case was a singularly unfortunate one. The husband, when called away, had left no direct provision for his family, for though he had insured his life, the office failed, and some investments he had made unfortunately proved worthless. In these circumstances he felt the help they were able to recommend would probably prove of a welcome character, besides proving the value of the Fund.

The report was then adopted.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

The SECRETARY read the report of this Committee. The preparation of the draft Annual Report had been referred to the President. A petition was presented from a number of students, asking for the use of a room for social intercourse. The consideration of this was deferred. The Committee recommended the addition of £25 per annum to the salary of the Librarian.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
February.....	{ Day	489	27	11	16
	{ Evening.....	214	18	7	11
Circulation of Books.	Total.	Town.	Country.	Carriage paid.	
February	199	111	88	£1 1s. 5 ¹ / ₂ d.	

Donations to the Library had been announced (*Phar. Journ.*, March 14, p. 207), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the under-mentioned books be purchased:—

For the Library in London:—

- Cole, Methods of Microscopical Research, 1895.
- Glazebrook, Heat and Light, 1895.
- Newth, Inorganic Chemistry, 1895.
- Roscoe and Harden, Dalton's Atomic Theory.
- Scott, Structural Botany, 1894.
- Zeitschrift für physikalische Chemie.

Museum.

The Curator's report had been received, and including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
February ...	{ Day.....	606	39	12	24
	{ Evening.....	54	7	1	2

Donations to the Library had been received (*Pharm. Journ.* March 14, p. 207), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The PRESIDENT moved the adoption of the report and recommendations, which was carried unanimously.

REPORT OF THE GOVERNMENT VISITOR.

The SECRETARY read a letter from the Privy Council Office, enclosing the following report on the examinations by Dr. Stevenson:—

"Report on the Examinations held by the London Board of Examiners of the Pharmaceutical Society of Great Britain during the year ending March 31st, 1896.

"To the Lords of the Council.

"My Lords,—I have the honour to report for your information that during the year ending 31st March, 1896, I have attended twelve examinations of the London Board of Examiners of the Pharmaceutical Society of Great Britain.

First or Preliminary Examination.

	Numbers.	Percentages.
Candidates examined	1468	—
" who passed.....	708	48.2
" " failed	760	51.8
Failed in Latin.....	502	34.2
" English.....	451	30.7
" Arithmetic	670	45.6

"These statistics show no large variation from those of the preceding year. The examination is an easy one, but as it is not necessary to pass it before commencing pharmaceutical study, it is too commonly put off till the last moment, with lamentable results. The weakness in Latin and arithmetic of some of the candidates who even pass this examination manifests itself at the later and more important qualifying examination.

Minor Examination.

	Numbers.	Percentages.
Candidates examined	772	—
" who passed.....	220	28.5
" " failed	552	71.5

Failed in Chemistry	305	39.5
„ „ Materia Medica	42	5.4
„ „ Botany	79	10.2
„ „ Prescriptions	34	4.4
„ „ Pharmacy and Dispensing	212	27.5
„ „ obtaining aggregate number of marks for a pass	60	7.8

“The number of candidates who presented themselves for this, the qualifying examination, shows a marked decrease when compared with those who presented themselves during the preceding year (1002), and the proportion of failures is considerably increased. Of the failures in Chemistry, 265 out of the 305 were in Practical Chemistry, *i.e.*, in laboratory work—assuredly one of the most important portions of the work of the chemist and druggist.

“The examination in this work affords the best test of practical knowledge, and cannot be adequately prepared for except by actual work in the laboratory; and in this preparatory study large numbers of candidates show a lack of experience. So long as a course of laboratory instruction is not obligatory, so long will, I fear, these deficiencies be revealed by a large proportion of failures.

“Although but few candidates were rejected for inability to read prescriptions, defects in Latin, especially in Latin grammar, are very manifest in the majority of candidates.

“The standard demanded at this examination was, in my opinion, a fair one and the stringency of the practical examination in chemistry is commendable.

Major Examination.

Candidates examined	Numbers.	Percentages.
„ who passed	120	—
„ „ failed	54	45.0
„ „ failed	66	55.0
Failed in Chemistry and Physios	31	25.8
„ „ Materia Medica	20	16.7
„ „ Botany	14	11.7
„ „ Practical Work	4	3.3
„ „ obtaining aggregate number of marks for a pass	17	14.2

“There was an appreciable diminution in the numbers presenting themselves for this examination. Only about one-third of those who qualify by passing the Minor examination proceed to the higher diploma of pharmaceutical chemistry. The failures in the scientific subjects of this examination, chemistry, physics, and botany, were greater than in the preceding year.

“I am, my Lords,

“Your obedient servant,

“March 14th, 1896.”

“(Signed) THOS. STEVENSON.”

The PRESIDENT said the most striking point about this report was the observation with regard to the Preliminary examination. They had known of this weak spot for a long time, and many of their younger members, both in the north and south, had called attention to it at their meetings. It seemed to him that it would shortly become a matter of duty on the part of the Council to consider whether in the interests of those entering the trade the standard of the Preliminary might not be raised. It appeared that after twenty-eight years of compulsory powers, apprentices were still taken by chemists and druggists without having passed the examination, and those young men spent a large part of their time while in the shop in getting up one after another the three subjects of Latin, Arithmetic, and English. Anyone trained in that way must be at a great disadvantage in after life, and it would be really more merciful if the examination appeared on paper more stringent, so as to deter young people who really had no school knowledge worth speaking of from attempting to pass it. It might also be a question whether the fee for the examination should not be raised after at least a second failure. Certain facilities were now given for repeated attempts, and there seemed to be an idea that when once the fee had been paid there was a financial advantage in coming up time after time; but he had grave doubts whether the present system was a good one, and whether it would not be better to increase the fee after a second failure. The Preliminary examination was the finger-post at the entrance to the calling, and it was only right to say that the possession of a certain amount of money by the candidates, or their parents and guardians, was essential for the payment of fees and securing a sufficient amount of instruction. In his view the exaction of moderate but fair fees, not for the purpose of making money, but to check the perpetual attempts of young people of seventeen years or older to pass an examination for which they were not adequately prepared,

would be beneficial. At last night's meeting of the Committee he reported the case of a candidate about twenty-five years of age who had been up for the Preliminary examination sixteen times, and still failed. The Preliminary was a test of knowledge at a particular period of life, and it was quite a mistake for a young man of nineteen or twenty to take up the study of Latin if he had had no preliminary school preparation. It was not right for parents or guardians to apprentice their sons or wards to chemists and druggists until they had passed the examination, and it was not morally right for chemists to take apprentices under such circumstances.

Mr. ATKINS having expressed his obligations to the President for the remarks he had made on this subject, said he much feared they would not have the practical result they well deserved to have. This was a very old story. He supposed it was some five and twenty years ago that he ventured to express strong views on this very question, and he should like to hear whether there were any legal difficulties in the way of the Preliminary examination or its equivalent being made compulsory. Until such compulsion was brought to bear, he feared very little would be accomplished, and the exigencies of trade and the fierceness of modern competition seemed to him only to accentuate that feeling. Emphatically endorsing, as he did, the President's remarks as to the cruelty of launching unfortunate fellows into business without a realisation of the severity of the tests which would afterwards follow, he did hope that at no distant day some steps would be taken in the direction he had indicated. He was also, he might add, painfully struck with the reference by Dr. Stevenson to the failures reported upon by him.

Mr. CROSS said, as having for some time supervised Preliminary examinations, that he had often felt it his duty to look over the papers, and he could not fail to be struck with the want of intelligence displayed by not a few of the candidates. He did hope, therefore, if only in the interests of the youths themselves, some restraint would be put on the number of times candidates might sit for the Preliminary examination, it being perfectly hopeless that some of them could ever become qualified.

The PRESIDENT said he feared a considerable number of failures were due to the apparent simplicity of the examination and the prevalence of an idea that it was possible to pass tests for which no sufficient preparation had been made.

The report was then adopted.

THE COMPANIES BILL IN PARLIAMENT.

The SECRETARY read a letter, addressed to the President of the Pharmaceutical Society, from Mr. John Junor, Hon. Secretary of the Inverness Chemists' Association, stating that the Association intended to send a signed petition to the Member of Parliament for the Inverness Burghs (Sir R. B. Finlay, Solicitor-General for England) inviting him to use his influence, when the Companies Bill was presented to the House of Commons, to get a clause inserted which would benefit pharmacy. The Association noted with pleasure that the President and several other representatives had actively interested themselves in the attempt to remedy some of the grievances respecting company trading. Sir R. B. Finlay being an influential member of the Government, the Inverness Association thought the present opportunity should be grasped, be the results what they might, and the grievances presented in the form of a petition to the Solicitor-General, on similar lines to those set forth by the Pharmaceutical Society's Committee to the Board of Trade. What the Inverness Association desired was that the Society should forward a memorial embodying the statements applicable in petition form, so that they could get the signatures of the masters to the same. They anticipated about twenty signatures within Sir Robert's representation, and if they went a little outside it they might number about thirty. The Association was indebted to the Editor of the *Pharmaceutical Journal* for his courtesy and advice in the matter.

The PRESIDENT said of course there would be no difficulty in meeting the request of Mr. Junor when the proper time came for moving in the matter. It might be convenient both to some members of the Council and to others who took an interest in this subject to hear that the Companies Bill introduced into the House of Lords was in the same form as that drafted by a special committee, appointed when Mr. Bryce was at the Board of Trade. The result of the interview between the President of the Board of Trade and their “Watch Committee,” as it had been designated, was that representatives of medical and other bodies equally interested in the matter had held a long meeting in connection with another Department of the

Government, with a view of getting an amendment introduced into the Bill. He was not in a position, nor did he think it would be wise, to say what they were doing, but the Council should know that they were not relaxing their efforts in the way of moving as quickly as possible in the matter. The initial difficulty they had in dealing with the matter was that of finding language which would give them what they wanted without fettering the Board of Trade in what that authority called industries and businesses. This was essentially a business nation, and so enormous an amount of money was invested in companies trading legitimately as contrasted with what some thought illegitimately, that the Board of Trade hesitated to introduce the amendments this Society had suggested, thinking they were too wide and sweeping. They were now, however, in a position to get assistance from another Department of the Government, and he was happy to tell them that they might possibly also get some assistance in their future deliberations from the distinguished member of the medical profession who had just been selected as President of the Royal College of Physicians. He would only add that the Watch Committee would not relax its efforts in the matter.

In answer to questions from the Treasurer and Mr. Atkins, the PRESIDENT said he understood the Bill was introduced into the House of Lords by the Government, because it was thought that the technical and legal difficulties with which it bristled might be better met and dealt with in the Upper House than in the more purely business atmosphere of the House of Commons, and consequently that it might be more speedily pushed forward.

PRESCRIBING PROPRIETARY MEDICINES.

The SECRETARY read a letter received from the secretary of the Western Chemists' Association of London, enclosing the following resolution which was passed *nem. con.* at a meeting held on March 18:—"That this meeting of the Western Chemists' Association of London is of opinion that the practice of prescribing proprietary medicines is becoming so extensive as to be seriously injurious to the progress of pharmacy and detrimental to the best interests of the medical profession, and considers it to be most desirable that all prescribers should adopt the practice of writing prescriptions without the name of any particular maker attached so that they may be dispensed by any chemist from recognised formulæ."

It was resolved that the resolution be referred to the General Purposes Committee for consideration.

EARLY CLOSING.

The SECRETARY said he had received from Mr. J. Anderson Russell, Secretary of the Glasgow and West of Scotland Pharmaceutical Association, a copy of a letter which had been sent to Sir John Lubbock, as follows:—

"Sir,—The Council of this Association desires to congratulate you upon progress made with Bill for Early Closing of Shops, and desires at the same time to draw your attention to circumstances connected with shops for the sale of drugs in Glasgow and the West of Scotland. In this city the majority of drug shops are the property of doctors who are the occupiers of the premises, and in many towns throughout the West the same statement applies, though it is believed the district is peculiar in this respect. There are also drug shops kept open by persons who are neither chemists nor doctors. Though many speak of these as 'chemists' shops,' and of persons engaged in them, though unregistered, as 'chemists,' these terms in any legal enactment would not apply to them, unless that were specifically stated, because the definition of the term 'chemist' extends only to persons registered under the Pharmacy Acts. It appears to be only fair that whatever conditions by legal enactment are made to apply to the keeping open of chemists' shops should be made to apply equally to all shops kept open for the sale of drugs and medicinal preparations.

"I am yours faithfully,
" (Signed) J. ANDERSON RUSSELL."

LEGAL PROCEEDINGS IN SCOTLAND.

The following letter had been received from the Glasgow and West of Scotland Pharmaceutical Association:—

"26th March, 1896.

"Sir,—Will you kindly submit the following communication to your Council:—
"We the members of the Glasgow and West of Scotland Pharmaceutical Association urge upon the Council of the Pharmaceutical Society of Great Britain the advisability of directing the attention of the Home Office to the

manner in which the Pharmacy Acts are represented in the Scottish Law Courts. In our opinion the Pharmaceutical Society, to which the enforcement of these Acts has been entrusted, is unduly hampered in its administration, and its purpose in prosecuting offenders is misrepresented by the Judges, so that the public sympathies are abused; and convictions against offenders are not represented by the Bench in a manner calculated to prevent further offences, or to give due significance to the fact that the law has been infringed. These circumstances are subversive of a due regard for the observance of the law and wanting in the spirit of equity.

"We particularly cite the following trials:—

"1st.—On October 23rd, at Dundee, before Sheriff-Substitute Campbell Smith in the case of the Pharmaceutical Society *v.* Stewart, and also on the 25th, *v.* Finlayson.

"2nd.—On October 26th, at Edinburgh, before the Lord Justice Clerk, Lord Young, and Lord Trayner in the appeal cases, the Pharmaceutical Society *v.* Turnbull, and *v.* Hume.

"3rd.—On December 16th, at Glasgow, before Sheriff Fyfe in the case of the Pharmaceutical Society *v.* Kerr.

"From these cases it will be seen that the comments made and the modified penalties inflicted are calculated to negative the good effects sought to be produced by securing convictions.

"We regard amendment of the Pharmacy Acts as being urgently needed, but while they remain on the Statute Book we look to seeing them enforced in legal equity, with a view to the attainment of that at which they are aimed.

"I am,
"Yours faithfully,
"J. ANDERSON RUSSELL,
"Secretary."

The communication was referred to the General Purposes Committee.

THE CONSTITUTION OF THE SOCIETY.

The SECRETARY read the following letter, which had been received from the Local Secretary in a large city, who did not desire his name to be published:—

"I wish your Council would take early steps to remove the inequalities of relations of members and associates of the Society. I have before expressed to you the belief, and I hold the opinion more strongly now than ever, that we shall never have pharmacists a united body till they are equal in qualification and in every other respect.

"To the ambitious and able pharmacist, as to everyone else, all honours in life are open, and if he desires to be marked beyond his fellows he should find his honours outside his profession. If he does not, and if he tries to distinguish himself from them by saying 'I am a better chemist and druggist than my neighbours, because I have passed an examination which he has not passed,' then he must not be surprised, and has no right to complain if his despised neighbour leaves him alone in his glory.

"Given a united body, the members equal in every respect, divide it into grades with different honours, rights, and privileges, and the body will at once disintegrate.

"The Council ought to realise by now that in the future it is likely they will have associates only as the backbone of the body. I speak thus strongly on this matter because of my experiences in collecting subscriptions, which I find a very hard and thankless task.

"I can assure you it is not through any respect or love for the Pharmaceutical Society that thirteen out of the eighteen qualified chemists in this town subscribe to the Society, and sixteen of them to the Benevolent Fund, but this is a standard which I can see will be quite impossible to maintain unless the associate is treated more liberally. Raising the status of associate to that of member is not in my way of thinking the goal, but it is a decided step in the right way, and is perhaps as much as could be looked for as a start, and would on its initiation bring in a number of members."

Mr. WARREN said he expressed some doubts at the annual meeting two years ago as to the wisdom of passing any measure which did not ensure a majority of pharmaceutical chemists, and though he had not spoken on the subject since, time and consideration had convinced him that nothing but the cordial co-operation of all qualified to practise pharmacy would be adequate to the work they wanted to do. He did not think the time when they had so many enemies was the time to give a half-hearted reception to their friends. In their social excursions they often met gentlemen who would do great service to the Society and be an honour to the Council, whom they regretted to find were not eligible to a seat there; but

he could conceive nothing more likely to give life and energy to the Council than to have a number of capable men eager and qualified to serve the Society upon it. He had felt the deepening of interest in the corporate welfare, which even a brief experience brought with it, and such as he hoped would be retained long afterwards. He trusted that whatever they went to Parliament for, they would achieve this object.

Mr. CORDER agreed with Mr. Warren, and with the views expressed in the letter from the local secretary.

The VICE-PRESIDENT moved that the letter be referred to the Law and Parliamentary Committee for consideration. It opened a very wide question on which his opinions were pretty well known, but the letter came from a gentleman who, he understood, had been very zealous and successful in enrolling members, and was certainly worth careful consideration.

Mr. WARREN seconded the motion, which was carried unanimously.

RESIGNATION OF PROFESSOR DUNSTAN.

The following letter, dated from the Research Laboratory of the Society, March 30, 1896, was read by the Secretary:—

"Dear Mr. President,—Having accepted the appointment of Director of the Department of Scientific and Technical Research of the Imperial Institute, I must ask the Council of the Pharmaceutical Society to accept my resignation of the professorship of chemistry and directorship of the Research Laboratory.

"I make this request with many feelings of regret at the termination of my official relationship to the Pharmaceutical Society, with which I have been intimately connected, as student and teacher, during a period of nearly twenty years.

"In looking back I have the satisfaction of realising that during this time a number of important improvements in the educational arrangements of the Society have been made by the Council, in the initiation of which I have been glad to take a prominent part.

"I beg that you will convey to the Council my sense of indebtedness for the kindness and consideration they have so often shown me and my desire in the future to render any assistance that may be in my power in furthering the educational and scientific work of the Society.

"I am, dear Mr. President,

"Yours very faithfully,

"WYNDHAM R. DUNSTAN.

"MICHAEL CARTEIGHE, Esq.,

"President of the Pharmaceutical Society of Great Britain."

The PRESIDENT said this was the first time in his experience that he had had to announce the resignation of a professor or lecturer. He proposed to ask the Council to accept the resignation, and to suggest to Professor Dunstan that it should date from the 1st of October, which he hoped might be arranged without difficulty. He would move the following resolution, which he suggested should be forwarded to Professor Dunstan:—

"That this Council, in accepting the resignation of Professor Dunstan, desires to record its appreciation of the services which, as Professor of Chemistry in the Society's School and Director of the Society's Research Laboratory, he has rendered to the Council in assisting to increase the efficiency of the educational and scientific work of the Society."

When the Research Laboratory was founded he pointed out that it was part of the educational advantages which ought to belong to such an institution, and he had been surprised since then to find in how many other places research laboratories had been founded on similar lines. Whatever differences of opinion there might be as to the character of the work done there—whether it was too purely scientific, and not so much in touch with what some called practical pharmacy as it might have been, he could not help saying that the mere fact that Professor Dunstan had been asked to take this position at the Imperial Institute, which had received annual grants of a considerable amount from the Commissioners of the Exhibition of 1851 for this purpose, and to undertake the organisation of a research laboratory, which would deal not only with the chemistry and pharmacology of drugs, but of the whole of the vegetable products of the colonies and of India, indicated that those in authority felt that the experience he had gained in their institution and the ability he possessed pointed him out as the right man for the position. He believed that if Professor Dunstan were properly supported in the new sphere to which he was removing he would be able to render important services to science. The work he would have to do would be on a much larger scale than he has had the

opportunity of undertaking hitherto, and he would really have to build up a scientific department dealing with all the vegetable products of the colonies and of India—dyes and so forth. If he succeeded as he had done in their institution in encouraging his co-workers and pupils, and creating in them an enthusiasm for original work, he thought they would have reason to congratulate themselves on the fact that one of their professors had been appointed the first director of this important scientific institution. He understood the contemplated work would include the examination of drugs, and it might be that later on they would find it convenient to be in touch with Professor Dunstan and his colleagues, and that they on their side should be in touch with the work of this Society, which possibly later on might be asked to assist with advice in certain branches of research work in which the Pharmaceutical Society had special advantages. Whether this should be so or not, he wished Professor Dunstan, who was still a young man, every success in this new enterprise, both on public and on personal grounds. He believed it was intended eventually to make this scientific department a very big concern, and he had no doubt Professor Dunstan would find there abundant scope for his activity and his unwearied ability and industry.

Mr. HAMPSON seconded the motion with much pleasure, and hoped Professor Dunstan's future career would be both brilliant and successful.

Mr. HILLS desired to bear testimony after twenty years' experience to the marked ability and exceptional industry displayed by Professor Dunstan. He congratulated him on this new appointment and on the honours he had already attained, and had no doubt that further marks of distinction awaited him.

Mr. MARTIN also desired to join in congratulating both Professor Dunstan and the Imperial Institute on the appointment. He had felt it his duty to criticise some of the work in connection with the Research Laboratory, as not being sufficiently connected with pharmacognosy and pharmacy, but in this new sphere the work he had already done would be of service, and he would find a wide field for his energies. He wished him personally every possible success, and a great and brilliant future for the laboratory over which he was to preside.

The resolution was carried unanimously.

The PRESIDENT then moved:—

"That it be referred to the General Purposes Committee to consider and report (a) as to what steps should be taken to fill the vacancy caused by the retirement of Professor Dunstan, and (b) to consider generally the relations of the Society to its educational work and to the School of the Society."

The resolution was seconded by the Vice-President, and carried unanimously.

GENERAL PURPOSES COMMITTEE.

The portion of the report of this Committee dealing with the School of Pharmacy prize examinations having been read, the President moved that upon it the following awards be made:—

Practical Chemistry.

Bronze Medal..... George Senter.
Certificates of Honour { John Arthur Dewhirst.
Francis Underwood Stamp.

Chemistry and Physics.

Bronze Medal..... George Senter.
Certificates of Honour { Harold Wilson.
James Hamerton.

Botany.

Bronze Medal..... John Arthur Dewhirst.
Certificates of Honour { Francis Underwood Stamp.
William Neale Ellis.

Materia Medica.

Bronze Medal..... George Senter.
Certificate of Honour John Arthur Dewhirst.

Pharmacy and Practical Pharmacy.

Bronze Medal..... Harold Wilson.

The proposition was unanimously agreed to.

The Council then went into Committee to hear and consider the report of the General Purposes Committee so far as it referred to legal proceedings.

On resuming, the report and recommendations of the Committee were adopted, and special resolutions were passed authorising the Registrar to institute proceedings against certain persons for breaches of the Pharmacy Acts.

SCHOOL OF PHARMACY

PRIZE EXAMINATION QUESTIONS.

Session 1895-96.

(Continued from page 252.)

CHEMISTRY.

PROFESSOR DUNSTAN.

Friday, March 27.—11 a.m. to 2 p.m.

- Describe the preparation and chief properties of the chlorides of phosphorus. Explain the action of water on each.
- Describe and explain the action of concentrated sulphuric acid on each of the following substances:—Sodium chloride, bromide and iodide, hydrogen sulphide, sulphur, carbon, and alcohol.
- What is the chief ore of mercury? How is the metal obtained from it and purified?
- Briefly describe the chief properties of arsenic, antimony, and bismuth. How are these elements classified?
- Calculate the latent heat of steam from the following data:—
Weight of copper calorimeter, 80 grammes.
" " calorimeter and water, 180 grammes.
" " calorimeter, water, and condensed steam, 198.42 grammes.
Initial temperature of water, 10° C.
Final temperature of water, 80° C.
Specific heat of copper, 0.092.
- Write a short account of the phenomena of diffusion of gases and liquids.

MAJOR EXAMINATION QUESTIONS.

CHEMISTRY.

March 31, 1896.—10 a.m. to 1 p.m.

[Six questions only are to be attempted.]

- Mention any instances you are acquainted with of the synthesis of hydrocarbons from bodies containing a smaller number of carbon atoms.
- How would you propose to separate the elements copper, arsenic, antimony, and tin? Indicate by equations the reactions upon which the method of separation is founded.
- Give a clear and full account of how you would prove that the molecular formula of ethylene is C_2H_4 .
- How can the following substances be obtained:—Potassium hypophosphite, sodium metaphosphate, silicon chloride, perchloric acid, metastannic acid, hypochlorous anhydride?
- What is the acetylene theory of the luminosity of flame, and upon what experimental evidence does it rest?
- Indicate several different methods by which ethylamine could be obtained from ethyl alcohol.
- Show how the specific heat of an element in the solid state can be approximately calculated from a knowledge of the specific heat of one of its compounds.
- Compare the principal reactions into which acetone and acetaldehyde respectively enter.
- Describe carefully how you would prepare ortho- and para-nitrophenol from phenol, and how you would separate these two nitro-compounds from each other.

PHYSICS.

March 31, 1896.—2 to 5 p.m.

[Six Questions only to be attempted.]

- Describe the methods employed for the liquefaction of gases. What is the explanation of the fact that the gases formerly known as "permanent" have only recently been liquefied?
- What is the law of diffusion of gases? Describe the method by which this law was determined. How may it be shown by means of gaseous diffusion that ammonium chloride is dissociated by heat?
- Explain the following statement:—"The atomic weight of a solid element is that quantity which at any given temperature contains the same amount of heat as seven parts of solid lithium at the same temperature."
- What is meant by the dew-point, and how is it determined?
- Describe the phenomenon of double refraction. Explain the principles that account for it.

6. Describe the construction of a reflecting telescope, and show how its action depends on the laws of reflection.

7. How is the electrical resistance of a metallic wire determined? What relations exist between the resistance, length, and diameter of the wire?

8. Describe how magnetic declination and magnetic inclination are determined. What are isogonic and isoclinic lines?

9. Describe the construction and action of lightning conductors. On what principles do their action depend?

A Paper.*

BOTANY AND MATERIA MEDICA.

Wednesday, April 1.—10 a.m. to 1 p.m.

- What do you understand by a natural system of classification of plants? Point out its advantages over the artificial system of Linnæus. Illustrate your answer, as far as you can, by references to British Plants.
- Describe in detail two aberrant genera of the natural order *Scrophulariaceæ* and point out how they differ from the type of this family.
- Give some account of the manner in which plants reach to the external stimulus of light.
- What is *Jalap*? What substances are frequently found as substitutes for it, and how would you recognise the genuine drug? Briefly describe a method of estimating the different resins it contains.
- Enumerate the chief mydriatic alkaloids. From what plants and from what parts of such plants are they severally obtained?

B Paper.*

BOTANY AND MATERIA MEDICA.

Wednesday, April 1, 1896.—2 to 5 p.m.

- Give a general outline of the system of classification of plants proposed by De Candolle, and point out the chief characters in which its subdivisions are based.
- Write a general account of the natural order *Ranunculaceæ*, and illustrate by reference to British genera the various forms of flowers which are met with in this family. Give the floral formula of each genus mentioned.
- Give a clear account of the formation, function, and manner of occurrence of starch in plants.
- What active constituents are yielded by *Podophyllum peltatum*? Describe their preparation and mode of separation. From what part of the plant are they obtained?
- Enumerate the fixed oils which are the most important pharmaceutically. From what sources are they severally obtained? Give an account of the preparation of one of them, and state to what constituents its medicinal properties are due.

B Paper.*

PRACTICAL BOTANY AND MATERIA MEDICA.

Wednesday, April 1.—10 a.m. to 1 p.m.

- Write a concise description of A, and illustrate your account of its structure by means of microscopic preparations. Leave diagrammatic sketches of it, and not more than two sections, mounted in glycerine.
- Describe in technical language the flower provided, and refer it to its natural order, giving your reasons. Draw its floral diagram.
- Identify the leaf B, and demonstrate its histological peculiarities.

A Paper.*

PRACTICAL BOTANY AND MATERIA MEDICA.

Wednesday, April 1.—2 to 5 p.m.

- Write a concise description of C, and illustrate your account of its structure by means of microscopic preparations. Leave diagrammatic sketches of it, and not more than two sections, mounted in glycerine.
- Describe in technical language the flower provided, and refer it to its natural order, giving your reasons. Draw its floral diagram.
- Cut such sections of the leaf D as will exhibit any histological peculiarities which are of assistance in the recognition of the drug. Explain your preparation from this point of view.

* Part of the candidates received the papers A, A, and the remainder had the papers B, B.

RECENT WORK ON THE LIQUEFACTION OF GASES.

Professor Dewar's lecture at the Royal Institution, on March 27, was about "Further Researches on Liquid Air," and attracted an audience which filled the theatre to its utmost capacity. The Professor remarked at the outset that on previous occasions he had devoted attention mainly to the optical and electrical properties of liquid air, and it was now his intention to treat more fully of the production of low temperatures and the difficulties encountered in approaching the temperature of absolute zero. The question of low temperature results was, he said, a question of technique pure and simple, and all the advances which he had made in the required direction had been obtained by modifying the apparatus used in such a manner that the heat of the surrounding atmosphere was excluded as far as possible. A diagram of the apparatus in use at the Royal Institution ten years ago was shown, and contrasted with that now used, and it was pointed out that the disastrous results obtained with the former were mainly attributable to the fact that it was constructed on too theoretical lines. On the other hand, the fact was strongly emphasised that the principles of the production of extremely low temperatures by means of regeneration was involved in both forms of apparatus, the principle of which owed its conception in the first instance to Sir William Siemens. The vessels now used by Professor Dewar exclude 95 per cent. of the heat of the surrounding atmosphere, which would otherwise affect the cooling liquid by convection and radiation. This is accomplished by using highly exhausted vacuum vessels immersed in others containing liquid air.

Professor Dewar devoted a considerable proportion of time to carrying out experiments, the majority of which were quite novel. The first was familiar enough, and consisted in breaking the vacuum of one of the glass test tubes in which a quantity of liquid air had been placed. When this was done the liquid, formerly quiescent, began to boil very rapidly. Afterwards, the direct liquefaction of air was shown. The liquefaction of the oxides of nitrogen, NO_2 , N_2O_5 , N_2O_4 , was then demonstrated, the gases being contained in glass globes, which were rubbed with a sponge pad that had been soaked in liquid oxygen, and so cooled. A similar experiment to this was one in which bromine were introduced into a vessel which had been previously rendered vacuum, and in which a cavity was blown in the top to allow of liquid oxygen being placed therein. When this was done, the whole of the bromine was deposited in the form of red crystals around the cooled portion of the globe, the red fumes entirely disappearing. After removing the cooling agent the crystals reassumed the vaporous condition. The boiling point of oxygen, -184°C ., was shown by immersing a thermo-couplet and noting the deflection on a galvanometer scale. An apparatus was also shown by means of which two samples of air can be liquefied by means of contact with air that has previously been liquefied.

Professor Dewar passed on to the consideration of regenerators in the liquefaction of hydrogen. In the first of these a silver tube was arranged in the form of a coil, and it was shown that so long as this part was not exposed to the action of the cooling gases issuing from the minute, needle-like orifice of the tube, there was no appearance of liquefaction, but when the silver coil was inserted into the vessel, and the expanded air passed over the coils, a liquid jet very soon appeared. Passing on to more elaborate experiments, one was shown in which a jet of liquefied oxygen so reduced the temperature below that of the critical point of oxygen in a tube that the latter was seen to fill up with liquid oxygen supplied from a bottle in which it was under a pressure of about forty atmospheres.

Next followed a description of the method found to give the most satisfactory results in the liquefaction of hydrogen. The basis of this is the reduction of the temperature of a gas by means of forced expansion through a needle point aperture under high pressure. This process usually reduces the jet to the condition of a fine spray of liquid, but in the case of hydrogen various precautions connected with the regenerative principle have to be observed in order to obtain successful results. The advantages of copper coils for the purpose of easily obtaining liquefied gases were dwelt on, and in this connection a striking experiment was shown. A quantity of liquid oxygen was placed in a vacuum vessel, into which was inserted a copper coil fitted with a minute hole at the bottom. Then hydrogen, which had been previously cooled by liquid carbonic acid and liquid air, was blown through the oxygen in the tube, and the oxygen, after a few moments, became converted into a dense opaque solid mass.

NOTES AND QUERIES.

CANTHARIDES HAIR LOTION.

There are many formulæ for a cantharides hair lotion made on a similar plan to the prescription you quote—

R Tr. cantharidis	5iiss.
Ol. olivæ	3iiss.
Ess. stephanotis	ʒxx.
Aqua calcis	ad ʒx.

M. ft. lotio pro capitis.

The oil and lime water are shaken together to form an extemporaneous linimentum calcis. It is not stable, but is kept in suspension by adding a solution of white Castile soap, in the proportion of 1 drachm to a fluid ounce of the whole lotion—

Soap Solution.

Saponis duri	grs. 40.
Aquæ destillat.	ʒi.

M. leni calore; filter and use cold.

The spirit should be added last. [*Reply to "Calcis."*]

DEODORISED PARAFFIN OIL.

You will hardly succeed in deodorising ordinary paraffin oil without much trouble. There is a so-called odourless oil in the market, and you can prepare a very good article by thinning down vaseline oil with light petroleum spirit. A few drops of citronella or cassia oil will cover the slight odour of this. [*Reply to W. T. P.*]

PEARL-COATING PILLS.

The insolubility of these is generally due to a coat of impermeable varnish being applied first before the pearl coating is used. With a little practice you will get good results with the following method:—Moisten the pills, which must be perfectly dry and hard, with just sufficient of a mixture of mucilage of acacia, 1 drachm; syrup, 1 drachm; water, 5 drachms; rectified spirit, 1 drachm. Use for coating the following powder:—Finest French chalk, 6 drachms; rice starch, 2 drachms. Coat in the ordinary way in a round vessel, and finally burnish in another tin without any powder. Take great care not to add too much of the moistening liquid at first, yet enough to evenly damp the pills. [*Reply to W. T. P.*]

COPAIBA IN PILLS.

To dispense the following prescription:—

R Copaibæ Balsam	grs. 250.
Magnes. Calc. Levis	grs. 18.

M. ft. Massa in pil. 60.

Carefully evaporate the balsam on a slab to about 100 grains, to which, while still hot, add the light calcined magnesia. An excellent pill mass is the result. Rapid manipulation is required. [*Reply to C. T. Duncan.*]

COOLING POWDERS.

We cannot give any information as to the composition of proprietary articles. As a non-aperient cooling powder you may give 4 grains of potassium nitrate with 1 grain of powdered sugar. [*Reply to Pharmacist.*]

COMPOSITION POWDER AND ESSENCE.

The original formula for the powder is: Powdered bayberry bark, 4 ozs.; powdered *Pinus canadensis* bark, 2 ozs.; powdered ginger, 2 ozs.; powdered capsicum, $\frac{1}{4}$ oz.; powdered cloves, $\frac{1}{4}$ oz. The essence is made by percolating the above with a menstruum of 1 part of proof spirit to 2 parts of water, so that every ounce of powder may give 4 fluid ounces of percolate. [*Reply to Pharmacist.*]

HOUSEHOLD AMMONIA.

Strong solution of ammonia, 5 ozs.; yellow soap, 2 ozs.; pearl-ashes, 1 oz.; distilled water, 3 pints. Dissolve the soap in the water, made warm; add the pearlash, and when nearly cold, the ammonia. Keep well corked. [*Reply to P.E.L.*]

TO RELIEVE PAIN IN EXPOSED TOOTH PULP.

Solution of cocaine hydrochlorate (4 per cent.), 20 parts; oil of sassafras, 30 parts; carbolic acid, 50 parts. Shake the bottle before using [*Journ. Brit. Dent. Assoc., xvii., 127.*]

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany,
Austria, Italy, Russia, Switzerland, Canada, the
United States, South America, India,
Australasia, South Africa, etc.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, APRIL 4, 1896.

THE COUNCIL MEETING.

At the Council meeting on Wednesday, a letter from Mr. SCHACHT was read, acknowledging the compliment paid to him by the resolution passed at the last meeting.

The Secretary reported that he had received twenty-four nominations for the Council election, and that out of the number eighteen had declared their willingness to become candidates for the fourteen vacant seats. One retiring member of Council does not offer himself for re-election, and the additional candidates are MESSRS. ARMITAGE, of Leeds; BATESON, of Kendal; CAMPKIN, of Cambridge; PARK, of Plymouth; and SYMES, of Liverpool.

The nominations for the office of auditors did not introduce any alteration, and all the nominees have expressed their willingness to accept office.

In moving the adoption of the report of the Finance Committee, the PRESIDENT stated that the receipts consisted chiefly of subscriptions and examination fees, while the payments were of the usual nature. The receipts on account of the Benevolent Fund have been satisfactory, both from members and local secretaries.

The additions to the Society comprise ten members, thirty-four associates, and sixteen students.

On the recommendation of the Benevolent Fund Committee, grants amounting to fifty-seven pounds were authorised. The Vice-President in moving the adoption of the report instanced the benefit conferred by the Fund.

The report of the Library, Museum, School and House Committee, in addition to the usual details, mentioned a request made by students for the use of a room for social intercourse, the consideration of which is deferred.

The report of the Government Visitor of examinations received from the Privy Council Office was read, and will be found at page 265. In reference to it, the PRESIDENT called attention to the remarks on the Preliminary examination, and suggested that in response to the representations received it would be the duty of the Council to consider whether the standard of this examination should not be raised. Owing to the fact that apprentices are still taken by chemists and druggists without having first passed the Preliminary examination, many of them are placed at a great disadvantage in after-life when they discover that they have not been properly prepared for obtaining qualification in the calling they have entered upon.

Mr. ATKINS, in expressing his obligation to the PRESIDENT for his remarks, said that he feared they would not have much practical effect unless the passing of the Preliminary examination were made a compulsory condition of apprenticeship, and he hoped steps would be taken in that direction before long. Mr. CROSS referred to his experience in the supervision of the Preliminary examination as having afforded evidence that it is hopeless for some of the candidates to become qualified.

A letter relating to the Companies Bill now before Parliament, and addressed to the PRESIDENT, by Mr. JOHN JUNOR, the Honorary Secretary of the Inverness Chemists' Association was read. It stated that the Association intends to invite SIR R. B. FINLAY, as member for the Inverness Burghs, to use his influence in getting a clause inserted which would benefit pharmacy, and requested that a suitably prepared memorial should be forwarded for the purpose in view. The PRESIDENT mentioned that the Watch Committee has had an interview with another department of the Government, and that there is now a possibility of getting assistance in that quarter as well as from the new President of the College of Physicians.

The subject of prescribing proprietary medicines was raised by the reading of a letter from the Western Chemists' Association of London, enclosing a resolution passed at a meeting of that body last month. The matter was referred to the General Purposes Committee for consideration.

A copy of a letter addressed to SIR JOHN LUBBOCK by the Secretary of the Glasgow and West of Scotland Pharmaceutical Association, on the subject of early closing, was read. Another letter from that Association related to the recent decisions by Scottish Courts in prosecutions under the Pharmacy Act. The Association considers that the administration of the Act by the Pharmaceutical Society is unduly hampered in a manner subversive of due regard for the observance of the law.

A letter was read from the local secretary of a large city, pointing out the desirability of removing the inequalities in the position of members and associates of the Society, and urging that legal qualification under the Pharmacy Act, 1868, should constitute eligibility for membership of the Society. In reference to this letter, Mr. WARREN said that since the time when he expressed doubts as to the wisdom of the course suggested, further consideration had led him to a conviction that it is necessary to offer every inducement for increasing interest in the Society, and for bringing into it all capable and qualified men willing to serve it. On the motion of the Vice-President, seconded by Mr. WARREN, the letter was referred to the General Purposes Committee.

In a letter addressed to the PRESIDENT, Professor DUNSTAN requested the Council to accept his resignation in consequence of his appointment as Director of the Department of Scientific and Technical Research of the Imperial Institute. On the motion of the PRESIDENT, seconded by the Treasurer, a resolution was passed accepting the resignation of Professor DUNSTAN, and expressing appreciation of his services as Professor of Chemistry in the Society's School and Director of the Research Laboratory. Mr. HILLS and Mr. MARTIN joined in congratulating Professor DUNSTAN and the Imperial Institute on the appointment, and in the expression of wishes for his future success. It was then resolved that the General Purposes Committee should consider what steps should be taken to fill the vacancy caused by the retirement of Professor DUNSTAN and, generally,

the relations of the Society to its educational work, and to the School of Pharmacy.

The report of the General Purposes Committee gave the results of the examinations for school prizes (see p. 268), and the several awards were confirmed. After the portion of the report relating to legal proceedings had been considered in committee, it was resolved that the Registrar should institute proceedings in the cases to which the recommendation of the Committee related.

DR. STEVENSON'S REPORT.

THE Government Visitor's reports to the Privy Council on the examinations of the Pharmaceutical Society are always interesting documents, inasmuch as they furnish an absolutely independent and impartial view of the value of the pharmaceutical qualification, and the educational standard of those who obtain that qualification. The report presented to the Council on Wednesday on the examinations during the year ending March 31 (*vide* p. 265) is specially worthy of attention, though it is somewhat humiliating reading. In it the Government Visitor once more revives the impeachment of the First examination. Speaking of that examination Dr. STEVENSON says it is an easy one. "But," he continues, "as it is not necessary to pass it before commencing pharmaceutical study, it is too commonly put off till the last moment with lamentable results. The weakness in Latin and arithmetic of some of the candidates who even pass the examination manifests itself at the later and more important qualifying examination."

Comments of similar purport have been contained in former reports, and the present reiteration seems to imply an absence of any effort to remedy the evil so often adverted to. With the expression of opinion as to the practical worthlessness of the preliminary test adhered to by the Pharmaceutical executive, the duty of the Government Visitor terminates; and the Department to which he reports has little or no concern with the number of unprepared candidates presenting themselves for the Minor examination, beyond seeing in the public interest that the process of elimination in the examination room is sufficiently effective to reject incompetence. It is to the Pharmaceutical Society, therefore, that the warning would seem to be principally addressed.

It is not a matter of indifference to those who claim to have the highest interests of the pharmaceutical calling at heart that the Society should officially continue to recognise persons of little knowledge and no mental training as eligible for entry to the Minor examination, and little doubt can be entertained of the opinion held by thoughtful members of the calling. Indeed, there appears to be ample reason for supposing that the strictures of Dr. STEVENSON are not only well founded, but that a good many interested persons are fully alive to the fact. The First examination, however, still preserves its modest triumvirate of subjects, whilst the mildness of that "rule of three" has passed into the category of proverbial truisms. The Medical Council has erased it from the list of examinations received *pro tanto* in lieu of the medical preliminary, and it is regarded as a veritable pariah among professional entrance examinations—of no caste, despised and rejected. Yet the Pharmaceutical Society's First examination, slighted though it be, proves too difficult for 51.8 per cent. of potential pharmacists to pass at the first attempt, and it must further be borne in mind that the absence of any means of compelling youths to satisfy so modest a test of scholastic acquirement

before entering upon apprenticeship or pupilage makes the examination still less potent to effect the object for which it was called into being.

THE CULTIVATION OF SAFFRON IN KASHMIR.

ACCORDING to Mr. W. R. LAWRENCE, the latest authority on Kashmir (*vide* pp. 131, 227, and 275), the saffron of that country is famous for its bouquet, and is in great request both as a condiment and as a pigment for the "forehead marks" of the Hindoos. The cultivation of the saffron plant in the district is peculiar, and the industry is an ancient one, the saffron crop formerly constituting a large source of revenue to the State, but during a famine the people in their distress ate the bulbs, and although seed has been imported and land is set apart every year for the production of more seed, the process of reproduction is so slow that the deficiency is yet far from being made up. At the present time cultivation is extending as fast as the local method of seed-production will allow, but, as may be expected, this method is very slow, and out of a total measured area of 4527 acres of saffron land, only 132 acres were found to be actually under cultivation with the saffron crocus. For seed purposes a particular aspect and sloping ground are required, and it is three years before the bulbs can be planted out in the small square plots where the plants are grown. These plots are allowed to remain fallow for eight years, without the application of manure or water. In July or August the surface of the ground is gently broken up a few times, and a neat trench dug on all four sides to ensure the proper drainage of the plot. The bulbs, being then planted, will live for fourteen years without any interference by the cultivator, new bulbs being produced and the old ones rotting away. About the middle of October the flowers appear, and at harvest time the whole flowers are picked, put into bags, and then taken to the farmer, who keeps one bag for himself and gives the other to the cultivator.

The flowers having been dried in the sun, the next step is to remove the three long stigmata from each, this operation being performed by hand. The stigma has a reddish orange tip, and the first quality saffron (*shahi zafran*) consists of such tips only. The rest of the stigma is white, and is collected separately, and sold under the name of *mongla*. The flowers are next beaten lightly with sticks and winnowed, after which the whole mass is thrown into water, when the petals swim and the other parts of the flowers sink. The sunken matter (*nival*) is collected, and the parts which rise to the surface are dried, again beaten with sticks, and once more plunged into water, this process being repeated three times, and the *nival* each time becoming poorer. By mixing *nival* of the third stage with that of the first a kind of saffron is obtained, which is lighter in colour and of fainter odour than *mongla*. This mixture is known to the trade as *lacha*. It is said to have been found by experience that the cultivator never attempts to foist a bad bag of saffron flowers on the farmer, but this may be due less to native honesty than to the strict watch kept during harvest time, the cultivators being "as carefully watched and supervised as diamond-diggers at Kimberley." Apparently there is little chance of the industry extending to any considerable extent so long as the present primitive method of reproduction from seed is exclusively resorted to, and Mr. LAWRENCE is doubtless right in his surmise that the production of saffron in Kashmir might increase if the European methods of producing seed bulbs were adopted.

ANNOTATIONS.

THE RAPID ACQUIREMENT OF LANGUAGES.—We are yet far off the time when the English language will be familiar the world over, and English people are, every year, becoming more alive to the fact that a knowledge of other languages than their own, and especially of modern languages, is a matter of vital importance to them. Unfortunately, in most cases they are compelled to acquire French, German, etc., at home, rather than abroad where those languages are spoken, and the systems that prevail tend, for the most part, to disgust and deter would-be linguists. A notable exception in this respect is the method devised by M. Gouin some fifteen or sixteen years ago, and recently introduced into this country by Mr. Howard Swan. By means of the Gouin Series Method the study of any language is from the beginning rendered interesting, attractive, and practical, by dramatic scenes out of real life acted in front of the class. Indeed, it is difficult to speak too well of this system, under which it is claimed that a student can learn to speak any language well in about six months, devoting four hours a week to the work. Classes are now being conducted in London and in several provincial towns. Specimen lessons are given free to intending students, and it is announced that a special demonstration lesson in German will be given at Howard House, Arundel Street, Strand, on Thursday next, April 9, tickets for which may be obtained free on application. A special two months' course for persons proposing to spend a holiday on the Continent will commence on June 1, at the same address.

INTERNATIONAL MEMORIAL TO PASTEUR.—In connection with the proposed international memorial to Pasteur, a provisional committee has been formed to constitute a British section. At a meeting held under the presidency of Sir Joseph Lister, on Friday, March 20, it was decided to address an appeal for subscriptions towards the erection in Paris of a monument to Pasteur to persons in the British Empire interested in science, as well as to those engaged in industries benefited by Pasteur's labours. The Executive Committee consists of Sir Joseph Lister, Sir John Evans, Sir Henry Roscoe, Dr. Thorne Thorne, and Professor Percy Frankland who will act as honorary secretary. Pharmacists interested in the Memorial should send their subscriptions to the honorary treasurer, Sir John Evans, addressed Royal Society, Burlington House, W.

THE ACTIVE SUBSTANCE IN THE THYROID.—Dr. Robert Hutchinson, referring in the *British Medical Journal* to the recent claims by Baumann, Fraenkel, and Drechsel, that they have discovered the active ingredient of the thyroid gland, states that he has found the activity to reside in the proteids of the gland. These proteids are practically only two in number, a nucleo-albumin and the colloid matter, and the latter is the only one that is active. It has been isolated in a state of purity, and is described as containing a considerable quantity of iodine in organic combination (see *ante*, p. 161), Dr. Hutchinson has succeeded in splitting off from it a body apparently identical with that obtained by Baumann from the entire gland.

THE SERUM TREATMENT OF DIPHTHERIA.—According to the Berlin correspondent of the *Standard*, at a meeting held in Berlin on Saturday last, Professor Virchow stated that the serum treatment had been a brilliant success at the Emperor and Empress Frederick Hospital for Children. The percentage of deaths from diphtheria is stated to have fallen from 37.63 in 1891-93 to 27.8 in 1894, and 11.2 in 1895, the total number of cases treated during the last year being 538. Prophylactic injections were administered to 460 children, of whom 18 afterwards caught the disease, but only in a modified form.

THE RÖNTGEN RAYS.—Visitors at the conversazione held in the Goldsmith's Institute on Saturday last displayed somewhat remarkable anxiety to obtain ocular demonstration of the fact that they possess skeletons. Mr. Herbert Jackson demonstrated the osseous charms of all and sundry by means of a small glass globe emitting the mysterious *x*-rays, and a screen coated with fluorescent material. Any part of the body placed between the globe and the screen was instantly projected on the latter, the bones being distinctly revealed, whilst the fleshy integuments showed as faint shadows only. The bones of a man's foot were thus displayed, the rays easily penetrating both boot and stocking; nails driven several inches into wood could be seen throughout their entire length; whilst coins, keys, etc., contained in purses and bags were very clearly shown. Professor Stroud writes to *Nature* to say that in obtaining pictures by means of the Röntgen rays, the time of exposure can be reduced (from 12 or 15 to 2 minutes) by placing a card coated with barium platinocyanide immediately in front of, and in contact with, the sensitive plate. The suggestion is also made that the introduction of some suitable fluorescent substance into the emulsion used on dry plates would greatly shorten the time of exposure.

EARLY CLOSING BILL.—With no amendment of practical importance to our readers, other than those already reported in the *Journal*, the Shops (Early Closing) Bill passed the Grand Committee on Trade on Thursday last. Sir John Lubbock successfully opposed an attempt to postpone the coming into effect of the proposed law until next year. Further opposition to the Bill is threatened by Mr. H. Samuel, Major Dalbiac, and Mr. Duncombe, who have given notice of their intention to move, when the Bill is reported, that it be re-committed to a Committee of the Whole House of Commons. It is reported that an influential minority of the Grand Committee protests against "numberless blemishes" that disfigure the Bill, and a large majority of London Unionist members is understood to be opposed to the measure in its present shape. It may be anticipated, therefore, that there will be an interesting struggle on the Report stage. To correspondents who are anxious to do something, either to facilitate or impede the further progress of the Bill, it may be suggested that the most satisfactory course of procedure is for them to address the Members of Parliament for their respective districts individually and at once. One of the worst things about the Bill, according to a Glasgow draper, who writes to the *Daily Telegraph*, is that it will transfer trades and spoil one street to improve another. He suggests that it would be well named "The Transfer of Business Bill," and contends that if a trader is in the vicinity of better-class thoroughfares, where it suits the majority to close on Saturdays, this Bill will compel him, although he may have taken many years to build up a business amongst middle-class people, to close his premises at the only time large numbers of his customers can reach him.

PHARMACEUTICAL EXHIBITION AT PRAGUE.—The Executive Committee in connection with this exhibition appeals to English authors and publishers of books and papers connected with pharmacy to send copies for use in the library and reading-room which will be open for the use of visitors. The Exhibition will be held in the great Exhibition Palace of the Baumgarten, Prague, from August 15 to September 15, and applications with lists of works to be exhibited should be sent at once, addressed to O. Schreiber. The books, etc., should not be forwarded until July.

PROCEEDINGS OF SOCIETIES.

Chemical Society, March 26.—Mr. A. G. Vernon Harcourt, F.R.S., President, in the chair.—This was the anniversary meeting of the Society, and Fellows turned up in fairly large numbers to hear the President's address and vote for the new officers and Council. The President, with characteristic punctuality, commenced to read his address at 8 o'clock. This was to all intents and purposes a retrospect of affairs which had happened in the course of the Society's meetings during the past year—an eventful year in scientific respects. Thirty years ago, when holding the position of secretary, Mr. Vernon Harcourt said that a museum had been inaugurated in connection with the Society. This was not a success; and no doubt for want of proper curatorship a valuable museum has been lost to latter-day chemists. Decomposed specimens were a constant source of annoyance, and the President appeared to think that those specimens would at the present time have been of considerable value by virtue of their decomposition. "Chromic acid, now trioxide," was how he referred to one of his specimens. The most important of scientific achievements was, perhaps, the discovery by Professor Röntgen of the new "light" rays, and the Society was indebted to Mr. Jackson for his recent demonstration of the new photography. Professor Dewar's illustrated paper on liquid air was referred to in warm terms by the President, who said that contributions of the same kind would always be welcome. The acetylene theory of luminosity was also a subject that had aroused the liveliest interest among the members. In this controversy Professor Lewes had shown that cyanogen, when surrounded by nitric oxide, burned with a luminous flame. The President here mentioned that the disputants had requested him to give a decision *ex cathedra* on the controversy, but this he firmly declined to do, saying that differences between good workers like Professors Lewes and Smithells were best left to themselves. Reference was made to the classical researches by Lord Rayleigh and Professor Ramsay on the new atmospheric constituents. Helium, said the President, was most appropriately named. It was strange that hydrogen should be so easily locked up in chemical combinations whilst helium could not be induced to combine with anything; the sun seemed to be its natural resting-place. Professor Ramsay was to be congratulated on his great good fortune.

The President next made a timely reference to the difficulty the Society had to deal with in the matter of the large number of papers submitted for reading. A full meal in this respect was always provided, but it was to be regretted that so many really good and attractive papers should be left unread. They could not be put forward to future meetings, as each meeting more than provided its own supply, and the question naturally arose as to the order in which contributions should be read. The President suggested three methods of dealing with the difficulty—

1. With respect to the order in which they were received by the Secretary.

2. That when authors were present they should have preference.

3. That some papers were more likely to give rise to interesting discussions than others, and precedence might be given accordingly.

The life and work of Pasteur, a foreign member of the Society, was briefly noticed, and allusion was made to the hundredth anniversary of the Institute of France. Then the case of Dr. A. B. Griffiths came under notice. At a recent ballot a sensation was caused by Mr. Otto Hehner reading a letter written in answer to an advertisement of Dr. Griffiths, which had appeared in the *Chemical News*, professing to procure for the applicants the Fellowship of the Chemical Society. There was an animated discussion on the matter, and general indignation was felt and expressed at Dr. Griffiths' unprofessional conduct. It transpired that at this particular ballot the certificates of three candidates were signed by Dr. Griffiths, and a request was made that the certificates in question should be read aloud by the secretary. This was done, and the result of the ballot was that the three candidates proposed were blackballed, and the question of Dr. Griffiths' conduct was remitted to the consideration of the Council.

The jubilee of the Society was to be commemorated by Dr. Armstrong's account of the scientific work of the first fifty years, a record which would consist of two volumes, and would most probably be published in the course of the present year. Another jubilee would be celebrated, viz., Lord Kelvin's fifty years' tenure of office as Professor of Natural Philosophy in the

University of Glasgow. There was a round of enthusiastic applause when the President announced that the senior secretary, Professor J. Millar Thomson, would represent the Chemical Society at this function. The inquiry into the nature of the flaw in the steel rails, which resulted in the recent railway accident at St. Neots, would be conducted by Professors Thorpe and Dunstan. Finally, the President commented on the downward course of a number of Fellows, whose names had been removed on account of non-payment of subscriptions. The number of Fellows on the list at present was 2018, and there were 28 foreign members, to which number the President hoped more would be added.

Dr. J. H. Gladstone, in a short speech, proposed a vote of thanks to the President for his address, and alluded to the desirability of having experimental papers put prominently forward at the meetings.

Professor H. B. Dixon seconded the motion, complimenting the President on his lucid review of the annual work of the Society. Papers which required the performance of experiments, or even the mere exhibition of apparatus, would prove most acceptable at the meetings, as quicker ideas could be got in that way than from drawings.

The President having briefly replied,

The Treasurer, Professor Thorpe, next came forward with his financial statement. One item in his balance-sheet was the advertisements which had recently been appearing in the Journal of the Society. This, he said, was a pet little scheme of his own, and it had succeeded very well indeed. The financial report was exceedingly satisfactory. The President moved a vote of thanks, and Mr. David Howard in seconding, while giving the highest credit to Professor Thorpe for his admirable and business-like statement, was not complimentary to the professional chemist as a man of business. As a general rule, said Mr. Howard, he was a man who could not add up his washing-bill correctly.

After votes of thanks had been proposed to the other officers and to the abstractors, the ballot for the new officers and Council was taken. The applause which greeted the announcement by Mr. Vernon Harcourt that he had been re-elected President left no doubt in anyone's mind that the election was a popular one.

The Vice-Presidents elected are:—Brown, Horace T., F.R.S., Dewar, James, F.R.S., Japp, Francis Robert, M.A., Ph.D., F.R.S., Mond, Ludwig, F.R.S., Roberts-Austen, W. Chandler, C.B., F.R.S., Tilden, William A., F.R.S.

The other officers remain as formerly, viz.:—Secretaries: Thomson, J. Millar, Dunstan, Wyndham, R., M.A., F.R.S.; Foreign Secretary: Meidola, Raphael, F.R.S.; Treasurer: Thorpe, T. E., LL.D., F.R.S.

Royal Institution, March 21.—Lord Rayleigh began his fifth lecture on "Light" at the Royal Institution by referring to the colours of thick plates. The plates in question, however, were thick only in comparison with those of extreme thinness that had been spoken of in previous lectures, and the colours were due, or had their origin in a kind of diffuse reflection. The theory might properly be called the diffusion of colours, and several of the laws governing it were established by Newton. Lord Rayleigh illustrated it by taking a glass slightly dulled in front and coated with quicksilver behind. On the electric light being thrown upon the dull surface the light was reflected from the glass to the screen, and coloured rings were seen with greater or less brilliance. The colour was attributed to the way in which the particles of dust on the glass reflected the light; but the thickness of the glass and the angle of light were points also to be kept in view. The greater part of the lecture was devoted to a consideration of the resolving power of optical instruments on two things extremely close to one another, the lines of a fine grating, for instance. Giving an illustration in photography, Lord Rayleigh took a plate, which he coated on one side with a bichromated gelatin, and placed it over a plate bearing lines to the fineness of six thousand to the inch. This was exposed to the electric light for half an hour while the lecture was continued. When later the result was shown on the screen it was found to be exceedingly good. In dealing with the resolving power of instruments, Lord Rayleigh showed how much the power of the eye to resolve angular magnitude depends on the size of the aperture of the instrument used, whether the telescope, microscope, or spectroscope, though in the case of the telescope they were usually dealing with bodies that were self-luminous, and in the case of the microscope with those that were not so. Lord Rayleigh spoke of important principles in relation to gratings, concluding

that the resolving power of a grating depended on the number of lines that were there, provided they were accurately placed, the practical limitation being that they must get the lines into a space corresponding with the several instruments they wished to associate with the grating.—*Daily News*.

School of Pharmacy Students' Association, March 26.—Mr. H. A. D. Jowett, Vice-President, in the chair.—After the minutes of the previous meeting had been confirmed, a "Report on Analytical Chemistry," by Mr. J. R. Walker, was read by the Secretary, Mr. Tickle. At the conclusion of this report a paper was read by Miss R. S. S. Harrison, entitled the "Life and Work of Darwin." A discussion followed, in which Messrs. Henry, Brown, Payne, Sheldrake, and the Chairman took part. The Chairman having then asked for any miscellaneous business, Mr. Goulding, after a short speech, presented Mr. Tickle with a microscope on behalf of past and present students of the School of Pharmacy. Mr. Tickle, in reply, said that he required no such solid memento to remind him of the pleasant time he had spent at the Square, but he thanked the subscribers for the kindly feeling which had prompted them to make him this most useful present. A demonstration of some effects of the Röntgen rays with a phosphorescent screen was then given by Mr. F. H. Carr, after which the meeting adjourned.

Manchester Pharmaceutical Association, March 17.—Mr. Geo. S. Woolley, President, in the chair.—At the ordinary monthly meeting, held at the Victoria Hotel, the prizes gained by competitors in the recent competitive examinations were presented to the candidates by the President, Mr. Geo. S. Woolley. In the course of his remarks, the President said that youths who had the energy and perseverance which were requisite for them to attain these rewards were those who might afterwards be found in the higher walks of pharmacy. He congratulated those who had been successful on the excellence of their papers. The two candidates who headed the list in the senior division were so close together that it was with great pleasure he had himself given another special prize.

Mr. Rymer Young said it was most pleasing to him to find when so many complaints were floating about concerning hard examinations so many young men coming forward voluntarily. Such an illustration of love of hard work was gratifying; he was glad to see the prizes were appreciated, and especially to note the high standard of the candidates' papers.

The prize winners in the senior division were:—N. H. Schollar, special prize, presented by Mr. Rymer Young, and herbarium. T. O. Barlow, special prize, presented by Mr. G. S. Woolley, and herbarium. H. Gray, herbarium. Junior division: H. M. Halls-worth, special prize and herbarium. E. Tristram, herbarium.

Society of Arts (Indian Section), March 26.—At this meeting Mr. Walter A. Lawrence, I.C.S., C.I.E., read a paper on—

"KASHMIR: ITS PEOPLE AND ITS PRODUCE."

He said the beautiful valley of Kashmir was cradled in the Himalayas at an average height above the sea of 6000 ft. On the north, east, and west it was shut in from the outer world by ranges of mighty mountains, while on the south it was separated from the Punjab by rocky barriers fifty to seventy-five miles in width. The cultivated part of the valley was eighty-four miles in length, and twenty to twenty-five miles broad, traversed by the river Jhelum. One of the many legends relating to the Haramak mountain was that any traveller who scaled its peak would meet with instant death. In the crest of this mountain there was said to be a vein of emerald, which rendered all snakes that lay within its ken innocuous, and it was a curious fact that the poisonous snakes were only met with in the valley. The trees, such as the plane trees, walnuts, willows, poplars, elms, mulberries, and the countless orchards of apples, pears, and apricots, reminded one of a well-wooded English park. The crops of rice and the cotton belonged to the East, while the rounded forms of the trees, the rivers, and streams with their banks of green turf and willows, recalled the West. The very villages were English; instead of the ineffably dreary and unvillage-like look of the Indian hamlet, there were dotted about here and there picturesque homesteads, all having their little gardens and court-yards. One of the prettiest objects in the village was the graveyard, shaded by the *Celtis australis*, and bright with purple, white, and yellow iris. Kashmir could be reached in three weeks from London; it had a most delightful and varied climate. For a

holiday or change there could be no more restful and healthy life than a year or six months' sojourn in the valley of Kashmir, and any European with a medicine chest was always welcome. There was sport for the sportsman, wonderful scenery, mountains for the mountaineer, glaciers for the botanist, a vast field for the geologist, and magnificent scenes for the archæologist. Up to the end of the fourteenth century, Kashmir was the seat of a Hindu kingdom, when the people left their glorious temples and their picturesque religion for the sullen compromise of Islam. The beauty or rumoured wealth of the valley attracted the Moghals at the end of the sixteenth century, and Kashmir came under a foreign yoke.

The lot of Kashmir was not unhappy under the Moghals, but they were succeeded by the brutal and oppressive Pathans, who ruined the country and the people, and were ultimately driven out by the Sikhs. The Sikhs were a change for the better, but left much to be desired. Moorcroft narrated that the punishment for the murder of a Kashmiri by a Sikh was a fine of two rupees. In 1846, Kashmir was made over to the Maharaja Gulab Singh, who was a strong ruler, and his efforts were very effectual in stamping out crime. Kashmir had undergone many changes in its governors, who with their deputies had felt no sympathy for the people. It had been the deliberate policy of the Panjits, the Brahman officials of Kashmir, to exaggerate the difficulties of administration in the valley. They excused their own corruption, cruelty, and ignorance by assuring their masters that the Kashmiris were lying, lazy, and dishonest. Another cause of the hopeless state of the people was the fact that earthquakes, floods, fires, cholera, and famine were familiar to every generation. For example, in the village of Pattan, where there were about 165 families, in 1885 seventy persons perished in an earthquake, and in 1892 fifty-five persons were carried off by cholera. The tyranny of man on the one hand, and the terrible vagaries of nature had rendered the Kashmiris incredulous of the existence of good in man and nature. All their memories were sad, and hardly a day passed without mention of the great famine of 1877-79, when men turned cannibals, and three-fifths of the population perished. The dress of the men was like their character, effeminate. They wore a kind of heavy woollen nightgown falling to the feet, and under this, if the weather were cold or wet, they inserted a small earthen brazier of hot embers, known as a kanger. Though this kept them warm, it had its drawbacks, as they went to bed with their kanger and often set the bed on fire, and it was said that the brazier was a fruitful source of cancer. In Kashmir there was cultivation that would astonish Europeans, and the art wares in Srinigar had astonished the world.

The domestic life of the Kashmiris was admirable. One never heard of scandals, and, like the Irish, they were kind to their children and their old folk. They were also a very gentle people, and their quarrels never went beyond invective and abuse. The sight of blood was dreadful to them, and if a fowl had to be slaughtered for food the execution devolved on the village priest. At one time no doubt it was necessary to attract the attention of their rulers by some striking demonstration. Men who had a grievance would fling off their clothes and smear themselves with mud. The nakedness was to imply destitution, and the mud signified that they were reduced to the condition of a clod. Many a time the lecturer had seen a procession, one man wearing a shirt of matting, another having a straw rope round his neck with a brick pendant, another carrying a pan of hot embers on his head, while the rear was brought up by a woman bearing a number of broken earthen pots. If this was bad, still more inconvenient was the practice of casting a plough under his horse's feet in order to emphasise the fact that agriculture no longer possessed charms for the proprietor of the plough. Once while hearing petitions the lecturer noticed an old man standing for some time on his head; fearing that he might injure himself, he was asked why he did it. His reply was that, thanks to Mr. Lawrence's arrangements his affairs were so confused that he did not know whether he was standing on his head or his heels. A man once wanted to strengthen his case in some litigation which he had by arousing the lecturer's sympathy, and the course he adopted was to bring before him the dead body of his child, for which he said his neighbours would not allow him burying-ground. One bitterly cold night a man appeared at Nág marg stark naked, saying that his uncle had turned him empty into the world. Some English clothes were given him, and he was told by way of jest that as he was now dressed as an Englishman he could assert his rights. The next day the uncle appeared in the camp in a very shattered condition, charging his nephew with assault. This incident showed how dangerous it was to jest with the natives. The ruler of Kashmir was a Hindu, and

93 per cent. of his subjects were Mussalmans. The officials of the country for the most part belonged to the rigid Brahmin caste, but the much-talked-of oppression in Kashmir was entirely official, and did not arise from religious intolerance. In India of late great rivalry had arisen between the two great religions of Brahminism and Islam, but in Kashmir the Mussalmans and Hindus lived together in delightful amity. The chief reason of this was that the people of the Valley, though Mussalman in name, were really Hindus at heart. Kashmir was rich in superstitions, and lovers of the supernatural would find a grand field in the villages of the remoter valleys.

Turning from the people to the products of the valleys, it would be interesting to note that almost all the vegetable products that existed in a temperate climate could be grown in the vale of Kashmir. It was the lecturer's hope that Kashmir might become the California of India. The fruit was magnificent and was easily grown. There was everywhere an endless supply of wild stock, and from the nurseries many thousands of trees grafted or budded with the best English and French varieties of apples and pears were given out. The turning industry, introduced two years ago, was thriving. There were large vineyards from which excellent wine—Medoc and Barsac—was made. These vineyards had recently been replanted with American stock in order to combat the phylloxera which had penetrated even to remote Kashmir. Excellent cider was made, and the brandy which was distilled from the wild apples and pears was pure and potent. They had succeeded admirably with hop-growing, the financial results of which would surprise Kentish growers. Silk was an ancient industry in Kashmir, and it was probable that the valley produced the old Bactrian silk which found its way to Damascus; but evil days came in 1878, and disease obliterated the industry. In 1889 it was decided, on the advice of Sir Edward Black, to rehabilitate sericulture, and to stamp out disease by following the Pasteur system of microscopical examination. For the first two years the results were disappointing, a native with a microscope being a most uncertain combination. Success was, however, eventually obtained, and a few weeks ago the first Kashmir silk found a sale in London. He had advised the Government not to incur expense on improved reeling appliances, his idea being to demonstrate that good silk could be raised in Kashmir, and to make sericulture pay its expenses.

All that was wanted in the country was European capital, skill, and energy. Already Europeans were carrying on a successful manufacture of carpets, giving employment to the unfortunate weavers of the old shawls, for which Kashmir was once world-famed, this latter industry having been destroyed by the Franco-German war. There was splendid water-power everywhere, and if capital were forthcoming, cotton mills could be erected which would supply Central Asia with cloth. The valley abounded in fibres, one being especially worthy of European notice, called out there Yechkán. The *Abutilon avicennae* and its fibre had been pronounced superior to Indian jute, and finer than Manilla hemp. The iron of Kashmir was preferred to the imported metal, and the valleys and mountains were thought to be rich in minerals. The chance discovery of a rich sapphire mine in 1882 suggested that organised exploration might lead to further discoveries. It was no exaggeration to say that the Kashmiris detested mining, as it led to forced labour and the presence of numerous officials, who required to be fed. He had not time to refer to the floating gardens similar to the Chinampas of old Mexico, nor to the saffron for which the valley was renowned.

An interesting discussion followed the reading of the paper.

Liverpool Chemists' Association, March 19.—Mr. M. Conroy, President, in the chair.—One new member, Mr. Mortimer Parry, was elected. The Secretary read a letter from Mr. Ellams drawing attention to a letter he had received from the Inland Revenue authorities, concerning certain labels for "Brown's Harmless Headache and Neuralgia Powders," which were said to make the preparations liable to stamp duty, although as Mr. Ellams said, they were a simple drug vended entire. It was decided that the Secretary should write to Somerset House to get a final decision on the point whether a simple drug was liable or not. A new variety of stethoscope—the phonendoscope—was then shown by Mr. A. S. Buck. It is the joint invention of two Italian professors—a physicist, Eugenio Bazzi, and a pathologist, Aurelio Bianchi—and has the appearance of a large watch with two ear tubes of indiarubber attached to the back. The front consisted of a thin metallic plate with a socket in the centre to receive a flat-headed rod of ebony or vulcanite. In the interior is a thinner dia-

phragm, similar to the plate of a telephone receiver, which vibrates readily, and acts as a microphone, increasing the internal sounds of that part of the body upon which it is placed. An improved syringe for injection of organic liquids was also exhibited by Mr. Buck. This was similar to the usual Pravaz pattern, but had asbestos packing, easily sterilised by heat.

An excellent paper on "The Chemical Analysis of Water" was then read by Mr. H. A. Davies, M.A., B.Sc., F.I.C., who, in his reply, after a brief discussion, said that chlorides were peculiarly constant in proportion in the water from various districts, not varying for years. Lead certainly was dissolved in small quantities by the Vyrnwy water after standing in the pipes all night, but he had not made any direct determination of the power of Vyrnwy water in this respect as yet. A point he wished to emphasise with reference to the bacteriological analysis of water was that though it was to a certain extent a good thing, chemistry gave a better, quicker, and more reliable answer. An ordinary bacteriological examination of the number of colonies alone would require at least a week, whilst the isolation and identification of the bacteria would mean a work of weeks, and would be consequently very expensive. Chemical analysis was daily routine work, quickly done by competent analysts, certain in its results, and much the cheapest of any known method of water examination.

Cambridge Pharmaceutical Association, March 27.—Mr. A. S. Campkin, J.P., in the chair.—The Association received a deputation from the Proprietary Articles' Trade Association, which was represented by Messrs. W. S. Glyn-Jones (Hon. Secretary), J. Barclay (Messrs. Barclay and Sons, Ltd.), W. A. Gilligan (Liebig's Extract of Meat Company, Ltd.), and H. S. Norris (Condal Water Company, Ltd.). The members of the local Association present were Messrs. E. Saville Peck, M.P.S. (Hon. Secretary of the Cambridge Pharmaceutical Association), H. J. Parsons, D. Greenwood, E. Field, S. F. Barker, C. S. Addison, A. Ivatt, M.A., and L. Hutchin. Letters expressing sympathy with the movement and regretting absence were read from Messrs. Beall and Son, J. Yeomans, and J. Colston (Cambridge), J. S. Norman (Bedford), F. A. Barrow (Newmarket), E. Matthews (Royston), Wm. Sutton and Co. (London), and J. Sanger and Sons (Oxford Street).

After an address by Mr. Glyn-Jones, a discussion took place, and the following resolution was then agreed to:—

"That this meeting of registered chemists, residing in Cambridge and its neighbourhood, desires to express its pleasure at seeing that a number of influential manufacturers have already joined the Proprietary Articles' Trades Association, and to assure them, and all other manufacturers, that any steps they may take in connection with the Association to ensure fair profits will meet with the approval and cordial support of every legitimate retail trader."

Chemists' Assistants' Association, March 12.—Mr. E. W. Hill, President, in the chair.—The following report of Mr. Gerrard's paper has been unavoidably deferred:—

"ON NUTRIENT BEEF FOODS," BY A. W. GERRARD.

It was stated that the following process had been found to give the most satisfactory results in the preparation of meat peptone. One pound of good lean beef is finely minced and pulped through a No. 40 sieve, after which it is placed in a porcelain digester, and one pint of water, at 60° C. slowly poured in with constant stirring. Two ounces of the fresh and active inner lining of a pig's stomach are cut up into fine shreds and mixed with the meat, the whole being constantly stirred for at least five minutes, so as to bring the pepsine and meat as completely into contact as possible. Three more pints of water at 60° C., are now added slowly with continuous stirring, and then one fluid ounce of dilute hydrochloric acid. The digester and its contents are now heated in a water bath for two hours, constantly stirring, the temperature being kept at about 50° C. (not exceeding 52° C.). At the end of the time the mixture is boiled, neutralised with sodium carbonate, filtered, and evaporated to the consistence of a soft extract. It is important to notice that if the beef is merely minced and not pulped a digestion of four to six hours is required, but in that case the product is not of such good quality and the bitterness is much more marked. The average percentage of dry peptone yielded by eight experiments with lean steak was 18.1, whilst the anti-peptone amounted to 4.3.

Passing on to the discussion of peptonisation by means of the pancreas, the author stated that his observations had taught him that tryptic digestion can be carried on three or four degrees higher than with pepsin, without risk to the stability of the ferment and

with advantage to the product. When pancreatising meat it is usual to employ the mixed ferments, but on a large scale it is advantageous to use the fresh pancreas so long as care is taken that the sweet-breads are clean, fresh, and active. The most satisfactory process was found to be as follows:—Take 20 ounces of lean beef which has been pulped through a No. 40 sieve and mix it with 150 grains of pancreatin or 1 oz. of prepared fresh pancreas. Now add 5 pints of water at 60° C., and having stirred in 100 grains of sodium carbonate, place the mixture in a digester, keeping it at a temperature of 55° C. for two hours, constantly stirring. At the end of this time the mixture is neutralised with hydrochloric acid, boiled, allowed to cool, and filtered, after which it is rapidly evaporated to a soft extract, when it is ready for use. In regard to yield, 100 parts of good quality meat will give, by the process just described, 19 per cent. of dry peptone. Both varieties of peptone always contain a fair amount of common salt formed from the acid and soda used. This salt acts as a preservative and is enough to keep the concentrated product good for almost any length of time.

In pancreatic, as in peptic digestion, the whole of the meat does not pass into solution, for there always remains the same insoluble remnant called anti-peptone, the proportion being about the same as in peptic digestion. In this process the reduction of time from the usual four to two hours yields a product which is more palatable and serviceable to the invalid, but if digestion were prolonged to the longer period a peptone would result full of leucin and tyrosin. Pancreatised meat has a pleasant flavour and is freer from bitterness than the peptonised variety, and hence seems to be preferable to the latter.

Although a peptone of meat is, from a scientific point of view, an ideal food, since it contains all that is soluble of muscle, yet its use is not always possible on account of bitterness and want of savoury character, which often causes patients to turn against it after a few days. The most successful experiment tried with a view to obviating this distaste was to administer the peptone in combination with detannated wine, which combination may be called vinous peptone. This may be prepared by taking a pint of light-coloured invalid port, somewhat sweet, and adding to it a solution of isinglass until it ceases to give a precipitate. After standing a few hours it is filtered, and in each 15 ozs. of the product 3 ozs. of peptone is dissolved, after which it is again allowed to stand, and filtered. Another useful form of administration is to dissolve a portion of peptone in beef-tea, 1 oz. being added to each pint. This product is well tolerated by patients, and can be utilised in cases where wine is objectionable. It is important to mention that the addition of peptone to beef-tea makes it a perfect meat food, strongly nutrient; whereas in its simple form it is a mild stimulant and weak nutrient. The 1 oz. of peptone really adds 4 ozs. of good solid meat to the pint of beef-tea. In cases where administration *per rectum* is indicated, the peptonised beef-tea, either alone or together with the albumin of two eggs, can be used advantageously. Another method of rectal administration is in the form of suppositories, which are best made with the cacao-butter basis, containing 50 per cent. of peptone, the use of gelatin as a base being decidedly objectionable.

The following was recommended as a satisfactory working formula for beef essence:—Take 1 lb. of lean beef from the blade-bone, cut it into thin slices, and place it in an enamelled pan with 1 pint of soft water. Cover the pan and bring it to the boil, afterwards allowing the contents to simmer gently for four hours, a little water being added from time to time. When the cooking is sufficient, the meat will be technically "boiled to rags." The entire product should at once whilst hot be transferred to a perfectly clean flannel filter, to drain. To the filtrate, 60 grains of salt are added, and the volume brought, either by evaporation or addition of water, to 8 fluid oz. On allowing to cool a well-formed, transparent jelly will be the result. Beef essence or beef jelly, which is a great favourite with the public, approximately contains 9.06 of dry solids, the remainder being water, and it is noticeable that the richest jelly, from point of flavour, is obtained from the lean muscle of the blade-bone, but on the other hand, the muscle of the leg yields one of firmer consistence, owing to the fact that there is more gelatin-yielding tissue in the leg than in the shoulder. For the preparation of concentrated beef-tea, as sold in skins, the lean parts of the leg, shoulder, or neck of beef are cut and broken into small pieces, and some salt having been added the whole is boiled for eight or ten hours in about eight times its weight of water, the volume being constantly maintained by addition of water. When the boiling is com-

pleted the fats, extracts and gelatin will have been removed. The whole mass is next strained and allowed to cool and settle. Next day the layer of fat is removed, the gelatinous portion again heated, carefully filtered, and concentrated to a semi-fluid extract which is poured whilst hot into skins tied off into sections and allowed to cool. This preparation needs the addition of peptone to enhance its nutrient power to a suitable degree. Albuminous meat juice is made by placing slices of lean beef in horse-hair press bags and submitting to strong pressure. The juice which exudes is a nearly clear red fluid containing traces of fat and some blood corpuscles. Analysis showed it to contain 7.3 per cent. of solids, 3.9 of which was albumin. The mineral matter, mostly phosphates, constituted 1.1 per cent. The following process was also recommended for the preparation of a meat juice. One pound of finely pulped meat, 16 fluid ozs. of distilled water at 60° C., and 1 fluid drachm of strong hydrochloric acid are well stirred for ten minutes. Forty-four grains of sodium bicarbonate are then added, and after the effervescence has ceased the whole is poured on to a stout muslin strainer, when the juice is pressed out with the hands, the residue being finally mechanically pressed. Either of these juices is quite equal in nutrient power to any on the market, whilst they are not unpleasant in flavour. Unfortunately they will not keep for more than twenty-four hours without the addition of preservatives.

Mr. Gerrard referred to the extravagant and impossible claims which are put forward by many makers at the present time on behalf of their preparations, and drew attention to the fact that the most concentrated meat food cannot represent more than five times its weight of lean muscle. One of the most popular and expensive foods yielded on examination .12 per cent. of albumin, 57 per cent. of solids, boric acid being used as a preservative. This preparation appeared to be compounded of a good meat extract and a little added albumin, since the latter constituent is present in much too small a quantity to be natural to a concentrated meat juice. As a nutrient this article would be of no value, for an entire bottle only contains one grain of albumin. Another food of the same class was found to be a "doctored" blood, the corpuscles being evident under the microscope, whilst on heating a thick coagulum was formed. One hundred parts gave 35 of solids, of which 12.7 were found to be coagulable matter composed of a mixture of albumin and hæmatin. This preparation was evidently made by whipping ox-blood to remove fibrin, and then adding salt and boric acid as preservatives. Such a preparation being rich in serum albumin is a good nutrient.

In conclusion, Mr. Gerrard said that what is wanted is a genuine liquid beef of pleasant flavour, which could be guaranteed to contain the whole of the proteids. Peptone is at present the nearest approach to this ideal, but the bitter taste constitutes a serious drawback to its use, the author is at the present time carrying out a series of experiments with a view to check or prevent the formation of this objectionable constituent.

Brighton Junior Association of Pharmacy, March 25.

—Mr. T. F. Grindley in the chair.—Mr. Geo. Long, who had been announced for a previous meeting, read a paper on "Ancient Eastern Medicine Practice." The subject was dealt with in an exhaustive manner, the Egyptian Pharmacopœia and methods from the Papyrus Ebers proving especially interesting. A discussion followed, when Mr. Long adduced many interesting facts of Egyptian history, proving the high state of Egyptian civilisation. A hearty vote of thanks was accorded to the contributor for his very intellectual discourse.

Midland Pharmaceutical Association.—Mr. R. D. Gibbs in the chair.—The following resolutions have been passed at a meeting of the Council of this Association:—

"That this Council hears with pleasure of the candidature of Mr. Park, of Plymouth, for the Pharmaceutical Council, and promises to support him in every way it can."

"That the support of the Council be given to the Shop Hours Bill for the regulation of the compulsorily closing of chemists' shops at reasonable time."

Plymouth, Devonport, Stonehouse and District Chemists' Association (Junior Section), March 27.—Mr. H. O. Westcott in the chair.—Mr. Ernest A. Hodge gave a very interesting and instructive lecture on "Opium," and was able by the use of specimens lent from the Pharmaceutical Society's Museum to explain the manner of collecting the drug in Persia, Turkey, India, and Egypt.

Sheffield Pharmaceutical and Chemical Society.
April 1.—A paper was read by Mr. J. Austen, entitled "The Plants of the Bible." It was illustrated by a large number of specimens, several of which had been lent by Mr. E. M. Holmes, Curator of the Pharmaceutical Society's Museum, whose kindness in so doing was duly acknowledged. A very good specimen of hyssop was also shown, which had been collected by the Rev. A. Hall on Mount Sinai. A very cordial vote of thanks was passed to Mr. Austen at the close.

Edinburgh District Chemists' Trade Association
March 26.—Mr. Peter Boa in the chair.—Mr. C. F. Henry read a communication from the Edinburgh Decimal Association asking an expression of the Association's opinion on the introduction of the decimal system of weights and measures into this country, and inviting the members to memorialise the Government in favour of their recommendations (1) that Parliament should at once legalise the metric system for all purposes in trade, (2) that after a lapse of two years it should be made compulsory to use these weights and measures for all trade purposes, and (3) that it was desirable that in schools decimals should be taught at an earlier stage in the school curriculum.

The matter having been discussed, a resolution in favour of the first and third recommendations was unanimously adopted.

Mr. David McLaren then introduced a discussion on Sir John Lubbock's Shops (Early Closing) Bill, with special reference to its effect on pharmaceutical chemists and chemists and druggists. He moved a general recommendation that the Association should support the principle of the Bill, and after a long discussion, on a vote being taken, the motion was carried.

The meeting agreed to remit to a committee to consider as to the most suitable place for the annual picnic of the Association and to report to the next meeting. In view of the annual meeting in May, Messrs. Mackenzie and Wylie were appointed auditors. This being all the business, the meeting terminated.

Pharmaceutical Chemists' and Apothecaries' Assistants' Association of Ireland, March 27.—Mr. J. B. Alister, M.P.S.I., President, in the chair.—A short business meeting preceded a debate on the question whether infusions should be retained in the British Pharmacopœia.

Mr. Alister held that infusions should be retained in the B.P., and they should be made fresh and not in a concentrated form. To keep infusions caused them to darken in colour and lose their aroma and flavour. Mr. Hunt urged, on the other hand, that infusions could not be indispensable, since out of twenty-eight that were official only ten were in actual use, and the remainder were hardly ever prescribed. One half of the B.P. infusions might be expunged with advantage. From a therapeutic point of view infusions possessed no advantages over the tinctures of the same drugs, except the absence of spirit. The two cold water infusions were condemned entirely by a very high authority on pharmacy. The most serious objections to fresh infusions was their liability to decompose. Many of them would not keep twenty-four hours. The speaker referred to the United States Pharmacopœia, in which only three or four infusions were found. Concentrated infusions lacked colour, aroma, and flavour of fresh infusions, but in most cases the deficiency was marked by the other ingredients in the prescription. If infusions were regarded as convenient vehicles and flavouring agents merely, liquid extracts, capable of dilution at will, would be more elegant and permanent substitutes for them.

Mr. Ashe, for the affirmative, argued that the use of infusions pleased doctor and patient. They were old friends and should not be cast off. Mr. Payne agreed with Mr. Hunt, and humorously compared infusions to Chelsea old pensioners, good in their day, but now unfit for further service. Medical men nowadays merely added an infusion to their prescriptions to avoid using the word *aqua*, or, perhaps, to render the mixture more disagreeable to, and consequently more appreciated by, the patient. The speakers on both sides were supported by Messrs. Walsh, Ardill, Hardy, Harris, etc.

Mr. McCarthy (Vice-President) then summed up, and favoured the introduction into the B.P. of a number of standardised concentrated infusions. Many small chemists were at the mercy of the wholesale houses, but every pharmacist ought to be able to make his own concentrated infusions. On a vote being taken, it was agreed by a majority of six that infusions should not be retained in the B.P.

LEGAL INTELLIGENCE.

COURT OF CHANCERY.

In Re INGRAM, JONES, AND ELVEN'S PATENT, No. 1639 OF 1894.

This petition for revocation came before Mr. Justice Romer on Thursday, March 26, having been placed in the list of witness actions on account of the respondents declining to consent to the revocation when it was first in the list before Mr. Justice North. When it was called on, Mr. Sebastian, who appeared with Mr. Roger Wallace for the petitioners, the Pharmaceutical Society of Great Britain, said in these cases the respondents were entitled to begin, but he did not know whether they appeared.

On inquiry it was found that no one appeared on behalf of the respondents, and as this fact prevented any consent being given to affidavit evidence being taken, the case had to stand over for a short time until the witnesses were in attendance.

Mr. Wallace, Q.C., then opened the petition, saying it was for the revocation of Letters Patent No. 1639 of 1894. The patentees were Georgina Elizabeth Sarah Ingram, Edmund Ingram, and Rev. Richard Jones, Rebecca Jones, wife, and Margaret Elven, spinster. These people took out a patent, the original inventor being George Elven, who was a Baptist minister. It was a patent for liver pills consisting of podophyllum resin, compound extract of colocynth, extract of hyoscyamus, and powdered caraway seeds. The petition for revocation was by the Pharmaceutical Society of Great Britain, who under their Charter had certain duties to perform for the protection both of chemists and druggists and of the public with regard to the sale of poisons. This particular patent did not deal in any question regarding poisons, such as had been the subject of decision in Courts of Justice; but in those cases it had been held that when a medicine was a patent medicine it did not come under the Pharmacy Act, and consequently a large number of patents had been taken out for various compounds of drugs, and people who bought them believed there was some special protection from the fact that they were sold under Letters Patent. There appeared to be a widespread feeling that there was some special benefit in the medicine guaranteed by the patent if Letters Patent were granted. It was said in some of the text-books that no patent ought to be granted for medicine, as it was against public policy, but there had never been any actual case decided on that point. Probably that statement was introduced on the ground that statutory monopolies should not be granted for anything to the detriment of the public, but there was no decided case of that kind. The particulars of objection pointed out that all the individual drugs in this patent were well known, and that they were continually compounded in different proportions by chemists and druggists, and prescribed by medical men without let or hindrance.

Mr. Justice Romer suggested that Mr. Wallace should put in formal evidence, and that would conclude the matter.

Mr. Michael Carteighe was then sworn. He stated that he was a pharmaceutical chemist, carrying on business at 180, New Bond Street. He was President of the Pharmaceutical Society of Great Britain, and a Fellow of the Institute of Chemistry. He was one of the petitioners jointly with the Society. He had read the specification in question. The drugs named in it were podophyllin, colocynth, hyoscyamus, and caraway powder. Three recipes were given in the specification, each containing the same drugs, but in different proportions, except that the third left out the caraway powder. All those drugs were well known at the date of the patent, and long before, and were to his knowledge constantly prescribed and dispensed in various proportions.

Upon this evidence, his lordship revoked the patent and gave the petitioners the costs of the proceedings.

OBITUARY.

FLETCHER.—On March 16, Thomas Fletcher, Chemist and Druggist, Smallthorne, Staff. (Aged 60.)

SMITH.—On March 22, Morgan Smith, Chemist and Druggist, Aberdare. (Aged 41.)

SUTTON.—On March 27, Samuel Sutton, Chemist and Druggist, Gosport. (Aged 80.)

CORRESPONDENCE.

"THE OLD FIRM OF GODFREY."

Sir,—In your last week's issue there is an article entitled "The Old Firm of Godfrey," by Mr. Joseph Ince, late Director of Godfrey's laboratory.

With Mr. Ince's views concerning the Godfreys I have nothing to do, but the private formulæ of the firm which Mr. Ince, a former director of the laboratory, publishes as the original ones, I have as a member of the firm to protect.

These formulæ were confidentially entrusted to Mr. Ince to guide him in the conduct of the laboratory, and for the director of a laboratory to publish formulæ thus entrusted to him without the permission of the proprietor is to my mind a distinct breach of confidence.

I am surprised that the editor of a journal should not as a matter of principle have declined to publish, without permission, the private formulæ of an existing firm communicated by one of its late employés.

30, Conduit Street, W., March 31, 1896. THOMAS GREENISH.

* * * The foregoing letter is inserted according to the desire of Mr. Greenish that it should "without fail" appear in this week's Journal. The Editor regrets the mistaken impression under which it appears to have been written, the more so as he has been informed by Mr. Ince that the formulæ referred to had become obsolete even in his time, and obviously they are only of antiquarian interest.

UNDUE CUTTING IN THE RETAIL TRADE.

Sir,—Mr. Ferguson calls for a simple scheme, here it is:—Experiment—"Chemists' Proprietary Association"; 100 members start at 5s. per share, £25. They take half a dozen each "C.P.A. Liver Pilules."

50 doz. at about 5s. per doz.	£12 10 0
50,000 handbills, about	2 10 0
Carriage and other expenses.....	2 10 0

17 10 0

50 doz. bottles sold at 10d. each bottle	25 0 0
--	--------

Equal to 30 per cent. profit	£7 10 0
------------------------------------	---------

Points in favour:—No cutting, no signing agreements, fair profit, no secret medicine dealing (composition of articles stated on label), business confined to chemists and druggists, etc. Try above, Mr. Ferguson, and get 100 chemists to combine! Combine!!

London, March 19, 1896.

ASSISTANT.

CASH CHEMIST.

Sir,—I have read the letters bearing upon the above subject, and am quite of opinion that the use of the title chemist by any person or persons not registered under the Act of 1868 is illegal. I consider that the inaction of the Council in the matter implies blind indifference to the letter and spirit of the Act. We are told that it has been decided that a limited company is outside the Act, a thing inanimate, existing in name only, therefore cannot pass an examination, which, the Act says, shall be the test of efficient skill and knowledge. The Commission on the Limited Liability Act, the Lords Justices of Appeal, and the Common Law, which is understood to be common sense, say that the 1868 Act is sufficient. Then why is it not put in force?

What is required to carry out the Act? Let every member of the Council remaining by rote, unwilling to put the means into operation, retire or resign. Let the members seek out a pharmaceutical Cromwell and thirteen other good men and true as colleagues, and elect them on the Council in May next. For the present we have had enough of education and benevolence. The Government of the day placed the administration of the 1868 Act in the hands of the Council of the Society, which has registered all eligible persons who applied without fee, supplied all the machinery for carrying out the Act, and is charged with keeping correct Registers and granting certificates to competent individuals.

In the preamble to the Act the word persons (plural) occurs three times, namely, (1) "'persons' keeping open shop, etc., for retailing of poisons"; (2) "'persons' known as chemists and druggists"; and (3) "from and after the day named all 'persons' . . . be duly examined, etc." I contend, on the strength of all these data, that it is illegal for the Board of Trade to grant a certificate to any persons to carry on the business of chemists and druggists, and that it is the duty of the Pharmaceutical Council to set aside these illegal companies on the same grounds as patents have been set aside.

Can this be done? Yes! Is the Act sufficient? Yes! Does the present Council know how to do it? Yes! Then why is it not done? I will leave those who care to reply to speak for themselves. What are the members to do? Send men with definite instructions that it must be done. Justice and equity should predominate at the Square and Somerset House alike. I hope all our thinking men will take up this matter of the suppression of illegal companies and the illegal use of the title chemist in earnest, speak out boldly, and give definite instructions to the new Council in May.

Spital Hill, Sheffield, March 29, 1896.

G. ELLINOR.

THE BENEVOLENT FUND—A SUGGESTION.

Sir,—In the interests of the splendid Benevolent Fund of the Pharmaceutical Society, in which for many years I have taken a deep interest, I should like with your kind permission to make a suggestion, which, if put into practice, I am inclined to think would prove a strong incentive towards a largely-increased subscription list. I would recommend that at the end of the list of subscriptions which you publish in the Benevolent Fund Supplement of the Journal in February each year, a general summary of the different places contributing should be made, to be arranged in order of merit, namely, according to the value of the amounts sent up by each town for the previous year, and also giving details of population, name of the local secretary, and the number of the subscribers, thus:—

Name of Town (or Division in London).	Population.	Name of Local or Div. Sec.	Number of Subscribers.	Amount Subscribed.
---	-------------	----------------------------------	---------------------------	-----------------------

A little rivalry is a capital thing, and an annual list of this kind would doubtless create a considerable amount of interest amongst members of the craft throughout the country, as the chemists in each town will assuredly be anxious to see their own town or city standing well up in the list, and it would also serve the useful purpose of bringing into a strong light the varying amounts of energy and work put into their duties by the local and divisional secretaries, upon whom the responsibility of a good or bad annual collection chiefly depends. Nearly every chemist upon the Register can afford to subscribe something, say 2s. 6d. per annum, and the great majority of them would do so, provided it is put fairly before them year by year, and a small subscription like this, if given by all, would be amply sufficient to keep the Benevolent Fund in a flourishing state.

Cardiff, March 17, 1896.

ALFRED COLEMAN.

COCAINE IN OINTMENTS.

Sir,—*Re* the "caution" concerning cocaine in ointments, which appears in the *Ph. J.*, March 28 (p. 249), the experience of the chemist which occasioned its publication might be of some value to me as one of the "some readers of the Journal," had the narrator supplemented his tale with the "wherefore" of the dispenser's procedure. For instance, amongst other things, it might be of interest to know why the unfortunate dispenser found it necessary to use heat in making the ointment stated? What was his object, and had he scratched his head in formulating his method? Also, after his consultation with the Crown Counsel mentioned in the note, and the subsequent brightening of his mental sky by mental fireworks, was he quite sure that the reason was clear, viz., that the alkaloid was decomposed in the hot fat? Perhaps the gentleman who so vigorously recounts the incident, and so eloquently points the moral, will be further able to enhance the value of his note by some explanation on the lines indicated.

London, March 30, 1896.

P. GREEN.

SHOPS (EARLY CLOSING) BILL.

Sir,—It has been said by some that this Bill will interfere with individual liberty; but when individual liberty is carried so far as to make an assistant work fourteen or fifteen hours a day, it is time it should be curtailed. Generally, employers are so selfish that their employés require some protection from their tyranny, and what they will not do for humanity's sake, they should be compelled to do by law. The Bill aims a blow at one of the greatest evils of the present day, and there are employers who would be only too glad to close their pharmacies at an earlier hour if their neighbours would do likewise. Most assistants are strongly in favour of the Bill, and it is with great dissatisfaction they learn that the Council of the Pharmaceutical Society does not intend supporting this measure. It is earnestly to be hoped that at the next election men will be returned who will be more considerate of the interests of those they represent than the present Council.

London, March 23, 1896.

"LIBERTAS."

SHOPS (EARLY CLOSING) BILL.

Sir,—I have to thank you for the insertion of my letter in the Journal on March 10, as well as for the prominence given to the question of early closing since that date. In regard to your remarks on that letter, assistants cannot be always on the move when hours are not exactly as they would like. The correspondence has been very gratifying and instructive, and in one case amusing. Out of eight letters only two are opposed to early closing, so that this correspondence has not been amiss, but shows that a majority are favourable to the measure. If chemists are to be classed as professional men, why should not they, like medical men, be able to say that their hours are so-and-so? If there were the same professional etiquette amongst us there would be no difficulty as to early closing. It is rather late in the day now to suggest that a plebiscite of the trade be taken in regard to Sir John Lubbock's Bill, seeing the progress it has made; but if you, sir, were to take the trouble, I am sure everyone would be pleased to abide by the result. Would it be too much to expect the Council at its next meeting to take more decided action regarding it; as yet they have committed themselves to nothing but watching. What is watching without action? We are all watching the progress of the Bill. I am especially indebted to Mr. Sanders, of Cardiff, for his able letter on my behalf, as well as the other gentlemen who have written in favour of early closing. I hope all those who have votes will vote for those candidates for seats on the Council who are favourable to the Bill, and not for those who are opposed to what some called "grandmotherly legislation." With kind regards and best wishes for yourself, sir, and for the Journal, which I do not intend to be without.

Dundee, March 30, 1896.

EARLY CLOSING.

* * * With regard to our correspondent's suggestion, we are not so sure as he seems to be that "everyone" would be willing to abide by the result of an informal vote such as he suggests, and as he surmises, it is rather late for any such general expression of opinion to be ascertained. At the same time we shall be very glad to hear from anyone who either approves or disapproves of the principle of the Bill, and there could be no objection to recording the number on each side who take the trouble to express an opinion. [Ed. Pharm. Journ.]

Sir,—In my opinion, the Bill mentioned is sadly needed, and more especially by chemists and their assistants than any other branch of shopkeepers. At present the understood hour for closing shops in the district where I am engaged is 9 p.m., but it is not recognised, as certain shops are to be seen full blaze at 10, and even 10.30 p.m. Is that fair? I do not understand why shopkeepers, who would otherwise close at a proper time, should be debarred from doing so, all because a few grabbing employers keep open to all hours, praying for a chance copper, besides encouraging the public to come late. Is it reasonable to expect a higher grade of education from students under such unfavourable circumstances? How are we to qualify except by cramming? I am certain that earlier closing would prove beneficial in every way, and a boon to chemists' assistants; and by Act of Parliament is the only way to gain a satisfactory result.

Glasgow, March 23, 1896.

THOMAS BOYD.

Sir,—The different conditions which affect the chemist's business according to the locality in which it is placed will probably account for the different views taken of Sir John Lubbock's Bill. Otherwise everyone would welcome the prospect of shorter hours. Any law which imposed the same hour for closing on the wealthy and on the poor districts of a town would not only press heavily on the shopkeeper but would inflict such inconvenience on the public that it would be evaded or set at open defiance. The discussion on the subject should, however, be carried on without misrepresentation. Your correspondent, Mr. H. E. Durbin, of Putney, said in last week's Journal:—"Already in the Council Meeting Messrs. Hampson, Martin, Allen, Hills, and Gostling have objected to the State protecting assistants from the greed of employers. These gentlemen have not the welfare of the assistants at heart . . ."

Evidently Mr. Durbin is unacquainted with the gentlemen he criticises. Two of them have retired from business and no longer employ assistants, but I am quite sure that in the whole ranks of pharmacy there could not be found five gentlemen who have the

welfare of assistants and of the trade generally more at heart, and few establishments, indeed, where the business hours are shorter or the assistants better cared for than the respective houses of the gentlemen enumerated. The report of the proceedings at the last Council Meeting does not bear the interpretation Mr. Durbin puts on it. Surely it is permissible to object to Government interference without wishing to oppress employes or keep open the shop until 10 or 11 o'clock at night. If the principle is once established it may be carried to greater lengths than many of us will like.

225, Oxford Street, W., March 25, 1896.

J. R. WRETTS.

Sir,—I think this Bill ought to be supported, and that it will be a great mistake if chemists do not seize this opportunity of ending, once for all, the perennial difficulty of early closing. The entirely permissive character of the measure is a sufficient reply to those members of the Council who opposed it at the March meeting, and, if a two-thirds majority is not considered enough, by all means let it be three-fourths. The Act would simply confirm a resolution of the chemists themselves, and provide for the effectual and equitable carrying out of the same. In my opinion, however, the saving clause for chemists is too loose as it stands, and would operate unfairly on the large number who do not maintain a night service. The rule ought to be "all lights out" at the hour agreed on for closing. But undoubtedly the best plan would be to prohibit the sale of all articles whatsoever after closing time, except on the written order of a duly qualified medical practitioner, veterinary surgeon, dentist, or certificated nurse. I am convinced that nothing short of this would be satisfactory to the owners of "lock-up" shops, and as these form the great majority (at least in my part of the country), the adoption of the Act would rest with them. Although there might be a little friction just at first, I am sure the public would soon fall in with the new order of things, and get into the habit of keeping a stock of such domestic remedies as are likely to be required on an emergency. In conclusion, let us remember that whatever form the measure may ultimately assume, the adoption or otherwise of its provisions will rest entirely in our own hands.

Aberdeen, March 16, 1896.

SPES.

Sir,—Speaking after an experience of over thirty years behind the drug counter—most of which time I have worked fourteen hours daily, and sixteen hours on Saturdays—I may say I cordially approve of the measure, now in committee of the House of Commons. Of course, the single-handed chemist will reap most benefit from it, for he is practically tied to the shop so long as it is open. On the other hand, a man who can afford several assistants will not be so much affected by it, as he can go out and come in whenever he chooses, and, if he lives away from business, can go home as early as he wishes. The subject has been discussed over and over again, until I am heart-sick at the slow progress made. It is time we had deeds, not words. The chief objection urged against this Bill is that we shall lose business by it. Well, perhaps we may, but, after all, what is the loss of a few shillings to the gain in health and comfort which will be secured by shorter hours? I have looked forward for many years to the time when we shall close at 7 p.m., and should even like to see all shops closed at 5 or 6 on Saturdays—many shops already close about that time. This would make "life behind the counter" more what it ought to be, instead of the white slavery it is now.

Liverpool, March 24, 1896.

WALTER A. GRACE.

Sir,—Having served on the local committee for early closing, I am convinced that nothing but legislation will effectually curtail the present abnormal hours of labour. I have sounded many of my *confrères*, and all express the hope that Sir John Lubbock's Bill will speedily become law.

Richmond, S.W., March 25, 1896.

R. A. BLANCHFORD.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Blanchford, Blackburn, Cupit, Dott, Forrett, Greenish, Haigh, Hill, Ince, Jarvis, Jeeves, Lownsbrough, Midgery, Muir, Reynolds, Schneider, Taplin, Tame, Walker.

STERILISATION OF MILK.

BY J. A. FORRET.

Sterilised milk is now frequently used for infant feeding, especially for infants of tender age. Though it is a commercial article it is not always available as such; and in many instances there will be the desire to prepare the milk at home, as often and in such quantities as may be required.

It is generally accepted that milk subjected to a temperature of 100° C. for twenty or thirty minutes, undergoes practically the same chemical changes as result from sterilisation under pressure, *i.e.*, at a temperature above 100°. Dr. C. W. Earle* states that both clinical and chemical evidence lead to the belief that milk is injured as a food for infants by being heated to any temperature above 80°; and that pasteurisation at a temperature ranging between 70° and 80° destroys most of the ordinary germs of milk, including the bacilli of tubercle, typhoid, cholera, etc., whilst the milk itself is not injured.

How then can the "cooking" be carried out by means of ordinary domestic utensils, and without employing a thermometer? Dr. Earle says that milk may be pasteurised by simply immersing the vessel containing it in boiling water that has been removed from the source of heat, and leaving it so immersed for half an hour. There is no mention of the volume of water relative to that of milk necessary to raise the latter to the required temperature. Mr. Malcolm Morris† directs the bottle containing the milk to be placed in a suitable vessel containing cold water, and the temperature of the water slowly raised to the boiling point. The vessel is then to be covered with a woollen cloth and set aside for half an hour. Here, again, the proportion of water to milk is omitted. Obviously, if the same proportions of water and milk be taken in both cases, the maximum temperature of the milk will be much higher by the latter method than by the former.

A pint of milk contained in an ordinary jar requires a bath of from eight to ten pints of boiling water to raise its temperature sufficiently high. The amount of heat required by this method is enormously greater than by that of Mr. Morris. The directions given by Mr. Morris, however, are insufficient: if we "heat slowly on a stove," overheating of the milk may result, whatever be the proportion of water to milk.

Experiments were made with the view of determining suitable proportions and formulating simple directions for sterilising. "Heat slowly," "heat over a brisk fire," etc., are at best vague. Perhaps the best way to indicate the amount of heat is to state the time required to boil a given quantity of water in which the vessel containing the milk is immersed. If the heat employed take longer than the time stated, the temperature of the milk will be too high, and *vice versa*. "Place a jar containing a pint of milk in three pints of water contained in a cylindrical tin vessel, of such size that the level of the water and milk are about equal when the jar is supported about half an inch from the bottom of the water bath; raise the temperature of the water to the boiling point, after which allow the milk to remain in the water for about fifteen minutes. The heat employed should boil the water in not less than twenty-five minutes, and not more than thirty-five minutes." When the water boils the temperature of the milk is about 75°, and rises till it meets the falling temperature of the water, attaining a maximum of 78°-80°.

There is a further important point in connection with the sterilisation of milk which I think has not received sufficient attention. When the milk is heated the separation of cream is much

more complete, and the cream forms a more compact layer than is the case when the milk is merely allowed to stand at ordinary temperature. If the milk be treated in an open jar and not stirred, a tough skin forms on the surface, and such milk is impoverished by loss of fat in the removal of the skin, together with more or less of the cream adhering to its under surface. When a closed vessel is used for the milk this loss is avoided, but the cream is diffused with difficulty by stirring or shaking, and appears in small clots or flakes.

"As it is easier to prevent precipitation than to re-dissolve a precipitate once formed," so is it easier to prevent separation than to diffuse the cream once separated. The milk, therefore, should be frequently stirred while in the water bath and till its temperature is practically normal.

ON THE ASSAY OF CREAM OF TARTAR.

BY C. A. HILL, A.I.C.

Having been in the habit of determining the potassium hydrogen tartrate in "cream of tartar" by means of direct titration with alkali, and having found that this process gives accurate and trustworthy results, I have thought it desirable to bring these facts before the notice of pharmacists, not only because the method is far more convenient and expeditious than the ignition process recommended in the British Pharmacopœia, but also in order to notify the fact that the latter process is quite inaccurate, owing to the loss of potassium carbonate from reaction with the calcium sulphate which occurs in commercial "cream of tartar." The presence of calcium tartrate does not affect the result.

For the assay, about 1 gramme of the substance is weighed out into a flask, and warmed with a slight excess of $\frac{N}{5}$ soda. The excess of alkali is then titrated with $\frac{N}{5}$ sulphuric acid, phenol-phthalein being used as an indicator.

The following analyses show the composition of three commercial samples. The total calcium was determined, and the amount over and above that sufficient to account for the sulphuric acid was calculated as tartrate. In sample No. 1 the amounts of lime and sulphuric acid exactly tallied.

No. 1.	
Potassium Hydrogen Tartrate	96.00 per cent.
Calcium Sulphate.....	4.20 "

	100.20 "
The value found by the ignition process was	84.50 per cent.
Correction for 4.2 per cent. of Calcium Sulphate	11.61 "

	96.11 "

It will be seen that this corrected value agrees well with that found at once by the direct titration.

No. 2.	
Potassium Hydrogen Tartrate.....	89.41 per cent.
Calcium Tartrate	10.55 "

	99.96 "

The value found by ignition process was 89.35 per cent., showing that in the absence of calcium sulphate identical results are obtained by the two processes.

No. 3.	
Potassium Hydrogen Tartrate	90.73 per cent.
Calcium Sulphate	2.46 " "
Calcium Tartrate	6.69 " "

	99.88 " "

* *Pharm. Journ.* [3], xxiii., 263.† *Pharm. Journ.* [4], i., 149.

lower reducing flame until it has become brightly red hot. Break up the fused mass and charcoal in a small agate mortar, and carefully wash away with water everything but the reduced metallic beads or powder.

The following scheme shows how the metals may be distinguished, but of course it is advisable to apply confirmatory wet-way tests :—

Easily fusible to white metallic beads.	{ Ductile { Marks paper—Lead. Does not mark paper—Silver, Tin. Brittle { Antimony. Bismuth.
Difficultly fusible forming scales	
Infusible, forming gray or black powder	{ Red—Copper. Yellow—Gold.
	{ Magnetic { Very—Iron. Slightly—Cobalt, Nickel. Non-magnetic—Platinum.

Borax on platinum wire.—The oxides of certain metals have the property of forming variously coloured beads when heated with borax in the reducing and oxidising regions of a Bunsen flame. Many of the colours are quite characteristic. It must be remembered that these tests apply only to salts capable of conversion into oxides in the flame. Sulphides should first be roasted before being used.

Borax Beads.

Element.	Oxidising Flame.	Reducing Flame.
Manganese.....	Amethyst	Colourless
Copper	{ Hot, green Cold, blue	Brown-red, opaque
Iron.....	{ Hot, yellow; Cold, colourless or pale yellow	Pale green
Nickel..	Reddish-brown	Grey, opaque
Cobalt.....	Blue	Blue
Chromium	Green	Green

In conclusion, I should like to recommend a closer acquaintance with these tests to my younger friends. They are all extremely delicate, and often yield very decisive results with little loss of time, besides giving more exercise in the use of one's powers of observation than the more systematic methods of wet-way analysis.

THE CINCHONA PLANTATIONS OF MADRAS.

The Revenue Department of the Government of Madras has issued a report by Mr. M. A. Lawson, Government Botanist and Director of Government Cinchona Plantations, on the receipts, expenditure, and general condition of the plantations. From the report, which is dated June 10, 1895, and which deals with the Dodabetta, Nedivattam, and Pykara estates, it appears that the season during the past year was unusually dry, the rainfall on the Dodabetta estate being 26.85 inches, and on the Nedivattam estate 13.79 inches less than that gauged in the previous year; but the exceptionally dry season does not seem to have affected the crops to any appreciable degree, the output of bark on the three estates having been 125,557 lbs., which added to the amount in stock at the beginning of the year, made a total stock of 393,701 lbs.; of this quantity 198,572 lbs. were disposed of during the year, leaving in stock in the store-houses at the commencement of 1895, 195,129 lbs.

The Dodabetta estate has greatly improved, and the estimated annual output of bark, viz., 100,000 lbs., is double the quantity harvested in former years. This satisfactory result is to be attributed to deep trenching, deep digging, and heavy manuring. Where the soil is poor, weeds have been sown and manured, and these weeds being dug in every year have greatly decreased the poverty of the

soil. Fifty-one thousand pounds of dried crown bark were taken from this estate during the year, an amount which could easily have been doubled had the extra quantity been required. The several plots known as the "Picnic ground," and consisting of about forty acres, have not now been barked for many years; the trees upon it are very fine, very healthy, and are of a uniform variety. All other varieties or species have been uprooted, and it is from the best trees in the centre of this ground that the seed is taken which is required for the several estates; this means that a pure strain of the very best sort of the crown barks is ensured. The plants raised from this seed are undoubtedly more vigorous in their growth than those raised from hybrids, the latter having greatly deteriorated during the last twelve years. Nevertheless, it cannot be affirmed that the plants raised even from these carefully-nursed trees are nearly so vigorous or long lasting as those raised from seed taken from the same trees twelve or fifteen years ago, and it would therefore be very desirable if Government could procure a fresh supply of seed from South America.

The Nedivattam estate, the most difficult of all to deal with, owing to the great mixture of varieties which were originally planted out upon it, is not doing so well as had been hoped for, though for no fault or want of care on the part of the superintendent. All the new plantations have been deeply trenched, and dug, and heavily manured, and yet in many plots the trees do not show the same satisfactory growth as is visible on the Dodabetta estate. This appears attributable to two causes: First, most of the new plantings consisted of crown hybrids raised from Dodabetta seed (and these, as has been said above, have much deteriorated). Secondly, the land on which the trees have been planted was second-hand land, so to speak; that is to say, it was land upon which cinchona had been grown before. The plan now adopted on this estate is as follows:—When a plot is cleared, the trees are cut down, but not uprooted, and the ground is not meddled with for two or three years; by this time the stools of the trees have thrown up shoots three or four feet in height, and the ground is also covered with a dense growth of weeds. The land is then pitted, but the weeds surrounding the pits are not disturbed. The shoots afford shade and shelter to the young plants, and the weeds conserve and add to the nutritious properties of the soil. If the weeds are entirely removed, and the whole land kept perfectly clean, what little organic matter is left on the surface of the soil is burnt up during the hot weather, and the nitrogenous matter and all soluble salts are washed out of the soil during the rains, the result being that the land is left miserably poor. The Pykara plantation has greatly improved during the last ten years. The trees on it are for the most part of a good sort, crown and crown hybrids, and all the young plantations have been deeply cultivated and manured. There are still patches of red bark here and there, upon the plantation, and there is a considerable area which was planted up twelve years ago with Nedivattam hybrids. The trees on these plots will in due course be replaced with pure *Cinchona officinalis*; a small portion on a barren ridge has been abandoned for the present, as it is hoped that it may recuperate if left fallow for some years.

The manufacture of quinine and febrifuge in the factory at Nedivattam was carried on almost continuously during the past year; 4770 lbs. of sulphate of quinine, and 1756 lbs. of febrifuge were turned out during the twelve months, of which 3631 lbs. of quinine and 3956 lbs. of febrifuge were sold during the same time, leaving, together with previous amounts in stock, 4984 lbs. of quinine and 1946 lbs. of febrifuge on hand at the beginning of 1895. It is estimated that the value of the quinine, febrifuge, and other drugs manufactured at the factory during the past year would amount to 84,740 rupees.—*Board of Trade Journal.*

NOTES ON THE PREPARATIONS AND FORMULÆ OF THE BRITISH PHARMACOPŒIA.

SYRUPS.

(Concluded from page 225.)

Syrupus Rhei.—This is certainly a most objectionable preparation. It is very liable to become fermented or crystalline, it is nauseous in flavour and unsightly in appearance. It is, nevertheless, an important preparation, and the formula requires a considerable amount of revision. Primarily it is an alcoholic preparation, a dilute spirit being used to exhaust the two ingredients, which are ordered to be in No. 20 powder. This is too fine a state of comminution; a coarse powder percolates far better. These drugs are supposed to be exhausted by percolation only, no maceration or subsequent pressure being deemed necessary. It is a tincture; why not proceed as with a tincture—macerate, percolate, and press? This tincture is then ordered to be evaporated, which process involves the loss of both spirit and essential oil. The evaporated liquor is then directed to be filtered. If this is done whilst hot the filtering medium retains little or nothing, and if cold it takes hours to filter a pint, and seems a superfluous operation. A better plan to adopt, if the tincture has to be evaporated, is to dissolve the sugar in the hot liquor. By so doing the fine precipitate peculiar to rhubarb does not occur. It is difficult to imagine any sufficient reason why spirit which has done duty in connection with *syrupus papaveris* should be recovered by distillation, whilst under quite similar circumstances such spirit is directed, in the formula for *syrupus rhei*, to be evaporated into the atmosphere and lost.

A better-flavoured syrup would be obtained by omitting the coriander fruit and adding at the end of the process its equivalent of essential oil dissolved in a little rectified spirit. As now ordered to be made, practically the whole of the aroma of the coriander is driven off during the evaporation of the percolate. It is obvious to all who have made this syrup what a distinctly crude preparation it is, and how antagonistic to the first principles of practical pharmacy. The Continental and American practitioners seem to prefer an alkaline preparation in this syrup, for no fewer than nine pharmacopœias order it to be made in combination with alkalis, such as sodium or potassium carbonate and bicarbonate. This method does produce a nice syrup, but its introduction into English medicine is not likely to be appreciated as it is seldom called for, nor is it advisable to introduce a chemical preparation of a drug like rhubarb when so little is known about its constitution. Squire proposes using a liquid extract, dissolving the sugar in it and adding essence of coriander if necessary. This is an excellent proposal, but of no avail unless a liquid extract is to be introduced. Instead of this form, a modified one might be used with advantage by first preparing a liquid extract of the root and using glycerin and water as the menstruum, somewhat following the process given in the unofficial formula for making *syr. pruni virg.*—

Rad rhei, coarse powder	15 parts.
Sugar	70 "
Glycerin	15 "
Water to	100 "

Mix the glycerin with three times its volume of water, and in this mixture macerate and percolate the drug, and continue to percolate with water until 45 fluid parts have been collected. In the percolate dissolve the sugar, without heat and preferably by repercolation, and make the product measure 100 fluid parts. If desirable, an essence of coriander can be added. This produces a syrup which keeps well and is of pleasant flavour.

Syrupus Rhæados.—This formula is a good one but requires careful attention to detail, otherwise the syrup is liable to undergo fermentation on keeping. The poppy petals should be quite fresh and free from any signs of blackening due to heating or incipient fermentation. During the whole time of adding the petals the full heat of the water bath should be maintained, and the petals should be added very gradually, in order to ensure thorough contact with the hot water, and also to prevent the temperature from falling too low. When the liquor is pressed and strained it should be heated to the boiling point and filtered bright as quickly as possible. The sugar should then be dissolved in the filtered liquid, and taking care that the gravity does not at any time exceed the normal, the whole should be gently boiled for one or two minutes, any matter which separates being removed by skimming. When cold the spirit should be added and the syrup completed as officially directed. The flavour is not injured by ebullition, provided that it be not unduly prolonged. Attention to the foregoing points ensures a product, which, when properly stored, does not ferment or spoil. The use of enamelled iron or porcelain vessels might with advantage be specified, as contact with iron or copper injures the colouring matter.

Syrupus Rosæ Gallicæ is rarely used. Its omission has been recommended, but, if retained, the present unsatisfactory formula will doubtless give place to one constructed on the lines of the U.S.P. Coull (*Ph. J.*, liii., 786) has proposed a suitable modification of the latter, in which powdered rose leaves are percolated with a mixture of rectified spirit, glycerin, and water, and the percolate mixed with four times its volume of simple syrup. It is an easy matter to prepare a bright, clear syrup of the petals by this form:—

Rose petals	10 parts.
Glycerin	1 "
Spirit, rectified	10 " fluid.
Sugar	66 "
Water to	100 " fluid.

Mix the spirit and the glycerin, and macerate the rose petals, then percolate until 33½ fluid parts are collected. In this percolate dissolve the sugar without heat, and make the product measure 100 fluid parts. This formulæ produces a better syrup than by the infusion process now employed, which is open to many objections, as the infusion is only filtered with great difficulty, and often becomes mouldy before completion unless great care is taken.

Syrupus Scillæ.—The high specific gravity constitutes the chief defect of this formula, anything above 1.330 being incompatible with good keeping qualities. Reduction of the quantity of sugar ordered to 2¼ lbs. would set matters right in this respect. It is important that diluted acetic acid of full pharmacopœial strength, and squill neither damp nor mouldy through absorption of moisture, be used for the acetum scillæ, which, further, should be allowed to stand for a few days, and carefully filtered before being made into syrup. The weight of the finished product might also be stated, and directions added to adjust the weight when cold by the addition of diluted acetic acid. Syrup of squill prepared as above is unexceptionable. The use of an acetum scillæ containing a larger proportion of acetic acid has been suggested, but does not appear necessary.

Syrupus Sennæ is a palatable and efficient preparation of senna. The weak point about the formula is the evaporation by heat of the mixed expressed liquors. A high temperature, according to our present knowledge of the pharmacy of senna, is detrimental to the activity and general properties of the drug: improvement might doubtless be effected in this direction. Two methods are available. Either the senna might be treated twice by expression with a menstruum containing 25 per cent. of rectified spirit and the

pressings mixed and filtered, or the leaves might be exhausted, within the required volume, by repercolation with cold water, the remainder of the official process being carried out as it stands. In either case the application of heat would be avoided and an improved product result. A good process is to exhaust the leaves with cold water by repercolation, so as to obtain a liquid extract of a given volume. To this add the spirit and the coriander oil, and filter. It is best to add strong spirit of about 90 per cent., as the extractive present in the liquor is considerable, and requires often a large quantity of spirit to coagulate it. The spirit, unless it is strong, adds unnecessarily to the volume, besides which, strong spirit more readily separates the extractive and the filtration is more rapid. In the filtrate, dissolve the sugar without heat, and make up to a given volume. A process like this would avoid the application of heat, and is less trouble to manipulate than the present one.

Syrupus Tolutanus.—This formula requires modification. Boiling the balsam for half an hour in a lightly covered vessel with occasional stirring causes the loss of a large proportion of the odorous principle, and the liquid, when allowed to cool before filtering, deposits crystals of cinnamic acid, etc., much of which would otherwise be retained in the syrup and increase its taste and flavour. The directions might be altered as follows:—Heat the balsam and the water in a closely covered vessel to near the boiling point for half an hour, stirring frequently. Filter the solution whilst hot, and wash the contents of the filter with boiling distilled water to 16 fl. ozs. Dissolve the sugar in the filtered liquid. Slight decomposition of the cinnamic acid may take place under the prolonged application of heat, with formation of other bodies of the aromatic series which communicate a benzene-like odour to the syrup on keeping. Excess of heat should therefore be avoided. A similar odour also develops in syrup of tolu which has undergone slight fermentation through being improperly stored in too warm a situation. The use of porcelain or enamelled iron vessels might be specified. Contact with iron darkens the colour of syrup of tolu, and copper is taken up when preparations of tolu are made in vessels of that material.

With a view of producing a better flavoured syrup than that yielded by the official process, two other methods have been proposed. One, devised by F. Stephenson, consists in powdering the balsam with a portion of the sugar and extracting the soluble constituents with cold water, either by percolation or maceration. The liquid is filtered and the sugar dissolved in it by agitation without heat. Another process depends on the use of alcohol. Several formulæ have been published, but that given in Squire's 'Companion' is perhaps the simplest. "Dissolve bals. tolu, $1\frac{1}{4}$, in S.V.R., $1\frac{1}{4}$, add the solution to simple syrup, 34, shake thoroughly, and filter." Both these methods produce syrups of excellent flavour and are worthy of consideration by the compilers of the new pharmacopœia. These two formulæ well illustrate the increasing tendency of modern pharmaceutical practice towards the conservation, in unchanged condition, of the active principles and odorous constituents of drugs by the substitution of such processes as repercolation, cold maceration with expression, etc., for the time-honoured methods of decoction and boiling down generally, which even now characterise many of our official formulæ.

A very fragrant preparation is that prescribed by the U.S.P.—

R Balsam tolu.....	146 grs.
Alcohol.....	$12\frac{1}{2}$ fl. drs.
Calc. phosphate.....	$1\frac{3}{4}$ ozs.
Sugar.....	$33\frac{1}{4}$ ozs.
Water to produce.....	32 fl. ozs.

Dissolve the balsam in the alcohol, incorporate with it the calcium phosphate and 5 ozs. of sugar. Allow the alcohol to evaporate,

and then add 16 ozs. of water; mix well and filter. In the filtrate dissolve the remainder of the sugar, and bring up the final volume to 32 fl. ozs. by the addition of water.

Syrupus Zingiberis.—The unattractive appearance of the product of this formula renders it anything but illustrative of elegant pharmacy, and although lacking nothing in either pungency or flavour, a formula yielding a bright article seems to be a desideratum. It is doubtful if anyone can produce a better flavoured syrup of bright appearance miscible with water. None of the so-called soluble essences have any medicinal value. If an alcoholic solution of the ginger is saccharated, it will be clear, but directly it is diluted the resinoid matter will certainly be precipitated. On the other hand, if an alcoholic preparation is added to simple syrup, the syrup will become turbid, as at present.

The following modification is suggested:—

Strong tincture of ginger.....	1 fl. oz.
Distilled water.....	A sufficiency.
Pumice in fine powder.....	90 grs.
Refined sugar.....	$17\frac{1}{2}$ ozs.

Mix the pumice with one fluid ounce of the water. Add the tincture, shake well, and allow to stand for one hour. Filter bright, and wash the contents of the filter with water to 9 fluid ounces. In this dissolve the sugar by agitation in a closed vessel at a gentle heat.

Proposed New Official Syrups.—The following syrups have been recommended for insertion in the next edition of the Pharmacopœia:—Syr. codeinæ, ferri phosph. co., ferri quininae et strych. phosph., ferri quininae et strych. hydrobrom., hypophosph. co., picis liquidæ, and pruni virginianæ. Formulæ for these have been published and tested by experience, and the syrups themselves are extensively prescribed. By their inclusion the Pharmacopœia would be enabled to fulfil, as far as this class of preparations is concerned, not the least important of its functions, viz., that of truly reflecting the medical practice of its day.

PHOTOGRAPHY FOR CHEMISTS.

LANTERN SLIDES BY REDUCTION.

When a negative happens to be of larger size than a quarter-plate, it rarely happens that we can print a small portion by contact on a lantern plate without spoiling the composition of the picture. This is assuming, of course, that the operator has composed a picture, and not put his camera down anywhere. There is no great difficulty in making lantern slides by reduction; the exposure is the only bugbear, as usual.

There are two distinct methods of reduction: (1) daylight; (2) artificial light. There is nothing to choose between them, and the question of time and opportunity must decide which is to be adopted. The apparatus required is not expensive. It can be made in odd moments for a few pence, and is applicable to day and artificial light. It consists of a printing frame the size of the large negative, four pieces of bamboo a quarter of an inch in diameter, some black twill, the ordinary camera and lens, and a carrier to take lantern plates $3\frac{1}{4} \times 3\frac{1}{4}$ inches.

The negative is placed in the printing frame upside down and kept in position by four little slips of wood, or better still, a frame such as the gold slip used in picture frames, which will fit tightly into the frame and hold the negative securely. Of course brads may be driven into two sides of the frame, and the negative slipped behind them, but in this case it is necessary to safe edge the negative. This is done by cutting strips of tin foil just wide enough to cover the rebate of the negative so that no clear glass can be seen, these should be pasted and stuck on the glass of negative round the

four sides. The strips of bamboo are either nailed to the printing frame or merely fastened together by stout copper wire, the shape being exactly that of the printing frame. The other end of the bamboos are tied with stout string to a piece of cardboard tube, postal tube, which slips over the lens. The length of the bamboos depends upon the focus of the lens and the amount of reduction. It will sometimes be found convenient to have the bamboo in two lengths; thus, supposing we want as a general rule 36 inches, two pieces, 24 inches each, should be obtained, and by fastening these together in the middle by two loose rings of copper wire we can extend them to 48 inches or reduce them to 24 inches.

The black twill or the focussing cloth (or even a dark table-cloth may be used) must also depend for its size on the length of bamboo, but sufficient should be obtained to completely cover over the space between lens and negative, and hang down on each side.

Of course, two laths of wood can be used, merely resting them on the top of printing frame and camera, but the other plan is preferable, the arrangement being more complete and adaptable to both day and artificial light, and also more rigid, especially when the camera is sloped towards the sky.

The ordinary camera may be used, but a carrier to take lantern plates must be used in the dark slide. The ordinary lens may be used unless of inordinately long focus, when it becomes inconvenient on account of the great distance between negative and lens. To find the required distance there is a simple rule which is as follows:—

(a) Divide the longer base of the plate by the longer base of the image required, to the quotient add 1, and multiply by the focus of lens used; the result will be the distance between negative and lens.

(b) Divide the distance found as above by the quotient obtained in the first rule, and the result will be the distance between lens and plate.

Example.—What are the relative distances in reducing a whole plate negative, $8\frac{1}{2} \times 6\frac{1}{2}$ inches, to lantern size with an 8-inch focus lens?

Now that the whole of the lantern plate is not used, we reckon that 3 inches is all that can be used, because of the mask, hence:—

$$(a) 8\frac{1}{2} \div 3 = 2\frac{7}{6} = \text{the amount of reduction.}$$

$$2\frac{7}{6} + 1 \times 8 = 2\frac{2}{3} \times 8 = 30\frac{2}{3} \text{ inches.}$$

$$(b) 30\frac{2}{3} \div 2\frac{7}{6} = 11 \text{ inches (practically).}$$

Therefore, if we place our lens about 30 inches from the negative and rack the camera out to about 11 inches, we shall have an image on the ground glass which merely requires a little adjustment of the camera screw to be sharp and of the right size. In focussing it is always advisable to temporarily affix to the outside of the focussing screen a square mask, this being, of course, accurately placed as regards the centre of the screen, and to use a focussing magnifier to obtain critical sharpness.

Having satisfactorily arranged our image as regards composition by shifting the camera nearer to, or farther from, the negative—because it will be obvious that the nearer the lens to the negative, the less of the negative we shall include, and *vice versa*—we fill our dark slide and are ready for exposure.

For daylight work the arrangement of frame and camera should be placed near a window, and if anything but sky is seen opposite the negative, place outside the window a large sheet of white cardboard at an angle of 45° . This will reflect equal skylight through all parts of the negative. Now cover over the space between negative and lens, insert your dark slide, in front of the negative place an opaque card, draw the shutter of the dark slide, and remove the opaque card from negative and expose.

Very little assistance can really be given as to exposure, but with a negative of average density, which will give a good silver print,

and using a lens working at F/11 and a Mawson lantern plate at midday in May, ten seconds will give a good black slide.

There is one little point that has been missed—the diaphragm; always use the largest diaphragm which will give satisfactory definition, this will usually be F/11 or F/16.

Be very careful whilst exposing not to shake the camera—it is quite sufficient for anyone weighing about eleven or twelve stone to walk across the room to give double outlines.

Daylight is not a constant quantity, and although visually the same on two different days, the actinic power of the light varies enormously, therefore we prefer artificial light.

Precisely the same apparatus can be used for artificial light with one or two additions. In one such arrangement in use the printing frame containing the negative is fastened to the side of a cube sugar box in which a hole is cut.

Opposite to the negative on the other side of the box is placed a sheet of white cardboard bent slightly to the arc of a circle. The lights, etc.—two incandescent gas burners do well with tin reflectors behind them—are placed one on each side of the negative inside the box, so that the light is reflected on to the card and thence on to the negative, and no direct light reaches the negative. Absolutely even illumination, even of a large negative, is thus obtained, and the exposure, using the same conditions as stated for daylight, is only twenty seconds.

Of course, the light may be placed directly behind the negative, but in this case a diffuser, such as a sheet of opal glass, must be placed between light and negative, and even then, unless great care is exercised, uneven illumination of the negative and consequent unequal density of the slide must ensue.

We may use magnesium ribbon, and a diffuser of opal is then necessary, and the ribbon must be kept in motion the whole of the time. Magnesium is objectionable because the particles of magnesia form a voluminous cloud, which tastes and smells unpleasantly and settles down on everything. Still, for those who wish to work with this substance, about 18 inches burnt close to the opal and moved about all over it will be about sufficient to obtain good results under above-mentioned conditions. An ordinary oil lamp or gas may also be used, provided the light is diffused.

Only the bromide lantern plates are suitable for reduction, the exposure, especially with the chloride emulsion, being so long as to place them out of court. The chloro-bromide may be used for daylight and magnesium ribbon.

After development and fixing, which may be performed in the developers recommended by the makers of the plates used, the lantern slide must be well washed and cleared in an alum and acid bath, then again well washed and finally given a gentle rub with a piece of cotton-wool under the tap, and set up to dry.

The finishing off of a slide is not a difficult matter, but one which wants doing properly. Place the slide film downwards upon a piece of white paper, and with a box of assorted masks try various shapes till the one most suitable to the picture is found, and frequently a mask with a comparatively small opening will give the best results pictorially. Having found the most suitable mask, lay it on the slide, on the top of this a cover glass well cleaned, and it is ready for binding. Binding strips can be purchased commercially in long strips, but personally we prefer to use $3\frac{1}{4}$ strips, as somewhat easier to apply. Wet $3\frac{1}{4}$ ins. of the strip, lay it flat on the table, pick up the slide and cover glass and adjust on the wetted slip so that there is an equal width on either side; now press the glasses firmly on to the strip and lift from the table and with a handkerchief or soft duster wipe the strip on to the glass of the slide and cover, taking care that these do not slip; when it adheres firmly, that is,

does not immediately rise up, lay the whole on one side and go on with the next slide; by the time half a dozen have been thus treated a second side may be stuck down, and thus with the third and fourth. By working in this way a far neater and safer job is made of it than if all four sides are bound at once.

The final operation is titling and spotting. There are several makes of masks on the market on which a blank white space is left for the title, and it is just as well to write the title on the mask, as it is then protected by the cover glass. If the ordinary masks are used, Chinese white may be used for the titles.

"Spotting" the slides is affixing to them two marks, by means of which the lantern operator can tell which side is to be placed next the lantern, and these marks usually take the form of two white circles. Such "spots" can be bought commercially already gummed, or postage stamp edging may be used.

A few minutes' thought will show that the projecting lens of the lantern will reverse an image just as the lens of the camera does, so that we must insert the slide into the lantern carrier upside down and wrong way round, and as the spots are used to indicate this, they must be placed at the top of the slide, when the view appears to us as we saw it in nature. If it be a subject with lettering in it, the spots must be placed at the top of the slide, when we can read the lettering the right way as the slide is looked at against a piece of white paper.

OBLIGATIONS OF THE PHARMACIST.

Apothecaries in Germany, France, Holland, Belgium, Scandinavia, Russia, and some other countries, enjoy a relatively high position in the community. In England and the United States the average druggist has not yet attained the confidence and respect due to his calling, because of his comparatively inferior education, the laxity of the laws regulating the practice of pharmacy, and the excessively mercantile nature of his business.

While we explicitly aver that there may be found in our country (the United States) very many highly educated pharmacists who honour their profession and fully realise its dignity and obligations, we are obliged to admit that the great majority of our druggists are unable to sustain the high standard of professional skill and accountability which is necessary to establish their title to recognition as fit men to perform the exceptionally important duties of makers, examiners, and dispensers of medicines.

The obligations of apothecaries and their assistants are set forth in laws and regulations established in most of the older civilised countries, and are sufficiently understood to insure a general sense of security from danger and a sincere respect for the pharmaceutical profession. In our country, on the other hand, there is no definite understanding of the many serious obligations of the pharmacist to the community, nor any adequate legal requirements such as would compel respect if intelligently and rigidly enforced. Not only the whole community, but the pharmaceutical profession itself, must have an approximately definite and rational idea of the professional obligations of the pharmacist, before the latter can attain to his rightful position by a faithful performance of these obligations.

His first and most obvious duty is, of course, the possession of sufficient scientific and technical training to enable him to perform his special duties well. In the absence of that training it is useless to expect him to become a worthy member of the profession, even if he should meet with great success as a merchant. But there are many other obligations which the professional pharmacist is expected to perform, and which he must perform with fidelity, in order to deserve and receive the respect, confidence,

and gratitude of his fellow-men. Thus, he must resolutely set his face against every species of fraud and quackery, which, of course, includes his absolute refusal to sell any nostrum or other article which he knows to be in any degree fraudulent, whether "in the original package put up by the manufacturer" or not. He must never, either directly or indirectly, or by implied assent, recommend any ready made cure in order to effect a sale, even if he has no reason to believe that cure to be a harmful humbug. He must use reasonable diligence in examining all his drugs, chemicals, and preparations, as to their quality, purity, and strength, and must reject any and every article not in proper condition; the objection so often raised, that "no druggist can have time to test all his chemicals," is not well taken, and is generally advanced by those who have no knowledge on the subject. The pharmacist must further take care to properly preserve his medicines. He must see to it that his balances, weights, measures, and other instruments are accurate and reliable. He must demonstrate by his life and work and speech that he is, indeed, the honest and faithful protector of his fellow-man against the dangers of ignorance, fraud, and abuse in the employment of medicine. He must so conduct himself and his pharmacy that intelligent men may perceive that a pharmacist's *officina* is not a mere depôt for the sale of miscellaneous merchandise, including drugs and medicines of all kinds, atrocious quack nostrums not excepted, but that it is, instead, a place where specially trained scientific experts render important professional services intimately related to the health and happiness of mankind.

The apothecary should gladly assume his obligations, and the community should be educated up to a full realisation of the services he performs, for in no other way can he hope to occupy the position which is rightfully his. There can be no compromising.—*Bulletin of Pharmacy.*

THE SCIENCE OF EXAMINING.

BY PETER T. AUSTEN, PH.D., F.C.S.

Much severe criticism is being directed against examinations, and much of it is timely and fully deserved. And yet when the criticisms are carefully considered they appear to be directed not so much against examinations as a method in education as against certain forms of examinations which are very prevalent and which certainly do not show anything more than evanescent memorisation, adroitness, or trickiness on the part of the student. No one will deny, however, that much of actual life is a kind of examination, and that we are being continually pressed to solve problems of all kinds, apply knowledge, and in general to act, and that on the success of our efforts will depend the positions we will attain, or at least maintain. There seems to be no reason why examinations should not be made an extremely important part of education, instead of being, as I fear they often are, an unmitigated nuisance to both student and teacher, a bone for the pedagogical critics continually to snarl over, and, when all is done, to be of no real use to either teacher or student, and to show nothing as to the real nature of the teaching done, and the mental development of the student.

For the teacher who teaches from love of teaching, and who knows that successful teaching calls for the application of psychological principles far more than is generally supposed, there is a peculiar fascination in an examination paper. An examination may be made a test of the contents, capacity, quality, and action of a mind under defined conditions; but the paper must be a good one; I do not refer to the work of an inexperienced hand. The idea seems to be prevalent that anyone can write an examination paper. This is a great mistake. The elaboration of a paper that will really test not only the contents of the mind, but also its different func-

tions as developed by a particular study under the guidance of a particular teacher, requires experience and ability. It is true that a man may be a good teacher and a poor examiner, but this usually arises from a lack of attention to the science and art of examining. My experience in this branch of pedagogical science leads me to believe that there are not very many really good examiners, and that the average examinations do not test the minds of the students as they ought to be tested. The average examination calls mainly for an exercise of memory, and for some proof that the student understands the matter he has studied. No man values the faculty of memory more highly than I do, or requires a better understanding of a given subject. But memory and mere understanding are only the foundations of education. More than this is called for. Some examinations require skill in observation, others accurate definition; while others bristle with problems. Some call for knowledge in which the teacher is weak. Almost every pedagogic earmark may be found in examination papers, but rarely is the paper constructed on such a plan that it tests not only the quality and quantity of knowledge in the mind, but also the various workings of the mind, and ascertains what the mind can do when set in action by the particular subject.

In my own specialty of chemistry there is an excellent opportunity for examination papers which may test the mind qualitatively and quantitatively, and probe both absorptive and productive powers. I have always taken a great interest in working out examination papers and in studying the minds as they appear in the answers. I am accustomed to work out questions under various heads. The following example will serve to indicate my meaning, and may also encourage others to experiment in examinational science; and I think that the method will be found so interesting that the investigation will not be hastily dropped. I should add that in the examination paper as given to the students the questions are mixed up, so that the classifications given as follows do not appear:—

Questions for Testing:—

Memory.—(1) Give a brief history of oxygen. (2) Outline the theory of phlogiston. (3) What are "copperas," "bluestone," "tincal"?

Accuracy of Definition.—(4) State concisely the laws of Dalton, Charles, Mariotte, and Avogadro. (5) Define a mechanical mixture. (6) Define an element.

*Observation of Experimentally Demonstrated Facts.**—(7) Describe and sketch an apparatus for producing acetylene from calcium carbide, and explain the working of it. (8) Describe and sketch the combustion of nitric acid in iodohydric acid.

Accuracy of Detail.—(9) Explain with the aid of sketches the reduction of hot cupric oxide by hydrogen, heating the oxide in a combustion-furnace and preparing the hydrogen in a Kipp generator.† (10) Make a sketch of a section of Pepys' gasometer, and explain how the apparatus works.

Acquaintance with the Properties of Matter.—(11) Describe the properties and chemical behaviour of nitrogen, sulphur, zinc, silica, and iodine.

Retention of Oral Instruction.—(12) Explain the contamination of water by sewage. (13) Describe the process for making open hearth steel.

The Faculty of Comparison.—(14) State similarities and differences between the properties of oxygen and hydrogen. (15) What substances resemble lead sulphide in colour and solubility in nitric acid?

Lucidity of Statement.—(16) Describe minutely and without

* Given in lectures, and not in text-book.

† Given in text-book and demonstrated in lecture.

sketches the apparatus and method of preparing phosphine. (17) Prove by analysis of stibine by volume that the molecule of antimony is tetratomic.

Recognition of Substances.—(18) A yellowish green gas with a suffocating odour. What may it be? (19) A colourless gas, very soluble in water, gives white fumes with hydrochloric acid. What may it be? (20) A white powder, insoluble in water; heated with concentrated nitric acid it evolves red fumes and yields a solution, which, when excess of acid is evaporated off, and it is diluted with water, yields a precipitate which is insoluble in concentrated nitric acid. What may this white substance be? (21) A chemist wishes to fill a jar with red liquid. What substance may he use?

The Ability to Observe.—(22) Give four examples of chemical change which you observe in this room. (23) Describe an ordinary red building-brick, stating dimensions and properties of surface, weight, fracture, etc. (24) Water expands on freezing. Give five examples of results caused by this expansion which you have personally observed.

The Application of Facts to Proofs.—(25) Prove that water is formed by the combustion of a kerosene lamp. (26) Prove that hydrogen sulphide contains sulphur.

The Interpretation of Phenomena.—(27) A piece of white paper on being held for an instant in the flame of a candle and at right angles to it, a black ring is formed on the paper. Explain what the ring indicates, and how the particles of carbon are formed, and why they are deposited on the paper. (28) A Roman candle on being ignited and then thrust under water continues to burn. How can this be accounted for? (29) Why cannot fish live in lakes on the tops of very high mountains?*

The Application of Knowledge.—(30) The iodine falls into the sand box. How can the iodine and sand be separated? (31) A mixture consists of barium carbonate, sodium sulphate, and sulphur. How can they be separated? (32) A manufacturer has a waste product consisting of a liquid containing 40 per cent. of sulphuric acid, 10 per cent. sodium sulphate, and 5 per cent. ferric sulphate. How can he treat it so as to convert it into other products that have commercial value?

Deceptive or Misleading Questions.—(33) Dilute sulphuric acid is poured upon zinc. A gas with a slight bluish colour is evolved, which burns with a red flame. What is it? (34) Chlorine gas is collected in a jar over mercury‡ in the usual manner. It is then brought into a eudiometer, mixed with twice§ its volume of hydrogen, and exploded. How many volumes of hydrochloric acid gas will be produced?

The Imagination.—(35) Filthy water of the gutter, warmed by the sun's rays, escapes from a foul environment, and, condensing, sparkles like diamonds on the petal of the violet. Use this as basis for an allegory in life.

These questions do not by any means represent all the possible divisions of mental action, and I have purposely avoided those of a very technical nature, most of which, however, would fall under the heads given; but they will serve to indicate what opportunities there are to construct examination papers that shall test a student's knowledge and the working of his mind. It may be urged against the questions I have given that several of them might fall as well under one head as another, or that a few more elaborate questions could be made out, and each question marked under the several heads. My experience, however, has not been that the real ends are best attained in this way. The question that is distinguished by its

§ Once.

definite nature and object gets a clearer answer and gives a more satisfactory insight into the student's mental equipment and action than a long or complicated one. If, after teaching a student a subject for a certain time, an examination shows that he can bring forth nothing more than that which has been put into him, it may be inferred either that the teacher is incompetent, or that the student is intellectually deficient, assuming, of course, that the system in the particular institution permits the teacher to do his best, does not assign him more pupils than one man can teach, and requires the student to do the work assigned to him. In such case I think that the fault usually lies with the teacher. Still I admit that there are institutions in which educational work of a high pedagogical order is impossible, and mind development, as distinguished from mind cramming, is out of the question. In such a case students are produced who are saturated with knowledge, but who are incapable of utilising it. Like water-logged vessels they roll about aimlessly, and are unable even to keep out of the way of craft which are taking the fullest advantage of wind and tide. In such an institution the earnest teacher, when he fails, deserves sympathy more than blame.

The results of examinations, conducted on some plan like the one I have attempted to describe, are very interesting. Such examination papers are far more difficult to write than the calls for mere memorisation that are so frequently made on the student, and which a hasty cram will enable a fairly bright candidate to pass. The answers are more difficult to rate; and often an attempt to mark them according to the usual rules is unsatisfactory. It is quite easy to assign a mark to the amount that a student knows, or even to discriminate as to the quality of his knowledge. To assign a figure to his ability to apply this knowledge, to originate, to create, to act under its instigation, is more difficult; yet it can be done with a fair degree of success.

It must always be borne in mind that a man's value in this life does not depend merely on what he knows, but upon what he can do. *Cæteris paribus*, the more he knows, the more he should be able to do; for so much the greater should be the incentive, if the knowledge imparted to him acts on him as it should. Until technical education was introduced, this fact was not well understood, and it is still far from appreciated in many schools.

For instance: A shows in his paper an encyclopædic knowledge. In his answer to Q. 11 he recites with great precision the properties of silica and iodine. But he fails to answer Q. 30, which calls for a conclusion dependent upon this knowledge. He is like a recruit who has been given a gun, but has not been taught how to fire it off. Such a student demands the teacher's attention at once. His mental inaction is usually the result of poor teaching.

It may not be amiss for me to say parenthetically here that teaching is the most difficult of all professions. It is not usually regarded so, but I believe that it is. Much of what is called teaching is nothing more than a kind of pumping. Knowledge is forced in through the most convenient intellectual orifice, a great deal being lost *in transitu*, and not a little leaking out afterwards. The engorged recipient is like a boiler whose feed-pump is too big for it and will not cease pumping, but fills the boiler entirely full of water and leaves no space for steam; whereon the engine slows down and stops, or throbs soggly with its cylinder filled with lukewarm water instead of hot expansive steam.

Again, a student may fail in his attempts to state anything correctly or exactly; but he fills pages with attempts to apply his knowledge, suggesting all sorts of ideas and applications. Most of them may be impossible, some even ridiculous. But no matter, let the teacher take hold of this boy at once, for the mind of an Edison, a Siemens, or an Ericsson may be seeking nourishment an

development. Happy is the teacher who can discern what mean the instinctive strugglings of the embryonic master mind, and who can liberate it from the thralldom of routine—who can guide its first weak attempts to walk and climb, until it becomes hardy and venturesome, and fearlessly scales cliffs heretofore inaccessible; and so clambering by hitherto unknown ways to the peak discovers new fields for human activity, and cuts a wide path by which thousands may enter and take possession.

Examination papers constructed on the basis I have suggested, viz., to test not only the knowledge possessed by the student, but also the working of his mind upon the particular subject, will show more clearly the nature and condition of a mind than the daily recitation, because the case is more capable of systematic study and can be made to cover larger fields of mental activity. While I do not intend to suggest that such examinations should replace the regular recitation, I believe that they should be held frequently, and should serve a far wider purpose than that of merely noting the quantity of knowledge absorbed by the mind. Such an examination is not a mere matter of testing and registering; it is a creative exercise of the mind.—*Science*.

MYDRIATIC BASES.

Dr. O. Hesse has ascertained that the substance known in commerce by the name of scopolamine hydrochloride consists of salts of two bases—hyoscine and atropine—which can be separated by crystallisation from alcohol, in which they are unequally soluble.

Hyoscine, in combination with hydrobromic acid, turns the plane of polarised light to the left, while atropine is inactive, and by means of this difference the relative amounts of the two bases may be ascertained. It seemed possible that atropine might be formed from hyoscine, in the same way that atropine is formed from hyoscyamine, by the action of caustic soda, but further investigation has shown that hyoscine is first converted into oscine and lævotropic acid, which soon becomes inactive, and breaks up into water and atropic acid. Atropine, on the contrary, appears to break up at once into oscine and atropic acid, without formation of inactive tropic acid.

Atropine hydrobromide crystallises from water, like the hyoscine salt, in large rhombic plates, but it does not contain water of crystallisation, while the hyoscine salt has three molecules of water. When the two salts are dissolved together in water they crystallise out together, and with three molecules of water.

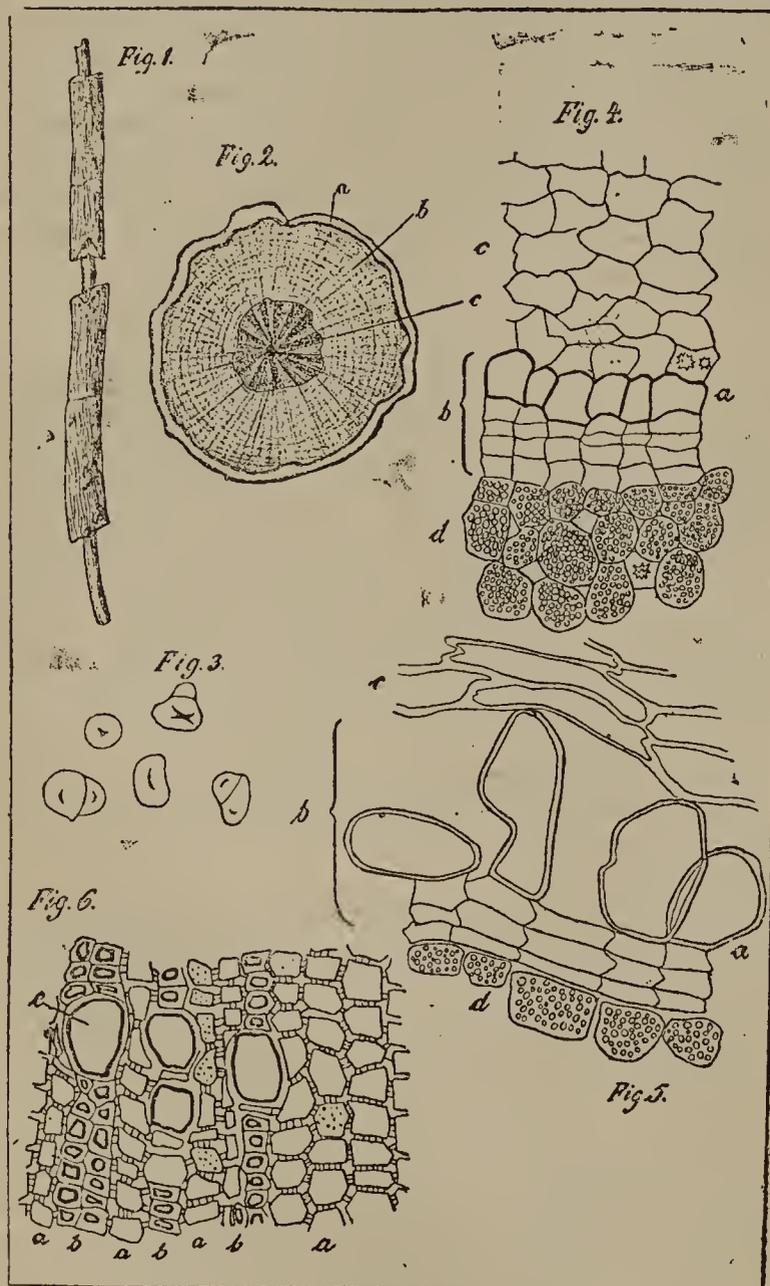

Atropine itself crystallises in concentric groups of needles, which melt at 36° C. and have the composition $C_{17}H_{21}NO_4 + 2H_2O$.

MENTHO-PHENOL AS AN ANTISEPTIC.—By mixing 1 part of phenol with 3 parts of menthol and melting the mixture, a transparent fluid with an aromatic odour and taste is obtained; the sp. gr. is 0.973, the fluid is nearly insoluble in water and in glycerin, but dissolves readily in alcohol, chloroform, and in oils. It dissolves iodine, iodoform, and aristol. Schaefer finds that this body has strong antiseptic and analgesic properties. It may be used preparatory to cauterising chancroidal sores and curetting necrotic surfaces. As a mouth wash 2 drops mixed with an ounce of aqueous menstruum may be advantageously employed. A case of abscess under the finger nail was painlessly lanced under a warm 5 per cent. aqueous solution of mentho-phenol, and rapidly healed when dressed with gauze containing 2 per cent. of the antiseptic. Equally good results were obtained in painful suppurating otitis media et interna. Wounds washed with warm 2 per cent. solution of mentho-phenol rapidly heal. In dental practice it is also useful, acting as a disinfectant and anodyne anæsthetic (*Bost. Med. Surg. Journ.*, cxxxiv., 111).

A NEW ADULTERATION OF SENEGA ROOT.*

BY C. HARTWICH.

In the early part of 1894, Ad. André, in Hanover, drew attention to an interesting adulteration found in senega root imported from New York, the drug containing nearly 25 per cent. of a foreign root which he referred to *Richardsonia scabra*. The structure of the drug, however, showed this identification to be incorrect; the starch in the two roots differed in character, and in the *Richardsonia* the oxalate of calcium assumed the form of raphides, whilst in the adulteration referred to it was present as cluster crystals. Hartwich believes the root to be that of

Triosteum perfoliatum, L., Caprifoliaceæ, which has recently appeared as ipecacuanha. Externally the roots showed the greatest similarity, and the histological and chemical examination proved their identity.

Triosteum perfoliatum is indigenous to the eastern and south-eastern United States, and might therefore easily be collected with senega, although the two plants are very different in appearance. *Triosteum* is a shrub with a thick knotty rhizome, from which arise several stems reaching nearly three feet in height; it is known in America as tinker's weed, bastard ipecac., etc., and is used somewhat extensively as an antipyretic, purgative and emetic.

* Abstract of a paper in the *Archiv. d. Pharm.*

The drug consists of a yellowish-brown or dark brown bent, knotty rhizome to the sides, and under surface of which are attached numerous roots, generally not over $\frac{1}{2}$ Cm. thick, and often much thinner; these are lighter in colour than the root-stock, show here and there transverse fissures (Fig. 1), and resemble many varieties of false ipecacuanha, especially *Richardsonia*. In general appearance it is so like senega that its presence seems to have been overlooked; it differs, however, in the absence of a keel.

The structure of the root is very characteristic. A transverse section (Fig. 2) exhibits a radiate wood without pith and a cortex, in which a narrow pale outer portion can be easily distinguished from a darker inner part. Next to the cork is a layer of large compressed cells (primary bark), containing here and there a cluster crystal of calcium oxalate. Between this and the secondary bark is a layer of four or five rows of cork cells, the outer of which have undergone an unusual radial elongation (Figs. 4a and 5), in consequence of which the primary bark has become compressed, and is eventually thrown off. The cortex contains numerous cluster crystals of calcium oxalate and starch in compound or simple grains reaching .015 Mm. in length (Fig 3). The wood is remarkable for the fact that the medullary rays are lignified, whilst in the xylem rays only the middle lamella yields the lignin reaction.

The *Triosteum* root contains an alkaloid which André considered identical with emetine. Hartwich, however, was unable to obtain the characteristic reaction with hydrochloric acid and chlorinated lime, and concludes, therefore, that the alkaloid is not emetine.

PHARMACEUTICAL SOCIETY.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 8th inst., the Librarian presented the following report of donations:—

To the Library (London).

University of Durham:

Calendar, 1896.

College of Preceptors, London:

Calendar, 1896.

Royal College of Veterinary Surgeons, London:

Register, 1896:

Philosophical Society of Glasgow:

Proceedings, 1894-5, vol. 26.

Royal Dublin Society:

Scientific Proceedings, new series, vol. 8, parts 3-4.

Scientific Transactions, 2nd series, vol. 5, parts 5-12; vol. 6, part 1.

Faculty of Physicians and Surgeons of Glasgow:

Memorials of the Faculty, by Alex. Duncan, 1896.

The following report of donations was presented by the Curator:

To the Museum.

Baron F. von Mueller, M. and Ph.D., K.C.M.G., etc., Melbourne:

Fruit of *Dammara robusta*.

Mr. J. Medley Wood, F.L.S., Natal:

Bulbs of a *Eucomis*, used as a remedy for the "Red Water" disease in cattle.

Mr. J. Newson, Pietermaritzburg, Natal:

Root of *Tephrosia macropoda*.

Mr. E. L. N. St. Cyr, Hayti:

Specimens of *Polyporus sanguineus*.

Messrs. Hodgkinson, Treacher, and Clarke, London:

Fine specimen of Peruvian coca leaves.

Mr. C. J. Lowes, London:

Entire leaves of Virginian tobacco.

Messrs. Parke, Davis, and Co.:

Specimens of Hoang-nan bark, as prepared for use in medicine in Cochin China.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany,
Austria, Italy, Russia, Switzerland, Canada, the
United States, South America, India,
Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, APRIL 11, 1896.

THE METRIC SYSTEM.

THE advocates of the metric system must not trust too confidently in the removal of opposition which might be inferred from the apparent progress recently made towards popular acquiescence in their views. A significant indication of this may be seen in the fact that the *Times* has opened its columns to a series of communications in which the objections to the metric system are very forcibly stated. Those objections have moreover been, to some extent, endorsed in a leading article upon the subject, where it is argued that there can be no need for making the metric system compulsory if it possesses the merits claimed for it, and is so superior as its advocates declare it to be. Hence it is held that the only practical and final test of convenience is to be reached by setting the community free to use whatever system it prefers. With that object the removal of any legal difficulties in the way of using the metric system is recommended as being the only immediate necessity. The keen competition everywhere prevailing will, it is believed, then determine the question as to the practical adoption of the metric system. When it is found to be advantageous people will adopt it and, until that has been done upon a very large scale, it is urged that no case can be made out for compulsory change of our standards.

In the communications here referred to, objection to the metric system is commenced by a protest against the allegation that "ignorant prejudice" is the origin of all opposition to the metric system. That may be regarded as mainly a sentimental grievance, though it has served to induce the *Times* correspondent to show the existence of more respectable reasons than mere unenlightened dislike of innovation. First among these are the opinions held by the late SIR JOHN HERSCHEL—stated in a work published by him in 1863—that the 10,000,000th part of the quadrant of a meridian is not a good unit of measure, and that a better one could be devised on the basis of the inch or yard, correlated with the polar axis of the earth, without the change being felt in ordinary commercial or other transactions of any kind. In like manner it was shown that weights and measures of capacity might be rescued from the present state of utter confusion. In a second article the fact is pointed out that, in France, although more than a century

has elapsed since the metric system was established, and notwithstanding compulsory measures, old customs have survived and the people still buy and sell by sous and fourths. Then in America the system has been departed from, and the quotations on the New York Stock Exchange are in halves, quarters, and eighths, the decimal division of the dollar being ignored, and division into parts is effected there as well as in England, by halving, re-halving, and again halving. There is a still more striking departure from the system in California, where prices are given in "bits" or eighths of a dollar, 15 cents being a long bit and 10 cents a short bit, these coins being given and received in payment indiscriminately without charge or supplement, so that lack of appropriate divisibility in accordance with the metric system has led to inexact payments.

In addition to the reasons deducible from persistence of habits, some natural facts are mentioned by the writer in the *Times* as offering strong evidence against the desirability of decimalisation. Though the French have decimalised the quadrant, astronomical observations, and nautical works based upon them, have so long been conducted by the older mode of measurement that alteration of this arrangement seems almost impracticable. That arrangement was, moreover, dictated by Nature, the division of the circle being the outcome of the Chaldeans' division of the heavens to fit their calendar. The attempt to decimalise the calendar in France was a failure, and various deeply-rooted customs would stand in the way of such a proceeding if it were practicable. Thus houses are let, and servants and assistants hired by the quarter year, while in other trading transactions the same system is in such constant use that much difficulty would be experienced in making a change. There is also a deeper reason than mere habit: a quarter of a year is the period in which the Earth describes a fourth of its annual journey round the sun, the intervals between the shortest day and the vernal equinox, and between this and the longest day, as well as the other divisions determining the seasons. The behaviour of the moon is equally inconsistent with a decimal system, and the fact that there are twelve full moons in the year gave rise to the calendar generally adopted by civilised peoples. The adoption of a decimal division of the compass is prevented by the natural relation of the cardinal points, as the intervals between them are necessarily four right angles. Hence it is argued that as there is no escape from the divisions forced upon us by the order of Nature, in any case the mixed system would in large part remain in use. Without assenting to the sufficiency of these reasons for objecting to the metric system it may be admitted that they fully dispose of the allegation that those who oppose the adoption of the metric system are actuated by merely "ignorant prejudice." It will be interesting also to see in what manner the suggested applicability of these reasons will be dealt with by the advocates of a metric system of weights and measures.

SHOPS (EARLY CLOSING) BILL.

THIS Bill is down for the report stage in the House of Commons on Wednesday next, April 15, and there is increasing evidence of strong opposition being offered to prevent it becoming law. Amongst the arguments being circulated by opponents of the measure it is stated that the proposed law will interfere with the liberty of the subject and adult male labour, and that whilst it would legalise the

principle of local option as to the hours of trading in shops it would not be operative in bad districts. Many of the definitions in the Bill are also objected to as vague and unsatisfactory. In addition, it is contended that putting the proposed law in force would add greatly to the rates, possibly affect the rateable value of many shops, add to the police duties, and press with undue severity on small shopkeepers. Finally, it is pointed out that the object aimed at—the limitation of the hours of work of shop assistants—could easily be attained by the promotion of a Bill limiting the number of hours worked per week, leaving the owners of shops to close when they please. It may be noted that the Bill has been before the Parliamentary Committee of the London County Council, but, in the absence of any expression of public opinion upon the subject in the metropolis, the Committee has felt itself unable to advise the Council to take any action in the matter.

Attention has been specially directed by one London paper to two clauses in the Bill, which seem well adapted to furnish an easy passage for the proverbial coach-and-four through the prospective law. The first is Clause 10, which provides that

Nothing in this Act, or in any Order made thereunder, shall render the occupier of any premises liable to a fine for supplying any article to any person lodging in such premises.

There is nothing here to prevent a lodger constituting himself a sort of middleman, and buying goods of the shopkeeper on behalf of individuals who would otherwise be debarred for a time from having their wants supplied. Then Clause 12 provides that

Where an order in force under this Act requires shops to be closed at an hour earlier than seven o'clock on any day of the week, the occupier of any shop to which the order applies and which is closed at such hour *on any other day of the week*, may apply to the local authority for an order substituting such day as regards such shop, and the local authority *shall make an order accordingly*.

The words here indicated by italics seem specially designed for the benefit of the shopkeeper who makes a point of keeping his place of business open when others are closed, and may be quite sufficient to render nugatory the main object of the Bill, which is to secure uniformity of action. Apart from these special points, however, the contemplated Act, regarded as a whole, will surely prove an extremely difficult piece of legislation to put in force satisfactorily, and the authorities upon whom the responsibility is cast will have no enviable task.

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

THE report of the Metropolitan Asylums Board, embodying the results of a year's experience of the use of diphtheria antitoxin in six separate hospitals, shows that the percentage of deaths has been much less since the introduction of the new remedy. In 1894, 3042 diphtheria patients were treated exclusively by the ordinary methods, and 902 died. During the past year, however, when the antitoxin treatment has prevailed, there were 3529 patients, of whom only 796 died. The percentage therefore fell from 29·6 to 22·5. The average severity of the disease is said to have been about the same in both years, and 1894 was the best year previously recorded. For the four years anterior to the introduction of the antitoxin treatment the death rate varied about 1 per cent. only from year to year, and the *Times* in a leading

article observes that the figures in the report establish the success of the new treatment beyond doubt.

In a letter to the *Times*, Mr. LENNOX BROWNE has since disputed the conclusion put forward by the leading article in that paper, that the report of the Metropolitan Asylums Board establishes "beyond doubt the beneficial influence of the drug." He shows that the statistical evidence of the report is vitiated by the assumption that the decrease in mortality in 1895 is due to the use of antitoxin, and that this assumption is not justified by facts. The subject is not one which can be usefully discussed in the columns of a newspaper, but it is at least deserving of note that a protest has been made against the mode in which a most interesting and important matter has been officially represented to the public. The following table is published by Mr. LENNOX BROWNE to illustrate the actual position:—

Year.	Treatment.	Cases.	Deaths.	Per cent.
1895	With and without antitoxin	3529	796	22·5
1895	With antitoxin	2182	615	28·1
1895	Without antitoxin	1347	181	13·4
1894	Without antitoxin	3042	902	29·6

It is thus shown that though the reduction on the whole mortality for 1895 is 7·1 per cent., it is only 1·5 per cent. on those cases treated with antitoxin. The variation in these cases is therefore approximately identical with that observed during the four years prior to 1895, and the great improvement has really been in cases under ordinary treatment. But it must be borne in mind that the importance of comparative figures in such matters is at best extremely problematical, and the actual value of the new method of treatment can only be definitely determined by noting its effects in individual cases.

THE USE OF OPIUM IN INDIA.

COPIES of the report of the Royal Commission on Opium (see *Pharm. Journ.*, April 27, 1895, p. 957) were sent, on publication, to the Government of India for consideration, and a Blue-Book issued this week contains a review of the report sent in response. It is pointed out that the result of the inquiry is a vindication of the past action of the Government of India in regard to the production, consumption, and sale of opium, the evil effects of which had been grossly exaggerated. Moreover, it is urged that, whilst the prohibition of the drug in India would be impolitic, its use cannot in any circumstances be prevented in native states, and prohibitive or restrictive legislation would lead to far worse consequences than any arising from the system under which the State is responsible for the production and distribution of the drug. At the same time, an effort will be made to check opium smoking, as distinct from other methods of consumption in India, by raising the price of the preparations—*chandu* and *madak*—most in vogue and limiting the number of places where they can be purchased. The arrangements with cultivators will also be modified with a view to getting rid of middle men, but the ordinary use of opium as a febrifuge, stimulant, and restorative is considered to have been proved comparatively harmless at the worst, whilst often distinctly beneficial, and the Government of India considers, therefore, that further interference is uncalled for.

ANNOTATIONS.

NEW JOURNAL OF PHARMACY.—France rivals the United States in the number of publications devoted to pharmacy, and another has recently been added to the list. This is the *Bulletin de Pharmacie*, the official organ of the Fédération des Sociétés de Pharmacie du Sud-Est et des Syndicats Fédérés. It is published quarterly, and each number contains eighty pages of matter, the proceedings of the Federation naturally occupying most of the space available.

NOVELTY IN COLOUR PRINTING.—A new process in colour printing has just been introduced into this country, by means of which it is said to be possible to print in any number of different tints by a single impression, as in ordinary black and white work. The object is effected by the addition of certain chemicals to the inks, which prevent them mixing and blending upon the ink disc of the printing machine, and it is stated that the cost of producing circulars or show cards in half-a-dozen tints is very little more by this process than work in black and white only.

A PHARMACIST IN VENEZUELA.—Professor Rusby, of the New York College of Pharmacy, is visiting the Orinoco River district and the country now in dispute between Great Britain and Venezuela, as botanical expert to a company of American capitalists, incorporated to develop gold fields in that part of the world. The company also desires to ascertain what commercial products can be grown in the district, and Professor Rusby is instructed to ascertain what drugs can be profitably produced there. He also proposes to collect herbarium specimens for the New York College of Pharmacy and other institutions.

TITLES FOR PHARMACISTS.—If there must be a new title for pharmacists, observes the lively *Spatula*, it should be as simple and distinctive as possible. P.M., standing for Master of Pharmacy, or P.D, Doctor of Pharmacy, seems to our contemporary about what is wanted. Of the two, however, it prefers the former, "as there are enough 'doctors' of varying breeds and descriptions already." Nevertheless, pharmaceutical colleges and schools in the United States appear to be more than ever bent upon conferring what they are pleased to term the "degree" of doctor upon their graduates, and doubtless "Doctors of Pharmacy" will soon be as thick as blackberries across the Atlantic. But why should they be as cheap?

DEATH OF COUNT MATTEI.—Cæsar Mattei, the maker of the so-called "electro-homœopathic" remedies—anti-canceroso, anti-sicrofoloso, anti-febbroso, etc.—has died at the age of eighty-six. He was a native of Bologna, and was made a Count by Pope Pius IX. in 1847. Subsequently, he served as Lieut.-Colonel of the Civic Guard, and as Deputy of the Electoral Chamber in Rome. Politics, however, soon ceased to interest him, and after devoting some time to the study of medicine, he announced the discovery of a means of preparing herbal remedies which imparted to them a peculiar efficacy. It is generally understood that repeated analyses of these preparations have failed to disclose the presence of anything except water. Notwithstanding this, a large number of people, including several possessing some little prominence in the civilised world, have publicly declared their complete belief in the accuracy of Count Mattei's statements with regard to his secret remedies. The formulæ for these remedies are left to the deceased's adopted son, Count Mario Venturoli Mattei,

THE USE OF TIN CANISTERS FOR PRESERVED FOOD.—The suspicion that dietetic preparations and articles of food put up in tin vessels may become contaminated with lead, derived from solder used in making the tins, has frequently led to objections that tin canisters are unsuitable for that purpose. Some experiments made by Dr. Marrell and Dr. Wilson Hake, and reported in the *British Medical Journal*, appear to show that the fear of contamination is not altogether justified. Several tins of meat essences were carefully examined, and though lead was found to be present in the solder, none could be detected in the contents of the tins.

THE ILL-REGULATED SALE OF POISONS.—Under this heading the *Lancet* expresses the opinion that the existing restrictions on the sale of poisonous medicinal preparations, such as laudanum, are not sufficiently rigid, and that such potent articles, as well as strong acids, etc., are too easily obtainable. The view is put forward that in this respect, and in order to provide against the unfortunate occurrences commonly described as accidental poisoning, "much more strenuous efforts are called for than have yet been made, to adapt the machinery of the law to its professed purpose of regulating the sale of poisons."

SOCIETY OF ARTS.—The arrangements of this Society for the meetings after Easter include lectures on several subjects of special importance at the present time. On April 22, "The Perfected Photochromoscope and its Colour Photographs" will constitute the text of a discourse by Mr. F. E. Ives; on April 29, Mr. E. W. Badger will treat of "Fruit Drying or Evaporation"; and at subsequent meetings papers will be read by Captain Abney on "Orthochromatic Photography"; by Mr. Hudson Maxim on "High Explosives and Smokeless Powders"; and by Mr. E. W. Moir on "Tunnelling by Compressed Air."

NATURE'S UNIVERSITY.—The London Geological Field Class announces the beginning of a summer course of lecture excursions at the end of the present month, the subject of the series being the physical geography and geology of the Thames and its tributaries. The object of the excursions is to visit suitable spots for geological expositions by Professor Seeley, F.R.S., on Saturday afternoons, the districts to be explored during the coming season including Purley, Caterham, Guildford, Farnham, Maidstone, Herne Bay, Addington, Hindhead, the Chiltern Hills, Bushey, and Watford. Special arrangements with the railway companies enable the conductors to keep the expenses of the excursions within moderate limits, and no more delightful way of spending a half day can well be conceived for those who can spare the time. Full particulars of the Field Class will be furnished by the honorary secretary, Mr. R. H. Bentley, 31, Adolphus Road, South Hackney, N., on application.

THE LIBERATION OF PLANT PERFUMES.—According to E. Mesnard (*Comp. rend.*), light is the principal cause of the transformation and destruction of odorous substances, and not oxygen, though the two agents act in concert in many cases. These effects of light are manifested both by chemical changes and mechanical action, the first being indicated in odorous plant products from their elaboration to their resinification, whilst the second regulates the periodical liberation of perfumes. The intensity of the perfume of a flower would seem then to depend upon the equilibrium maintained between the pressure of water in plant cells, which tends to drive out the elaborated perfumes, and the action of light which opposes the turgescence. These novel suggestions appear to be in accordance with the fact that flowers are less odoriferous in hot than in temperate climates, and also that trees and fruits in the East so frequently contain more or less resinified odorous substances.

PROCEEDINGS OF SOCIETIES.

Linnean Society of London, March 19.—Mr. C. B. Clarke, F.R.S., President, in the chair.—Messrs. James Backhouse and Spencer H. Bickham were admitted, and Messrs. J. H. Leigh and Edward Step were elected, Fellows of the Society.

Mr. Clement Reid exhibited fruits of *Naias marina* from a peaty deposit below mean-tide level in the new docks at Barry, S. Wales. In Britain it had only been found living at a single locality in Norfolk, but in a fossil condition it had been obtained in the pre-glacial forest-bed at Cromer. A discussion followed, in which Messrs. A. B. Rendle, H. Groves, and A. W. Bennett took part, and it was suggested that the living plant might be looked for in South Wales, where, being inconspicuous, it might have been hitherto overlooked. Mr. Reid also exhibited some wood forwarded by Mr. H. N. Ridley from the jungle near Singapore. It appeared to have been eaten into a honeycombed mass of peculiar character, and was found only in wet places, but always above ground, the entire tree rotting. Neither Mr. Ridley nor Mr. Reid had seen anything like it in England; and the latter, while suggesting that the small lenticular unconnected cavities in the wood were probably caused by insects or their larvæ, thought they were unlike the work of either beetles or white ants. Some critical remarks were offered by Dr. Haviland.

A paper was read by Dr. Otto Stapf on the Structure of the Female Flowers and Fruit of *Sararanga*, Hemsley. The materials utilised consisted of female flowers and fruits of *Sararanga sinuosa*, Hemsley ('Journ. Linn. Soc.,' vol. xxx., p. 216, t. 11) which had been collected by the officers of H.M.S. "Penang" in New Georgia, Solomon Islands, and were in excellent preservation. There were also photographs and a description, taken upon the spot, of the tree, about 60ft. high, shortly branched at the top, with terminal, nodding, white-flowered, very compound, and gigantic panicles. The leaves are like those of an ordinary screw-pine. The flowers consist of a rudimentary, sinuously bent, saucer-shaped perianth, and a subglobose, sinuously lobed gynæcium, with very numerous (70-80), dark, discoid or reniform stigmas which are arranged in double rows over the dorsal ridges of the main body and the lobes, having between them minute pores which end behind some way below the surface. There are as many ovary-cells as stigmas, each containing one anatropous ovule from the base of the inner angle. The vascular bundles of the gynæcium end below the stigma in a cluster of tracheids, and supply it probably with a viscid or sugary liquid. The base of the pore is surrounded by a compact, thin-walled parenchyma, very rich in plasma. It is suggested that the pollen-tubes grow from the stigma down into the pore, and descend from here through the conductive tissue to the ovule. The ripe fruit is a succulent drupe with numerous pyrenes, in shape like the flower, but much larger. The endocarp is bony, the albumin copious and oily; the embryo is as in *Pandanus*. The complex structure of the flower is explained as a modification of the type represented, e.g., in *Pandanus utilis*, and in accordance with Count Solms-Laubach's theory of the flower of the Pandanaceæ. On this paper some critical remarks were offered by Mr. Rendle.

On behalf of Mr. G. S. West, a paper was read by Professor Howes on two little-known Opisthoglyphus snakes. The author had examined and compared in respect of the structure of the buccal glands and teeth, specimens of the grooved and non-grooved varieties of *Erythrolamprus asculapii*, as recorded by Dr. Günther ('Biologia Centr.-Amer.' part cxxi., p. 166), and he proved that the latter were rightly referred to the species.

Royal Institution, April 4.—In his concluding lecture on light, Lord Rayleigh referred to the researches of Young and Fresnel, both of whom were unwilling to admit other than longitudinal vibrations of the ether. But the phenomena of polarisation compelled recourse to the theory of transverse vibrations, or vibrations at right angles to the direction of the ray. Nicol's prism was shown to stop all vibrations except those in a particular plane, while a crystal of Iceland spar showed the ray split up into two, consisting of vibrations at right angles to one another. The difference was proved by analysis by means of a Nicol prism. These phenomena could not be intelligently explained so long as light was assumed to consist of longitudinal vibrations like those of sound, while on the transverse hypothesis Fresnel fully worked out formulæ which experiment proved to be accurate. Light could also be polarised by reflection from glass at a particular angle, or conversely it could be shown that light already polarised could not be fully reflected except in the direction corresponding to the plane of its

vibration. By means of a mechanical model the relations between the plane of transverse vibration and the angle of reflection were graphically shown. When light was very bright there was no angle at which polarisation was absolute. For example, the image of the sun was always visible on water even at the angle of minimum reflection. This apparent disagreement with Fresnel's formula was probably due to the presence of a dust or grease film upon the water. A chemically-clean surface was almost impossible of attainment, but, if it could be secured, agreement with theory would probably be found to be complete. The dispersion of light by small particles was shown in a solution containing very finely-divided sulphur. When a polarised beam was employed the blue colour resulting from dispersion was seen in one direction only, there being no vibrations to be reflected at right angles to that direction. The blue colour of the sky is due to dispersion of light by small particles, not, as some have supposed, to the oxygen or ozone in the atmosphere. Were the blueness due to actual colour the sun would look blue and the rest of the sky black. It is obvious that media reflecting differently must have different qualities. The difference must be one either of rigidity or of density, but the behaviour of small particles showed the effect must be due to one or other of these qualities, not to the joint action of both. Referring to the Röntgen rays, Lord Rayleigh said that the difficulty in connection with them lay in the impossibility of applying the ordinary methods of analysis. Little or nothing could be done with rays which could neither be reflected nor refracted, nor passed through doubly refracting crystals.

Pharmaceutical Chemists' and Apothecaries' Assistants' Association of Ireland, March 13.—Mr. Wells, President of the Pharmaceutical Society of Ireland, in the chair.—At the first meeting of this Association held in the rooms of the Pharmaceutical Society of Ireland, the following paper was read—

THE HISTORY OF PHARMACY.

BY DR. NINIAN FALKINER.

The history of pharmacy is the history of the living world, and we must not, in the happy possession of the fruits of science, forget that all we have comes to us from those who have gone before. The great Burke says, "Those will not look forward to their posterity who never look backwards to their ancestors"; if this be true that in the ordinary mind there is an intense pride and anxiety to know, in generations back, that our ancestors were honourable men, how much the more shall we, who are the scientific descendants of those who have laboured in the past for the advancement of knowledge and for the good of their fellow creatures, endeavour to honour and cherish the memories of those who have left their footprints in the narrow pathway of mediæval knowledge.

From the earliest days of the history of mankind, two great necessities for the community have always existed, firstly, that of the minister of religion, and secondly, that of the healer of the sick.

Primitive man, gifted with powers of observation, saw that animals when sick were attracted by some instinct which we cannot understand towards some herbs, which relieved their indisposition. The dog doses himself with *triticum caninum*, the cat revels in the odour of *valeriana officinalis*, the Indian mongoose is said to procure an antidote for snake-bite in *mimosa octandra*.

Probably from the earliest time man would be led to observe the behaviour of animals when suffering from disease or injury. In savage man we must seek the beginnings of our civilisation, and it is in the lowest tribes and those which have not yet felt the influences of superior races, that we must search for the most primitive forms of pharmaceutical and medical ideas and the earliest theories and treatment of disease. The lowest form of belief that exists is called Animism, which may be defined as a belief which attributes death and all forms of disease to magic, which is influenced by the spirits of dead men. Amongst these people we cannot expect to find much of the early development of the science of pharmacy; they were, however, probably acquainted with the properties of some herbs and poisons, as in the case of the obi poison.

So far as we can judge by records of the past, the oldest place in the civilisation of the world must be assigned to Egypt. It is most probable that the first kingdom of Egypt existed 8000 years ago; its history is more reliable than that of China, and more recent than that of Assyria and Chaldæa. We require no further proof than the mummies in our museums to convince us that the Egyptians from the period from which those interesting objects date, must have possessed a very accurate knowledge of anatomy, of pharmacy, and a skill in surgical bandaging very far

surpassing that possessed now-a-days by even the most skilled professors of the art. Mr. Granville says there is not a single form of bandage known to modern surgery of which far better examples are not seen in the swathings of the Egyptian mummies; the straps of linen are found without one single joint extending to 100 yards in length.

Professor George Stokes, librarian to the interesting Dublin institution, Marshes' Library, after his appointment, when getting the place into order, found a box containing a mummy; he sent for me and asked me to examine it, and on doing so, found that there was a malformation of the bones of the right arm and fore-arm. I handed the specimen to Professor E. Bennett, who exhibited it at the Academy of Medicine. The famous "Ebers Papyrus" was purchased in 1874 by Dr. Ebers, at Thebes. This papyrus contains 110 pages, each page consisting of about twenty-two lines of bold Hieratic writing. It may be described as an encyclopædia of medicine as known and practised by the Egyptians of the eighteenth dynasty, and it contains prescriptions of all kinds of diseases—some borrowed from Syrian medical lore, and some of such great antiquity that they are ascribed to the mythological ages, when the gods yet reigned personally on earth. Among others is given the recipe for an application whereby Osiris cured Ra of a headache. In this papyrus is an example of an old Egyptian diagnosis and therapeutics as follows: "When thou findest anyone with a hardness in his re-hit (pit of the stomach), and when, after eating, he feels a pressure on his intestines, his 'hit' is swollen and he feels bad in walking like one who suffers from heat in his back, then observe him when he lies stretched out, and if thou findest his intestines hot and a hardness in his re-hit, say unto thyself, This is a disease of the liver. Then prepare for thyself according to the secrets of the science from the plant pa-che-test and dates, mix them, and give in water."

The Jews were indebted to Egypt for their primary ideas of medicine, but they cast away the ideas of demonology and magic which clouded what was good in the practice of Egypt. The Talmud recommends onions for worms, and wine, pepper, and asafoetida for flatulency. The Talmudists are responsible for calling the earth, air, fire, and water, elementary bodies. In the middle ages the Jews rendered service to the healing art, and had a large share in the scientific work connected with the Arab domination of Spain.

When a Chinese physician is unable to procure the medicine that he requires he writes the names of the drugs he desires to employ on a piece of paper, and makes the patient swallow it—Grecian medicine anti-Hippocrates. Turning now towards the history of the great empires that replaced the power of Egypt and Persia in the south of Europe, Greece and Rome, we find in Grecian mythology that a prominent place is given to the deity that presides over the branches of the healing art. Apollo was the father of Æsculapius the god, and instructed by the kind centaur Cheiron, and brought up with Jason and many other demi-gods. Melampus is believed by the Greeks to have been the first mortal who practised medicine: he was the first physician who prescribed iron in the form of rust and wine identical with the vinum ferri of the Dublin Pharmacopœia; he also practised with hellebore, whence its name melampodium. In Homer there are numerous instances of medicine, surgery, and pharmacy, perhaps the most interesting is the account of disinfection by sulphur—'Odyssey,' Book xxi., 481:—

"Bring sulphur straight, and fire, the monarch cries;

She hears, and at the word obedient flies,

With fire and sulphur, cures of noxious fumes,

He purged the walls and blood-polluted rooms."

Hippocrates (B.C. 460), the father of medicine, was the first teacher who endeavoured to eliminate the superstitious element from its practice: he first recognised nature in the treatment of disease, and that physicians and pharmacists are her servants. He prescribed vegetable mercury, elaterium, scammony, poppy juice; he used blue stone, white vitriol in the treatment of ulcers, and tar water in the treatment of wounds. With regret I must for want of time pass on from Hippocrates to the dawn of modern medicine in the sixteenth century.

The Royal College of Physicians was founded in 1518. The history of medicine, as recognised by Law, dates from the year 1511, when an Act was passed for appointing physicians and surgeons. The examination of these gentlemen was placed in the hands of the Bishop of London and the Dean of St. Paul's Cathedral. By this Act the faculty of medicine was vested in one body, the members of which practised medicine, surgery, and pharmacy; the assistants to the physicians were called apothecaries. This happy

and peaceful family party was broken up by the establishment of a Royal College of Physicians by Thomas Linacre, physician to Henry VIII., in the year 1518 A.D. This Act, we must observe, gave the College of Physicians full and penal powers against the apothecaries. In the same year the College of Surgeons was united to the College of Barbers, the surgeons abandoning the dignified and lucrative operation of shaving, while the barbers promised to confine their practice of surgery to the drawing of teeth. The surgeons appear to have behaved so badly that another Act was passed in 1542, which was directed at the quack system of practice without remuneration. In 1552 an Act was passed which declared that it was illegal for a surgeon to administer medicine. In the year 1553 the College of Physicians obtained a new Act, in which their former powers were confirmed and enlarged, and in which it is stated that their four censors, or any three of them, shall have power to examine, survey, govern, correct, and punish all and singular physicians and practitioners in the faculty of physic, apothecaries, druggists, distillers, and sellers of waters and oils and preparers of chemical medicines, according as the nature of his or their offences may seem to require. It is uncertain at what time the physicians gave up the practice of preparing their own medicines. The apothecaries, who had been incorporated with the grocers, obtained their charter in 1617; it was enacted at the same time that no grocer should keep an apothecaries' shop, and that no surgeon should sell medicines. The first pharmacopœia was published in 1618 by the College of Physicians of London. Twelve subsequent editions were published, the last in 1836. This Society prospered, and in 1671 built a laboratory. Mr. Bell gives an instance of the enormous charges of these people:—

Apothecaries' bill for attending Mr. Daly, of Ludgate Hill, five days. Total: £17 2s. 10d. The following are some of the items:—

	s.	d.		s.	d.
An emulsion.....	4	6	Another bolus	2	6
A mucilage	3	6	Another draught.....	2	4
Gilly of hartshorn	4	6	A glass of cordial	3	6
Blister	1	0	Blistering to the arms ...	5	0
An emollient glyster	2	6	The same to the wrist ...	5	0
An ivory pipe, armed.....	1	0	Two boluses again	5	0
A cordial bolus	2	6	Two draughts again	4	8
The same again	2	6	Another emulsion	4	6
A cordial draught	2	4	Another pearl julep	4	6
The same again	2	4			

This was the amount of medicine taken in one day by the unhappy victim. Misconduct of this kind on the part of the apothecaries gave their natural opponents, the physicians, a powerful weapon of offence against them, but their great public usefulness as a class prevented the annihilation of the Society then as in the present time. In 1748 the apothecaries appear to have obtained the same jurisdiction over the chemists that the physicians previously had over them, and led to the friction which has happily terminated in the foundation of the Pharmaceutical Society of Great Britain in 1841 and the foundation in 1875 of the sister Society in Ireland, whose guests we have the honour of being to-night. For those among you who wish to become more intimately acquainted with the history of medicine and pharmacy, I must refer you to the excellent work of Edward Berdoe, 'The Origin and Growth of the Healing Art,' and the 'Progress of Pharmacy in Great Britain,' by Jacob Bell and Theophilus Redwood.

I now come to the second section of my lecture, which is the Pharmacopœia. The earliest pharmacopœia was prepared by the Arabs in the ninth century. The first recognised by authority was published at Nuremberg in the year 1542. In England the first pharmacopœia under authority appeared in 1618, of which there were twelve subsequent editions, the last in 1841. The Dublin Pharmacopœia first appeared in 1807, the last edition being published in 1850. Until the Medical Act passed in 1858, the right of publishing the Pharmacopœia for England, Scotland, and Ireland was vested in the College of Physicians of London, Edinburgh, and Ireland respectively, and as these books contained several preparations similar in name and different in strength, such obvious danger arose for travellers that the British Pharmacopœia published in 1864, became, by Act of Parliament, the standard for Great Britain and Ireland. An amended edition was brought out in 1867. A second reprint with additions appeared in 1874, another edition was published in 1885, and a supplement to it in 1890.

With all its faults it is our pharmacopœia, and being ours we will all take our own method of abusing it. I, for my own part, am

going to speak of it in simple language, saying how I think it might be improved, and my first cry is for Utopia. Why should not the Pharmacopœia be an international volume, edited by an international pharmaceutical conference, and revised every ten years as is the case with the American Pharmacopœia, and printed in all languages? That solution, the best for mankind, will come, but I fear that at a time when the bones of the most junior apprentice are resting with his fathers. But if you will allow me I will descend from my Utopian flight and soberly assert that the Pharmacopœia may be viewed from three professional standpoints:—(1st) Student and teacher, (2nd) Pharmaceutical chemist, and (3rd) Medical practitioner.

From the educational standpoint the Pharmacopœia may be truly looked upon as a jewel casket that requires at least three keys to unlock it, one of gold, a knowledge of chemistry; the second of silver, a knowledge of botany and zoology; and the third of iron, the knowledge of experimental physics. No student can hope to understand this complex work unless he holds the three keys. With reference to education and the programme which I drew up for the course of materia medica and botany that was instituted last year, it might be said that my course was too comprehensive, but my answer to this will be given in the analogy of the three keys. For educational purposes I would therefore recommend (1) that all the chemical formula for reactions should be given; (2) that the natural orders of vegetable and animal products should be given; (3) that there should be a comprehensive glossary of the terms used in the Pharmacopœia with definitions; (4) that explanations of complex tests and processes should be given. As a pharmaceutical chemist, I should like to see all the processes definite, and when a difficulty in manipulation occurs it should be mentioned and the character of the product described. For instance, the *lin. crotonis*, *lin. potass. iodidi* and *sapon*, and *lin. terebinthinæ*. With reference to the second, I do not think the Committee could do better than adopt the formula of the elegant preparation devised by my distinguished colleague, Professor Charles Tichborne. Another preparation which is not always satisfactory when made by the official process is *liq. gutta-percha*. Indeed, I know that some practitioners are of the opinion that the lead carbonate is contained in solution in this preparation. Those present who have prepared it know that the lead carbonate takes a long time to subside, and that even when the bulk is deposited the solution does not clear. I adopted the following plan, using dried, clean sand as a filter. I diluted with about half as much more chloroform, then dissolved and filtered, with the result—a bright solution which was easily concentrated.

Lastly, as a medical practitioner, I ask for standardised preparations whenever it is possible to obtain them. I look with distrust on most of the aqueous and green extracts; they must be of uncertain strength, and the prolonged processes by which they are obtained must seriously alter the nature of their constituents. I consider that Fowler's solution is at present an unsatisfactory preparation, as the leading authorities are not agreed as to its chemical condition, whether the arsenious oxide is dissolved in potassium carbonate, or a true arsenite of potassium is formed. I consider that the doses of Donovan's solution are too high. The dose of arsenious iodidi is given at 1/30th part of a grain, and the solution containing 1/100th part of a grain in each minim is given in doses of 10-30 minims. I have too much respect for the idiosyncrasies of doctors, and perhaps also a kindly feeling to all the substances that are official as old friends to become a strong advocate for the removal of any of them. What harm do poor mastic and pyrethrum, and *hoc ille genus* do to anyone by being allowed to retain official distinction? I do, however, recommend that some preparations known to be used in enormous quantities be made official, such as chemical food, Easton's syrup, syrup of hypophosphites, syrup of lactophosphate of lime, and boroglyceride, and I think that fresh juices and abstracts are the types of medicines that when used will be likely to procure good results.

In conclusion, I take the opportunity of thanking the Council of the Pharmaceutical Society for the repeated acts of favour which they have done me, having successively appointed me as their examiner in chemistry and pharmaceutical chemistry, as their special examiner under the Pharmacy Amendment Act, and finally as their Professor of Botany and Materia Medica. I have also to express my feelings of satisfaction that they have allowed me to supplement the botany instruction by the appointment of Mr. Henry Dixon, Assistant Professor of Botany in Trinity College, Dublin, who is acting as my colleague in this School, and to whom I wish to express before you a strong sense of his great efficiency and

attention to the well-being of the students. The School will, I trust, under the enlightened directorship of your Council, soon be found fully equipped, firstly, by the institution of a course of lectures in theoretical chemistry and chemical physics, and, secondly, by a course in practical pharmacy. Also I hope that as time advances, and the Society, although yet young, develops its resources, that prizes and scholarships may be established, and a research laboratory attached to the School. From what I have seen in the past of the labours of the Society since its formation, I feel confident that the time is at hand when you will yield in nothing to the advantages which are enjoyed by your elder sister in the great metropolis of the world; and I thank you again, and congratulate you on the step which you have taken with respect to the Association that meets to-night for the first time beneath the paternal roof. By encouraging the association of the students of pharmacy you are advancing a movement important from an educational and social point of view. Thackeray more than once refers in his peculiar way to the special temptations of a chemist's establishment. We all here know that these temptations exist: how are they to be met? Only by the student's own determination and manliness. You members of this Association remember that he who cannot obey and serve his lawful master faithfully will never be fitted to command.

"Self-knowledge, self-reverence, self-control;
These three alone lead men to sovereign power."

I would not be treating you as men if I did not place this responsibility of your conduct in your own hands, but at the same time I observe with joy that the Council of the Pharmaceutical Society have extended an arm of friendship and protection to you. The special advantages of this Association are that it provides for the time of leisure, giving an opportunity of social intercourse to the students of pharmacy. It encourages the students to extra work, and to take more interest in the work that they are doing, and it provides the great want of teaching young men to think when they are on their legs and speaking. I venture to predict that this Association, founded under the auspices and nourished by the support of the Council of the Pharmaceutical Society, has a long course of useful and honourable work before it.

SCOTTISH NEWS.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION, April 2.—Mr. W. L. Currie, President, in the chair. The Hon. Secretary and Treasurer, Mr. J. Anderson Russell, in submitting his

FINANCIAL REPORT FOR THE YEAR, said the Association commenced the year with a balance in hand of £35 9s. 7d., which had now increased to £50 5s. 7d. The accounts of the Social Committee, which had been kept separate, showed a balance of £4 15s., which had been carried to the general account.

The Chairman said that it spoke well for Mr. Russell's powers of finance that he was able to show such a handsome increase in the Association's funds at the end of the year. They must also congratulate the Social Committee, and particularly its convener, Mr. McKellar, on the very admirable way in which he had managed its affairs. He hoped that next year they would have not one "at home," but several. He might add that the accounts had been audited and found correct, and he moved that a very cordial vote of thanks be passed to Mr. Russell for his labours.

Mr. Russell then submitted his secretarial report. While there was nothing of transcendent importance to record in connection with the meetings during the fourth session of the Association, the Council were pleased to be able to announce a gratifying increase in membership and in the interest taken in the Association by the country members, who had sent numerous letters of well wishing. Reference was made to the friendly intercourse which had taken place among the members, and to the various papers of practical value which had been read during the session. There were at present 155 members on the roll, a net increase of eleven on the year.

The Chairman, in moving the adoption of the reports, said it would benefit the Association generally, and the members of the trade in particular, if they would turn out to the meetings in very much greater numbers than they had hitherto done. Personally, he had only missed one meeting, and none of them had more claims upon their time than he had. If Sir John Lubbock's Early Closing Bill became law it might have some influence on the attendance.—Mr. Alexander Boyd seconded the motion for the adoption of the report, which was then agreed to.

Mr. Thomas Blair, the librarian of the Association, reported that the number of books issued from the library was five times greater than in the preceding year.—Mr. James Moir said he thought that the time had now come when they should consider the advisability of having a room exclusively for themselves, which would be open one or two nights a week, so that students might come and examine the specimens, and have the library always accessible.

Mr. Thomas McKenzie said that the students attending the Glasgow and West of Scotland School of Pharmacy had formed themselves into an Association, which had a membership of over fifty. He would be very pleased to put the cabinet of *materia medica* into a locked room to which the members could have access. He also asked if the members of the junior association, which might be looked upon as a feeder for the senior association, could have the use of the books in the library.—On the motion of Mr. Moir, seconded by Mr. Boyd, it was remitted to the Council to consider Mr. McKenzie's proposal.

Mr. Alexander Laing suggested that the Council should be empowered to lend the cabinet of *materia medica* to any member who desired it, on condition that it was returned in the same condition as received.

The Chairman said he thought that the whole question as to the lending of the cabinet should be remitted to the Council for consideration. As regarded the renting of rooms for the exclusive use of the Association, the Aberdeen chemists paid a rent of about £35 a year, and had not only rooms, but teachers for the younger students. He would be very willing to contribute annually towards the keeping up of rooms in Glasgow, and he thought that the time had come when that should be done. This question, as well as Mr. McKenzie's proposal, would be considered by the Council. He moved that a very hearty vote of thanks be awarded to Mr. Blair for the trouble he had taken in connection with the library.

SHOPS (EARLY CLOSING) BILL.

The Secretary said that as the outcome of a matter which came under the consideration of the Council at its last meeting, he had written a letter to Sir John Lubbock with reference to the Bill for the early closing of shops (see *ante*, p. 287). He had received a reply from Sir John Lubbock in which he said that he would consider the suggestion of the Council.—The Chairman said that he regarded the Bill as a step in the right direction, and he was sure that most of the members would be of the same opinion. Their hours of labour were far too long at present, and were not good for them either physically or mentally. He did not approve of grand-motherly legislation, but they should welcome this opportunity of making it compulsory to close places of business earlier. Generally speaking the provisions of the Bill were entirely favourable to their supporting it, but they should get a better definition as to what medical appliances were.—Mr. Laing said he would like the Association to give support to the Bill as far as possible. Legislation could not err when it protected a majority from a selfish minority. He was only sorry that the Bill was so much safeguarded as to leave its adoption absolutely to the discretion of the localities concerned. He very much feared that it would be a difficult matter for them to be able to utilise it to any practical purpose in Glasgow.—Mr. Thomas Adams said he was afraid that so far as they were concerned this Bill would be a dead letter. Druggists were so scattered, and there were so few of them in a ward that it would be very difficult for them to take the initiative. He would prefer that an early closing district should be formed composed of all the shops in that district.

The Secretary, who remarked that he was strongly in favour of the Bill, said that, so far as Glasgow was concerned, the whole of the chemists in the city might move in the matter, because it would be in the hands of the Town Council. As to the point referred to in the letter to Sir John Lubbock, if the Bill simply referred to the class of shops mentioned as chemists' shops, it would leave the other drug shops out, and they would be a trouble to them, and, again, if an exemption were made in favour of pharmaceutical chemists and druggists that did not make an exemption in favour of the doctor or his man if he was not qualified. Though they could not prevent a medical man or a limited liability company speaking of themselves as chemists, at the same time any enactment applying to chemists would not apply to them unless they were specified in it, and that was a proof that they were not chemists.—Mr. Laing said that local authorities had the power of assigning to every shop what class it belonged to.

Mr. D. Watson, speaking in support of the Bill, said that Sir John Lubbock would never have introduced it if it had not been

that shopkeepers could not agree among themselves to close at a certain hour.—Mr. Boyd said he was decidedly against the Bill. He did not think that the Legislature was justified in interfering with a man's liberty to work. The result of a strict compliance with the Act would be that the conscientious man would suffer. Chemists should be on the same footing as doctors.

Mr. Moir said that he must take the same view as Mr. Boyd. Every district of a city had its own time for business. In the centre of Glasgow, chemists could close at six o'clock, while in the suburbs their business was only beginning then. They were to be allowed to supply medical appliances, but where were they to draw the line? A bottle of castor oil or an ounce of ipecacuanha wine might be vital in many cases. He could not see how the Act could work in their trade. He had no objections to the law interfering with employés. In the interests of the small shopkeepers, who contrived to eke out a livelihood after the larger places of business were closed, he would oppose the Bill. The House of Commons was playing more and more into the hands of the large capitalists.

The Chairman said that the point they were most interested in was getting included in the Bill all shops where drugs were sold. The members of Council who were present at the meeting referred to were unanimously in favour of the Bill. They saw the difficulty of working out the details, but they were going to leave the future to itself. It would be a very difficult matter to include chemists and druggists in the Bill.—Mr. Boyd moved that the Association petition Parliament that all pharmaceutical chemists and shops where drugs were sold should be entirely exempted from the provisions of the Bill.—Mr. Moir seconded.—Mr. Laing moved that the Association should heartily approve of the principle of early closing, and give its support to the Bill now before Parliament.—Mr. Watson seconded.—On a show of hands being taken, twelve voted for Mr. Laing's amendment, and two for Mr. Boyd's motion, several members declining to vote.

The Chairman, in his retiring address, said that he had been connected with the drug trade for twenty-six years and certainly the position now was very much better than what it was in his young days, and he did not despair of seeing it in a very much improved position from what it was at present. If a chemist and druggist paid attention to his business and he gained the confidence of the public, all the limited liability companies in the world would not affect him.

On the motion of Mr. Boyd, seconded by Mr. Laing, a hearty vote of thanks was passed to Mr. Currie for his services as President.

ELECTION OF OFFICERS.

Mr. James Robb proposed and Mr. Moir seconded the re-election of Mr. Currie as President, which was unanimously agreed to. The following office-bearers were also elected:—Hon. President, Mr. Daniel Frazer; Hon. Vice-Presidents, Messrs. John McMillan, Alexander Kinninmont, and J. W. Sutherland, Dumfries; Vice-Presidents, Messrs. John Foster, Thomas Robinson, Alexander Laing, and James Robb; Secretary and Treasurer, Mr. J. Anderson Russell; District Secretaries, Messrs. James Bruce, A. Miller, George Robertson, and Mungo Wallace; Librarian, Mr. Colvin Gates; Committee, Messrs. Hugh Lambie, James Moir, J. W. Miller, Alexander Boyd, A. McKellar, Robert Brodie, D. S. Robertson, James McNiven, James McMurray, R. M. McCowan, J. Stewart, Robert Tocher, Thomas Adams, Alexander Bruce, and John Neil.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND, April 1.—Mr. W. F. Wells, junr., President, in the chair.—Mr. Conyngham, pursuant to notice, brought forward two motions, the first of which was that a resolution passed at a previous meeting, refusing to admit Mr. Cleland and others for examination should be rescinded; and the second was in the following terms:—

"That our legal adviser be instructed to draw up a bye-law admitting these young men and any others in a similar position who have applied for the privilege (It being ascertained the number is not as large as was anticipated.) The Council does this, having vindicated the right to refuse certificates from limited companies, but as a matter of grace the request of these young men be granted. Let it be clearly understood that on and after this date (Mr. Cleland's case) no certificates will be received from any apprentice or assistant claiming time in the employment of a limited company."

In moving his first resolution Mr. Conyngham said not more than eleven or twelve persons would have to be admitted, but the President thought there would be a good many more.—Mr. Hayes seconded the motion of Mr. Conyngham.

Mr. Grindley said what Mr. Conyngham asked could not legally be done. This was really a grievance of the limited companies and not of their apprentices and assistants.—Mr. Beggs said there was no way out of the difficulty except by rescinding the regulation of 1884. Their law adviser had told them that.—Mr. Baxter concurred with Mr. Beggs.—Mr. Whitla said if they opened their portals so widely as by rescinding the regulation the number of applicants of this class would be trebled. Within the last two days he had heard that it was a common thing in a prominent house in the city to give certificates to young men who began as cash boys, and who afterwards learned to compound, then after a certain number of years received certificates of apprenticeship.—The Vice-President opposed the motions of Mr. Conyngham, remarking that if passed the resolutions would only be operative until the next case of hardship should be brought forward, to which the Council should be soft-headed as well as soft-hearted enough to yield.—After further discussion Mr. Conyngham was allowed to withdraw his motion, but he intimated that he would take further action in the matter.—The President said he would not receive further resolutions on the subject unless they were legal or proposed to rescind the regulation altogether.—Other business having been disposed of, the Council adjourned.

PHARMACEUTICAL CHEMISTS' AND APOTHECARIES' ASSISTANTS' ASSOCIATION OF IRELAND.—A committee meeting of this Association was held on Friday, Mr. James B. Alister, M.P.S.I. (President), in the chair. The following were present:—Messrs. McCarthy, M.P.S.I. (Vice President), Harris, Hunt, Payne (Hon. Treasurer), Carroll, Walsh, and Hardy (Hon. Secretary). The minutes of the last meeting and correspondence were read. On the suggestion of Mr. Hardy, Messrs. Payne, Hunt, Harris, O'Sullivan, and Hardy were appointed to act as an arrangement committee, whose duty would consist in the procuring of lecturers, essayists, and speakers for the future meetings of the Association. The Hon. Secretary would in turn notify beforehand the general body of members as to the nature of the business, etc., to be transacted at each fortnightly meeting. Mr. Hardy was thanked for the satisfactory result of his arrangements for the inaugural meeting on March 13, and Mr. W. F. Wells, President of the Pharmaceutical Society, who presided thereat, was warmly eulogised for having infused new life into the Association by his presence and support. Hopes were entertained that Mr. Wells would become an honorary member thereof, and that others of the Council would follow Councillor Cunningham's and Dr. Falkiner's example in this respect. Mr. W. McCarthy's advice not to suspend the working of the Association for any period, however short, during the summer was acted upon. It was absolutely necessary at present to keep well before the trade generally, and increase the membership by enrolling all who were connected with, or friends of, the pharmaceutical profession. The President said it would be unwise to hold another social evening until they discussed a few more papers, and held one or two additional debates, after which a members' musical "at home" might be advantageously arranged. They would, he hoped, find that the Association had been started to inform, to instruct, and to amuse, but the two first-named should get priority. Their reputation was now at stake, and he trusted that the members would ably sustain the very best traditions of pharmacy by making the Association a medium for developing their intellectual faculties, and raising themselves and their position in the social and professional scale of the country. He was pleased to learn that abstracts of their proceedings would appear henceforth in the *Pharmaceutical Journal*, and this augured well for their future success. A suggestion to obtain a reprint of the rules and amendments thereto was noted for future attention. The financial report and statement of accounts will be presented at next meeting, at which the question of finances—past, present, and future—will be gone into, and suggestions made for the good of the Association.

A CENTRAL DRUG DEPÔT.—Dr. Watson, the Dispensary Officer to the Limavady Union, says that tendering for medicines by drug contractors has developed into such a science that it is impossible to say which is the cheapest tender. He suggests that the Local Government Board establish a drug and medicine depôt in Dublin, which would supply all dispensaries in Ireland. £2000 would, he says, provide the place and pay one good buyer.

THE BELFAST CORPORATION has set up an examination for the position of Sanitary Sub-Officer, the subjects including hygiene and elementary chemistry. Two corporators have been set apart to test the candidates.

FOREIGN NEWS.

NEW HAIR DYES.—The prejudicial effects of hair dyes containing lead and silver salts has been so often pointed out by medical men that numerous attempts have been made to prepare a dye free from metallic salts, and latterly several have been introduced into the Paris market and guaranteed to be free from any mineral substance. These on analysis were found to conform to the statements made, and their colouring properties ascertained to be due to diamidopheno¹, which, used in combination with peroxide of hydrogen, imparts a beautiful brown colour to the hair. Doubts have lately been entertained, however, as to whether these so-called vegetable dyes are as non-injurious as the makers claim them to be. Several instances have occurred of persons using them being attacked by intense headache, local eczema, etc., which have led medical men to suspect these dyes to be the cause. One case in particular is recorded of a man thirty years old, who was in the constant habit of using one of these preparations, being seized with apoplectic symptoms and expiring after ten days' illness. Although the occupation of the deceased (who was a restaurant proprietor) may have been the primary cause of the attack, the doctors assert that while positive proof is necessarily absent, they are of opinion that the use of this preparation must have been a powerful accelerative cause in bringing about the fatal *dénouement*.

NEW APPLICATION OF THE RÖNTGEN RAYS.—Dr. Brouardel, Dean of the Faculty of Médecine, placed before the Académie des Sciences numerous photographs taken by MM. Girard and Bordas, of the Municipal Laboratory, of a book in which had been fitted a tin case containing an explosive, which the act of opening the book would detonate. They affirm that the different explosives usually contained in these destructive engines can be distinguished on account of their varying opacity to these rays. For obvious reasons Dr. Brouardel did not enter into details. One of the photographs exhibited represents the missile which was sent some little time ago to a prominent politician, causing at the time a considerable sensation. In view of the numerous cases arising where packets suspected of containing bombs have to be examined at the Municipal Laboratory, and the risk incurred in opening them, the great practical value of this application of the new photography can be at once realised. At the French Astronomical Society, Dr. Dariex states that, having attempted to photograph the human eye by means of the cathodic rays, he failed to do so, as he found that they cannot penetrate the cornea, and their invisibility is thus explained.

STRYCHNINE AS AN ANTIDOTE TO CURARE.—At the Société de Biologie, M. Bourquelot read a note of M. Sadoréanu, who reported a remarkable cure of strychnine poisoning by the curare treatment. A woman, having absorbed 60 centigrammes of strychnine, was administered immediately an injection of 25 centigrammes of 5 per cent. solution of curare, after eight hours a second injection of 10 centigrammes was given, and the following day a further dose of 2 centigrammes. By the sixth day the patient had entirely recovered.

THE PHARMACEUTICAL ASSISTANTS OF PARIS held their annual banquet recently, at the Restaurant Coquet, under the auspices of their syndicate. The company present, numbering about a hundred, included several members of the Chamber of Deputies, one of whom, M. Louis Brunet, presided.—In the course of the after-dinner speeches, M. Robert, the President of the Syndical Association, took the opportunity to thank the deputies who had so kindly responded to the invitations for the encouragement given by their presence, and eulogised the sympathetic attitude of the present Ministry towards the profession.—The Chairman, in responding, while assuring pharmacists of the support of his party during the impending discussion of the proposed Pharmacy Laws in the Chamber, exhorted them to personally use their utmost endeavours to improve the present unfavourable condition of pharmacy, and to uphold the privileges to which their important duties towards the Community entitled them. The réunion, which proved most pleasant and successful, terminated with the presentation by M. Brunet, on behalf of the Minister of Public Instruction, of the 'Palmes Académiques' to the devoted and capable President of the Association.

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

POWDER FOR WRITING ON STEEL.

There is no alum in the sample of powder you send. As far as can be ascertained from the very minute quantity sent, it consists of copper sulphate and sodium chloride, the latter being disguised by the admixture of a considerable amount of ferric oxide. Confirmation of this is afforded by the fact that on smearing a knife-blade over with soap, then writing on it with a pen and covering with a strong solution of a mixture of equal parts of copper sulphate and salt, an "etching" exactly similar to that obtained with your powder is obtained. [Answer to "Pharmacist."]

THYMOL CAMPHOR.

On heating together camphor and thymol a transparent oily liquid is obtained resembling phenol-camphor, but milder in its action. Schaefer recommends it for use in dermatological practice, it has given good results in scrotal pruritus and in pediculosis pubis. On the normal skin it does not produce any irritation or redness (*Bost. Med. and Surg. Journ.*, cxxxiv., 111).

RESORCIN-CAMPHOR.

This body is obtained as a liquid by heating together equal parts of camphor and resorcin. Schaefer finds that it is superior to mercurial ointment in removing pediculi (*Bost. Med. and Surg. Journ.*, cxxxiv., 111).

NEW REACTION FOR ERGOTININE.

A small quantity of powdered ergot is shaken with ether for a quarter of an hour and filtered. To the filtrate is added 10 drops of ether, acidulated with hydrochloric acid (obtained by shaking ether with 5 per cent. of its volume of hydrochloric acid, and decanting). A yellow flocculent precipitate of ergotinine hydrochlorate is thus formed, which is collected on a filter, washed with ether, and finally dissolved in 2 C.c. of glacial acetic acid. This acetic solution gives, on the addition of sulphuric acid and ferric chloride solution, a blue coloration. Keller states that this reaction is very delicate if care be taken not to add an excess of the acidulated ether (*Répertoire*, lii., 80, after *Neder. Tijdschrift*).

QUICK METHOD OF MAKING MERCURIAL OINTMENT.

Ettore Barbi gives in *Il Farmacista Italiano* a formula by which he says a 1 in 2 ointment of mercury can soon be made. A few grammes of decoction of saponaria root are put in a strong jar or bottle, 500 grammes of mercury are added, and the whole shaken until globules of the metal are no longer visible. The emulsified mercury is poured into a mortar containing 400 grammes of lard and 100 grammes of white wax melted together, and on triturating the metal is soon taken up, and a smooth and perfect ointment results.

RESINATE OF COPPER.

A combination of the acid resins of colophony with copper has been suggested for veterinary use. It is prepared by dissolving 50 grammes of cupric sulphate in a litre of water, and adding 100 grammes of colophony to the boiling solution, shaking well for about ten minutes, and allowing to cool. The resinate thus obtained is insoluble in essential oils and in alcohol, but soluble in amylic alcohol. For use, a solution is made with 100 parts of soft soap in 100 parts of fusel oil, and 60 parts of the resinate added. A limpid solution of a fine green colour is thus obtained (*Journ. de Pharm. d'Anvers*).

CHINOSOL.

Under this name a neutral combination of oxyquinolin has been introduced as a bactericide, in the form of a yellow crystalline powder, said to be forty times more active as a germicide than phenol, and non-toxic.

CORRESPONDENCE.

CO-OPERATION A REMEDY FOR LOW PRICES.

Sir,—It has often appeared to me that the best remedy to provide for the profitable conduct of a retail chemist's business in these days of severe competition with limited companies would be a more economical system of purchasing pure drugs, chemist's requisites, etc. This might be attained by retail chemists subscribing a small amount each (not necessarily exceeding £5) for the formation of their own large wholesale manufacturing limited company, whereby the subscribers might receive back as a bonus proportionate to their purchases the nett profits accruing from the carrying on of this concern after paying, say, a fourth part of the nett profits as dividend on the original shares. If this combination were well supported by a large number of the chemists in business the company would be such large buyers and producers that it must save a substantial amount to the retail chemist. Some advantages would be as follows:—(1) The abolition of the middleman's profits, (2) the guarantee of the purest of drugs and chemicals, (3) preparations of stated and uniform composition, (4) exclusion of limited companies, (5) the institution of copyrighted proprietary articles for sale at fixed prices only, thus ensuring a substantial profit, (6) the reception and publication of new ideas advantageous to chemists, (7) the sale of shares to registered chemists only, (8) the expenses of travellers and advertising saved, (9) a powerful combination for legislative purposes, (10) a good investment. With a view of putting something like the above into practical shape, the writer will be pleased to receive short post-card communications from chemists in business who may be interested, expressing their approval or disapproval of the above scheme, and he will communicate a condensed report to the Journal as soon as possible.

95, Waller Road, New Cross Gate, S.E.
April 6, 1896.

G. T. COOPER.

THE PHARMACEUTICAL SOCIETY'S SUBSCRIPTIONS.

Sir,—Having been connected with the Pharmaceutical Society for some ten or twelve years, and having during that time invariably forwarded my subscription in the usual way (the subscription for this year having been sent some time back), I was very much surprised to receive a post-card from our local secretary "regretting that owing to stress of work he was unable to call upon me for my annual subscription, and stating that he would esteem it a favour if I would send the same to Mr. Bremridge by post." At the foot of the post-card was a note, stating that if I had already sent my subscription I need not take any notice of this. Is it usual for a business man to go collecting accounts without first ascertaining which have been paid and which have not? Personally, I object to being called upon for my subscription at any time, and further, I object very much to such a notice being sent to me on a post-card, which may be read by anyone through whose hands it passes before I receive it.

Manchester, April 1, 1896.

T. R. ASHTON.

SHOPS (EARLY CLOSING) BILL.

Sir,—I have been surprised that so few chemists have written against this shameful early closing Bill. I can only account for it on the supposition that chemists have so continually been ignored with regard to any rights they have by Government, that they look on protest as useless. We know the minority always make the most noise, but that will not altogether account for it. This Act is a most unjust one; it is being forced through principally in the interest of co-operative stores and the like. M. P. S. is correct in saying two have no right to dictate to one, while H. S. Young's statement that a law must hurt somebody if it benefit someone else is absurd. Every law should be founded on moral right. But there is no moral right that two persons should dictate to a third in his own personal business. In London especially, if ever put into force, this Act will do great wrong. There are numbers of small shopkeepers who depend principally on evening trade and are a convenience to a certain portion of the public. There are streets where the most of the business is done early, whilst within a few yards—as the crow flies—are streets where most is done late; it would be gross tyranny that the man whose business naturally comes in the afternoon should compel the man to shut whose business is principally in the evening. The selfishness is all on the other side. The correspondence on this subject is certainly instructive, "Spes," of Aberdeen, would make it penal to supply anything

without the order of doctor or nurse. He does not explain how you are to know if the order is genuine. But on a case of emergency he would say, find a doctor or dentist or nurse, and if your friend is alive when you have got their order come again. And for whose interest is this suggested? Why the man who locks up his shop and goes right away. It is only a selfish attempt to prevent anybody else selling a pennyworth after he has turned the key in his door. Selfishness of one class, with no consideration for the public, is at the bottom of the suggestion. I cannot think why chemists writing to chemists are ashamed to give their names.

91, *Hampstead Road*, April 7, 1896.

WM. G. TAPLIN.

Sir,—“Many men, many minds,” is certainly applicable with a vengeance to the correspondence in your columns on the Shops (Early Closing) Bill. Whilst one man sees in it nothing less than financial ruin to a large number of the trade, another hails it as a ladder to literary and scientific culture, with increased opportunities for outdoor exercise and social intercourse. One opinion, however, all sides must hold, that if early closing for chemists is ever to be an accomplished fact, it is legislation alone that will work the oracle. “M.P.S.” tells us that a two-thirds majority has no moral right to coerce the remaining third. Quite so, and it should be the duty of the Legislature to protect the minority against overbearing action of the majority. Now we, sir, representing considerably more than a two-third majority, want the State to protect us from the infinitesimal minority, who, filled with an insatiable craving for the “last bawbee,” would keep their shops open all night if there was the faintest hope of their picking up a customer from their less avaricious brethren. A few of us are able to adopt an independent line of conduct and close our shops at eight, quite indifferent as to whether Mr. Graball-Smith opposite, or Mr. Everopen-Jones up the street follows suit at nine or midnight. The majority, unfortunately, are not in such an enviable position; they, whilst most sincerely wishing for shorter hours, are obliged to keep open till 9.30, 10, or 10.30, because some brother pharmacist in their district insists upon running a modified “all night pharmacy.” Voluntary closing has been tried repeatedly, with ever the same result. Brotherly kindness, unity, and sympathy are not in the B.P. (they may find a place in the millennium edition), and so, of course, are not dispensed by the minority, against whom I must earnestly hope the trumpet of the law will give a not uncertain sound.

Brighton, March 29, 1896.

ARTHUR T. JEEVES.

Sir,—You ask for an opinion for or against above Bill. I am heartily with it, and cannot understand anyone's objection. There is no necessity for late hours, either in a wealthy neighbourhood like this, or in a poor one like the Harrow Road. I have had a business in both places, and am competent to judge. The poor enjoy short hours, especially those in mechanical trades, and can shop early if so minded. The real reasons for long hours are excessive competition and the fact that there are too many chemists; but if all were compelled to close, as much business would be done as now and a trader enjoy a reasonable amount of freedom from the harassing cares of business, and especially single-handed men would transact their business with more energy, more go, with shorter hours than they do now.

South Hampstead, April 3, 1896.

ARTHUR SANGSTER.

THE OLD FIRM OF GODFREY.

A CORRESPONDENT interested in Mr. Ince's article has drawn attention to the following ancient

Epitaphium:

Here lieth to Digest, Macerate and Amalgamate with Clay, In Balneo Arenæ, Stratum super Stratum, the Residuum, Terra Damnata, and Caput Mortuum of Boyle Godfrey, Chemist and M.D. A Man, who in this Earthly Laboratory pursued various processes to obtain Arcanum Vitæ or the Secret to Live; also Aurum Vitæ, Or the art of getting, rather than making Gold. Alchemist; like all his Labour and Projection, as Mercury in the Fire, Evaporated in Fumo, when he dissolved to his first principles, He departed as poor as the last drops of an Alembic; For Riches are not poured on the Adepts of this World.

Though fond of News, he carefully avoided the Fermentation, Effervescence and Decrepitation of this Life. Full seventy years his exalted Essence was hermetically sealed in its Terrene Matrass; But the radical moisture being exhausted, the Elixir Vitæ spirit had exsiccated to a cuticle. He could not Suspend longer in his Vehicle, But precipitated gradatim, Per Campanam, to his original dust. May that light brighter than Bolognian Phosphorus preserve him from the Athanor, Empyreuma and Reverberatory

Furnace of the other World, Depurate him from the fæces and scorix of this, Highly rectify and volatilize his ethereal spirit, Bring it over the helm of the retort of this globe, Place it in a proper recipient or Chrystalline orb among the elect of the Flowers of Benjamin, Never to be saturated till the general Resuscitation, Deflagration and Calcination and Sublimation of all things.

Note.—Campana, a bell: in old Chemistry, a receiver in which gas was concentrated and condensed into a liquid. Sulphuric acid was described as Oleum Sulphuris per Campanum Athanor, a digesting furnace.

ANSWERS.

“MORTAR.”—Such an arrangement would not come under the exemption that limited companies are held to enjoy, and consequently the provisions of the 1868 Act would apply to it.

J. W. SANDERS.—The plan you suggest is not feasible. Besides, what is required is to ascertain the general wish of the trade, and not of the Society only.

A CORRECTION.

“GRANULAR EFFERVESCENTS.”—A correspondent having pointed out that Mr. Clarke's formula for a slightly acid basis, as printed in the *Pharmaceutical Journal* at page 235, would yield a product containing over three parts of sodium bicarbonate without acid to decompose, the author has been communicated with. The corrected formula is now given as follows:—

Sodium Bicarbonate	17 parts.
Tartaric Acid	9 „
Citric Acid.....	6 „
Sugar	6 „

It appears that an error occurred in type-writing the paper, the proportions of tartaric acid and sugar being transposed.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Arblaster, Baker, Bindloss, Brown, Cooper, Cracknell, Dawson, Evans, Mitchell, Sanders, Sangster, Scoville, Selby, Sinclair, Smith, Stewart, Stow, Taplin, Thompson, Tunnicliffe, West, Wiles.

THE PHARMACOLOGY OF IZAL.

BY F. W. TUNNICLIFFE, M.D., M.R.C.P.

[From the Scientific Workroom, St. Bartholomew's Hospital].

In considering the properties of Izal I shall first describe the result of the pharmacological experiments, shall then consider, for the purpose of comparison, the action of other antiseptics, and, finally, give some suggestions with regard to the probable therapeutic uses of Izal, the emulsion of Izal oil.

PHARMACOLOGY.

For these experiments we had the choice of two preparations, the pure medical oil and the emulsion; control experiments with the mother liquid of the emulsion showed it in the quantities given to have no action. Hence, the only difference in these preparations was one of strength, the activity of the emulsion being entirely due to the 40 per cent. of the oil which it contained. In describing the experiments the equivalent of emulsion will be given.

I.—ACTION OF IZAL ON THE INVERTEBRATA.

Experiments were made upon the tubifex rivulorum. Into three beakers, each containing 100 C.c. of New River tap water, an approximately equal number of tub. riv. were introduced; one of these beakers contained, in addition, 1 C.c. of a 1 per cent. solution of Izal emulsion. After a quarter of an hour's immersion it was found that the worms in the beaker containing Izal emulsion were becoming lethargic and opaque at the ends, whereas the worms in the other two beakers were unchanged. Three-quarters of an hour after immersion the majority of the worms in the beaker charged with Izal were dead, the ones in the other beakers still remaining unchanged. In a second series of experiments the third beaker was "medicated" in double the strength, that is, 2 C.c. per cent.; this strength killed the majority of the worms in fourteen minutes.

Experiments with earth-worms gave similar results.

II. ACTION ON FROGS.

(a) General Action.

Izal emulsion is lethal to frogs in doses of .015 C.c. per 100 Gm. body weight when injected *sub cutem*. Immediately after the injection of the drug in the case of decapitated frogs the "reaction time" becomes increased (Turks' method). Later, although the frog responds by a kick to cutaneous irritation, it is powerless to perform co-ordinated acts, such as returning to the prone from the supine position, or jumping away, as a normal frog would, from an irritating object. At this stage the indirect irritability of the muscles and the motor conductivity of the spinal cord are greatly diminished. The heart continues to beat after other signs of life have disappeared.

(b) Action on the Excised Heart.

When to the Ringer's fluid perfused through the excised frog's heart in a Williams' apparatus, Izal (pure medical oil) is added in the proportion of 1 part in 12,000 the beat is considerably slowed; the slowing is caused by a prolonged pause between the beats. When the Izal is increased to 1 in 8000 the beats become somewhat irregular and diminish in volume. When it reaches the strength of 1 in 6000 the heart stops. Ringer's solution recovers such a heart in fifteen minutes.

(c) Action on the Frog's Muscle-nerve.

Two gastrocnemius nerve muscle preparations were taken from the same frog. Their direct and indirect irritabilities were determined in the usual manner, they were approximately the same. One was placed for two hours in tap water saline solution, to which Izal (pure medical oil) had been added in the proportion of 1 part in 2500. The direct and indirect irritability began rapidly to decrease, and at the end of this time this preparation was both

directly and indirectly unirritable and opaque. The other preparation which had been placed for the same time in tap water saline solution preserved its irritability unimpaired.

To sum up the action of this substance upon the invertebrata and frogs we may say that to the tubifex rivulorum it is rapidly fatal, and that when applied directly to the heart or muscle nerve preparation of the frog it exerts a marked action. When, however, it is administered through the medium of the circulating fluid, it is very much less active, but, when given in relatively large doses it destroys the functions of the spinal cord and medulla. The significance of these experiments will be seen later.

III. ACTION ON MAMMALS.

To determine the pharmacological action of Izal on the higher animals, guinea-pigs, rabbits, cats, and dogs were used. In these animals the effect of Izal was qualitatively but not quantitatively identical. Rabbits being the least and cats the most susceptible to its influence. If in any experiment it is not stated otherwise, it may be taken that the subject of it was a cat.

(a) General Action.

The more highly developed an animal is, the more perfectly developed its protective mechanisms, the less susceptible does it seem to the action of this substance. When a dose exceeding .25 C.c. pro kilo body weight is continued without break for several days, a definite train of symptoms occurs. These consist in restlessness. This is soon followed by inco-ordination of movement. Twitching of the limbs appears next, especially when the animal attempts to perform a co-ordinated act, such as scratching itself. The gait becomes spastic. If no larger a dose has been given these symptoms pass off. If, however, it is still more increased up to .5 or 1 C.c. pro kilo body weight, a stage of paralysis supervenes. The animal presents all degrees of this according to the dose. The sensory part of the reflex arc remains practically unaffected. The temperature falls, and death takes place from paralysis of the respiration, the heart continuing to beat for a considerable time after the respiratory movements have stopped.

It was found that in some cases the paralytic stage was absent; under these circumstances the stage of spinal cord and medullary irritation continued till death. Animals can recover from the effects of this drug even when the paralytic stage has been entered. In some cases the dose can be greatly increased; in one cat, weighing 4 kilos, 4 C.c. of the emulsion were given during four days with temporary symptoms of spinal cord irritation and paralysis, but with perfect recovery on the tenth day; 2 C.c. of this quantity were given *sub cutem*. It was found that the action of Izal was a somewhat cumulative one. It will be obvious from what follows that the doses required to produce these symptoms are far in excess of those necessary to obtain the therapeutic effects of Izal, hence are rather of pharmacological than of practical interest.

(b) Action on the Digestive System.

This substance appears to have, in therapeutic doses, no action on the digestive processes. Animals, even after large doses, retain a good appetite and do not suffer from diarrhoea or vomiting; the faeces smell of Izal, showing that it is capable of exerting its antiseptic influence throughout the alimentary canal. Experiments made *in vitro* confirmed these results.

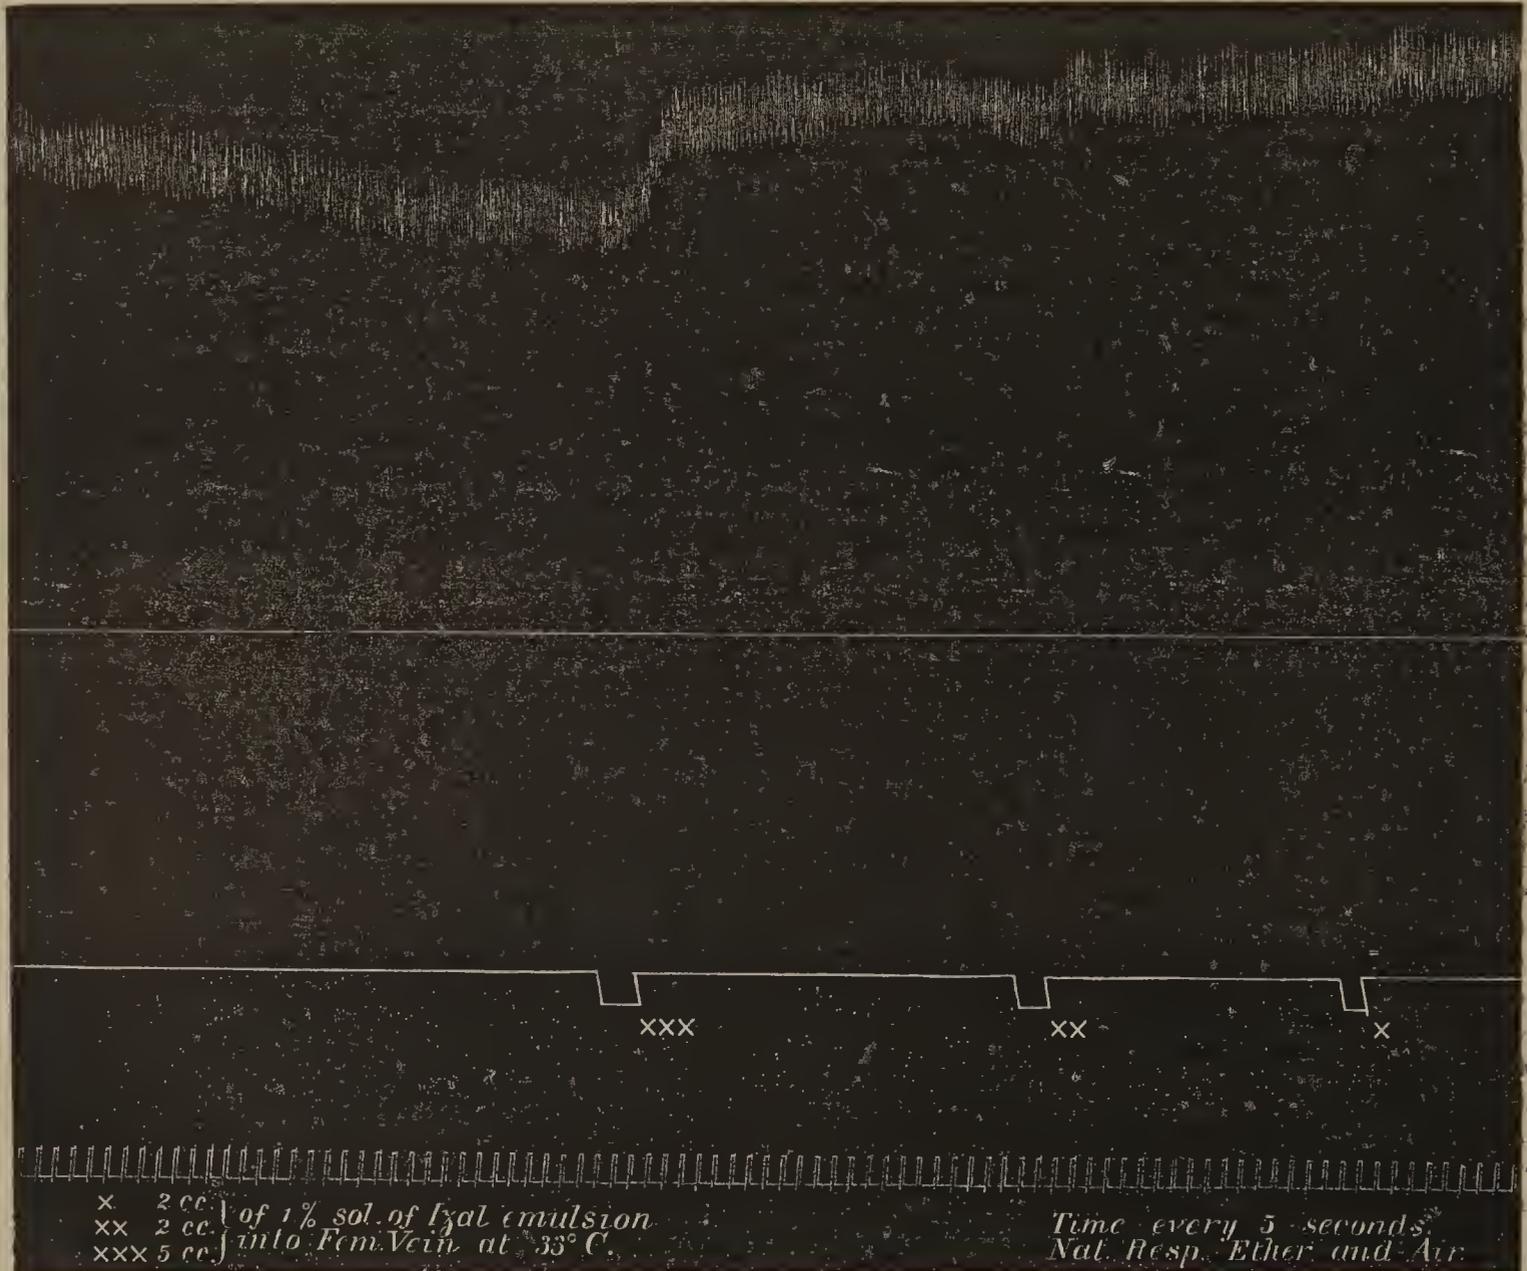

(c) Action on Respiratory System.

In animals taking Izal in large and small doses the lungs and breath smell very strongly of this substance. This is not solely due to the fact that they contain a large quantity of blood, as the liver and the kidneys—equally vascular organs—do not smell. The most probable explanation of this fact is that Izal is excreted by the pulmonary and tracheal mucous membranes.

(d) Actions on Secretions.

Izal causes an increased secretion of tears and probably an increased secretion from the skin; as the animals experimented upon had hairy coats it is impossible to speak definitely upon this subject. In large doses some irritation of the skin seemed caused by Izal, as the animals had a great tendency to scratch themselves. Izal is not eliminated as such in the urine, large doses increase the amount of urine secreted, but, in the cases watched, no sign of irritation or congestion of the kidneys, nor any phenomenon

blood pressure of 2, 2, and 5 C.c., of a 1 per cent. solution* of Izal emulsion in tap water saline solution, injected into the femoral vein.† This cat weighed 4000 grammes. Reckoning its blood-weight at 1-20th of its body weight, this latter would amount to 200 grammes. If we assume that 1 C.c. of Izal emulsion weighs 1 gramme, this means that the blood in this experiment was "Izalated" to the extent of .045 per cent., or approximately one part in 2500. Since outside the body Izal exerts a marked anti-septic action in the strength of 1 part in 200, the above facts are

analogous to carboluria was observed. It is not possible to say what is the ultimate chemical fate of Izal in the body.

(e) Action on the Nervous System.

The action of Izal on the nervous system has been so fully discussed under the description of its general action that it will not be necessary to speak further upon this subject.

(f) Action on the Circulation.

Izal in relatively large doses exerts no deleterious action on the heart, either when introduced into the stomach, into the subcutaneous tissue, or into the blood. A transient and slight fall of blood pressure is produced, which is due to a dilatation of the vessels. This soon passes off, and the blood pressure rises to its former level. The accompanying curves show this. Curve I. is the record taken by a mercurial manometer on a slow revolving cylinder, and shows at X, XX, XXX, the effect on the

of great interest and importance, and show to what a considerable extent the blood can be "Izalated" without any deleterious action on the circulatory organs ensuing.

Curve II. is a record of the blood pressure in the carotid taken by means of a Fick's spring manometer which was allowed to write on a quickly revolving cylinder. It shows the effect of a smaller

* For the sake of brevity, the term solution is used to indicate a mixture of Izal (emulsion or pure medical oil) with water or saline solution, as the case may be.

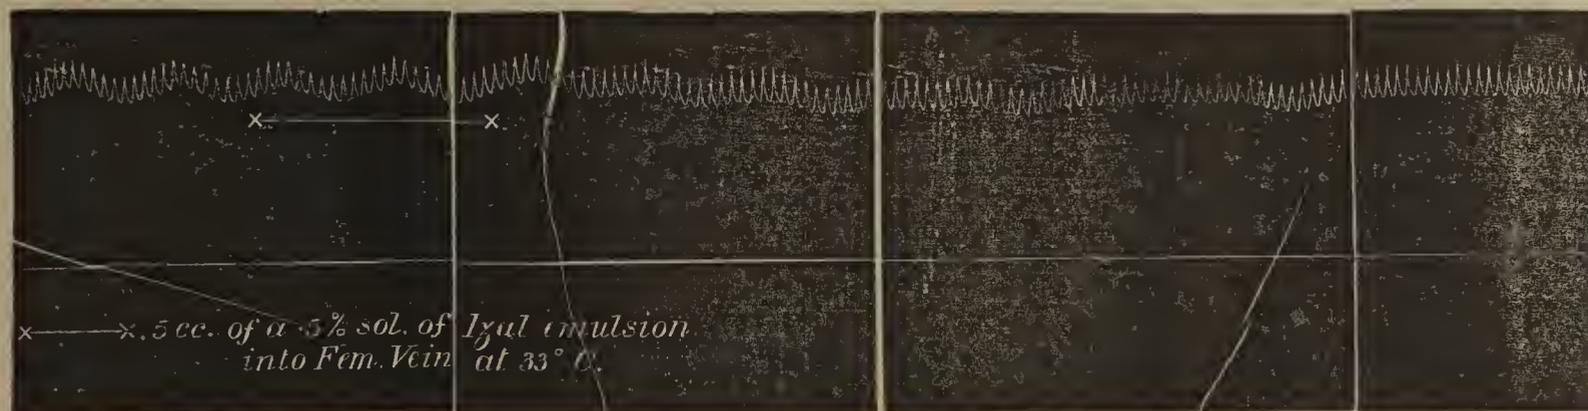

† In this curve, which is to be read from right to left, the topmost line is the blood pressure tracing, which owing to the slowness of the recording cylinder shows only the respiratory and not the cardiac oscillations in pressure. The second is the abscissa, and indicates the level of the mercury in the manometer when the artery was disconnected and the arterial cannula was open to the air at the level of the artery. The third line is that of an electric signal, the descents of the lever marking the beginning, the ascents, the end, of the injections of Izal. The lowest line is traced by an electric time marker arranged to mark five second intervals.

but still relatively large dose of Izal emulsion on the heart, between X and X, 5 C.c. of a .5 per cent. solution of Izal emulsion was injected into the femoral vein. As can be seen from the curve absolutely no effect was produced upon the activity of the heart.

To sum up then the pharmacology of Izal on mammals as deduced from our experiments on rabbits, cats and dogs, it appears that when the emulsion is introduced into the stomach in doses of .2 C.c. pro kilo body weight diluted with water or milk, even in some cases in doses of .8 C.c. pro kilo, it produces no symptoms whatever. It can be injected under the skin in doses of .1 C.c., and into the blood in doses of .02 C.c. in the form of a 1 or .5 per cent solution, without producing any toxic effects. Large doses introduced into the stomach pass down the alimentary canal and some of the substance is contained in the fæces. It also gives evidence of its presence in the breath. If the doses are still considerably increased it exerts the specific action on the central nervous system which has been described above. But it is not until the relatively large dose of from .5 to 1.5 C.c. pro kilo body weight is reached that dangerous symptoms occur, and even when these are pronounced if the large doses are discontinued the animals most often recover.

II.—COMPARISON OF IZAL WITH OTHER ANTISEPTICS.

To determine the capability of any antiseptic to exert its antiseptic action within the living body a judgment must be formed

on the relation between its antiseptic power and its toxicity, or what Bouchard* has termed "the equivalent toxique." The antiseptic power of Izal is high, 1 in 200 (Sheridan Delépine,† Klein),‡ its toxicity has been shown to be low—.5 to 1.5 C.c. of the emulsion pro kilo body weight. The following comparison will show the relation between Izal in this respect and other well-known antiseptics:—

Substance.	Toxicity.	Antiseptic power.
Izal emulsion5-1.5 C c. pro kilo ...	1:200
Carbolic acid§12 gramme	1:50
Guaiacol 5 gramme	1:50
Veratrol 	1.5 grammes	1:100
Binioidide of mercury¶15 gramme	1:4000
β-Naphthol**	3.00 grammes	1:1500
Strychnine††0008 gramme	—

Strychnine has been introduced into this table to show the minimal poisonous dose of an active medicinal agent. From this table it will be seen that Izal compares favourably with many other antiseptics. This method of comparison is, however, not free from error, and must be regarded as approximate and not absolute. The antiseptic power of any substance is not only different for different

micro-organisms but for the same micro-organism under different conditions, hence it is by no means a constant quantity. The same is true of the poisonous power of a substance. Such tables are, however, useful, and may be regarded as sufficiently accurate for practical purposes.

III. SUGGESTIONS WITH REGARD TO THE PROBABLE THERAPEUTIC USES OF IZAL.

From the above experiments it is manifest that Izal can be administered to man for the purpose of exerting its antiseptic properties *in vivo*. For this object it may be given by the mouth in doses of from ℥xv.-℥i. or more of the emulsion, made into an ordinary ounce or half-ounce mixture, or diluted with water or milk, three or four times a day. If a prolonged treatment is desired, for instance, in cases of obstinate foetid diarrhœa or auto-intoxication a day's pause should be allowed at first after from ℥iv.-℥vi. have been administered to avoid the possible occurrence of any accumulation of Izal in the system.

The question of the possibility of appreciably diminishing the number and activity of the micro-organisms in the intestinal canal by the administration of any so-called intestinal antiseptic is at present a disputed one, and this monograph is no place to enter into this controversy. That cases of auto-intoxication from the intestinal canal are improved by the exhibition of such drugs as uaiacol, salol, naphthol, carbolic acid, etc., is, I think, established,

and what should be pointed out here is that Izal is justified in holding a prominent place amongst such remedies, and is well worthy of an exhaustive trial. Its action in the early stage of typhoid fever, cholera, etc., will be similar to that of the antiseptics hitherto used, and since it is in relation to its antiseptic power less irritant and toxic than the majority of these, it may with benefit be substituted for them.

The action of Izal upon the tubifex rivulorum established by these experiments and the similarity between this organism and the thread-worms and tape-worms of the human intestine, render it in the highest degree probable that Izal will act as an anthelmintic. For the oxyuris vermicularis it will be best given in the form of an enema of a strength equal to a 2-3 per cent. solution of the emulsion.

The excretion of Izal by the pulmonary and bronchial mucous membrane points to the fact that it will be of use in cases of foetid bronchitis, bronchiectasis, etc. The extensive use of such substances as creosote, guaiacol, etc., in phthisis indicates that Izal may also be useful in this connection. The entire absence of any depressing action on the heart is for this purpose a great point in its favour, as is also the absence of any disturbing influence on the digestive organs.

The uses of Izal in surgery have been thoroughly investigated by Mr. Bruce Clarke, and upon this subject readers are referred to his article in the *Lancet*,* and the *St. Bartholomew's Hospital Journal*.†

LESSONS IN PHYSICO-CHEMISTRY.*

GRAVITY, DENSITY, AND VOLUME.

SPECIFIC GRAVITY OF GASES.

In all matters relative to the specific gravities, or densities of gases, the state of affairs differs considerably from that which obtains with solids and liquids. In the first place the pressure under which a gas exists has a direct influence on its density; increased pressure causes contraction of the gas, and hence increased density, and *vice versa*; whereas the influence of pressure on the densities of solids and liquids is so small that except for very great pressures it is quite negligible. In the second place, all gases, unlike solids and liquids, are equally affected by equal changes of either pressure or temperature, at least as long as they are under conditions far removed from those under which they pass into liquids. Hence, if a certain ratio exists between the densities of two gases at a given temperature or pressure, the same ratio will exist between them at any other temperature or pressure that is the same for both gases, and the conditions of temperature and pressure under which the density of a gas is determined may simply be those that are most convenient at the time of experiment, so long as they are accurately known. As this is an operation that is now rarely necessary, the densities of practically all known "permanent" gases being already fixed, the working details, which are necessarily extensive, need not be given, but the method of procedure is as follows:—A glass globe of two or three litres capacity, fitted at the neck with a brass stop-cock, is completely exhausted of air by means of the air-pump; it is then accurately counterpoised on the balance, a globe of similar size being hung on the other arm and necessary adjustments made by weights. The second globe is employed in order that both sides of the balance may be equally supported by the air, and that deposition of moisture from the atmosphere on the glass may not affect the correctness of the weighing. The gas under examination is now admitted into the first globe by means of the stop-cock, its temperature and the pressure upon it being accurately noted, and the globe is closed and weighed again, the increase being the weight on the gas. The volume is ascertained by filling the globe with a gas of known density and weighing it, or with water, and then measuring the latter. From the information so obtained the weight of 1 litre of the gas measured at 0° C., and a pressure equal to that of a column of mercury 760 millimetres in height, is calculated, the conditions just mentioned being those that are adopted as standard ones. The following are the data required for this calculation:—Any quantity of gas expands or contracts by .00367 of its own volume at 0° C. for every 1° C. through which it is heated or cooled respectively, and when the pressure on the gas is altered it expands or contracts to such an extent that the volumes before and after the change are inversely proportional to the pressures. If both pressure and temperature are changed simultaneously, the effect is the same as if the alteration had occurred in first one and then the other, and it is immaterial which is considered first. It is particularly important to notice that whatever the temperature of a gas may be, the change of volume that it undergoes for every degree through which it is heated or cooled is the above-named fraction of its volume at 0°, and not of its volume at the temperature at which it happens to be. By way of example, suppose it is found that 2½ litres of a gas weigh 3.8200 grammes, the globe having been filled at 12° C., and with a pressure on the gas equivalent to 750 Mm. of mercury. If the gas measures V at 0°, it will

measure $V + (12 \times .00367 \times V)$ at 12°, according to the rule just stated, and this equals 2½ litres, from which, by elementary algebra, we find $V = \frac{2\frac{1}{2}}{1.04404}$ litres. Since this is its value under 750 Mm.

pressure, under 760 it will be $\frac{2\frac{1}{2}}{1.04404} \times \frac{750}{760} = 2.363$ litres, and therefore 1 litre under standard conditions would weigh $\frac{3.820}{2.363} = 1.616$ grammes.

The absolute weights of 1 litre of different gases under standard conditions having been found, it is clear that the ratio between these weights is the ratio between the densities of the gases. It is only necessary, therefore, to adopt one gas as a standard, and refer the others to this one. In physical work air has often been taken as a standard in the past, but in view of the facts that hydrogen is the lightest body known, and is taken as a standard in comparing many other properties, and that air, as a mechanical mixture, is not quite of invariable composition, it is better to adopt hydrogen for all purposes, and its density is therefore taken as unity. Now, since equal volumes of gases under the same conditions contain equal numbers of molecules, the ratio between the weights of equal volumes of two gases is the ratio between their molecular weights as well as between their densities. The density of hydrogen being taken as 1, and its molecular weight being 2, it follows that the molecular weight of any gas is double its density referred to hydrogen; in fact, it is chiefly for fixing the molecular weight of a gas that its density is required to be known.

VAPOUR DENSITY.

The last remark applies not only to those gases which are permanent at ordinary temperatures, but also to those substances that only retain the gaseous state at higher temperatures, and easily condense on cooling to either liquids or solids. It is clear that if a solid or liquid can be brought into the state of gas without undergoing chemical change, the density of this gas and hence its molecular weight can be determined. Gases that condense at ordinary temperatures to liquids or solids are usually distinguished as vapours, and the operation here referred to is spoken of as determining the vapour density of a substance. It is always desirable to know the molecular weight of any new body that may be prepared; when it can be vaporised unchanged this is the method that is always employed. Other methods will be considered later. Several methods are in vogue for determining vapour densities; in some of these the weight of a given volume of vapour is ascertained by a modification of the above process for gases; in others the volume of vapour formed from a given weight of the substance is found directly or indirectly. The method of Victor Meyer, in which the latter principle is followed, is one of the most useful; this is described in *Pharm. Journ.* [3], ix., 936.

SPECIFIC VOLUME.

Specific gravity may be defined as synonymous with relative density, *i.e.*, the ratio of the weight of a given volume of a substance to the weight of an equal volume of a standard substance under similar conditions, and it is in this sense that the term is generally employed. But the expression "specific gravity" is also used to express the idea of absolute density, which may be defined as the mass of unit volume of a substance. Thus the relative density of a substance referred to water at 15°·5 C. is not the same as its absolute density, since the absolute density of water at that temperature is not 1 but about .999. The absolute density of water at 4° C. is 1, that is, 1 unit volume of water at 0° contains 1 unit

* Articles on weighing, correction of apparatus, and specific gravity of liquids appeared in volume xxv. [series 3], pp. 889 and 1141.

of mass, or 1 cubic centimetre weighs 1 gramme.* The quantity of matter in, or the mass of, a given body, is invariable; but its weight varies slightly according to the latitude in which it is weighed, since it is further from the earth's centre, and is therefore less attracted, or weighs less, at the equator than when nearer the poles. This, however, is such an unimportant error that in practice weight is always dealt with instead of mass, and the absolute density of a substance may for practical purposes be defined as the weight in grammes of 1 cubic centimetre of it; and, as has been said, this is sometimes called its specific gravity. The latter term is best discarded altogether, and the terms absolute density and relative density used.

The absolute density of substances is a very important property, it is more conveniently employed, however, under the form of specific volume. The absolute density has been defined as the weight in grammes of 1 C.c.; the specific volume is the volume in C.cs. of 1 gramme. This is clearly the reciprocal of the absolute density; for if 1 C.c. of a substance weighs say d grammes, 1

gramme will obviously measure $\frac{1}{d}$ C.c.

The specific volumes of bodies in the liquid state have received most attention. It is a rather difficult matter to decide on a satisfactory temperature at which to measure this quantity for comparisons; to select any one temperature for all bodies would be of course quite arbitrary; and the best results have been obtained by determining the specific volumes of substances at their respective boiling-points. It is argued that since at these temperatures their vapour-pressures are equal, each being equal to the pressure of the air, they may be supposed to be to some extent in similar and comparable conditions. The adoption of the boiling point, has, however, been objected to by some, and other temperatures have been also employed.

In order to make the specific volumes of different substances more comparable with each other, the quantity $\frac{\text{volume}}{\text{weight}}$ is multiplied by the molecular weight of the substance in question. It is clear that the numbers of molecules contained in equal weights of two substances will be inversely proportional to the molecular weights, whereas if, instead of equal weights, weights proportional to the molecular weights are taken, these will contain equal numbers of molecules. Thus m grammes of a substance of molecular weight m will contain as many molecules as n grammes of another substance whose molecular weight is n . If 1 gramme of the former measured v C.c., that is, if its specific volume is v , m grammes measure $m \times v$ C.c.; similarly, if 1 gramme of the second substance measures w C.c., n grammes measure $n \times w$ C.c. Therefore, mv and nw represent the volumes of equal though unknown numbers of molecules of the two substances; these quantities have been called molecular volumes; similarly, when dealing with an element the specific volume multiplied by the atomic weight gives the atomic volume. The terms "molecular volume" and "atomic volume" are in fairly general use, but several chemists have abandoned them, and denote these quantities by the one term "specific volume." For the sake of clearness, we shall use the terms "atomic" and "molecular" volumes, and reserve "specific volume" for the quantity so defined above, and into which atomic or molecular weight does not enter.

* This is not quite correct. The gramme was originally defined and taken to be the weight at Paris of 1 C.c. of water measured at 4° , and a standard weight of 1000 grammes (1 kilogramme) was made of platinum, and is kept in Paris. The gramme is defined as the one-thousandth part of the weight of this standard, and more accurate measurements have shown that this is not exactly the weight of 1 C.c. of water at 4° , but differs by about a tenth of a milligramme.

The method of determining specific volumes is simple. A glass bulb having a narrow neck and a small opening is filled with the substance in question, and hung in the upper part of another vessel in which the same substance is being boiled. By this means the liquid in the bulb is brought to the temperature of its boiling point, though it is not made to boil; it will expand, and some will be driven out of the bulb until what remains just fills it at the temperature of boiling. The bulb is now taken out, wiped, cooled, and weighed, and its weight when empty subtracted from the weight so found. The volume of its contents at the boiling point of the liquid is ascertained by filling it with water at that temperature and weighing; since the density of water at different temperatures is already known, the volume is found by simple calculation. On dividing the volume so found by the weight of the liquid, the quotient is the specific volume of the latter.

A great deal of the work that has been done on the subject of specific volumes is due to Kopp, and he discovered some important relations, which may be briefly summarised; nearly all the results obtained refer to organic substances. In the first place, a definite difference between the composition of two bodies is accompanied by a definite difference in molecular volume. For instance, in ascending a homologous series, a difference of 22 in molecular volume corresponds to a difference of CH_2 in composition. Further, this difference may be resolved into its component parts, a difference of 11 being due to the carbon, and of 5.5 to each of the hydrogen atoms. Similarly, a definite value may be assigned to each element and is called its atomic volume. When the specific volume of an element in the free state can be determined, the result found multiplied by the atomic weight gives an atomic volume usually identical with that found as just described for the element in combination. The latter value, however, depends to a certain extent on the mode in which the element is combined; thus oxygen in the condition of hydroxyl, that is, when attached both to hydrogen and to carbon has a very different value from that found when it is united solely to one carbon atom, and in this respect it is resembled by sulphur. It appears, too, that carbon in the "unsaturated" condition has a different value from "saturated" carbon; when combined in the benzene ring, again, its value is not the same as when in an open chain. Sufficient data of this kind have been accumulated to enable chemists to predict with tolerable accuracy the molecular volume of a substance whose constitution is known, but very much remains to be done, and the matter is of great importance for the light it should throw on the nature of combination and on the constitution of matter.

(To be continued.)

ALLSPICE, OR PIMENTO.*

BY J. CH. SAWER, F.L.S.

The name "allspice" is given to the dried, unripe berries of the *Eugenia pimenta*, De Cand., by reason of their aroma and flavour, which are considered to resemble a mixture of cinnamon, cloves and nutmegs.

This handsome evergreen tree is indigenous to the West Indies, and is found on calcareous soil near the coast, on the islands of Cuba, Hayti, Trinidad, Domingo, Antigua, all through the Leeward and Windward Islands, and more or less in all the islands of the Carribean, but is most abundant in Jamaica; the groves of this spice tree found there are magnificent, and produce more than one-half of the allspice used in the United States. It is also found in Central America, Mexico, Venezuela, and Costa Rica.

The usual height of the tree is from twenty to thirty feet; occasionally it exceeds forty feet. The trunk is slender, straight, and

* Reprinted from the *Imperial Institute Journal*.

upright, much branched at the top, and covered with a smooth, grey, aromatic bark. The leaves are from four to six inches long, and are very aromatic in the fresh state, abounding in essential oil.

The pimento tree is particularly fond of a white marly or chalky soil having a shallow surface of mould, and therefore thrives on rocky lands which are fit for little else. Strictly speaking, the pimento tree is not really cultivated at all in Jamaica. The trees are found in greater or less numbers all over the island; but in some sections of the country they are the predominating trees, indigenous and growing wild. The nearest approach to their cultivation in these localities is to clear away the underwood and keep the groves free from brushwood and creepers—a difficult task where everything grows spontaneously in the wildest luxuriance. Sometimes the trees will be found singly, sometimes in groups of six, twelve, or twenty. In other places a few hundred will be found; while in ten principal pimento districts in parishes of Manchester, above Kingston, and St. Ann's, there are great forests of pimento trees. These last-named mountainous districts are some 6000 feet above the sea-level; there the harvest is gathered later than in the low-lying districts near the coast.

When a plantation of pimento is laid down, the trees begin to fructify in the third year, and arrive at maturity in seven years, when they abundantly repay the patience of the planter.

In the month of July the head of the tree is covered with an exuberance of branches of very small, greenish-white, fragrant flowers. The fruit is a smooth, shining, succulent berry of a black or dark purple colour when ripe, and containing two kidney-shaped, flattish seeds. When ripe, it is filled with a sweet pulp, and the aromatic property which so strongly characterises it in the unripe state, has, in a great measure, disappeared. The gathering of the berries therefore takes place as soon as they have reached their full size and whilst still green, because if the fruit is allowed to ripen on the tree, it is of no commercial value. A problem which faces the pimento producer is, therefore, the rapid picking of the berries when they are just fully grown. It is often difficult to secure enough help among the indolent natives to pick the crop. A recent instance is known of a producer losing fully 3000 bags of his pimento, which had ripened and fallen to the ground simply because he could get no one to pick it.

The berries are gathered by hand, and for such as cannot be reached by climbing, recourse is had to ladders. The small twigs bearing the bunches of berries are broken off and brought down. During the first and second days they are often turned to be fully exposed to the sun. When they begin to dry they are frequently winnowed to remove the stalks, and are laid in cloths to preserve them from rain and dews, still being exposed to the sun every day and removed under cover every evening until the fruit is sufficiently dry, which usually happens in twelve days, and is known by its having acquired a reddish-brown colour, also by the rattling of the seeds. Some planters kiln-dry the berries, especially when the crop is abundant, security against rain being essential. After the drying process is completed, the pimento is packed in bags, very much in the same way as coffee, and transported to the coast for shipment. In Jamaica, the principal port of shipment is Kingston, but large quantities of the crop are shipped from various other ports along the coast.

In the dried state, pimento is a small, dry, roundish fruit, varying somewhat in diameter, but on an average about the size of a small pea. It is crowned with the remains of the calyx, usually in the form of a slightly elevated scar-like ring; and, rarely, at the other extremity of the fruit there is a short stalked attached. The berry consists of a brittle, somewhat woody shell or pericarp, externally dark brown, and more or less rough on its inner surface from the

presence of small oil receptacles; and of two dark brownish-black, somewhat compressed, kidney-shaped seeds, each contained in a separate cell. The aromatic properties are more evident in the shell than in the seed. The berries yield, on distillation, 3 to 4½ per cent. of a volatile oil, which is a little heavier than water, having a specific gravity of 1.04 to 1.05 at 15° C. Pimento is sometimes adulterated with a Mexican spice called "Pimenta de Tobasco," which is a larger berry and less aromatic; it is produced by the *Myrtus tabasco* (Mocino), a native of the hot regions in Mexico, and is considered to be a variety of the true pimento tree.

Another tree, as variable as *Eugenia pimenta*, and yielding analogous products, is *Myrcia pimentoides*, D.C.; it is a native of the West Indies, and is now cultivated in the East Indies. Its leaves, berries, and flower-buds have a hot taste and fragrant smell like those of *Myrcia acris*, from which the West Indian "Bay" leaves have long been considered to be produced.

Wild Allspice.—During the American war, when allspice was difficult to obtain in the United States, a substitute was found in the berries of *Laurus benzoin*, Linn., commonly known as "Wild Allspice, Spice Bush, Fever-wood, Benjamin-bush, and Spice-bush" (not the Californian "Spice-bush"). Growing to a height of ten or twelve feet, this bush bears an aromatic fruit of about the size of an average olive, bright red, and in clusters. These fruits contain nearly 33 per cent. of a thick fixed oil, of about the consistence of castor oil, greenish-brown in colour, and of a pungent, aromatic taste, which is due to an abundance of volatile oil also contained in the fruit; the amount has been estimated at from 4 to 5 per cent. All parts of the shrub possess pleasant aromatic odours, which, however, are strikingly different from one another, the essential oil of the bark being something like wintergreen, and that from the twigs like camphor and calamus; while the leaves smell very pleasantly of lavender.

MISCIBLE LIQUID EXTRACT OF COCA.

BY J. F. BROWN, DOVER.

It would appear very desirable that the present necessity for keeping two fluid extracts of coca leaf should, if possible, be avoided.

When prepared as officially directed, by maceration and percolation of the powdered leaf with proof spirit, so much chlorophyll is carried into solution that an unsightly turbid mixture is obtained on adding it to water or wine of low alcoholic strength. Hence it is rejected by the public, who generally desire to use it thus. To meet the demand a miscible preparation is supplied by most wholesale druggists, which is certainly more elegant, as it forms a perfectly clear mixture with, say, orange or ginger wine. Probably it is prepared on the lines suggested by Mr. Cripps (*Pharm. Journ.*, [3], xxv., p. 1169) by repercolation with a mixture of one part of rectified spirit with two and a half or three parts water, with or without the subsequent addition of glycerin.

The difficulties to be overcome are two—the solubility of chlorophyll in spirituous menstrua, and the liability to damage of the coca alkaloids on exposure to heat.

Since Squire states that the drug is far from being exhausted by three-fourths of the menstruum in following the Pharmacopœia process, it is not possible to obtain a concentrated percolate and then add to it rectified spirit to bring it up to proof strength. Evaporation of a watery percolate is inadmissible, on the second ground. The question arises whether any objection exists to the employment of a weaker spirit. Two instances in the Pharmacopœia of such employment may be worth considering.

The liquid extract of hamamelis—also a leaf extract—is made with a mixture of one part rectified spirit and two parts water. Apparently this strength does not altogether exclude chlorophyll

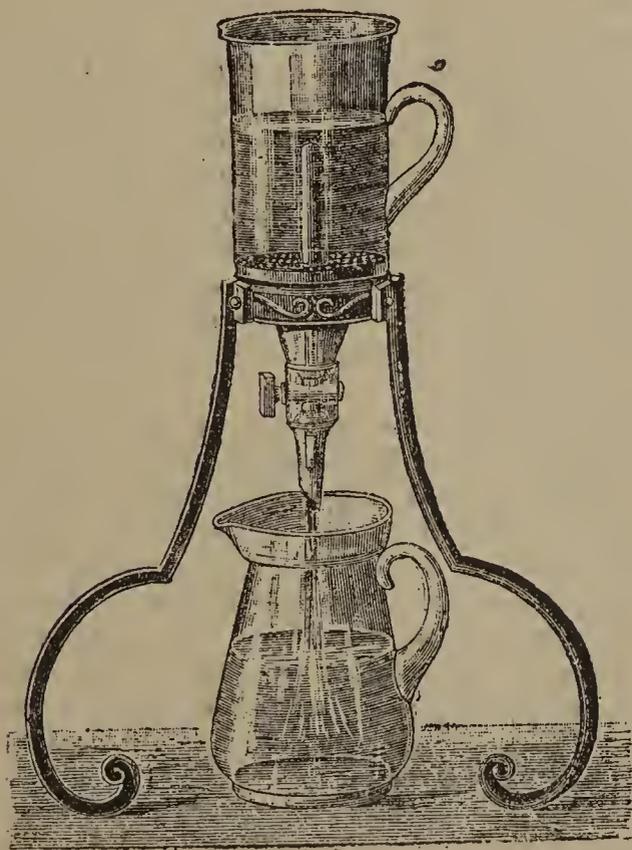

since the extract is somewhat turbid when diluted with water. For liquid extract of pareira, a mixture of one part spirit and three parts water is deemed sufficiently strong to ensure its keeping properties. The strength suggested by Squire for liquid extract of taraxacum, viz., equal parts of proof spirit and water, is practically the same as Cripps', one of rectified spirit to two and a half of water; each containing about 24 per cent. of absolute alcohol by weight. I have found that a liquid extract of cascara made by re-percolation with one part of rectified spirit to three of water had a specific gravity of 1.059, and was much more intensely bitter than the Pharmacopœia extract obtained from the wholesale houses, which had a specific gravity of 1.075.

Unless any loss of therapeutic efficiency should seem likely to ensue, I would suggest that the formula for liquid extract of coca should be altered so as to provide for its being made with equal parts of proof spirit and water, by re-percolation, so as to obtain official sanction for the preparation which consumers decidedly prefer.

NOVELTIES IN PHARMACEUTICAL APPARATUS.

THE "LIGHTNING" FILTER.

At the last meeting of the Austrian Apotheker Verein, a new filter called the "Lightning" was exhibited (*Oesterr. Zeits. für Pharm.*) It consists of a cylindrical vessel of glass, metal, or stoneware, open at the upper end, and tapering at the lower, where it is provided with a tap. A perforated plate in the shoulder receives the filtering medium, which is covered and kept in place by a second perforated disc. In using it the liquid to be filtered is poured into the vessel, from which the upper disc has been removed, and stirred until

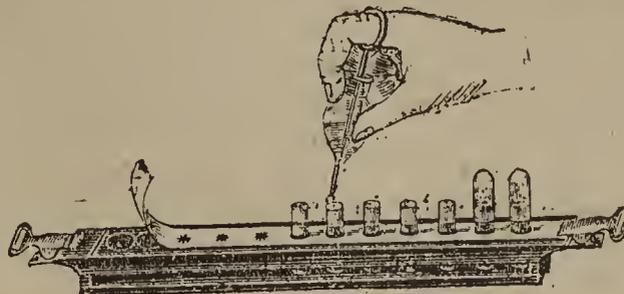

all the air is displaced. The necessary quantity of filtering medium is then mixed with it, and the tap opened. As soon as the liquid has sunk to within about 5 Cm. of the perforated plate, the upper disc is introduced and carefully lowered on to the filter-bed, so as to protect it from being disturbed. The first portions of filtrate must be returned; in two or three minutes it will run perfectly bright. For pharmacists the filter is made in two sizes of 3 and 5 litres

capacity; they are said to deliver 40 and 60 litres of water respectively per hour.

STAND FOR FILLING CAPSULES.

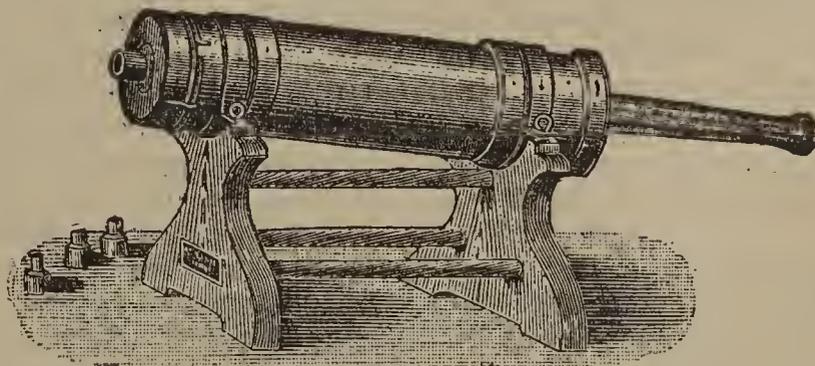

Tschanter, in Oppeln, is introducing a new stand for filling hard gelatin capsules (*Pharm. Zeit.*). Two slips of wood are fixed parallel to, and at a little distance from, one another; the upper is pierced with holes and covered with a strip of paper, in which suitable star-shaped incisions have been made. The empty capsules are passed through the incisions in the paper and the perforations of the upper slip of

wood until they rest upon the lower slip. They will be found to be held sufficiently firmly to allow of their being conveniently filled. This is best effected by a pear-shaped pipette (for liquids), the aperture of which is closed on the inside by a pointed rod provided with a ring, through which the forefinger passes; by this means the flow of liquid can be easily regulated.

APPARATUS FOR FILLING TIN TUBES.

Messrs. Schantz and Junghans, of Vienna, have devised a practical and useful apparatus for filling tin tubes (*Oesterr. Zeits. für Pharm.*). It consists of a strong, neatly made cylinder measuring 35 Cm. by 9 Cm., coppered and doubly nickel-plated on the outside, and closed at

one end by a cap kept in position by a bayonet catch; to this cap points corresponding to the usual sizes of tin tubes can be fastened. In the cylinder a wooden piston works in such a manner as to prevent escape of the mass to be filled. The apparatus is secured to a wooden stand, and can be made to order in various sizes.

NAPHTHALIN AS A VERMIFUGE FOR OXYURIS VERMICULARIS.—Schmitz (*Wien Med. Presse*) employs naphthalin for the expulsion of oxyuris, commencing by administering a cathartic. After a few evacuations have been produced, the naphthalin is given in eight or ten successive doses of $\frac{1}{4}$ to $\frac{1}{2}$ of a grain in powder four times daily. The drug should not be given after eating, and the ingestion of oils or fats should be avoided during treatment. A week later, the same treatment should be repeated, and if needful, a third course at another week's interval. It is seldom necessary to resort to a fourth repetition (*Med. Chron.*, iv., 299).

REVIEWS AND NOTICES OF BOOKS.

A NEW METHOD OF INHALATION FOR THE TREATMENT OF DISEASES OF THE LUNGS by W. H. SPENCER, M.A., M.D., Cantab., M.R.C.P., Lond. Pp. 54. (London: The Scientific Press, Limited, 428, Strand, W.C. 1895.)

The author first sets forth the principles upon which any inhalation method for the direct application of antiseptics and other remedies to the interior of the lungs should be founded, and the conditions under which it should be conducted, prior to describing his new method. In this, volatile oils, with or without the volatile constituents of solid bodies dissolved in them, are evaporated at fixed temperatures, and in such a manner that evaporation is steady and uniform at the temperature decided upon. The patient is kept in the medicated atmosphere produced for days, weeks, or months, as may be thought necessary. The book deals fully with the practical application of the method, and should prove useful to everyone interested in the subject of which it treats.

ESSENTIALS OF VEGETABLE PHARMACOGNOSY. By HENRY H. RUSBY, M.D., and S. E. JELIFFE, M.D. Pp. 149, with 500 illustrations. Price \$2.50. (New York: D. O. Haynes and Co., 1895.)

This work is divided into two parts, the first treating of the gross structure of plants, and the second of their minute structure. It has a special interest for students, inasmuch as the preface indicates that it "represents fairly well the teaching of the subject in the author's class-room." The first part, which is by Dr. Rusby (who is the Professor of Botany, Physiology, and Materia Medica in the College of Pharmacy of the City of New York), is decidedly different in style to that of most European text-books for pharmaceutical students. The keynote to the plan adopted may be found in the following extracts from the first few pages:—"The pursuit of pharmaceutical botany would demand a thorough knowledge of nearly all departments of scientific botany. . . . The pursuit of the study to such an extent would almost necessarily involve the average pharmacist, at least in this country, in financial failure, through the inattention to practical affairs which would ensue. . . . The directions in which botanical knowledge is most useful to practising pharmacists will determine the most important requirements for botanical study. The identification and selection of drugs, that is to say, pharmacognosy, constitute the principal field for the exercise of botanical knowledge on the part of the pharmacist, and it is those departments of botany which bear directly upon this subject, and upon materia medica, to which attention will be restricted in this essay." The practical character of the American people in estimating the relation between the necessities of daily life and the kind of education most useful for the purpose of providing them, is here evident. While admitting that "in attempting a comparative view of the series of plants, it is unquestionably well to begin with the lowest forms and follow the lines of upward development," the author remarks that "in gaining our first knowledge of the structure of the plant organism, sound and accepted rules of pedagogy require that we begin with the more obvious characters of the higher plants," for "not until mankind shall learn to breathe by some different method than that followed by his ancestors will any method of studying botany become popular which passes over the rose, buttercup, and aster, for the making of microscopical preparations of myxomycetes or the sectioning and staining of tissues."

For many reasons the author advises pharmaceutical students to commence with the flower. Beginning, then, with this usually

most interesting part of plants, under the heading of anthology, the author arrests the attention of the student by showing that a flower is merely a reduced shoot modified for the production of seeds. He especially emphasises the laws which regulate the formation of the generality of flowers, and points out in a very interesting manner how the great variety of form is dependent upon the requirements of the plant as affected by its surroundings. In fact, the student is led to feel in perusing the chapters that botany does not so much consist of a knowledge of hard names as of a series of interesting rules that govern the life of plants, and that the number of modifications of plant forms brought about by various conditions render the use of names to distinguish them a necessity. The facts, and not the names, are the prominent features in the mode of teaching adopted. Many of the illustrations are taken by permission from Engler and Prantl's 'Pflanzen Familien,' but there is a freshness about them to European eyes, and a clearness of definition in the explanation of the terms used, especially in those applied to the leaves and fruits, that will well repay the student who consults the work. If there is any part that might be a little more developed, it is that referring to the inflorescence. But the amount of suggestive information conveyed in 101 pages devoted to what may be termed macroscopical botany as opposed to microscopical botany or histology, is simply astonishing.

There is no index, and as there are some terms, such as Phytomer and Antidromy, etc., that are not often met with, and a good many illustrations that possess an interest beyond their immediate use in the text, it may be hoped that this deficiency may be remedied in any future edition that may appear. It should perhaps be mentioned that the botany given in this work is only intended to help in the recognition of parts of plants as met with by the student of pharmacy, and does not enter into systematic botany at all. It is, in fact, botany treated from the point of view of pharmacognosy only.

Of the second section of the work, Professor Jelliffe's "Outline of Practical Plant Anatomy," it is, unfortunately, not possible to speak in commendatory terms. The title is a misnomer in so far as the section is in no way an introduction to practical plant-anatomy. It will, moreover, be readily conceded that in any work written for beginners, as this avowedly is, the style should be simple, and free from ambiguity, and the statements made should be accurate. These two fundamental conditions are, however, frequently unfulfilled, as may best be exemplified by quotations from the work itself.

Of alkaloids, the author says that "they are generally rich in the meristematic tissues, but their exact locality is still in doubt. It is probable that in an unaltered condition alkaloids are not to be detected by the microscope. By means of microscopical tests, however, many have been isolated and studied. In many cases the active medicinal principles depend upon alkaloids, as in Morphine, Strychnine, Physostigmine, etc. Many of the alkaloids are highly poisonous, but there are a number that are inert" (p. 122). Nor is the matter simplified by the statement that "the Alkaloids and Glucosides, microscopically, are more of a hope than a reality in practical work" (p. 149).

Remarkable is the author's idea of the cell wall and of lignification. The cell wall "generally consists of a mixed substance called cellulose," but "cellulose which is generally taken as the substance of the typical cell wall is a carbohydrate with the empirical formula $C_6H_{10}O_5$ " (p. 123). "Lignin is a hypothetical substance which gives a number of certain micro-chemical reactions, but its nature is far from being understood" (p. 124). No less remarkable are the constituents which the cell sap may hold in solution; they include "hesperidin, inulin, asparagin, tyrosin, aloin, sugar, mucilage, tannins, alkaloids, glucosides, bitter stuffs, ethereal oils, gums,

resins, rubbers, milky juices, balsams, plant acids, and various crystals" (p. 149). Nor is the author more happy in the properties of the cell wall or the cell contents, for his cellulose turns blue with strong sulphuric acid, and his oxalate of calcium is unaffected by acids. The frequency with which such statements as these occur render it impossible to recommend this section of the work either as a desirable introduction to plant anatomy for elementary students, or as an aid to those who are more advanced.

RÉPERTOIRE DES RÉACTIFS SPÉCIAUX. By F. JEAN and G. MERCIER. Pp. 121. Price 2 francs, or post free 2 fr. 25. (Paris : F. Jean, 17, Faubourg St. Denis, and G. Mercier, 158, Rue Saint Jacques. 1896.)

The authors of this little book have endeavoured to remove the difficulty so often experienced in searching for particulars of the numerous special reagents distinguished generally by the names of their authors. Those who have had occasion to seek vainly for such information in one work of reference after another, will certainly appreciate the goodness of the authors' intention, and ought gladly to respond to the appeal that intimation should be sent of any errors noted in the book. The arrangement adopted is first to give a list in alphabetical order of the materials employed, and under each name a list of the special reagents into the composition of which the substance enters. This is followed by a list of the special reagents, arranged under the authors' names, full details being given regarding their composition, method of preparation, uses, etc. Each page of matter is faced by a blank page for notes, and the book seems likely to be exceedingly useful for reference.

THE PHARMACOPŒIA OF THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK. Second edition. Pp. 53. Price 1s. 6d. (London : J. and A. Churchill, 7, Great Marlborough Street. 1896.)

A work of this sort naturally appeals to but a limited number of people, and it must therefore be gratifying to the compilers that the first addition was sold out within a few months. In the present edition, the various formulæ—for balnea, glycerina, guttæ, haustus filicis, linctus, lotiones, misturæ, oleum acidi carbonici, pigmenta, pilula diuretica, pulveres, solutio cocainæ hydrochloratis, unguenta, vapores, and vinum ferri tartarati—have been carefully revised, and such additions made to them as have been considered expedient. Each prescription is written in English, and the dose regulated for a child six months old. The appendix includes a series of diet tables—milk, broth or beef-tea, fever, fish, and meat diets—suitable for children, the kinds and quantity of the different articles of food being specified for each of the four meals—breakfast at 7 a.m., dinner at 12 noon, tea at 4 p.m., and supper at 6 p.m. In addition there are directions for the preparation of peptonised foods and nutrient enemata, and finally, brief directions for the use of nurses, to enable them to detect albumin and sugar in urine. The book is interleaved, and constitutes a very compact little pharmacopœia.

THE DISEASES OF CHILDREN'S TEETH: THEIR PREVENTION AND TREATMENT. By R. DENISON PEDLEY, M.R.C.S., L.D.S., Eng., F.R.C.S., Edin. Pp. 268, with ninety-nine illustrations. (London : J. P. Segg and Co., 289 and 291, Regent Street, W. 1895.)

Medical practitioners in country districts are frequently called upon to perform for their young patients one or more of the many minor operations in dental surgery, and it is well for their reputation as it is in many cases for the future well-being of the

patient if they possess at least a good elementary knowledge of the subject. Those who are desirous of obtaining such cannot do better than carefully study Mr. Denison Pedley's able work, in which they will find described in simple language the relative and important part that dentition and its pathology play in the causation of many of those ailments which are most common to children.

The work covers a field sufficiently wide to embrace all those cases that are most likely to be met with, and while it does not contain any information that can be strictly called original, it has the great merit of being thoroughly up to date, therefore is equally valuable to the dental student and busy practitioner as the medical man.

The neglect which exists on the part of parents and guardians as to the proper supervision of children's teeth (often so painfully illustrated in after years) is well known to all who are connected with our Dental Hospitals. This is amply exemplified by the author, who quotes some startling and instructive figures culled from his own investigations and other sources. On p. 145 is a table showing that out of 3800 boys and girls in our public schools around London, and who were surrounded by the most favourable conditions, their ages ranging from three to sixteen years, only 828 had teeth that were in a thoroughly sound condition. There were 3187 temporary teeth which required filling among 1786 children, whose ages varied from three to ten years, and no less than 2491 teeth required to be extracted. The permanent teeth were found to be in even a worse condition. These figures demonstrate how much rests with the family doctor in preventing such a sad state of affairs. The author writes:—"The facts mentioned show very clearly that hygiene of the mouth requires some consideration from another point of view, viz., as it affects the community."

A considerable portion of the work is devoted to the important subject of irregularities, their various causes and proper methods of correction. Under the heading "Treatment" the different methods are carefully and plainly described, so that if a physician cannot, through want of previous training, do all that is laid down, he can, at least until the services of a dental surgeon are obtained, greatly mitigate much of the terrible suffering from dental troubles that must at times come under his notice.

The book is well arranged, printed on good paper, and well bound. It contains a large number of excellent illustrations and deals with a subject that it is the duty of every physician to make himself conversant with.

DENTAL MECHANICS. Part II.—THE DENTAL LABORATORY. By HARRY ROSE, L.D.S., pp. 117, with 66 illustrations. (London : J. P. Segg and Co., 289 and 291, Regent Street, W. 1895.)

This is a handy book, dealing with the various departments of the dental laboratory, and has the great merit of being essentially practical. The author explains numerous simple methods of overcoming many of those difficulties which the dental mechanic so frequently meets with. The information is evidently the outcome of Mr. Rose's practical experience, and not obtained from books, nor does he confuse the reader with a lot of unnecessary words, but states in plain language those methods that he has found most expeditious and accurate; no one can read it without more or less profit. Some good hints are given as to fitting up a workroom—how to work with economy, and the proper use of tools, which dentists would do well to place before their students. Some valuable advice is given about taking impressions, and how to overcome the various difficulties met with, also simple devices are described for good models of undercut cases. The book is well illustrated, clearly printed, and the matter carefully arranged.

PHARMACEUTICAL SOCIETY

EXAMINATIONS IN LONDON.

April, 1896.

MAJOR EXAMINATION—PASS LIST.

Candidates examined.....	25
„ failed.....	13
„ passed.....	12

Barritt, Wesley.	Martin, John Woolcock.
Beachell, John.	Playfoot, Frederic Hubert.
Blunt, Henry Rowland.	Smedley, Walter Graham.
Bridges, Herbert.	Williams, John (of Bagillt).
Elwell, Frederick Budd.	Willson, Robert Wherry.
Howard, Alfred.	Wright, Frederick.

EXAMINATIONS IN EDINBURGH.

April 1, 1896.

MAJOR EXAMINATION—PASS LIST.

Candidates examined.....	5
„ failed.....	3
„ passed.....	2

Crombie, James. | Wilson, Thomas.

“FIRST” EXAMINATION QUESTIONS.

April 14, 1896.

LATIN.

Time allowed—from 11 a.m. to 12.30 p.m.

I. For all Candidates. Translate into Latin:—

- The soldiers were fighting very bravely.
- Both the daughter and the sister will be praised by the queen.
- We cannot defend ourselves and our property from them.
- What business have you here?
- The book which we are reading has not yet been sold.

II. Translate into English either A (Caesar) or B (Virgil).

(Candidates must not attempt both authors.)

A.—CAESAR.

1. Cognito Caesaris adventu, Ariovistus legatos ad eum mittit: Quod antea de colloquio postulasset, id per se fieri licere, quoniam propius accessisset; sequi il sine periculo facere posse existimare. Non respuit conditionem Caesar, jamque eum ad sanitatem reverti arbitrabatur, quum il, quod antea petenti denegasset, ultro polliceretur; magnamque in spem veniebat, pro suis tantis; opulique Romani in eum beneficiis, cognitis suis postulatis, fore uti pertinacia desisteret.

2. Hoc proelio trans Rhenum nuntiato, Suevi, qui ad ripas Rheni venerant, demum reverti coeperunt; quos Ubii, qui proximi Rhenum incolunt, perterritos insecuti, magnum ex his numerum, occiderunt. Caesar, una aestate, duobus maximis bellis confectis, maturius pau'o, quam tempus anni postulabat, in hiberna in Sequanos exercitum deduxit: hibernis Labienum praeposuit; ipse in citeriorem Galliam ad conventus agendos profectus est.

Grammatical Questions.

(For those only who take Caesar.)

- Give the gender and the genitive case singular of all the substantives in Paragraph 1.
- Give the third person singular of the subjunctive present and pluperfect, and the present participle, of all the verbs in Paragraph 2.
- Parse fully:—*Ipsa in citeriorem Galliam ad conventus agendos profectus est.* (Paragraph 2.)
- How do you express in Latin (i.) *purpose*, (ii.) *value*?

B.—VIRGIL.

- Lucus in urbe fuit media, laetissimus umbrae;
Quo primum jactati undis et turbine Poeni
Effodere loco signum, quod regia Juno
Monstrarat, caput acris equi: sic nam fore bello
Egregiam, et facilem victu per secula gentem.
Hic templum Junoni ingens Sidonia Dido
Condebat, donis opulentum et numine Divae;
Aerea cui gradibus surgebant limina, nexaque
Aere trabes, foribus cardo stridebat aenis.
- “Quassatam ventis liceat subducere classem,
Et silvis aptare trabes, et stringere remos.
Si datur Italiam, sociis et rege recepto,
Tendere, ut Italiam laeti Latiumque petamus:
Sin absumpta salus, et te pater optime Teucrum,
Pontus habet Libyae, nec spes jam restat Iuli;
At freta Sicaniae, saltem sedesque paratas,
Unde huc advecti, regemque petamus Aecesten.”

Grammatical Questions.

(For those only who take Virgil.)

- Give the gender and the genitive case singular of all the substantives in Passage 2.
- Give the third person singular of the subjunctive present and pluperfect, and the present participle, of all the verbs in Passage 1.
- Parse fully:—
Lucus in urbe fuit media, laetissimus umbrae. (Pas. 1.)
- How do you express in Latin (i.) *purpose*, (ii.) *value*?

ARITHMETIC.

Time allowed—from 12.30 p.m. to 2 p.m.

[The working of these questions, as well as the answers, must be written out in full.]

- Find the value of a gold vase weighing 740 oz. 12 dwt. 12 gr., at £4 4s. 6d. per oz.
 - After walking $4\frac{1}{2}$ miles, a man has accomplished $\frac{2\frac{1}{2}-1\frac{1}{3}}$ of $2\frac{1}{4}+1\frac{1}{5}$ of $\frac{3}{11}+\frac{1}{2}$ of his journey. How many miles has he still to walk?
 - If 4 ozs. of tea cost 5625s., what is the value of 15625 cwt.?
 - If 12 men can dig a trench 40 yards long and 4 ft. wide in 10 days of 8 hours each, how many hours a day must 55 men work in order to dig a trench of the same depth, 220 yds. long and 5 ft. wide, in 18 days?
 - Find the difference between—
£216 + 48 of a shilling and £216 + 48 of a shilling.
 - By selling goods for £225 10s., I gain 12½ per cent. What shall I gain or lose per cent. by selling the same goods for £187 10s.?
- The following question must be attempted by every candidate:—
- A bath contained 4.55 hectolitres; then a tap was turned on which let 32 litres per minute run into the bath. How many gallons (*approximately*) were in it at the end of two hours and a half?

ENGLISH.

Time allowed—from 3 p.m. to 4.30 p.m.

- State the grammatical difference between (i.) *rise* and *raise*, (ii.) *lie* and *lay*, and illustrate their use by examples. Give the past tense (3rd person singular) and perfect participle of these four verbs.
 - Parse fully:—“Let merry England proudly rear her blended roses.”
 - Analyse:—“He inferred from this that the opinion of the judge was that the prisoner was guilty.”
 - In the following passage supply the necessary capital letters, and put in the stops and inverted commas where necessary:—in January Miss Allcard took that step her period of postulancy was an unusually short one and she has told us herself how that came to be I asked her during the three months had you been considering the duties you were to take upon yourself and she said yes I asked why she was admitted so soon and her answer was partly because I wished it then I asked what reason did you give for wishing to be admitted so soon and her reply was I was infatuated with the work
- The following question must be attempted by every candidate:—
- Write a short composition on *one* of the following subjects:—
(i.) Life in the country.
(ii.) Thrift.
(iii.) Arbitration in international disputes.
(iv.) “Absence of occupation is not rest,
A mind quite vacant is a mind distressed.”

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, APRIL 18, 1896.

THE SALE OF DRUGS IN ANCIENT TIMES.

It will doubtless be news to most of our readers that the sale of drugs and poisons in Glasgow, as well as the practice of medicine, was carefully restricted and regulated nearly two hundred and seventy years before the passing of the Pharmacy Act, 1868. Yet such was really the case, evidence to this effect being afforded by the text of certain documents included in the 'Memorials of the Faculty of Physicians and Surgeons of Glasgow, 1599-1850,' recently published by Mr. ALEXANDER DUNCAN, the Secretary and Librarian of the Faculty. Under the terms of a charter granted to the Faculty by King James VI., and dated November, 1599, visitors were appointed and they were given

Full power to call, summond, and convene before thame, within the said burgh of Glasgow, or onie otheris of our said burrowis, or publict places of the foirsa ds boundis, all personis professing or using the said airt of Chirurgie, to examine thame upon thair literature, knowledge and practize; gif they be fund wordie, to admit, allow, and approve thame, give them testimonial according to the airt and knowledge that they sal be fund wordie to exercise thareftir, resave thair aithis, and authorize thame as accordis, and to discharge thame to use onie farder nor they have knowledge passing their capacity, laist our subjectis be abusit.

It was further provided by "James, be the Grace of God, King of Scottis," in his fatherly solicitude for his subjects, that

The saidis visitouris sall visit everic hurt, murtherit, poison't, or onie ither persoun tane awa extraordinarily, and to report to the Magistrate of the fact as it is.

The visitors were also empowered, with the advice of their brethren, to make regulations for the common weal anent the art of surgery, and to inflict punishment upon those infringing them. With regard to the sale of drugs, it was provided that—

Na manir of personis sell onie droggis within the Citie of Glasgow, except the sam be schtitt be the saidis visitouris, and be William Spang, apothecar, under the pane of confiscatioune of the droggis.

The responsibility of the seller is clearly defined in a clause which further stipulates that—

Nane sell retoun poison, asenick, or sublemate, under the pane of ane hundred merkis, excep onlie the apothecaries quha sall be bund to take caution of the byaris, for coist, skaith, and damage.

These powers were confirmed by Charles, "King of Great

Britain, France, and Ireland," in "General Signet Letters, the Surgeons of Glasgow *against* the Magistrates, and all and sundry," dated July 31 and signeted August 14, 1635, whilst King James' Charter to the Faculty of Physicians and Surgeons was ratified on September 11, 1672, by Charles II. —"OUR SOVERANE LORD, with advice and consent of his Estates of Parliament," in the following terms:—

It shall not be leisum to any maner of persons within the foresaids bounds, to exercise medicine, without ane testimoniell of ane famous universitie, wher medicine is taught, or at leist the persons above mentioned ["the chirurgians and professors of medicine within the city of Glasgow for the tyme"], and their successors, under the pains contained in the said Gift; and that no maner of persons sell any drogs within the citie of Glasgow, except they be sighted be the foresaids persons, under the paine of confiscation of the drogs; and that no ratton poyson be sold, except by the apothecaries, who shall be bund to tako caution of the buyers, for coast, skaith, and damage.

An Act for better regulating the privileges of the Faculty of Physicians and Surgeons of Glasgow and amending their charter of incorporation was passed on June 10, 1850. The only powers possessed under the charter, which are quoted in that Act, are those whereby the Faculty was entitled to examine all persons practising surgery within the city of Glasgow, and the Counties of Lanark, Renfrew, Dumbarton, and Ayr; to admit and grant licences to such of those persons as they should find qualified; and to debar all others from exercising the profession of surgery within the specified limits. Nothing whatever is stated regarding the regulation and restriction of the sale of drugs and poisons, which had doubtless by this time ceased to be regarded as functions of the Faculty of Physicians and Surgeons. In view, however, of the fact that the passages in the Charter bearing on the subject do not appear to have been revoked, it is probable that the peculiar powers conferred by the document still remain, though latent.

The "sighting," or inspection of drugs sold in the shops, was rendered necessary by the frequent insufficiency of the druggists' stock and the lack of potency of some of his preparations. A Minute quoted by Mr. DUNCAN reads as follows:—

Because ther ar sundrie who sells drogs wthin this burgh and hes not sufficient drogs. (Minute, January 28, 1612.)

The sophistication of drugs appears to have been, at the time referred to, an unknown art. The "WILLIAM SPANG, apothecar," mentioned in the charter as an inspector of drugs, is said to have been a burgher of note. The development of the class to which he belonged was not the same in Scotland as in England, where the apothecaries ultimately became a corporate body with power to license both as regards the preparation and administration of drugs. In the northern kingdom the surgeon and apothecary were often united in the same individual, known as a chirurgion-apothecary. It often happened, however, that choice or necessity led some individuals to limit themselves to the duties of pharmacists only, and the appointment of WILLIAM SPANG, who was included in that category, to assist the visitors would seem to indicate that his services were required as a specialist and expert. He was in practice in Glasgow as a pharmacist as early as 1574, but was at the same time a member of the Faculty of Physicians and Surgeons of that city.

The founder of the Faculty was PETER LOWE, a fine portrait of whom graces the 'Memorials.' Other notable members were WILLIAM CULLEN, professor of chemistry and medicine in the University of Glasgow; JOSEPH BLACK, the

discoverer of carbonic acid, and exponent of the doctrine of latent heat, who succeeded CULLEN; WILLIAM IRVINE, who studied under and assisted BLACK, and subsequently became lecturer on materia medica and chemistry; and THOMAS CHARLES HOPE, F.R.S., who succeeded Dr. BLACK as professor of chemistry in the University of Edinburgh, The name of ANDREW URE, author of the 'Dictionary of Chemistry,' also appears on the roll of members, together with that of THOMAS THOMSON, the famous chemist and editor of the third edition of the 'Encyclopædia Britannica.' THOMAS GRAHAM, F.R.S., Master of the Mint, who will ever be remembered for his work in connection with the diffusion of gases, entered in 1830. Later additions to the roll are the names of WILLIAM DAWSON HOOKER, the son of Sir WILLIAM JACKSON HOOKER; JOHN D. MUTER, father of the late editor of the *Analyst*, and JOHN ALEXANDER EASTON, professor of materia medica in Anderson's University, who devised the preparation so widely known as "Easton's Syrup." It is noteworthy that the calling of those who were admitted members of the Faculty is variously stated in different cases, the list including physicians, surgeons, apothecaries, pharmacians, barbers, and apprentices. But in addition to these, "all of whom may be regarded as regularly qualified practitioners of the period, there was a motley array of nondescripts, many of them specialists of a kind, nearly all of them very ignorant, who swarmed all over the country."

SHOPS (EARLY CLOSING) BILL.

THE opposition to this Bill has not been destroyed by the heavy defeat inflicted in Grand Committee, and there is reason to believe that a strong effort will be made to prevent the passage of the measure in its present form. As a matter of fact, the Shops Bill is in danger of being killed by the criticisms of too candid friends. Over two pages of amendments stand on the notice paper to testify to the desire of metropolitan and other members to bring the Bill a little nearer perfection, hence the third reading is likely to be still in the future. In the present state of public business, with those Government embodiments of controversy—the Irish Land Bill and the Education Bill—blocking the way, there is very little opportunity for discussing a private member's Bill, especially if it is opposed. It will be a matter for surprise therefore to many persons if the Shops (Early Closing) Bill passes from the House of Commons to "another place" for some time to come. The consideration of the Standing Committee's amendments was to have taken place on Wednesday last, but Irish Boards of Guardians and other vexed questions of Irish local Government were the responsible causes of a very discouraging postponement until June 10. Clause 9, or, as it may be termed, the chemists' clause (*ante*, p. 212), has again attracted the attention of Mr. BANBURY (Peckham), who has notified his intention of moving for its deletion, and the removal of all registered chemists from the operation of the Bill. Mr. MILBANK (Radnor) desires to insert after the word "druggist," in line 1 of the clause, the words "herbalists or vendors of patent medicines." There is reason to believe that Mr. BANBURY'S action is dictated by a conviction that a person standing in so important a relation to the public as a duly qualified chemist, ought not, in the public interest, to be placed under legal restriction such as the Bill seeks to impose.

ANNOTATIONS.

A VALUABLE DISINFECTANT!—A powder laying claim to the possession of powerful disinfecting properties has recently been analysed by Don Gabriel de la Puerta in the Spanish Revenue laboratories, and proves to be nothing but finely crystallised sulphate of magnesia, containing a little menthol, and coloured with carmine. This precious product goes by the name of Chabanel's Disinfectant.

ADULTERATION OF CODEINE.—A Monsieur Etiévant, of Lyon, has come across a new and rather ingenious adulterant of codeine, viz., sugar candy, whose crystals resemble those of codeine very closely. Fehling's solution soon detects the sophistication, whilst the spectroscope shows the dextrogyre rotation of the sugar candy. Codeine should be lævograte.

A NOVEL APPLICATION OF PHOSPHORUS.—An American contemporary states that the Cuban insurgents have adopted a method of firing sugar plantations which is distinctly novel. A small piece of phosphorus coated with wax is fastened to a snake's tail, and the reptile let loose to make its way among the canes. The sun melts the wax, ignites the phosphorus, and the business is done.

QUASSIA AFRICANA has been submitted by Dr. L. Claudel to a careful histological, chemical, and therapeutical investigation. According to the *Annales de l'Institut Colonial de Marseille*, he finds that this species, which is used as a tonic by the natives of the Congo and the Gaboon, is almost identical in structure, and entirely similar from a morphological point of view, with the American species *Q. amara*, thus adding another to the large number of plants that seem to connect the tropical floras of America and Western Africa. Dr. Claudel has also found in the plant a bitter principle which seems to be identical with quassin in its chemical characters and therapeutic properties. A plant very similar to *Quassia africana*, but evidently belonging to the Sapindaceæ, is found in the same countries in Africa, and is described by Dr. Claudel under the name of *Pancovia heckeli*. It is, however, easily distinguished when growing by bearing tendrils towards the apex of the branches. M. Schlagdenhauffen has ascertained that it does not possess any principle available for therapeutic uses.

A NEW METHOD OF PREPARING SERUM AGAR-AGAR.—Drs. Kanthack and Stephens suggest in the *Lancet* the utilisation of pathological serum, such as ascitic, pleuritic, and hydrocele fluids, of which there is always a large supply at a hospital, for the preparation of the serum agar-agar culture medium for the separation of the typical diphtheria bacilli. The following method gives a beautifully clear and transparent medium in less than half an hour. To every 100 C.c. of serous exudation, 2 C.c. of 10 per cent. caustic potash is added; 1.5 to 2 per cent. of agar-agar previously soaked in acidulated water is next added. The mixture is then boiled in a Koch's steamer until the agar is dissolved, after which it is filtered through a hot-water funnel, and 4 or 5 per cent. of glycerin added to the filtrate. The medium is now ready for sterilising in test-tubes in the ordinary way. Sometimes the serous fluid is very rich in albumin. Before adding the potash a little should, therefore, be boiled in a test-tube; if it become practically solid or contain a large excess of albumin, it should be diluted with at least twice its bulk of distilled water.

THE PHARMACEUTICAL SOCIETY'S HERBARIUM.—The whole of the large collection of medicinal plants in this herbarium is now rendered available for reference by the publication of a special catalogue of those plants. A separate catalogue already exists for the plants in the "Daniel Hanbury Herbarium," and a large number of specimens received since the present catalogue was completed are enumerated in the recently published 'Museum Report for 1893-4.' To obviate the necessity of searching three indices, therefore, the curator, Mr. E. M. Holmes, has compiled an index in which the whole of the botanical names appear, together with references to the particular catalogue in which each name appears. This general index is bound up with the new catalogue, and may be regarded as a complete record of the medicinal plants in the Pharmaceutical Society's Herbarium up to the date of publication.

'SCIENCE PROGRESS' for April has for one of its most important articles Part I. of a disquisition by G. C. Bourne, M.A., of New College, Oxford, on the present position of the cell-theory. A few years ago, as he remarks, a discussion of the cell-theory would have seemed superfluous. To-day, however, adverse criticism and increase of knowledge respecting cell structure have led to the acknowledgment of the advantage and even the necessity of such a discussion. The cell-theory is, therefore, examined in the light of recent criticisms and researches. An equally important, and perhaps more directly useful, article is that by A. G. Tansley, B.A., on the stellar theory. The history is given of this theory, which is also criticised, and a perusal of the article should prove of value to botanists who are yet in doubt as to the exact bearings of the theory. Professor James Walker, of Dundee, treats of solid solutions, or mixed solids which seem to partake of the nature of solutions, as in the case of mixed crystals of potash and ammonia alums. The theory of solid solutions has been applied with success to many processes, but the author is disinclined to agree with Witt that the state of dye-stuff in fibres can be fully explained by that theory. Captain Ettrick W. Creak, R.N., contributes an article on the general bearings of magnetic observations, and Dr. E. H. Starling concludes his paper on some applications of the theory of osmotic pressures to physiological problems.

OPIUM IN PERSIA.—The cultivation of opium in Kennan, Persia, increased to an enormous extent during 1894-95 (*vide* Foreign Office Report, Annual Series, No. 1671), and there was also a considerable rise in price. In this district opium for export is dried in the sun, then rubbed with an instrument until quite clear, and packed in paper or poppy-stalks, in lumps resembling a quince in shape and weighing a little over one pound each. It is mainly purchased by merchants of Yezd (see *ante*, p. 173) for the China market. The amount produced is estimated at 12,000 mâns (a mân = $6\frac{1}{2}$ lbs.). Of this, 900 mâns was exported to Yezd, where it is more carefully prepared and then re-exported to India for Hong-Kong, 2500 mâns being consumed locally and 500 mâns exported direct to India. The habit of opium smoking is said to be greatly on the increase in South-Eastern Persia, women especially indulging in the narcotic.

THE PHARMACEUTICAL SOCIETY'S SUBSCRIPTIONS.—Members, associates, and students of the Pharmaceutical Society are reminded that Thursday, April 30, is the latest day upon which the current year's subscription can be received by the Secretary and Registrar, Mr. Richard Bremridge, 17, Bloomsbury Square, W.C.

CHEMISTS AND THE SHOPS (EARLY CLOSING) BILL.—The total number of correspondents who have so far sent expressions of opinion with regard to the Shops (Early Closing) Bill is 22. Of these, 16 are in favour of the Bill becoming law, whilst 6 are opposed to the principle it embodies. A great deal of vigour has been displayed by most of those who have sent letters on the subject, especially the supporters of the Bill, but it cannot be said that the above figures indicate the existence of much anxiety on either side.

CASES FOR BINDING THE JOURNAL.—In response to several inquiries, arrangements have been made by the publishers of the Journal to supply cloth cases, gilt-lettered, for binding the numbers for the half year (one volume), at 1s. 6d. each, post free. Applications should be addressed *Pharmaceutical Journal* Office, 5, Serle Street, Lincoln's Inn Fields, W.C., where reading covers to hold twenty-six numbers of the Journal can also be obtained, in accordance with the notice on page 320.

INTERNATIONAL PHARMACEUTICAL EXHIBITION AT PRAGUE.—Attention has already been directed to the fact that the second international pharmaceutical exhibition will be held at Prague from August 15 to September 15 next (*ante*, pp. 33, 112, and 273). We have now received from the Under Secretary of State for the Home Department a programme of the exhibition, forwarded by request of the Austrian Ambassador. Information with reference to the exhibition, and the facilities afforded to intending exhibitors, will be supplied by Dr. K. Fragner, Apotheker, of Prague, President of the Executive Committee.

THE WINE TRADE OF FRANCE.—During 1894-95 there was a considerable decline in the yield of wine in the Bordeaux and other wine districts of France, and as a result the importations of foreign wines increased, the increase being most marked in the case of Spain and Algeria, and especially the latter, as the following figures show:—

Export countries.	Annual importations in gallons.		
	1893.	1894.	1895.
Spain	16,274,742	11,574,112	17,436,186
Algeria	4,439,996	4,815,360	8,696,930
Italy ..	639,870	245,938	106,436
Portugal	32,142	21,164	25,256
Other countries ...	1,322,288	245,608	1,072,456
Total...	22,709,038	16,902,182	27,337,264

These foreign wines are, of course, used for blending with the lighter and less expensive wines of France. The large increase in the importations of Algerian wines is attributed to the annually increasing production in Algeria, and the greater care now bestowed in that country upon vinification.

THE RÖNTGEN RAYS AND BACTERIA.—According to the daily press the latest application of the now ubiquitous x -rays is as a bactericide. Professors Pratt, Wrightman, and Bennett, of the Medical College, Chicago, are said to claim that they are able to kill the bacteria of anthrax, cholera, diphtheria, glanders, influenza, pneumonia, typhoid, and tuberculosis by the action of the rays. Whether, however, this statement represents sober fact or the "tall imaginings" of the Yankee seeker after marvels yet remains to be seen.

PROCEEDINGS OF SOCIETIES.

Brighton Junior Association of Pharmacy, April 8.—Mr. T. F. Grindley, President, in the chair.—At this general meeting the decision was given regarding the best two essays on the "History of Dispensing," for which prizes were offered. 1st, a guinea's worth of books, by Mr. W. H. Gibson; 2nd, Cripp's 'Galenic Pharmacy,' by the author. Mr. A. H. Price was awarded first, Mr. A. H. Cupit second. Mr. C. S. Ashton acted as scrutineer. The officers elected for ensuing session are Mr. A. T. Jeeves, President; Mr. G. B. Savage, Vice-President; Mr. C. A. Blamey, Hon. Secretary; and Mr. A. H. Cupit, Hon. Treasurer. Committee: Messrs. Yates, Beckwith, Biffin, Davies, Armour, and Kent. Votes of thanks were passed to the retiring officers, Messrs. Grindley, Gosling, and Cupit. This brings to a close the work of a most successful and well-attended session. At a previous social evening, Mr. W. H. Gibson presiding, a handsome smoking cabinet, subscribed for by members and friends, was given to Mr. A. E. Colman, an ex-president and secretary. The Chairman made the presentation, accompanying it with some well-chosen remarks concerning the recipient's long connection with the Society. Messrs. Yates and Jeeves, also old members, spoke in eulogistic terms of Mr. Colman's good services and popularity, to which the latter appropriately responded.

Linnean Society of London, April 2.—Mr. J. G. Baker, F.R.S., Vice-President, in the chair.—On behalf of Dr. F. Arnold, of Munich, the Secretary exhibited several photographs of typical lichens, received in continuation of a series which has been for some time past in course of issue by that well-known lichenologist. Mr. M. F. Woodward exhibited a very young example of the "Spiny Ant-eater," *Echidna aculeata*, taken from the mammary pouch of the parent at Newcastle, Western Australia, by Mr. H. B. Woodward, Curator of the Perth Museum. It was intermediate in size between the two stages described by Prof. Parker, but showed no trace of the calcaneal spur characteristic of the male, nor any trace of the mammary pouch peculiar to the female. He called attention to the flattened and beak-like appearance of the snout and the vestiges of the "egg-breaker," and to the disposition of the spine papillæ. For the purpose of comparison Mr. Woodward exhibited also the heads of *Ornithorhynchus* and *Echidna*, and a male and female mammary fœtus of *Perameles*.

A paper was read by Mr. C. H. Wright, "On the Genus *Stemona*, Lour.," one of the few monocotyledonous genera whose flowers are constructed on a tetramerous type, and remarkable for the diversity of its vegetative characters, while its floral structure varies between comparatively narrow limits. In habit, the plants of this genus are generally climbers, but *S. sessilifolia*, Miq., and *S. erecta*, C. H. Wright, are exceptions. The leaves, whose primary veins are connected by very numerous approximate transverse ones, can be either alternate, opposite, or whorled, and in a few cases their petioles are adnate to the peduncles. The most remarkable structure in the flower is the stamen, in which a broad connective, surmounting a very short filament, is produced on the inner side into a feel completely separating the anther-cells, and also prolonged for a considerable distance above their apex. The pollen of each cell is united into mass connected with that of the other cell by an appendage resting upon the top of the keel. Of the twelve species enumerated by Mr. Wright as concentrated in Eastern Asia, two of them extend to North Australia. The paper was commented on by Mr. J. G. Baker.

Lieut.-Col. C. T. Bingham, in a paper on some exotic fossorial hymenoptera in the British Museum (communicated on his behalf by Mr. W. F. Kirby), enumerated thirty-four species, of which no less than thirty were previously undescribed. The discovery of many of these was due to the researches of the author, who had spent twelve years collecting in Sikhim, Burma, and Tenasserim. In the arrangement of the *Pompilidæ*, a confessedly difficult group of fossoreia, he had adopted the classification proposed by Professor Kohl, of Vienna, but he was of opinion that a thoroughly satisfactory classification had yet to be devised. A new genus, *Paragenia*, was proposed for an insect, described originally from Borneo, but which he had found also in Burma and Tenasserim, possessing the characters of both *Agania* and *Macromeris*, resembling the former in neuration and in habits, and the latter in the conspicuous development of the coxæ and femora, especially in the male.

The President then gave a descriptive account of the Khasia Hills from personal experience, dwelling on their geological formation,

the extraordinary rainfall of the district (120 inches in five days), and the chief characteristic feature of the flora and fauna. His remarks were illustrated by a number of lantern slides, several of which had been prepared from photographs taken by himself, and others from sketches made by Sir Joseph Hooker. Some additional remarks were made by Col. Sir Henry Collett, K.C.B., from experience gained during two years' residence whilst commanding the British forces in that part of India.

Midland Chemists' Assistants' Association, April 8.—Mr. T. C. Clarke, President, in the chair.—Mr. F. H. Alcock, F.I.C., read a paper on volumetric analysis, in which he dealt more particularly with the B.P. test solutions, and the paper was illustrated by practical demonstrations throughout.

Cambridge Pharmaceutical Association, April 10.—Mr. Alderman Deck in the chair. Mr. E. Saville Peck gave an account of a "Holiday Ramble in Switzerland." The lecture was illustrated by means of lime-light views reproduced from photographs mostly taken during the trip. A short stay in Paris was filled up by visits to some of the most important places of interest, such as Notre Dame, the Louvre, and La Sainte Chapelle. The journey to Zermatt was taken *via* Lausanne, the Lake of Geneva, Montreux, Chillon, with a fine view of the Deut du Midi, Martigny, and Visp, and then up the Zermatt Valley. Here a fine view of the Matterhorn was given, about which many a thrilling story of some perilous venture has been told again and again. From the Gorner Grat views were shown of some of the peaks which form the remarkable panorama of snow-covered mountains visible from that point, such as Monte Rosa, the Breithorn, Weishorn and Dôm. Saas Fêe, with its amphitheatre of glaciers and rocky summits, was shown, together with that of the Allalinhorn, 13,235 feet high, which Mr. Peck climbed with two friends in the early summer of last year. The ascent of the Weissmies, 13,225 feet, was also narrated amongst others. The view taken from the Matterhorn Lake of the Schwarzee Chapel, with the Rothhorn and Gabelhorn as a background, was much appreciated, and his experience at the summit of the latter during a storm was listened to with much keenness. The return journey was taken *via* the Rhone Glacier, St. Gothard Pass, with the Devil's Bridge, Goeschenen and Lucerne. After several questions had been put and answered by Mr. Peck, the Chairman moved a hearty vote of thanks, which was seconded by Mr. A. Ivatt, M.A., and carried. Mr. Peck, after responding, moved a vote of thanks to Mr. Hayles for so ably working the lantern, and to Mr. S. F. Barker, the Assistant Secretary, for all the help he had rendered during the session. This was seconded by the President, and after a few interesting scientific slides were exhibited by Mr. Hayles, a very enjoyable evening was brought to a close.

LEGAL INTELLIGENCE.

FATAL DOSE OF SULPHONAL.—An adjourned inquiry into the cause of the death of Mr. John Dillon, aged 69, chemist's traveller, of Sheffield, was held at the Royal Infirmary, Newcastle, where he died on April 6. While at Newcastle on business the deceased was taken ill, and was removed in an unconscious state to the above institution. His friends thought he had died from an overdose of chloral taken to induce sleep, but the medical men did not quite concur, and a post-mortem was made. Extensive disease of the kidneys and lungs was found, but death was due to an overdose of sulphonal tabloids, which in deceased's unhealthy state had acted powerfully upon him. Had he been a sound man he might have thrown off the effects of the tabloids.—The Coroner said no doubt he had been a great sufferer and had taken the tabloids to obtain sleep. There was no reason to suppose that the deceased had taken his life intentionally, and a verdict in accordance with the evidence of the medical men was adopted.

CHARGE OF OBTAINING DRUGS BY FALSE PRETENCES.—At the Mansion House, George Thomas Millership,* 42, dispenser, was charged on remand before Alderman Sir Stuart Knill with obtaining drugs by false pretences from Messrs. Baiss Brothers and Co., wholesale druggists, Jewry Street, Aldgate. The prisoner was now further charged with obtaining and attempting to obtain drugs by false pretences from Messrs. Burgoyne, Burbidges,

* This name does not appear on the Register of Chemists and Druggists for 1896.

and Co., wholesale druggists, Colman Street.—Mr. Humphreys, solicitor, conducted the prosecution. It was alleged that the prisoner, representing himself to be Dr. Miller, wrote to Messrs. Baiss Brothers and Co., and to Messrs. Burgoyne, Burbidges, and Co., requesting them to forward some drugs to an address which he gave. The drugs were sent to the address given, but the prisoner did not pay for them. It was alleged that the prisoner, in the name of Millership, subsequently attempted, by similar false pretences, to obtain other drugs from Messrs. Burgoyne, Burbidges, and Co., but the drugs were not sent to him.—Alderman Sir Stuart Knill committed the prisoner for trial.—*Times*.

PARLIAMENTARY INTELLIGENCE.

PROPOSED SIMPLIFICATION OF PROCEDURE.—If Sir A. Rollit has his way the procedure for parliamentary Bills will be considerably simplified in future. He proposes that every Bill shall, after its second reading, stand committed to a Committee of the whole House of Commons, unless before such second reading a motion is made for the committal of the Bill to a Grand or a Select Committee. Sir Albert further provides against obstruction by proposing that any motion for committal to a Grand or a Select Committee shall be put from the Chair without amendment, notwithstanding that the time for the interruption of public business may have passed.

THE FOOD ADULTERATION COMMITTEE has completed its labours so far as taking oral evidence is concerned, and will devote the remainder of its meetings chiefly to the consideration of its report. If that report be a reflection of the evidence tendered to the present Committee and that accumulated by its predecessor, one may look for a wide alteration in the adulteration laws being recommended. The Committee has been made fully acquainted with the pharmaceutical view of the existing Sale of Food and Drugs Act.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND'S EXAMINATIONS.—*Preliminary.*—The following have passed: Messrs. (S. Browne and A. Wilson, equal), W. J. Burke, F. B. Angley, M. J. Cogan, J. T. Dwyer (R. Prior and G. Wilson, equal), R. L. M. Boyd, A. Hogan, J. W. Burns, E. A. Reilly, P. M. Nugent, A. V. Flynn, and S. Hill. Ten candidates were rejected. *Pharmaceutical Licence.*—The following have passed: Messrs. J. W. McClean, A. Gibson, R. J. Savage, F. H. R. Brady, J. G. W. Boggs, J. Ritchie, J. Horgan, T. O'Sullivan, and R. Barron. Twelve candidates were rejected. *Examination for Registered Druggist Licence.*—The following have passed: Messrs. J. H. Bowden, J. E. Cooper, R. C. Dorman, R. Hall. One candidate was rejected. Mr. J. H. Bowden has also passed the Pharmaceutical Assistants' Examination.

PHARMACEUTICAL CHEMISTS' AND APOTHECARIES' ASSISTANTS' ASSOCIATION OF IRELAND, April 10.—Mr. James B. Alister, M.P.S.I., President, in the chair.—There was a good representative attendance. Some routine business having been transacted and Mr. Alfred H. Barnes, Charlemont Street, elected to membership, a paper on "Camellia Thea" was read by Mr. D. O'Sullivan, L.P.S.I. The reader said *Camellia thea* or *Thea chinensis* was classed by botanists in the natural order Camelliaceæ, or, more correctly, Ternstroemiaceæ. He passed over the tea plant in its dry state and described its chief botanical characteristics, including the nerves, veins, and midribs of the leaf and its flowers and fruit. The history of the tea plant was buried in antiquity. The Chinese ascribed the original discovery of the beverage to a monkey, not a flattering thought to the pharmacist that an ape infused decoctions centuries before pharmacy or the B.P. existed. The essayist quoted Confucius (550 B.C.) and Yo Lu, who flourished in the Tang dynasty (618 to 906 A.D.), on the antiquity of tea, which was even then subject to taxation. It was known to the Arabs in the ninth century, and the leaf was cultivated by the Japs a century later. Its appearance in Europe was only made in the year 1610, when a Dutch merchant introduced the first sample. Half a century later the presentation of a few ounces of the leaf was considered worthy of

acceptance by Catherine, wife of Charles II. At that time tea was known as "chaw," and in 1660 its selling price ranged from 15s. to 60s. per lb., according to quality. In 1666 the import of tea was under 100 lbs. per annum, and in 1745 the figures had run up 730,000 lbs. At present the consumption of tea in the British Islands was over 91 million pounds yearly, or an average of 5.33 lbs. per head. Mr. O'Sullivan referred to the growth of the plant and mentioned the chief varieties thereof; he discriminated between green and black tea, commented on the nomenclature of the plant in various growing centres, and described in an entertaining manner the process of picking the leaves, drying, and preparing them for export. The constituents of tea consisted chiefly of an alkaloid caffeine or theine, and it was the presence in the leaf of an essential oil which imparted the aroma. Tannin to about 26 and 15 per cent. was present in green and black tea respectively. Albumin and dextrin were found in variable quantities in tea, besides chlorophyll and cellulose, which formed the structural composition of plants. The effect of tea-drinking was next referred to, and its action on the cerebral organs dwelt upon. Green tea caused giddiness, and acted as a most powerful stimulant. The effect of the alkaloid of tea was similar to that produced by strychnine. The action of caffeine on frogs was deadly. The imbibing of tanninated tea caused anæmia, and this wide-spread evil might be checked if only the public paid a little attention to the proper infusing of tea. A graphic description of tea-making all over the world was given by the speaker. In Western Siberia tea was both food and drink, the spent leaves being mixed with fat and eaten by the inhabitants. England compared unfavourably with other nations in regard to tea-making, the pernicious habit of "stewing" the leaves being deeply rooted. The use of tea interfered with the gastric juice and prevented the proper digestion of fresh meat, the tannin hardening the soft fibres and lessening its nutritive qualities. Mr. O'Sullivan showed by the following table the results obtained by long and short infusion of the leaves:—

	5 minutes' infusion.	10 minutes' infusion.	20 minutes' infusion.	40 minutes' infusion.
	Per cent.	Per cent.	Per cent.	Per cent.
Extractive matter by water	21.78	25.35	26.81	28.14
Theine	1.11	1.30	1.16	—
Tannin	6.85	8.52	11.73	16.32
Nitrogenous matter...	1.11	1.16	1.11	1.04
Ash.....	3.52	4.09	4.15	4.48

This table shows how prejudicial it is to allow tea to stand longer than ten minutes at the furthest; the caffeine or theine would lessen or disappear altogether if allowed to "stew," and the tannin would proportionately increase. The essayist spoke of the "doctoring" of tea by means of inferior leaves which were artificially scented by dried flowers of the sweet-scented olive (*Olea fragrans*). 500 millions of people used the teapot as a "household god," and greatly outnumbered the worshippers at the shrine of Bacchus. Exhaustive statistics in connection were given, and the use by the Indians of *Ilex paraguayensis* or Brazilian holly, called Paraguay tea or "maté," referred to. The Creoles of Central America drink this "maté" at every meal and chew the leaves in between. Mr. O'Sullivan concluded his paper by briefly alluding to the myrtle tea of the inhabitants of the Eastern Archipelago, and to the "kaat" of the Abyssinians. The paper was favourably commented on by Messrs. Hardy, Hunt, Ewing, Hendrick, Alister, and others, all of whom agreed as to its worth and suitability to those who were studying botany for the coming examinations, and to others who were partial to the "cup that cheers." A hearty vote of thanks to Mr. O'Sullivan was then passed.

EASTER VESTRIES.—The following pharmacists, chemists, and druggists have been elected vestrymen of their respective parishes in Dublin and the surrounding district:—Sir George B. Owens, pharmaceutical councillor, St. Anne's Church; Mr. E. M. Hodgson, J.P. (McMaster, Hodgson, and Co., chemists, Capel Street), Zion Church, Rathgar; Mr. George H. Grindley, L.P.S.I., St. Thomas's parish; Mr. George D. Beggs, pharmaceutical councillor, the Medical Hall, Dalkey, to the vestry of Dalkey parish; Mr. W. Allen, Trinity Church; Mr. Robert White, druggist, churchwarden Molyneux Church; and Mr. Samuel Gordon, chemist, churchwarden Sandford parish.

FOREIGN NEWS.

PUBLIC HYGIENE IN FRANCE.—At the last meeting of the Board of Health of the Department of the Seine, several important decisions relating to pharmacy and public hygiene were announced, in reply to questions formulated by the Prefect of Police. Regarding the application of india-rubber (in which a notable quantity of oxide of zinc had been found) for hermetically sealing vessels containing preserved foods and alimentary liquids, the Board gave its opinion that the use of oxide or other compounds of zinc should be prohibited as prejudicial to health in the manufacture of the rubber employed. A committee of five members had been appointed to ascertain whether for the public welfare it was expedient to permit the purification of rancid butter by a process of washing and afterwards flavouring, and also whether this process constituted a fraud intended to deceive purchasers as to the quality. On this latter question, the Commission estimated that the subject should be decided by the judicial authorities rather than a sanitary board. With regard to the first, it was decided that as no injurious properties were communicated to the butter by the process, there was no reason to prohibit its employment.

The Council also carried the two following resolutions concerning the prohibition of sale and seizure of compounds recognised officially as dangerous to public health:—

"This Board deems it expedient that the Prefects of Police of each department should be authorised by law to seize provisionally and hold, until a judicial decision has been given, all substances—simple or compound, classed as medicines or even as perfumery, offered for sale—which should be recognised by the authorities as dangerous to the public health."

"In view of the power of the authorities in cases of illegal practice of pharmacy to order the closing of the establishment, the Board considers it advisable that the confiscation in cases of illegal sale applied to poisonous medicines by the law of July, 1845, should be extended to any medicines whatever, and expresses a wish that the Prefect of Police will call the attention of the Government to this matter before the discussion takes place of the proposed new pharmacy laws at present before Parliament."

A FIRE AT LYONS is reported, having taken place at the chemical and pharmaceutical manufactory of MM. Givaudan and Trouillat, 35, Quai Fulchiron. The outbreak occurred during working hours and occasioned severe losses, which, however, are covered by insurance.

SOCIÉTÉ LIBRE DES PHARMACIENS DE PARIS.—The centenary of the above Society, parent of the existing Society, occurred on the 20th of the past month, it having been founded in the fourth year of the Republic, conformably to the 300th Article of the Constitution. Its object was to aid the progress of science, especially of pharmacy, chemistry, botany, and natural history, by perpetuating the educational establishment founded by Paris pharmacists, and by continuing in the laboratories and gardens of the Rue de l'Arbalète (Jardin des Plantes) the gratuitous courses of public lectures upon the different branches of pharmaceutical science.

ILLEGAL PRACTICE OF PHARMACY.—The Nîmes Court has just delivered judgment on an appeal made by the Syndicate of Pharmacists of the Department of Lozère for the amplification of a decision given by a local court under the following circumstances:—M. Barnouin, pharmacist, of Villefort, conjointly with the Syndicate, instituted proceedings for illegal practice of pharmacy against a member of a religious order, Sister Victorius, who directed the compounding of medicines at the Hospice de Villefort, and also against M. Réboul, Mayor of the town, acting as President of the Board. The tribunal at Mende, where the case was tried, had condemned Sister Victorius to a fine of 500 francs and 50 francs damages, but, however, declined to grant an order for closing the dispensary. It was against this refusal that appeal was made, with the result that whilst the former judgment is confirmed, the Higher Court has, in addition, ordered the closing of the pharmacy in question.

MIGNONETTE AS A VERMIFUGE.—The *Revue Médico Pharmaceutique* reports a case attended with satisfactory results in which reseda (mignonette) was used as a vermifuge. A strong decoction of the flowers, followed by a dose of castor oil, was administered fasting to a woman suffering from tænia, after three hours the worm was entirely expelled in a mass. This plant has long been a popular remedy against tapeworm in Russia.

ACETYLENE GAS AS AN ILLUMINANT.—The new method of lighting carriages has been lately practised on the Lyons and Mediterranean Railway, and was utilised during the recent journey of the President of the Republic to the South of France. It consists in the substitution of acetylene for coal-gas, and the results, so far, have been completely successful. On account of its marked superiority over coal-gas as an illuminating agent (in the proportion of 1 to 16) a great extension of its use may be anticipated. At present the principal obstacle to the more general employment of acetylene is the relatively high price of the calcium carbide from which it is generated, but as that chemical becomes a current article of commerce, on account of the increased demand, its cost will necessarily diminish. The first experiment in France with this illuminant for railway carriages took place on the same line in the month of October last.

SOPHISTICATION OF DRUGS.—One of the leading Parisian daily papers, *Le Matin*, has lately interested itself with the sophistication of drugs, which it states is unfortunately of only too frequent occurrence. Owing to numerous complaints, a police official had been instructed to make purchases at various suspected pharmacies, and the analyses of the substances bought disclosed a very unsatisfactory state of affairs—50 per cent. of bicarbonate of soda was found when antipyrin was prescribed; quinine was entirely absent in a salt which was represented to be that alkaloid, and various galenicals were seriously sophisticated. Up to the present time, no legal action has been taken in the matter, and the journal in question has sent representatives to interview the Archivist of the "Syndicat des Pharmaciens de Paris," M. Crinon, and also M. Girard, Chief of the Municipal Laboratory. M. Crinon, in course of the conversation, pointed out the illegality of any interference on the part of the police or the Municipal Laboratory with pharmacists, as the *École de Pharmacie* is the body especially charged by law with the regulation and inspection of pharmacies. Two of its officials accompanied by a Commissaire de Police make an inspection of each pharmacy once or twice a year, and if necessary seize any adulterated medicaments. Whilst acknowledging the right of the Prefect of Police to cause visits to be made at pharmacies when he considered necessary, or when a complaint was lodged, M. Crinon said that he personally should resist any seizure by other officials than professors of the *École de Pharmacie*, and quoted the judgment given in a case (from which no appeal had been made) brought against a pharmacist at the request of the Municipal Laboratory for exposing for sale a "Sirop Pectoral," coloured with fuchsine, in contravention of a police regulation. In this case the municipal authorities were condemned in costs as not possessing the right of control over pharmaceutical products.—M. Crinon also stated that for the last three years a committee had been appointed by the Syndical Chamber to prevent malpractices on the part of pharmacists, any one of whom, if suspected of fraud, either in quantity or quality of medicine supplied, became the subject of surveillance, and in case of repetition legal action was taken. Several complaints are now before the Committee, and severe measures will possibly be taken.

M. Girard was at first very uncommunicative, and denied any knowledge of seizures having taken place, stating that he had lately been absent from Paris. He asserted, however, that if instructed by a police magistrate to make a perquisition at any pharmacy on account of complaints received, he did not anticipate any opposition on the part of the proprietor, and explained that the reason the Municipal Laboratory made no such inspections was owing to want of time, as to do so would necessitate a doubling of the staff. When a medicament is brought for analysis, and it is found to be adulterated, the result is communicated to the *École de Pharmacie*, and further action in the matter is left to that body. M. Girard concluded by expressing his opinion that the *École de Pharmacie* is too lenient towards delinquents, and that the public welfare would be best served by prosecution and affixing a copy of judgments obtained on the front of the pharmacy in fault.

DETECTING COLOURING MATTER IN WINE.—At the meeting of the Congrès des Sociétés Savantes, M. Mosnier, Professor at the School of Medicine at Clermont, presented a method for extracting any colouring matter fraudulently added to wine. The reagent used is a cold saturated solution of lead nitrate, which precipitates in the form of lakes any colouring matter, vegetable, animal, or coal-tar derivative (fuchsine excepted). The natural colour of the wine is not affected.

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

DARK TONES IN PHOTOGRAPHIC TONING.

Unfortunately, no information is given as to what paper is used, but, assuming it to be the ordinary gelatino-chloride printing out paper, it may be stated that dark tones are more dependent upon the negative and depth of printing than any particular toning formula. Place a sheet of flashed chromium green glass over the negative whilst printing, and print till the high lights are strongly tinged. Then tone the print—until the shadows, on looking through them, have lost all yellow tinge—in the following solution, after cooling:—

Gold chloride.....	1 gr.
Sodium acetate.....	30 grs.
Hot water.....	8 ozs.

Next rinse the print and tone in—

Potassium chloroplatinite.....	2 grs.
Phosphoric acid (dilute).....	$\frac{1}{2}$ oz.
Water.....	8 ozs.

Then the print should be well washed and fixed. Very dark brown-black tones will thus be secured. For dark purple tones use—

Gold chloride.....	2 grs.
Sodium carbonate.....	120 grs.
Water.....	6 ozs.

Finally fix and wash. [Reply to J. H. Coleman.]

LINIMENT OF SOFT SOAP.

This preparation is official in the U.S. Pharmacopœia, being prepared by dissolving linseed oil soft soap, 650 Gm., in a mixture of alcohol, 300 C.c., and oil of lavender, 20 C.c., then setting aside for twenty-four hours, filtering through paper, and afterwards passing enough water through to make the product measure 1000 C.c. A simple method, devised by C. E. Smith (*Am. Journ. Pharm.*) accomplishes the formation of the soap and liniment at the same time, and gives a product of more uniform strength than is possible by the older process. He dissolves 90 per cent. potash, 75 Gm., in water, 200 C.c., then shakes in a bottle of 1500 C.c. capacity with linseed oil, 325 Gm., and alcohol, 300 Gm. The shaking is repeated from time to time until there is no further separation of oil on standing, and after the solution has been kept in a moderately warm place for twenty-four hours, oil of lavender, 20 C.c., is dissolved in it by agitation and enough water added to make the product measure 1000 C.c. Mix and filter. Refined cotton-seed or olive oil may be used in place of linseed oil, and a lighter coloured preparation will then be obtained.

CHRYSAROBIN GLYCERIN SAPONAT.

The following is the formula of Hebra for this preparation:—Neutral coco-nut soap, 9 parts; glycerin, 81 parts; chrysarobin, 10 parts. Dissolve. [Reply to "Search-light."]

REFINING GELATIN.

Gelatin is rendered bright by straining through flannel while kept at a temperature of 100° to 120° F. A filter pump would be useful for this purpose if large quantities have to be dealt with. It is bleached by exposure to sulphurous acid gas. [Reply to "C. P. R."]

GINGER BEER.

Loaf sugar, 4 lbs.; bruised ginger, 2 ozs.; cream of tartar, 1 oz.; soluble essence of lemon, 4 ozs.; soluble essence of ginger, 2 ozs.; allspice, freshly crushed, 1 drachm; boiling water, 4 gallons. Pour the boiling water on the solid ingredients, cover over with a lid or cloth, and infuse for two hours, then strain. When the temperature has fallen to about 100° F. add a piece of compressed yeast the size of a large walnut, let it stand in a warm place for two or three days, then strain and bottle off. This will give you a far better beverage than that generally sold. Compressed German yeast is best for this purpose. [Reply to "Student."]

HANGING ANAGLYPTA PAPER.

Probably if you first put up a layer of thin brown paper with good stiff paste, allow this to dry, and then cover it with the anaglypta paper, it will not crack. If this does not answer, write to the makers of the paper for special instructions. ["Reply to D. M."]

PERMANENT GREEN FOR SHOW COLOURS.

Soluble indigo, 1 grain; picric acid, 9 grains; distilled water, 20 fluid ounces. Dissolve the picric acid and indigo separately in 10 ounces of water each. Mix. This will give you a splendid permanent green colour which will not fade. If too dark dilute still further. By adding more indigo or picric acid solution you can make almost any tint of green you like. [Reply to "Myrtle."]

MIST. BISMUTHI COMP.

Something on these lines may suit you:—

Ammonio-citrate of Bismuth.....	256 grains.
Scale Pepsin.....	256 grains.
Strychnine Sulphate.....	2 grains.
Prussic Acid B.P.....	128 minims.
Compound Tincture of Cardamoms..	4 fluid ounces.
Syrup.....	2 fluid ounces.
Spirit of Chloroform..	2 fluid ounces.
Distilled Water, to produce.....	16 fluid ounces.

Mix. Dose: 1 Drachm.

[Reply to "Search-light."]

LIQUOR PAPAIN ET IRIDIN.

Papain.....	16 grains.
Glycerin.....	4 fluid drachms.
Distilled Water.....	4 " "
Iridin.....	16 grains.
Carbonate of Potassium.....	12 grains.
Distilled Water.....	4 drachms.

Mix and dissolve with stirring, at a gentle heat, on the water bath.

Mix and warm until dissolved; mix the two solutions and add—
Rectified Spirit..... 4 fluid drachms,
and, if necessary, make up to 2 fluid ounces with water. Dose: 1 drachm.

[Reply to "Search-light."]

EMULSIONS OF CARBOLIC ACID, ETC., FOR AGRICULTURAL PURPOSES.

The best substance for this purpose is an alkaline resin soap something like this:—Resin oil, 5 parts; resin, $3\frac{1}{4}$ parts; soft soap, $2\frac{1}{2}$ parts; caustic potash, $1\frac{3}{4}$ parts; water, 8 parts. Break up the resin small, dissolve it with heat in the resin oil, add the soft soap, and then the potash dissolved in the water. Boil vigorously, with constant stirring, until saponification is complete, then stir in the phenol or hydrocarbon oil with the warm soap. [Reply to Thomas and Co.]

MERCURIC OXIDES.

The experiments of Varet (*Zeit. Phys. Chem.*) have proved the identity of the heats of formation of the two mercuric oxides, hence the total energies are equal for these compounds. Ostwald and Mark find, also, that a galvanic cell of mercury, red oxide, caustic potash, yellow oxide, mercury, gives no E.M.F., whilst also no change in E.M.F. of various cells takes place when red and yellow oxides replace one another. Hence the free energy of the two forms is also equal, and the two compounds are not isomeric but identical.

ANTINOSINE.

This is a new antiseptic, described as a blue powder containing phenol and iodine, combined with sodium. It is readily soluble in water, and is stated by Kruse to be a powerful antiseptic, arresting the development of nearly all pathogenic microbes. It is free from odour and from toxic properties, and has no irritant effects. It has been employed both as a dressing and for washing out cavities; also for mouth washes, gargles, with a half per cent. solution, and for injections into the bladder in cystitis. Lewin has employed it with great success as a dressing for chancres.

CORRESPONDENCE.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

THE SOCIETY'S LOCAL SECRETARIES.

Sir,—Mr. T. R. Ashton's letter would have been better sent direct to me than through your columns, as his complaint is a purely personal one of my action as an individual. Through the same channel, and with as much publicity, I should like with your permission to express to Mr. Ashton my apology for having wounded his hypersensitive feelings, and trust he will accept the same with as much readiness as he did the unintentional offence when he received my post-card. In extenuation of my offence I may just add that as I have not the pleasure of Mr. Ashton's personal acquaintance, I have had no means of learning of his singular objection to having his subscription "collected"; and, further, in reply to his question about business men collecting accounts, I would explain that the list of unpaid subscriptions forwarded to me on February 27 was my latest advice, and my lack of acquaintance with business men and business customs must be my excuse for having thought that the foot-note he refers to would be sufficiently self-explanatory to the average chemist. In the choice of a humble post-card as a medium of conveying my message to nearly one hundred subscribers, I am bound to say I fail to see the slightest ground for objection, but I will promise to bear the matter in mind, and when I have occasion again to write Mr. Ashton I will avoid "the open letter" which Mr. Gladstone and other notables have done so much to popularise. To show him that all do not view my communication in the same light, I give you quotations from two letters received by me in reply to that same post-card: "Many thanks for your kind reminder. . . . One is apt to overlook these little annual affairs." The other wrote: "P.O.'s herewith for 21s. Sorry you have had to remind me." Unwittingly, Mr. Ashton has done me a good service by writing to you, as some kind forbearing correspondents will now see why their letters are still unanswered.

254, *Stretford Road, S.W., Manchester.* HARRY KEMP.
April 11, 1896. *Local Secretary for Manchester.*

Sir,—The appropriately dated note of your Manchester correspondent affords painful evidence of the fact that even twelve years' association with this Society does not, with him at all events, necessitate the exercise of common civility or forbearance to its officers, especially if they happen to be local. Your correspondent appears to have rendered unto Cæsar the things that are Cæsar's with commendable regularity, and is full of virtuous indignation because of a post-card which oddly enough indicated in a foot-note that its substance did not apply to such as himself. He further expresses his emphatic objection to being called upon for subscriptions—and affects to be oblivious of the trifling detail

that he has never been so canvassed—and has no experience of this popular mode of collection, so far as Mr. Kemp is concerned. In view of these facts, our friend's displeasure appears to be strangely misplaced. Surely in these troublous times, full of trade worries and real anxieties, Mr. Ashton might employ his time and ability in better fashion than in conjuring up petty bogus grievances, and in seeking cause of offence where none exists and where none is meant. Mr. Kemp may rest assured that Mr. Ashton is quite singular in his petulant puerile criticisms, otherwise the position of local secretary would be simply intolerable. In the meantime—it will be unwise to treat the matter too seriously—probably the real *casus belli* may be found in some derangement of hepatic origin. We chemists do need a holiday sometimes.

40, *Sankey Street, Warrington,*
April 14, 1896.

J. RYMER YOUNG.

Sir,—It may be some little comfort to Mr. Ashton, of Manchester, to know that he is not the only one who has to complain of the doings of the local secretaries appointed by the Council of the Pharmaceutical Society of Great Britain. During the short time I have been acquainted with the Society I have seen about half-a-dozen gentlemen appointed and re-appointed to the honourable position of local secretary in my district, and yet not one of them ever condescended to call upon me, or, as far as I am aware, on my neighbours, to press home the claims of the Pharmaceutical Society. That duty was delegated to the apprentice whose caligraphy would stand the light of day. When asked the reason why, the answer was they always went by a precedent. Well, but the precedent they looked to happened to be one of those very superior persons who, alas! was "too big for his job," and thought it menial work to make a personal call and collect subscriptions. How does the Society suffer? Associates, members, and money simply slip through its fingers, while those who do subscribe to the Benevolent Fund could easily be made to double their subscriptions if local secretaries would get out of the old ruts.

Inverness, April 14, 1896.

SCOTTISH PHARMACIST.

Sir,—Your correspondent, Mr. Ashton, of Manchester, appears to be the owner of a somewhat thin epidermis. In his position I should congratulate myself that I was in the district of a local secretary with sufficient enthusiasm for, and interest in, his work to trouble to write and send out post-cards in the manner described. The foot-note frees the card from any note of offence. I may say that I have been connected with the Society for fifteen years and in that time have only once received any sort of communication from the district representative. In face of this apathy, which is, I think, general, it seems to me unjust that Mr. Ashton should endeavour to throw scorn upon a gentleman who at the worst was guilty only of excess of zeal. Fortunately, the sympathies of your readers will be with this gentleman, who is quite unknown to me, rather than with your irascible correspondent.

Westgate-on-Sea, April 15.

FREDERICK MARCH.

AUCUBA JAPONICA (BLOTCHED AUCUBA).

Sir,—Although the female plant has been extensively cultivated since the year of its introduction, 1783, under the name of "spotted laurel" (as it is still popularly termed), it produced only blossom until that enterprising botanist and collector, Mr. Robert Fortune, brought home the male plant. Nowadays, thanks to insect fertilisation, it is no uncommon thing to see a profusion of glossy scarlet fruit in lovely contrast with gold and green foliage. In an old neglected garden are growing a considerable number of aucubas, and they present a very degenerate appearance, the blotches being diffuse and pale instead of bright yellow. One very ancient plant, nevertheless, which has leaves resembling those of the male, is in full fruit and bearing flowers also, the peduncles drooping and distorted, the fruit, too, though abundant, much smaller than usual and nearly globular.

It is a recognised natural law that aged female animals are prone to assume the masculine appearance, as instanced in the domestic fowl; when permitted to enjoy the full term of her life she will personate her tyrannical husband with comb, wattles, and ornamental tail, thus asserting her claim to admiration with greater show and circumstance than the most distinguished "woman of the period" is capable of, moreover, as a consummation, crowing lustily as any chanticleere, thus originating the old distich—

"A whistling woman and a crowing hen
Are neither of them good for God nor men."

Yet notwithstanding this vain show of sexual superiority, she is obliged occasionally to drop a tell-tale egg, although of very small size. The hen wife is, however, deceived, and shows it as a great curiosity—an undoubted "cock's egg."

Twickenham, April 14, 1896.

R. GOODWIN MUMBRAV.

CO-OPERATION AND LOW PRICES.

Sir,—I am so enamoured with G. T. Cooper's plan that I shall sacrifice (?) a good deal to attain the ends he so lucidly advocates. The retail chemist has been all along "paying through his nose" for his goods from so-called "wholesale chemists," who are not chemists but simply small capitalists, mostly enrolled under the Limited Companies Act. We have in Liverpool two or three "wholesale chemists" who are not registered individually as chemists, and some of them know no more about chemistry or even druggistry than a cow does about astronomy. The mysteries of the law are so queer that I am sick to inquire into it when we see such a state of things existing. The time has clearly come when we must either abolish the "middleman" or ourselves, and Mr. Cooper has certainly come forward as a benefactor to his comrades. The value of his plan may be illustrated by quoting a few items which have come prominently under my notice lately, in connection with the procuring of a small wholesale contract—

	Usually:	Now.
McDude's mixture	6s. 6d. per lb.	3s. 3d. per lb.
Liq. ammon. fort.....	5d. or 6d. "	2½d. "
Nitric acid	8d. "	2½d. "
Sulph. "	2d. "	½d. or ¾d. "
Acetic "	5d. "	2d. "
Muriatic "	2d. "	½d. "
Potass. cyanid.	2s. 6d., 3s. 6d., 4s., 5s.	11d. "
Meth. spt.	3s. per gallon.	1s. 7d. per gallon.
Resin	8s. per cwt.	4s. 6d. per cwt.

Then with regard to proprietary articles, individual chemists rarely take five pounds' worth of Siegel's Syrup, a thing we sell for nothing, but it would bring in a fair profit under Mr. Cooper's plan. Pears' Soap, ditto. In fine—pseudo "wholesale chemists," with their travellers, etc., constitute the barrier which must be removed. Another point in favour of the proposed plan is that obsolete articles might be exchanged or sold to mutual advantage, and quack nostrums by long firms demolished at will.

Prescot, Lancashire, April 12, 1896.

H. M. WILLIAMS.

CO-OPERATION FOR CHEMISTS.

Sir,—Will you kindly allow me a little space to make known some particulars of a company which is being formed among chemists to meet the ruinous and unfair competition felt on every hand? If chemists can buy as well, or even better, than the limited companies they will be able to sell at the same prices, make a living profit, and increase their trade, besides reducing that of the illegitimate traders, and perhaps in some cases closing their shops for them. Only properly qualified chemists actually in business on their own account will be admitted. Central premises will be rented, and an adequate staff engaged. Members will send in their orders every fortnight for drugs and proprietary articles, etc., the orders will be dissected when received, and the quantities of the various articles required, ascertained. Quotations will then be invited from actual manufacturers, importers, or agents, and the firms giving best quality and price will get the orders. Another feature will be the introducing of some good specialties, more particularly those which do not pay chemists to put up themselves; these will be supplied at just over cost, and the prices protected.

It is not intended to keep much stock in hand, so that the actual capital invested will be comparatively small, but articles such as tinctures, which are better and more cheaply made on a large scale, than bought, will be manufactured at the depôt. Each member will take a share of £5 as an entrance fee, and he will be supplied at a small percentage over first cost. No credit will be given. Result, no making others pay for bad debts; no middleman to support; no travellers to keep going; and it is confidently calculated that a minimum saving of 25 per cent. on drugs, 15 per cent. on those sundries traded in, and 7 per cent. on so-called "patents," will be effected; besides which mutual help will be extended at the same time among the members. To ensure

all drugs, etc., being of the utmost purity and just what they should be, every article will be carefully examined as it comes in (analytically when required) and some trouble will be expended to maintain a high standard of quality. If any of your readers would like further particulars they may be had by addressing a post-card to the subjoined temporary address.

29, Earlsmead Road, S. Tottenham, N. A. GARNETT, Secretary.

April 14, 1896.

COCAINE IN OINTMENTS.

Sir,—In reply to Mr. P. Green's humorous criticism, I am afraid any supplementary information on the above that I can give will neither satisfy his thirst for knowledge nor quench his love for badinage. He wishes to know on what grounds it was concluded that the cocaine hydrochlorate was decomposed in the over-heated lanolin. I thought the therapeutical evidence given was sufficient, but if Mr. Green knows of a more feasible explanation of the phenomenon referred to in my note, we will feel obliged to him if he will let us know what it is. In solving the problem he must please take into account two factors which are absolutely fixed:—(1) The spoiled pot of ointment was prepared from the same sample of hydrochlorate that was used in the preparation of a subsequent lot, which was satisfactory. (2) Exactly the same quantity of hydrochlorate was used on each occasion. The essence of Mr. Green's query is, what is the temperature at which cocaine hydrochlorate decomposes in a neutral and partly aqueous medium? I cannot tell him. As eminent a chemist as Flückiger has stated that an aqueous solution of it cannot be evaporated without decomposition; in other words, that a temperature of 212° F., or less, will decompose it in the presence of water. An equally eminent authority on alkaloidal chemistry, Dr. B. H. Paul, has disputed that statement. He says (*Ph. J.*, March 17, 1888, p. 783) that he has evaporated solutions of pure hydrochlorate of cocaine to dryness over a water bath, and found no decomposition to result. Observe, that was at water bath temperature; our friend's lanolin was warmer than that. What the actual temperature was, of course I do not know; but at any rate, in the exhaustive paper referred to there is nothing to bar the assumption that cocaine hydrochlorate is decomposable in hydrous lanolin at temperatures something over 212°, in fact, there are several passages which rather favour the idea. If Mr. Green will take this knotty question up, and satisfactorily settle it, he will prove that he has less chlorophyll in his composition than his name would seem to indicate.

Now a word in response to his other question, viz., "Why heat the lanolin at all before adding the cocaine and creolin?" Both the cold and hot ways have been tried, and it has been found that the latter yields decidedly the better result. Made in the former way, the lanolin is apt to become "disemulsified" (to show drops of moisture here and there); whereas, when the mortar is warmed, a nice, creamy ointment is producible. As an additional precaution, to retain it in that state, the pot may be slightly warmed before filling the ointment into it.

Whilst on this subject, it may be mentioned that there appear to be two kinds of anhydrous lanolin on the market at present—one almost cheesy in consistence, the other softer and more like the hydrous variety. I am inclined to suspect that the soft kind has been diluted with oil. That makes it easier to manipulate, but lessens its emulsifying power; therefore I should say that, on the whole, the hard kind is preferable.

W. JOHNSTON.

69, Loughborough Road, London, S.W.

April 13, 1896.

SHOPS (EARLY CLOSING) BILL.

Sir,—I perfectly agree with Mr. Wm. G. Taplin's protest against this new Bill, which should be named "A Bill to Encourage Bankruptcy." Trade in Portsmouth is carried on at wholesale prices until 8 o'clock p.m., after which there is a chance to do a little retail trade; but if this chance is taken away, some of us will have to discontinue our subscriptions to the Pharmaceutical Society, as we shall want our guineas and half-crowns to make up our deficiencies at the end of the year. Business nowadays must be transacted as it comes in our way. We are not all independent, neither can we all afford to slam the door in the face of a customer, even at a late hour. Some of your correspondents evidently were born with the proverbial silver spoon in their mouths, and it may be easy for these, who have "plenty," to cry enough! enough! But how about those of us who are making a business, who have life before us, and are anxious to serve those who patronise us? I consider it is hard

and unfair to have forced down our throats this new, but thoroughly up-to-date commandment:—

Thou shalt have no other gods but this "Early Closing" one,
But it thou shalt bow down and serve.

I agree that it may be for the benefit of shop assistants and for those proprietors who are so often anxious to spend a night at the club or elsewhere, but it is of little value to small traders, and I hope will not be enforced in this locality.

Portsmouth, April 11, 1896. HERBERT HENRY BAILEY.

Sir,—In reference to the inclusion of chemists in the proposed early closing legislation, I should like to ask what effect its adoption would be likely to have upon the public health. Would its operation be negative, or would it be deleterious? Speaking from a somewhat lengthy experience in working-class districts, I venture to say that by far the greater portion of the trade done after 8 p.m. is in that which may be properly be called "preventative medicine." The ever-present baby, maybe, is found to be feverish, and an aperient powder, given at once, stops it; or the bread-winner comes home exhausted and aching from exposure or wet, and a sudorific, taken directly, relieves, and permits the resumption of his work on the following day, and many other similar cases. Now I feel certain that in such neighbourhoods as this—were the slightest difficulty put in the way of the inhabitants in getting such medicines—no attempt, involving any extra trouble, would be made to obtain the remedies—at least not until the morning, the proverbial "stitch in time" being thus lost. Personally, I have always looked upon the trade as having somewhat higher duties than the mere selling of physic, and I flatter myself that upon very many occasions the advice given to either call in the doctor or to try some simple remedy overnight has been the means of arresting much suffering and illness, and I should be glad to know if my experience is shared by others in the trade, so that I may draw a more just conclusion as to the merits of supporting or opposing the inclusion of chemists in the proposed Act.

71, Old Kent Road, April 14, 1896. FRANK W. TRUMAN.

A DISCLAIMER.

Sir,—I have received a letter from the President of the Chemical Society, and he denies entirely the statement, published in the *Pharmaceutical Journal* of April 4, p. 274, that he alluded to me in his address at the anniversary meeting of the Chemical Society. As the whole affair is a malicious libel on my character, I hope you will kindly correct the error in your next issue.

12, Knowle Road, Brixton, S.W.

A. B. GRIFFITHS.

April 11, 1896.

[COPY.]

"St. Clare,
"Ryde,
"9th April, 1896.

"Dear Sir,

"You have been misled. At the anniversary meeting of the Chemical Society I did not allude to any letter from you, nor to you in any way.

"I am
"Yours faithfully,
"(Signed) A. VERNON HARCOURT.

"Dr. A. B. Griffiths, F.C.S."

GRANULAR EFFERVESCENTS.

Sir,—Mr. Clarke should have stated that his "base" was the B.P. effervescent citrotartrate of sodium, with the addition to the stated formula of one ounce of sugar. That is what his correction brings his basis to, not a large alteration by any means.

Edinburgh, April 10, 1896.

G. LUNAN.

ANSWERS.

J. H. THOMAS.—The formula for ung. ferri sulph. (St. Bartholomew's) is as follows:—Powdered sulphate of iron, 10 grains; lard, 1 ounce.

H. W. WILLIAMS.—In reply to your first question the retail sale of scheduled poisons by unregistered persons is illegal, whoever the purchaser may be. There is nothing to prevent a medical man setting his stable boy to compound and dispense medicines for his patients if his sense of the fitness of things permits him so far to outrage professional decency.

"MANUFACTURERS."—We see no reason to publish your comments on statements respecting a rival firm which appear in another paper.

"DENTIST."—The *Journal of the British Dental Association* (Baillière, Tindall and Cox, 20, King William Street, Strand, W.C.), or the *British Journal of Dental Science* (J. P. Segg and Co., 289, Regent Street, W.) Either should serve your purpose equally well.

"SUBSCRIBER."—Coal gas of average composition yields roughly its own volume of carbon dioxide, when completely burnt, as in a Bunsen burner, but an illuminating flame in which the carbon is only partially consumed will, of course, yield proportionately less. The volume of carbon dioxide formed by the combustion of any substance capable of yielding it is precisely equal to that of the oxygen combining with the carbon present, and the calculation is extremely simple, the necessary data being obtainable from any elementary work on chemistry. The following will give you an idea how to proceed:—

Substance burnt.	Amount of Oxygen required.	Carbon Dioxide produced.
CH ₄	2 volumes.	1 volume.
CO	$\frac{1}{2}$ volume.	1 "
C ₂ H ₄	3 volumes.	2 volumes.
C ₂ H ₂	$2\frac{1}{2}$ "	2 "

etc., etc.

JOHN HOLDING.—There is no better small book on the subject than Cross and Cole's 'Modern Microscopy' (Baillière, Tindall, and Cox, 20, King William Street, Strand, W.C. 3s. 6d.), but for your purpose reference to Dallinger's edition of Carpenter on 'The Microscope' should also prove especially useful. You can borrow this from the Society's library.

QUERY.

MANUFACTURE OF COAL-TAR PRODUCTS.—"Student" asks "where would a chemist be likely to get practical instruction in modern methods of manufacturing coal-tar products on a commercial scale?"

OBITUARY.

STYLE.—On April 8, J. W. Style, Chemist and Druggist, late of Peckham. (Aged 42.) Mr. Style was an associate of the Pharmaceutical Society. He was on the Chemists' Ball Committee for 1896, and took a great interest in pharmaceutical matters generally.

DOBSON.—On April 9, John Dobson, Shipley, Chemist and Druggist. (Aged 60.)

LONGLEY.—On April 11, J. W. Longley, Leeds, Chemist and Druggist. (Aged 48.)

DODD.—Wm. H. Dodd, Chemist and Druggist, Prescott, passed away last week at the ripe age of 85 years. He was born in Prescott, and for years conducted a splendid business, and was familiarly recognised as "Dr. Dodd." The dapper old gentleman was severely of the old school of pharmacists, and the doctor of the children. He was a contemporary of Alderman Sir Thomas Dakin, George Harker, Colonial Secretary, and Thomas Kershaw, the pioneer of the lozenge trade. His familiar figure will be missed for a long period.

PUBLISHERS' NOTICE.

CASES FOR BINDING AND READING COVERS.

CASES for binding the half year's numbers (one volume) of the *Pharmaceutical Journal* are now ready. Cloth, gilt lettered, price 1/6, post free.

READING COVERS to hold twenty-six numbers of the *Journal* can also be supplied. Plain cloth with strings, and gilt lettered, price 2/3 each, post free. Or, Slade's patent covers, with leather straps and copper wires in place of strings, price 3/6 each, post free.

APPLICATIONS should be sent, accompanied by remittance, to the *Pharmaceutical Journal* Office, 5, Serle Street, Lincoln's Inn, W.C.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Bailey, Bindloss, Brown, Callis, Cracknell, Cupit, Currie, Ferrall, Garnett, Griffiths, Gunn, Hannah, Holding, Ince, Johnston, Kemp, Kirkby, Laing, MacHardy, Mitchell, Mumbray, Peck, Sawyer, Thomas, Truman, Turner, Williams, Young.

CACAO AT THE SAN CARLOS ESTATE, TRINIDAD.

BY WALTER H. INCE, PH.D., F.I.C.

Government Laboratory, Port of Spain, Trinidad.

To reach a cacao estate is by no means always an easy task. From the Port of Spain one is forwarded by rail to (in my case) Arima, the train speeding over the somewhat uneven metals past quaint tropic villages, over shallow brawling streams, through groves of coco-nut palms, past cane patches and swamp. The station at Arima is conveniently separated from the town by about two miles of glaring shadeless road. This may, however, be much shortened by taking a place in an old dilapidated fly. Arima, the centre of a fertile tract of cacao-land, resembles most other West India towns that I have visited. It is striking and somewhat picturesque. As architecture, however, it is not inspiring. The estate lies some five miles to the south. This may be ridden on mules. The road is charming, as all the Trinidad roads are, for the pedestrian; one passes so many beautiful sights, so many quaint peoples, and so many quaint smells. On arriving at the estate an obstacle was reached—a river. After much shouting and whistling, a long glabrous-legged Indian appeared on the opposite side, waded across, and took over the visitors in Sindbad style. A few yards further we were met by the genial host.

After a night's rest we were aroused at dawn from our slumbers, and went to the river to bathe. Then we proceeded to the cacao. The cacao is a stunted tree, standing about twelve feet high. It is very angular, and has no main stem. Its spreading branches are topped by long leaves, about thirteen to fifteen inches long. The undergrowth is carefully kept down, and, as in the culture of the vine, all outward suckers trimmed, so that the whole of the strength of the tree shall be preserved for the formation of pods. The top branches are thinned, but not entirely removed, as the cacao requires shade. Cacao only grows at its best in shady places, so that wherever a plantation is started, immortels as shade trees are planted as well. This "Mother of the Cacao" (immortel, *Erythrina umbrosa*) is a large tree with spreading umbrageous branches, and always forms a characteristic accompaniment to a Trinidad cacao plantation.

With new plantations, where shade trees do not exist, temporary shade is produced by planting the quickly-growing "fig" (banana), whose broad leaves shield the young plants from the overpowering heat of the tropic sun. The cacao plant is, happily, free from many insect pests. It suffers, however, from two deadly enemies. First and foremost is a grub, larva of the beetle (*Stirostoma depressum*), which eats its way in a corkscrew manner under the bark and eventually destroys the tree. The second is a bird, which provides for its coming needs by making the cacao pod its future larder. It picks a hole in the pod, and soon after follows a family of grubs, which some kindly insect deposits therein. As soon as these are established, the bird descends and devours its meal, to the prejudice, however, of the pod which is naturally spoiled in the process.

The flower of the cacao is very small and insignificant. Several flowers appear on the stem at the same place, but usually only one bears a pod. The pod grows from the stem, not as in European pods or fruit from the ends of the branches. First green, then as it ripens it turns yellow or red. In a tropic country one sees spring, summer, autumn, and winter all at once. The cacao trees are always at various stages of ripeness, so that the harvest goes on more or less continuously. The chief harvest is in the spring and autumn (English time). When the pod is ripe, it is severed from the tree with a dexterous whisk of a cutlass—never torn off—and transported to the fermenting boxes in baskets on the backs of mules. The pod is cut open, and the beans, bedded in a glutinous sweet-acid pulp, are placed in a square box to ferment. During

this process heat is developed, and the outer integument becomes loose and falls off. The pods are removed four times (every two days) from one fermenting box to another, and then placed an inch thick on a flat shed to dry in the sun. Here they are danced, *i.e.*, coolies go through the beans with their bare feet to turn new surfaces to the action of the sun. This dries the beans and rids them of the last remnants of the membranous husk which partly adheres after the sweating process. Should rain fall during the drying, the beans are covered by a sliding roof till climatic influences are more propitious. On the estate they have also a steam drying shed, which renders the owner more or less independent of the weather and the desiccating influences of the torrid sun. Good beans when dry are plump and round, and when broken open show a characteristic colour. The quality of the bean, which means its market value, depends on the peculiar shade of the husk and the nibs. If the beans are over-sweated in the fermenting boxes, or become wetted by rain in the drying process, they darken considerably and become much lowered in value. On estates where inadequate drying sheds are provided, this is by no means a rare occurrence. To bring back the blackened beans to their normal (*i.e.*, marketable) light colour, they are "ochre-danced." This consists of stirring up the beans with a mixture consisting of the glutinous exudation of a tree, called in patois *bois d'homme*, the juice of bitter oranges and yellow ochre. After this treatment, they are again exposed to the action of the sun, and "danced" as before.

When dry, the beans are ready for exportation. They are packed in bags, which, when full, weigh about 170 lbs., and taken to the nearest railway station on mule back or in native springless carts.

When the outer husk is removed it is known as cacao (or cocoa) nibs, and in this form is treated in Europe by the various processes for consumption, and is returned to Trinidad in the shape of chocolate and, strange to say, cocoa! For cocoa-essence it is deprived of its fat, which is unpalatable to delicate stomachs, or it is mixed with starch or farina, and sold as "soluble cocoa," or it is mixed with sugar and other substances and appears under the name of chocolate. But with the manufacture we are not at present concerned.

On a first-class estate the ground is as "clean" as a well-kept orchard; at every few yards are ditches to carry off excess of rain, as cacao requires dampness, but objects to swamp. Cacao, with its deep, penetrating roots requires a deep soil. Hence it thrives best in the valleys, where through constant weathering of the mountains a deep alluvial soil is found. Heavy soils, clays and the like, are fatal to the growth of the cacao tree.

In Trinidad the labour is almost entirely supplied by "indentured" coolies recruited from India or East India. These come over passage paid, and bind themselves to work for a certain rate for five years. After this time they are free either to return (passage paid) or in lieu of their passage money they may take a piece of Government land and cultivate for themselves. The free negro, roughly speaking, objects to work of any kind, and he is a *rara avis* on a cacao estate. Nothing could be more picturesque than this imported coolie labour. This coolie population forms one of the most characteristic and, at the same time, picturesque feature of the Trinidad landscape. Most of them retain, at least for many years, their native dress. The women, who in times of stress of work labour with the men, are dressed in long flowing garments. A sort of veil (worhance) comes over the head and reaches to the ground, a sleeveless Zouave-shaped jacket (juláh) of various colours, and a skirt (gangàr) complete the textile part of the costume. Besides this, innumerable articles of jewellery are worn, some common to all creeds, as the bangle, chureah, and bearah (bracelets), and others particular to tribe and religion. The men wear a turban, a sort of loose shirt

and loin cloth, and usually the legs and feet are bare. Emphasis to artistic grace is given by the carriage of the East Indian. Accustomed from childhood to carry everything conceivable on their heads, they walk like sons and daughters of the gods. We left the San Carlos Estate and its manager with regret, which I hope was mutual, and we sorrowfully exchanged the aromatic odours of the estate for the heat radiating asphalt of the streets of the capital.

THE TESTING OF LEMON OIL.*

BY HENRY GARNETT.

This short paper is the outcome of an endeavour to place the valuation of this important oil on a more rational and scientific basis than has hitherto been possible.

In common with most other essential oils whose chemical constituents have been unknown or difficult of exact determination, the physical constants of lemon oil have been chiefly relied on as tests of purity, and, as far as they go, these data are still of great service in helping to form a judgment on the quality of the oil. They comprise specific gravity and optical rotation, and to these has lately been added the refractive index of the oil. With respect to the latter, however, it would appear that its indications are of little value, as the presence of a considerable percentage of such an adulterant as oil of turpentine affects the reading to only a slight extent.

Specific Gravity.—Doubtless the figures afforded by a genuine lemon oil vary within a comparatively narrow range, the addition of oil of turpentine causing a rise in density, yet in view of the fact that the so-called "citrene," a bye-product in the manufacture of the "terpeneless" oils, may be added without materially altering the specific gravity of the oil, it will be seen that too much reliance cannot be placed on this test alone. Further, according to A. A. Barrett (a manufacturer at Messina),† the occurrence of dry and sultry weather during the harvesting of the oil materially increases its density. The United States Pharmacopœia gives the figures .858 to .859 at 15° C. as the limits of specific gravity for a pure oil, and in my experience it should certainly be between .857 and .860, most oils of undoubted purity which I have examined falling between .857 to .859 at 15.5° C.

Optical Rotation.—Doubtless, when first introduced as a test, the polariscope was the means of detecting adulteration to a large extent, as all the varieties of oil of turpentine have a lower rotation than true lemon oil, or one of an opposite nature; but it would now appear, according to Barrett in the paper above referred to, that the wily manufacturers and dealers at the seat of the industry have learned the use of the instrument, and that a product can be arrived at by a judicious mixture of terpene or orange oil with turpentine, which approximates closely in its specific rotation to oil of lemon itself. The figures usually given for a pure oil appear to vary much more than those for specific gravity, but the majority of samples fall within the limits of +60° to +65° for a column of 100 Mm. I have, however, observed as low a rotation as +58°·38 in a genuine oil, and Barrett guarantees the figure +69° as of frequent occurrence.

Fractional Distillation.—This does not appear to afford very much information of value in an assay of the oil, though the presence of any considerable amount of turpentine may be detected in the lowest boiling fraction, its rotatory power being much lower than that of the limonene contained in the pure oil.

Chemical Constituents.—By far the greater part of lemon oil consists of the hydrocarbon limonene, together with probably a very

little pinene and a small percentage of a non-volatile stearopten but the distinctive aroma of the oil is due to the presence of an aldehyde, citral, first discovered to be present in this oil by Schimmel and Co. In passing I may mention that I have found that pure limonene, freed from citral and twice or thrice distilled, and boiling within very narrow limits, still retains an agreeable lemon-like odour; and it is certain that a solution of pure citral in alcohol fails to recall entirely the odour of fresh lemon.

Citral has the formula $C_{10}H_{16}O$, or $C_9H_{15}CHO$: its specific gravity at 15° C. is .895 to .899, and if quite pure it is optically inactive; its boiling point at normal pressure is about 224–228° C., but it probably undergoes some decomposition at this temperature. It may, however, be distilled unchanged in a vacuum. It exists in the free state in several essential oils, among others, in verbena oil (so-called) from *Andropogon citratus*. Semmler* has ascertained that citral is identical with the aldehyde obtained by the oxidation with chromic acid of the alcohol geraniol, $C_{10}H_{18}O$, one of the principal constituents of Indian geranium and of pelargonium oils. Citral also results from the oxidation of the isomeric alcohol linalool, the chief constituent of bergamot and lavender oils; further oxidation converts it into geranic acid.

Hitherto there has been no reliable process published for the determination of the citral in lemon oil. In common with other aldehydes, it forms a crystalline compound with the acid sulphites of the alkali metals, and in a paper read before this Association† J. C. Umney states that he has obtained at least comparative results by absorption of the citral by a strong solution of acid sodium sulphite, the percentage of citral being calculated by difference from the non-absorbed portion of the oil. In my hands, however, this process has given much lower results than the one I am about to describe. Citral also forms a compound with phenyl-hydrazine, and the so-called citryl- β -naphthocinchonic acid on heating it with equivalent weights of β -naphthylamine and pyrotartaric acid; both these compounds, however, are difficult to determine, as their quantitative separation is almost impossible in presence of such a large amount of inactive limonene.

It is true that of late certain analysts have published reports on lemon oil showing a definite citral percentage, but in no case is any hint given of the process by which these figures have been obtained. This is to be regretted, as a working process for the determination of citral in lemon oil has undoubtedly been a desideratum for some time. Schimmel and Co. state in their *Bericht*, October, 1894, that they have repeatedly emphasised the necessity of a quantitative determination of citral "as the sole reliable criterion of the value of lemon oil."

The process which I propose for the quantitative determination of citral is founded on the fact that just as geraniol yields its aldehyde citral on oxidation, so citral can, by a process of reduction, be converted into the alcohol geraniol; this has been ascertained by Tiemann and Semmler.‡ Geraniol, as has been shown by Schimmel and Co.,§ is capable of exact determination by conversion into its acetic ester, the amount of the latter being determined by saponification with a standard solution of alcoholic potash.

It remained to be seen whether this reduction and acetylation could be quantitatively effected in presence of a large excess of an inactive terpene. For this purpose a specimen of citral was prepared from verbena oil, the aldehyde of which, constituting about 75 per cent. of the oil, has been shown by Hefelmann to be citral, identical with that obtained by oxidation of geraniol. The oil was

* *Berichte Deutsch. Chem. Ges.*, xxiii., p. 3556; and xxiv., p. 213.

‡ *Berichte Deutsch. Chem. Ges.*, xxvi., p. 2708.

§ *Bericht*, April, 1893.

* Read before the Chemists' Assistants' Association.

† *Pharmaceutical Journal*, September 29, 1894, p. 255.

shaken with a strong solution of acid sodium sulphite, the solid mass of aldehyde compound collected, squeezed in a cloth, washed several times with ether to free it from adhering oil, and exposed to the air till all traces of ether had disappeared. Finally, the aldehyde was regenerated from the compound by heating it with a strong solution of sodium carbonate and distilling the separated aldehyde in a current of steam; after drying with calcium chloride it presented the following characters: s.g. .8952 at 15.5° C, optically inactive. A sample of citral subsequently obtained from a well-known Continental firm had a s.g. .8975, and was also inactive.

In order to work under the same conditions as obtain in natural lemon oil, the citral was dissolved in its natural solvent, limonene. The limonene was obtained by fractional distillation from lemon oil, that portion boiling between 170° and 176° C. being separated and twice re-distilled after drying with calcium chloride. A solution of citral in limonene was made of a definite percentage, approximately that occurring in the natural oil; this solution, it may be added, possessed to a large extent the fresh aroma of a pure lemon oil.

Reduction of the Citral.—Various conditions were tried, and different reducing agents, such as zinc dust, sodium amalgam, etc., but eventually it was found that metallic sodium, cut in small pieces and added gradually, gave the best results. About 20 or 25 C.c. of the oil is dissolved in rather more than an equal volume of glacial acetic acid in a flask holding 200 C.c., and the sodium (about 5 Gm.) added slowly, controlling the action so that the contents of the flask become hot but do not actually boil, a little more acid being added towards the end to hasten the process, which usually occupies about half an hour. When all the sodium has dissolved, the cooled contents are largely diluted with water, transferred to a separator, and the separated oil well washed with water till free from more than traces of acid. The separated oil is then dried by allowing it to stand over night in contact with anhydrous sodium sulphate.

Acetylation of the "Geraniol."—The dried oil is then acetylated by Liebermann's method, *i.e.*, boiled with acetic anhydride and a little anhydrous sodium acetate to convert the geraniol into its acetic ester. Although a much smaller quantity would be theoretically required, I have usually employed of acetic anhydride from one-third to one-half the volume of the oil, with about one-tenth part of anhydrous sodium acetate. The boiling is continued for two or two-and-a-quarter hours in a flask connected with a reflux condenser; when cold, water is added, the whole heated on a water bath to decompose excess of acetic anhydride, further diluted with water, transferred to a separator, and the oil again washed with repeated quantities of water until quite neutral to litmus. The oil is then dried by contact with anhydrous sodium sulphate, and the whole or a portion of it taken for determination of the acetic ester formed. To a weighed quantity of the acetylated oil in a flask, excess of a normal or semi-normal alcoholic solution of potash is added and saponified by boiling for half an hour under a reflux condenser; water (freed from CO₂ by boiling) is then added, and the excess of alkali titrated with a standard solution of acid; the difference gives the amount of alkali absorbed by the oil. From the figure obtained, the percentage of citral in the original oil is calculated from the following formula:—

$$\frac{N \times .152 \times 100.}{W - (N \times .044)}$$

where N = the number of C.c. of normal alkali absorbed, W = weight of acetylated oil taken, 152 is the molecular weight of citral, and .044 represents the increment in the weight of acetylated oil operated on, due to the fact that citral has been increased by

reduction and acetylation to geraniol acetate, molecular weight 196. The following figures were thus obtained:—

1. Percentage of citral in solution in limonene, 7.46. Of this solution, reduced and acetylated as above described, 17.405 grammes required 16.63 C.c. semi-normal alkali, = 7.42 per cent. citral found.
2. Percentage of citral in solution, 6.3; 21.376 grammes required 16.5 C.c. semi-normal alkali, = 5.97 per cent. citral found.
3. Percentage of citral in solution 7.59; 16.516 grammes required 16.5 C.c. semi-normal alkali = 7.76 per cent. citral found.
4. Percentage of citral in solution 6.66; 26.417 grammes required 25.0 C.c. semi-normal alkali = 7.34 per cent. citral found.

In this last case the source of error was probably the fact that the oil, after acetylation, had not been washed absolutely free from acid. The results seem sufficiently accurate for ordinary purposes, especially as the citral employed was probably not absolutely pure.

The process was then applied to lemon oils of good quality, all obtained from first-class firms, with the following results:—

Sample.	Sp. gr. at 15°5.	Rotation 100 Mm.	Citral per cent.
1.....	.8572	+ 62°35'	6.72
2.....	.8588	+ 58°38'	7.07
3.....	.8581	+ 62°30'	6.92
4.....	.8582	+ 62°18'	6.49

The above samples are probably absolutely pure oils; the second sample is remarkable as having an abnormally low rotation, yet the citral percentage comes out slightly higher than in any of the others.

I ought to add that, according to Doebner,* besides citral, a small percentage of citronellal (the aldehyde of citronella oil) is present in lemon oil; at present it seems uncertain whether it would be determined along with the citral by the above process, although theoretically it would seem probable that it would be so included, being probably reduced to its corresponding alcohol. I am making experiments with a view to clearing up this point.

I regret that time has not permitted me to make an examination of a larger number of samples of lemon oil from various sources, but I think I have shown sufficiently that the process is a workable one and probably gives at least comparative if not absolute results. Doubtless the process might be improved or shortened; for instance, it might be possible to effect both reduction and acetylation in one operation, as is done with some organic bodies.

There are other points of interest in connection with lemon oil which also require elucidation, especially as regards the nature of the changes which take place so rapidly in the oil under certain conditions, and whether both citral and limonene are affected.

In conclusion, I must express my best thanks to Messrs. Blondeau et Cie, in whose laboratories the above experiments were conducted.

ARGONINE (SILVER CASEINATE) IN GONORRHOEA.—Bender confirms the statements of previous observers that argonine affords one of the most rapid and certain cures in the treatment of blennorrhagia. He employs a solution of 7½ per cent. in water, 10 grammes of which is injected into the urethra three or four times daily. The injection should be retained if possible for about ten minutes. Of fifty-four cases treated, the longest period before cure was six weeks; in twelve acute cases gonococci disappeared in less than a week (*Rev. de Thérap. Med. Chirurg.*, lxi.iii., 119, after *Ärztl. Raktok.*).

COMPOUNDS OF CAMPHORS AND PHENOL DERIVATIVES.*

BY THEODORE WM. SCHAEFER, M.D., KANSAS CITY, MO.

I have previously drawn attention to the fact that when common or Japan camphor and crystallised carbolic acid are mixed together and heated, a colourless liquid, possessing antiseptic properties, is the result. This substance is now known under the names of carbolated camphor, phenolated camphor and campho-phenique.

At the time when I was experimenting with phenol-camphor the thought naturally occurred to me to extend my investigations to the other camphors and phenol derivatives. I found that a large number of such compounds could be easily obtained, closely analogous to combinations formed by the union of camphor, with the different phenols.

Besides the common or Japan camphor occurring in the *Laurus camphora* there are many labiate plants which contain camphors. *Matricaria*-camphor, for instance, is found in the oil of *Matricaria parthenium*; absinthol, in the oil of wormwood; myristicol, in the oil of nutmeg; patchouli-camphor, in the oil of patchouli (caryophyllin, in cloves, I find, is no camphor at all); and homologous with these are a number of others found in many essential oils, showing a great analogy in their composition, physical and chemical properties, to common camphor. Most of these camphors readily unite with the different phenols and form characteristic chemical compounds.

The reaction between camphor and chloral, the result being a liquid, has been repeatedly observed. Acetic, benzoic, citric, salicylic, and valerianic acids, salol, alpha- and beta-naphthol form similar liquid combinations with camphor. All these combinations, as well as the one obtained when menthol is acted upon by chloral, have been recently employed in medicine. Even trichlor-acetic acid, as I have observed, forms a liquid compound with menthol. Thymol, when heated with camphor, forms a transparent oily fluid. In this connection I should not fail to mention camphor-menthol, a clear liquid formed by the union of menthol with camphor. Dr. Seth Scott Bishop was the first who described it.

Menthol, like camphor, forms a large number of compounds with the different phenol derivatives. The compound formed by the union of menthol with phenol will be described later on.

Some of the di- and tri-atomic phenols unite with menthol and form characteristic compounds. Pyrogallol-menthol, for instance, is a thick, oily liquid. Resorcin-menthol is even less mobile than the one just mentioned, and gives a beautiful dark-blue colour on the addition of concentrated commercial sulphuric acid. Resorcin-camphor likewise gives a blue colour with the acid.

The compound of menthol with alpha-naphthol is a syrupy liquid, possessing the same properties which characterise phenol-camphor. Beta-naphthol forms with menthol a combination which is exactly like the one just mentioned. Thymol-menthol is a transparent, mobile liquid.

No doubt combinations of this kind, of menthol with the phenols of hydrocarbons allied to anthracene (α -anthrol, β -anthrol, etc.), are theoretically possible. There is no end, so to speak, to these combinations. I do not propose to enter minutely into the chemistry of these compounds, for the constitution of the different camphors has not yet been fully established, especially as there is still some doubt in regard to the manner in which the benzene-nucleus is united. The benzene-nucleus is supposed to exist in the form of a para-compound in common and Borneo-camphor, and it is claimed by some chemists that they (the camphors) do not contain any

bivalent ethylene combination. These phenolated camphors, I would suggest, show a great similarity to ac. tetra-hydro-beta-naphthol.

MENTHO-PHENOL.

Mentho-phenol, as its name indicates, is obtained by adding one part of phenol to three parts of menthol, and then melting the mixture. A transparent liquid is obtained, having an aromatic odour and taste. Applied to the tongue it produces a temporary anæsthesia similar to that of cocaine, although not so lasting as the latter. It is, of course, lighter than water, having a specific gravity of 0.973. It is nearly insoluble in water and glycerin, but readily dissolves in alcohol, ether, chloroform, and most of the light and heavy oils. It dissolves iodine, iodoform, and aristol. Water of ammonia mixed with mentho-phenol changes it to a dark vinous colour in a few days. It is antiseptic with strong analgesic properties. It may be used preparatory to cauterising chancroidal sores and curretting necrotic surfaces. As a mouth-wash it may be used with advantage, two drops being mixed with an ounce of the aqueous menstruum.

My brother, Dr. Edward H. Schaefer, has recently investigated the therapy of mentho-phenol. He employed the agent in chancroidal sores of the penis. In a case of phagedenic chancroid, where there seemed to be imminent danger of sloughing of the entire glans penis, the frequent use of ablations of warm water mixed with mentho-phenol (three per cent.) soon stopped the destructive process and established resolution. He employed the agent in mucous patches, syphilitic in character, making daily application of mentho-phenol, which resulted in the healing of the abrasions.

In a case of facial erysipelas in which the submaxillary and cervical glands were threatened by a destructive, suppurative process, the daily syringing of the suppurating tracks with warm water, mixed with 3 per cent. of mentho-phenol, soon resulted in a subsidence of the suppuration. The most admirable results he obtained in a case of an abscess under the finger-nail, the result of traumatism. There was considerable pain and swelling as is usual in such cases, the slightest touch to the inflamed member being unendurable. The finger was dipped in warm water mixed with mentho-phenol (5 per cent.). My brother plunged the lancet deeply under the finger-nail into the abscess, and to his surprise the patient uttered no cry nor manifested any demonstrations indicative of pain. The patient assured him that the pain had ceased like magic when the finger was immersed in the warm mentho-phenol mixture. The finger was dressed with gauze rendered antiseptic with 2 per cent. of mentho-phenol and healed in a few days.

In a case of suppurative otitis media et interna, accompanied with great pain and throbbing, an offensive purulent discharge created an eczematous eruption in the vicinity of the outer ear. The frequent syringing of the auditory canal with very warm water mixed with mentho-phenol soon checked the suppurative, inflammatory process, and resulted in the disappearance of the eczema. In another case in which a small insect had crawled into the ear of a lady, a warm mixture of 2 per cent. of mentho-phenol produced the insect to the great satisfaction of the patient. Wounds, incised, punctured, lacerated, etc., will heal kindly when cleansed with warm water mixed with 2 per cent. of mentho-phenol.

In dental practice mentho-phenol finds its indications, as an anodyne anæsthetic, in odontalgia, obtunding the sensitiveness of dentine and as an antiseptic in alveolar abscess, suppurating pulps of teeth, periodontitis, etc.

I have used the medicament in pustular acne. The pustules may be opened without causing much pain after having been first touched with vaselin containing 5 per cent. of mentho-phenol.

* Reprinted from the *Boston Medical and Surgical Journal*.

Mixed with almond oil or alcohol, in the proportion of 2 per cent. of the medicament, I have used it as an external application in itching of the skin. I have never used it subcutaneously nor by the mouth. Mentho-phenol, like every other remedy, has its natural limitations of employment. It cannot, for instance, be used in ophthalmological practice on account of the unpleasant burning which follows its use when applied to the conjunctiva. This ends the enumerations of clinical trials with mentho-phenol.

THYMOL-CAMPHOR.

This substance is prepared by heating camphor and thymol together. It is a transparent, oily fluid, and behaves the same way as phenol camphor does towards its solvents. It is milder than mentho-phenol and I often use it in dermatological practice. I have used thymol-camphor in pruritus of the scrotum and in pediculosis pubis with apparently good results. Applied to the normal, healthy skin it does not occasion any irritation or redness.

RESORCIN-CAMPHOR.

This liquid is simply obtained by heating equal parts of resorcin and camphor. Its indications are the same as those of thymol camphor. It is superior to the old mercurial ointment in removing pediculi.

PREPARATION OF OPIUM IN PERSIA.

By no means a small or unimportant industry in Ispahan is the preparation of opium. Almost every native or European merchant who trades in this drug sees the opium prepared under his own eye. The following is the usual manner of doing this in Ispahan:—The people commence to collect the drug early in May. The poppy-head is lanced in the afternoon, and the opium, which exudes and dries during the night, is collected into copper pots early the following morning. The opium gathered is kept in store until it is required to be prepared, in thick earthenware or copper pots. For the process of preparing into cakes, special men are engaged who understand the manipulation of crude opium. First the opium is taken out of the pots and assorted, it is then put into a very large copper pot (as the quality of various villages give different "touch" and morphine), for this reason, they are obliged to mix the bulk together so that all the cakes should be of one quality. Each manipulator has a smooth board about 23 inches long and 11 inches broad, he takes from the bulk about 1 lb. of the crude opium and rubs it on the board, puts in the sun for about ten minutes, and afterwards takes it into the shade and rubs it continuously on the same board with an iron implement having a wooden handle something like a small solid spade, and continues in the same manner until it dries up to a certain degree, it is then collected together in a mass sufficient for about a day's work, and then heated over a slow charcoal fire, in trays, until it becomes plastic; again each man takes about a $\frac{1}{4}$ lb. weight and keeps kneading it on the board and manipulating it with the implement, as already described, until it dries up to the standard degree and assumes a somewhat golden colour.

The opium is then collected and made up into cakes of 1 lb. each. The cakes after a couple of days are wrapped up in pink paper and tied round with string, then put into tin boxes, packed in layers with poppy chaff, so that the cakes do not roll about, then again packed into wooden boxes; the boxes are covered with hide and gunny, and the opium is then ready for exportation. If the drug is prepared in cold weather, it has to be dried in the beginning by artificial warmth and by rubbing on the board, and keeping the boards while in manipulation near a charcoal fire. The highest morphine of Persian opium is 12 per cent., and the "touch" 90 per cent. The tests are made by the best known methods as used in London.—*Consular Report.*

THE MODIFIED-MILK QUESTION.

BY A. WORCESTER, A.M., M.D.

I have lately had opportunity for studying the remarkable work that has been done in Dresden in preparing a perfect substitute for breast milk.

The superiority of the Dresden modification rests mainly upon the recognition of an essential difference between casein and lactalbumin. Professor Lehmann's analyses of breast milk and cows' milk show that while cows' milk is more than twice as rich in casein, it is much poorer than human milk in lactalbumin, as may be seen in the following tables:—

	Cows' Milk.	Human Milk.
Casein	3.0 per cent.	1.2 per cent.
Albumin	0.3 "	0.5 "
Fat	3.5 "	3.8 "
Sugar	4.5 "	6.0 "
Ash.....	0.7 "	0.2 "
Water.....	88.0 "	88.3 "
	100.0	100.0

If, therefore, cows' milk be diluted with water sufficiently to reduce the casein of the mixture to the amount found in human milk, the mixture will contain only one-third enough lactalbumin.

Furthermore, if the milk be sterilised, still further loss is occasioned, as the coagulated albumin is wasted in the scum and by clinging to the sides of the bottle.

We know the disadvantages of too much casein. We rightly dread the cheese-curds in the dejections, for such undigested lumps not only show that the infant has not received the needed albuminous nourishment, but has had its intestine irritated by these foreign masses. But if we dilute the cows' milk sufficiently to avoid these cheese-curds, we shall be starving the baby, unless we add some soluble albumin.

Three forms of soluble albumin are available—peptonised grain-albumin, meat juice, and the white of egg. The last is undoubtedly the best, because of closest resemblance to lactalbumin and of easiest attainment.

THE DRESDEN METHOD.

To the white of one fresh egg slowly add 13 drachms (52 Gm.) of milk sugar, and vigorously stir, taking care not to beat air into the mixture, for egg foam will not mix well with water. To this paste slowly add $1\frac{1}{2}$ pint of water, stirring constantly. This emulsion is then strained through fine linen into a pint of milk. Slight stirring or shaking completes the mixture.

The milk should have $3\frac{1}{2}$ per cent. of fat. The cheap lactometer gives a fairly accurate measurement. When the source of supply is not known to be unquestionable, it is probably better to sterilise the milk. The fresh egg partly compensates for the deadness of sterilised milk. Scurvy is becoming more prevalent in children fed wholly on sterilised milk. The milk sugar ought also to be sterilised in a sealed jar if we wish the mixture to keep good for months. Vessels, strainers, and cover-cloths also should be sterilised.

It is a common mistake to add lime-water or soda to modified cows' milk. Although to litmus cows' milk appears to be acid, it really is not so. The litmus test is deceptive in estimating the acidity or alkalinity of phosphate solutions. Lime-water added to an infant's food overtaxes the stomach by wasting just so much gastric juice as is needed to offset the alkali. When the infant's digestion is weak, dilute hydrochloric acid added to the milk mixture is right in theory and of marvellous advantage in actual practice.

Again, as regards the custom of increasing the richness of the infant's food, or of prescribing different qualities for different ages, it needs only to be said that it is as nonsensical as to prescribe increasingly richer beef and bread and potatoes for children as their

years increase. A mother's breast milk increases in quantity as her baby's stomach grows larger, but there is certainly no such change in its quality as the intricate tables of our text-books would lead us to believe.—*Boston Medical and Surgical Journal*.

THE RELATIONS OF EXPERT PHARMACY TO MODERN MEDICINE.*

BY WYLLYS ANDREWS, A.M., M.D.,

Professor of Surgery North-Western University Medical School, Surgeon of Mercy Hospital and Michael Reese Hospital, Chicago.

When I received the honour of appointment to address you on this crowning occasion of your educational career, I knew that it was a tribute not personal, but to the co-ordinate branch of our great University to which you are most closely related—the Medical School of North-Western University.

As student for seven years, first in the grand old home school at Evanston, and later in the school of medicine, in which I have been a teacher ever since, I saw with satisfaction that on several occasions you honoured some member of our faculty by inviting him to join in your commencement exercises. But aside from this question of a loyal university spirit among the schools, is there not a special significance in the effort to bring into closer harmony the two sister professions of pharmacy and medicine?

Certain conclusions on this subject of the relations of the two professions have been gradually matured in my mind, and I am glad of an opportunity frankly to express them, trusting that you will receive as charitably as you can the suggestions of an outsider, who can lay no claim to that intimate knowledge which you have of your chosen profession.

Pharmacy and medicine surely appear at the present hour to be at the meeting or the parting of the ways. The time is nearly at hand when either a closer union must be formed between the two or else they must drift further apart, with perhaps the gradual intervention of a third and unnecessary profession to fill the gap between them, a danger I will try to explain later on.

Who is to blame for this wrong tendency a wiser head than mine must determine, but to me as a physician the error on the side of the medical profession is exceedingly obvious. From the medical standpoint it is clear that practising physicians have thrown away valuable opportunities for improvement in not acquiring greater insight into this very practical science and art of pharmacy. You have created schools and colleges, and a technological literature, which includes and transcends our own works on materia medica our dispensatories and pharmacopœias. All the refinements and intricacies of modern chemistry, with its marvels of new synthetic remedies are yours. Your art science is upbuilding and expanding in a manner truly inspiring, but the busy physician, perhaps from want of early training, is unable to keep pace with this progress so as adequately to grasp the resources you put at his command.

From sheer helplessness he is led to accept partisan and interested testimony as to the therapeutic value of each new compound, knowing full well that many of them are superfluous if not valueless, but lacking the technical knowledge to discriminate.

Even with common remedies well-educated physicians are only theoretically familiar. They have not handled, weighed, and mixed them with their own hands in the laboratories as you have done. A little of this early training would save many a well-meaning physician from life-long violation of pharmaceutical principles. The average doctor is often intolerant of suggestions from the druggist who puts up his prescriptions. Yet, the druggist may be,

often is, an expert whose candid advice would make his combinations more eligible, palatable and therefore more efficient.

Is it any wonder that physicians sometimes suffer in competition with proprietary and semi-patent preparations which are skilfully combined? It is not to be forgotten that a prescription, whose ingredients are not grossly incompatible, may yet be an offence to pharmaceutical good taste. An early training in pharmacy would prevent the physician from falling into these errors and create a stronger bond between him and his pharmacist as well as his patient.

The limit of pharmaceutical knowledge with most of us physicians is reached when we know what drugs are chemically or physiologically incompatible, and we consider that we have attained much in mastering this. Set the average well-educated doctor to compounding anything, and his ignorance will be fathomless as to the proper order of mixing ingredients, methods of dividing, weighing and other routine matters. This is true in my own case, and I wish that before or during my medical course I had been compelled to take a laboratory course in practical pharmacy and to pass an examination upon it.

If well grounded in these matters, physicians would no longer be the easy dupes of nostrum-makers whose well-advertised proprietary remedies depend for their success upon the easy credulity of the doctors who recommend them. When once these professional recommendations are obtained, many of these products are advertised, not only in medical journals, but in public newspapers as well and become ordinary "patent medicines."

In interviews with plausible drummers and distributors of these over-rated proprietary mixtures I have often felt my ignorance of pharmacy a serious handicap in disposing of what I knew to be ridiculous claims of merit for some good, bad, or indifferent combinations.

"This may be a good formula for some cases." I have sometimes said to these medicine puffers, "I have used such combinations. This is obviously taken from some doctor's prescription book. But why crystallise it into one form? why should I prescribe your one copyrighted article, rather than vary the ingredients for each individual case? Surely you do not claim that your workmen are superior to the expert pharmacists of this city?"

"But, doctor," they declare, "we have facilities for purifying and combining these agents which no local druggist can attain. Specify our 'anti' or our 'ine' with our trade mark. Your druggist will then keep it in stock (and be very careful you don't let him use the *anti* or *ine* of any rival chemical company, which is a gross and worthless imitation)."

By implication, too, they say, "You, as a physician, are not likely to hit upon any combination as reliable as ours which we stole from some other physician or some medical book. Therefore do not try and do not trust your pharmacist to help you, but buy our numerous combinations variously labelled with the diseases for which they are good, and you will find your mental labour very much lightened."

This appeal to indolence and credulity meets some response among the weak sisters of the profession, but I need not tell you that the strong creative minds, those who devote scientific study to individual cases, are not the ones that come to an anti-climax by choosing from a printed list some ready-made remedies for the sick ones whose lives are entrusted to their skill.

Were it so, the outlook for the pharmacist would be indeed a gloomy one, destined as he would be to be ground between the upper and the nether millstone of professional indifference and remorseless commercialism.

Were I an expert chemist, I think, too, I could dispose more

* An address delivered to the graduating class of the School of Pharmacy of North-Western University, Chicago. From the *Apothecary*.

easily of the fellow who calls on me and imputes untold virtues to various earthly leachings called mineral waters. To a man naturally agnostic these claims rank with mind-cure and other superstitions of the weak-minded. Many mineral waters contain salines or alkalis in large and definite amounts, which have the same effect if prepared by a pharmacist—no more, no less.

To the exploiters of mineral springs such a statement is rank heresy. They have one stock answer to anything so commonplace as mere chemical analysis, which is that "Nature's chemistry is best." Deep down in the rocks and soil these substances undergo a subtle and potentising influence which no human chemist can imitate, however accurately he mixes the same ingredients together. "How can this be," I have said. "An expert analytical chemist of my acquaintance tells me there is nothing in it. Besides I have too much sense to believe it anyway."

An appeal to my supposed credulity always angers me. I would rather not be thought gullible.

The physician and pharmacist should co-operate more to fight the devil. For in science the demons we have to overcome are avarice, shams, fanaticism, and superstition, which really did not die in the middle ages, as some suppose.

There are other therapeutical mists and superstitions as to the potencies of drugs, which a basic knowledge of chemistry and pharmacy would do much to dispel from foggy and credulous medical minds.

Turning now to the other side of the question we may as well ask frankly: should the pharmacist make a closer study than hitherto of any matters considered medical?

The time was when every physician was his own druggist—as he is now in remote districts. The profession of pharmacy grew out of the necessity of expert aid to medical art. Are there no other branches of the art which need this aid to an equal or greater extent? A generation past the practising physician knew of but one kind of laboratory, the chemical or pharmaceutical. To-day the conscientious physician frequently spends more time at the laboratory table than at the bedside or operating room. One who equips himself for scientific research in every case has come to be recognised as a "good pathologist" by his associates.

By this they mean that he is one who goes beneath the surface of things, and surpasses his fellows in the application of bacteriology, physiological chemistry, and microscopy to the daily study of disease. Privately, they will tell you that he is the only physician they would call in case of personal need, and although the general public did not at first fully appreciate such men, they are rapidly coming to do so, and rightly regarding others as below the standard.

It is becoming more and more a burning question to physicians, who will do their laboratory work.

The conscientious, advanced worker in medicine and surgery is to-day applying in daily routine practice tests, chemical, biological, bacteriological, microscopical, which only a few years past were unheard of outside the laboratories of a few European pathologists.

To be specific, a physician, and above all a surgeon, must know in grave cases all about the urine, not only as to specific gravity, reaction, albumin, sugar, urea, peptones, blood, pus, epithelium, but many of these tests must be quantitative as well as qualitative. Some of them require troublesome apparatus, separators, pipettes, flasks, and reagents galore, as well as the microscope and accessories. Blood, feces, vomit, stomach washings, fluids aspirated from almost every conceivable cavity, must be tested chemically, biologically, and microscopically in hundreds of cases before even a diagnosis can be made. Bacteriological and microscopical examination is anxiously awaited in tuberculosis, diphtheria, anthrax,

actinomycosis, Asiatic cholera, typhoid fever, and cancer, malaria, a daily increasing list of diseases, before treatment is instituted in many cases. The microscopical examination of tumors alone is made the basis of important decisions as to capital operations. The ever-ready culture tube, sometimes prepared at an immense sacrifice of the physician's time, is daily carried to the operating table or bedside in modern practice, and sometimes turned over for study to the hands of an assistant too busy with many kinds of examinations to be an adept in any one.

On the therapeutical side, dressings, instruments, powders, solutions of various antiseptic soaps, the skin of patients, the surgeon's own hands, nail cuttings, etc., the silk, catgut, kangaroo tendon, etc., must from time to time be tested experimentally for various kinds of infection. The case often needs a chemist's aid.

All these and numerous other forms of expert work have multiplied in the physician's daily life until they threaten to engulf him in a mass of details leaving no time for bedside work.

The systematic and complete study of a single case would, if carefully followed out, absorb all the time of a painstaking physician had he no expert assistants.

How, then, you may ask, does the busy practitioner manage to do his duty to his patient and to himself in the twenty-four hours of one day? The answer to this is that he must employ assistants, often trained by himself, to carry on work in his private laboratory, or he must send numberless specimens to public laboratories. In hospital practice the laboratory question has become a difficult and burning one. In most hospitals it has been found necessary to double the staff of house physicians, one or more internes or externes being assigned to laboratory work alone, and spending the entire time making chemical microscopical, or biological examinations.

Every hospital also contains a pharmaceutical laboratory with one or more registered pharmacists in attendance. Why has it never occurred to any one to combine these two working laboratories into one? Probably the answer would be that the pharmacist could not be considered competent to do biological work, and certainly no ordinary physician is capable of doing the work of a pharmacist.

Since the pharmacy cannot be delegated to the medical assistant, it follows that the pharmaceutical expert must enlarge his sphere to include all laboratory work. If this is true in hospital economy, why is it not true of outside practice? Why multiply public and private laboratories of a separate kind when nearly all the apparatus and reagents are ready at hand in the chemical and pharmaceutical laboratories. Do we not have to send to you pharmacists for the very materials we use, and do we not come to you with formulæ of various kinds to be prepared before we can begin our laboratory work?

If your technical skill and working equipment enable you to compound our reagents for us more quickly, reliably, and cheaply than we can afford to do it ourselves, why not extend the argument to the practical use of these reagents? There is no answer to this except the stock answer of rooted conservatism. "It sounds well, but it would not work." The inferior pharmacist is too timid or too commercialised to realise his opportunity and enter boldly upon his rightful heritage of a professional career.

The unprogressive physician would say "What? send my urine analysis, or sputum examination, or blood tests to the drug store? Why, no! That would be contrary to common sense. The druggist and his clerks know nothing of such important things. A drug store is a place where they sell ice-cream soda, perfumery, toilet articles, postage stamps, and have a public telephone, as well as all patent medicines, and some prescription business."

Nevertheless, the world moves on, and the amount of laboratory work required in medical practice will constantly increase. Either the pharmacist must qualify himself to assume this important work for which he is already by training or equipment partly prepared, or he must see a class of independent laboratories spring up, to which the physician will send a large amount of his best patronage.

To the students of this school I should say, study and cultivate this inviting field. Not only will it be stimulating and attractive to you as professional men, but it will tend to educate the public to a higher idea of your profession. The pharmacist will command the respect and patronage of the other allied professions, of the veterinarian, of the sanitary expert, of the bacteriologist. He will become recognised as a member of a scientific and honoured profession, and not as a mere tradesman.

SPHÆROLITHIN.

A crystallisable albuminous body, familiar to everyone interested in physiological chemistry, is hæmoglobin. Another similarly crystallisable proteid has been named sphærolithin by its discoverer, Hofmeister. Hæmoglobin is an association-product of a proteid belonging to the globulin group and the iron-containing body, hæmatin. The study of the conditions under which proteids can be made to assume a crystalline form is of great importance, inasmuch as it may serve to elucidate some of the problems of nutrition, *i.e.*, the elaboration of living matter. And in this connection a comparatively recent research* upon the composition of sphærolithin is of interest.

Sphærolithin is precipitated when a solution of pure (ash free) casein is treated with ammoniated solution of magnesium chloride prepared in a special way. The deposit, when examined under the microscope, is found to consist of minute spherical masses, which present radial striæ. When the globules of sphærolithin are subjected to pressure they break up into radial segments. If the solution with the deposit is allowed to remain undisturbed for several weeks, Moraczewski found that the globular bodies change to minute crystals, some of which are arranged in groups, the appearance of the latter recalling sheaves of tyrosin crystals, whilst other crystals are isolated and needle-like.

The mass of crystals thus obtained represents only 1 per cent. of the casein employed in the experiment. Sphærolithin thus obtained has the characters of albumin, giving for instance the xanthoproteic reaction and yielding a smell of burnt feathers when heated. It also has the character of a globulin, *i.e.*, it dissolves in sodium chloride solution, from which it is precipitated by acids and by heat. When digested with pepsin, a sediment which resembles nuclein remains. After being washed with saline solution, and heated with nitric acid, the deposit was found to be rich in phosphorus, and in so far resembles casein, from which it differs, however, in being insoluble in weak saline solutions.

The ash of sphærolithin contains magnesium, 22.71 per cent., and phosphorus, 22.31 per cent. The nitrogen was 14.98 per cent., carbon, 51.64 per cent., hydrogen, 13.33 per cent. A trace of sulphur was found, but no chlorine or calcium.

The material for analysis was obtained by washing with the magnesia mixture, filtration, and drying, followed by washing with water and drying over sulphuric acid.

The result showed that sphærolithin is a crystallisable, albuminous body, which cannot be nuclein owing to its being partly digestible by pepsin, yet its richness in phosphorus points to its having some relation to nuclein, probably it may be regarded as a nucleoglobulin allied to casein and associated with magnesium.

REVIEWS AND NOTICES OF BOOKS.

PROOF SPIRIT AND FISCAL HYDROMETRY. By BENJAMIN DERHAM, M.D. (London: John Heywood, 2, Amen Corner.)

The object of this publication is two-fold, viz., to point out the defects in the construction and incidence of the legal Sikes' hydrometer now in use for assessing the dutiable value of spirits and the advantage which would result from substituting for it the natural hydrometer designed by the author.

It is well known that for fiscal purposes the standard for charging the spirit duty is proof strength, and proof spirit is defined by the Act 58, George III., c. 28, to be a mixture of spirits and water, which at the temperature of 51° Fahr. weighs exactly 12-13ths of the weight of an equal volume of distilled water. Unfortunately in this definition it is not stated what the temperature of the water should be for comparison, and this omission has given rise to much discussion as to its exact meaning of the definition.

In this treatise the value of proof spirit is examined from three points of view, viz., the text of the definition, the evidence obtainable from the construction of the hydrometer, and the evidence of the tables accompanying the hydrometer. The conclusion come to is that legal proof spirit has a specific gravity of .92366 at 51° Fahr., distilled water being unity at 60° Fahr.

It is admitted by Sikes, and evident to every student of this branch of hydrometry, that the tables which accompany Sikes' instrument were founded on those prepared by Gilpin and read before the Royal Society on June 19, 1794. These tables are marvellously accurate, and will bear the most rigid examination at the present time. How Sikes built up his tables from them we are not told, and, except to gratify curiosity, it is quite immaterial whether they were founded bodily on Gilpin's work or on original experiments controlled and revised when necessary by comparison with Gilpin's tables.

In their construction Sikes applied to a spirit at all temperatures the strength he had computed to belong to it at one standard temperature, and as a consequence, the tables do not take into account the difference which occurs in the bulk as the temperature is above or below this standard. It follows that, as far as bulk is concerned, the duty on spirits can only be accurately levied at the standard temperature, and that when spirits whose temperature exceeds or falls below this standard are charged with duty the Revenue gains or loses accordingly.

The principle of averages is resorted to to establish a basis for calculation whether the Revenue gains or loses by the use of Sikes' hydrometer, and by a series of assumptions as to the times of the year and localities in which spirits are charged with duty, coupled with the quantity of spirit actually brought to charge, it is estimated that the Revenue sustained a loss of £93,271 in the years 1892-3. To establish this loss the calculations are based on a mean temperature of 46° Fahr. for charging duty, while the standard temperature for Sikes' table is assumed to be 55° Fahr. This portion of the book indicates that the author is not fully acquainted with the regulations for charging the duty on spirits, and he may be certain that if the intricate meteorological observation of temperatures used to prove his case agreed with the actual temperatures of the distillery spirit stores and warehouses of the United Kingdom at the time the spirit was charged with duty, a revolution in the spirit duty assessment would long ago have taken place, and another instrument legalised practically free from the constructive errors of Sikes' hydrometer.

The fact is that in 1838, the Royal Society, at the request of the Treasury, undertook, under the direction of Mr. Lubbock, then the Vice-President, a full and exhaustive inquiry into the whole subject of official hydrometry. The result of that inquiry is thus stated:—"The errors are of little importance as they affect the Revenue," and it was added that there was no necessity to introduce a new instrument free from the defects of Sikes' hydrometer. Such an instrument was prepared at the time, but it has never been brought into use to supersede Sikes.

If the accuracy of the author's conclusions were conceded, it would follow that the necessity of replacing the present system of Revenue hydrometry by a truly scientific one is apparent, but in effecting this substitution it is very properly contended that this reform should only take place with due regard to the public convenience. Thus the standard of proof and the notation of over and under proof should be retained, but true specific gravity should take the place of the present "arbitrary and meaningless indications."

* Moraczewski, 'Zeitschrift für Physiol. Chemie,' July, 1895.

In the reformed system the changes suggested are a slight alteration of the external form of the hydrometer and the substitution of specific gravities for indications.

The manual gives a sketch of the natural hydrometer, and a specimen of the specific gravity tables with corresponding strengths to accompany the instrument. The hydrometer is thus described:—It consists of a ball, stem, and the counterpoise to the latter called the cage, in which the poises are inserted. There are ten poises cylindrical in shape, and they are made to fit very accurately within the basal ring of the cage. The stem of the instrument is graduated from 0 to 20, each division being subdivided into two, the value of each subdivision being .0005.

The stem with the different ten poises indicates specific gravities ranging from .780 to 1.000.

The principle on which the instrument is constructed is mathematically accurate, and the formulæ used for its construction and verification are familiar to those accustomed to verify the accuracy of hydrometers, and especially the one which was officially adopted seventy years ago for determining the gravity of wort and wash, and is familiarly known as Bate's saccharometer.

These two instruments in the hands of a skilled worker soon show their defects and advantages. Both in worts and in spirit solutions the difficulty which has to be encountered in obtaining correct readings is the presence of air bubbles, which attach themselves to the base of the ball and weights, and often seriously jeopardise the accuracy of the work of a careful operator. In Bate's saccharometer the ball and weights are made sharply conical to offer the least resistance to the rising of the bubbles, but in the natural hydrometer its flat cage and cylindrical weights with sharp edges render it, from the same cause, a most tedious instrument to work with, and in unskilled hands not accurate in its reading.

It is remarkable that Bate's instrument, made seventy years ago, should be so vastly superior in form to the natural hydrometer, and from this fact alone it is probable that if at any time Sikes' instrument should be superseded by one indicating specific gravities, a companion to Bate's saccharometer, showing specific gravities lighter than water through the same range as the natural hydrometer, would be brought into use, and not one whose mechanical construction is very objectionable, and presenting so many difficulties in working without any compensating advantages.

HANDWÖRTERBUCH DER PHARMACIE: PRAKTISCHES HANDBUCH FÜR APOTHEKER, AERZTE, MEDICINALBEAMTEN UND DROGUISTEN. Edited by E. A. BRESTOWSKI. In 24 parts at 2 M. 40 Pf. each. (Vienna and Leipsic. Wilhelm Braumüller.)

The twenty-fourth part of the 'Dictionary of Pharmacy' that has just appeared completes the first or general part of an excellent and useful work. This first section comprises two volumes and deals with all the new remedies, single substances, etc., about which the pharmacist, physician, or druggist is likely to require information as well as with the explanation of all terms that he is likely to meet with. A careful examination of the work as a whole shows that the objects the editor had in view, which have already been alluded to in a previous notice of the work (*Ph. J.*, liv., 39), have been satisfactorily attained. Reference to a number of subjects selected at random will easily convince the sceptic that as a work of reference the dictionary will prove of great value, as it is free from that verbosity which frequently robs a busy man of much valuable time, its information being conveyed in language that is at once clear and concise. The last part includes an appendix, bringing the work up to date, a list of errata, and an index. The latter might appear at first sight to be superfluous in a work that is arranged alphabetically. It is, however, extremely useful for cross-references, for synonyms, and for reference to such substances as are not described under their own names, as for instance cephaeline, which is described under emetine. A few omissions in the work are, however, noticeable, conspicuously so is that of a therapeutic agent of such acknowledged value as the thyroid gland, which one would expect to find fully considered, but which is dismissed with the bare mention. Such defects might be remedied in an appendix to the whole work. In the second or special part of the work galenic preparations, formulæ for retail articles, proprietary medicines and specialties will be dealt with, so that, when complete, it will form a veritable 'Dictionary of Pharmacy.'

PARLIAMENTARY INTELLIGENCE.

SHOPS (EARLY-CLOSING) BILL.—No less than eight "blocking" motions await the re-appearance of this Bill before the House, and opponents of the measure are manifesting increasing activity. Mr. Duncombe, in the rôle of the people's friend, notifies his intention of moving that "this House declines to proceed further with a Bill which will inflict great hardship on working men and small shopkeepers," whilst the member for West Bradford (Ernest Flower) dealing with principles, wants the House to express a righteous abhorrence of every attempt to apply the principle of local option to adult labour. Sir John Lubbock has given notice to move the amendment of clause 9 of his Bill, so as to render the saving clause for chemists less liable to be abused. Other honourable members, thinking doubtless that a good Bill cannot have too much committee, have motions for re-commitment of the measure to a committee of the whole House.

THE METRIC SYSTEM.—It was intimated (*ante*, p. 210) that Mr. Arnold Forster contemplated bringing forward the question of the use of the metric system in private Bill specifications. He has now done so in the form of a question to the First Lord of the Treasury. But he did not confine his attention to the alteration of Standing Orders. In an elaborately worded question he placed before the Minister the fact that the system is in use in all civilised countries save Great Britain and the United States; that even the latter nation seemed to be setting its face towards salvation, seeing that all (?) its pharmaceutical dispensing is dealt with metrically; and that in view of these things, he asked whether immediate effect could not be given to the practically unanimous recommendation of the Select Committee on Weights and Measures. Mr. Balfour admitted the facts recited by his honourable friend, but thought the imposition by law of a system so widely differing from the one at present used by the inhabitants of Great Britain was not within the range of practical politics. Mr. Arnold Forster (anticipating Mr. Godson, of Kidderminster, who has a question on the paper on the subject) referred to a Bill before the United States House of Representatives for the compulsory adoption of the metric system, but could not impress the First Lord of the Treasury that that circumstance altered the case. The member for West Belfast will return to the charge by asking whether the Government intends to introduce a Bill this Session legalising the use of metric weights and measures in all transactions in the United Kingdom.

DR. FARQUHARSON has called the attention of the Home Secretary to the loss of time and money incurred by medical witnesses who are compelled to leave their practices to give evidence at sessions and assizes for inadequate remuneration. Pharmaceutical and other professional witnesses have equal reason to complain on this account, and the Home Secretary, in replying to the hon. member for West Aberdeenshire, confessed that the question of remuneration of witnesses generally needed consideration. He did not feel justified in altering the remuneration of any particular class of witnesses, but thought that revision of the scale of payment, which was fixed as long ago as 1858, would have to be undertaken sooner or later. The only lugubrious note in the reply was Sir Matthew W. Ridley's warning that any alteration in the fees would be attended by an increased expenditure on the county rates.

THE COMPANIES BILL will be taken in Committee of the House of Lords on Monday next, the 27th instant. Lord Davey, who, it will be remembered, was Chairman of the Board of Trade Departmental Committee appointed to inquire into the law relating to limited liability companies, has given notice of a few amendments, but they are principally technical alterations—one might almost say finishing touches—suggested by the proposer's ripe legal experience. The modifications in the allotment clauses will render the Bill distinctly less accommodating as a highway for the proverbial "coach and four." No other amendments have as yet been notified, but there is reason to believe that the suggestions of Lord Davey are not the only ones which the Committee will be asked to consider. From a pharmaceutical point of view, the winding-up clauses of the Bill are the most interesting, and if the definition of the words "illegal purpose" in clause 36, Section I., sub. sec. b, should engage the attention of their lordships, it is hoped that the representations of the Pharmaceutical Society to the Board of Trade Committee may influence them to declare specifically that the assumption by companies of the personal privileges granted only after examination to a competent person is illegal.

A NECESSITY OF THE TIMES.

PROMINENT amongst the worries of professional life, and especially affecting those who are yet engaged in making rather than in enjoying a position, is the dread of leaving children insufficiently provided for, and particularly with regard to educational matters. One result of this feeling of uncertainty respecting ability to do what each individual thinks he ought to do in the way of providing for the future of his offspring, has been the creation of a number of educational foundations, the privileges of which are confined to certain classes. One such institution is the Royal Medical Benevolent College, Epsom, which—in addition to providing pensions for aged medical men, and the widows of medical men in reduced circumstances, much the same as the Pharmaceutical Society's Benevolent Fund—boards, clothes, maintains, and educates fifty foundation scholars selected from among the necessitous orphans or sons of such medical men as would be professionally qualified for pensionerships.

Our attention has been specially directed to this excellent institution, at the present time, by the receipt of a syllabus of the College, sent indirectly. It appears that an appeal is being made to pharmacists to help in supporting the College, the reasons urged in the circular received being the great advance in the education and qualification of the pharmacist, and the large increase in the number of medical men who prescribe through chemists. It is difficult, however, to see that such reasons, or any amount of inter-dependence between pharmacists and medical men, affords any sound argument in favour of the view that one class of individuals should be expected to support an institution the privileges of [which are exclusively reserved for another and much more numerous class. Pharmacists do not appeal to medical practitioners to support their Benevolent Fund, though there would be just as good reason for so doing as in the alternative case under consideration.

The circulation of the appeal may, nevertheless, serve a useful purpose if a number of pharmacists receiving it should be led to consider the advisability of making similar provision for the education and future career of the children of necessitous members of their own profession. There is no reason why the Orphan Fund of the Pharmaceutical Society should not be developed upon lines which would, at least, enable the trustees to endow a number of scholarships or exhibi-

tions in some first-class modern school. The need is as great in pharmacy as in any other craft or profession, perhaps even greater, and there is no way in which spare cash can be put to more profitable use. British pharmacists have ever proved themselves equal to the task of maintaining their own institutions and caring for their distressed fellow-craftsmen. Surely they are no less able to promote efficiently the future welfare of those whom stress of circumstances has prevented their natural guardians properly providing for.

SOCIETY OF CHEMICAL INDUSTRY.

WE have been favoured with a copy of the "provisional" programme of the proceedings at the forthcoming annual general meeting of the Society of Chemical Industry, to be held in London, under the presidency of Mr. THOMAS TYRER, F.I.C. The presidential address will be delivered (probably in one of the City Companies' Halls) on Wednesday morning, July 15, and after luncheon on that day visits will be paid to the Mint and the Tower Bridge, a reception being held by the Lord Mayor at the Mansion House during the evening. On the following day there will be an excursion on the river Thames from Reading to Windsor, the members and their friends leaving Paddington Station for Reading about 9.45 a.m., and proceeding thence by launches, which will stop at Medmenham for luncheon, after which the journey will be resumed to Windsor, where tea will be provided. A special train will leave Windsor for Paddington in the evening.

The third and last day will be devoted to an excursion down the river in the new steamer "Queen Elizabeth," starting from Westminster Pier. Special permission has been given for members to visit the Siemens' Company's Telegraph Cable and Electric Construction Works at Silvertown, the Anglo-American Petroleum Storage and Distributing Works at Purfleet—where luncheon will be provided—and the Royal Arsenal, Woolwich. On returning, about 7 p.m., an informal dinner will be held either at the new Hôtel Cecil or Cannon Street Hotel, and a smoking concert, with a special musical programme, will be held after dinner.

Dr. EDWARD SCHUNCK, F.R.S., has been nominated for election in July as President of the Society, in succession to Mr. TYRER, and he will preside at the Manchester meeting in 1897, the local section having sent a cordial invitation to the Council to visit the northern city in that year. Sir F. A. ABEL, Bart., F.R.S., Mr. HORACE T. BROWN, F.R.S., and Sir JOHN EVANS, K.C.B., F.R.S., are the retiring vice-presidents. Mr. A. H. MASON, an old friend of many pharmacists, vacates the chair of the New York Section and will be nominated as Vice-President of the Society, whilst Professor CHANDLER, Ph.D., M.A., of Columbia College, N.Y. has been elected to succeed him as chairman of the Section. Finally, Dr. KOHN, formerly secretary to the Liverpool Section, has been elected to the chair of that Section.

ANTITOXIN IN LONDON.

Mr. DEMETRIUS C. BOULGER has published in the *Daily News* a statement in which he challenges the accuracy of the statistics and conclusions contained in the recently-published report of the Metropolitan Asylums Board (see *ante*, p. 292), with respect to the effects of diphtheria antitoxin. He disputes the main conclusion that, because the gross death-rate for the year 1895 was 22.5 per cent. as against 29.6 per cent. in the year 1894, "in antitoxic serum we possess a remedy of distinctly greater value in the treatment of diphtheria than any other with which we are acquainted."

It appears that the first nine months of the year 1895 were exceptionally light ones for diphtheria, with a very low total of deaths, whereas the last three months were as clearly marked by the excessive prevalence of the disease and by a high total of deaths. Mr. BOULGER resolved, therefore, to ascertain how far the results at one hospital for the last quarter of the year accord with those published for the whole year. The figures given are the complete returns from October 1 to December 31, 1895, and were taken from the bed cards of the patients. There were in all 193 cases of diphtheria. "Of these, fifty-eight received antitoxin, with the result that thirty-four died, giving the appalling death rate of 58.6 per cent. Of the other 135, who did not receive anti-toxin, only 20 died, or a death rate of 14.8 per cent. The rates for the year in the hospitals were 28.6 for antitoxined cases, and 13.4 for non-antitoxined cases, so that in this fatal quarter the antitoxined cases were 30 per cent. higher than on the whole year, and the non-antitoxined cases only 1.4 per cent."

IMMUNISATION AGAINST SERPENT VENOM.

THE symptoms of poisoning and the fatalities consequent upon the infliction of wounds by serpents of various kinds are due to the venom introduced into the wounds. This venom, as pointed out by Professor T. R. FRASER, F.R.S., in an address recently delivered at the Royal Institution, is a complex mixture of poisons and non-poisonous substances. The first are not ferments, and have no power of reproducing themselves in the animal body, but they produce effects having a direct relationship to the quantity introduced into the system. That quantity varies with the size and bodily and mental condition of the serpent, as well as with the nature of the bite, whilst further variation is caused according as one or both fangs have been introduced at the time of biting, and have penetrated deeply or only scratched the surface. Again, if the serpent had recently bitten another animal, it would probably have parted with a portion of the venom stored in its poison glands. Whilst, therefore, a bite may prove rapidly fatal, it may, on the other hand, result in very little danger. To produce death, a quantity of venom, spoken of as the minimum-lethal dose, must be introduced into the tissues, this quantity being different for different species of animals, and for different individuals of the same species. The body weight of the individual is the chief factor influencing the quantity of venom required to produce death, which is very exactly related to each pound or kilogramme of weight. Although serious and alarming symptoms will be produced, death will not follow an effective bite if a minute fraction below the minimum-lethal dose be introduced into the tissues, but only by the result itself can it be determined whether a fatal quantity of venom has been introduced.

Since then the introduction into the system of a less quantity than the minimum-lethal is bound normally to be followed by ultimate recovery from the effects of the bite, it is obvious that in such a case the recovery may often be attributed erroneously to the use of remedies that have been administered. Consequently a large number of substances have acquired an unjust reputation as antidotes, a similar state of affairs being exemplified in the treatment of many diseases. Experience has proved, however, that all these so-called antidotes are valueless to prevent death when even the smallest quantity of venom required to cause a fatal result has been received by an animal. Such an opinion

was expressed by Sir JOSEPH FAYRER, who stated that after long and repeated observations in India, and subsequently in England, he was forced to the conclusion "that all the remedies hitherto regarded as antidotes are absolutely without any specific effect on the condition produced by the poison." The failure to secure immunity has not been universal, however, if we may put any faith in legends and statements originating with nations and tribes existing outside of the civilisation of the time. In connection with facts derived by Professor FRASER from experiment, many of these appear to be of great significance and possess a deep interest. From a remote period, the belief has existed that immunity may be acquired by drinking, or otherwise assimilating, the poison of serpents, and it is difficult to understand how venomous serpents could resist the effects of absorption of their own venom through mucous surfaces unless a sort of protective inoculation exists. Since this and other evidence, therefore, pointed to the possibility of protection against venom, it was decided to experiment with a view to proving or disproving that possibility, the attempt being made to accustom animals to the effects of serpent bites by the introduction into their bodies of a succession of doses of the venom, no one of which at first approached the minimum-lethal dose.

Small supplies of cobra venom were obtained by Professor FRASER, and he was soon able to satisfy himself that, after the administration of a succession of minute doses, animals became able to receive the minimum-lethal dose without any distinct injury. Larger quantities of venom from different species of serpents were, later, procured from various parts of the world, but meanwhile the results of experiments on the inoculation of disease toxins and proteid toxins of vegetable origin had suggested to several observers that serpents' venom, because of its chemical analogies with some of those substances, might possibly be found capable, like them, of producing immunity against the effects of poisonous doses. In this way further important evidence was obtained in favour of the reality of the protection already referred to. Multitudinous experiments have since been conducted, with varying success, but the practical result at the present time is to show that inoculation with venom in the manner briefly described above confers protection which lasts for a considerable length of time, even when the last protective dose has not been a large one, but the experiments must proceed further to show exactly for what length of time the protection conferred by any final lethal dose may last. Subsequent investigations have had for their object the testing of the antidotal properties of blood-serum from immunised animals. Preliminary experiments showed that such properties are possessed by the serum, and as the result of an endeavour to preserve the latter without any appreciable loss of antidotal power, the powder termed "antivenene" was obtained. This is prepared by drying freshly-separated serum from the blood of immunised animals, in the receiver of an air-pump, over sulphuric acid. The solid residue is easily powdered, and readily dissolves in water when it is required for use. Experiments with antivenene indicate that by its use human life may probably be saved in a considerable proportion of the cases of snake bite which would otherwise terminate in death. Such a result would be eminently desirable, for, in addition to some twenty thousand deaths from snake bites which occur annually in India, there are many thousands in all the tropical and sub-tropical regions of the world.

ANNOTATIONS.

THE ANNUAL DINNER.—Tickets for the annual dinner of the members of the Pharmaceutical Society and their friends can now be obtained from the Honorary Secretary, Mr. Richard Bremridge, 17, Bloomsbury Square, W.C. A list of stewards will be found in our advertisement pages. The dinner will be held in the King's Hall, Holborn Restaurant, London, on Tuesday, May 19, and the price of tickets is one guinea each, including wine.

RADIOGRAPHS BY FLUORESCENT SCREENS.—In last week's *Nature*, Mr. J. W. Gifford, of Chard, explains how by the use of a potassium platino-cyanide screen, the length of electrographic exposures can be diminished to a fourth of the time usually necessary. The screen is first laid on the dark-room table, platino-cyanide uppermost, and a celluloid rapid sensitive film placed upon it, gelatin side downwards and in contact with the platino-cyanide. The object to be electrographed is next placed on top, in contact with the celluloid, and the whole enclosed in a light-tight cloth bag. Finally, expose under a Crookes' tube in the usual way. As the grain of the screen shows, care should be taken to powder the platino-cyanide finely before preparing the screen. Mr. L. Bleekrode, of the Hague, has obtained rapid results by using stiff black paper coated with crushed scheelite or native calcium tungstate suspended by means of gelatin. This paper was laid on a very sensitive dry plate (glass), with the fluorescent side in contact with the film, the objects were placed on top, and on applying Newton's focus tube with an induction coil, sharply-defined radiographs of keys, etc., were obtained in twenty-five seconds. The bones of the fingers required ninety seconds, and the plate then showed distinctly the eye of a needle that had been put in the epidermis of one of the fingers.

INCANDESCENT GAS MANTLES.—Decisions were given in the case of two alleged infringements of the Welsbach patent for incandescent gas burners on Saturday last. Mr. Justice Wills adopted Professor Dewar's view that Dr. Welsbach was the first to show how an enduring incandescent mantle or skeleton could be constructed out of the oxides of the rare metals, and pronounced against the manufacture and sale of lamps in which "plumes" like a small handbrush replaced the Welsbach "hood." In the second case, however, the holders of the original patent were worsted on technical grounds, the judge giving a verdict for the defendants almost in spite of himself. The *Times*, after noting that a cloud of scientific witnesses was in attendance, and that men of great eminence were called on both sides, observes that it must strike any impartial mind that the length of such enquiries would be curtailed, that the expert would be more in his true place than he often now is, and that there would be fewer exhibitions of startling conflicts between the opinions of high scientific authorities, if the Court frequently did what it is not customary to do—namely, took the evidence more into its own hands, nominating one expert, or it may be two, to report for its guidance on some of the matters of controversy. "An expert reporting as the delegate of the Court would sometimes express himself very differently from one paid for his evidence, and many cases would occupy as many hours as they now occupy days."

THE PHARMACEUTICAL SOCIETY'S SUBSCRIPTIONS.—All subscriptions to the Society for the current year must be received by the Secretary, Mr. Richard Bremridge, 17, Bloomsbury Square, W.C., by Thursday next, April 30, at latest. Subscriptions sent after that date must be accompanied by the minimum restoration fee of one shilling.

THE MANUFACTURE OF CALCIUM CARBIDE.—An interesting account of this industry is given in the *Journal of the American Chemical Society*, in a paper by J. T. Morehead and G. de Chalmot. The process as carried on at the works of the Willson Aluminium Company, is a very simple one, and, except for looking after the dynamos, no special skill or training is required. Coke and lime are ground and mixed, a water-wheel is started to drive the dynamos, and as soon as the electric arc is formed the mixture of coke and lime is shovelled into the furnace. This is built of ordinary brick and measures two and a-half by three feet at the base inside. The current enters at the bottom, where there is an electrode consisting of an iron plate covered with eight inches of pieces of carbon. The electricity is conveyed by means of sixteen copper cables, each 0.75 inch in diameter. A similar set of sixteen cables is connected with the top electrode, in the upper part of the furnace, which is composed of six carbon pencils, each thirty-six inches long by four square. They are held together by a sheet of iron, and attached to a bar which can be raised or lowered at will, so as to increase or lessen the distance between the electrodes. The water-wheel employed is of 300-h.p., and the electric current is generated in two dynamos, which give a current of 50 to 100 volts. The carbide is always found in one piece between the electrodes, surrounded by a mixture of unaltered coke and lime. The piece has a conical form, being broader at the base, and may be as high as two and a half feet. A very pure product has been obtained, which yielded 5.59 cubic feet of gas per pound, but it is more economical to produce carbide yielding not more than 5.0 cubic feet per pound. It can be produced at less than \$25.00 per ton, including wear and tear and interest on capital.

PHARMACEUTICAL EDUCATION IN THE UNITED STATES.—According to the *Apothecary*, there are about four thousand students annually attending colleges and schools of pharmacy in the United States. About three-fourths of that number finish less than one-third of a year's school work and do not graduate. Of the thousand who do graduate each year only about one hundred complete courses equal to two years' school work, and not more than three hundred complete courses equal to one full year's school work or over. Only about five per cent., therefore, of all the students of pharmacy in the United States ever finish courses exceeding forty weeks' full school work, whilst the great majority of persons employed in drug stores never attend any pharmaceutical college or school. To meet the requirements of those who wish to be trained for their chosen profession systematically, two courses of instruction are open to students in the School of Pharmacy of North-Western University, Chicago, one of the leading institutions in the United States. The first course—for the title of Graduate in Pharmacy—occupies forty weeks, thirty hours' instruction being given weekly and students being expected to devote their whole time to study. For the title of Pharmaceutical Chemist, students must devote their whole time to study during about eighteen months—forty weeks in the first year and thirty-eight in the second.

A NEW FERMENTING MOULD.—The organism responsible for the production of "Soja" or "Tao-Ju" has been isolated and carefully studied by Dr. C. Wehmer, who has named it *Aspergillus wentii*. It closely resembles *A. oryzae*, but can only be obtained by covering beans which have been boiled and superficially sun-dried with the leaves of *Hibiscus tiliaceus*. The organism then invariably makes its appearance on the leaves. It is described in *Nature* as being easily distinguished from the Japanese form, inasmuch as it produces a light chocolate pigment, whereas *A. oryzae* elaborates a greenish-yellow growth. The method of collecting the mould exactly resembles that employed by the Chinese in the manufacture of arrack.

MEETING OF THE EXECUTIVE OF THE NORTH BRITISH BRANCH.

A meeting of the Executive of the North British Branch was held in the Society's House, 36, York Place, Edinburgh, on Friday, April 17, at 12 noon, Mr. J. Laidlaw Ewing in the chair. Present: Messrs. Bowman, Coull, Currie, Davidson, Ewing, Fisher, Hardie, Henry, Johnston, Kermath, Kerr, Lunan, McAdam, Moir, Nesbit, Storrar, and Strachan. An apology for absence was received from Mr. Paterson, Aberdeen. The minutes of last meeting were read and approved.

Motion anent First Examination.

The Executive resumed the adjourned discussion of Mr. Coull's motion, which was read by the Assistant Secretary as follows:—

“That it is the opinion of this meeting of the Executive of the North British Branch of the Pharmaceutical Society of Great Britain that the time has now arrived for making the First or Preliminary examination a more efficient test of a candidate's general knowledge.”

The amendment by Mr. Fisher was also read as follows:—

“That the Executive delay further consideration of this matter in the meantime.”

Mr. COULL said he did not think the motion required very much argument in its favour. It appeared to be thought that it would be an act of temerity on their part to move in a matter of this kind before the headquarters had acted. But since their last meeting Mr. Carteighe had taken the thing into his consideration, and he had no doubt that by simply moving the motion now it would be carried. Scotland had been in the forefront as regarded education ever since John Knox's institution of parochial education, and even yet, in the Board schools, they were in advance of those in England. It would be very strange if Scotland did not take first place again in calling attention to the fact that the time had come when the Preliminary examination should be made more stringent.

Mr. LUNAN said it was time they were taking some action in this matter. He did not think Mr. Coull's motion was at all premature. Already the Minor examination had been considerably stiffened on a line with most examinations, including University examinations, and if they stiffened the Preliminary examination they would just be bringing it into line with their other examinations. The fact was that the Minor examination really required a higher elementary education than their Preliminary examination at present demanded, for there were many things in the Minor examination which they were not able to tackle without looking far beyond the requirements of the Preliminary, and if they wanted a monopoly and a higher professional status they required a stiffer Preliminary examination. People outside looked at that examination and measured their Minor examination by it, for they did not know much about the latter. If they had a Preliminary examination almost, if not altogether, equal to the medical preliminary, it would show what was demanded of them, and would be calculated to give them a greater monopoly. If they were able to say that they were really prepared to demand an examination like that, they would be better able to get that monopoly. He thought Mr. Coull at the last meeting stated his case clearly, and the motion should not have been opposed. He did not think it was a right thing for Mr. Fisher to say that the trade was not worthy of a more difficult examination. He thought it was worthy. The Pharmaceutical Society was to-day what it was, because it had passed from voluntary to compulsory examination. If chemists had not put shackles on themselves they would have been nowhere. They were able to get legislation simply because they stiffened their examinations. He sincerely trusted that the North British Branch, representing Scottish chemists, who he knew had the advancement of pharmacy at heart, would be very much in favour of this change, and that it would be agreed to unanimously.

Mr. FISHER said he thought when he made the amendment it was to this effect, that he had no objection in the world to the Preliminary or any of the examinations being made stiffer. But in the meantime, and until they had a compulsory curriculum for the other examinations, it would be folly to stiffen the Preliminary examination more than it was at present. Mr. Lunan had quite misunderstood him in saying that the trade was not worthy of having a more difficult examination. His view was, and always had been, in favour of a curriculum if their status was to be improved, and when that came he would say, let them have as stiff an examination as the medical Preliminary. It was as stiff already for the subjects they had, but let them have as many subjects as in the medical, and let them get a class of young men specially trained, knowing that they would have to study a certain number of years at the university and have a regular curriculum. Until they got that he moved the amendment that it was not time to make the Preliminary any stiffer than it was.

Mr. C. F. HENRY said he would like to say a few words from the point of view of the candidates themselves—the young men entering their trade. It seemed to him that the Preliminary examination was a fairly easy one, and that the Minor examination was a very difficult one; and he thought it was not right that a man should have an easy examination in the first instance. It was too much of the "Will you walk into my parlour, said the spider to the fly" policy; a candidate found it very difficult to get further than the Preliminary. He was led to look at statistics on the subject, and he thought it would be interesting to the Executive to know the percentages and passes in the Preliminary and Minor examinations. As statistics on such a subject were of no use unless one went over a considerable period, he had gone over a period of twenty-five years—from 1870 to the end of 1895—with the following results:—

	Minor Passes.	Preliminary Passes.	Percentage of Preliminaries passing Minor.
1870 to 1875	1335	2899	46.0
1875 to 1880	1505	3293	45.7
1880 to 1885	1582	3424	46.2
1885 to 1890	2377	3853	61.6
1890 to 1895	2479	4268	58.8
	9278	17,737	

That is to say, of 17,713 who passed the Preliminary in twenty-five

years, 9278 passed the Minor and 8459 failed to do so, or during the twenty-five years only 51.6 per cent. of those who passed the Preliminary have since passed the Minor. That appeared to him to be a very serious matter for consideration. There was a number of young men who had recently passed the Preliminary and who would yet pass the Minor, and that would so far account for the deficiency. But taking that into account and the number of young men who went abroad or entered the medical profession, and also those who died, who would amount to one or one and a half per cent., he thought they might take it that there were fully 4000 young men in the trade who had passed the Preliminary who had not yet passed the Minor examination. That did not prove that the Preliminary should be made easy because trade was bad, but that trade was bad because the Preliminary was easy, because these young men were filling positions which ought to be filled by qualified men. If the Preliminary was a bar at the beginning, and if they told the young men "you have a difficult examination to begin with, and if you have not brains or education to pass that, you will not pass the next," that would be a fair way of doing. But at present they were enticed by this Preliminary examination, and when they were in they found it a very difficult matter to get any further. It appeared to him that was a very strong argument for making the Preliminary examination more strict. The institution of a curriculum might be an argument for making the Minor examination stiffer, but he thought it did not at all affect the argument for having the Preliminary examination stiffer. He thought, therefore, as a matter of justice to the young men, that they ought to make the Preliminary a test of their capacity to go further, for if they were not able to pass a stiff Preliminary, they would not have the capacity, and many had not the leisure or means of passing the Minor examination. He could not support the amendment, because the longer the Preliminary remained easy the worse matters would get instead of better.

Mr. KERMATH asked what would be the effect of this motion.

The CHAIRMAN said they would send it to the Council as the resolution of this meeting of the Executive.

Mr. CURRIE said he expressed his views pretty strongly at the last meeting, and he was still of the same opinion. That opinion had been pretty considerably strengthened by what was to him the apparent result of the last Preliminary examination, because the Preliminary paper which had been set was to him a comparatively easy one, and yet to those whom he superintended on Tuesday last it seemed to prove a very serious stumbling block. He felt that it was too easy, for this reason, that he submitted the paper to an ex-sixth standard boy of thirteen years of age, who completed the three subjects in two and a half hours, and he got practically the same answers to all the questions which he (Mr. Currie) got in the examination room. Three of the candidates at that Preliminary examination spent an hour over one of the sums in arithmetic, and one of them came to him afterwards with the paper and said it was too bad that this examination should be so stiff. To spend one hour over one arithmetical question seemed to him ridiculous. He said to the candidate, "Was it necessary to spend one hour over it? I did the sum in twenty minutes," and he replied that he thought there were not many who could do that. He could quite sympathise with those who were averse to making the Preliminary any stiffer than it was at present, but speaking for the good of their trade, he thought it was far too easy, and he was strongly of opinion that if they stiffened the Preliminary it would keep back many who were unworthy to step into the ranks of pharmacy. They in Glasgow had a very great evil to contend with, as he had often stated, and that was the employment of boys in doctors' shops. Of course, doctors took any sort of boys, but he was glad to say chemists did not. The boys they employed generally had a fair idea of elementary education, and if a chemist took an apprentice without letting him know the kind of examination he had to go through was a fairly stiff one it was not fair to that boy. If any young fellow of eighteen or nineteen came up for the Preliminary examination, and failed to pass, he thought he should not be in the ranks of pharmacy at all. He had a conversation with a young fellow of twenty-three or twenty-four years of age who had been four times up, and he was convinced he was "plucked" again. He said that man was not worthy of being in the ranks of pharmacy, and was not capable of conducting himself as a pharmacist. If he made such a mess of the Preliminary, what would he do when he got to the Minor? He thought it was a shame to allow such candidates to go forward. He would go further than Mr. Coull, and say that if a man failed to pass the

Preliminary after a certain number of times he should be debarred from coming up in future. He would apply the same principle to the Minor examination. He did think it was time to step into the breach and get the examinations stiffened all round.

A vote was then taken, when three voted for the amendment and ten for the motion, which was therefore declared carried.

General Purposes Committee.

The Executive then went into Committee to consider the report of the General Purposes Committee, and on resuming, Mr. Fisher moved the adoption of the report, which included an expenditure of £6 3s. for cleaning and painting window-blinds and sashes on the street front of the Society's House, and an expenditure of £31 2s. 4d. for additional fittings and some minor alterations in new laboratories. The report also recommended that the scheme for rearrangement of the Society's House should be again remitted for further consideration, in view of certain proposals that are yet only in the initial stage.

Mr. JOHNSTON seconded the motion, and the report was unanimously adopted.

Annual Report.

The Executive went into Committee to consider the annual report to the Council, and, on resuming,

Mr. CURRIE, in moving the adoption of the report, said he was glad that it gave such a full analysis of the results of the Minor examinations, because the figures fully bore out what he had been contending. The percentage of failures was simply alarming.

Mr. STORRAB, in seconding the adoption of the report, referred to the care which had been bestowed by the Chairman, the Committee, and the Assistant Secretary on its compilation. As the Vice-Chairman had already said, the outstanding feature of the report was the increase in the number of candidates coming up. That bore out what was said that possibly one great reason for the numerous failures in the Minor examination was the imperfect general education of the candidates who came forward. The only way they could increase the percentage of passes was either by increasing the stringency of the Preliminary, or by decreasing the stringency of the Minor examination. These alternatives should not be altogether left out of mind. They could go on increasing the stiffness of the Minor examination and increasing the qualification of the men who joined their body; but unfortunately there was another aspect of the question. Whatever they did there, there was no doubt that young men were taken into shops who were not qualified, and who had not the general education fitting them to become a success in the trade. What would be the result of stiffening the examination knowing that these lads were in the trade? If they made the Preliminary and the Minor also too stiff, it meant that such lads would not even try to pass. They would simply lay themselves out, their object in life would be not to become efficient chemists and druggists but simply to make a living, and they would be "hewers of wood and drawers of water" in the trade all their lives. In his opinion the moment they stiffened the examination it would have a tendency to create greater evils than existed at the present time. They would have a class in the trade who would have no ambition, who would have no means to enter business for themselves, and who on account of the creation of these difficulties would be rendered useless in the trade. The whole question required to be very carefully considered so as to hit upon a happy medium of qualification. They must not have too stiff an examination to quench ambition, and it must on the other hand be stiff enough to secure what they all wished to see—the gradual improvement of the trade itself. The raising of the Preliminary examination was not a question that could be settled in one or two debates.

Mr. KERMAITH said it would be interesting to get some idea of the training these young men had before presenting themselves as candidates; whether they simply came on chance and took the risk of passing, or prepared themselves in any methodical manner. Any apprentice he had under his charge, he asked to leave the shop for a half or whole year and to go in for regular study, because he thought it was a very great hardship to expect young men who worked from morning till night to prepare themselves and make a decent appearance in the Minor examination. It was a very serious question, as Mr. Storrar had said, for provincial men. He had great difficulty in getting young lads with a fair knowledge, such as would enable them to pass the Preliminary examination to enter his shop at all. But he made it a point to let them understand that that was the first thing they had to do, and if he could get them

to pass the Preliminary before they came to him at all he preferred it. He aimed at that and made it a point to give them every encouragement by paying their fees and otherwise, and for the reason already stated, before they left him he always advised any one in his employment, trying to pass the Minor examination, to leave the shop for a half or whole year. There must be some haphazard way in which they came up merely to bother the examiners, and it was terrible to have such a large percentage of failures. He did not object to them paying the fees, but he did object to them coming there and very likely casting a reflection on the method of the examination and the extent of the education they had before they came.

Mr. MOIR said he supposed about 75 per cent. of the Minor candidates came from some school.

The CHAIRMAN said they could not tell how the candidates had been trained, but they might safely say the greater number of them had had most of their training at a school of pharmacy. The weakest part of the candidates' training was their elementary training in science, and in particular they had not acquired the elementary principles of chemistry and botany.

Mr. LUNAN said they were no worse than in the medical examination.

Mr. CURRIE said if they looked at the last report to the Council they would see that the great percentage failed in dispensing. That seemed to him a serious matter.

The CHAIRMAN said that had reference to the London examinations, but not to Scotland. He would say with regard to their examinations that about twice as many failed in practical chemistry as in dispensing.

Mr. COULL asked if it was the case with regard to the Edinburgh candidates that they got more than the six volumetric solutions in the Pharmacopœia.

The CHAIRMAN said they could not discuss that matter there.

Mr. COULL said they got more in London, for he had seen the papers.

The report was then unanimously adopted, and ordered to be forwarded to the Council.

Election of Executive.

On the motion of Mr. Bowman, seconded by Mr. Davidson, it was agreed:—

"That the next election take place on Friday, June 19, and that the Chairman and Vice-Chairman be appointed Scrutineers of the voting papers, with power to add to their number."

Mr. CURRIE said he spoke at the last meeting with regard to the entire body being elected annually. He thought it would be desirable to get some other mode by which a portion only would retire each year, and to get the resolution of Council passed in 1886 altered.

The CHAIRMAN said he did not think they could do that at this meeting.

Mr. CURRIE asked when it could be done.

The CHAIRMAN said he would have to table a motion there and send it up to the Council.

Mr. CURRIE said he thought it was unfair that the whole Executive should retire at one time. The continuity should be preserved.

Mr. MOIR asked why the Executive should not be elected in the same way as the Council of the Society in London.

The ASSISTANT SECRETARY explained that the method of election was so specified in the resolution of Council that the idea of a partial retirement each year could not be easily carried out. It was not like the election of the Council, inasmuch as they had no legal status further than a resolution of Council. They had to make up the number of the Executive to twenty-one, including the President and Vice-President and the members of Council resident in Scotland. The latter was an indefinite number, and they might have one, two, three, or none, and for that reason they could not have the election of Executive till after the Council election was completed, for they could not tell till then how many members fell to be elected in any one year.

It was agreed that the annual meeting on June 19 should be at 11 a.m., instead of 12 noon.

Early Closing Bill.

In answer to Mr. Kermath, the Chairman said Sir John Lubbock's Early Closing Bill had been considered and dealt with by the Edinburgh District Chemists' Trade Association.

The meeting then closed.

PROCEEDINGS OF SOCIETIES.

Midland Chemists' Assistants' Association, April 8.—Mr. T. C. Clarke, President, in the chair.—A lecture on "Volumetric Analysis" was given by Mr. F. H. Alcock, F.I.C., who commenced with a definition of volumetric analysis and its uses, and then made some remarks on the necessary apparatus. Special attention was called to the fact that the B.P. operations in volumetric analysis could be performed at a small cost, and with tolerable accuracy. This was followed by an enumeration of the official standard solutions, their advantages and disadvantages, and the reasons for their adoption. A mineral acid was advocated for alkalimetry in place of oxalic acid. The deterioration of thio-sulphate solution was specially referred to, and a suggestion was made that it could be preserved with some degree of satisfaction by the addition of a little carbon bisulphide which greatly retarded decomposition, and did not interfere with the reactions in which the solution was concerned in the B.P. The stronger oxidation solutions of bichromate of potassium and permanganate of potassium were alluded to, and it was suggested that the latter might be made official, for it could be used for the determination of most of the ferrous salts, and also with care for the hypophosphites. The lecture was illustrated by numerous experiments.

At a meeting held on Wednesday, April 15, the Shops (Early Closing) Bill was discussed. There was a small attendance owing to an extra-ordinary meeting of the Midland Pharmaceutical Association being held at the same time. Mr. T. C. Clarke (the President) occupied the chair.

Mr. H. S. Lawton, who opened the discussion, said he was aware it was to pharmacists a subject of great difficulty to satisfy everyone, and required to be approached with great care. He considered it advisable in opening the discussion to set out the disadvantages that many laboured under on account of the late hours the custom of the business imposed; to criticise and examine the necessity (if it really existed) for keeping these late hours; to discuss the practicability of doing business in more reasonable time, and to declare an opinion favourably or otherwise on the Bill now before Parliament. He had come to the conclusion that the disadvantages were only to be removed by legislation, that there was no real public necessity for keeping pharmacies open so late into the night, and that by actively supporting the Bill, and assisting in putting its provisions into operation, benefit would accrue to all engaged in pharmacy, and that they would also have the sympathy and support of the public at large.

In support of these opinions he remarked that the average time for closing the shops for general trade in that part of the country was 9 or 9.30 p.m., which compared very unfavourably with that of any other well-regulated calling, and the chief cause of this lateness had arisen, not by any public necessity, but by the competition of rival establishments to gain public favour by being available at all hours. In many suburbs, especially working-class neighbourhoods, there was undoubtedly a habit of leaving the purchases until the last hour the shops were open. If all shops in these localities were compulsorily closed at a uniform time which was well known, the trade would be done an hour or two hours earlier as the case might be. Everyone who worked until 9.30 p.m. knew that if they kept open until 10.30 the same customers who rushed in just in time to be served at 9.30 would rush in just the same an hour later, and there was no doubt that those people, if the shops closed earlier, would, instead of hurrying to the chemist just before bedtime, come after tea or earlier in the evening.

He particularly wished to call attention to one disadvantage of the late hours system, one that was equally prejudicial to the interests of masters and assistants, and constituted a great danger to the welfare of legitimate trade. It was this: Every three months men were qualifying as chemists and naturally looking round to turn their abilities and qualifications to the best advantage to themselves. The legitimate chemist in business offered them occupation for their talents at fair remuneration according to the market value of labour, but in most cases the hours were 9 or 9.30 p.m., and many evenings he had to remain on duty until bedtime, with an arrangement for one evening per week at liberty. This left no opportunity for the social intercourse and intellectual pursuits which were the privilege of any other educated and professional man than the one whose lot had been cast in the groove of legitimate pharmacy, as at the present time conducted. On the other hand there was another and apparently a more alluring path for the newly-qualified pharmacist to follow. Offered equal inducements in point

of salary in well-appointed shops, with hours strictly set, averaging 7.30 closing in the evening and one day a week earlier, could it be wondered that so many sold their qualifications to limited liability companies, who almost universally offer the special inducement of early closing and still gained for the shareholders their 10 per cent. dividend?

Not until the hours of legitimate pharmacy were brought into line with these so-called cutting shops should they be able to battle successfully with the degenerate and humiliating tendency to let a great and valuable portion of their trade fall into the hands of grasping and dividend-seeking speculators, who, having unlimited capital to call up, were allowed by the present state of things to wolf the living of legitimate traders. This was a real danger and placed the genuine pharmacy at a serious disadvantage, but those men who lent their aid and qualification to the detriment and injury of their fellow-craftsmen were only as much to blame, he took it, as those who, from motives quite as selfish, would prevent—and, by their opposition to any scheme of early closing, do prevent—their neighbours enjoying any outdoor enjoyment by daylight.

He would deal with the great disadvantage of having a uniform closing-time by illustration. Most people made periodical visits to the bank and in every case reached there before 4 o'clock. Why? Because if they got there later the doors would be closed. Why not transfer the account to another bank? Simply because all the banks close at the same time and therefore each bank keeps its own customers and no one has any grievance to complain of on account of early-closing. That principle he took it applied to all trades.

The Chairman, Mr. J. Selby and Mr. Bindloss also joined in the discussion, and eventually it was agreed that the meeting was in hearty sympathy with the objects of the Bill.

Chemists' Assistants' Association, April 16.—Mr. E. W. Hill, President, in the chair.—Several short papers were read by members. The first was a—

"NOTE ON CREAM OF TARTAR," BY H. H. ROBINS.

In this the author remarked on the faulty nature of the test at present set forth in the British Pharmacopœia. A paper on the same subject by C. A. Hill, which was published in the *Pharmaceutical Journal* (*ante*, p. 281) dealt with the same subject, but Mr. Robins considered the subject of sufficient importance to re-emphasise the necessity for directions being given in the official test which would ensure the detection of calcium tartrate, and also guard against the loss of potassium carbonate from reaction with the calcium sulphate, which occurs in commercial cream of tartar in the process of assay.

Mr. A. Gunn then contributed a—

"NOTE ON AN IMPURITY IN QUININE PHOSPHATE."

It was noticed that a sample from a freshly-opened 10-oz. tin of quinine phosphate, which gave a perfectly clear solution in hydrochloric acid, yielded, upon the addition of sulphuric acid, a dull mixture that, after standing for some time and moving occasionally, gave distinct precipitation. In order to clear up the nature of this deposit one ounce of the salt was dissolved in hydrochloric acid, and after the addition of sulphuric acid the precipitate formed was collected and examined, when it was found to consist of barium sulphate, the weight being 0.364 gramme. This impurity was an unusual one, and Mr. Gunn brought the matter forward for the purpose of ascertaining if anyone else had met with a similar experience. He then gave a demonstration of the use of the filter pump for the purpose of effecting a clear separation of the emulsion-like substance which is frequently formed when dealing with chloroform and ether in the processes of alkaloidal determinations. The method devised by Mr. Gunn evidently acts admirably and greatly facilitates work.

Following this a paper was read by Mr. H. Garnett on—

"THE TESTING OF LEMON OIL" (*see page 323*).

Mr. H. Robins, after complimenting Mr. Garnett upon the practical nature of his paper, remarked that in his own work he often ascertained the commercial value of lemon oils comparatively by preparing a mixture of sugar and glucose with the samples under examination, and those were afterwards exposed for about twenty-four hours, when they could readily be classified. He would like to ask what time was necessary to carry out the process which had been described in the paper?

Mr. W. Crouch asked if Mr. Garnett could give any idea of the results as shown by his process and those given by the bisulphite method.

Mr. Gunn remarked that he had known a case in which a sample of citral crystallised after being kept for some time, and he would like

to know if Mr. Garnett had met with a similar experience. He could confirm what had been said in regard to solutions of the active constituents of oils not having the same bouquet as the natural product.

Mr. H. Garnett, in reply, said that it was rather difficult to give the exact time occupied by the process, but, generally speaking, if started during the afternoon of one day it could be finished during the forenoon of the following day. In regard to a comparison of the bisulphite method with his own, he had found that a sample of lemon oil which yielded between 6 and 7 per cent. of citral by his process only gave between 3 and 4 per cent. by the other method. He had not had any experience of the crystallisation of citral referred to by Mr. Gunn, and concluded it was due to the action of the air.

Sheffield Microscopical Society, April 17.—The members of this Society held what is termed a practical night at the Rutland Institute, Fargate. Mr. Bernard H. Hoole gave a short demonstration on "Dark Ground Illumination as applied to the Microscope," and exhibited a number of views of marine zoophytes and diatoms.

Royal Institution, April 16.—In the course of a lecture on "Recent Chemical Progress," Professor Dewar, F.R.S., commented on the great future opened out to synthetical chemistry by the employment of the electric arc. Some of the most interesting results have been obtained from the electric furnace by Moissan in the shape of carbides, stable bodies produced by the combination at high temperatures of carbon with various metals. Many of these carbides are decomposed by water, the hydrogen of the water combining with the carbon to form hydrocarbons. Thus calcium carbide gives acetylene, that of aluminium gives marsh gas, while others, again, give these and other gases and liquid petroleum. Many years ago Professor Mendeleef speculated that the only reason for the immense localisation of petroleum at Baku is that it is being generated there—probably by the action of water on carbides. His idea was rather ridiculed then, but now it is his turn to smile. When acetylene is heated to a dull red heat, it is polymerised to benzene, which is the source of all the new modern colours, and thus by three direct stages we are able to reach the nucleus of all the colours hitherto manufactured from coal-tar products. First there is the combination of lime and coke in the electric furnace; second, the decomposition of the carbide thus formed by water; and third, the transformation into benzene of the resulting acetylene by means of heat. Professor Dewar concluded by briefly discussing some of the properties of acetylene, explaining, among other things, that the cause of its extraordinarily great luminosity is due to its peculiar endothermic structure.

Liverpool Pharmaceutical Students' Society, April 16.—Mr. T. S. Wokes, President, in the chair. A smoking concert was given by the members of this Society, assisted by their friends, at the Kardomah Café. A very good and varied programme of songs and recitations was contributed by Messrs. Clegg, Field, Jones, Pierson, and others. The attendance was nearly double that at the previous smoker, the students evidently falling in with the new idea of the Committee, in having a smoker on temperance lines. A collection was made on behalf of the Pharmaceutical Benevolent Fund during the evening, a sum of about £1 10s. being the result.

SCOTTISH NEWS.

INTERNATIONAL PHARMACEUTICAL EXHIBITION IN PRAGUE.—The Lord Provost of Edinburgh has received from the Austrian Ambassador, through the Under-Secretary of State for Scotland, a programme of the International Pharmaceutical Exhibition to be held in Prague from August 15 to September 15, 1896. It has been arranged that intending exhibitors from Scotland may communicate with Mr. J. Rutherford Hill, Assistant Secretary to the Pharmaceutical Society of Great Britain, at 36, York Place, Edinburgh.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION, April 17.—Mr. J. Mackintosh Cameron in the chair.—At the annual business meeting the Chairman reported that at the request of the Treasurer the accounts had been audited by Messrs. Rowland and J. D. Sinclair, and this was approved of.

The Secretary read the report of the Prize Committee on the "Ewing" Pharmacy Prize Competition. Only one of the candidates who entered had attended the examination, and he obtained 60 per cent. of marks and had been awarded a third prize.

The President then presented a copy of the British Pharmacopœia, given by Mr. S. G. Crowden, to the prizeman, Mr. Alexander MacSween, 23, Bernard Street, Leith. In doing so the President expressed regret that so few had offered themselves for these prizes, and mentioned that a former prizeman, Mr. George Senter, had further distinguished himself by carrying off three sessional medals at Bloomsbury Square. He had also just observed that another former prizeman had, after a distinguished career as a student, been appointed medical officer of health for Shanghai. He referred to Dr. James T. Grant, M.B., B.Sc.

The Secretary read a letter from Professor Patrick Geddes inviting the members of the Association to visit his botanic garden at University College, Dundee, on the Queen's birthday holiday, May 21 next.

On the motion of Mr. Hay, seconded by Mr. Gordon, it was agreed to accept the invitation, and it was remitted to the Committee to make arrangements.

The Secretary and Treasurer then read the annual report and financial statement, which were approved of. The former showed an increased membership, and that the attendance at the meetings had been good, the average being forty and the highest ninety. The summer meetings instituted last season had also been very successful. The financial statement showed a balance of £3 12s. 1d., and it was agreed to vote a sum of £1 1s. to the Benevolent Fund of the Pharmaceutical Society.

The following office-bearers were elected for the ensuing year: President, James McBain; Vice-President, George Sinclair; Secretary, William F. Hay, 139, Princes Street; Assistant Secretary, J. Harris Burns; Treasurer, Alexander Murray; and as Members of Committee, Messrs. Cameron, Cowie, McSween, Rowland, Seivwright, Sime, J. R. Thompson, and Thwaites. Messrs. Cameron, Dey, and Cowie were elected members of the Prize Committee.

The arrangements for summer meetings and botanical excursions, and the consideration of the prize scheme having been remitted to the Committee, the meeting closed with a hearty vote of thanks to the retiring office-bearers.

LEGAL INTELLIGENCE.

INCANDESCENT GAS BURNERS.—In the Queen's Bench Division on Saturday last, Mr. Justice Wills gave judgment in the case of the Incandescent Gas Light Company, Limited, *v.* De Mare Incandescent Gas Light System, Limited. He said it had long been known that certain substances, notably lime, magnesia, and zirconia, when subjected to the heat of a flame of mixed coal gas and air will produce a brilliant incandescence, but it was quite safe to say that for all practical purposes Welsbach discovered a practical and simple method of arranging oxides to be rendered incandescent in a shape which made it possible to use them in burners, and also discovered that a class of substances, which for convenience and brevity are generally spoken of by chemists and throughout the hearing of this case have been called "rare earths," would afford at once the necessary illumination and the necessary coherence. The process adopted by Welsbach begins by taking a fabric made of cotton of suitable pattern, then proceeding to impregnate it with salts of the rare metals lanthanum and zirconium, or of those with salts of yttrium added, and lastly ammoniating it. The result of the soaking is to get the salts into every minutest portion of the fibres of the fabric, so that when finally the cotton fabric itself is eliminated by fire there may be left a solid substance occupying almost the very portions of space now filled by the impregnated fabric. The result of ammoniation is to convert the salts into hydrated oxides, filling, as did the salts, the innermost recesses of every portion of the fabric. The fabric is not yet fit for permanent use in the burner. The last operation is when the hood is placed in the burner and set on fire by lighting the gas. This process drives off all the water of the hydrated oxides and reduces them to their final condition of anhydrous oxides, in which state they perform the business purpose of giving illumination by incandescence. The claim made by the patentee is the combination of the various essential elements in the process described.

As to the question of infringement it was clear that the defendants intended to construct and sell in this country plumes for incandescent lamps. A plume consists of a number of threads tied on to a platinum wire and arranged so as to form a sort of fringe, all the threads of which are brought very closely together while they are strung on to the wire, but allowed to separate as they leave it, so that the apparatus looks like a housemaid's small handbrush, the cross sections of which would take the shape of a fan. This plume is then to be dipped into a solution consisting preferably of one part of sulphate of magnesium, two parts of sulphate of erbium, and two parts of sulphate of zirconium (all chemically pure) in 25 parts of water. The plume may be dipped into collodion or varnish, for the sake of strength, and is then to be suspended in the flame of a gas-burner to produce incandescence. Moreover, fringes delivered by the defendants as specimens of what they propose to make were found to consist of oxide of zirconium, 84 per cent. ; oxides of yttrium sub-group, 9 per cent. ; and oxide of magnesium, 7 per cent. Welsbach's limits of proportion are very large. Enough appeared to satisfy the Judge that, unless the omission of ammoniation, the omission of lanthana, and the variation in the form of the illuminant appliance prevented him from saying that the substance of Welsbach's patent had been taken, the defendants were about to infringe and ought to be restrained. Judgment was therefore given for the plaintiffs.

In the case of the Incandescent Gas Light Company (Limited) v. the Sunlight Incandescent Gas Lamp Company (Limited) and Others, Mr. Justice Wills, in giving judgment, said the defendant company was formed to work a patent granted to one Dellwik. The defendants take the idea of the skeleton hood produced by the Welsbach process, but make it of about 50 to 60 per cent. of alumina, about 30 per cent. of zirconia, and then coat this with a thin coating of oxide of chromium. It seemed to him that this is essentially different from what is claimed by the Welsbach specification. Welsbach might have claimed the hood made of any materials, but that would have entirely altered his patent and would have exposed it to a fresh set of dangers. He might have claimed the hood, of whatever material, applied for the purpose of illumination, but that would again have altered his patent and have made it void, for it would have been a patent for the use in the form of a hood of whatever substances would answer. But he did claim nothing of this kind. The use of the rare earths is beyond all doubt of the essence of his invention. He could not by any adaptation make a strong groundwork of alumina, or alumina and zirconia, and then spray it or saturate it with the salt of an illuminant oxide to be reduced to the oxide on putting it into the flame, which is what the defendants have done. It was a necessary consequence of the nature of Welsbach's process that his skeleton should be absolutely homogeneous throughout. He felt that the defendants were taking a very valuable process bodily from Welsbach without any remuneration ; but that is the necessary fate of a patentee who confines himself to claiming the aggregate of a whole string of processes of which this is one. The fatal difficulty in this case was that the formation of a Welsbach skeleton by other means and of other substances than those pointed out in the specification is not claimed. No use is made by the defendants of any of the rare earths, and their choice of substances and their method of applying the illuminants appeared to be as far asunder as the poles from that contemplated by Welsbach. He must therefore give judgment for the defendants upon the issue of infringement.

A CORONER ON THE SALE OF CARBOLIC ACID.—Some severe remarks were uttered by the coroner, Mr. Smelt, at an inquest held at the City Coroner's Court, Manchester, on April 16. A woman had died as the result of taking carbolic acid, which she had sent a boy of nine years to purchase. According to the evidence, the poison was supplied after little, if any, inquiry, and the coroner, commenting on this, said that if chemists did not exercise more discretion, the sooner they were prevented from selling poison the better. It was naturally expected, he continued, that a chemist should exercise a little more discretion than was indicated in that case, and not sell such a dangerous poison indiscriminately simply for the sake of the paltry profit got on it. Common decency suggested that every chemist who had any respect for himself should of his own free will exercise discretion, and not be compelled to do so by law. It was ridiculous that an Act of Parliament should have to be got to prevent the sale of such a poison to children of tender years when chemists held the alternative in their own hands. Whilst agreeing that the seller had done all that was legally required of him, he was astonished that he had not acted with more discretion.

CORRESPONDENCE.

SHOPS (EARLY CLOSING) BILL.

The following letter has been addressed to the Secretary of the Pharmaceutical Society, and serves as a good example of the extent to which a fancied grievance will lead some individuals. The writer would surely act more wisely by remaining a member and continuing to bring his influence to bear upon the Council in regard to matters that interest him. But perhaps in this case, as in so many others, there is no resisting the fascination of the all-pervading cycling craze.—[*Ed. Pharm. Journ.*]:—

[COPY.]

"Sir,—I intend to discontinue my subscription to the Pharmaceutical Society. The reason I give is the apparent disinterestedness (*sic*) of the Council to the welfare of assistants and small chemists, chiefly with regard to the Shops (Early Closing) Bill at present before the House of Commons. I had intended becoming a life member, but I now think I should derive more benefit by investing the money in a bicycle."

Sir,—Having read with interest the expressions of opinion in regard to the above Bill I should like to mention one thing. Why do qualified assistants go over to the large general stores? The greatest attraction undoubtedly is the shorter hours and weekly half-holiday. I have now several in my mind who have given themselves to the stores almost solely for that reason, and others who are oscillating. So by supporting this Bill and getting our hours shortened we shall make the ranks of true pharmacy more inviting for qualified assistants to remain with us.

Knightsbridge, April 18, 1896.

QUALIFIED ASSISTANT.

Sir,—In reply to the invitation for expressions of opinion on the shops Bill, I desire to enter an emphatic protest against it. "Early closing" and holiday time are not so intimately associated as to be necessary for each other's existence, and even under this measure it is not to be conceived that the chemists and all their assistants would be out scouring the country in search of health, or whatever it is supposed to be necessary they should shut their shops for, so, unless the "single-handed" man were willing to place his business at a great disadvantage compared with others, he would still have to stay in himself. Any adverse or detrimental effects which might accrue from this scheme would primarily affect and have to be borne by, proprietors; and it is not universally admitted that the best way assistants could redress any grievance they may have is by curtailing the time during which employers obtain their income. Every purchase made by the public is not a necessity, and it may reasonably be conceded that the passing of this Act would result in a material proportion of business being absolutely lost. Possibly this would benefit the health of the public more than that of the shopkeepers.

With regard to the suggestion of "Spes" that the public should have a supply of remedies on hand—can it be expected of the great mass of working-men to keep a medicine chest in their homes? Consider that they are only able to provide much more commonly necessary domestic commodities in a "hand-to-mouth" way. Also I do not think the majority of chemists do, or should wish to, relegate themselves to such a subsidiary position as to require the authority of a medical practitioner or nurse during certain hours for the exercise of their calling. In conclusion, I think the Bill a most vexatious interference with individual rights, and broadly, does it not stultify itself by having to exclude from its workings such a large proportion of notorious offenders? The attainment of its object might be left to the progress and enlightenment of the age, which will surely develop a higher perception of the duties employers and employes owe to each other; and also a greater spirit of charity in not ascribing every difference of opinion to a desire for the extermination of our *confrères*, but rather to a wish to conform to what one considers the requirements of his district.

Exeter, April 20, 1896.

C.

MANUFACTURE OF COAL TAR PRODUCTS.

In reply to "Student," a correspondent says the best book on the manufacture of coal tar products is probably the second edition of Mr. George Lunge's 'Treatise on the Distillation of Coal Tar' (London: Gurney and Jackson), which contains 191 working diagrams to scale.

ILLEGIBLE HANDWRITING.

Sir,—The enclosed order was handed in to-day, written by a local surgeon. As we are acquainted with his handwriting we managed to execute the order, but we send the original to you as a rather good sample of illegibility.

Bognor, April 18, 1896.

[FACSIMILE OF ORDER.]

Pharmaceutical Journal

London

Edw. Ashton Esq

THE SOCIETY'S LOCAL SECRETARIES.

Sir,—I am much obliged to Mr. Kemp for his letter of the 11th. The replies he has had to some of his post-cards show that there are some people who do not object to that form of notice. Nevertheless, I still think that where it is necessary to send a reminder to subscribers, the method adopted by the Pharmaceutical Society is far preferable to that of the humble post-card. Mr. Rymer Young, who speaks as one having authority, assures Mr. Kemp that I shall be quite singular in my criticisms. That is merely an assumption on the part of Mr. Young, and one which I can assure him is incorrect. Mr. March is mistaken in supposing that I wish to throw any scorn upon our local secretary. As to my epidermis, he may be right; all men are not alike. It is just as possible for one man to have a rather thin epidermis as for another to be blessed with an excessively thick one.

Manchester, April 20, 1896.

T. R. ASHTON.

THE VAGARIES OF PUBLIC ANALYSTS.

Sir,—The cocksureness of paid analysts is a spectacle to make angels weep. How many would have to report before two could be found alike as regards the prescription dispensed by Mr. Meacher (*vide* your last Supplement)?

Ingredients according to Dispenser.	Found by Vestry Analyst.	Somerset House Analysis.
Pot. iodid. gr. 99	gr. 108	gr. 103·8
Iodine gr. 66	gr. 57	gr. 92·4
Aqua ℥iij.	℥iij.	℥iij.

Where does the public benefit come in?

London, April 20, 1896.

E. WARRELL.

* * * The Somerset House analysts appear to have expressed the opinion that the iodine was not fully dissolved when the division of the medicine into three parts took place. The cause of the discrepancies would be quite clear if that were so, but the dispenser would then be open to criticism for sending out an imperfect solution.—[Ed. *Pharm. Journ.*]

CAFFEINE IN TEA.

Sir,—Under the heading "Irish News" in your last issue you publish a report of a paper on "Camellia Thea," by Mr. D. O'Sullivan, which states that caffeine would lessen or disappear altogether from an infusion of tea if it be allowed to "stew." My experience, and that of other observers, is that caffeine is not volatilised by the evaporation of an aqueous infusion of tea on a water bath, and, further, that by boiling tea with water for several hours a larger proportion of caffeine is extracted than by boiling for half an hour. It would be interesting to know the cause of the diminution and subsequent disappearance of the caffeine from Mr. O'Sullivan's infusions, for certainly his results are sufficiently original to call for some confirmation.

7, Oseney Crescent, N. W.
April 22, 1896.

C. EDWD. SAGE.

MODERN PRESCRIBING.

Sir,—I am living in a country town, and received the following prescription to dispense (?) save the mark! I had to write to the different manufacturers; D. and F. and tabloids I know, but who is Randall, or of what his emulsion, castor oil, or any other oil?

Miss.—

℞ Blaud's pill c quina and arsenic.

"Duncan and Fleckhart's," No. 2.

Mitte 48. One to be taken twice a day after meals.

℞ Randall's Emulsion.

One tablespoonful to be taken every morning.

One tabloid of cascara sagrada, 2 grs., to be taken when an aperient is required at bedtime.

Of what use are the examinations, Minor or Major? What use is the B.P., of which I read, see preface: "It is intended to afford the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined." Cannot the medical man of the present day trust himself to write a prescription without being obliged to fall back upon some fellow's syrup, emulsion, or liquor?

April 20, 1896.

"MAJOR."

ANSWERS.

"ANTITOXIN."—The sample of so-called egg powder for colouring milk, which you send, is nothing but a water-soluble aniline dye, probably a "safranine" yellow.

J. BIENVENU.—The specimen you send is the seed of *Martynia diandra* (Pedaliaceæ).

"AMICUS."—You will find full information in the 'Regulations for Army Medical Services,' published by Eyre and Spottiswoode, East Harding Street, Fleet Street, E.C., price 1s. 6d.

"A REGISTERED ONE."—The regulations of the Local Government Board relative to the appointment of dispensers apply to poor law infirmaries and dispensaries only. You will find particulars in the 'Calendar of the Pharmaceutical Society.' See also the *Pharmaceutical Journal* for March 30, 1895, p. 841, and June 22, 1895, p. 1178.

J. HICKING.—The licence is required for the still, not for the condenser.

J. H. W.—There are differences of opinion as to what preparation should be dispensed when "liquor taraxaci" is ordered in a prescription. Some dispensers think the liquid extract should be used, others, again, dispense the succus. But there is no reason for assuming that an official preparation is of necessity intended, the more especially as there is a distinct preparation known as "liquor taraxaci" (*vide* Squire's 'Companion'). This differs from the succus; spirit being added to the bruised fresh root directly before pressing, instead of being added to the expressed juice.

QUERY.

SYRUP OF CAMPHOR.—Can any reader of the Journal supply the Bristol Royal Infirmary formula for syrup of camphor? It appears to be published, as the preparation is supplied by chemists in the West of England.

OBITUARY.

PARKER.—On April 14, William Parker, Chemist and Druggist, Derby. (Aged 26.)

PEIRCE.—On April 15, P. S. Peirce, Chemist and Druggist, Croydon. (Aged 33.)

POWELL.—On April 17, Edward Powell, Chemist and Druggist, late of Winchester. (Aged 81.)

LITTLEFIELD.—On April 19, in London, James Wavell Littlefield, Pharmaceutical Chemist, of Ventnor, I.W. (Aged 68.) Mr. Littlefield had been a member of the Pharmaceutical Society since 1854, and was local secretary at Ventnor.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs, Adams, Ashton, Bard, Bayley, Bienvenu, Bindloss, Bolton Burrell, Charles, Hickering, Hill, Jones, Lander, Lunan, Russell, Sage, Sawyer, Thomas, Tyrer, Wallace, Ward, Warrell.

“THE MONTH.”

A New Zirconium Carbide.

Some time ago H. Moissan pointed out that zirconium could easily be obtained in the metallic state on reducing zirconia by means of carbon in the electric furnace, and at the same meeting of the Academy of Sciences, Troost

described the formation of a carbide of zirconium, ZrC_2 . Later experiments by Moissan and Lengfeld have resulted in the discovery of another compound of the same metal with carbon. This carbide, ZrC , was obtained by heating its components in the now celebrated electric furnace, and is described as crystalline and non-decomposable by the action of water up to $100^\circ C$. This great stability is in marked contrast to the behaviour, when exposed to the action of water, of the metallic carbides previously formed (*ante*, p. 241), and seems especially curious when it is considered that carbide of thorium—a metal very near to zirconium in Mendéléeff's classification—decomposes readily when acted upon by cold water, acetylene, ethylene, methane, and hydrogen being evolved. Zirconium carbide has a greyish colour and metallic appearance, and remains unaltered in both dry and moist air. It scratches glass and quartz easily, but does not affect the ruby. The hydracids attack it readily—hydrofluoric in the cold, hydrochloric at 250° , hydrobromic at 300° , and hydriodic near 400° . At a red heat the carbide burns in oxygen, and in the presence of sulphur vapour a small quantity of sulphide is formed. Ammonia and hydrochloric acid are without action on the new compound, but it is decomposed by nitric and sulphuric acids, whilst strong oxidising agents attack it energetically (*Comp. rend.*, cxxii., 651).

Constitution of Rhodinol.

Barbier and Bouveault recently alleged that the so-called “rhodinol” extracted by Eckart from rose oil is in reality a mixture of two alcohols—lemonol and rhodinol, the composition of the latter being represented by the formula

$C_{10}H_{20}O$ (*ante*, p. 241). By oxidation of this “pure” rhodinol they have obtained a volatile product, boiling at 90° under a pressure of 10 Mm., possessing a very strong odour of mint, and apparently corresponding to the formula $C_{10}H_{18}O$. This aldehyde, which they name “rhodinol,” was associated with an oily monobasic acid—rhodinic acid, $C_{10}H_{18}O_2$ —which possesses a strong and disagreeable odour, boils at 147° , and is identical with a product of the oxidation of rhodinol from pelargonium oil, to which the formula $C_{10}H_{16}O_2$ was wrongly attributed at the time it was described. A third product of the oxidation of the new rhodinol is a neutral oil, $C_{20}H_{36}O_2$, which boils at 190° and also possesses a disagreeable odour. This body—the rhodinate of rhodinyll—is easily split up into rhodinol and potassium rhodinate by the action of alcoholic potash. The authors claim that the results of these later experiments afford further proof of the identity of the so-called “rhodinol” yielded by the oils of rose and pelargonium, and prove that true rhodinol is a primary alcohol with closed chain, possessing an ethylenic bond (*Comp. rend.*, cxxii., 673).

This aldehyde, as mentioned above, was observed by Barbier and Bouveault to possess a very strong odour of mint. Pursuing their investigations, the later results of which are published in another paper, they find that it is in reality a mixture of true rhodinol and menthone. The presence of menthone in the oxidation products of rhodinol naturally suggests the idea that the alcohol may have been mixed with menthol, but this is disproved by the fact that no odour of menthol was distinguishable in the rhodinol, and there is, moreover, a difference of 20° between the boiling points of the two

alcohols, so that the presence of menthol should have been readily apparent. It seemed more probable, therefore, to the authors that the menthone was formed by isomerisation of rhodinol, and they claim to have effected such a change experimentally. They point out also that more light is thus thrown upon the constitution of rhodinol, or dimethyloctenol, as they now prefer to regard it (*Comp. rend.*, cxxii., 737).

A New Elementary Substance.

E. Demarçay publishes evidence in support of a suggestion that a hitherto unknown element exists in the rare earths yielding samarium. From these earths he has obtained a colourless, slightly-soluble nitrate, showing only slight traces of the absorption bands of samarium, together with the spectrum of gadolinum, an element discovered by Marignac, and other lines not belonging to that spectrum. The oxide prepared from this nitrate is distinguished by its lack of colour, the formation of colourless salts without absorption spectra, and differences between its spectrum and those of the oxides of lanthanum, cerium, gadolinum, ytterbium, and terbium, the only ones so far known that form colourless salts. It is further distinguished from lanthanum and cerium oxides by its relatively feeble basicity and the solubility of its double potassium sulphate; from ytterbium oxide it is distinguished by its relatively strong basicity and the slight solubility of its double sulphate; but it strongly resembles the oxides of gadolinum and samarium, the use of the spectroscope being required to distinguish it from them. The new element is provisionally designated as Σ , and its oxide is therefore Σ_2O_3 . It is stated that spectrum analysis also indicates the existence of another oxide, but further comment on this point is deferred. Since samarium oxide prepared by Clève, and supposed by him to be pure, has been found by Demarçay to contain definite traces of terbium and gadolinum oxides, together with a considerable proportion of the newly-discovered oxide, it is suggested that the atomic weight ascribed to samarium—150—may probably require to be modified (*Comp. rend.*, cxxii., 728).

Kresochin.

A disinfectant preparation introduced under this name by F. Fritzsche, of Hamburg, is described as consisting of neutral quinoline tricresyl sulphonate and a combination of quinoline with tricresol: it contains 33 per cent. quinoline and 17 per cent. tricresol. It differs from other cresol solutions in being free from alkali, and the constituents are said to be in a condition especially favourable for the exercise of their bactericide action. This preparation dissolves in water to the extent of 5 per cent., and the solution does not give rise to the slimy feeling of soap preparations (*Pharm. Centralh.*, xxxvii., 247).

Scopola Bases.

In reference to the observations by Hesse, Professor Schmidt points out that in his examination of the bases of scopola root he was never able to detect hyoscine, $C_{17}H_{21}NO_4$, or the base named by Hesse atroscine, but he obtained scopolamine $C_{17}H_{21}NO_4$, in considerable amount. The material employed in this investigation was the definitely crystallised hydrobromide, having a rotation of $-25^\circ 43'$. A substance having the same characters was isolated from a salt supplied by E. Merck as hyoscine hydrobromide (Ladenburg). It was not until 1894 that scopolamine salt of lower rotatory power ($[\alpha]_D = -14^\circ 58'$) was observed in the course of an examination with Luboldt of a crystalline salt obtained from Gehe and Co., and the base isolated from that salt had in water solution a rotation of $-4^\circ 30'$, in alcohol solution only $-1^\circ 37'$. Further quantities of scopolamine hydrobromide obtained this year from E. Merck and from Gehe and Co. gave respectively rotations $= -17^\circ 9'$ and $-6^\circ 62'$. The last-mentioned salt was not distinguishable from that having a higher rotation, which was prepared

by Professor Schmidt, and a careful crystallographic comparison by Dr. Busz showed no difference between them. This was also the case with the gold salts and the products obtained by the action of baryta water. In both cases the scopoline melted at 109°–110° C., and the atropic acid boiled at 241°–243°. In reference to the observation by Hesse that the rotation of scopolamine is much reduced by contact with caustic soda, Professor Schmidt mentions that by the action of silver oxide upon scopolamine hydrobromide having high lævo-rotation, he has obtained scopolamine that was almost inactive, and that the very soluble hydrobromide of this base generally crystallises without water. It is suggested that these observations, together with the known facts relating to the conversion of hyoscyamine into atropine, offer a simple explanation of the varying rotation of commercial scopolamine, and in fact Schmidt has succeeded in obtaining from the same scopolia roots products of different rotatory power according to the method of preparation adopted. When ammonia or sodium bicarbonate was used, a product of normal rotation was obtained, and when caustic soda or other strong base was used, the product was but slightly rotatory. Hence the reduced rotation may be due to the presence of inactive scopolamine—a base that does not pre-exist in normal scopolia root, but is formed during the process of extraction. On these grounds the application of the name atropine to this inactive base is thought by Professor Schmidt to be undesirable. This view is held to be supported by the circumstance that there is no practical difference in the action of the substances having different rotation. This has been ascertained by Drs. Uthoff and Axenfeld, and, moreover, it is possible to produce scopolamine salts of the same rotation as formerly by avoiding the use of strong bases (*Apotheker Zeitung*, xi., 260).

Under this name a substitute for cocaine has been introduced by the Schering Company. It is the hydrochloride of an oxypiperidine derivative, and has been found useful for producing local anæsthesia. The base itself is almost insoluble in water, but the hydrochloride is readily soluble (*Pharm. Zeit.*, xli., 279).

This is a compound of tannin with albumin, which is not readily dissolved by the gastric juice, but is soluble in the intestinal canal. It has been prepared in accordance with the suggestion of Dr. Gottlieb by Knoll and Co., of Ludwigshafen, for use as an intestinal astringent. It is prepared by long continued heating of tannin albuminate, which has the effect of rendering that preparation highly resistant to pepsin digestion. Tannalbin is a pale yellow tasteless powder, containing about 50 per cent. of tannin. It is recommended by Dr. von Engel in cases of acute diarrhoea and intestinal catarrh (*Deutsch. Med. Wochens.*, 1896).

E. Kremers and O. L. Schreiner have prepared pure carvone by fractionating caraway oil under reduced pressure (30 Mm.), and collecting two fractions—one up to 110°, and the other 110° to 125°. These were mixed and again distilled, the fraction passing over between 120° and 123° being collected separately. The specific gravity of this was 0.957 at 20°, and the angle of rotation in 100 Mm. tube = +59° 7' at the same temperature. One-fourth its volume of alcohol was added to the fraction and the carvone precipitated as hydrosulphide. This was re-crystallised from a mixture of chloroform, 3 parts, and alcohol, 1 part, as suggested by Beyer, and the angle of rotation of a 10 per cent. solution in chloroform was then found to be +8°, and sp. gr. 1.426 at 20°, "hence $[a]_D = +56.101$, and not +5° 53 as reported by Beyer." The carvone was regenerated by Beyer's method, 3 parts of the hydrosulphide being treated with a cold solution of potassium hydrate, 1 part, in

alcohol, 20 parts, and allowed to stand three or four hours in the cold. The mixture was then poured into ten times its volume of water, and the separated carvone collected and dried. It was slightly yellowish in colour, and the following constants were indicated: Sp. gr. 0.979, angle of rotation = +58° 47', hence $[a]_D = +61.19$. Upon distillation with water the carvone came over perfectly colourless. The sp. gr. of the dried oil was 0.96058 at 20°, and in a 100 Mm. tube it turned the plane of polarised light 60° 11' to the right, hence $[a]_D = +62.65$. The changes in specific gravity and angle of rotation during purification are therefore very slight (*Pharm. Rev.*, xiv., 77).

Dextrogyrate carvone is a natural constituent of the oils of caraway (*Carum carvi*) and dill (*Anethum graveolens*), whilst lævograte carvone occurs in spearmint oil (*Mentha viridis*), the allied krauseminz oil (*Mentha crispa*), and in kuromoji oil (*Lindera sericea*). Various methods have been devised for assaying the carvone content of these oils, but Kremers and Schreiner have found them all more or less unsatisfactory. They have experimented, therefore, upon pure carvone, prepared as described in the preceding note, with a view to finding a satisfactory assay process, and now publish the details of one which gives results that come within one per cent. of the true carvone content. A mixture of 5 grammes each of pure carvone and limonene was dissolved in 25 C.c. of alcohol; hydroxylamine hydrochlorate, 5 grammes, and sodium bicarbonate, 6.5 grammes, were added, and the mixture was then boiled for half an hour upon a water bath, in a flask connected with a reflux condenser. Water, 25 C.c., was next added, and the alcohol distilled off, carrying with it a large quantity of limonene. Steam was then passed through the liquid until traces of carvoxime came over, the last portions of the distillate being collected separately in test tubes and the operation interrupted when traces of crystals of carvoxime appeared on the surface. The tube of the condenser was now washed with a little hot water which was afterwards run into the flask, together with the last collected distillate. After the contents of the flask had cooled, the solidified carvoxime was removed from the sides of the flask by means of a stiff wire-loop, then thrown upon a pressure filter, washed, and dried by suction. The air-dried carvoxime was transferred to a tared glass dish, heated for one hour on a water bath, and weighed when cool. To the weight obtained, 0.100 Gm. was added to allow for loss during heating, and the amount of carvone calculated from the weight of carvoxime, as follows:—

$$\frac{C_{10}H_{14}NOH}{164.67}, \frac{C_{10}H_{14}O}{149.66} = 1:0.9088$$

or, the weight of carvoxime expressed in grammes, when multiplied by 0.9088, gave the weight of the equivalent amount of carvone. A 50 per cent. carvone mixture was found to give by this method the following figures:—

I.	5.525 grammes Carvoxime	=	50.22 per cent. Carvone.
II.	5.592	"	" = 50.88
III.	5.579	"	" = 51.71
IV.	5.508	"	" = 50.00

When more than 50 per cent. of carvone is present, a larger quantity of hydroxylamine must be used (*Pharm. Rev.*, xiv., 78).

A. Reychler has confirmed Barbier's statements that the body $C_{10}H_{17}Cl$ cannot be isolated, and that geraniol reacts with two molecules of hydrochloric acid to form a liquid dihydrochlorate, $C_{10}H_{13}Cl_2$, which when decomposed by means of a boiling solution of potassium acetate yields dipentene. Schimmel's geraniol, extracted from citronella oil, was used in Reychler's experiments, and readily absorbed gaseous hydrochloric acid, 40 grammes of geraniol taking up 22.4 grammes of acid. On

Geranyl Chloride.

washing with dilute sodium carbonate solution, part of the acid was removed, and subsequent analysis proved that 40 grammes of the alcohol had combined with 18 grammes of acid, theory requiring 18.9 grammes. It was also found, thus confirming an observation by Eckart, that the whole of the chlorine could be removed from the geranyl dihydrochlorate by boiling it for two and a half hours with an alcoholic solution of caustic potash, geraniol being thus regenerated (*Bull. de la Soc. Chim.* [3], xv., 364).

E. Cabannes has confirmed the results of Borscow with regard to the localisation of the glucoside, frangulin, in the bark of *Rhamnus frangula*. He examined sections of the bark as they were being acted upon by alcoholic potash solution, and observed a reddish colour at once develop in the bast and cortical parenchyma, being especially marked in the medullary rays. On treating sections of the bark of *R. purshianus* in the same manner a different result was apparent, the coloration affecting only the five or six layers of bast adjoining the cambium, then spreading through the medullary rays and developing in one or two layers of the cortical parenchyma. Red granulations were observed in the bast cells, which were unaffected by acetic, nitric, hydrochloric, and sulphuric acids. Ammonia and soda were found to produce the same reddish coloration as potash, and the conclusion drawn from the experiments is that the active principles of the bark—in so far as these are represented by cascarin, rhamnetin, frangulin, rhamnoxanthin, and chrysophanic acid—are concentrated in the layers of bast immediately adjoining the cambium, and in the medullary rays traversing those layers (*Répertoire* [3], vii., 97).

According to W. A. Setchell and W. J. V. Osterhout, the selection of aqueous media for preserving algæ for class purposes is a matter requiring careful consideration. They find, too, that no one medium can be used indiscriminately for all kinds of material. The Cyanophyceæ are best prepared with a solution containing 1 per cent. each of chrome alum and formalin. The gelatinous sheath and matrices are rendered firm by this solution, the cell contents are kept in a very natural condition, and in most cases the colours are retained in their ordinary tints. Formalin solution, 1-2 per cent., preserves the cell contents very well, but does not preserve the colours or the softer gelatinous sheaths and matrices. Camphor water fails with many blue-greens, and is not strong enough for species preserved in the mass and associated with many bacteria. The Chlorophyceæ are very satisfactorily preserved in any of these media, but chrome alum is preferable in most cases, though membranaceous forms like *Ulva lactena*, etc., are rendered very brittle, and are, therefore, better placed in simple formalin solution. The Phaeophyceæ do well when placed immediately in 1 per cent. formalin solution in sea-water, but the larger forms are better fixed in 1 per cent. chrome alum for three to six hours and then preserved in 2 per cent. formalin solution or camphor water. Specimens for crushing may remain indefinitely in chrome alum solution. The coarser forms of the Rhodophyceæ may be kept in excellent condition in any one of the three solutions recommended, chrome alum preserving more colour than formalin or camphor water. For finer study, specimens are best left in a concentrated solution of picric acid in sea-water for twenty-four hours, then washed in plain sea-water for twenty-four hours longer, and preserved in camphorated sea-water. Such genera as *Nemalion*, *Champia*, *Rhabdonia*, *Cystoclonium*, etc., respond best to this treatment. Delicate species like *Griffithsia bornetiana*, *Callithamnion baileyi*, *C. borneri*, *C. seirospermum*, etc., must be placed in 2 per cent. formalin in sea-water, with plenty of fluid, so

as not to be crushed, and though the colour disappears, the cells keep their shape and the plants present a life-like appearance so far as form goes. To prevent *Dasya elegans* dropping its hairs, and the more delicate species of *Polysiphonia* breaking up into short pieces, they should be put whilst fairly fresh into formalin or chrome alum solution (*Bot. Gazette*, xxi., 140).

A. Sapin remarks that creosote perles and capsules are usually bought ready for use by the pharmacist, and that to facilitate their preservation it is usual to diminish the causticity of the creosote by adding to it a certain proportion of oil. He finds, however, that the articles supplied often contain only traces of creosote, and the following method of assaying them is recommended:—Fifty perles are placed in a conical flask, covered with distilled water, and allowed to macerate for some hours in the cold. The application of moderate heat then suffices to liquefy the contents of the flask, and the oil holding the creosote in solution rises to the surface. On cooling the flask, the lower layer—containing gelatin, gum, and water—solidifies. The upper layer should then be shaken with 25 C.c. of ether and decanted into a tared vessel after which the gelatin mass is reliquefied and treated with ether in a similar way. The ethereal liquids are next mixed, the ether is distilled off, and the creosote separated from the oil by solution in ethylic or methylic alcohol, on evaporating which the amount of creosote actually present can be readily ascertained by weighing unless the oil should be castor oil, which is easily distinguished. Usually, however, the oil employed is liver, almond, or nut oil, and the following table shows the results that have been obtained with mixtures specially prepared for the purpose:—

Quantities of Creosote and Oil mixed.	Found after two exhaustions with Alcohol.	Found after three exhaustions with Alcohol.
Creosote 2.2902 Gm.	2.4162 Gm.	2.4762 Gm.
Liver oil..... 2.1022 „	2.3762 „	2.3162 „
Creosote 2.6820 „	2.8157 „	2.8797 „
Almond oil..... 2.3742 „	2.2405 „	2.1765 „
Creosote 2.6176 „	2.7428 „	2.8352 „
Nut oil 2.4792 „	2.3540 „	2.2616 „

—(*Moniteur*, xlvi., 1081).

In the Journal for November 23 last (p. 445) there appeared a notice of a new form of accumulator, described by H. N. Warren, in which plates prepared by compressing spongy lead were employed. He now describes in detail the preparation of such plates for a non-sulphating phospho-accumulator. Lead grids of special construction are treated with a paste composed of litharge mixed with phosphoric and sulphuric acids, and these, after drying at 250° F. for several hours, are further treated with acids and dried until biscuit-like plates are obtained. The plates being then arranged in pile fashion, with alternate layers of amalgamised zinc, and insulated from each other by small carbon blocks, the pile is immersed in dilute sulphuric acid, when a somewhat violent reaction takes place, gas being copiously evolved from the lead plates. They are rendered porous by this treatment, and are afterwards freed from zinc salts by washing. They are then treated electrically until the whole of the spongy lead is converted into peroxide, and finally rendered non-sulphating by soaking in dilute phosphoric acid. It is claimed that such plates compare most favourably with any now upon the market and that they can be formed in less than half the usual time (*Chem. News*, lxxiii., 191).

Creosote in Perles.

A New Storage Cell.

Action of Copper Compounds on the Organism.

Filehne has studied the action of copper when combined with albuminous substances, and finds that a cupratin compound, analogous to Schmeideberg's ferratin, can be administered to dogs and cats in doses of 2·6 grammes within twenty days without injurious effects. He infers that compounds of copper with albumin would not be injurious in human food, and that from ·01 to ·02 gramme of copper daily in this form would not cause any sensible disturbance. The case is very different with copper stearate, which causes serious degeneration of the liver and kidneys when administered for some long time, though it was not possible in this way to produce acute poisoning (*Deutsch. Med. Wochensh.*, 1896)

Oysters and Disease.

Professor W. A. Herdman points out, in the report for 1895 of the Lancashire Sea-Fisheries Laboratory, at University College, Liverpool, that experiments conducted in that institution demonstrate the beneficial effects of aëration to oysters, by the addition of air or change of water. With regard to the food that is found suitable, oysters are said to thrive best upon living Protophyta (diatoms, desmids, algæ) and Protozoa (infusoria, etc.). Sugar is found to exercise an exceedingly harmful effect on the bivalves, causing them to decrease in weight and die. Oatmeal and flour, on the other hand, enable them to maintain their weight, or even increase, but after a time they sicken and die. Peptonised broth is tolerated by oysters to a considerable extent. Stagnation of the water above the oyster beds produces deleterious effects, owing to the collection of excretory products, growth of micro-organisms, and formation of scums upon the surface. Up to a certain point oysters have been found capable of rendering sewage-contaminated water clear, and they can live for a prolonged period in water rendered completely opaque by the addition of faecal matter, that from typhoid cases proving more inimical than that obtained from healthy subjects. With regard to infection by micro-organisms, the typhoid bacillus dies off very rapidly in ordinary seawater, and it seems possible that, by methods similar to those employed in the "Bassins de dégorgeement" of the French ostreiculturist, where oysters are carefully subjected to a natural process of cleaning, oysters previously contaminated with sewage can be freed from pathogenic organisms or their products without spoiling them for the market. The green coloration of certain oysters, which has been attributed to the presence of copper, is considered at length in the report, but the opinion is expressed that, though copper is probably always present in oysters, the green colour is due to disease, the liver in specimens exhibiting "this pale green leucocytosis" being in an abnormal, shrunken, and degenerate condition. Practically, no more copper is found in the green parts than in the corresponding parts of colourless oysters.

Natural Aluminium Succinate.

J. H. Maiden and H. G. Smith have examined a natural deposit found in the wood of *Grevillea robusta*, R. Br., and proved that it consists of aluminium succinate. In describing this deposit before the Royal Society of N.S. Wales, they stated that it was quite soft, almost white, and partly crystalline, minute acicular crystals being seen between crossed Nicol prisms, with a quarter-inch objective. The composition of the substance is given as succinic acid, 43·464 per cent.; alumina, 31·447 per cent.; water, 25·089 per cent., and it is regarded as a basic aluminium succinate, $Al_2(C_4H_4O_4)_3 \cdot Al_2O_3$. A trace of acetic acid was detected, and its identification is probably indicative of the mode of formation of the succinic acid by fermentation of malic acid. The probability is that the aluminium originally circulated through the vessels of the

tree in the form of malate, in aqueous solution. The insoluble aluminium succinate, however, does not appear to have been found in any tree before.

Reference has already been made to Buguet's observations on the possibility of distinguishing diamonds and jet from many of their imitations by the application of the x -rays (*ante*, p. 244). The transparency of aluminium to the rays has since led them to study the effects produced in the case of precious stones of which that metal is a constituent. They find that the crystalline forms of alumina known as the corundum, ruby, sapphire, emerald, topaz, and cat's-eye, may be classed between their imitations and the diamond with regard to the effect produced. The turquoise, which consists of aluminium phosphate, is also clearly distinguished from its substitutes by means of the rays, and mellite is almost as transparent as carbon. Fine pearls of small size are less opaque to the rays than false ones of the same size, and may be clearly distinguished from them; but in the case of larger specimens the result is less certain, depending greatly upon the manner in which the false pearls have been made (*Comp. rend.*, cxxii., 726).

Arsenic in Coal.

At a recent trial in Sydney, N.S.W., in connection with a case of arsenical poisoning, the accused was alleged to have disposed of the arsenic remaining in his possession by burning it in the kitchen stove, and on examination the soot and flue dust was found to contain eight grains of arsenic to the pound. In defence, however, it was urged that arsenic exists naturally in some portions of coal seams, and that the poison found in the flue might thus be present quite innocently. To discover if it were possible to find arsenic in New South Wales coal, W. M. Doherty obtained and examined various samples of soot, taken from flues where coal had been burned for years, in addition to samples of coal from the different coal seams in the colony. In no instance could the slightest trace of arsenic be found, though copper and lead were found in two instances, and arsenic-free brasses occurred in comparatively large quantities in some of the samples (*Chem. News*, lxxiii., 191).

The report for 1895 on the trade of the continental district of Suakin shows that there has been during the year a large increase in the quantity of gum exported. More than 1900 tons, valued at £61,711, was shipped during the twelve months and considerable stocks remained on hand at the end of the year. The market price in March of the present year was 16½ to 17 dols. the "kuntar," this being roughly equivalent to £2 per cwt. At the time of writing the report large quantities of gum were believed to be on their way from the interior, but the Berber road had recently been closed by the Dervishes at Kokreb, so preventing any of it from reaching the coast at present.

Poisoning by Caterpillars.

Girard, a veterinary surgeon, at Barnewit, has observed numerous fatal cases of poisoning in ducks after eating caterpillars, notably those of *Pieris brassicae*, the large, white cabbage butterfly. About six hours after eating these larvæ poisoning became evident, diarrhoea and staggering gait, followed by dyspnoea, and ultimately by death. Autopsy showed the essential lesions to indicate inflammation of the digestive tube. It is probable that these symptoms are caused by the inflammation produced in the alimentary canal by the very minute hairs with which this caterpillar is covered. It has been noticed that chickens invariably refuse the larvæ of *P. brassicae*, although they greedily eat the smooth larvæ of the various Noctua.

A BOTANICAL RAMBLE IN SPRING.

BY E. F. SALMON.

Certainly a pharmacist ought to take some interest in the flowers of the field, since botany forms an essential part of the syllabus prescribed for his training. Therefore when an ardent Brighton botanist invited the writer to a day's botanising on Chailey Common, he felt in duty bound to accept at once, if only for the honour of the profession to which he is attached, including as it does many men of first-class botanic reputation, although, perhaps, with the majority the interest in the science is less keen than in their student days.

Since Sussex, then, is a county of delight to the field botanist, and Chailey Common one of its happy hunting grounds; since the guide was one of those men who have the Sussex flora at their fingers' ends—"a man" who, as "Dr. George Baker, one of Her Majesty's chief surgeons," said of John Gerard, "I protest, upon my conscience, I do not think for the knowledge of plants he is inferior to any"—the writer was only too pleased to find himself with his botanical friend and guide at the Haywards Heath railway station, on a fine morning when April was nearly three parts spent. Both the local Natural History Society and the Corporation are greatly indebted to my guide—the one for the greater part of the specimens and the mounting, etc., connected with the Society's herbarium of Sussex plants which it is forming, and the other for assistance rendered, as well as specimens contributed to the exhibition of wild plants, which has been held the last two years in the Corporation Museum during the flowering season (an exhibition, by the bye, which ought to prove extremely valuable to pharmaceutical students in the locality). Starting then on a four-mile walk to the Common, passing woods filled with anemones, primroses, and violets, the signs of bursting buds everywhere visible on the trees, save the oaks, Scayne's Hill was reached, where stone is being quarried for the Brighton Parish Church. Here in a hedge *Vinca minor*, the lesser periwinkle, was gathered, and in a field daffodils had been abundant, but now nothing except their leaves remained visible. However, specimens of *Orchis mascula* and *O. morio* were gathered, this being tolerably early.

Chailey Common at last reached, *Carex præcox*, the earliest sedge, was very much in evidence, and a few specimens of *C. glauca*, so named from its glaucous foliage. "What is this?" said the writer, as he picked a piece of straggling stem with catkins on it, "it looks like willow." "Oh, yes, *Salix repens*, there are several varieties of it," said the guide, and, as a matter of fact, Sowerby gives seven plates of the varieties. Passing down to one of the boggy spots, water blinks, *Montia fontana*, var. *rivularis*, is seen, a little plant with inconspicuous flowers, yet occurring in clusters, and therefore easily seen; farther on in another bog the marsh violet, *V. palustris* was found, which, says Dr. Arnold,* is rare. In a pool was found *Ranunculus peltatus*, var. *floribundus*, one of the water crowfoots, in another a far rarer species, *R. lenormandi*, the petals of which are not so broad and do not overlap one another as in *R. peltatus*. "In a pond over there," said the leader, "Mr. Druce and I found specimens of *Damasonium stellatum*," a rare plant (Mr. G. C. Druce, M.A., of Oxford, is no stranger to the Sussex flora). Passing by the cotton sedges, not yet sufficiently advanced to show their curious cottony tufts, the writer and his botanical friend pushed on, for the Common is of very large extent, to where it was hoped to find *Carex montana* which by Dr. Arnold is marked very rare. Everywhere was the *Viola sylvatica* conspicuous, this led to a discussion on the dog

violet. To the public every violet not possessing the strong perfume of *V. odorata* is a dog violet; true it is sometimes called Gerard's dog violet, but the botanist needs be more careful; *Viola canina* of the London Catalogue has a central flowering stem, whereas the flowers of *V. sylvatica* are axillary only; the petals are of lighter colour and the spur is often tinged with yellow. After diligent search some specimens of the true *V. canina* were found, though it was early for them.

The mention of Gerard provokes a reference to his herbal, where says he, in his chapter on violets, speaking of the March violets in particular and flowering plants in general, "the recreation of the minde which is taken hereby, cannot be but very good and honest, for they admonish and stir up a man to that which is comely and honest, for floures through their beautie, variety of colour, and exquisite forme, do bring to a liberall and gentle, manly minde, the remembrance of honestie, comeliness, and all kindes of vertues." But this is a digression, resuming the journey, the field woodrush, *Luzula campestris*, with its clustered heads, and *L. pilosa*, with its panicle of solitary flowers are noticed, with their curiously hairy leaves; the milkwort, *P. vulgaris*, var. *serpyllacea*, the petty whin, *Genista anglica*; bitter vetch, *Orobus tuberosus*, anemones, the sphagnum moss, and at last the spot is reached where *Carex montana* is to be found, but twenty minutes or more elapse, spent in diligent search before a plant is discovered, and then but a few others are to be seen. Having secured a specimen of this rare sedge, which has an appearance something like that of *C. pilulifera*, the spikes being roundish, the walk is resumed, when, lo! a veritable plantation of *C. montana* is discovered and more samples gathered. Still onward pushes the enthusiast, followed by the pharmacist, to a part where the oxlip is said to grow.

Now the common narrows, and a copse appears on one side. Presently a little clump of *Oxalis acetosella*, the beautiful wood-sorrel, is seen in full flower; in another place a sprig of common broom is cut, and then, as the common is finally left, a meadow whose banks are studded with primroses is itself bearing cowslips abundantly, and a little search soon reveals the oxlip. But this beautiful flower is not the *Primula elatior* (Jacquin) which Dr. Arnold says is found only in the eastern counties, it is a hybrid between the primrose and cowslip, *Primula vulgaris*, var. *caulescens*. Thus farewell to Chailey Common. But the journey stationwards is made somewhat circuitous that a small copse at Freshfield may be visited for the sake of the woodruff, and we notice on the way plants in full flower of species common enough, yet pleasing withal—goldilocks, marsh marigold, celandine, cuckoo flower, and so on. Now the copse is reached, and here the wild hyacinth is beginning to show itself abundantly, presently to make a brave show.

Penetrating within, signs of *Asperula odorata* are perceived, and at length some plants are gathered in flower of this sweet-smelling species, and agreeing with Master Gerard's description of it, the day's botanical ramble is brought to a close, and the "enthusiast" and the "pharmacist" return home laden with spoils of from between thirty and forty different species. Appended is old John Gerard's description of woodrooffe:—"Woodrooffe hath many square stalkes full of ioints, and at euery knot or ioint seuen or eight long, narrow leaues, set round about like a star, or the rowell of a spurre; the floures grow at the top of the stems, of a white colour and of a very sweet smell, as is the rest of the herbe, which being made up into garlands or bundles and hanged up in houses in the heat of Sommer doth very wel attemper the aire, coole and make fresh the place, to the delight and comfort of such as are therein."

* 'Flora of Sussex,' by the Rev. Dr. Arnold.

MALT EXTRACT.*

BY M. CONROY.

In consequence of this article being now largely made for confectionery and other purposes quite outside the range of pharmacy, it is being offered to pharmacists at very low prices. Several samples of this kind of extract have recently come under my notice, and I have found them to be absolutely devoid of diastasic power. A peculiar and important feature about these extracts, in which the diastase has been destroyed by over-heating, is that they keep much better than extracts that have been prepared at a low temperature and of full diastasic strength. I have seen samples of this non-diastasic kind twelve months old, quite good and mobile, whilst samples only a few weeks old of carefully prepared extract of full diastasic strength have become granulated and quite solid. This has been a common experience with me for some years past, and there can be little doubt that diastase in malt extract has a tendency to promote granulation.

Medical men attach great importance to the diastasic value of malt extract, and prescribe it in cases of weak digestion on this account quite as much as for its nutrient value in waiting diseases. It is, therefore, of importance that pharmacists should examine this extract for diastase on account of the large quantity that is manufactured and offered containing no diastase whatever. The following simple method is a good one:—Take 10 grains of potato starch or arrowroot, and boil in 2 oz. of water for three minutes, cool to 110° Fahr., and add 10 grains of the extract to be tested, dissolved in oz. of water. Keep the solution at 100° Fahr. until small quantities (about 30 minims) taken out at intervals of one minute cease to give a blue colour with 1 drop of tincture of iodine. A good extract should not take longer than five to six minutes.

NOTE ON CREAM OF TARTAR.*

BY M. CONROY.

In the *Pharmaceutical Journal* of April 11 there is a communication by Mr. C. A. Hill on the assay of cream of tartar, in which he recommends the direct titration process with standard alkali. Mr. Hill explains that he recommends this process not only because it is far more convenient and expeditious than the ignition process of the Pharmacopœia, "but also in order to notify the fact that the latter process is quite inaccurate, owing to the loss of potassium carbonate from reaction with calcium sulphate, which occurs in commercial cream of tartar." Mr. Hill gives examples of three samples of commercial cream of tartar, one of which contains 4.2 per cent. and another 2.46 per cent. of calcium sulphate. By the direct process recommended by Mr. Hill, the first of these samples tests 96 per cent. potassium acid tartrate, whilst by the B.P. ignition process the percentage found is only 84.5 per cent., this difference being due as explained to the loss of potassium carbonate from reaction with the 4.2 per cent. of calcium sulphate. I quite agree with the figures given by Mr. Hill, and also with his statement that the direct process is much more expeditious and convenient, but I must take exception to his statement that commercial cream of tartar contains calcium sulphate in sufficient quantity to appreciably affect the B.P. method of assay. Hundreds of samples have passed through my hands, and in only three instances have I found calcium sulphate present in quantity sufficient to affect the B.P. method. Those three samples I wish particularly to point out were from cream of tartar imported in the powdered state, and I have reason to believe they were all from the same source. In no instance have I found more than a trace of sulphate in crystallised cream of tartar.

Judging by my own experience of these facts, I think I am justi-

* Read before the Liverpool Chemists' Association.

fied in saying that cream of tartar containing the amount of calcium sulphate found by Mr. Hill must have been wilfully adulterated, and does not represent the commercial article. There is no difficulty in obtaining cream of tartar of 98 to 99 per cent. purity, and I would recommend that the B.P. standard be raised from 92.15 per cent., at which it now stands, to at least 96 per cent. The United States Pharmacopœia requires it to be not under 99 per cent.

One advantage of the B.P. ignition method is that it excludes samples containing any appreciable quantity of calcium sulphate, but provided a qualitative test for sulphate be included in the B.P., as is done in the U.S. Pharmacopœia, it would certainly be an advantage to adopt the direct alkali titration method as the official test. In adopting this method, we cannot do better than follow on the lines laid down in the U.S. Pharmacopœia test, which is as follows:—“A solution of 1.88 Gm. of potassium bitartrate in 100 C.c. of hot water should require for complete neutralisation not less than 9.9 C.c. of normal potassium hydrate V.S. (each C.c. corresponding to 10 per cent. of the pure salt), phenolphthalein being used as indicator.”

MEDICINE AND PHARMACY IN CHINA.*

In many Buddhist monasteries in China the science of medicine is taught to those who wish to dedicate themselves to its practice, and some of these establishments are, either directly or indirectly, under Imperial patronage. There are some extremely well-endowed monasteries, which, in addition to the fat incomes they enjoy, are the possessors of libraries of medical literature, consisting of more than 40,000 volumes; but the teaching given is of the poorest and most deficient description one can well imagine. Official protection exists only in name, and the exercise of the medical and pharmaceutical professions is entirely free. Any individual becoming tired of his proper calling, be it labourer or cobbler, can soon become a doctor if he has a wish to do so, and to attain his object must first enter one of these monasteries, where he is allowed to copy out certain volumes of medical books, particularly such as treat of the pulse and of herbal remedies. Afterwards, without any other instruction or information than what he has derived from these books, he is a fully fledged medical man, ready to practise, and when he wishes to do so he locates himself in some central position, at a street corner, in a square or market, or any spot where there is plenty of traffic and people passing to and fro, there to wait consultations. But in order that a consultation should bear fruit, our improvised doctor must give an air of mystery to his acts and words. With this in view, he procures a small bird about the size of a sparrow, which he trains to draw a little folded paper from a tin box. This paper has written on it, in Chinese characters, the number of a certain paragraph in his dictionary of medicine, which is thereupon turned to, and such remedies as are therein mentioned are applied to the patient, whether they are appropriate or not. The bird, when its duty is accomplished, is regaled with a grain of rice, and hops back into its cage. Before proceeding to specify the remedies to the patient, the doctor feels his client's pulse, and whilst noting its peculiarities discourses learnedly on the infirmities from which the sick man's ancestors suffered, which he pretends are revealed to him by the pulsations. The advice and remedies having been given the consultation is paid for at the rate of ten or a dozen "cash." If the doctor succeeds in making a name for himself in this fashion, which in China is not difficult, he stops his street practice and establishes himself in a house, whereupon the fees increase in amount until, if he be very fortunate, he may even receive one or two dollars for each, or about

* From "La Cronica de Ciencias Medicas de Filipinas."

1600 to 2000 cash. In China a doctor's fame is measured not by his numerous *clientèle*, or by his learning, but by the number of sick persons who have died under his treatment; and whenever a patient dies in his hands the authorities place a small lantern by night over the doctor's door, so that the public may know of his want of success. To lend an air of wisdom and gravity to their appearance, Chinese doctors wear large spectacles with gold or silver mounts, and with smoked glasses; they clothe themselves with brown or yellow silk garments, and for head-gear adopt a sort of black biretta, shaped like a Grecian helmet, and topped with a red ball the size of a walnut.

They wear the Chinese shoe, more or less artistically worked according to lucrativeness of their practice. A long pigtail is by them regarded as a sign of distinction and well-being, so that they all have this adornment carefully plaited and dressed; but if this, by reason of its scantiness, does not lend the requisite tone to their presence, they increase its length artificially until it meets with their approval. During the time the medical apprentice remains in the monastery, his tonsured masters, the monks, feed him upon boiled rice, vegetables, and tea, so that by simplicity of diet he may become impressed with the small amount of food really necessary to bodily well-being. By this means he is so imbued with the monkish ideas concerning medicine, that on his setting up in practice he tells his clients that the origin of all suffering are the good or bad spirits, cold, heat, hunger, or abundance. Medical schools on the European system have been established by the English Protestant missionaries in various parts of the Chinese Empire, but their halls are nearly deserted, for the Chinese say that European doctors' science consists simply in the use of the knife—an instrument for which the Chinese have an ineradicable horror.

PROCEEDINGS UNDER THE PHARMACY ACT.

ALLEGED ILLEGAL SALE OF TOWLE'S CHLORODYNE.

At Leeds County Court, on April 29, 1896, the case of the Pharmaceutical Society *v.* Sleight came on for hearing before His Honour Judge Greenhow. In this action the Council of the Pharmaceutical Society of Great Britain sought to recover a penalty of £5 from Ernest Sleight, of 265, Hunslet Road, Leeds. Mr. Grey, barrister, of London, appeared for the plaintiffs, and Mr. Sheppard, barrister, for the defendant.

Mr. Grey stated to His Honour that the defendant was sued for selling, on January 30 last, poison in the shape of chlorodyne which contained morphine. The Act under which this proceeding was taken was the 31st and 32nd Victoria, c. 121, which is an Act to regulate the sale of poisons, and one of the sections makes it unlawful for any person to sell scheduled poisons unless he is registered under this Act. Morphine, opium, and all preparations of opium are specifically mentioned in the Schedule. Another important section is the 13th, which makes the Register of Chemists and Druggists evidence of qualification, and the defendant's name did not appear there. Section 15 provides that any person who shall sell any of the drugs in the Schedule without being qualified shall for every such offence be liable to pay a penalty of £5.

Mr. Arthur Foulds was then called and said he resided at Manchester. In consequence of instructions received from the Pharmaceutical Society, he went to 265, Hunslet Road, Leeds, to make certain purchases, on January 30 last. On going into the shop, witness saw a person behind the counter, and that person was now present in court. He asked for a bottle of glycerin and a bottle of Towle's chlorodyne. Witness identified the bottles produced as those he purchased on the day in question. The bottle of chlorodyne was sealed up in the usual way, and was wrapped in the printed paper now produced. He asked the person in the shop if Mr. Sleight was out, and he was told "yes." He afterwards handed over the articles he purchased to Mr. Harry Moon, and they were then in the same condition as when he bought them.

Cross-examined by Mr. Sheppard, witness said he was an inquiry agent, and was occasionally employed by the Pharmaceutical Society. His instructions in this case were to go into the shop and

purchase some poison from the assistant. He knew Towle's chlorodyne contained poison, because he had purchased it previously at different shops, for the same purpose.

Mr. Harry Moon said he was clerk in the office of the Pharmaceutical Society. He received the two bottles produced from the last witness, and handed them over to Mr. E. J. Eastes.

Mr. E. J. Eastes said he was an analyst, a pharmaceutical chemist, and a Fellow of the Institute of Chemistry. He received the bottle of chlorodyne produced, and it was opened in his presence. He analysed the contents of the bottle, and found it to contain among other ingredients a quantity of morphine. The quantity was seven-tenths of a grain, and the bottle contained three fluid drachms of the mixture. Morphine was the chief active constituent of opium, and the quantity of morphine in the bottle was sufficient to be fatal to a grown-up person.

Mr. Sheppard then addressed the court and said his case for the defendant was that as this was an action for a penalty it must be strictly proved. His instructions were that the person now sued for a penalty of £5 never was in the shop at all, as alleged in the evidence for the plaintiffs. The defendant did not work there, and so far as he knew he never saw the private detective before that day in court. He submitted that this action being for a penalty the plaintiffs must have the right person there or they failed. His Honour would remember that the plaintiffs' detective never saw the defendant before, and had never seen him since, a material fact regarding the question of identity.

Ernest Sleight was called by Mr. Sheppard, who informed the Judge, in answer to his inquiry, that defendant was not the owner of the shop. He was only an assistant. Witness said he had never served in his father's shop in Hunslet Road. On January 30 last, he was at Burley Road with his brother, William Wilson Sleight. They were working there together all that day making neuralgia mixtures. He was not in Hunslet Road at all that day, and there was no truth in the allegation that he sold the bottle of chlorodyne to Mr. Foulds on that day. He never saw him.

Cross-examined by Mr. Grey: He was served with a summons in this case, and had got the summons with him. It was brought to him from the Hunslet shop, and was not served on him personally at all. His father was the owner of the shop, and witness had two brothers.

Mr. Sheppard objected to this cross-examination. He said this was substantially a criminal prosecution, and it was obvious what the object of those questions was. His friend wanted to find out who it was that really had sold this poison, and he (Mr. Sheppard) felt he was bound to protect his client from being led to divulge what the plaintiffs should have found out for themselves.

Mr. Grey: We say this man was not served with the summons. This is not the man we are suing to-day.

Cross-examination resumed: The name of one of witness' brothers was William Wilson Sleight, and the other Herbert. They were both in court that day.

William Wilson Sleight was called, and examined by Mr. Sheppard. He said he had heard what his brother said about January 30. He was on that day working with him the whole day in Burley Road. He never sold poison in his father's shop on that day, and was not even in his father's shop in Hunslet Road on that day.

Cross-examined by Mr. Grey: He had never served in the shop in Hunslet Road at all. He was not served with the summons in this case, and had never seen Mr. Foulds before. He would swear that he never served him with chlorodyne. He was never away from the Burley Road shop on January 30. He was down below in the laboratory, as he did not serve in the shop—not in either of the shops.

Herbert Sleight, in answer to the learned counsel, said he lived at 134, Burley Road. He was in charge of the Hunslet Road shop, and had been for two years. His brother Ernest never served there, and was not there on January 30, nor was his brother Wilson. He did not remember seeing Mr. Foulds on January 30 and selling him anything.

The Judge: Mr. Sheppard, you say the defendant had nothing whatever to do with it.

Mr. Sheppard: It is obviously so, because you hear that the defendant never was in this shop at all, nor was Wilson. I have put the three brothers into the witness box. I may say to your honour that we now have a properly qualified assistant to sell such articles as chlorodyne, and he could have sold it with impunity.

Mr. Grey: I cannot carry the case any further, your Honour, Verdict for the defendant with costs.

THE SALE OF POWELL'S BALSAM OF ANISEED
AT BRADFORD.

An action by the Pharmaceutical Society of Great Britain against James William Savage, of Bradford, came on for hearing before His Honour Judge Gates, Q.C., at the Bradford County Court, on Tuesday last. The plaintiffs sought to recover a penalty of £5, which they alleged the defendant had incurred by selling, on January 30 last, a bottle of "Powell's balsam of aniseed," containing morphine, he being at the time of such sale an unqualified person within the meaning of the Statute. Mr. T. R. Grey, barrister, instructed by Messrs. Flux, Thompson, and Flux, on behalf of the Pharmaceutical Society, appeared in support of the action, and the defendant was represented by Mr. W. H. Hines, of Messrs. Gaunt, Bottomley, and Hines, Bradford.

At the outset of the proceedings, Mr. Grey remarked that the summons had been amended. It was originally taken out against J. L. Savage, but the defendant was J. W. Savage. This was an action, Mr. Grey went on to state, in which the plaintiffs sued for a penalty of £5 against the defendant under the Pharmacy Act. The plaintiffs in this action, owing to complaints as to the sale of poisons, instructed a Mr. Foulds, of Manchester, to go to the shop, 140, Listerhills Road, Bradford, and there make a purchase on January 30 last. Mr. Foulds went there and bought, among other things, a bottle of Powell's balsam of aniseed, and Mr. Foulds would tell the Court that at the time of the purchase he saw James William Savage in charge of the shop, and that the defendant actually supplied this bottle of Powell's balsam of aniseed. The bottle was purchased and paid for, and since that time the contents had been analysed, the certificate of analysis showing that the mixture contained morphine (which was a poison scheduled under the Act, as would be shown). The balsam was what was called a proprietary medicine. The bottle was labelled and contained in a wrapper—as was also a bottle of glycerin, which was among the purchases made—bearing the printed address, "J. L. Savage, chemist, 140, Listerhills Road, Bradford; also 190, Westgate, Bradford, and 238, Manchester Road, Bradford." Mr. Grey went on to state the terms of the Statute under which action had been laid. The Statute, he said, was one which regulated the sale of poisons, and set forth in the first section that it was illegal for any person to sell any poison unless he had been duly registered under this Act. The word poison was applicable to the scheduled poisons, not only when sold separately, but also when they were used in dispensing and compounding, or contained in made-up medicines. Under Section 15 it was enacted that any person offending against the Statute should be liable to a penalty of £5.

Mr. Grey proceeded to refer to the case of the Pharmaceutical Society *v.* Wheeldon, and quoted the judgment delivered by Mr. Justice Hawkins at length. He also spoke of the judgment given for the Pharmaceutical Society against Armson, in which Powell's balsam of aniseed was the medicine in question.

Mr. Arthur Foulds, Manchester, was the first witness for the plaintiffs. He said he was instructed by the Pharmaceutical Society to go to Bradford. He went to Bradford, and proceeded to the shop at 140, Listerhills Road, where, at his request, the defendant supplied him with a bottle of Powell's balsam of aniseed. The bottle produced was the one he obtained. He handed the bottle as he received it to Mr. Moon. He also purchased a bottle of glycerin.

Cross-examined by Mr. Hines, witness said he did not know that the late Mr. J. L. Savage carried on business at 140, Listerhills Road, up to the time of his death, for a great many years. He also said he did not know that he could buy as many of these bottles of balsam as he liked at the large drug stores. Only qualified chemists were entitled to sell the balsam anywhere.

Harry Moon, clerk in the office of the Pharmaceutical Society, deposed to the receipt of the bottle of balsam and the wrappers, and to handing the balsam to Mr. Eastes.

Ernest John Eastes gave evidence that he had analysed the balsam. Among other ingredients he detected morphine. There was one-seventh of a grain in the whole bottle. That was sufficient to be injurious to a child if the whole bottle were taken.

Mr. Hines, in defence, said the facts were these. Mr. J. L. Savage was a well-known chemist in Bradford for many years. He died in the year 1893, and he left behind him trustees under his will, one of these trustees being his widow. Mr. Grey had quoted Section 15 of the Act, and he (Mr. Hines) would go on to quote the succeeding Sec-

tion. That section, he submitted, made it legal for the administrators or trustees or widow of a deceased chemist to continue the business with the aid of a properly-qualified assistant. In this case the business of the late J. L. Savage was being continued by the widow, who actually had in her employ at the time this purchase was made a registered chemist and druggist. The young man, J. W. Savage, would undoubtedly be in the shop when the purchase was effected, and so, too, would the registered chemist. Both would be called, and, although neither of them remembered this actual sale, they would both swear that the business had been carried on with full regard to the provisions of the Act.

His Honour: It must be under a qualified man's direction; personal superintendence.

Mr. Hines said it was only a small shop, and in any part of it the qualified assistant is in direct supervision. He went on to say that the time the purchase was made was 2.50 p.m. Now Mr. Simpson was always in the shop at that time in the afternoon. But it appeared as though the object of this prosecution was to prosecute Savage, who was actually qualifying for a position on the Register of chemists and druggists, and whose apprenticeship had been retarded to some extent by the sudden death of Mr. J. L. Savage. No doubt the Society, in directing this prosecution, thought that the business was being carried on by unqualified persons, and therefore in an illegal manner. They never took the pains to inquire whether there was a properly-certificated assistant in charge. Since this action was entered, both Mr. Simpson and Mrs. Savage had written to the Society to explain the circumstances; and what he (Mr. Hines) would say further was this, that if there was any case for a penalty, the case was one in which His Honour was only bound to inflict a nominal penalty. It was not a case for the full penalty of £5, and a nominal penalty would certainly meet the justice of the case under the circumstances.

Mr. Grey protested against any suggestion that the prosecution wished to punish Mrs. Savage through her son. According to the Act they must proceed against the actual offender.

His Honour: That is what I understand.

James Wm. Savage, who was then called by Mr. Hines, said he was twenty-one years of age last June. The business at 140, Listerhills Road was conducted by his mother, and he was an assistant under Mr. Simpson, who was registered as a qualified chemist. He did not remember selling a bottle of the balsam to the witness for the prosecution. He could not swear he did so supply a bottle.

Alexander H. Simpson said he was a duly registered chemist and druggist, and managed the shop of Mrs. Savage at 140, Listerhills Road. He entered the employ of Mrs. Savage on January 20. He had been in the shop from nine o'clock until evening every day, with the exception of an hour for dinner between one and two o'clock. In the course of cross-examination he admitted that on certain occasions he had to go to the other shop in Westgate.

After this witness had been disposed of, Mr. Hines said: As I have said, I think the intention of this prosecution was to prosecute the owner of the shop, and not this young man only.

His Honour: I do not think so.

Mr. Hines: We have heard that some of the other chemists had been making complaints. There are a great many chemists, I may state, who are anxious to get a repeal of Section 16 of this Act if it could be done, and prevent a widow being able to carry on business in this way.

His Honour: It may be so, but I shall have to deal with the Act of Parliament.

Mr. Hines: My friend has said that before the alteration the summons was against J. L. Savage.

His Honour: That was clearly an error. The name was obviously wrong. If they had desired to prosecute the widow they would simply have had to fill in her Christian name.

His Honour, in giving judgment, said there could be no doubt that this medicine was sold by an unqualified man. The next question was that of the amount of the penalty. Mr. Hines had suggested that a nominal penalty would be sufficient to meet the case. What did Mr. Grey say to that?

Mr. Grey: The penalty is £5 or nothing. Your Honour has no discretion. It has been decided over and over again that the penalty, if a penalty be found against the defendant, must be £5, and no less.

His Honour, after some further discussion, said there would be judgment for the plaintiffs for £5, and it was intimated that the judgment would carry costs in the usual way.

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

DISPENSING DIFFICULTY

"Doubtful" asks what changes occur when the following mixture is compounded:—

R̄ Acid. Phosph. Dil.	℥xx.
Liq. Strychninæ	℥iii.
Ferri et Quin. Cit.	gr. v.
Glycerin	ʒss.
Aqua Chlorof. ad	ʒss.

A basic phosphate of iron is thrown down. Mix the citrate of quinine and iron with the glycerin and three drachms of chloroform water; dissolve, and add the dilute phosphoric acid and solution of strychnine, previously mixed with the remainder of the chloroform water. Attach a "Shake the bottle" label.

CONCENTRATED SOLUBLE ESSENCE OF LEMON.

Probably something on the following lines will suit you: Freshly grated lemon peel, free from white, 10 ozs.; rectified spirit, 15 fluid ozs.; glycerin, 1 fluid oz. Macerate for fourteen days in a closed vessel, shaking well once daily; then strain, press, add citral, 4 fluid drachms, filter, and make up to one pint with rectified spirit. [Reply to "Subscriber."]

CONCENTRATED ESSENCE FOR GINGER ALE.

Soluble essence of ginger, 7 ozs.; burnt sugar, 1½ drachm; soluble essence of lemon, 30 minims; oil of pimento, 10 minims; tincture of quillaya, 2 drachms; oil of bitter orange, 5 minims; tincture capsicum (quadruple B.P.), 2 drachms; water to 10 ozs. Mix and allow to stand for twenty-four hours, then filter bright through clean powdered pumice stone. [Reply to "Subscriber."]

DISPENSING PHENAZONE.

E. C. Evans asks for an explanation of the decomposition which appears to take place on compounding the following mixture:—

R̄ Chloral. Hydrastis,	
Phenazoni.....aa	ʒiss.
Atropin. Sulph.	gr. ʒo.
Aq. ad	ʒii.
Ft. Mist.	

What really happens is that chloral separates from the mixture in oily drops on account of the water being insufficient for perfect solution. On the addition of a little more water, the chloral re-enters into solution. [Reply to E. C. Evans.]

ASEPTOL AS A TEST FOR ALBUMIN.

Barral (*Lyon Méd.*) finds a new reagent for albumin in aseptol, which is a mixture of sulphuric acid and phenol. It is extremely delicate and precipitates as little as 3 or 4 milligrammes of albumin in a litre. It dissolves phosphates and urates but precipitates mucus and peptones.

NAPHTHA FOR CLEANSING WOOL.

According to *Les Nouveaux Rems.*, naphtha is coming into use for removing the fat from wool. The solvent is pumped several times over the wool, by which means not only is all the natural fat removed, but the fleece is left in excellent condition for working, since naphtha does not act upon the fibres as alkaline washes do. The wool fat removed by this method is available for many purposes.

NON-IRRITATING EXCIPIENT FOR OPHTHALMIC OINTMENTS.

Dr. Jamieson, *Brit. Journ. Dermat.*, finds the following formula to afford "an ideal ophthalmic salve."

Lanolin	ʒij.
Olei Amygdalæ,	
Aquæ Dest, aa.....	ʒss.

M.

A couple of grains of boric acid may be added to correct any slight tendency to rancidity.

PARLIAMENTARY INTELLIGENCE.

THE COMPANIES BILL was not, as contemplated, taken in Committee on Monday last, but has been deferred for a week. Meanwhile amendments are growing on the notice paper with weed-like rapidity. One, at least, of those amendments should create in the minds of chemists something akin to interest, for it is an outward and visible sign of an inward pharmaceutical activity. The motion in question is that of which the ex-Lord-Chancellor—Lord Herschell—has given notice. His Lordship has evidently been made fully acquainted with the extent to which the decision in the case of the Pharmaceutical Society v. London and Provincial Supply Association has been utilised for abusing the privileges of incorporation, and he proposes to so amend the law that it will be impossible for an incorporated group of unqualified and unregistered men to hold themselves out to the public as possessing personal professional qualifications. The words of the proposed clause are as follows:—

"No company shall be registered under a name which shall include or consist of a name, title, sign, description, or addition which cannot by law be taken, used, or exhibited by a natural person unless such person has a personal qualification.

"If any company shall take, use, or exhibit any name, title, sign, description, or addition which cannot by law be taken, used, or exhibited unless the person taking, using, or exhibiting the same has a personal qualification, such company shall (1) be deemed to be carrying on business for an illegal purpose within the meaning of this Act, and shall (2) be subject to the same consequences in all respects as though the company were a natural person taking, using, or exhibiting such name, title, sign, description, or addition without having such qualification.

"No petition for the winding-up of a company on the ground that it is carrying on business for an illegal purpose within this section may be presented except by or with the authority of a society or association empowered or entitled by Act of Parliament, Royal charter, or letters patent to grant, confer, or inquire into the qualification entitling any person so taking, using, or exhibiting such name, title, sign, description, or addition as aforesaid."

Whether the Government will be induced to accept this inhibitory clause is an open question, for the dread of fostering monopolies unawares renders Ministers exceedingly circumspect. It may be difficult to convince them that no new professional tyranny is in contemplation, but that it is desired simply to effect an equitable adjustment, and to render the law as to the use of professional titles equally applicable and operative in the case of a "company" as it is in the case of a natural "person."

THE FATE OF PRIVATE BILLS.—A Government with a majority ranging from one hundred upwards is apt to be somewhat brutal so far as regards private members' Bills. The present Government is no exception to the rule, and by swallowing up the whole time of the House for Government business for the remainder of the session it has not only sealed the fate of Sir John Lubbock's Shops Bill, but has destroyed the hopes of those who looked to the Bill as a kind of harbinger of pharmaceutical prosperity. Sir J. Lubbock feebly protested that Bills which had passed through Grand Committees ought to be exempted from the general massacre of private members' measures, but Mr. Balfour could only promise that the first two Wednesdays, and possibly the third, after Whitsunside might be set aside for discussion of Bills which had passed the Committee stage. With this grain of cold comfort the promoter and the supporters of the Shops Bill have to rest content.

SHOP ASSISTANTS' HALF-HOLIDAY BILL.—A Bill to provide that all shopassistants shall have one half holiday in each week was on Tuesday introduced into the house by Messrs. Duncombe, Dalbiac, Richardson, Harry Samuel, and Flower—members who have become somewhat prominent by their consistent hostility to the Shops Bill. The promoters of the Assistants' Bill claim that it is free from the grave objections which exist in other Bills introduced with similar beneficial intent to persons employed in shops. The second reading is down for Wednesday, June 10, which, curiously enough, is the date fixed for the further consideration of the Shops Bill.

PHARMACEUTICAL SOCIETY

"FIRST" EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Wednesday, April 29.

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination:—

Collins, Samuel Morrison, Norwood. | Livesey, Henry Ayrton A., Bradford.
Kidd, David Bell, Melton Mowbray. | Smith, Harold James, Grimsby.

The report of the College of Perceptors on the examination held on April 14 was received.

408 candidates had presented themselves for examination, of whom 234 had failed.

The following 174 passed, and the Registrar was authorised to place their names upon the Register of Apprentices and Students:—

Ainelle, John, Galashiels.
Alcock, Robert Frank, Southampton.
Alexander, Isabella, Banff.
Anderson, James Archibald, Lockerbie.
Archer, William Taylor, Cambridge.
Atkins, George David, Heaton.
Bailey, Arthur Joseph, Birmingham.
Bailey, Thomas Harvey, Bournemouth.
Baines, Richard, Lancaster.
Barnes, Ernest Edward, Hackney.
Barry, Robert Allan, Ayr.
Beardsley, Cyril, Belper.
Bentley, Henry Percy, Bradford.
Blunt, John Henry, Northampton.
Braggins, Albert Edwin, Banbury.
Bussey, James Edward, Wareham.
Butterworth, Ernest, Rochdale.
Caesar, Henry Wilkin, Dumfries.
Cairns, Thomas, Alnwick.
Caitness, Augustus, Liverpool.
Campbell, George, Penrith.
Carson, Robert William, Bradford.
Church, William Elsey, Batley.
Clarke, Herbert Renshaw, Nottingham.
Clarke, Thomas John, Toabridge.
Clarko, William J., Stockton-on-Tees.
Cleeland, Robert Henry, Belfast.
Coles, Charles Avery, Reading.
Collins, Joseph Henry, Falmouth.
Cook, James Booker, Banff.
Corke, Harry Malcolm, Woolston.
Cornish, Archibald Franklin, Taunton.
Cox, Horace Nelson, Edinburgh.
Crossley, Arthur, Gorton.
Darroll, Horace Henry, Clun.
Davies, Henry Charles, Groydon.
Davison, Henry Spours, Gateshead.
Daykin, Albert Ernest S., Ripley.
Derman, Thomas John, Bath.
Dewar, A. Owen Cameron, Cupar.
Duncan, Charles, Dundee.
Elliott, Bertie T. J., Newport, Mon.
Elms, Henry, Hornsey.
England, Thomas, Scarborough.
Ewart, Samuel, Crofton.
Farrow, Leslie John, Lowestoft.
Fewtrell, Patrick Roy, Turriff.
Findlay, Adam, Aberdeen.
Fionis, Sydney, Dover.
Fisher, William Edgar, Camberwell.
Futty, Alfred, Scarborough.
Gamer, Stanley R., Newark-on-Trent.
Gartside, William, Oldham.
Gellately, James Blair, Dundee.
Gill, Henry John Turton, Brighouse.
Gittings, Arthur Henry, Bilston.
Glaholm, William, Jarrow.
Gooch, James Bowles, East Dereham.
Gordon, John R. C., Friockheim.
Graham, Margaret T., Lochgelly.
Granger, Ernest R., Whitby.
Griffith, Robert William, Portmadoc.

Griffiths, Thomas, Carmarthen.
Hadfield, James Ernest, Buxton.
Hall, Henry, Cardiff.
Hammond, Albert, Bollington.
Harrison, Clement, Caversham.
Heald, Gerard, Heckington.
Helliwell, Hubert Wellesley, Bradford.
Henderson, John McGregor, Ayr.
Hewitt, Joseph, York.
Hibbert, Arthur Byron, Chester.
Hocking, Samuel John, Redruth.
Holden, Wilfred Curtis, Southampton.
Hopkins, Cyril John, Towcester.
Hovell, Thomas Henry, Norwich.
Howell, James Bonnell, L'anely.
Howell, Taliesin Thomas, Llanblethian.
Hughes, Ernest Ethelbert, Altrincham.
Hull, Edward Frank, Croydon.
Hume, George, Gatehouse.
Humphreys, Sidney, London.
Hunt, Frederick, Chichester.
Innes, John Langland, Dumbarton.
James, Edmund, Kidderminster.
James Lewis August, Ruthin.
Jolly, William Isaac, Bradford.
Jones, John William, Plymouth.
Jones, William Brittain, Brynmawr.
Jones, William Richard, Bangor.
Kendrick, Robert Edward, Wrexham.
Kitching, George C, Morecambe.
Klein, Frederick, Carlisle.
Lemmon, Reginald John, Chichester.
Lewis, Thomas Ed. Banks, Grimsby.
Lewellyn, Thomas, Oswestry.
Lloyd, Robert Edmunds, Portmadoc.
Loney, Sidney Thomas, Eltham.
Lord, William, Bury.
McCallister, William, Bolton.
McCreath, William Fletcher, Leven.
McDougall, Duncan, Campbelltown.
McGeorge, Richard, Edinburgh.
McGuffie, David, Stranraer.
McIntyre, George, Ellesmere.
Macintosh, John, Brechin.
Mackay, James D., Leith.
McRobb, William, Lochleask.
Male, Charles Edgar, Cottenham.
Mann, John, Alness.
Manson, John, Glasgow.
Martin, Harry, Aylesbury.
Martin, John Muir, Sunderland.
Masterton, William David, Brechin.
Mathers, Ernest Thomas, Cambridge.
Moffat, William John, Dumfries.
Mogford, Frederick Thomas, Tiverton.
Mogg, Ernest Hubert, Wells (Som.).
Moore, John William, Wigton.
Mortimer, Harold, Cleckheaton.
Morton, William Jas., Newton Stewart.
Muir, John, Laurieston.
Murray, Alexander, Aberdeen.
Nicholson, Thomas Brightmore, Hanley

Oliver, John James, Liverpool.
Oswald, John Seath, Kinghorn.
Otter Wilfred, Otley.
Parsons, Maurice James, York.
Pearce, Stanley Littlejohn, Tavistock.
Perkins, Francis G., Hammersmith.
Petrie, William Peddie, Dundee.
Porter, Frank, Leicester.
Powell, Charles W., Middlesbrough.
Priestley, George Edward, Paisley.
Prosser, Thomas William, Oxford.
Rapson, Florence Helena, Bungay.
Rayner, George Lancelot, Cranswick.
Reavley, Robert, Jarrow-on-Tyne.
Redfern, Harry Chaplin, Leek.
Rennard, Herbert, Leeds.
Richardson, Herbert Stanley, Hull.
Richardson, Joseph, Louth.
Ripley, John H., Berkhamstead.
Robertson, Bessie Brown, Markinch.
Russell, William, Leith.
Scott, William, Newcastle-on-Tyne.
Sharp, Jeremiah, Drumburgh.
Shelley, George A. Henry, Southwark.
Shepperd, Henry George, Penzance.

Smith, Frank, Downham Market.
Smith, Robert Harman, Chelmsford.
Starmer, George F., Tunbridge Wells.
Stiles, Percy C. G., St. Ives (Hunts).
Stopforth, William Henry, Wigan.
Storey, Richard, Ulverston.
Swaby, Harry Coupland, Lincoln.
Swinnerton, George, Hanley.
Tait, Joseph, Edinburgh.
Thomson, Robert B., Thornhill.
Thornhill, H. John, Gosforth.
Turnbull, William, Grangemouth.
Turner, George, Longton.
Warmington, Frank E., Loamington.
Watts, Bertram Adam, Woolwich.
Webb, Walter J., Newcastle-on-Tyne.
Whittingstall, Ernest E., Wakefield.
Wigglesworth, William, Ingrow.
Williamson, Andrew, Fortrose.
Williams, David Gwilym, Tycross.
Williams, Edward, South Petherton.
Wilson, Alexander W., Edinburgh.
Wilson, John A., Askam-in-Furness.
Wood, Robert John, Driffield.
Wright, William, Newcastle-on-Tyne.

The questions set at this examination were published in the *Pharmaceutical Journal* for April 18, p. 310.

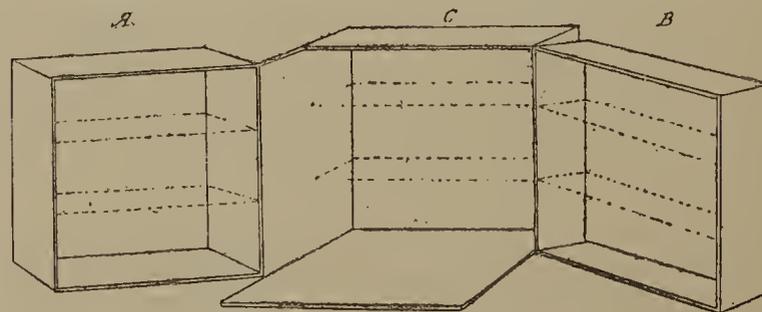

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre, and the result.

	Candidates.				Candidates.		
	Exam-ined.	Passed.	Failed.		Exam-ined.	Passed.	Failed.
Aberdeen	18	6	12	Lancaster	8	4	4
Birmingham	20	6	14	Leeds	29	11	18
Brighton	7	3	4	Lincoln	7	4	3
Bristol	8	3	5	Liverpool	16	6	10
Cambridge	8	4	4	London	26	15	11
Canterbury	5	1	4	Manchester	34	11	23
Cardiff	10	4	6	Newcastle-on-T....	18	11	7

A FOLDING CUPBOARD FOR STORING SMALL BOTTLES.

BY ARTHUR A. DECK, CAMBRIDGE.

The accompanying sketch is that of a cupboard I have had made after my own design, and I send it in the hope that it may prove useful to some of the readers of the *Pharmaceutical Journal*.

As shown in the sketch, B folds on C, and A on B. A has a glass front, so that when closed it looks like an ordinary cupboard. The dotted lines represent shelves, which should have a piece of picture wire about an inch above them, on A and C, to prevent the bottles slipping off.

LONDON: SATURDAY, MAY 2, 1896.

THE ACTIVE PRINCIPLE OF THE THYROID GLAND.

THE interesting observation made by Professor BAUMANN as to the existence of an iodine compound to which the therapeutic action of the thyroid gland is due (see *ante*, p. 161), has acquired additional importance from the results of further investigation undertaken with the object of isolating the active therapeutic constituent. In the newly-issued number of the *Zeitschrift für Physiologie* there is an account of the work carried out in that direction by Professor BAUMANN and Dr. ROOS, from which the following particulars are extracted. The frequent occurrence of goitre in the Black Forest has afforded favourable opportunity for testing the efficacy of the preparations obtained by chemical treatment of thyroid glands, and the prompt effect produced, in such cases, by an active preparation, as pointed out by EMMINGHAM and REINHOLD, has been made the test of remedial activity, the administration of these preparations to patients in the Freiburg Hospital having been carried out by the resident medical officers, Dr. THOMAS and Dr. ESCHBACHER. It has been ascertained that the active principle of the thyroid gland is not destroyed by exposure to a temperature of 100° C., or by the action of strong mineral acids. When the minced gland is digested for some time with 10 per cent. hydrochloric acid its activity is scarcely at all affected. After neutralising the acid with caustic soda and evaporating, the dry residue obtained was found to have a marked effect when administered, in cases of goitre, in quantities corresponding to one gramme of the fresh gland. On boiling the gland with about four times its weight of dilute sulphuric acid (1:10) almost perfect solution is effected after a few hours, only a finely divided flocculent precipitate remaining suspended in the liquid, the quantity of which is not reduced by longer boiling. The fat always present in the interior of the glands collects at the surface of the liquid, and can be separated, after cooling, by straining through muslin. By this treatment it was found that the active substance was not destroyed even when the boiling was continued for three days: it passed into solution and was for the most part deposited on cooling as a brownish precipitate amounting to from 0.75 to 1.5 per cent. of the gland material operated upon, according to the length of time the boiling had been continued. After separating the precipitate by filtration, the acid liquor still contained a small portion of the active thyro-iodin. By neutralising nearly all the

acid with caustic soda, and evaporating the liquid to one-fifth or one-sixth, most of the thyro-iodin separated on cooling: the deposition being more complete when the sulphuric acid was removed by treatment with barium carbonate before concentrating the liquid. Even then the liquid contained some thyro-iodin, and when a considerable quantity of it was administered to a goitre patient it was found to have a slight action. By treatment of the evaporated liquor with alcohol the thyro-iodin can be extracted, but at the same time other substances also pass into solution, and they cannot be readily separated. The chief portion of active principle is contained in the residue remaining undissolved after treatment of the gland material with sulphuric acid as above described. This product still contains fat, fat acids and other substances as well as thyro-iodin. For further purification it was repeatedly washed while moist with 90 per cent. alcohol, which gradually dissolved the thyro-iodin; the residue obtained on evaporating the alcoholic solution was then mixed with ten times its weight of milk sugar and digested with petroleum spirit or a mixture of it with dry ether, to remove fat.

For the separation of thyro-iodin from the milk-sugar the powder was dissolved with a little dilute caustic soda, the liquid filtered, if necessary, and on acidification thyro-iodin was deposited in flocks, collected on a filter, washed, again dissolved with caustic soda, and re-precipitated. By this treatment some portion of the adherent colouring material was separated without much loss of thyro-iodin. The purified thyro-iodin thus prepared was, after drying, a brownish-coloured powder, insoluble in water, sparingly soluble in alcohol and readily soluble in caustic alkaline solutions. It contains a considerable amount of nitrogen, some phosphorus (about 0.5 per cent.), and about 10 per cent. of iodine. When heated it evolves an odour of pyridine bases. The iodine is very intimately combined: it is only with difficulty separable by the action of alkalis. Even by treatment with sodium amalgam the iodine is but gradually separated. Further information as to the chemical nature of thyro-iodin will be given in subsequent communications. In the administration of thyro-iodin prepared in the manner described, it has been found that a dose of one milligramme produced, after two or three times, a very distinct and appreciable effect in cases of goitre. The inference is that the effect is not due to the minute quantity of iodine present in the thyro-iodin given, but that it is produced by the specific action of a peculiar organic iodine compound which is formed in the thyroid gland under normal conditions from the minute traces of iodine compounds contained in food materials. In the preparation of thyro-iodin by the method above described, a loss of from 25 to 30 per cent. of the quantity actually present in thyroid gland material is unavoidable. Such loss is reduced when the separation of thyro-iodin from the gland material is effected by digestion with artificial gastric juice. The product thus obtained is also less coloured than that resulting from treatment with acids. The most suitable procedure is to use a digestive liquor containing three-thousandths of hydrochloric acid and to digest for two days at a temperature of 40° C. Almost the whole of the thyro-iodin then remains undissolved, while the rest of the gland material passes into solution as hemi-albumose and peptone, this solution being almost free from iodine. The residue obtained by evaporating the solution was found to have only a very feeble effect in cases of goitre when administered in relatively large quantities.

In reference to the question as to the condition in which thyro-iodin exists in the gland, BAUMANN and ROOS are of opinion that only some small portion of it can be there in a free state; they come to that conclusion because experience has shown that the thyroid gland extracts prepared in various ways with water or glycerin are less active than equivalent quantities of the fresh gland. For the elucidation of this question the following experiments were carried out. A quantity of fresh sheeps' thyroid (25 grammes) was boiled three times with alcohol: the residue obtained by evaporating the alcoholic liquor was found to contain iodine and the iodine compound to be identical with thyro-iodin; but the quantity was not more than a fifteenth part of that corresponding to the total quantity of iodine in the gland material operated upon. Further experiments showed that though the greater part of the iodine compound can be extracted by treating thyroid gland with cold water, a considerable portion remained in the undissolved residue, as shown by the effect produced when it was administered to goitre patients. The extraction of the iodine compound is effected somewhat better by treatment with glycerin; but even in that case the residue, after three or four extractions, contains very sensible quantities of iodine. By extracting three or four times with 0.75 per cent. salt solution the iodine compound is so completely dissolved that only slight traces of iodine can be detected in the residue. On diluting the extract with fifteen times its volume of water, it becomes turbid, and on passing through it carbonic anhydride, flocks separate consisting of the globulin substance described by BUBNOW and NOTKIN. It contains iodine and the smaller part of the thyro-iodin present in the gland. On boiling it with sulphuric acid, thyro-iodin is separated. The liquid from which this globulin has been separated by filtration gives, on acidification with acetic acid, an abundant precipitate of an albuminous substance, which also contains iodine and contains the greater part of the thyro-iodin combined with it. Both these albuminous substances are active, but the liquor is free from iodine and inactive. The same result is arrived at by coagulating the salt-water liquor before separating the globulin. It appears, therefore, that thyro-iodin exists in the glands for the most part in combination with the albuminoid substances which BUBNOW has examined and found to be analogous to globulins. The substance isolated by NOTKIN and named thyreoproteid, was considered by him to be a product of metabolism and the poison which, accumulating in the system after extirpation of the thyroid gland, gives rise to the consequent phenomena. He considers that, under normal conditions, this thyreoproteid is destroyed by an enzym—thyroidin—contained in the gland secretion, and is thus rendered innocuous. According to that view the enzym would be the specific active constituent of the gland. The results obtained by BAUMANN and ROOS have led them to entirely different conclusions, namely, that the activity of the thyroid gland has nothing whatever to do with an enzym or any similar substance, but is entirely referable to thyro-iodin—the specific constituent of the gland—existing partly in a free state, and partly combined with albuminoid substances from which it may be detached by digestion with gastric juice or by treatment with acids. Lastly, it is stated to have been established by numerous observations that thyro-iodin is capable of producing all the effects which have been recognised as characteristic of thyroid gland treatment, even to

the specific action in myxœdema, this point having been conclusively established by Professor LEICHTENSTEIN, of Cologne, and more recently also by Professor EWALD.

ROYAL MEDICAL BENEVOLENT COLLEGE.

SINCE referring to this institution in last week's Journal, we have been favoured with additional particulars regarding it. In addition to the fifty foundation scholars—who must be the necessitous orphans and sons of medical men—the College is open to receive about two hundred ordinary scholars, and admission is in no sense limited to any particular class. These "non-foundationers" are eligible for nearly all the exhibitions and scholarships offered, including open entrance scholarships offered for competition every July for boys under fourteen; thirty "College" exhibitions, of the value of fifteen pounds per annum, for boys under thirteen; four annual "School" scholarships for boys already in residence; four scholarships of forty to sixty pounds per annum, tenable at the Universities; and ten annual scholarships at various London hospitals, each of the value of about one hundred and twenty guineas a year.

The School is divided into upper, middle, and lower schools; also into classical and modern sides. The classical side is chiefly intended to prepare pupils for the Universities and the learned professions, the education being therefore mainly classical. On the modern side, the subjects are arranged more in accordance with commercial requirements. Particular attention is paid to the teaching of natural science, a well-appointed chemical laboratory and lecture theatre being supplemented by a physical laboratory, and a class-room for biological studies. The arrangements for recreative purposes and physical training also appear to be very complete, and any pharmacist desirous of doing the best he can educationally for his son might do worse than apply for full particulars of the College to the Secretary, 37, Soho Square, London, W.

As suggested last week, it seems well worth the consideration of pharmacists whether the Orphan Fund of the Pharmaceutical Society might not be developed in the direction of supporting one or more scholars on the foundation of such an institution as this. Assistance would thus be provided in the manner best calculated to give satisfactory results in the case of orphan children—whether boys or girls, and a comparatively small annual payment by every registered chemist and druggist would yield a total amount which would probably have the effect of serving as an efficient educational assurance fund.

PHARMACEUTICAL CONGRESS AT BUDAPEST.

THE business of this Congress will commence on June 26 with an introductory address by Mr. A. Z. ZBORAY, President of the Association of Hungarian Pharmacists, and after the election of an honorary president, the following papers will be read:—

- "History of Hungarian Pharmacy," by Alex. Schédy.
- "Importance of the Pharmacy in Relation to State Hygiene," by Géza Gallik.
- "Education of Pharmacists," by Prof. Etienne Györy.
- "On Personal-Right Pharmacies," by Etienne Lukács.
- "The Flora of Hungary and the Cultivation of Medicinal Plants," by Prof. Charles Schilberszky.
- "The Question of Chambers of Pharmacy," by G. Karlovsky.
- "Reports on Pharmacy in the Great European States," by Jules Muzsa.
- "The Question of an Institution for Retired Hungarian Pharmacists," by Etienne Lukács.

The reading of papers and discussions thereon will be continued on June 27.

ANNOTATIONS.

SUBSCRIPTION TO THE BENEVOLENT FUND.—The Editor has pleasure in acknowledging the receipt of an annual subscription of one guinea to the Benevolent Fund, sent through him by Dr. Constantine Holman, J.P., Treasurer of the Royal Medical Benevolent College, Epsom. The sending of the cheque, which has been duly handed to the Secretary, Mr. Richard Bremridge, serves to point the moral of the good understanding that should exist between medical men and pharmacists.

GERMAN APOTHEKER VEREIN.—The general meeting of the German Apotheker Verein will be held this year in Dresden, and in addition to the attraction offered by the central position of that town, the celebration of the fiftieth anniversary of the Verein may be expected to ensure a more than ordinary assemblage of members and visitors. In connection with the meeting, an exhibition of objects of pharmaceutical interest is being organised.

RADIOGRAPHS PRODUCED BY A MAGNET.—In the *Scientific American* for April 18, Professor John S. McKay publishes an account of some experiments with magnets, which resulted in the formation of "shadowgraphs" similar to those produced by the action of the Röntgen rays. The method of procedure followed is to place a paramagnetic substance upon the sensitive film of a photographic dry-plate, and the poles of a permanent or electro-magnet are then brought near the other side of the plate. After a time the plate is removed, and when developed shows a clearly defined image of the object. Positives prepared from such plates will give in shadow the outlines of any object used as armature, well-defined silhouettes of keys, pliers, or any iron or steel implements being thus obtained. Again, if the dry plate be placed with its sensitive side facing the poles of a magnet, and a disk of iron nearly as large as the plate be placed on the opposite side, in the position of armature, "shadowgraphs" will be formed upon the plate, of any non-magnetic or diamagnetic bodies placed on the other side, between the plate and the poles of the magnet. The shadow pictures produced by either of these methods are said to be as clear and distinct as those produced by the Röntgen rays. With an electro-magnet capable of lifting a hundred pounds or more, a "magnetograph" has been obtained through a block of wood two inches thick. The object must be in contact with the sensitive film, and a thin sheet of mica or paper seems to check the action, whilst the best results have been obtained by suspending the magnet in a vertical position. It is suggested that the results of these experiments seem to indicate that the ether in the field of a magnet is in a state of permanent stress, perhaps due to ether vortices, and that any change in magnetic force produces a change in the degree of stress, and thus originates ether waves capable of affecting sensitive plates. The question is also asked: "May not the Röntgen effects be due to the magnetic component of a Hertz wave?"

MORE SENSIBLE ADVICE.—In the *Ph. J. Supplement* for April 11 the advice of the *Patent Medicines Journal* was quoted, to the effect that "grocers and other unregistered persons should stop off all poisonous proprietaries." It is gratifying to find that similar sensible advice to obey the law is given to its readers by the *Grocer*, which observes that for the retail grocer who has been selling proprietary medicines there is but one course open, and he should therefore "absolutely decline to stock any proprietary preparations the manufacturers of which refuse to give him a written guarantee that they contain none of the scheduled poisons, and a written indemnity against all costs, expenses, and charges which he may at any time find he has incurred by their sale."

THE METRIC SYSTEM IN THE UNITED STATES.—Great Britain and Russia are frequently quoted as the sole remaining important adhesions to the older systems of weights and measures, but apparently the United States must yet be regarded as belonging to and likely to remain in the same category. A Bill proposing to make the metric system the only legal standard was brought before the House of Representatives at Washington, on April 8, and passed by the narrow margin of two votes only, the figures recorded being 119 for and 117 against. Later, however, the vote was "reconsidered," and to save the Bill from defeat its supporters were fain to consent to have it recommitted to the Committee on Coinage, Weights, and Measures. The use of the system has now been authorised and permitted by law for the last thirty years, but it has not been adopted, except to an exceedingly limited extent. Even pharmacists in the States do not appear to take to the newer system very kindly, in spite of the fact that it is exclusively used in the U.S. Pharmacopœia. Many seem to continue to employ their old weights and measures, even when compounding or dispensing quantities specified according to the decimal system, thus troubling themselves with quite unnecessary calculations. As illustrating the prevailing tendency to continue to think in accordance with the old system whilst working with the new, the following ingenious compromise, quoted in an American journal, is worthy of passing reference:—"When making use of a 2 ounce mixture, remember that the number of grains ordered of any medicament should be exactly the dose in minims or grains of the medicine. In other words, write (for a 2-ounce mixture) the same number of grains of a remedy that you wish grains or minims administered."

BOTANICAL EXCURSIONS FROM EDINBURGH.—The Committee of the local Pharmaceutical Association at Edinburgh has once more arranged an attractive summer programme for the members. Botanical excursions to Blackford Hill, Colinton Dell, and Craigcrook Quarry are to take place on June 5 and 19, and July 17, respectively, at a convenient hour in the evening, whilst meetings for the examination of collected plants will be held in the Pharmaceutical Society's House on May 8, June 12, and July 15. A book prize will be presented to the apprentice member who writes the best report on the excursions and demonstrations. Last in the programme, but not least attractive, is a statement to the effect that the Association has accepted an invitation from Professor Geddes to visit his botanical gardens at Dundee, on May 21. The Secretary, Mr. W. F. Hay, 139, Princes St., Edinburgh, will be glad to hear as early as possible from members who intend joining the excursions.

CALIFORNIA COLLEGE OF PHARMACY.—According to the prospectus of this College, the requirements for admission are now made to cover the first year's work in the High Schools of the State of California. Intending students are also advised to gain some experience in a pharmacy before they begin to attend the College, as "the practical knowledge thus gained enables students to comprehend readily, and therefore to make more satisfactory progress." The College syllabus is an extremely satisfactory one, and the title of Graduate in Pharmacy is not conferred except the candidate be of good moral character, is twenty-one years old, and has attended two full courses in each of the departments of the College, or one course after attending a course at another recognised College of Pharmacy. He must also have had four years' experience in a pharmacy "where physicians' prescriptions are compounded," present an account of some special work done in the laboratory in lieu of a thesis and exhibit some chemical or pharmaceutical product made under supervision, and finally he must have attended at least three-fourths of the lectures, reviews, and laboratory work. The California College graduate ought to be a good pharmacist.

PROCEEDINGS OF SOCIETIES.

Chemical Society, April 23.—Mr. A. G. Vernon Harcourt, F.R.S., President, in the chair.—The first paper down for reading in the published list was "On the Temperature of Certain Flames," by Professor W. N. Hartley, F.R.S., but for some reason or other it was not forthcoming. That there would have been some discussion on this polemical subject it is evident, as more than one authority on the matter was noticed among the audience. The published list of papers turned out to be no indication of the nature of the meeting which was held, as only two out of this list of five papers were read, and those only in brief abstract. These were: "On the Constitution of the Cereal Celluloses," by C. F. Cross, E. J. Bevan, and Claud Smith, read by Mr. Cross, and "Ethereal Salts of Optically Active Malic and Lactic Acids," by Professor Purdie, F.R.S., and Sydney Williamson, Ph.D., read by the latter.

A paper, from a supplementary list, of considerable interest was that by Mr. R. G. Durrant, "On a New Compound of Cobalt." The author has studied the action of hydrogen dioxide on salts of cobalt and a few other metals, and finds that a green compound is formed, under proper conditions, in the case of cobalt. As hydrogen dioxide is very unstable in solution of caustic potash, it occurred to the author that potassium acid carbonate might not be so active as the caustic solution, and he found that when applied to his new test for cobalt it answered the purpose admirably. An experiment was next performed. A solution of cobaltic chloride in a small quantity of water was made, then a solution of potassium acid carbonate, as concentrated as possible, added. This gave a slight precipitate. Excess of hydrogen dioxide was now added, and the precipitate became green and then went into solution, the latter remaining green. At the same time there was effervescence which the author thinks is probably due to carbon dioxide. The green body is supposed to be cobaltic acid, or a cobaltate of potassium. The green colour may also be produced by using the "aërated" water of a syphon. The lecturer then proceeded to perform five experiments, arranging five glass cylinders in front of the bench, where they could easily be seen by the audience. Into the first he ran some of the syphon liquid, then two drops of the solution of cobaltic chloride and a little solution of potash. The order in which they are added does not matter much. In the second glass he used solution of soda, in the third solution of calcium hydrate; the fourth had barium hydrate, which acts somewhat better than calcium hydrate, and the fifth glass contained solution of ammonia. Ammonia, it appears, tends to decompose the body, and there is only a green solution for a few moments. Hydrogen peroxide was, of course, added to each, and the green colour was seen in each case. The author sketched on the board an equation, which, he believes, expresses the reaction that occurs in the production of this green compound. It is as follows:—

The CoCO_3 of the equation expresses the result of the action of the carbonate on the cobalt chloride originally used. The green compound produced when potassium acid carbonate is used may remain perfectly stable for the matter of a month or so. The latter part of the paper was devoted to the consideration of this test as a means of separating cobalt and nickel, as no similar compound is formed in the case of the latter. Some pure nickel carbonate, however, which the author obtained from a certain London drug house, which he named, for the purposes of his research, was found to be anything but pure, as it contained more than an appreciable proportion of cobalt as shown by his test. Cobalt in nickel in the proportion of one to a hundred, or even very much less, can be easily demonstrated. Incidentally, he remarked that most salts of nickel are liable to contain cobalt to a greater or less degree. Experiments performed with nickel salts containing cobalt as impurity were very distinct, and evidently quite satisfactory. Instead of attempting to isolate the green compound with a view to its identification, the author proposes to arrive at that result by means of a series of standardised solutions.

The discussion which followed the reading of this paper was carried on in a sort of *dolce far niente* style, at least, in so far as the author himself was concerned, for he remained in the sitting posture whilst replying to his critics, answering each question as it was put to him. Dr. Rideal said something about cyanides and their blue colour, but it was difficult to understand exactly what he meant, especially as the author of the paper particularly drew attention to the formation of a green compound.

The President mentioned that there was no decomposition of

hydrogen peroxide with CO_2 in alkaline solution when the solutions are dilute.

Acting up to the suggestion put forward in his address at the anniversary meeting a few weeks ago, the President made a commendable effort to find another paper which could be illustrated either by experiment or apparatus, but without success, and the meeting was therefore brought to a close.

The following papers were taken as read:—

"Halogen Additive Products of Substituted Thiosinamines," by Augustus E. Dixon, M.D.; "An Apparatus for the Detection of Boic Acid," by W. M. Doherty; "Metadichlorobenzene," by F. D. Chattaway, D.Sc., and R. C. T. Evans; "The Determination of the Composition of a 'White Son' by a Method of Spectrographic Analysis," by Professor W. N. Hartley.

Midland Chemists' Assistants' Association, April 22.—Mr. T. C. Clarke, President, in the chair.—The following paper was read:—

"THE SPECTROSCOPE AND SOME OF ITS WORK," BY F. SMITH.

The spectroscope may justly lay claim to be placed in a prominent position among the greatest discoveries of this century, for although the bare fact that a prism decomposes white light into its component parts was known so long ago as the time of Newton, it was not until the early part of this century that any decided advance was made in the study of spectroscopy, whereas, since then the spheres of work opened out by this science, its capabilities and the actual work accomplished, are nothing less than marvellous.

The experiment of Newton in permitting a ray of sunlight to enter a darkened room through a circular hole in the shutter and interposing a prism in the path of the ray, by which means he obtained a band of colours upon a white screen, is a well-known historical incident. For nearly a century and a half after this time no further development took place.

Then an important step was taken by Wollaston, who, in place of the circular aperture for the admission of the light, used a narrow slit, thus obtaining a spectrum of greater purity, and thereby discovering that the band of colours was not absolutely continuous, but was crossed by a number of dark lines. A few years later (in 1814) Fraunhofer further improved the process by introducing a telescope, by which to observe the spectrum, and since then various other improvements have been introduced by various workers, resulting in the efficient instrument of the present day.

The spectroscope may be defined as an instrument for the analysis of light, this being accomplished by passing it through a prism, and so separating the diverse rays of which it is composed. To understand the action of the prism in producing a spectrum an acquaintance with the elementary principles of light is necessary. I will, therefore, recall to your minds as I go on a few of those principles that you may the more readily follow my description. Light consists of a wave-like motion of the particles of ether which penetrate all space, and in which the molecules of matter are so to speak bathed. The waves of light which are emitted by all self-luminous bodies are exceedingly minute, averaging but a 50,000th of an inch in length, and are in nearly all cases exceedingly complex, being composed of an almost infinite variety of wave-lengths, blended together, and all travelling with an equal velocity of 186,000 miles per second. It is the work of the spectroscope to sort out these waves of different lengths, to arrange them in their proper order, and to demonstrate which are present and which absent. When light passes from one medium into another of greater density, its direction is altered unless it falls perpendicularly upon the surface, and this bending of a ray of light, which is known as refraction, is unequal for the rays of different wave-lengths; therefore, when a ray of white light enters a glass prism, all the rays which are of one definite length take a certain direction within the prism, while rays of other wave-lengths take other directions, and as these are almost infinite in their variety, we have on their emergence from the prism, where the refraction is further increased, a fan-shaped ray; and if we place in its path a sheet of white paper we shall have delineated thereon a line of light, one end of which will represent rays of greatest wave-length and the other end the shortest waves, and each intermediate point will represent the rays of a certain definite and determinate wave-length which varies gradually from one end to the other. If now this line of light be widened into a band of light it will be found that the rays at one end of the continuous spectrum thus formed are violet in colour, and passing along the spectrum they change by imperceptible gradations through violet, indigo, blue, green, yellow, and orange to red. If we draw a line at right angles across this band of light, this line will

represent rays of one definite refrangibility, and the whole band of the spectrum may be looked upon as an almost infinite number of such lines placed side by side, each being of a slightly different colour from its nearest companions. Such a continuous spectrum as this we obtain from all solids and liquids which are in a state of incandescence, or, in other words, which are white-list. If, on the other hand, the light that is emitted from a glowing gas or vapour be examined after it has passed through a prism, an entirely different result will be obtained. One of the simplest of spectra is that belonging to the vapour of sodium, and if a loop of platinum wire, dipped in a solution of a sodium salt, be placed in a Bunsen flame, and the spectroscopy directed thereto, instead of a band of various colours we shall see merely two very brilliant yellow lines, as if the whole of the continuous spectrum had been blacked out with the exception of two thin transverse lines in the yellow portion. The explanation of this is to be found in the fact that the vapour of sodium emits light which is composed of but two different wave-lengths, these being of that particular length that corresponds to the yellow portion of the continuous spectrum. The light is admitted by means of a narrow slit, and each of these two lines is actually an image of this slit produced by that portion of the light which is of one particular wave-length. A continuous spectrum may similarly be regarded as an almost infinite number of images of the slit placed side by side, so that the finer and truer the slit of the spectroscopy the purer and more exact will be the spectrum obtained. I should perhaps mention that in the spectrum of sodium, as obtained under the best conditions, there are nine lines in all, but the two yellow lines stand out with such distinctness, and are so universally present, that the other lines are in ordinary cases neglected.

The spectrum obtained from sodium vapour is known as a line spectrum, and whatever vapour or gas is examined a spectrum similar in character will be observed—similar in that it will consist of a certain number of fine lines upon a dark background.

These lines spectra vary in the number of lines they contain, from four in the case of hydrogen to four or five hundred in the spectrum of iron vapour, and the spectrum of any particular vapour or gas varies according to the temperature and pressure at which it is examined. With an increase of temperature certain of the lines lose in distinctness and ultimately disappear, while others make their appearance, and in general higher temperatures lead to the simplification of spectra.

With increased pressure other lines make their appearance, and, as the pressure is still further increased, these continually grow in number until at length, when the vapour has become condensed into a solid or liquid, the spectrum becomes continuous.

The general construction of the spectroscopy is as follows:—Upon a stand, raising it some 8 or 10 inches above the table, is a glass prism, with its axis vertical, and fixed and pointing towards the prism are three metal tubes, each somewhat like a telescope in general appearance.

The first of these, known as the collimator, is fixed in position, and serves to collect a suitable beam of light for examination. The light is received upon the end of the tube, and by means of a narrow slit is allowed to enter; it is then rendered parallel by means of a lens, and passes on to the prisms. After passing through the prism this beam of light enters the second of these tubes, which is in effect a telescope, and by properly focussing this tube and looking through it the spectrum is seen. By means of the third tube, at one end of which is a microscopic glass with lines ruled thereon, and illuminated from a separate light source, a fixed scale is thrown upon the prism, and is observed along with the spectrum, serving for the identification of the various lines of the spectrum.

So far I have dealt only with radiation spectra; I have now to speak of what are known as absorption spectra.

When the light given out by an incandescent solid is examined, we have a continuous band of colours, but if between the source of light and the prism we interpose a gas or vapour, relatively cool, the coloured band is crossed by a number of dark lines; if, for instance, the light from the carbons of an arc lamp be allowed to fall upon the slit of the spectroscopy after passing through the vapour of sodium, the spectrum will be crossed by two distinct lines in the yellow portion, and if this be examined side by side with the spectrum obtained from glowing sodium vapour, which may readily be done by placing a special appliance over a portion of the slit, it will be seen that the two bright yellow lines radiated by sodium and the two dark lines, caused by the absorption of sodium, are identical in position. This is explained by the fact that sodium both emits and absorbs rays of the same period.

The molecules of the sodium vapour vibrate under the influence of light and heat in a certain definite period, and if mixed light is passed through sodium vapour those vibrations which are of this definite period are spent in communicating their motion to the molecules of the sodium vapour, in consequence of which, when the various portions of the mixed light are separated by the prism, these particular vibrations, and these only, are found to have been retained or absorbed, so that the images of the slit which would have been produced by these rays are absent, and we have dark lines in their places. This is true of all vapours and gases; all absorb exactly the same rays as they radiate, and consequently the absorption spectra are the exact negatives of the radiation spectra, and consist of a number of dark lines across the bright background of the continuous spectrum. Perhaps an illustration from the theory of sound will help to make this clear. A tuning-fork produces waves of sound of one particular wave-length yielding a definite note. If this particular note be sounded in the vicinity of the tuning-fork a portion of the vibrations will be spent in communicating motion to the tuning-fork, which under their influence will commence to vibrate, whereas a note of a different pitch will have no such effect.

One of the principal applications of the spectroscopy, and the one which has most conduced to the development of the science, is the examination of the light we receive from the sun. If a ray of sunlight be examined by this instrument, the spectrum is seen to consist of a band of colours such as is formed by light from an incandescent solid or liquid, which band is crossed by an exceedingly large number of dark lines, and as the greater number of these lines may be identified as corresponding with those connected with various elements with which we are familiar, the physical and chemical constitution of the sun can by means of the spectroscopy be approximately arrived at. The dark lines upon the bright background teach us that the light-emitting portion of the sun is either in a solid or liquid condition—probably liquid, in somewhat the same manner that the clouds which float in our atmosphere are in reality liquid—and that before leaving the sun the light has to pass through a vaporous atmosphere. In this atmosphere upwards of thirty of the elements known to us have been proved to exist, chief among which may be mentioned sodium, calcium, iron, magnesium, chromium, nickel, zinc, and hydrogen. Several other elements are probably present, while others have as yet given no indications of their presence.

A portion of this atmosphere forms what is known as the chromosphere, and for the examination of this solar appendage the spectroscopy has proved eminently useful. Except during the last two or three decades, the chromosphere could only be observed at the time of a complete solar eclipse, when the direct light of the sun being obscured by the moon, all round the dark disc were to be observed glowing red prominences, presenting the appearance of an enveloping discontinuous ring of flames. By using a spectroscopy the moon's help is dispensed with, and it is found possible to examine the chromosphere and solar prominences at any time during which the sun is visible. The spectroscopy shows them to be composed of glowing gases, chief among which are hydrogen and magnesium.

When the sun's light is allowed to fall upon the slit of the spectroscopy in the ordinary way, the spectrum obtained is that of the sun taken as a whole, for it is evident that any part of the slit is illuminated by light from every portion of the sun's disc; for the examination of a portion of the sun's surface, the chromosphere, for instance, or sun-spot, a different procedure is needed. By means of a telescope an image of the sun is obtained and projected upon the spectroscopy; any portion of this image may then be brought into coincidence with the slit, and the light from that portion alone will enter the instrument and so yield its spectrum. It is by a modification of this method that the chromosphere is examined and is shown to extend completely round the sun, forming a kind of atmosphere of vapours, principally metallic, the denser of which are situated close to the sun's surface, while some of the lighter constituents, such as hydrogen, extend outwards to an enormous distance, and this atmosphere is found to be in a state of intense activity, uprushes of vapour from the sun's interior to a height of hundreds of thousands of miles being of frequent occurrence.

By means of the spectroscopy our knowledge of the frequently observed phenomena of sun-spots has been considerably extended, and their vortex-like character established. They are probably caused by the partial condensation of huge masses of vapour in the sun's atmosphere, which are drawn downwards under the influence of gravitation.

The light we receive from the planets and stars may likewise be subjected to analysis, and from the former of these bodies conclusive proof may be obtained—if any such were needed—that they shine merely by reflection of the sun's light. The fixed stars, on the other hand, although giving spectra similar in general character to that of the sun, yet show marked distinctions.

Those dim patches of light which may be observed in various parts of the heavens, and which are known as nebulae, yield spectra of a different order from those of the sun and stars. Instead of bright spectra crossed by dark lines, due to absorption, the spectra obtained from them consist of bright lines upon a dark background, conclusively proving that these nebulae, which are inconceivably great in extent and of almost infinite variety of form, are composed of masses of heated vapour, thus bearing out the nebular hypothesis, which assumes that they are primary aggregations of matter destined in future ages to become suns. Following this hypothesis, the stars spectroscopically considered may be separated into four great classes.

Of the first of these, Sirius may be taken as an example. The spectrum obtained from this star, which you will recognise as the brightest in the heavens, is much simpler than that of the sun. It consists of a bright background crossed by only six dark lines, and this characteristic of a small number only of absorption lines is shared by other very bright stars, which we have independent evidence for believing to be in a younger and hotter state than our sun. The lines distinguished in Sirius are those of hydrogen with faint indications of magnesium and sodium.

Of stars belonging to the second class our sun may be taken as a type; there is probably no need to remind you that the sun is actually a star, and only appears so much larger and brighter to us on account of his comparative proximity. Stars belonging to this division, and which we may reasonably consider to be passing through the same stage of existence as our sun, resembling him to a certain extent as regards temperature and physical constitution, yield spectra crossed by a great number of dark lines, while the hydrogen lines are less prominent, showing that their atmospheres are much more complex than those in the former division.

In the third class of stars, these dark lines are still further increased by elements of higher atomic weight, such as bismuth, tellurium, antimony, and mercury, and in the fourth division a still further darkening of the spectrum is observed by the change from dark lines to wide bands. The stars in this last class are probably much cooler than our sun, and some of them are possibly on the verge of extinction as far as their light emitting properties are concerned. This great variation in the spectra of the stars is, according to Lockyer, not necessarily to be regarded as proof of distinctly different chemical constitutions, but is indicative rather of different physical conditions, temperature and pressure being the chief determining causes. A totally different kind of information which the spectroscope affords to astronomers is in measuring the velocities at which the so-called fixed stars are moving. In examining the spectrum of a star it is sometimes found that the dark lines are shifted to a minute degree either to right or left of their positions in the spectrum of the sun, and the cause of this phenomenon lies in the fact that the star is either approaching or receding from us at a velocity which will bear comparison with the velocity of light. If we stand at the side of a railroad, and a train approaches at a high rate of speed while blowing a whistle, the note heard will be higher in pitch than it would be were the train at rest; because the number of sound waves impinging upon the ear each second is greater in the one case than in the other. Similarly, if a body emitting light of one particular wave-length, light, for instance, yielding one of the sodium lines, be rapidly approaching us, the number of waves falling upon the prism in each second will be greater than if the source of light were at rest, and consequently will be differently refracted by the prism, and the bright line will occupy a different position upon the scale of the spectrum.

The same reasoning will hold good in the case of the dark lines due to absorption, and by this means the motions of a great number of stars on the line of sight, that is, towards or away from us, has been determined.

By astronomical methods it is impossible even to recognise these movements, only those taking place in a transverse direction evidencing themselves to the eye of the telescope, while by a combination of the telescopic and spectroscopic observations, the true motions of the stars may be obtained. These, in some cases, are found to be exceedingly great, some speeding through space with velocities upwards of a hundred miles per second.

In some cases, too, double stars have been discovered by means of the spectroscope. Although the telescope has failed to divide them, yet the spectroscope is enabled to do so, a double series of dark lines appearing in the spectrum, one due to one star whose motion is towards us, and the other to the companion star which is moving in the opposite direction, by this means even the period during which the one star revolves round the other may be determined.

The grouping of stars into systems, which can only with probability be accomplished by the telescope, is often rendered certain by spectroscopic examination, either on account of their yielding similar spectra, or on account of their movements being shown to be similar. As a case in point, the stars in the great nebula in Orion all show similar spectra and are evidently closely connected with each other and with the nebula.

Apart from the astronomical side of the question, although the spectroscope is a most useful instrument in a thoroughly equipped chemical laboratory, yet spectroscopy as a means of chemical analysis has not undergone the vast development which it has in astronomical work. Still, from the extreme delicacy of the work it is capable of doing it is in some departments of chemistry most useful. As an illustration of this delicacy I may mention that it has been calculated by Kirchoff and Bunsen that the eighteen-millionth part of a grain of sodium can be distinguished by the spectroscope, and this with entire independence as regards admixture of other ingredients. In fact the occurrence of sodium as an adventitious integer is so general that it is a difficult matter to obtain a spectrum in which no trace of sodium may be observed. Lithium also, which before the time of the spectroscope was known only as an ingredient of four minerals, is now found almost everywhere. Of other metals, we owe caesium, indium, rubidium, and thallium to the discovery of the spectroscope.

The instrument is occasionally found to be of practical utility in manufacturing processes, and as an example may be quoted the production of Bessemer steel. In this process everything depends upon turning out the mass of metal when a certain chemical composition has been reached, and a mistake of a few seconds might result in the whole batch being spoiled. The vapour given off by the heated mass is watched by means of the spectroscope, and directly certain lines in the spectrum due to carbon disappear it is known that the correct moment has arrived, and the mass of metal is run off.

When light yielding a continuous spectrum is passed through smoked glass or neutral tinted glass, a general absorption ensues, causing a decrease of brilliancy along the whole of the spectrum. If it be passed instead through coloured glass, a selective absorption ensues, that is to say, certain portions of the spectrum retain their brilliance while other parts are darkened. Various liquids yield a like result, absorbing each certain definite portions of the light, and so yielding certain definite and distinctive spectra.

Solution of magenta, of iodine, of permanganate of potash, and in fact nearly all coloured solutions, may be distinguished by their absorption spectra. Blood yields a quite distinctive spectrum, and it has been stated that a blood stain containing but one thousandth part of a grain may be thus detected.

A chemical salt is found to have a definite spectrum when observed at a comparatively low temperature, and if the temperature be gradually raised, a variation in this spectrum is observed, until at length the spectrum is that of the elements concerned, showing that the increase of temperature has resulted in the breaking-up of the chemical compound into its elements.

Increase of temperature on a higher scale when examining certain of the elements leads to a similar alteration and simplification of the spectrum; and reasoning from analogy, Lockyer has advanced the hypothesis that at the higher temperatures of the electric arc and spark, and especially in the spectra of the sun and stars, where the temperature is far beyond any that we can utilise in our laboratories, there exists a certain dissociation of the so-called elements, and that what we know as the elements consist of molecular combinations of similar or dissimilar more elementary bodies, and that continued increase of temperature leads to continued dissociations into simpler forms.

It is at least possible that important discoveries with regard to the ultimate constitution of matter may be made with this instrument; at any rate the history of spectroscopy up to the present day is such as to amply justify our looking forward hopefully to its future; and no new sphere of its usefulness could be specifically greater than those in which it is already established.

A hearty vote of thanks was conveyed to Mr. Smith and proceedings terminated.

Nottingham and Notts Chemists' Association, April 22.—Mr. C. A. Bolton in the chair.—This meeting was held to hear the report from the secretary of the Proprietary Articles Trade Association, and if necessary, to take steps to support the movement by local organisation. Mr. Bolton was supported by Councillor Fitzhugh, President of the Association, and there were also present: Messrs. Gascoyne, Spencer, Parker, Sergeant, Lumby, Ashby, Widdowson, Wilford, Lane, Gill, Aberlin, Rayson, Middleton, Holgate. Delegates from the new association were Messrs. Glyn-Jones, Corbett, and Jones, Birmingham.

The Chairman said that the meeting was one of the greatest importance, and there was no chemist in Nottingham but what had thought very earnestly for some time past on the subject. No doubt every chemist had felt that the difficulty of cutting was one of grave consideration to all members of the trade. Hitherto they had looked at the question from an independent point of view. The scheme of the Proprietary Articles Trade Association seemed a practical solution of the cutting difficulty, and he could not help feeling that Mr. Glyn-Jones looked at the matter with a view of benefiting brother chemists. They were not asked to look at the question from a childish point of view, but as business men.

Mr. Glyn-Jones then spoke, and explained the history of the movement, and declared that the difficulty of cutting could be solved on a firm business foundation. The three sections of the trade had everything to gain by co-operation. Mr. W. Jones said it was to the interest of chemists to support an association which was *bonâ fide*. Mr. Norris, Condal Water Company, and Mr. Corbett Halls, cocoa wines, also spoke.

Mr. Eberlin, Secretary of the Nottingham Chemists' Association, at this point announced the receipt of letters from a number of chemists, without exception all expressing themselves strongly in favour of the objects of association. Mr. Bell Stapleford next spoke. He said the movement was a good movement, and he should be most happy to forward it. Mr. Widdowson would be very pleased to join if he was not hampered in competing with neighbours. Mr. Gascoyne expressed entire approval of the objects of association, and said he was in favour of full-faced price.

Mr. Middleton moved "That this meeting of chemists residing in Nottingham and district pledges itself to support the Proprietary Articles Trade Association, and calls upon the Council of the Nottingham and Notts Chemists' Association to act in conjunction with the London organisation." Mr. Sergeant seconded, remarking that three halfpence was the proper distinction between book and cash purchases, and thought the shilling limit would be best. Messrs. R. Widdowson, Gill, Warriner, and Beverley took part in the discussion. Mr. Lumby asked if it was likely that patent medicine proprietors would fall in with the scheme. Mr. Beverley considered that they should not stipulate prices, but leave them to the manufacturers.

Mr. Jones having replied to questions, the resolution was carried unanimously. Mr. Gill then proposed the following resolution:—"That this meeting of Nottingham and district chemists desires to point out to manufacturers who have not joined the Proprietary Articles Trade Association the importance of their assisting the movement in the interests of themselves and of the distributors of their articles. We also state that they decline to exhibit show-cards, distribute handbills, or in any way encourage the sale of articles upon which adequate profit is not guaranteed to us." Mr. Wilford seconded the resolution, which was supported by Mr. Gascoyne, and carried unanimously. Twenty members joined the Association at the close of the meeting, and votes of thanks were accorded to the deputation and to the Chairman.

British Pharmaceutical Conference (Meeting of Executive), April 22.—Mr. Wm. Martindale, President, in the chair.—The other members of Executive present were Mr. Moss (Treasurer), Messrs. Bird, Farr, and Holmes, Messrs. Naylor and Ransom (Hon. Gen. Secretaries), and Mr. Nightingale (Assistant Secretary). It was announced that letters had been received from Messrs. Atkins, Martin, Ewing, Conroy, Coull, Wells, and Smith, regretting their inability to be present. The minutes of the previous meeting were read and confirmed.

The senior Honorary Secretary was requested to communicate with each member of the Executive, asking for suggestions relative

to additions or alterations in the Blue List, and having adopted such as might seem desirable, to issue the list to members.

Mr. Naylor reported that since the last meeting of the Executive the Publication Committee had met, and had considered by what means the cost of the production of the Year-Book might be reduced. Tenders for printing had been submitted by London firms and a provincial house, and that of Messrs. Butler and Tanner had been accepted. Certain alterations, mainly editorial and sectional, connected with future issues of the annual volume had been discussed and agreed upon.

The secretaries reported that in accordance with instructions given at the last meeting of the Executive, they had conferred with the local committee as to the date of the Liverpool meeting. It had been decided that business should commence on Tuesday, July 28, the reception being held the previous evening.

Some discussion ensued as to the best methods to be adopted for increasing the membership, and the hope was expressed that considerable additions would be obtained from the populous district in which the meeting is to be held this year. Thirteen gentlemen having been duly nominated were elected to membership.

Liverpool Chemists' Association, April 23.—Mr. Conroy, President, in the chair.—The Secretary, Mr. Wardleworth, said that he had not written to the Inland Revenue authorities concerning the point raised at the last meeting by Mr. Ellam's letter relating to the liability to stamp duty of pure drugs vended entire as proprietary articles. His reason for this was that an authoritative opinion on the subject could be found on page 104 of Alpe's 'Medicine Stamp Duty.'

A fine specimen of bdellium was shown by Mr. Wardleworth, and also some canaigre bark from the root of the *Rumex hymenosepalum* (Linnaeus) grown in Mexico and the Southern States as a source of tannin. A packet of snuff done up in plaited palm-leaf found in a bale of Egyptian senna was also exhibited by Mr. Wardleworth.

A Röntgen photo of a bullet embedded in the hand of a patient of Dr. Robert Jones was passed round by Mr. P. H. Marsden, pharmacist to the Royal Infirmary, who mentioned that a patient in the wards of that institution had been examined by means of the Röntgen rays to see if a Murphy's button used in an intestinal operation was still *in situ*. The result was satisfactory in the extreme, the button being clearly visible.

Mr. H. Wyatt, Junr., said he had been lately asked by a photographer for a solution of Schlippe's salt, 10 grains to the pint, to be used to restore printing density of negatives which had faded after mercurial intensification. Such a salt was not mentioned in Watts' 'Dictionary,' nor in Meldola's 'Chemistry of Photography'; in fact, in none of the usual sources of information. An order was therefore sent to a retail dealer in photographic materials, from whom a packet of this Schlippe's salt was received, labelled: "Sulphate of Soda." That the contents were anything but the latter could be seen at a glance, for they smelt strongly of H₂S, and were covered with a red-brown efflorescence. An examination proved that the substance was sodium sulphantimonate. References were then discovered in 'L'Officine de Dorvault,' p. 921, 1893 edition, where it is mentioned as Sel de Schlippe or Kermès des Allemands, and in Remson's 'Text-Book of Inorganic Chemistry,' p. 346, 1889. It is a salt with the formula Na₃SbS₄·9H₂O, made by dissolving Sb₂S₅ in NaHS. By the action of acids or exposure to the air it gives off H₂S, and deposits Sb₂S₅, or the golden sulphide of antimony. When a negative is intensified with a solution of mercuric chloride, a deposit of mercurous chloride is left on the portions of the film containing the reduced silver; washing with ammonia removes traces of silver chloride, and converts this mercurous salt into a compound mercurous ammonium. This gradually loses its intense black colour, so that the Schlippe's salt very likely remedies this by converting the mercurous salt to sulphide. The difficulty of finding any mention of the body as Schlippe's salt was the reason for bringing it before the meeting for the members' information.

Mr. Cowley had been asked to prepare some a while ago, but not as Schlippe's salt—sulphantimonate of sodium was what was demanded. There was considerable care necessary in its crystallisation as it very quickly became coloured on concentrating its solutions.

The President then read papers on "Cream of Tartar," and "Extract of Malt" (see page 346).

In the discussion following the paper on cream of tartar, Mr. Wardleworth said that it was an undoubted and much to be

deplored fact that cream of tartar was very seriously adulterated, but in his opinion the standard demanded by Mr. Conroy of 96 per cent. could easily be obtained for medicinal use, at, however, a proportionate rise in price.

Mr. Wokes was somewhat surprised to hear that a 96 per cent. cream of tartar could be obtained commercially, for, if his memory served him, a short time since it was said to be impossible to get even the B.P. standard, low as it was.

Mr. Conroy replied, and, in answer to a member's suggestion that tartaric acid might be present, stated that he had never yet found it in any sample he had examined, nor had he noticed very low grades of cream of tartar in crystals, it was invariably the powder that was not up to the mark.

After the paper on malt extract there was a lively discussion in which Messrs. J. Smith, Wardleworth, and Marsden joined, a vote of thanks being afterwards accorded to the President for his two practical papers.

Pharmaceutical Chemists' and Apothecaries' Assistants' Association of Ireland, April 24.—Mr. T. J. Walsh, L.P.S.I., in the chair.—The programme for the evening consisted of short discussions on pharmaceutical questions of every-day interest, of which the following formed the greater part: (1) The best methods of dispensing curious prescriptions (submitted by different members); (2) the most approved system of pearl-coating pills; (3) in spreading plasters what is the objection to the use of a water bath for melting the plaster? (4) what is the best way of dispensing resinous tinctures in mixtures, as per examples given? The questions were debated at some length, amongst those who spoke being Messrs. O'Sullivan, Hunt, Payne, Ewing, Hardy, Hegarty, etc. Mr. O'Sullivan's remarks in favour of the use of mucilage of acacia were well received. He acknowledged his indebtedness for the information to the late Dr. Digges, of Messrs. Hamilton and Long's state pharmacy, whose plan in dispensing a resinous tincture ordered in the prescription was to fill the bottle with water, pour off a drachm of the liquid, dry the neck of the bottle, then drop in the tincture, and shake thoroughly. Mr. Payne, thought a very nice way was to rub up the tincture and then add syrup. Mr. Hardy deprecated the addition to a prescription of any substance not ordered by the physician, but generally speaking, he was in favour of the use of mucilage on account of its binding qualities. Mr. Hunt concurred, but feared the after effect of mucilage was to clog the bottles. Mr. Hegarty spoke on the dispensing of croton chloral. He found the use of hot water very beneficial, as it gave the best results. The solution in cold spirit was slow and apt to precipitate the compound. He had tried both methods of dispensing. Mr. Payne spoke at some length on the best method of pearl coating pills. His plan was to varnish the pill and roll it in French chalk, after which the chalk would be blown away and the pill rubbed with waxed paper. This operation was invariably found successful and in some cases the pills were indistinguishable from those made by Barren, Harveys and Co. Mr. Harvey thought the use of varnish was unwise in pill making on account of its insolubility in the stomach. He favoured coating with pulverised white sugar and a thin solution of gum. He admitted that varnish filled up the pores in the pill and made the powder uniform, but the same result could be secured by the use of gum, which had the advantage over varnish on the score of solubility. Mr. O'Sullivan thought the use of varnish in pill making was unavoidable, but it need not be applied so strong that the gastric juices would not dissolve it. If the doctor wanted the therapeutic action of the medicine to be experienced at once by the patient he need not order the pills to be coated. If the varnish be of the proper consistency, an interval of from fifteen to thirty minutes after taking them would suffice to peel off the outer coating. Mr. Hunt favourably criticised Mr. Payne's description of pill making; the action of chamois leather as a polisher of sugar and chalk-coated pills was uniformly successful. Generally speaking, pearl-coated pills were not an unmixed blessing. Occasionally it took as long a time as forty-eight hours before they obtained the desired result. Mr. Hegarty was in favour of gelatin-coated pills. Mr. Payne, speaking on plaster spreading, thought the ordinary mode of preparing plasters was the best way, there was less to clean up afterwards. Mr. O'Sullivan deprecated the conservatism of pharmacy in forbidding any deviation from the beaten track: the etiquette of pharmacy restricted the boundary of progress, and it was considered unprofessional to go outside that limit. If he had to make a plaster a yard and a half long he would certainly use the warm bath. He

referred to the test of plaster spreading given at the examinations of the Society, and said, like Euclid, there was no royal road to plaster spreading.

Subsequently a short business meeting was held, at which the report of the visiting committee was read. Mr. Ewing was co-opted a member of the Committee. Some financial business having been transacted, and the holding of a social reunion discussed, the proceedings terminated.

LEGAL REPORTS.

PROCEEDINGS UNDER THE COMPANIES ACT.

PROSECUTION OF BOOTS' PURE DRUG COMPANY AT BRISTOL.

At the Bristol Police Court on Friday, April 24, before Messrs. J. C. Godwin and W. Lane, a case of interest was heard in which the complainants were the Pharmaceutical Society of Great Britain, and the defendants were Boots' Pure Drug Company, of 16, Island Street, Nottingham, who have a branch at Queen's Road, Clifton.

Mr. R. E. Vaughan Williams (instructed by Messrs. Flux, Thompson, and Flux) appeared for the Pharmaceutical Society, and Mr. H. J. Stanger, Q.C. (instructed by Messrs. Wells, and Hind) represented the defendant company.

The information was laid by Thomas William Stroud, of Walthamstow, in the county of Essex, on behalf of the Pharmaceutical Society of Great Britain, for that the defendant company on April 16, 1896, at No. 13, Queen's Road, Clifton, in the city and county of Bristol, unlawfully did not paint or affix, and keep painted or affixed, the name of the said company on the outside of the office and place there in which the business of the company was then carried on, in a conspicuous position in letters easily legible.

Mr. Vaughan Williams, in opening the case, explained that it was a summons taken out under the Companies Act of 1862, Sections 41 and 42, against Boots' Pure Drug Co., Limited, and it was for not lawfully affixing the name of the said company to the premises in which they carried on business. He might say that these proceedings were taken in the interest of the public by the Pharmaceutical Society. It was considered desirable that since limited companies were allowed to sell drugs and poisons, every precaution should be taken to make them comply with the Companies Act, so that those persons who dealt with them might know that they were dealing with a limited company. While chemists and druggists individually were required to pass a very stringent examination, so that in the case of anything going wrong it was very easily detected and investigated, a limited company could not pass an examination. More than that, it was very difficult to ascertain in a big business of that sort whether the individual at the head of it had passed his examination, and whether the men who served behind the counter were qualified chemists. Therefore in a great business having many branches it was difficult to bring anything home to any individual. Under these circumstances he thought he should succeed in the summons if he proved that that company was a duly registered company, that it had carried on business at 13, Queen's Road, Clifton, and if he proved that on the outside of the premises the name of the company did not appear.

Mr. Stanger said his friend had said he was going to prove the three matters mentioned in the summons. He admitted these three things, but the explanation was a very simple one, which he would be able to make when his turn came.

Mr. Vaughan Williams said under those circumstances he should put the case very simply. He was much obliged to his friend, as it enabled him to make the matter very much shorter and save the time of the Court. Their Worships would see by the photograph he produced that there was no trace on the outside of the premises that they were occupied by a limited company. There was not even what was sometimes found, an "L" with a small "td.," and even if there were so, he did not think that it would be complying with the Statute, which required the word to be put in full. At any rate, that was how it was spelt in the Statute. Moreover, in that case they did not have the name of the company. There they had only the name Boots, whereas the name of the company was Boots' Pure Drug Company, and any ordinary person going into that shop to make a purchase would fail to know that he was dealing with a limited company. Their worships would see that the forty-first section imposed a penalty of £5 for every day during which the name was not put up. There was no doubt

that the name had been absent from the time the business was started about three months ago. It was, however, thought sufficient to claim a penalty for one day only, as there was no desire on the part of the Pharmaceutical Society to appear to act with vindictiveness against the company. He asked their worships to look at the extreme desirability of the public being protected in those matters, and to inflict the penalty he had named.

Mr. Stanger said it would save much time by his admitting that on the 16th April the name was not put up. He would dispense with proof of that, as the managing director, who was there, admitted it through him (the speaker).

Mr. Vaughan Williams said if his friend pleaded guilty he had only to prove the facts.

Mr. Thomas William Stroud said on April 15, he was in Bristol and about six o'clock in the evening he went to the premises, 13, Queen's Road, Clifton. He saw a shop there with the name "Boots, Cash Chemists," put up. A chemist's business was being carried on there, and perfumery, brushes, and various other things were offered for sale. He did not see on the outside of the shop "Boots' Pure Drug Company, Limited," or the abbreviation "Ltd." He saw over the shop the words "Boots, Largest Chemists in the World." Upon three other places there were the words "Boots, Cash Chemists," and on each plate of the door there was the same. On the pavement in connection with the shop appeared the word "Boots" simply. That was in the doorway. There was no word "Limited," or the name of the company. He went into the shop and made some purchases, and received the receipt produced, on which he saw the name "Boots' Pure Drug Company" for the first time. Except from that he had no other indication as to who carried on the business. The labels used in the business did not bear the name of the company or the word "limited." He again visited the shop on April 16. The name was in the same state as on the previous evening. He looked at the shop three times and made some purchases in the shop. Amongst other things he bought some soap liniment and laudanum. The bottles in which they were supplied he produced.

Mr. Stanger said the offence was not for omitting to put the name on the bottles, but for not setting up the name outside. As soon as the information came to the head office in Nottingham the name was put up.

Witness said he was at the shop on the previous evening, and the name of the company was not there.

Mr. Stanger replied that he had been there and seen the name.

This was the case for the complainants.

Mr. Stanger said it was only fitting that he should make an explanation. It was a very simple one, and he thought the magistrates would be of opinion that it was a most trivial case, and need not have been taken there. The company was well known, and had a branch at Clifton. The firm was known as "Boots' Pure Drug Company," though it was chiefly known as "Boots." As to that branch, it was opened on February 6, and there was no object to be gained by the company in concealing that it was a company. The facts of the case were that on February 8 the man who was sent down to fit up the shop sent to the Nottingham headquarters asking for a glass tablet for the door, and on February 10 the order was given for the plate which was to be put up. The plate which had been used before for the fitting up of shops was of an inferior character, and though there were some of these plates in stock it was desired to put on the shop in question one that would correspond to the fittings, and an order was given for plates of glass with bevelled edges. Either of these plates would have complied with the Act of Parliament; though the order was given on February 10 the plates were not supplied immediately as they were out of stock. The simple explanation of the whole matter was that the order was not completed for the opening of the shop, and, therefore, there had been a technical breach of the law. His friend had said that it was important that every person purchasing anything at the shop should know it belonged to a company. He should be able to prove by his friend's own evidence that everyone making purchases there had a paper given him, on which was printed "Boots' Pure Drug Co., all complaints to be made to the managing director." It was only through inadvertence that the name was not put up. The plate was there in the court, ready to be put up, and there was a substitute placed on the premises at the present time which fully complied with the Act. He was anxious to lay stress upon the fact that it was only through inadvertence that the offence had been committed, so that the Court might look more lightly upon the case, the more especially when it was seen that no mischief was likely to take place. His friend had said it was

desirable that the names of limited companies should be known, because it was necessary to pass examinations, and it was not known if the persons behind the counter had passed those examinations. He was happy to be able to relieve the feelings of the Pharmaceutical Society upon that matter, for all the branches of the company were under the care of properly qualified pharmaceutical chemists. There was no desire on the part of the company to hide the fact that it was a limited company. No harm had been done and no one had been injured. There had been what he said under the circumstances was a technical breach of the law, and he asked their worships to consider it as a very trivial matter indeed. He had only this further observation to make. It was this: the magistrates were asked by his learned friend to inflict a penalty of £5 for the one day, but he, on behalf of the company, asked the Bench to take the view that it was an extremely trifling matter. He did think that if the Pharmaceutical Society was so anxious to protect the public, the attention of the company should have been directed to the matter. Instead of that, a summons was issued, and that was the first intimation the company had. There had been no contumacious breaking of the law, and, on the other hand, as he hoped he had made clear, no mischief could have been caused.

Mr. Frederick James Mead was called, and said he was a pharmaceutical chemist, and manager of Boots' Pure Drug Co., in Queen's Road, Clifton. He was assisted by Mr. Pitt, who was a qualified chemist and druggist. It was his practice to give invoices, similar to that given to Mr. Stroud, to all purchasers, and the name of "Boots' Pure Drug Co." appeared on the invoices.

Mr. Jesse Boot said he was the managing director of Boots' Pure Drug Company, and also of a company called Boots', Limited. There was a distinct registration in the case of each, and they were different companies—one company in the Midland and the other in the Western district. There were branches of the Pure Drug Company at Clifton, Bath, and other towns. There was no desire on his part to conceal the fact that it was a company which owned the shop; it was understood that in every case where a shop should be opened by the company a plate should be put up. Whenever anyone made a purchase he was given a receipt, upon which was the name of the company in full.

Cross-examined by Mr. Vaughan Williams: There were two companies, the one being Boots' Pure Drug Company and the other Boots', Limited. He was managing director of both. He admitted that on the photograph produced the name of the company did not appear. He gave the order for the plate for the shop in question. The company ordered the plate from one of its own departments. There was a shop fittings' department, which was a private one of his own.

The accounts of the fittings' department were kept in his own name. That was an entirely different concern. He did not make any personal profit out of the shop fittings, but it was done for the benefit of the company.

Mr. Albert Edward Smith, manager of the shop fitting department, said he had charge of the fitting up of the branch at Clifton, and on February 8 a letter was received asking for a glass tablet for the door. He had no glass tablets in stock such as in his judgment should be put up, and he gave an order for some on February 10, which, however, was not completed before the day previous to that on which the summons was received. He was on the point of sending it off when the summons came.

Mr. Stanger asked the magistrates if they did not see their way to dismiss the summons, to inflict the smallest fine in their power.

After a short consultation, the Chairman, Mr. J. C. Godwin, said the case had been very carefully argued on both sides. It was admitted that there had been a technical offence, and as they were there to administer the law and see it was not broken they would fine the defendant 20s. and costs.

PUBLICATIONS RECEIVED.

KING'S COLLEGE HOSPITAL REPORTS, 1894-95. Pp. 376. (London: Adlard and Son, Bartholomew Close, E.C. 1896.) From the Publishers.

FOODS: THEIR COMPOSITION AND ANALYSIS. By ALEX. W. BLYTH, M.R.C.S., F.I.C., etc. Fourth Edition, revised and enlarged. Pp. 735. (London: Charles Griffin and Company, Limited, Exeter Street, Strand. 1896.) From the Publishers.

CORRESPONDENCE.

SYRUP OF CAMPHOR.

Sir,—In answer to query on page 340 of this week's *Pharmaceutical Journal*, I shall be very pleased to forward him the correct formula for the B.R.I. Syr. Camphoræ Co. if he will communicate with me. The majority of chemists in and around Bristol prepare a Syr. Camph. Co. according to a formula in the *Infirmiry Pharmacopœia* which has long been obsolete.

Bristol Royal Infirmary, F. J. KILNER, Head Dispenser.
April 25, 1896.

C. J. M., in answer to our correspondent (*ante*, p. 340), gives the following as the formula for compound syrup of camphor:—

℞ Syr. Opii ʒj.
Tr. Camph. Co. ʒii.
Oxy. Scillæ ʒvi.

Misce.

The syrup of opium is prepared as follows:—

℞ Gum Opii ʒii. { Macerate 12 hrs.
Aq. Oiss. {
Brown Sugar, 7 lbs. in Aq. Oii.
Misce sec. art., and make up to 6 pts.

D. KINGAN says his formula for syr. camphor co. (*Bristol Infirmary*) is as follows:—

℞ Syr. Opii ʒi.
Tinct. Camph. Co. ʒij.
Oxymel Scillæ ʒvj.

and for the syrup of opium—

℞ Gum Opii gr. viij.
Sacch. alb. ʒviiss.
Aquæ ʒviij.

* * * As the differences in the two sets of formulæ are important, perhaps Mr. Kilner will kindly settle the matter authoritatively. [*Ed. Pharm. Journ.*]

RE THE APPROACHING COUNCIL ELECTION.

Sir,—I hope the gentleman who intends to discontinue his subscription to the Society (*vide* page 339) will reconsider that decision, forward the usual amount, and exercise his vote and influence to make the Council more representative of the trade. I also have a grievance, that my last communication to the Journal, about the anti-cutting scheme, was severely cut down before insertion, but possibly you were justified in so doing. However, it is my intention, on receipt of the voting paper for the Council, to erase the names of all who are not openly pledged to support the same. If 1500 voters who never return their papers will do likewise all the newer aspirants for the Council will be elected. It will be with regret that I shall erase names of some gentlemen for whom I have voted for, possibly, the last eleven years, but a more vigorous trade policy must, in my opinion, be inaugurated.

Northampton, April 27, 1896.

J. CLOWER.

As a fitting supplement to the above letter, the following passage is quoted from a letter received by the Secretary of the Pharmaceutical Society this week:—"With pride and pleasure I enclose you postal order for one guinea, my first full subscription, as an Associate, to the Pharmaceutical Society. I would like very much to support the wheels (like your correspondent), but consider supporting the Society I have worked so hard to become connected with will pay me better."

* * * The correspondent referred to is evidently the one whose letter was quoted last week (p. 339). Thus do opinions differ. [*Ed. Pharm. Journ.*]

THE TESTING OF LEMON OIL.

Sir,—The determination of the aldehyde citral by reduction to its corresponding alcohol geraniol, acetylation and saponification, put forward by Mr. Garnett in his paper under the above title—as well as the estimation of citronellal by the same means—has formed the subject of experiments for some time past with me. There are, however, several points in connection with the simple process suggested in his paper that make its application open to doubt. No check experiment is first made by Mr. Garnett to ensure the absence or determine the amount of alkali-fixing bodies in the lemon oil, such as one makes in peppermint oil in the process for the estimation of menthone. I have found, however, as a result of

many experiments, that after acetylation without reduction of lemon oil, and most thorough washing, as much alkali-fixing power indicated as would be equal to 6 or 7 per cent. of citral in the original oil. The body that effects this absorption may be an alcohol or an acid formed by the reaction between the aldehyde citral and acetic anhydride (Perkin's synthesis). Whether the percentages of citral obtained by Mr. Garnett, and calculated by him from the saponification equivalent of the ester of the alcohol, geraniol, formed by reduction, are in reality such or the equivalents of other alkali-fixing bodies formed by the action of acetic anhydride on the aldehyde, needs proof. If it could be shown that quantitative formation of an acid by the reaction between citral and acetic anhydride occurred, this method might be available for the determination of citral. I have placed the results of my experiments, both with lemon and citronella oil at the disposal of Mr. Garnett to clear up the difficulties that appear to be indicated by them. Whether the determination of citral as a means of ascertaining the value of lemon oil has the significance that has recently been attached to it, is very doubtful. The high percentage of citral in some lemon oils, the other characters of which show unmistakable sophistication, and the advance in price of lemon grass oil (it yields about 60 per cent. of citral!) are suspicious circumstances.

London, April 29, 1896.

JOHN C. UMNEY.

SHOPS (EARLY CLOSING) BILL.

Sir,—I am an old-fashioned Conservative and do not much approve of interference with the liberty of the subject, but the question seems to be whether a man should be obliged to keep his shop open half the night or submit to legislation until common sense is driven into our heads all round. I consider my hours of business to be from 8 a.m. until 7 p.m. I have two customers from outside who have occasion to send into the town soon after 7 p.m. They expect me to be up and wait upon them and if they happen to meet me with my carriage and pair (of wheels) to turn back and spoil an early spin. Then neighbouring brother chips keep open, one until 10 p.m. the other very often until 11.30 p.m. Of course I do not imitate them; at the same time they give the public the idea that chemists keep open very late and my customers come pretty regularly until 9 o'clock, and I contend that there is no necessity for it and that the only way to stop it is the closing. Therefore my vote is for the early closing Bill.

April 25, 1896.

GILGEN.

UNQUALIFIED DISPENSERS.

Sir,—The leading article in your issue of the 28th ult., on the subject of "Poor Law Dispensers," merits more attention than has been bestowed upon it, and points out the direction in which an amendment is most urgently required in the existing Pharmacy Act. I am perfectly aware that it is needless going to the Legislature with an appeal for protection or with a cry that our craft is in danger, but if we proceed on the lines of the Act of 1868 and propose legislation for the safety of the public, we shall probably get, with a little diplomacy, all that we can reasonably look for. If it is expedient for the safety of the public that persons keeping open shop for the retailing of poisons should be qualified, surely it is far more necessary for the general safety that those who are constantly employed in dispensing potent poisons for the consumption of a very considerable portion of the public, should be so qualified. The ever-growing class of unqualified dispensers, continually flowing from the services of the Crown and seeking employment in civil life, constitutes a very real danger, both for the outside public and for the Society. Restriction is therefore loudly called for.

April 22, 1896.

ARUNDO.

RANDALL'S EMULSION.

Sir,—The information which your correspondent "Major" seeks will be found on the enclosed label for cod-liver oil emulsion with hypophosphites, supplied by this firm.

Southampton, April 27, 1896.

RANDALL AND SON.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs, Barclay, Bignon, Bindloss, Bolton, Clower, Cruickshank, Deck, Elms, Essam, Gardner, Greenhalgh, Guyer, Hay, Hill, Idris, Ince, Ingham, Kilner, Kingan, Leslie, Littlefield, Miles, Mitchell, Muir, Randall, Reade, Reynolds, Rimmington, Salmon, Skinner, Stanley, Thomas, Umney, Wall.

ANNUAL REPORT OF THE COUNCIL.

The fifty-fifth financial statement submitted with this Report shows an increase in several items of expenditure. The adverse balance on law charges is large, but not out of proportion to the work done. The duty of carrying out the provisions of the Pharmacy Act imposed on the Council can only be efficiently accomplished by considerable expenditure, which the costs allowed, even if obtainable, fail to cover. The Council has spent a considerable sum in completing the decoration of the rooms of 16, Bloomsbury Square. It has also invested in the remodelled *Pharmaceutical Journal* a considerable portion of its annual income, the financial benefit of which, it is believed, will appear in succeeding years in reducing the balance against that account. The Council has had to meet in the years 1894 and 1895 a capital expenditure in the building and equipment of the examination hall and laboratories in Edinburgh, of about £3300, of which a sum of £2243 has been provided from revenue. The income from fees was considerably less than in the preceding year owing to there being fewer candidates for examination. Variations of this kind occur from time to time, followed by increased receipts.

The number of candidates presenting themselves for the pharmaceutical technical examinations during 1895 was considerably less than in the preceding year. The total number of candidates was 1450, of which 1304 were for the qualifying examination and 146 for the Major examination. The rejections in the case of the Minor examination were 65.72 per cent.; 857 candidates (574 in London and 283 in Edinburgh) having been found to lack that "competent practical knowledge" which the Pharmacy Act, 1868, declares it essential for persons practising pharmacy to possess. This high percentage is doubtless due to the increased scope of the examination, which, to quote from the last report of the Government Visitor for England and Wales, is "a fair one, and the stringency of the practical examination in chemistry commendable." The statistics for the Major examination show that of 146 persons presenting themselves (130 in London and 16 in Edinburgh), 78 failed, or 60 per cent. There were 1430 candidates for the First examination in 1895, as against 1541 in the previous year. The rejections, which were a little over 50 per cent. a few years ago, have steadily risen to 52.65 per cent. during the past twelve months. In connection with the examinations, it may be noted that the Executive of the North British Branch has forwarded a resolution to the Council, advocating the increasing of the standard and scope of the Preliminary examination. The Resolution will receive the careful consideration which the subject demands.

Considerable progress has been made in cataloguing the rich collections of the Society. The catalogue of the medicinal plants in the herbaria of the Society is now complete. An annual report of 105 pages, including the additions to the Museum and Herbaria in London during the year 1893-4, has been issued. The catalogue of the Herbarium of British plants is now in the printer's hands, and will be published in the course of the year, having been thoroughly revised and brought into accord with modern botanical nomenclature. Duplicate specimens of drugs and medicinal plants have been distributed to various local associations, and exchanges made with other museums. Numerous and important donations have been received from correspondents, both at home and abroad. In addition to other

services rendered to pharmacists by this department of the Society, reference may be made to the large number of enquiries relating to drugs which are addressed to the Curator, and dealt with by him.

The maintenance of the Libraries in London and Edinburgh is a prominent feature in the Council's work, and during the past year many additions have been made to that department. The main growth in the Libraries is in the periodicals, of which the Society possesses many very valuable sets. Nearly all new books which are considered worthy of a place are obtained, either by purchase, or through the much appreciated generosity of the authors.

The fifty-fourth session of the School was inaugurated in October by an able address from Dr. F. T. Roberts, Professor of Medicine in University College. The distribution of prizes to successful students was rendered more than usually interesting by the attendance of Count Siegfried Clary from the Austrian Embassy to receive the Hanbury gold medal on behalf of Professor August Vogl, of Vienna, to whom it had been awarded.

The scientific meetings in London and Edinburgh have furnished a number of papers, which were in many cases productive of interesting discussions on important practical matters relating to pharmacy. In London, papers were provided by Professors Dunstan and Greenish, Messrs. Martindale, F. Browne, A. Gunn, Tickle, Carr, and J. C. Umney; in Edinburgh, by Dr. Lockhart Gillespie, Dr. W. Inglis Clark, Messrs. Dott, Boa, and Forret, whilst Dr. Gibson delivered an admirable introductory address.

At the meeting of the Council in June a resolution was adopted appointing a special committee to inquire as to how far the objects of the Research Laboratory had been attained. The Committee was also asked to report upon any suggestions that might appear desirable to adopt in the future conduct of the laboratory. The Committee after full and careful deliberation reported (a) that in its opinion "the completed work which has emanated from the laboratory is on the whole satisfactory, and reflects credit on the Society," and (b) suggested that "concurrently with such work as has already been undertaken, it is desirable that attention be devoted to the chemical and physical examination of substances used in medicine, whether official or non-official." It was further suggested that the Director of the Laboratory should attend each meeting of the Library, Museum, School, and House Committee, and that the Research Committee should report to the Council twice a year. These suggestions were adopted at the July Council meeting, and in accordance therewith an Interim Report of the Research Committee was presented early this year.

During the year 1895 upwards of 350 cases of alleged infringement of the Pharmacy Acts were reported to the Registrar, and investigated. In the majority of cases in which proceedings were taken, the penalties incurred were paid without contest, and it is satisfactory to note that in practically every instance in England and Wales where it was necessary to go into Court, judgment was given for the Society. One of these cases was that of the sale of arsenical fly-papers by a firm of oilmen, wherein it was held by the County Court Judge that they had sold "a poison" within the meaning of the Act. Leave was given to appeal, but the manufacturers ultimately accepted the decision of the County Court Judge, and have since intimated that they do not intend to issue any more fly-papers

containing arsenic. In several cases proceedings were instituted against unqualified persons for the sale of arsenical weed-killers, and in two cases penalties under Section 17 of the Act have been imposed on limited liability companies.

In the Scottish courts the principal cases were those of Turnbull and Hume, who respectively used the titles "photographic chemist" and "technical chemist," kept open shop, and sold poisons. The Sheriff-Substitute held that the words "photographic" and "technical" so qualified the title "chemist" that the use of such a description was not an offence under the Act. Upon appeal to the High Court of Justiciary, the Lord Justice Clerk, Lord Young, and Lord Trayner unanimously reversed this decision, and gave judgment for the Society.

The Society has experienced some difficulty in carrying out the provisions of the Pharmacy Acts in Scotland. In an action taken against a firm of seedsmen in Glasgow for selling an arsenical preparation unlabelled, the Sheriff held that the Registrar of the Society had no title to proceed in Scotland under Section 17 of the Pharmacy Act, 1868, and that the proper person to take action was the Procurator Fiscal for the district. All the evidence in the case was sent to that officer, who, however, declined to take any action in the matter. Proceedings were afterwards instituted by the Society against the unqualified assistant who sold the article above referred to, and although the respondent pleaded guilty, the Sheriff dismissed him with an admonition and refused the Society any expenses. In other cases in Scotland, although the evidence of infringement has been quite clear, only nominal penalties have been inflicted.

During the year the official list of applicants for patents has been carefully watched, in order to prevent any scheduled poisons from becoming the subject of a patent. In fifty-nine cases of applications in respect of medicinal preparations, the prospective patentees were communicated with, and in most instances abandoned further patent proceedings after receipt of intimation that the Society would move for revocation. The result has been that only three actions have been necessary in the Court of Chancery for the revocation of patents for medicines. None were seriously contested, and in each case the revocation asked for was granted.

The Council has been fully alive to the **Parliamentary** necessity for carefully watching the work of the Legislature during the session, and with that view sanctioned the appointment of a Standing Sub-Committee of the Law and Parliamentary Committee to act in cases where prompt action seemed expedient to preserve the interests of chemists in Great Britain. Much good work has been effected by judicious representations to Public Departments, and the Council may refer to the efforts made to secure an amendment in the law relating to limited liability companies as an indication of the determination not to permit the evils which press against pharmacy to remain unremedied for want of official protest. With the valuable co-operation of various corporate bodies representing medicine, dentistry, and veterinary surgery, the Council hopes that the Companies Bill now before Parliament may be so modified as to effect a satisfactory amendment of the law relating to limited liability companies.

The Report of the Executive of the North **North British Branch** British Branch presented to the Council at its last meeting, indicates that the work of the Examinations and of Administration have been efficiently carried out. The advantages offered by the extension of the Society's premises, and the erection of the new Chemical and Pharmacy Laboratories, have facilitated Examination work very considerably.

The Council has recently added to the roll of **Honorary and Corresponding Members.** Honorary Members the following:—Professor I. Bayley Balfour, F.R.S., Director of Royal Botanic Gardens, Edinburgh; Professor T. E. Thorpe, F.R.S., Head of the Government Laboratories, Somerset House; and Professor Tschirch, Professor of Pharmacognosy, Berne. The following have been elected Corresponding Members:—W. R. Carles, H.B.M. Consul at Corea, and Dr. Louis Planchon of the Montpellier High School of Pharmacy.

The Council has agreed to act as trustees of the **Burroughs Memorial Scholarship.** the Burroughs Memorial Fund, and with the consent of the subscribers and the approval of the Council, it is intended to endow an annual scholarship of the value of about £25 per annum in advanced pharmaceutical education.

There was a slight falling off in the annual **Benevolent Fund.** subscriptions in 1895, £1694 having been received as against £1712 in 1893, and £1702 in 1894. The amount distributed in casual grants and in the payment of annuities was £2693. The generous gift of one hundred shares from the Chemists' Aerated and Mineral Water Association, Limited, and its Chairman, Mr. H. Davenport, will produce an encouraging addition to the annual income. Mr. Wm. Hooper's legacy of £100 was received during the year, but the aggregate amount of donations and legacy falls short of that received from the same source in 1894 by nearly £400. In view of the falling revenue of the Fund, the Council hopes that local and divisional secretaries will make special efforts to bring to the notice of their fellow craftsmen—who are non-subscribers—the claims and needs of the Benevolent Fund.

Among deaths the names of the following have **Deaths.** to be recorded:—Dr. H. Cleghorn and Professor Pasteur, Honorary Members; M. A. Lawson, M.A., and Dr. R. Godeffroy, Corresponding Members; B. Cordley, Colchester; W. Gunn, Duns; J. W. Littlefield, Ventnor; and R. H. Swingburn, South Molton, local secretaries; T. Howard Hall, Divisional Secretary for East Islington; J. S. Linford, a former Examiner; and J. W. Forbes, of Bolton; H. B. Cocksedge, of Sandown; H. H. Millhouse, of London; G. Dudgeon, of Nottingham; and E. Taylor, of Rochdale, well-known members of the Society.

CHROMATIC PHOTOGRAPHY AND RADIOGRAPHY.*

BY E. J. WALL.

CHROMATIC PHOTOGRAPHY.

Chromatic photography is the reproduction of objects in the colours of Nature by the aid of photography. This can be accomplished by three distinct methods, (a) the direct, (b) the interference method, and (c) the indirect method. The first method is based upon the power of the subchloride of silver to assume certain colours when exposed under coloured objects, but no method has been discovered of fixing them, that is, of removing the unaffected subchloride without destroying the colours. The second method is based upon the interference of light by thin laminae of silver, and was discovered by M. Gabriel Lippmann in 1891. He used a very transparent and thin film of gelatino-bromide of silver in contact with a reflecting surface of mercury, which sent the incident light back on itself, and thus formed stagnant waves. This caused the deposition of the silver in strata, which, similar to the thin films of the soap bubble, reflect light of one wavelength only. The thickness of the gelatin film was at the most about 1/10th Mm., and in this thickness were no less than 500 separate laminae of silver required to reproduce violet light. The

* Report of a lecture delivered before the Society of Chemical Industry on May 4.

development and fixing were precisely the same as in ordinary photography. The third and indirect method is based upon the Young-Helmholtz theory of the three colour sensations. A negative is made through a violet screen, another through a green screen, and a third through an orange screen, and from these negatives printing blocks or surfaces are prepared, which are printed in yellow, red, and blue on top of one another, the results being more or less faithful reproductions of the original.

RADIOGRAPHY, OR THE NEW PHOTOGRAPHY.

Possibly there has been no discovery since the practical introduction of photography in 1839 which has caused so much noise as the so-called "New Photography." To some extent this is due, of course, to the fact that the possibility of seeing through and photographing through opaque objects has struck the public fancy, and, secondly, the process itself is so simple and easy that anyone who has a little capital can obtain the results.

There are two forces employed in the production of these wonderful results which possibly should be briefly explained; the first is light, the second electricity. When a beam of white light is allowed to fall upon a prism it is refracted or bent out of its course, and is at the same time dispersed or split up into its constituents, forming a ribbon of colours, called the spectrum, ranging from red through orange, yellow, green, blue, into violet. By the aid of photography we are able to prove that the visible spectrum is an extremely small part of the constituents of light; beyond the red lies a region which is called the infra-red, where really lie the majority of the heat rays, and Professor Langley, of the Smithsonian Institute, has proved by means of the bolometer, an extremely delicate calorimeter, that the infra-red spectrum extends fourteen times the total length of the visible spectrum beyond the red. Schumann, of Vienna, has proved by the aid of photography, using Iceland spar prisms and quartz lenses, and the whole apparatus being exhausted of air, that the ultra-violet or that portion lying beyond the violet extends almost as far on the other side.

Electricity may be defined as an invisible agent which may be produced by chemical action as in an ordinary Grove, Daniell, or bichromate battery, or by dynamic or mechanical work, as with the dynamo. If the two poles or elements of a battery or series of batteries be connected by a wire, the electric current, though absolutely invisible, may be made manifest by its raising the temperature of a thin wire or filament to the point of incandescence, when we obtain the ordinary incandescent lamp. If, however, we break our wire and separate the ends by a very small air-gap (for instance two-thirds of an inch), it will be found that it requires an enormous number of cells—10,000, actually—to overcome the resistance of the air. The electric force, therefore, which produces lightning must be of very high potency or potential. What is wanted for radiography is not a very great amount of electricity, but electricity of high potential to enable it to overcome the resistance offered by various media. This can be produced in two ways—by the aid of a Wimshurst machine, or, better still, the modified form known as the Bonetti-Wimshurst, or preferably by means of an induction coil, usually known as a Ruhmkorff coil. An induction coil may thus be explained:—If we take a closed coil of wire and place beside it another coil with a battery in its circuit, then pass a current of electricity through the second coil, we find a current is generated or induced in the first coil, but flowing in the opposite direction to the other. A coil of wire is used, and outside this another coil of very fine wire very carefully insulated, the former being called the primary, the latter the secondary. The primary is always constructed of stout wire, and inside there is placed a bundle of iron wires which increases the strength of the magnetic field. The primary circuit is joined to the terminals of a powerful Grove or other primary battery, and there is also included an interruptor, hammer or contact breaker, which makes and breaks the primary circuit in very rapid succession. By this means an alternating current of extremely high electro-motive force is induced in the secondary coil, which will discharge itself across an air gap, giving the well-known spark. The length of wire required for the secondary is extraordinary; for instance, for a 6-inch spark, that is a spark which will pass across a 6-inch air gap, about ten miles of wire are required. Mr. Spottiswoode has a veritable giant induction coil, the secondary of which contains no less than 280 miles of wire, wound in 340,000 turns, and with thirty Grove cells this yields a spark $42\frac{1}{2}$ inches in length.

If the terminals of the wire from an induction coil are connected with two platinum wires fused into the ends of a tube or bulb of glass, which is filled with air or some other gas and connected

with a mercury pump so that the gas may be drawn out and a vacuum formed, we shall find that the ordinary sparking will take place at first, when the current is turned on; but as the exhaustion of the air is continued, the sparks lose their definite form, and are seen rather as a glow of reddish colour, or if carried still further bluish-violet bands of light are formed.

The well-known vacuum tubes, known as Geissler tubes, have approximately a pressure in the tube of $\frac{1}{500}$ th of an atmosphere, and when the current is passed through such a tube the negative or cathode is seen to be surrounded by a bluish-violet light, whilst from the anode or positive a purplish-red light or glow proceeds, which reaches very nearly to the cathode.

Faraday was the first to study the phenomena of electric discharges through attenuated gases.* The subject was further examined by Abria in 1843, Spottiswoode, Fernet, and lastly Hittorf,† Gassiot, and Hertz. Hittorf showed that when the rarefaction of the gas was extremely great, 0.5 Mm. for hydrogen, the rays proceeding from the anode always sought the cathode, and would follow any curves, contortions, or twists of the tube, whereas the rays proceeding from the cathode proceeded in a straight line, and were, so to say, too haughty to take the slightest notice of the anodes. It was also found that substances, such as the ruby, the diamond, etc., which were not fluorescent to ordinary daylight, glowed with great brilliancy under the cathode rays.

Crookes, in his presidential address to the British Association in 1879, first put the facts known on this subject in a popular and taking form, hence his name has become so intimately associated with the tubes. He proved that not only would the cathode rays cause fluorescence in gems and other chemical substances, but that ordinary glass fluoresced very brilliantly, and that the glass struck by the cathode rays might under certain circumstances be heated so much as to be unable to withstand the external pressure of the air, and it would then give way. Further, by using a Maltese cross cut out of mica he proved the absolute rectilinearity of the propagation of these cathode rays, that is, they moved in a perfectly straight line; further, by mounting a small paddle-wheel with mica blades on a pair of rails he proved that the cathode rays could cause the paddle-wheel to revolve and traverse the rails from end to end. Crookes considered that there was a stream of gaseous molecules proceeding from the cathode at enormous speeds, and he called this "radiant matter."‡

Goldstein, a German *savant*,§ who had been studying this subject since 1871, opposed Crookes' arguments, and many other physicists joined in the dispute, ranging themselves on one or the other side. Wiedemann, Ebert, Hertz, and others took up the study of the subject with vigour, and Thompson|| considered the theory of the discharges in the tubes to be ascribed to the disassociation of the gases. But the most important researches were made by M. Ph. Lenard, of Bonn.¶ These were founded on a discovery of Hertz, that the cathode rays could penetrate thin sheets of metal,** and Lenard proved that not only did these rays penetrate metal, but they were rendered visible at a distance of 3 Cm. if tissue paper soaked in pentadekylparatolyketone was placed at this distance, and that an electroscope was discharged at a distance of 30 Cm. from the tube. He also discovered that ordinary sensitised paper was blackened by these cathode rays, and that they acted upon the ordinary dry plates, a fact which was also noticed by Goldstein, in the interior of the tube. One of the most interesting observations of Lenard was that the cathode rays could be deflected by a magnet, and that when the rays struck a body charged with electricity, no matter whether positive or negative, it was discharged.

In December 1895†† Professor Röntgen discovered quite accidentally that a piece of paper coated with platino-cyanide of barium fluoresced when near a Hittorf or Crookes' tube, although the latter was entirely surrounded by opaque card, and, further, that it was also feebly illuminated behind a ponderous German treatise of 1000 pages, a sheet of wood, and a piece of aluminium 15 Mm. thick. It was, of course, but a natural sequence of experiment to

try whether a photographic plate would be affected by these rays, which Röntgen called x -rays.

Röntgen has stated that these rays proceed from that part of the tube where the cathode rays strike, and that they must be considered distinct from the cathode rays themselves. On the other hand, there are, of course, many who consider these the same. Then, again, they have been considered to be ultra-violet rays, but it may be pointed out that whereas ebonite, wood, and glass are approximately opaque to ultra-violet light, they are transparent to the x -rays; quartz, however, which is extremely transparent to ultra-violet, is comparatively opaque to the x -rays, and, further, the rays cannot be regularly reflected, and their power of being polarised has not been definitely determined although Prince Galitzine and M. de Karnojtzky state that they have been able to discern slight traces of polarisation after the rays had passed through tourmaline. As a matter of fact the precise nature of these rays is not yet known, and speculation is useless, although it should be stated that Edison considers them to be sound waves, but his reasoning is somewhat weak at present.

The conditions necessary to produce the x -rays are extremely simple; a Bonetti-Wimshurst machine may be used, and the ordinary sparking or discharging terminals must be removed, and the tube connected by wires with the pillars at the back of the machine. The chief objection to the influence machine is the tremendous vibration which it is not possible to avoid, and further it is no easy task to keep on turning the handle for about five minutes. With an induction coil, the tube is of course held by a Wolf's holder or any convenient support, and the electrodes are connected up with the terminals of the coil.

The Ruhmkorff need not be designed for a very long spark unless of course experimental research is the object, when anything above a 6-inch spark will be an advantage, whereas for ordinary work a 3 or 4 inch, or even a 2-inch spark coil is quite enough. At present so little is known actually of the subject that we do not know whether the secret of success lies in the coil or tube, or both, although it would seem that more depends upon the tube than the coil.

There is one form of tube which so far has given excellent results, that is the so-called focus tube, which has a concave plate of aluminium for the cathode, and at the centre of curvature of this concave surface is placed at an angle of 45° a flat plate of platinum, which is the utilisation of a principle laid down by Hittorf. In this case undoubtedly the platinum plate is the source of the x -rays which proceed at right angles to the surface and strike the glass wall of the tube, proceeding thence in straight lines in the air. Another very quick-acting tube is that devised by Prof. Puluj, of Prague—in this the principle of M. Piltchikoff and Silvanus P. Thompson is utilised, which is to place in the path of the cathode rays, at an angle of 45° , a mica screen covered with a phosphorescent substance like calcium sulphide. This tube was used by Puluj for his researches on the cathode rays in 1892, but he has slightly altered the shape of the tube, making it now more bulbous and utilising a larger fluorescent screen.

The focus tube can be obtained from several dealers, but Puluj's tube can, so far, only be obtained from Dollond and Co., of Ludgate Hill. There has not been sufficient time to experimentally prove which is the more active tube, as, in consequence of a breakdown of the coil in use, resource had to be made to a Bonetti-Wimshurst machine, which did not permit of such careful comparisons.

For obtaining photographs or radiographs, or radiograms as they are sometimes called, there seems to be some doubt as to the best plates to be used, but, so far, the most successful results have been obtained with the new cathodal plate specially placed on the market by the Imperial Dry Plate Co., of Cricklewood, N.W. The plates should be placed in light-tight negative bags, such as are placed on the market by Tylar, of Birmingham. On these envelopes should be placed the object to be radiographed, and the larger the object and plate the further away must be the tube, about 5 or 6 inches is enough to cover a whole plate, or $8\frac{1}{2} \times 6\frac{1}{2}$ ins. The exposure will vary from two to five minutes, according to the nature of the object, three minutes being sufficient to obtain distinct images of the bones of the hand, whilst for the arm or foot it may vary from ten to fifteen. Far sharper results, sharper as regards outlines, may, it is said, be obtained by limiting the source of the x -rays, or rather their field, by means of a metal plate, lead for preference, pierced with a comparatively small aperture. On this point, however, more experiments are required.

(To be continued.)

PHARMACEUTICAL SOCIETY

MEETING OF THE COUNCIL.

WEDNESDAY, MAY 6, 1896.

Present:

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. JOHN HARRISON, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Corder, Cross, Gostling, Grose, Hampson, Hills, Johnston, Martin, Martindale, Savory, Southall, Storrar, Warren, and Young.

The minutes of the last meeting were read and confirmed.

DIPLOMAS.

The undermentioned, being duly registered as Pharmaceutical Chemists, were granted diplomas stamped with the seal of the Society:—

Barritt, Wesley.	Martin, John Woolcock.
Beachell, John.	Playfoot, Frederic Hubert.
Blunt, Harry Rowland.	Smedley, Walter Graham.
Bridges, Herbert.	Williams, John.
Crombie, James.	Willson, Robert Wherry.
Elwell, Frederick Budd.	Wilson, Thomas.
Howard, Alfred.	Wright, Frederick.

ELECTION OF MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Beachell, John, Boston Spa.	Leslie, Robert, Aberdeen.
Blunt, Henry Rowland, Birmingham.	Marsh, Albert, Caislehurst.
Bridges, Herbert, Norwich.	Playfoot, Frederic Hubert, Dorking.
Brown, Wm. J., St. Leonards-on-Sea.	Smedley, W. G., Kingston-on-Thames.
Elwell, Frederick Budd, Southsea.	Tully, Fred Herman, Torquay.
Jones, Charles, Royton.	Williams, John, Bagillt.
Jones, John, Bridgend.	Willson, Robert Wherry, Peterborough.

Chemists and Druggists.

The following who were in business before August 1, 1868, having tendered their subscriptions for the current year, were also elected "Members" of the Society:—

Gooch, Thomas Pratt, Leiston.	Hardman, James William, Leeds.
-------------------------------	--------------------------------

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed the respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Adams, Herbert Samuel, Forest Gate.	Nosworthy, Allan P., Tunbridge Wells.
Attenburrow, James, Melton Mowbray.	Owen, Alfred Herbert, Christchurch.
Beckwith, Christopher, Hove.	Page, William Irwin, Boston.
Beringer, Heinrich Roland, Camborne.	Palmer, Frank Elijah, Ipswich.
Brauer, Frederick H. F., Middlewich.	Payne, Hiram, Welshpool.
Burge, William George, London.	Pendlebury, James, Castleton.
Corrigall, Peter, Newcastle-on-Tyne.	Pepperdine, Harry, London.
Evans, David Llewellyn, London.	Reynolds, Albert Bright, Wallingford.
Harper, James William, Starbeck.	Robinson, Ernest Temple, Leeds.
Harries, John D., Milford Haven.	Rogers, Francis Alfred, London.
Jackson, F. W., Ashton-under-Lyne.	Ross, Andrew Leighton, Montrose.
Jones, H., Blaenau Festiniog.	Scmerville, W. A., Upper Brighton.
Kitchin, George Shiach, Glasgow.	Spinks, Louis Leopold, Liverpool.
Lee, John C., Barton-on-Humber.	Stewart, Charles, Kirkcaldy.
Lee, John Edward, London.	Swinburn, Banks, Penrith.
Maley, George J., Douglas (I. of M.)	Talintyre, William John, London.
Medley, Fred, Barnsley.	Uttley, John Richard S., Masboro'.

Modified.

Clark, William George, London.	Reedman, William H., Birmingham.
--------------------------------	----------------------------------

ELECTION OF ASSOCIATES.

The following, having passed the Minor examination and tendered or paid as "Students" their subscriptions for the current year, were elected "Associates" of the Society:—

Batty, Thomas Edward, York.
Beckwith, John Batty, Liverpool.
Benney, John Herbert L., Constantine.
Brice, Henry Doyle, Guernsey.
Burnett, Albert Edward, Bristol.
Campkin, Francis Sidney, Cambridge.
Cannell, John Wilfred P., Douglas.
Casson, Frank, Birmingham.
Clark, George R. H., Hammersmith.
Coggin, Archibald H. G., Ware.
Coverdale, Arthur E., Kennington.
Creswell, Harry George, Bremsgrove.
Dann, Charles, Whittington Moor.
Daubeny, George, Sutton-in-Ashfield.
Davies, David Jonathan, New Quay.
Dean, John, Asbourne.
De Morgan, Fred. F., Newport, Mon.
Edge, William D., Newcastle, Staffs.
Ellis, William Neale, Peterborough.
Finlayson, Wm., Stockton-on-Tees.
Forrester, Thomas, Edinburgh.
Foster, Ernest Lionel, Plymouth.
Gerrish, Emerson, Bristol.
Goodo, Arthur Frederick, Nuneaton.
Green, Samuel Marston, London.
Halstead, Joseph Ernest, Burnley.
Hamerton James, Oundle.
Hewitt, Silas, Duk'nfield.
Hill, Charles Alexander, London.
Hilde, Ernest Lionel, Stoke Ferry.
Hitt, Thomas Gabriel, Long Eaton.
Horniblow, Frederick H., Worcester.
Jones, John Richard, Aberystwith.
Langham, Ebenezer, Salisbury.
Last, Ernest Charles, Ipswich.
Last, George Valentine C., Liverpool.
Leak, Frederick Thomas, Edinburgh.

Lean, Wilfrid, Ackworth.
Lloyd, Hugh William, Bala.
Lloyd, Thomas Henry, Southport.
McCorquodale, John C., Dumbarton.
Mason, Herbert, Wigan.
Meynell, Henry, Northallerton.
Mitchell, Willie, Halifax.
Munton, James Boughton, Stamford.
Orchard, Fred, Highbridge.
Payne, Roger, Saffron Walden.
Pearson, George Ernest, Wakefield.
Pileher, Daniel Garnet, Margate.
Rackham, Charles G., Halesworth.
Rhodes, John William, Leeds.
Roberts, William Henry, Chester.
Round, William Hopkins, Oldbury.
Scotchburn, Alfred, Driffield.
Scott, John Wilson, Birmingham.
Senter, George, Mossat.
Shakerley, William Arthur, Clapham.
She'drake, Albert Mason, Colchester.
Smart, Harold W., Willesden Park.
Smith, William Henry Harold, Cromer.
Spurge, Edward C., Stratford-on-Avon.
Stabler, Edgar, Levens.
Stamp, Francis U., Hampstead.
Stearn, Ralph M., Cambridge.
Sutcliffe, Lot Bains, Thorne.
Swanson, Alexander J. R., Edinburgh.
Taylor, Alfred, Morrision.
Thompson, Frederick W., Southend.
Thompson, John Robert, Edinburgh.
Thorpe, Arthur Muxlow, Spalding.
Truscott, Gilbert Edgar, Southampton.
Ward, Tom Goodrich, Tiverton.
Whitchurch, Ernest W., Nottingham.
Wileman, Frederick Walter, Lincoln.

Woodruff, Walter, Stockport.

ELECTION OF STUDENTS.

The following, having passed the First examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Allen, William John, Cardiff.
Callander, Thomas Gardner, Falkirk.
Carnegie, J., Kibworth Beauchamp.
Cassells, Thomas Henry, Southend.
Chalmers, Edward, Willesden.
Cleland, Robert Henry, Belfast.
Collins, Joseph H., Falmouth.
Collins, Samuel Morrison, Norwood.
Crossley, Arthur, Gorton.
Daniel, Robert, Derby.
Drust, John Hubert, North Ormesby.
Elms, Henry, Hornsey.
Ford, Meade Leahy, Forest Gate.
Foster, Charles Elkins, Brixton.
Gellately, James Blair, Dundee.
Gregory, Arthur, Weymouth.

Livesey, Henry A. A., Bradford.
Moore, Kate Lillian, Hampstead.
Pollard, Evelyn William, Ryde.
Priestley, George Edward, Paisley.
Rae, George Ernest Alfred, Exeter.
Russell, Robert, Lerwick.
Shelley, Geo. A. H., Southwark.
Smith, Harold James, Grimsby.
Smith, Richard Wallis, Hornsey.
Starmer, George F., Tunbridge Wells.
Storey, Richard, Ulverston.
Trick, P. W. C., Stoke Newington.
Warmington, Frank E., Leamington.
Watkins, Archibald G., Brecon.
Watts, Bertram Adam, Woolwich.
Williams, John, Carmarthen.

Wilson, Harold Oates, Nottingham.

RESTORATION TO THE REGISTER.

The name of the following person, who had made the required declarations, and paid the restoration fee, was restored to the Register of Chemists and Druggists:—

George Jeanes, 323, Park Road, Liverpool.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and the nominal restoration fee of one shilling.

ELECTION OF HONORARY MEMBERS.

The PRESIDENT moved that the following be elected honorary members of the Society:—Professor I. Bayley Balfour, F.R.S., Regius Professor of Botany, Edinburgh, and Director of the Royal Botanic Gardens, Edinburgh; Professor T. E. Thorpe, F.R.S., D.Sc., Chief of the Government Laboratory, Somerset House; Professor A. Tschirch, Ph.D., Professor of Pharmacology, University of Bern. These names had been selected by the Council sitting in Committee and the list had been suspended in the Library for a month, in accordance with the bye-laws. He now asked the Council to elect these gentlemen as honorary members. It was unnecessary to do more than mention the names, so well were they known in connection with botany, chemical science, and pharmacology, and to say that he was sure these gentlemen would add dignity and lustre to the roll of honorary members.

The VICE-PRESIDENT, in seconding the motion, said the Committee exercised very great care in the selection of the names, and he thought all would agree that their choice had been a wise one.

The resolution was carried unanimously.

ELECTION OF CORRESPONDING MEMBERS.

The PRESIDENT proposed that the following be elected corresponding members of the Society:—W. R. Carles, H.B.M. Consul at Corea; and Dr. Louis Planchon, École Supérieure de Pharmacie, Montpellier. Mr. Carles was an ardent botanist, and one of those typical Consuls who took care to keep his country informed of anything new in the way of drugs.

The resolution was carried unanimously.

REPORT OF THE EXECUTIVE OF THE NORTH BRITISH BRANCH.

This report was as follows:—

"The Executive of the North British Branch has now to submit the following report on the work of the year, from March, 1895, to March, 1896.

"At a meeting of Executive, held on April 19, 1895, it was arranged that the annual election should take place on Friday, June 21, 1895, and the present Executive was accordingly elected at a meeting of members and associates in business of the Society residing in Scotland, held on the above date.

"The Executive has held three meetings during the year. At the first meeting on June 28, 1895, Mr. James Laidlaw Ewing, Edinburgh, was elected Chairman, and Mr. William Little Currie, Glasgow, Vice-Chairman, and the resident members, with the Chairman and Vice-Chairman, *ex-officio*, were appointed a General Purposes Committee to attend to business arising between meetings of Executive.

"The General Purposes Committee has met three times and has had charge of the arrangements for evening scientific meetings, the completion of furnishings etc., for new premises, and the preparation, in consultation with Mr. Blanc, architect, of a plan for the rearrangement of the Society's House, consequent on the removal of examination work to the new hall and laboratories.

"At the meeting of Executive in June, 1895, a special committee for nomination of examiners was appointed. This Committee held two meetings, and reported to the meeting of Executive in November, when the following were nominated for election by the Council as the Board of Examiners for Scotland for 1896:—

"Professor Patrick Geddes, Dundee; Professor John Gibson, Edinburgh; Peter Boa, Edinburgh; James Laidlaw Ewing, Edinburgh; Jonathan Innes Fraser, Edinburgh; James Jack, Arbroath; John Nesbit, Portobello; and John William Sutherland, Dumfries.

"The financial statement for the year ending December, 1895, showing a total expenditure of £2550 17s. 4d. as compared with £3114 12s. for the previous year has already been forwarded to the Council. The expenditure for 1894 includes a special expenditure of £2015 0s. 9d. in connection with the new buildings, leaving a sum of £1099 11s. 3½d. as the ordinary expenditure for 1894. The expenditure for 1895 includes a special expenditure of £1149 9s. 9d., also in connection with new buildings, leaving a sum of £1401 7s. 7d. as the ordinary expenditure for 1895. This indicates an apparent increase of £301 16s. 3d. on the ordinary expenditure, but this includes a considerable expenditure for chemicals and apparatus, including additional chemical balances, microscopes, etc., required to stock the new laboratories, and extra service required during the removal to and fitting up of New Hall and Laboratories. There has also been permanent increase in taxation on the new buildings, the assessment valuation of which has been fixed at £100, the Executive having succeeded in obtaining a reduction of £50 from the annual value first fixed by the assessor. The permanent additional cleaning and service, and also fuel, light, and water rendered necessary by the extension of premises, also accounts for some of the increase. Otherwise the additional expenditure is entirely owing to an

increase in the expenses connected with the examinations, which have been larger than usual.

"The following particulars indicate that the departments connected with the Branch continue in a satisfactory state:—

"*The Examinations.*—The minor alterations and improvements in the fittings and fixtures of the laboratories referred to in last year's report have all been carried out, and the work of the Board of Examiners is now carried on in a convenient and efficient manner, the slight alterations having given entire satisfaction. A longer experience only tends to confirm the opinion that the scheme sanctioned by the Council and carried out by the Executive is admirably adapted for examination work, and has enabled the Board to cope with the increased numbers of candidates presenting themselves with a facility and expedition that would have been impossible under the old arrangement.

"There has been an increase in the number of Major candidates, 18 as compared with 10, and there has been a decrease in the number of passes, 44.4 per cent as compared with 60 per cent. last year, the percentage of passes in the previous year being 30.8 per cent.

"The number of Minor candidates shows a considerable increase, 540 as compared with 453 last year, and 395 in the year before that. The percentage of passes remains unsatisfactory and shows a slight decrease, 40 per cent. as compared with 42.17 per cent. in the previous year, and 40.25 per cent. in the year before last.

"*Evening Meetings.*—The session was opened in November with an able and most interesting address by Dr. John Gibson, Professor of Chemistry in the Heriot-Watt College, when a large audience completely filled the new hall. Three evening meetings have been held, and a fourth had been arranged for, but had to be abandoned at the request of the lecturer, who had been medically advised to avoid all extra labour for a time. All the meetings have been well attended, and the Executive take this opportunity of recording their thanks to all those gentlemen who gave valuable help by contributing papers.

"*Library.*—The Library continues to increase, and a number of standard works on Chemistry, Botany, Materia Medica, and Pharmacy have been added during the year, chiefly by purchase, and a few also by donation.

"The donations include an interesting parchment manuscript containing the 'Articles of Association of the Society of Druggist-Apothecaries in Edinburgh in 1785,' presented by Mr. James MacKenzie, F.S.A. Scot. The need for extended accommodation for the larger number of books is increasingly felt.

"The number of volumes lent out during the year is seen from the following table:—

April, 1895, to March, 1896	1494
April, 1894, to March, 1895	1346
Increase	148

"The number lent to provincial readers was:—

April, 1895, to March, 1896	140
April, 1894, to March, 1895	130
Increase	10

"This shows an increase of 148 over last year and 271 over the year before that, indicating a steady increase in the lending department of the Library. The circulation of books to provincial readers also shows a satisfactory, though still comparatively small, increase. During the year 1894-95, 130 volumes were circulated to readers outside Edinburgh and Leith; during 1895-6 140 volumes were so circulated, being an increase of 10 volumes for the year. There is, therefore, still ample room for the extension of this feature of the Library's usefulness, to which special attention was directed in last year's report.

"For purposes of reference the Library is, to a gradually increasing extent, consulted by university and extra-mural lecturers and others engaged in teaching science and in scientific and historical research, who cannot become members of the Society. It is also increasingly consulted by members, associates, and students of the Society. The Executive has to record thanks to several gentlemen who have given donations of books during the year.

"*Museum.*—The Executive has to record thanks to several donors of specimens, and a few have also been received from London. The additions to this department have, however, been fewer than usual during the year. The students' specimens are in good order and are largely taken advantage of. It is felt, however, that in connection with the re-arrangement of the Society's House, an extensive alteration and improvement may be effected in this department, which is in abeyance till the plan has been finally adjusted.

"The Library and Museum continue to attract a large number of visitors. A considerable number from various parts of Scotland and England have visited the Society's House during the year, and all have expressed the highest admiration of the way in which the Council has provided for the interests and requirements of the Society, as represented by the handsome premises now devoted to the work carried on in connection with the North British Branch.

"*House.*—The Society's premises in Edinburgh are now all in thorough repair and good order. In addition to the slight alterations in the laboratories already

referred to, some necessary cleaning and painting on the street front of the Society's House have been effected, but nothing of an extensive or important character has been done. The scheme for the re-arrangement of the Society's House, referred to last year, has been fully considered and is still under deliberation. The chief reason for some further delay is that a proposal for making an addition to the Museum is in process of adjustment, and nothing definite can be decided upon till the terms of this proposal have reached a more advanced stage.

"33, York Place, Edinburgh,

"JAMES L. EWING, Chairman.

"April 17, 1896."

The PRESIDENT having said that he thought this a very satisfactory report, and invited a member to move its reception,

Mr. STORRAR said he had pleasure in congratulating the Council on the general tone of the report. A little friction which once existed amongst the Scotch pharmacists had, he was glad to say, entirely disappeared, and he believed that at the present moment the Pharmaceutical Society had no more ardent supporters than the Scots. The principal work of the local executive during the past two years had been the building and setting up their new premises. This had necessarily involved a considerable increase in the annual expenditure, but he believed they had provided no more than was absolutely necessary to meet their needs and what was required for examination purposes, and he thought there was a general feeling that what had been accomplished was perfectly satisfactory and a credit to the Society. Most of the work in carrying out the scheme in its details had been done by the General Purposes Committee; in fact, that Committee had shown such diligence and energy as to leave the Executive nothing to do, but anything they had done, he felt sure, had been rendered willingly and in the hope that it would give satisfaction to the Council.

Mr. JOHNSON, in supporting and corroborating the views to which Mr. Storrar had given expression, said the Executive had met, he believed, in respect to those works only some three times, but they had done their best, and he hoped had succeeded in giving satisfaction.

Mr. HAMPSON said he did not know whether it was due to the climate of Scotland, but it had been brought home to the Council that law matters were carried out there in what he might call a rather ruinous fashion. He did not suppose the Executive there had any influence in the matter, but should that be the case he trusted it would be exercised in the right direction. He must express his great gratification at feeling that their Scotch friends were now thoroughly in touch with the Pharmaceutical Society, and he trusted that they in England would take care to reciprocate that feeling, so that the union might result in the next report of the North British Branch showing an appreciable increase in the number of members, especially in view of the considerable sum that had been expended in doing justice to Scotland.

The VICE-PRESIDENT, whilst thoroughly agreeing with the Treasurer that a considerable sum had been spent in Scotland, hoped it would not go forward that any idea was entertained of their having done anything more than justice. They all regarded Edinburgh as a great centre of learning, and they had done well to advertise the Society and its work by having in that city a building and home worthy of the aims they had at heart. He had listened to the report with exceeding pleasure, and thought it most satisfactory to find every branch of their work in so thoroughly satisfactory a condition. He hoped that as time went on and their Scotch friends came to realise the Society's aims, and the way in which its work was done, they would find no reason to complain, and that the result would be a substantial accession to the membership of the Society. He moved the reception and adoption of the report.

Mr. MARTINDALE expressed his gratification with the report, and looked forward, now that he supposed their arrangements in Edinburgh were about as complete as they could be made, to the Board of Examiners in that city materially contributing to the usefulness of the Society. As everybody knew, a not inconsiderable number of students went to Edinburgh to be examined, and now that there were better facilities than had hitherto prevailed, he trusted the two Boards would work together with the object of making the best use of their advantages.

The report was then adopted.

The PRESIDENT said that as arising out of this report he might here add that a resolution had been received from the North British Branch as follows:—

"That it is the opinion of this meeting, and the Executive of the North British Branch of the Pharmaceutical Society of Great Britain, that the time

has now arrived for making the First or Preliminary examination a more efficient test of a candidate's general knowledge."

He would suggest that this resolution be referred to the General Purposes Committee, which could thrash out the subject and bring up a report respecting it.

This suggestion was adopted.

FINANCE COMMITTEE.

The SECRETARY read the report of this Committee, which was of the usual character, and recommended the payment of various accounts.

The PRESIDENT, as Chairman of the Committee, moved the adoption of the report and recommendations. He said the principal receipts were from subscriptions and examination fees. The payments did not call for any special comment. On the Benevolent Fund account £745 had been received in subscriptions, and a donation of £10; also 13s. 3d., the result of a collection by the Liverpool Pharmaceutical Students' Society at a social meeting.

The report was unanimously adopted.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

The SECRETARY read the report of this Committee, which had held two meetings. It had considered the petition from some of the students for a room to be allotted them for social purposes, and recommended that the signatories be informed that their request could not be acceded to. The draft annual report was considered and referred to the Council. A request from the Pharmaceutical Association of Quebec for a copy of the Calendar had been received, and the Committee recommended that it be sent and also the Journal as published.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average
March.....	Day.....	610	31	14	23
	Evening.....	214	20	2	10
Circulation of Books.	Total.	Town.	Country.	Carriage paid.	
March.....	198	96	100	£1 4s. 6d.	

Donations to the Library had been announced (*Pharm. Journ.*, April 11, p. 290), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the under-mentioned works be purchased:—

For the Library in London:—

Atlas Chemical Company, Chemical Recipes.

For the Library in Edinburgh:—

Roscoe and Schorlemmer, Treatise on Chemistry, new edition.

Dittmar, Analytical Chemistry (Qualitative), latest edition.

Museum.

The Curator's report had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
March.....	Day.....	719	42	14	27
	Evening.....	56	17	1	2

Donations to the Museum had been received (*Pharm. Journ.*, April 11, p. 290), and the Committee recommended that the usual letter of thanks be sent to the respective donors.

The PRESIDENT, in moving the adoption of the report and recommendations, said the chief matter dealt with, apart from the routine business, was the application from the students for a common room. The Committee carefully considered the matter, and having regard to the peculiar condition of the building, found there were great difficulties in providing any room in a suitable part for this purpose. There were also other difficulties of a somewhat serious character, which, having been carefully considered, weighed with the Committee to the extent of recommending that the request be not granted. The sympathies of the Committee were, of course, with the students in any desire for social converse and mutual improvement; but, on the other hand, it was the duty of the Council not to afford facilities for the neglect of work during working hours, and the Committee had a difficulty in seeing at what time a common room could be made use of, excepting meal times, and its view was that the best place for meals was outside

the house. Looking to the fact that the students only attended during certain hours, and that there was a great deal for them to do in those hours, and also to the fact that there were no second or third year's students as there were in the large institutions to which the petition referred, besides the difficulty of maintaining discipline and good order where there were no senior students to take the lead, the Committee had no hesitation in recommending the Council to say that it was not practicable to accede to the wishes of the students.

The report was unanimously adopted.

BENEVOLENT FUND COMMITTEE.

The report of this Committee included the recommendation of grants amounting to £55 in the following cases:—

The widow of an associate who died in 1893. She has seven children, five of whom are dependent on her. (Carnarvon.)

A chemist and druggist member from 1869 to 1893, and subscriber for one year to the Fund. Was in business for twenty-seven years, and is now seeking a situation. (Rotherham.)

The widow of a registered chemist and druggist with four children, one only dependent on her. She has had five previous grants. (Redhill.)

A former associate, 1842 to 1846, who has had several previous grants. (Croydon.)

The widow of a chemist and druggist who has had nine previous grants. (Birmingham.)

The widow of an associate in business and subscriber. (Crawley.)

One case was deferred for further inquiries, and another one was not entertained.

Mr. BOTTLE moved the adoption of the report and recommendations, and said there was very little need for comment. He would like to say, however, with regard to the case which the Committee declined to assist, that it appeared the applicant was in possession of £170 under her own control. It was very natural that she should desire to allow the money to remain at interest, and get some little addition to the income it yielded, but the Committee could not relieve cases of that sort.

Mr. ATKINS said the Committee was greatly helped in dealing with the applications by the assistance of members, local secretaries, and others who furnished valuable information. One case struck him very forcibly and he feared it was a typical one. It was that of a man of reputation and intelligence who had simply collapsed, it seemed to him, under the pressure of fierce modern competition, a man against whom nothing could be said, and of whom they heard everything that was good. Some assistance had been given him, and it was hoped he would be put in the way of earning his own living for some years to come. It had occurred to him that practically they had a set of small annuitants, most deserving cases, who received aid year after year, but never seemed to be able to improve their position. He felt that much good was done in assisting those persons, and thought that some day the Society might see its way to establish annuities on a smaller scale to meet those cases. He knew the value of the annuities now given, but thought there were many cases in which a smaller sum, supplemented from other sources, would be also very useful.

Mr. CROSS hoped the time was very distant when the Council would adopt the suggestion just thrown out. By having these cases coming forward time after time, the Committee could review the circumstances, and either increase or diminish the assistance given according to circumstances; but if small annuities were granted they would continue to be paid with very little inquiry. He thought the present system was far preferable to the one suggested.

Mr. ATKINS said he did not wish to press the matter, nor did he desire in any way to interfere with the principle of making grants from time to time.

The resolution was then put and carried.

PHARMACEUTICAL CONGRESS AT BUDAPESTH.

The PRESIDENT said he had received a circular announcing the holding of a Congress of Pharmacists at Budapesth, on June 26 and 27, and stating that the Committee would be glad to welcome any foreign pharmacists who could attend. If any members of the Council or of the Society would like to attend, he was sure the Council would authorise him to give them the necessary credentials.

The PRESIDENT then announced the receipt of a photograph of the Philadelphia College of Pharmacy from Mr. Howard B. French, in recognition of the courtesy shown him by the Society when in

England. He had also received from Mr. Sandell, an associate of the Society and a specialist in photography, a number of very fine photographs of different parts of the Society's House and School taken with the Sandell plates.

REPORT OF EXAMINATIONS.

The following report was presented:—

April, 1896.

	Candidates.		
	Examined.	Passed.	Failed.
England and Wales:—			
Major	25	12	13
Minor	234	81	153
Scotland:—			
Major	5	2	3
Minor	188	66	122
First Examination	408	174	234

27 Certificates by approved examining bodies were received in lieu of the Society's First examination.

Certificate in lieu of First Examination.

The PRESIDENT moved that the Board of Examiners be authorised to receive the certificate of the Annen-Realschule of Dresden in lieu of the First examination, in the case of Arthur Rosenloecher.

This was agreed to.

THE COMPANIES ACT AMENDMENT BILL.

The PRESIDENT said he had to report officially what many might have seen in the press that Lord Herschell, with whom he had an interview on the subject of this Bill, had placed an amendment on the paper, which was in the terms agreed to by the Joint Committee representing that Council, and other bodies representing medicine, surgery, dentistry, etc. The committee stage of the Bill having been postponed from Monday week to last Monday he then attended at the House of Lords and had another interview with Lord Herschell, and then learned that an amendment would be moved to refer the Bill to a Select Committee, which was done. He was present during the discussion, and the observations of Lord Salisbury seemed to show the intention that the Select Committee should receive evidence. Consequently, he took it, it would be the duty of the "Watch" Committee to take such steps as might be necessary to appear before the Committee in due course. He thought this reference to a Select Committee might be an advantage. Anything which required or enabled them to put their case before a number of careful and thoughtful men was an advantage, and whatever might be said about the House of Lords, a Select Committee of that body was generally very painstaking, and inclined to listen to the representations of any class which felt itself aggrieved, and possibly educational qualifications might be considered more carefully than they would be in the House of Commons. Even if it involved a year's delay, he was inclined to think it was well that the Bill had been referred to a Select Committee.

The VICE-PRESIDENT concurred in the view expressed by the President. He felt convinced that if they could, in conjunction with other bodies similarly constituted, have an opportunity of laying their case before men of legal mind, sound judgment, and ripe experience, their claims would be fairly considered, and very probably granted.

Mr. HAMPSON also thought it an advantage that the Bill should go before a Select Committee. The law officers were most able men, and would give due attention to the matters brought before them.

THE ANNUAL REPORT.

The draft annual report and statement of accounts having been considered, were ordered to be printed and circulated (see page 361).

GENERAL PURPOSES COMMITTEE.

The Council went into Committee to receive and discuss the report of this Committee, dealing with legal matters.

On resuming, the report and recommendations of the Committee were adopted, and special resolutions passed authorising the Registrar to take proceedings against certain persons for alleged infringements of the Pharmacy Act.

PRELIMINARY REPORT ON TWO BURMESE TURPENTINES.

BY PROFESSOR HENRY E. ARMSTRONG, F.R.S.

Large samples of *Pinus khasya* and *Pinus merkusii* have been received by me through the kind offices of the Imperial Institute; and the following are the results arrived at by their preliminary examination:—

The crude turpentine from *Pinus khasya* was a grey, thick, pasty mass, containing a quantity of small pieces of wood. That from *Pinus merkusii* was more fluid and cleaner in appearance. By distilling with steam, I separated about 13/100th of its weight of oil from the *Pinus khasya* turpentine, and nearly 19/100th from the *Pinus merkusii* turpentine. On a previous occasion I obtained nearly 17 per cent. of oil from a sample of the first-named turpentine. I imagine that the present supply of turpentine was collected under less favourable conditions, and that some oil was lost by evaporation, in the case of the sample now under examination.

The original turpentine and the distilled oil in each case have a very slight but agreeable odour, which is even less pronounced than that of French turpentine, and distinctly characteristic, although indescribable. The two oils are very similar in this respect. I am satisfied that the oil from *Pinus khasya* is identical with that which I received from the Colonial and Indian Exhibition, and examined several years ago, but which I was then led to believe came from the same tree.

The examination of oils of this description, with a view to determine their precise composition, is a matter of great difficulty, and we are but beginning to discover methods. From the experiments I have been able to make thus far I am satisfied that the oil from *Pinus khasya* is strictly comparable with French oil of turpentine, thus confirming the opinion I arrived at several years ago. The oil from *Pinus merkusii* is very similar to that from *Pinus khasya*. Like French oil of turpentine, both these oils distil within a very narrow range of temperature, near to 155° C., but the oil from *Pinus khasya* appears to contain a somewhat larger proportion of a constituent of higher boiling point.

The two oils are very nearly alike in relative density, viz.:

	<i>P. khasya</i>	<i>P. merkusii</i>
at 20° C.	·8627	·8610

They both turn the ray of polarised light to the right, the so called specific rotatory power being—

	<i>P. khasya</i>	<i>P. merkusii</i>
	+36"28	+31"45

The rotatory power of French turpentine is practically always about -36". The *Pinus khasya* oil now examined agrees with that I previously obtained from British Burma in this respect.

Practically, French oil of turpentine and that from *Pinus khasya* exactly correspond in properties. The difference between the oils from the two Burmese turpentines is of such a kind as to be of no practical consequence—they are essentially similar, and the slight difference is due to the presence, in one or the other, of some substance besides the chief constituent. I am at present inclined to think that the oil from *Pinus merkusii* may be the more uniform. It will be my endeavour to thoroughly examine the two oils in comparison with French turpentine, and, if possible, to discover their exact nature.

Meanwhile, I may say that both oils are of the highest quality, and that I believe they would serve every purpose for which oil of turpentine (French or American) is used. They even compare favourably with the French oil, which is the highest quality in the market. The rosin left on distilling off the oil would also, I believe, be available for all purposes for which ordinary rosin is used. There is no reason, I venture to think, why India should not obtain whatever turpentine is required from native sources, if the industry can be developed, and the cost of carriage be not too great. I hope, later on, to submit a more detailed report, if I should be successful in devising methods of separating the constituents of the oils; and, in any case, to obtain results of considerable scientific interest which may throw light on the, at present, obscure relationship between the various oils of the turpentine class.—*Imperial Institute Journal.*

LONDON: SATURDAY, MAY 9, 1896.

THE COUNCIL MEETING.

At the meeting last Wednesday the additions to the Society comprised 16 members, 111 associates and 33 students. Three honorary members were elected, viz., Professor I. BAYLEY BALFOUR, Professor T. E. THORPE, and Professor TSCHIRCH, and two corresponding members, Mr. W. R. CARLES, British Consul at Corea, and Dr. LOUIS PLANCHON, of Montpellier.

The report of the Executive of the North British Branch (printed at page 367) was then read. It gave a satisfactory account of the facilities afforded for examination work by the extension of the Society's premises in Edinburgh, and showed generally that in other departments the Branch continues its efficiency. Both Mr. STORRAR and Mr. JOHNSON gave expression to the belief that the Society has loyal supporters in Scotland, and that the expenditure which has been incurred in properly providing for the requirements of the examinations was a credit to the Society. The Treasurer hoped that the good feeling existing in Scotland would be reciprocated, and that it would result in an appreciable increase of members. The Vice-President, in moving the adoption of the report, repeated that hope, and pointed out the desirability of having an establishment in Edinburgh worthy of the Society's aims. An important resolution relating to the Preliminary examination was then mentioned by the PRESIDENT as having been sent by the Executive of the North British Branch, and it was referred to the General Purposes Committee for consideration. This resolution was carried at the meeting of the Executive on April 17 last (*ante*, p. 334), on the motion of Mr. GEORGE COULL, B.Sc., and after a lengthy discussion, which had been adjourned from a previous meeting. Mr. COULL remarked on that occasion that Scotland had long been in the forefront as regarded education, and it would be strange if it did not again take a prominent position in calling attention to the fact that the Preliminary examination ought to be made more stringent.

The report of the Finance Committee did not offer any exceptional feature for comment. In addition to a considerable amount received from subscribers to the Benevolent Fund, the Liverpool Pharmaceutical Students' Society

had sent a donation resulting from a collection made at a social meeting.

The report of the Library, Museum, School, and House Committee included a reference to the provision of a room to be used by the students for social purposes, and the decision that the request could not be acceded to. This was explained by the PRESIDENT as having been the unavoidable result of careful consideration of all the circumstances of the case.

In accordance with recommendations in the report of the Benevolent Fund Committee, six grants, amounting in all to £55, were ordered to be paid. In moving the adoption of the report, Mr. BOTTLE mentioned that in the case of an application the Committee had declined to entertain, the applicant having possession of a sum of money was not in such a condition of distress as would call for assistance from the Benevolent Fund. Mr. ATKINS spoke of the useful assistance afforded to the Committee by members who supplied information concerning applicants for assistance. He suggested that the recipients of grants were in many cases practically small annuitants, and that the good done from time to time might lead to the establishment of annuities on a smaller scale to meet the needs of such applicants as are deserving, but unable to improve their position. Mr. CROSS objected that such annuities would be paid as a matter of routine, and the Committee would not be able to review the circumstances which might require consideration.

Mention was made of an invitation from a committee of pharmacists at Budapesth in reference to the Congress to be held there on June 26 and 27.

A resolution was passed authorising the Board of Examiners to receive the certificate of the Annen-Realschule of Dresden in lieu of the First examination in the case of ARTHUR ROSENLOECHER.

In reference to the Companies Act Amendment Bill, the PRESIDENT reported that the amendment placed on the paper by Lord HERSHELL was in the terms agreed to by the joint Committee representing medicine, surgery, dentistry, etc., as well as the Council of the Society. The observations of Lord SALISBURY in the discussion last Monday appeared to indicate not only the intention that the Select Committee to which the Bill had been referred should have power to receive evidence and seek legal assistance if requisite, but also that in dealing with interests of the highest importance the views of those practically acquainted with the working of the commerce of the country should be heard and considered without restriction. From this it may be inferred that the "Watch" Committee would require to take steps for being heard before the Select Committee of the House of Lords. The reference of the Bill to a committee might therefore be an advantage, even if it involved some delay. Both the Vice-President and the Treasurer expressed themselves as holding similar views as to the prospect of a fair consideration being accorded to the claims put forward by the Society and by other bodies.

The annual report and statement of accounts were considered in committee, and subsequently ordered to be printed (see page 361).

After the discussion of the report of the General Purposes Committee in reference to legal matters, the report was adopted, and on the recommendation of the Committee, the Registrar was authorised to take proceedings in various cases of alleged infringement of the Pharmacy Act.

THE CENTENARY OF VACCINATION.

THURSDAY next, May 14, will be the one-hundredth anniversary of the day upon which Dr. EDWARD JENNER performed his first vaccination, the subject being JAMES PHIPPS, a boy of eight. The Editor of the *Practitioner* celebrates the occasion by publishing a "vaccination number," in which many writers deal with as many aspects of the case for vaccination, whilst EDWARD JENNER poses as the month's hero of medicine. JENNER came of a Gloucestershire family and was born at Berkeley, a village in that county, of which his father was vicar. His tastes early led him to investigate living things rather than to study dead languages, and on leaving school he was apprenticed to a country medical practitioner at Sodbury, near Bristol, of considerable reputation. Whilst residing at Sodbury JENNER was struck by the remark of a young countrywoman that she could not take small-pox, having already had cow-pox. The idea thus suggested remained in his mind, slowly maturing, but did not attain its realisation for some thirty years.

It was in 1770 that JENNER arrived in London, to finish his medical education at St. George's Hospital and work as a pupil with JOHN HUNTER, under whose roof he lived for two years. His skill as a naturalist accompanied him, and on Captain COOK's return from his first voyage of discovery, Sir JOSEPH BANKS recommended JENNER for the purpose of preparing and arranging the natural history specimens that had been collected by the illustrious circumnavigator. Two years later, in 1773, the young practitioner returned to his native place, and soon won for himself a high reputation for skill in the art of healing and general scientific knowledge, the study of natural history continuing meanwhile to engage as much of his attention as his professional engagements allowed. In 1788 he presented a paper to the Royal Society on "The Natural History of the Cuckoo," and in the same year he was elected to membership of that body. Four years later he graduated as M.D. at the University of St. Andrew's, having determined to confine himself to the practice of medicine.

After worrying all his medical friends for years about the supposed protective effects of cow-pox, JENNER at last obtained an opportunity of testing the prophylactic efficacy of inoculation of the healthy human subject by cow-pox virus. On May 14, 1796, matter was taken from the hand of SARAH NELMES, who had been infected by a cow, and inserted by two superficial incisions into the arms of a healthy boy, named JAMES PHIPPS. On July 1 the boy was inoculated with matter from small-pox pustules without any result, and thus proof was obtained of the success of JENNER's first vaccination. A book on the subject was published by JENNER in 1798, and he was continually kept busy vaccinating people who came to his house for the purpose, as many as three hundred sometimes being at his door at one time. He also conducted an enormous correspondence and sent out lymph where required. As a result, his practice was interfered with to such an extent that it required grants from Parliament, amounting in all to £30,000, to prevent him being impoverished. He died at Berkeley, of apoplexy, on January 26, 1823, having been the recipient of honorary degrees, diplomas, etc., from nearly every learned body in the world, whilst medals had been struck in his honour and his praises sung by poets as if he were a conqueror. It has been estimated that during his own lifetime he saved more lives than the ambition of NAPOLEON destroyed.

ANNOTATIONS.

THE ANNUAL DINNER.—The annual dinner of the members of the Pharmaceutical Society and their friends will be held on Tuesday, May 19, in the King's Hall, Holborn Restaurant, London, and applications for tickets, accompanied by a remittance (One Guinea) must be received by the Honorary Secretary, Mr. Richard Bremridge, not later than Saturday next, May 16, after which date it will not be possible to allot seats.

THE VOLUMETRIC COMPOSITION OF AMMONIUM CHLORIDE.—Experimental proof of the fact that a certain volume of ammonia combines with an equal volume of hydrogen chloride to form ammonium chloride, by the usual method, requires the use of a mercury trough and a large supply of mercury. Carnegie and Wales, however, have devised a method which does not involve the use of mercury, and appears, moreover, to prove the volume composition of ammonium chloride to a much higher degree of accuracy than usual. The mercury is replaced by kerosene saturated with dry ammonia, and an illustrated description of the apparatus employed will be found in the *Chemical News* for May 1.

RECENT WORK WITH THE RÖNTGEN RAYS.—Probably no scientific discovery has ever excited so much interest from the very outset as that of the x -rays by Röntgen, and certainly it would be difficult to find a parallel for the number of investigators at work upon the subject within so brief a time. Perhaps it is because nearly everyone at the present time knows something about photography, and a very large number of people had most of the necessary apparatus at hand. A remarkable illustration of the amount of detailed information already brought together is afforded by the fact that *Nature* last week devoted four pages of its extremely valuable space to a collection of notes on papers and communications on the subject received during a few days only. This indicates that a special journal of Röntgenography may shortly be needed to record the multitudinous results obtained by the small army of workers. A report of an interesting lecture on the subject by Mr. E. J. Wall will be found on page 364 of our present issue.

PHARMACY IN VICTORIA.—According to the report for 1895 of the Pharmacy Board of Victoria, the number of would-be pharmacists in that colony is greater than ever, 148 students having entered for the Preliminary Examination, and 71 passed, during the year, as against 126, of whom 60 passed in 1894, the highest number previously on record. For the certificate of the Melbourne College of Pharmacy, 48 students presented themselves for examination in chemistry and practical chemistry (30 passed), and the same number in materia medica and botany (26 passed). Having passed the Preliminary Examination before apprenticeship, served for not less than four years as an apprentice, attended courses of lectures in materia medica, botany, chemistry, and practical chemistry, and passed College examinations in those subjects, 29 candidates presented themselves for the Final Examination in Practical Pharmacy and 16 passed. In 1891 there were 37 entries and 26 passes. For the Modified Examination, open to those whose apprenticeship commenced before the passing of the Pharmacy Act, 1876, 4 candidates presented themselves and all failed. The additions to the register of pharmaceutical chemists during 1895 were 20 only, the smallest number for any year on record, but the number of apprentices registered was 51, the highest on record. There are now 1170 pharmaceutical chemists registered under the Act, of whom 137 were registered under certificates from the Pharmaceutical Society of Great Britain, and 523 apprentices.

A SATISFACTORY RESOLUTION.—The Royal College of Physicians of Ireland has signified its disapproval of the practice by which the services of professional men are exploited for the financial benefit of other persons, by passing the following resolution: "That the Royal College of Physicians of Ireland desires to express their (? its) disapproval of their (? its) licentiates accepting office in medical aid associations as at present conducted in England, inasmuch as the independence of the physician is destroyed by the system, and the services of the physician are used so as to produce a profit for lay persons." It would doubtless prove useful were pharmaceutical associations throughout Great Britain to pass similar resolutions as guides to conduct, and endeavour to enforce them so far as they were able, by moral compulsion.

CASES UNDER THE SALE OF FOOD AND DRUGS ACT.—In two cases that were recently brought before Mr. Bros, at the Clerkenwell Police Court, the defendants were charged with improperly dispensing a mixture that ought to have consisted of tartarated antimony, 1 grain, potassium nitrate, 1 drachm, and water, 6 ounces. One defendant, a registered chemist and druggist we regret to say, had omitted the tartarated antimony, and pleaded that this was the result of a mistake. Mr. Bros, who probably thought that such carelessness was as deserving of punishment as a wilful breach of the law, remarked that it was important that drugs should be mixed in accordance with prescriptions, and imposed a fine of ten shillings and costs. In the second case, Elizabeth Horton, whose name is not on the Register of Chemists and Druggists, was charged with omitting one-third of a grain of the tartarated antimony. The solicitor for this defendant having called in question the value of an analysis of one-third only of the mixture, Mr. Bros said that where the skill of a chemist was called in question he thought the whole mixture should be analysed, and the case was adjourned to allow the remaining two-thirds to be examined. The magistrate said also that it seemed to him such cases should be heard before a different tribunal than a police court, a statement with which many people will cordially agree.

VOLUNTARY EARLY CLOSING.—Reference was recently made to the fact that the chemists and druggists of Hunslet had decided to close their pharmacies every Wednesday afternoon until the end of October, and this good example is now being imitated by the whole of the chemists in Darlington, who close their places of business at 1 p.m. on each Wednesday. Cannot chemists all over the country agree to limit their hours of work in a similar way, and so remove the reproach that they must be compelled by Act of Parliament to treat their assistants and apprentices considerately in this respect?

CASE UNDER THE APOTHECARIES ACT.—Actions are not often brought against chemists nowadays by the Master, Wardens, and Society of the Art and Mystery of Apothecaries of the City of London, and it is doubtless only in flagrant cases that such steps are taken. In the case of James Eteson Walker, of Preston, who is described in the Register of Chemists and Druggists as having been in business before August 1, 1868, the defendant prevented the consideration of the case by paying the penalty of twenty pounds into court, and so rendered it impossible to judge whether his conduct had been illegal and unprofessional or not. His Honour Judge Coventry, before whom the matter was argued last week, considered however that it was of interest to the public to know whether defendant was or was not a qualified apothecary, and decided that under the circumstances he must allow costs for the plaintiffs on the higher scale.

OPPOSITION TO THE METRIC SYSTEM.—The writer of the letters that recently appeared in the *Times*, advocating the re-organisation of the existing system of enumeration on a duodecimal basis, in preference to adopting the decimal system of weights and measures, is now stated to be Mr. Herbert Spencer. The letters will shortly be reprinted in pamphlet form, with appendixes, by Messrs. Williams and Norgate.

"KNOWLEDGE—AN ILLUSTRATED MAGAZINE OF SCIENCE, LITERATURE, AND ART."—Founded many years ago by the lamented Richard A. Proctor, this paper has undergone many changes since it commenced, and now seems to have settled down as a sober monthly organ of exact but popular science. The current number has a remarkably healthy appearance, and contains an attractive series of articles, appealing to astronomers, coin collectors, chess players, botanists, geologists, and naturalists generally. The twenty-four pages of literary matter are profusely illustrated, and the high class of the contents of the paper should render *Knowledge* a necessity to every one interested in the world around him.

THE CHANCES OF THE COMPANIES BILL.—The *Times*—commenting on the fact that the Companies Bill was referred by the House of Lords on Monday night to a Select Committee, with the admission that there was very little chance of its becoming law this session—observes that whether the Bill is passed by the Upper House in May or June or July, its ultimate destiny is clearly marked out for it by the fact that in the House of Commons it must come after the Rating Bill, the Education Bill, and the Irish Land Bill, besides other Ministerial measures that excite much interest. It is also pointed out that it is certain the Bill cannot escape criticism in the House of Commons, from the point of view of those who object to it on the ground that it does too little, as well as from that of those who consider it goes too far.

WORKHOUSE DRUG CONTRACTS.—Speaking last week in London at a conference on the subject of Irish workhouse reform, Dr. Jacob, who represented the Irish Medical Association at the conference, condemned in strong language the system of contracting for the supply of drugs to workhouses. An exhaustive inquiry into workhouse administration was suggested.

BACTERIA IN OYSTERS.—On outbreak of typhoid fever amongst those who attended the Stirling County Ball in October, 1895, gave rise to the suspicion that the oysters supplied on that occasion were the carriers of infection, but Dr. Chalmers, one of the Glasgow medical officers of health, investigated the matter and concluded that the cause of the enteric fever infection was not conveyed in the oysters. A bacteriological examination of oysters from the same oyster-bed was undertaken later by Mr. D. M'Crorie, lecturer on bacteriology at St. Mungo's College, and he was able to isolate from them six distinct germs, of which four, including *Bacillus fluorescens liquefaciens* and a vibrio, liquefied gelatin. The fifth was a typhoid-like bacillus and the sixth a torula. The typhoid-like bacillus was found to differ considerably from the *Bacillus typhosus* of Eberth, Drs. Kanthack and V. D. Harris agreeing with Mr. M'Crorie on this point, and it was therefore assumed to be one of the pseudo-typhoids. It was found to differ from Eberth's bacillus in being virtually non-pathogenic to animals, and having a different optimum temperature, besides which it did not seem to possess so many flagella. The vibrio isolated was larger than Koch's cholera vibrio, but closely resembled the Finkler-Prior bacillus, and there was no reason to suspect that it played any part in the causation of the fever.

PARLIAMENTARY INTELLIGENCE.

THE COMPANIES BILL.—The House of Lords was occupied for an unusual time on Monday in discussing the fate of this Bill. Objection having been taken to the motion to go into committee, Lord Melville (who is connected with the firm of Melville, Fickus, and Co., Limited, bankers) moved that the Bill be referred to a Select Committee, and the Earl of Dudley not resisting, the Bill was so referred. From a pharmaceutical point of view the chief interest in the debate preceding the committal is contained in Lord Herschell's speech. His lordship, probably having fresh in his mind the cases submitted to the Board of Trade by the Pharmaceutical Society, declared that it was the bounden duty of Parliament, when grave evils had been manifested, as they had been in regard to some companies, to pass some measure which would in the highest degree possible minimise those defects. He suggested that as reference to a Select Committee would probably involve the delay of much-needed legislation on the subject for a whole year, it might be convenient to divide the Bill into two parts, one to embody the more urgent and less controversial provisions, which might then stand a chance of passing this session. The suggestion was not, however, accepted by the House, and with the relegation of the Bill to a Select Committee (which, by the way, has not yet been constituted) the expectation of repressing one-man bogus companies this year may be sorrowfully dismissed. There is a remnant of hope, however, in the view that the delay may make it possible for the Pharmaceutical Society, with the help of chemists and druggists throughout Great Britain, to strengthen its position and become next session a more powerful factor in parliamentary matters.

THE SHOP ASSISTANTS BILL, in so far as it affects chemists, does not materially differ from the Shops (Early Closing) Bill, but the principles of the two measures are widely dissimilar. The local option, which many think the best thing about Sir John Lubbock's Bill, is absent in its rival for parliamentary favours, and is replaced by compulsion. It is proposed, in fact, that every shop in the United Kingdom shall be closed, willy-nilly, one afternoon a week. The shopkeepers and inhabitants of each district are, however, to have the privilege of deciding which afternoon it shall be, for the local authority is charged with the duty of taking a plebiscite (after the manner prescribed by the Public Libraries Act, 1892) on the subject, and will defray the expense of the same out of the local rates. With regard to the supply of medicines to the public, the promoters of the Assistants Bill have been guilty of plagiarism in taking Sir John's saving clause for use in their own Bill; but, like most stolen literature, it has been marred in the stealing, in other words, the clause has been extended to embrace the sale of medicines and medical appliances by herbalists. The only businesses absolutely exempted from the operation of the Bill are those of licensed victuallers, refreshment and eating house keepers, confectioners, barbers, tobacconists, and newsagents. The police are charged with the administration of the law relating to half-holiday closing, and a first offence under the act will carry liability to a maximum fine of 20s. A second offence is regarded as sufficiently serious to call for a maximum penalty of £5, and a third of £25.

HOPE FOR BELATED BILLS.—If Sir Edward Clarke can get his motion accepted there will be joy in the hearts of honourable members in charge of delayed measures. Sir Edward desires the amendment of the practice of the House, so that Bills which have passed the second reading in one session, but, owing to pressure of public business, obstruction, or other unforeseen circumstances, have not become law, shall be resumed in the succeeding session at the stage of Committee. But, alas, the member for Plymouth has not yet had a day fixed for his motion, and the hope of private members is again deferred.

PARLIAMENTARY GRANTS FOR SCIENCE AND ART.—Her Majesty's opposition, or at any rate that portion of it representing Mansfield and S.W. Bethnal Green, does not look with favour upon the provision made in the Civil Service estimates for universities and colleges. Mr. Carvell Williams and Mr. Pickersgill have both given notice of their intention to move the reduction of the vote by £1700—the grant to King's College, London. Mr. Hobhouse (E. Somerset), who has temporarily joined the opposition, is also anxious to distinguish himself by moving the reduction of the vote in respect of science and art by £100.

PROCEEDINGS OF SOCIETIES.

Plymouth, Devonport, Stonehouse and District Chemists' Association, April 30.—Mr. F. W. Hunt in the chair.—Mr. J. D. Turney read an able paper on the "Cell Structure of Plants." Mr. Turney exhibited twenty-six lantern slides prepared by himself, and pointed out the various characteristics of the slides. On the motion of Mr. Hunt, seconded by Mr. Roper, the lecturer was accorded a hearty vote of thanks.

Commencing on May 6, the members of the Association will hold botanical rambles, weather permitting, on every Wednesday throughout the summer season. Mr. O. A. Reade, of the Royal Naval Hospital, Stonehouse, has very generously placed his services at the disposal of the Association, and will conduct the rambles. With the exception of May 20, when no ramble will take place, members are asked to assemble at the headquarters of the Association, Foresters' Hall, Plymouth Octagon, at 2.30 p.m. The Junior Section is taking a lively interest in the series of rambles, and Plymbridge and Bickleigh Vale were down on the list to be visited last Wednesday.

Midland Chemists' Assistants' Association, May 2.—The last social evening of the session was held at Exchange Rooms, Birmingham. It proved a great success, and Mr. Meggeson, who had charge of the arrangements, is to be highly congratulated. The instrumental portion of the programme was provided by Messrs. Woodward (piano) and Duncuff ('cello). Recitations were given by Mr. H. Martin, and songs were rendered by Messrs. Lidbury, Lloyd, Osborne, Walton, Jones, Cornish, and others. There was an attendance of between forty and fifty.

Linnean Society of London, April 16.—Mr. W. Percy Sladen, Vice-President in the Chair.—Mr. George Massee read a paper on the types of Fungi in the collection of the late Rev. M. J. Berkeley, which was presented to Kew in 1879, and contains rather more than 11,000 species. Many of the species were described more than fifty years ago; hence the diagnoses are in some cases too brief, and do not embody points which at the present day are considered to be of importance. In many instances this has led to the same species being re-described by others as new. Mr. Massee now supplied careful descriptions of the types, with a view to obviate future confusion, and to secure for Berkeley as the original describer the priority in nomenclature which is justly his.

Mr. A. D. Michael read a paper upon the internal anatomy of *Bdella* (the Red-snouted Mite), giving the results of three years work and of many hundreds of dissections and serial sections. The material was furnished chiefly from the Zoological Station at Port Erin, and the subject is practically new, only one paper (describing a few parts of the female) having been hitherto published. The male organs of *Bdella* are extraordinarily complicated: a pair of testes on each side of the body are joined by a tubular bridge to those on the other side. In *Bdella basteri* these testes are sunk in the thick walls of great "embedding sacs," which are glandular, but are absent from other species. The vasa deferentia are transformed into immense mucous glands, which communicate by "antechambers" with the penial canal, into which a great azygous accessory gland and another divided by a number of fine lamellæ discharge. Two chitinised air-sacs, spiked inside, are sunk in the genital organs and communicate with the outer part of the penial canal. The female organs are very simple. There is a large stalked organ, resembling the so-called "sucking-stomach" of Diptera, arising from the œsophagus; no such organ has hitherto been known among the Acarina. It is proposed to call it the "receptaculum cibi." The pharynx is exceptional in having a wholly flexible roof, instead of the chitinised one found in allied Acari. This involves numerous other modifications. The brain and nervous system are fully described. The respiratory organs consist of a long tubular air-sac on each side of the body, which gives off a multitude of fine unbranched tracheæ and communicates by a single tracheal trunk running along its exterior with the stigma by the mandibles. The salivary glands are very large and elaborate, but allied to the *Trombidium* type. The epipharynx is a highly specialised organ.

Chemists' Assistants' Association, April 30.—During the first half of the session an innovation was introduced by devoting one of the evenings to an inspection of the St. Pancras Electric Light Power Works. This was so much appreciated by the members and their friends that the Council arranged for a visit to

Messrs. Idris and Co.'s mineral water factories and laboratories in Pratt Street, Camden Town. About 160 availed themselves of the opportunity, among those present being Messrs. J. Moss, J. Ince, and several other well-known pharmacists. Readers of the Journal will doubtless be familiar with the exceptional manner in which every preparation is manufactured at these works, since an account of a visit of inspection was published in the *Ph. J.* Supplement for February 29 last. It may, however, be mentioned that, commencing at eight o'clock, the company were conducted in parties, each numbering about a score, through the various departments, the details being explained by members of the firm or by some prominent official. The ginger-beer brewery first claimed attention, after which those present wended their way through the water-tank gallery to the cordial and syrup departments, and thence to the analytical laboratories, where Dr. W. H. Symons, the chemical adviser to the firm, and Mr. F. R. Stephens, his assistant, did the honours. On leaving the laboratories the bottling and aerating departments were next shown, the different types of machinery being inspected with great interest. The section devoted to the preparation of show tablets and sand-glass blasting also received a visit, and much interest was shown in the various stages of these operations. Passing thence through the bottling room, the engine room with its extensive plant was seen, whilst last of all the buildings on the other side of the yard were visited in order to see the various stages necessitated in the fitting up of syphons, including the casting, finishing, and electroplating of the tops. After a glance at the stables, the whole party adjourned to the large warehouse, where Mr. T. H. W. Idris, J.P., L.C.C., the founder of the firm, gave a short but interesting account of its history. At the conclusion of this address, refreshments were served, which Messrs. Idris and Co. had been good enough to supply. This terminated an extremely pleasant evening, and the opportunity of inspecting a unique mineral water factory was much appreciated by every one present.

Royal Institution.—The annual meeting of the members of the Royal Institution of Great Britain was held on the 1st inst., Sir James Crichton-Browne presiding. The annual report of the committee of visitors for the year 1895, testifying to the continued prosperity and efficient management of the Institution, was read and adopted. The real and funded property now amounts to above 100,000*l.*, entirely derived from the contributions and donations of the members and of others appreciating the value of the work of the Institution. Seventy-two new members were elected in 1895. Sixty-three lectures and nineteen evening discourses were delivered in 1895. The books and pamphlets presented in 1895 amounted to about 260 volumes, making, with 594 volumes (including periodicals bound) purchased by the managers, a total of 854 volumes added to the library in the year. Thanks were voted to the President, Treasurer, and the Honorary Secretary, to the committees of managers and visitors, and to the professors, for their valuable services to the Institution during the past year.

The following gentlemen were unanimously elected as officers for the ensuing year:—President, The Duke of Northumberland, K.G.; Treasurer, Sir James Crichton-Browne, M.D., F.R.S.; Secretary, Sir Frederick Bramwell, Bart., D.C.L., F.R.S. Managers, Sir Frederick Abel Bart. K.C.B.; Sir Benjamin Baker, K.C.M.G.; Mr. John Wolfe Barry, C.B.; The Right Hon. Lord Halsbury; Mr. Charles Hawksley, M.Inst.C.E.; John Hopkinson, F.R.S.; Mr. Victor Horsley, F.R.S.; Mr. William Huggins, F.R.S.; The Right Hon. Lord Kelvin, F.R.S.; Mr. Alfred B. Kempe, F.R.S.; Mr. George Mathev, F.R.S.; Mr. Ludwig Mond, F.R.S.; Sir Andrew Noble, K.C.B., F.R.S.; The Right Hon. Earl Percy; Mr. Basil Woodd Smith, F.R.A.S. Visitors, Mr. Gerrard Ansdell, F.C.S.; Sir James Blyth, Bart.; Mr. Arthur Caromael, Sir William James Farrer, M.A., F.S.A.; Mr. Carl Haag, R.W.S.; Sir Francis Laking, M.D.; Mr. Hugh Leonard, M.Inst.C.E.; Mr. James Mansergh, M.Inst.C.E.; Mr. Lachlan Mackintosh Rate, M.A.; Mr. Felix Semon, M.D., F.R.C.P.; Mr. Henry Virtue Tebbs; Mr. John Isaac Thornycroft, F.R.S., M.Inst.C.E.; Mr. Thomas Tyrer, F.C.S., F.I.C.; Mr. John Westlake, Q.C., LL.D.; Mr. James Wimshurst.

A general monthly meeting of the members was held on the 4th inst., Sir James Crichton-Browne, M.D., F.R.S., Treasurer and Vice-President, presiding. The following were elected members:—Mr. J. H. Badcock, M.R.C.S., Mr. F. J. Bennett, Mr. Dugald Clerk, F.C.S., Dr. W. J. Gow, M.R.C.S., Mr. J. C. Graham, Mrs. E. Patten Jackson, Sir John Jackson, Lady Jackson, Mr. W. L. Jordan, Mr. J. W. Mackean, F.C.S., Mr. J. S. Mackintosh, Mr. J. Moeller, Dr.

Thomas Oliver, F.R.C.P., Sir Frederick Pollock, Bart., LL.D., Mr. Harry F. Pollock, M.P., Colonel Sir Charles Euan-Smith, K.C.B., Mr. James Swinburne, M.Inst.C.E., Mr. Arthur J. Walter, LL.B., and Mr. E. Weldon.

Midland Chemists' Assistants' Association.—The first annual meeting of the Midland Chemists' Assistants' Association was held on Wednesday evening, at the Exchange Rooms, Birmingham, Mr. T. C. Clarke, President in the chair. Mr. W. Bindloss (Hon. Sec.) read the annual report, which stated that notwithstanding that the Association was formed late in the past year, sixty-two members had been enrolled, including nine honorary members. In all twenty-one meetings had been held during the session, and considering that the Association was so young, the results had been satisfactory. The President moved the adoption of the report, and said that, considering all things, it was eminently satisfactory, and gave them encouragement to continue the work they had taken in hand. The report was adopted. The result of the scrutiny for the election of the Committee having been reported by Mr. Bland, the President delivered a valedictory address, and said that he vacated the chair with mingled feelings of reluctance and satisfaction. The most satisfactory feature they had before them was the fact that they had established themselves among the substantial and well-organised pharmacists of the country. He called their attention to the various valuable papers that had been read to the members during the session, and said that on the social side they had been most successful in establishing good-fellowship among the members. Although the finances were not as flourishing as they might wish, they were in a good position in view of the fact that that was the first year of their existence. He was strongly of opinion that if they had established such an association years ago they would not now be struggling with hardships they were battling with. In conclusion, he expressed his thanks to the officers and Committee for the cordial and liberal support they had accorded him during his term of office, and hoped his successor would be equally well supported. Mr. Casson, in moving a vote of thanks to the President, bore testimony to the excellent services he had rendered to the Association. Mr. Selby seconded the motion, which was carried with acclamation. The President said that what he had done had been to him a pleasure, and he was gratified to know that his services had been appreciated. On the proposition of the President, seconded by Mr. Lawton, a hearty vote of thanks was passed to the Honorary Secretaries (Messrs. Bindloss and Selby) for their valuable and devoted services. This was also carried with unanimity. Mr. Bindloss, in reply, said that the knowledge that their work had borne fruit was in itself a reward for anything they had done. The members of the new Committee are as follows:—Messrs. Clarke, Bindloss, Selby, Lawton, Jessop, Williams, Meggison, Boucher, Foster, Bland, Shorthouse, Osborne, Casson, and Featherstone.

SCOTTISH NEWS.

EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION—ANNUAL EXCURSION.—At the close of the meeting in connection with the Proprietary Articles Trade Association, held in 36, York Place, Edinburgh, on Friday, 1st inst. (see page 375), Mr. McLaren intimated that it was proposed this year to hold the annual excursion in the west. The proposal was to take the train to Cra'gendorran, boat to Arrochar, walk or coach to Tarbet, dine and tea there, then take steamer over Loch Lomond to Balloch, and return by way of Stirling and Forth Bridge. After Mr. Boa had asked what would be the most suitable date it was agreed to report to the Association that Wednesday, June 17, would be suitable.

PRESCRIBING PROPRIETARY MEDICINES.—At a meeting of the Glasgow Parish Council on Tuesday, the inspector, Mr. Dempster, reported that, as instructed at last meeting, he had written to Dr. Fortune for an explanation as to prescribing proprietary medicines, and a reply had been received to the effect that he had been under the impression that the recommendation was not intended to be absolute, or most certainly he would not have prescribed it. The members of the Medical Committee expressed themselves as satisfied with the explanation, and as the doctor appeared now to understand the position, the inspector was instructed to write to him intimating the Committee's acceptance of his explanation.

PROPRIETARY ARTICLES TRADE ASSOCIATION

MEETING AT EDINBURGH.

A meeting of chemists and druggists in Edinburgh and district was held on Friday, May 1, in the Pharmaceutical Society's house, 36, York Place, Edinburgh, to hear the statements of a deputation from the Proprietary Articles Association, with the view of securing an increased membership. The deputation consisted of Mr. G. R. Barclay, London; Mr. Glyn-Jones, Secretary; Mr. J. Norris (Condal Water Company); Mr. C. H. Corbett (Stephen Smith and Co.); Mr. J. Cameron (Liebig's Extract of Meat Company), and Mr. J. R. Robertson (Bovril, Limited). There was a large attendance of chemists and others.

Mr. Peter Boa, Chairman of the Edinburgh and District Chemists' Trade Association, explained the origin of the meeting. He said they were all aware that an association had been started in London called the Proprietary Articles Trade Association, the object of which was to prevent extreme cutting of prices. The Secretary of that Association, Mr. Glyn-Jones, had entered into communication with Mr. C. F. Henry, their Secretary, as to calling a meeting of their Association to consider the matter. While their Committee thought they might reasonably have a meeting to hear what Mr. Glyn-Jones and his colleagues had to say, they felt that as the regulation of prices was a matter which their Association had agreed not to take up, it was a question with which they could not directly associate themselves. But many of them thought it was a matter of some interest to the trade, and that it might be well to afford Mr. Glyn-Jones an opportunity of explaining the objects of his Association to the members of the trade as such and outside the Association, and therefore this meeting had been convened. He had pleasure in proposing that Mr. Barclay should take the chair.

Mr. Barclay, on taking the chair, said he felt certain that if he chanced to ask any one who was in business touch with the great bulk of the trade in this country whether chemists on the average were advancing financially in the same ratio as they were educationally, he would be told that they were not. The reason of that was the insane cutting of prices that was going on. He did not think any one would dispute the use of the adjective "insane" because the cutting of prices benefited no one except the public. The trader who began cutting did not benefit very long, because in a very short time other traders adopted the same prices. This meeting had been convened to give the Proprietary Articles Trade Association an opportunity of laying its views before them. It had been urged in some quarters, and he had seen it in the trade papers, that it was ridiculous for them to go about the country holding these trade meetings, and that if chemists did not see it to be to their advantage and interest to support this Association they should leave the matter alone. He felt sure that was a mistake. There was an enemy at their gates in the shape of the drug stores which were spread all over the country, and unless they combined together to fight shoulder to shoulder against them they could not do anything. Here was an organisation already formed. They asked them to enrol themselves under its banner, and if they did not achieve success they would not have themselves to blame.

Mr. C. F. Henry stated that he had received a large number of apologies from chemists and druggists in Edinburgh and the surrounding district. They said they would have liked to hear Mr. Glyn-Jones explain the aims and objects of the Association. Eighteen expressed their approval of it, one or two said they would abide by the result of the meeting, and two did not express any decided opinion on the matter.

Mr. Glyn-Jones, having thanked the Edinburgh and District Chemists' Trade Association and Mr. Henry, their Secretary, for the very valuable help they had given in arranging for that meeting, stated that the new association was made up of business men engaged in the manufacture and distribution of proprietary articles. It arose, and he wanted specially to enforce this point, in the retail trade. A few retail chemists who met together were agreed that there was a grievance, and thought there was a way out of it, or, at any rate, a way of minimising it to a very large extent. He described the steps they had taken in approaching the wholesale houses and manufacturers in London, the result of which was that an association had been formed which included all the wholesale houses in London but two. He had no doubt, when they had an opportunity of laying the thing before the other well-known houses in the country that they would have no difficulty in getting their co-operation. He further explained the constitution of the Council of the Association, and with regard to its objects he said the chief was the

prevention of cutting and of what they knew to be a result of cutting, namely substitution. That was an object with which he believed every pharmacist was in sympathy, but as business men they wanted to know what chance there was of success. Mr. Barclay had said they had got an enemy at their gate—he was going to say that they as retailers had the enemy almost in their bedrooms—and they had got to deal with him. Their main ground-work was based on this, that manufacturers might put a good or bad proprietary article in the market, and by advertising create a demand for it, but they could not distribute it, and they could not expect any one else to distribute it for nothing. As a matter of fact there were people who were distributing these goods if not for nothing at any rate for an absurdly inadequate profit. A man ought to have something else to do than keep open shop for the sale of proprietary articles at 5 per cent. or less profit. And that was the crux of the whole business. When the drug stores were first started the manufacturers thought they could turn their backs on the ordinary chemists. But they were finding out that they were suffering from substitution, for the drug store made a business on the reputation of these proprietary articles, and then became manufacturers on their own account. Mr. Glyn-Jones then explained how it was proposed to attempt to put a stop to the cutting of prices, by the manufacturer or wholesale trader getting the retailer's signature binding him not to sell the article below a certain price, the penalty of infringement being that the supplies would be stopped. They had got the opinion of counsel that such an agreement could be enforced, and he was satisfied that it would be effectual. This was a question that affected every pharmacist. There could be no doubt about the proprietary medicine trade being their trade in a moral, if not in a legal, sense, and he warned them that if they did not take action the stores would not stop at cutting prices there, but would cut prices in the dispensing department also. Personally, as a pharmacist, he would be very glad if there were no proprietary medicines, but he recognised the fact, much as he disliked it, that so long as they were advertised, so long would there be a demand for them, and he wished to make money by meeting that demand if he could. He concluded by urging those present to support the movement by becoming members of the Association.

The Chairman stated that in order to put any discussion which might follow in order, he would ask them to move and second the following resolution:—

"That this meeting of chemists in Edinburgh and District pledges itself to support the Proprietary Articles Trade Association, and urges upon all manufacturers of proprietary articles the importance of co-operating in the movement."

Mr. David McLaren, Edinburgh, said he would move the adoption of the resolution, and would only say he thought it was a step in the right direction.

Mr. McDougal, Leith, seconded, and

Mr. Norris (Condal Water Company) spoke in support of the proposed resolution, urging the necessity for co-operation between traders and manufacturers. He said Pears' Soap Company had written to him saying they had no sympathy with this movement, and they seemed to have an idea that the cheaper their soap was sold the better it would be for them, because their profit was not interfered with. As at present situated, their Association had not power to go to Pears' Soap and use persuasive or coercive measures, because they were not strong enough. It was only by the support of local chemists that in due time they would be able to exercise an influence over such firms.

Mr. Morison, Edinburgh, asked how the proposed scheme would work with reference to co-operative stores.

Mr. C. F. Henry said that under their present agreements the manufacturers gave too little profit to the retailers, and he wished to know what profit the Association proposed to give them, would they guarantee a profit of 20 or 25 per cent.? How was the Association to trace an article sold, say, at Manchester, by a professional and civil service store or any drug store in order to stop the supply? And was there any idea of putting a price on the article other than the face price, and maintaining it as the price which should be charged to the public by all parties.

Mr. McGlashan, Edinburgh, asked what the Association would do in the case of a man selling an article under price, and increasing his business very much by advertising to the public that his neighbours had boycotted him and got his supplies stopped for selling at a fair profit?

Mr. Wylie, Edinburgh, expressed the opinion that the only scheme

that would be satisfactory was to keep to the face price of the article.

Mr. Mackenzie asked if it was proposed to work this Association alongside the Grocers' Federation.

Mr. Glyn-Jones, in answering the questions, said—with reference to co-operative stores—that there was a serious difficulty with them, and it wanted looking at from different standpoints. They said that to sell an article at a shilling, and afterwards to give a dividend or bonus back, was really cutting. They would ask manufacturers to make the stores understand that upon protected articles they would not be able to give a dividend, or that in the first instance such a price would be charged for the article that when the dividend was taken off it would bring it down to the same value. The manufacturer had to decide between the legitimate trade and the cutters. They recognised the importance of not tying the individual trader's hands and allowing the co-operative stores to go unfettered. If the fox-terrier was to be muzzled, the collie would have to be the same. The next question was in regard to the amount of profit. He was very glad Mr. Henry had mentioned it. They, as an Association, were not responsible in any way for the amount of profit guaranteed in the past by the firms connected with their Association. But there would have to be a division of proprietary articles, if he might so put it. They had articles of a medicinal character—goods upon which they should get a larger profit than goods which had a very much more considerable demand. They recognised, too, that there were luxuries, and the question of the selling price of such articles might be matter for serious consideration. But, in his opinion, a fair profit upon proprietary medicines should be not less than 20 or, if possible, 25 per cent. There were proprietors who had told him they did not care a snap of the finger for the retail trade, or in other words, that retailers were so many automatic slot machines into which people put their money and got out what they wanted. But they had their rents to pay and their premises to keep up, and they did not intend to get their linoleum wasted if they could not make a profit off these articles. With regard to the tracing of those who might sell an article under the regular price, that was a more simple matter than might be supposed, and he described the method of numbering adopted by Elliman's embrocation. As to the question of face prices, he said he had, up till now, been speaking as the Secretary of the Association, and he could not pledge it to this matter, but speaking as a retail chemist, he would say that the price was going to be what retailers made it. If the bulk of the retailers combined, they could enforce almost any commission they liked. That was a broad statement, but he made it advisedly. Whatever they did, they should not have two prices to the public. With regard to the point raised by Mr. McGlashan, he said the public was not unreasonable, and he did not think that in these days it would do any trader good if the manufacturers decided to do this and refused to supply them. The Association, he said, was prepared to work with the Grocers' Federation in this matter, and chemists might very well take an example from that Federation.

In answer to Mr. McLaren, Mr. Glyn-Jones said they had had a conference with a committee of the Grocers' Federation, which was appointed to meet them. The grocers had full sympathy with the chemists and stated that they would report to their annual conference at Cardiff.

The resolution was unanimously agreed to.

Mr. Peter Boa then moved—

"That a trade committee of Edinburgh and District chemists be appointed to act with the Proprietary Articles Trade Association."

Mr. C. F. Henry seconded, and said it was not for want of sympathy that the committee of their Association could not see their way to act. They did sympathise, but by their rules they were so far limited in their operations. They were a committee interesting themselves in trade matters, but they were scarcely a trading committee, and they had not as yet touched the question of trade prices.

The resolution was adopted.

Mr. Barclay moved a vote of thanks to the Pharmaceutical Society and Mr. Hall for the facilities they had granted for holding that meeting there.

Mr. C. H. Corbett seconded, and this resolution was also agreed to.

Mr. McLaren said he was in hearty sympathy with this movement, but there was just a danger of overstepping the bounds of discretion with regard to the question of co-operative stores, and he mentioned an instance where a manufacturer stopped supplies to a grocer who advertised 2½ per cent. discount for cash accounts

of 5s. and upwards, while he continued the supplies to the co-operative store, who gave a 15 to 20 per cent. dividend. He thought both should have been supplied on the same terms.

Mr. Glyn-Jones said it was recognised that this matter was one which it would have been impossible for the Pharmaceutical Society to take up; but they were exceedingly obliged to them for the support that had been given them. He stated that there were two new members of the Council of the Pharmaceutical Society to be elected, and as no Scotchman had been nominated he asked the meeting to support the nomination of Mr. Park, Plymouth, and Mr. Campkin, Cambridge, both of whom were members of the Proprietary Articles Trade Association.

MEETING AT BRADFORD.

A meeting of the chemists of Bradford and the neighbourhood, promoted by the council of the Bradford Chemists' Association, at the request of the Proprietary Articles Trade Association, was held in the saloon of the Mechanics' Institute, Bradford, on Wednesday evening last. There was a capital attendance. Mr. E. Mackay officiated as Chairman, and he was supported by Mr. Geo. Rimmington and County Alderman H. Dunn (vice-presidents), R. W. Silson (treasurer), S. Norman Pickard (hon. sec.), and Messrs. A. Knight, J. M. Newbould, T. Stead, F. K. Taylor, and A. H. Waddington, members of the council; Messrs. W. Simpson (Liebig's Extract of Meat Company), W. S. Norris (Condal Waters Co., Ltd.), J. F. Garratt (Frog in your Throat), F. Hoy (Bovril, Ltd.), and W. S. Glyn-Jones (secretary of the Proprietary Articles Trade Association); and Messrs. Pollard (vice-president), H. W. Seeley (sec.), Geo. Cobb (treasurer), and Councillor J. H. Wilson, of the Halifax Association; Messrs. Chaplin, Green, Duffin, and Pollard, Wakefield; Mr. Hirst (Hirst, Brook, and Hirst), Leeds; and others.

The Chairman said that with respect to anti-cutting he would just like to say he thought they were all at one in regard to that object. That was something. It was time something was done for the benefit of the trade all round. He did not suppose they would agree on other points. There was a time for everything, and he was of opinion that the time was now ripe for them to take this movement in hand. No doubt there were many of them who would say this ought to have been done before. Well, they all knew it ought to have been done before, but it had not been done, and there were perhaps reasons for the delay. They did not all understand why it was that the proprietor had kept aloof from the chemists. The chemists had followed the lines they had done because they thought they had been forced to do it. He referred to the power of the proprietor, and went on to commend this movement and the ability of Mr. Jones as Secretary. The chemists, he said, felt that they had not been treated for the last twenty years as they ought to have been. They must all pull together in effecting an improvement. They ought to be in a position to take a happy middle course, neither prescribing proprietary medicines, as was the practice of his old master, nor pushing anything rather than proprietary medicines.

A number of letters of apology were read by the Secretary, one of them from Mr. Geo. Walker, Dewsbury, being as follows:—"I am quite in sympathy with the object in trying to put a stop to the extreme cutting, and I think chemists have been backward so far in supporting you because you have only just now put forward a practical scheme."

Mr. Glyn-Jones then proceeded to explain the object of the Association and its series of meetings, and his remarks were very heartily appreciated. He read a list of proprietors who were prepared to fall in with the proposals of the Association.

Mr. Silson moved: "That this meeting of chemists residing in Bradford and district, having heard the report of the Proprietary Articles Trade Association, pledges itself to support that organisation, and urges upon all manufacturers the importance of at once assisting in the movement." He said that in coming to the meeting he had been cheered or consoled with the thought that whatever happened to the trade they could not possibly get any worse.

Mr. Wilson (Harrogate) seconded the motion, and after a brief discussion the motion was adopted with enthusiasm.

County Alderman Dunn (Shipley), moved that the members of the Bradford Association should act as a local executive in conjunction with the P.A.T.A.

Mr. Herbert Rogerson seconded the motion, which was carried.

Votes of thanks concluded the proceedings.

MEETING AT LEEDS.

On Tuesday evening a meeting of the registered chemists and druggists of Leeds and District was held at the Law Institute to receive a deputation from the Proprietary Articles Trade Association.

Apologies for non-attendance and expressing sympathy were received from Messrs. S. Taylor, E. Yewdall, W. Johnson, R. H. Smith, N. Armstrong, W. N. Armstrong, and W. Jones, Chairman of the Birmingham Trades Committee. Amongst those present were Councillor Hebden, Chairman, and Mr. Seeley, Secretary, of the Halifax Association, and Mr. Mackey, President, Mr. Pickard, Secretary, and Mr. Dunn, Vice-President of the Bradford Association; Mr. Frank Floy (Bovril, Ltd.), Mr. Simpson (Liebig's Extract of Meat Co.), Mr. Corbett (Hall's Coca Wine), Mr. H. S. Norris (Condal Water Co.), Mr. Hirst (member of Council), Mr. Norris (Bovril, Ltd.), Messrs. G. W. Worford, R. Reynolds, G. Ward, B. Hirst, F. W. Branson, James Fawthrop, R. Furniss, T. W. Fawcett, — Reindhardt, — Metcalfe, — Hardman, — Crosby etc., Leeds; — Maud, Pontefract; — Wilson, Harrogate; — Hebden, Halifax; — Dunn, Shipley, etc. Altogether, there were about forty present.

Mr. G. Ward (Hirst, Brook, and Hirst, Leeds) was, on the motion of Mr. Reynolds, voted to the chair, and in opening the proceedings said the object of meeting together was to hear what the representatives of the Association had to lay before them with regard to its objects. He hardly thought there would be amongst chemists two opinions as to the desirability of bringing about a modification of the present system. The state of things was now such that proprietary articles were scarcely worth handling from a commercial point of view. During 25 years there had been a very large reduction in the retail prices at which these articles were sold. Prices were being cut in a manner which was simply suicidal. Unfortunately this state of things was maintained not only amongst retail chemists, but it existed to some extent in wholesale houses. In some cases, far from there being a profit there was an actual loss. Under these circumstances it was considered that something should be done, if anything could be done, to put a stop to this condition of business. Manufacturers were beginning to feel that it was imperative they should take action in the matter; in fact, he believed the first initiative in this movement came from the manufacturers. It was the first time the matter had been approached from this aspect, and if any practical method could be devised to combat the evil, it would be greatly to the benefit of everyone, and the retailers, the wholesale houses, and the manufacturers should combine to bring it about.

Mr. Glyn-Jones (Secretary of the Proprietary Articles Trade Association) explained the constitution of the Association, which he said comprised retailers, wholesalers, and proprietors, and said there was now quite a formidable array of wholesalers who had promised to join; in fact, so far only two wholesale houses had not gone in with the movement in London, and they were only playing a waiting game. He then proceeded to explain the constitution of the governing body of the Society, and also its objects, the latter chiefly relating to the prevention of "cutting."

Mr. Reynolds thought if the retail trade had tried to carry out this scheme alone, the case would have been perfectly hopeless. It would have been impossible for retailers to carry it through unaided, but when he found the head men in the business taking it up, he felt there was something in the prospect of such Associations existing successfully. From the list of names of those who had joined the scheme, they would see that a large body of influential men favoured the scheme, and were convinced they were not wasting their time, and that the thing deserved to be tried. He moved "That this meeting of registered chemists residing in Leeds and neighbourhood, having heard the objects and proposals of the Proprietary Articles Trade Association, considers they are worthy of support by chemists generally, and would urge upon all manufacturers and wholesale distributors the importance of assisting the movement in bringing about some modification in the present system."

Mr. Well (Ilkley) seconded this, and after some discussion, the resolution was put and carried unanimously.

Votes of thanks to the Chairman and the members of the deputation closed the proceedings.

PROCEEDINGS UNDER THE PHARMACY ACT.

SALE OF LAUDANUM BY AN UNREGISTERED PERSON.

At the Clerkenwell County Court, on the 6th inst., before His Honour Judge Meadows White, the Council of the Pharmaceutical Society of Great Britain sued James Thomas Thorne, of 117, Lever Street, St. Luke's, E.C., for two penalties of £5 each, for selling, or keeping open shop for the retailing, dispensing, or compounding of, poison on December 5 and 14, 1895.

Mr. T. R. Grey, instructed by Flux, Thompson and Flux, appeared for the Council. Mr. Yelverton, instructed by Mr. E. F. Weldon, defended.

Mr. Grey stated that defendant carried on a business at 117, Lever Street, where a witness, instructed on behalf of the Society did, on the 5th and 14th days of December, purchase laudanum, one of the poisons included in the Schedule to the Pharmacy Act, 1868. Defendant did not possess the qualification requisite to entitle him to carry on the business of a chemist and druggist, and was consequently an offender against the Statute. Not only had the purchases been made at defendant's shop, but the defendant, who was a man of colour, had himself sold the poison. He referred to the section of the Act by which the selling and keeping open shop for the retailing of poison by an unregistered person were made offences, and quoted decisions of the superior courts in support of his contention that defendant had rendered himself liable under each class of offence.

John Partridge, examined by Mr. Grey, proved that on December 5, 1895, he went to 117, Lever Street and purchased twopennyworth of laudanum and twopennyworth of soap liniment, and was served by defendant. He visited the shop again on December 14 and made a similar purchase, defendant serving him. He identified defendant, a black man, as the person who served him on each occasion. He purchased some other articles, upon the wrappers of which the premises were described as "The Surgery, 117, Lever Street, E.C."

Cross-examined by Mr. Yelverton: I asked defendant for laudanum and soap liniment mixed. He took them from two bottles in my presence and mixed them before giving them to me. In the window there were some bottles and a number of articles exposed for sale. On both days I went about the same time in the afternoon. I swear that I kept the bottles locked up until I handed them to Mr. Eastes. I made an entry of the purchases in my book.

Mr. E. J. Eastes, F.I.C., examined by Mr. Grey: I received the bottles from Mr. Partridge; they were sealed up. Bottle No. 1 contained 1 oz. 7 drachms of fluid. Upon analysis, I found, among other ingredients, a preparation of opium; it contained 1.1 grain of morphine, or 11 grains of opium. Bottle No. 2 contained 1 oz. and 3 drachms of fluid. Upon analysis, I found it to contain 1.9 grain of morphine, or 19 grains of opium, Pharmacopœia strength.

Mr. Yelverton, for the defendant, admitted that defendant resided at 117, Lever Street, and that his name was not on the Register of Chemists and Druggists, and he was only a medical student. He contended that the plaintiffs had not attempted to show that there had been a general sale by defendant at his premises, and that defendant's premises were a private house and not a shop, and plaintiffs had failed to prove that he kept an open shop within the meaning of the Act. He could not contend that the evidence of the analyst did not show a sufficient quantity of poison to bring the mixture within the Act, but defendant denied either selling or keeping a shop wherein he sold laudanum, and he should prove that Dr. Thorne, defendant's brother, served the witness on December 5, and that on the other date defendant was away, and could not have served the witness.

James Thomas Thorne, examined by Mr. Yelverton: I am a medical student of the Aberdeen University. I reside at 117, Lever Street, St. Luke's. I have passed first and second examinations for M.D. I do not keep an open shop. I was out on December 14. My sister-in-law was in charge. My brother is M.D. of Edinburgh. I was at the British Museum on the 14th. I am certain I did not serve Partridge on that day with anything. On December 5, might have been in house. I did not sell any laudanum. I do not remember Partridge coming on December 5. I do not sell scheduled poisons.

Cross-examined by Mr. Grey: I am not a legally qualified medical practitioner. I have not passed any examination under the Pharmacy Act. The shop or surgery belongs to me. There is a glass tablet in the window bearing the words "prescriptions dispensed." I make up eye-washes, etc. I keep laudanum in the shop in case of emergency. If any one comes to me in extreme

pain and I cannot relieve them by any other means, I use the laudanum. I make a charge if the person can afford to pay it. I bought labels similar to those on bottles from a traveller. I should say the liquorice powder and jalap came from my shop. If I am out my sister-in-law looks after the place. In the window are exhibited glycerin and cucumber and other articles for sale. If I am not in my sister-in-law sells.

Florence M. Thorne, examined by Mr. Yelverton: I am the wife of Dr. Albert Thorne, M.B., of Edinburgh. He is a coloured gentleman; he is practising in Edinburgh. I arrived at 117, Lever Street with my husband on November 24 last. Never saw Partridge before to-day. Had recollection of a woman asking for laudanum on December 14. She was not supplied. On December 14 defendant gave me directions not to sell laudanum. My husband is in Edinburgh. He is so much like his brother that it is difficult to tell one from the other.

Cross-examined by Mr. Grey: Never went into the surgery until December 14.

Mr. Grey submitted that there was abundant evidence that defendant kept open shop, and that he had sold the poison himself.

His Honour, after reviewing the evidence, said: Nothing can be clearer than that this is a shop where anything is sold to persons who choose to buy them; the evidence of defendant and Mrs. Thorne is conclusive that it is a place where drugs are sold—that there was a sale of poison on two occasions is absolutely clear, if I believe Partridge. Partridge has his memorandum book in which he made an entry of what he bought. He says he locked up the purchases, and reported, as was his duty, to the Society. I accept his evidence. It is quite clear to me that defendant is the person who keeps the shop. The whole question is reduced to one of fact, and I am of opinion that defendant himself sold, and I am sure if it had been otherwise his brother would have been here. I am sorry to say it, I do not believe all that Mrs. Thorne has said. In my opinion the case is so clear that I feel no hesitation whatever, and am of opinion that both the penalties claimed have been incurred, and there must be judgment for the plaintiffs for the two penalties and costs.

Mr. Yelverton applied for leave to appeal.

His Honour: It is a question of fact. I have found the facts against you, and I must decline to give you leave to appeal.

LEGAL REPORT.

SALE OF A CHEMIST'S BUSINESS.

The action of Green v. Williams, which was tried on Monday, the 4th inst., before Mr. Justice Lawrance and a Common Jury, was brought to recover damages for breach of agreement to purchase a chemist's business carried on at 38, Heath Street, Hampstead, for £375. The defendant admitted that he entered into the agreement, but said he was induced to do so by the fraudulent misrepresentations of the plaintiff, and by way of counter-claim he sought to recover damages for the loss he had sustained. The plaintiff denied the fraudulent representations. Mr. McIntyre said the plaintiff, Mr. John Henry Green, who had for some years carried on the business in question, being desirous of parting with it, put it in the hands of Messrs. Judd and Manners, and gave them certain information which they wrote down. The business remained on their books till October or November, 1895, when Mr. Williams made inquiries about it. The takings were represented as being £706 in 1894, £759 in 1893, and £705 in 1892, but he was advised to make his own inquiries. The price asked was £500. Mr. Williams after making inquiries wrote to Judd and Manners that the house and shop were in a bad way, that the shop was lightly stocked, that the takings were only £10 a week, and concluded by making an offer of £350 for the business. This offer was declined, and, after some negotiation, an offer of £375 was accepted, and a deposit paid. The defendant also ordered and paid for stock, and had new labels printed, but ultimately declined to complete, alleging that the takings had been misrepresented, though, according to letters written at the time, it appeared that he was unable to find the money. Ultimately the business was sold by tender for £120. Evidence having been given in support of the plaintiff's case, the defendant, Mr. Stephen Williams, deposed that he entered into the contract relying on the statement that the takings were over £700 a year, which was not true.—Mr. Abel Thomas, Q.C., and Mr. Bowen appeared for the defendant.—In the result the Jury found for the plaintiff for £229 18s., less £64 0s. 11d., the amount paid by way of deposit and for goods supplied.—His Lordship entered judgment for the plaintiff for £165 17s. 1d.

CORRESPONDENCE.

SYRUP OF CAMPHOR.

Sir,—In reply to your request in the Journal of last week, I wish to state that from 1863 to February, 1875, the Bristol Royal Infirmary syrupus camphoræ compositus was prepared according to the following formula, which was published in the 'Infirmary Pharmacopœia' in 1871:—

Syr. Camphoræ Co.

℞ Syrupi Opii	ʒi.
Træ. Camphoræ Co.....	ʒii.
Oxymellis Scillæ	ʒvi.

M. Dose: One teaspoonful occasionally.

Syr. Opii.

℞ Opii	ʒv.
Sacchari non-purificati	lbs. 112.
Aquæ	ad Cong. xii.

Dissolve the opium in one gallon of boiling water, and mix with the remainder when cold.

This is the preparation sold by most chemists as the Bristol Royal Infirmary syrup of camphor.

The following is the correct formula of the syrup of camphor we now prepare and supply to our patients, and with the exception of a slight alteration in the form published in 1882, by which we save a quantity of spirit of wine in the course of a year, the recipe has been the same since the change was made in 1875:—

Syrupus Camphoræ Compositus.

℞ Acidi Benzoici	ʒiiij.
Acidi Acetici Glacialis	ʒiiij. ʒv. ℥xx.
Aceti Scillæ B.P.	ʒxl.
Aceti Ipecacuanha (B.P. Additions)	ʒxl.
Olei Anisi	ʒij.
Camphoræ.....	ʒij.
Tincturæ Opii. B.P.	ʒx. ʒv. ℥xx.
Sacchari Albi (cryst.)	lb. 28.
*Sacchari Usti.	ʒs.
Aquæ Destillatæ	ad Cong. iv.

Misce.

ʒj. fl. contains one minim of Træ. Opii.

Dose:—One teaspoonful occasionally.

* Sufficient to give the mixture the colour of Træ. Camphoræ Co. B.P.

Some chemists colour it pale-straw, others dark brown, and I have seen it exposed for sale in chemists' windows as black as tra. catechu.

Bristol, May 4, 1896.

F. J. KILNER, F.C.S.,
21 years Dispenser to the Bristol
Royal Infirmary.

Mr. GEORGE STEVENS, of Liverpool, sent the following variant on the formula for syrupus camphoræ compositus last week, but pressure of matter prevented its immediate publication:—

Syrup Camph. Co.—(Bristol Royal Infirmary).

℞ Tinct. Camph. Co.	ʒv.
Oxymel. Scillæ	ʒxxv.
*Syrup Opii	ʒxxx.

M.

*Syrup Opii.

℞ Tinct. Opii	℥xv.
Syrupi	ʒi.

M.

* * The marked differences in the formulæ sent clearly indicated the advisability of publishing an authoritative expression of opinion on the subject, and thanks are due to Mr. Kilner for the information so promptly and fully given in his letter. [Ed. Pharm. Journ.]

ILLEGIBLE HANDWRITING.

Sir,—After pondering over the order sent you by "X" my rendering is "Please let George have fol. boldo ʒss." I received the following order the other day, written in a very plain hand, "1 oz. epileptic wine." This was a poser; I asked the lady who brought it in to read it over, when the sound she gave it immediately suggested eucalyptus oil, and this I found on further inquiry to be correct. Can any of your readers hit the mark? "BOLDO."

Aberdeen, April 27, 1896.

THE TESTING OF LEMON OIL.

Sir,—The letter from Mr. Umney with reference to the determination of citral in lemon oil calls for some reply from me, although as yet my experiments have not enabled me to clear up all the points raised. The real questions at issue appear to be the following:—First, does lemon oil contain bodies of an "alcoholiform" character, *i.e.*, capable of fixing the acetyl group when acetylated in the usual way (before reduction)? And, secondly, is citral capable of reduction to its corresponding alcohol (geraniol) and determination by conversion of that alcohol into its acetic ester? If the first were true it would necessitate some such correction as Mr. Umney suggests, though I know of no evidence of the existence of such bodies in the work already done on lemon oil. In some preliminary experiments made with a view to answering this question, I have been able to confirm Mr. Umney's statement that a certain amount of alkali-absorbing bodies is formed on acetylation only of lemon oil, and further experiments made with a solution of pure citral in limonene led to the interesting observation that on acetylating such a solution and well washing the resulting oil, a saponification with standard alkali showed an absorption of alkali (approximately) equal to one molecular equivalent of acetic acid for each molecule of citral taken.

In order to ascertain if a new acid or anhydride were formed, as in Perkin's synthesis (although this seemed on the face of it improbable on account of the perfect neutrality of the oil before saponification), the potassium salt formed was examined as follows:—Sulphuric acid was added in excess with some silver sulphate to get rid of chloride, and the volatile acid distilled with steam till the distillate was no longer acid. The distillate was converted into the sodium salt, which gave all the reactions of acetate, though a small quantity of an oily acid appeared to be present. To make certain it was converted into the silver salt, and the latter analysed. It contained 62.57 per cent. of silver. Silver acetate contains 64.67 per cent. It would appear, then, that in some way or other, possibly by first undergoing some isomeric change, citral has the property of combining with the acetyl group. I hope, however, to ascertain the exact nature of the change which occurs, as well as the behaviour of the aldehyde citronellal under similar conditions. I am much indebted to Mr. Umney for his kindness and courtesy in placing at my disposal the facts and figures he has already obtained.

As to the second point, there is no doubt that geraniol can be quantitatively determined by means of its acetic ester, and as to whether it is formed quantitatively on reduction of citral with sodium I had relied on published statements (see references in my paper), merely endeavouring to check results by quantitative experiments with known amounts of citral, the amount of alcohol formed on reduction being determined as stated. Even if the figures I have obtained are not absolutely true, there seems no reason to doubt that the process gives useful and at least comparative results. It is greatly to be regretted if, as Mr. Umney suspects, recent chemical discoveries have in this case only been the means of enabling unscrupulous dealers to sophisticate inferior oils so as to bring them up to a high "citral value." If true, it only emphasises the necessity of a complete physical, as well as chemical, examination of the oil.

London, May 5, 1896.

H. GARNETT.

CO-OPERATION—A REMEDY FOR LOW PRICES.

Sir,—In fulfilment of my promise in my letter of April (*ante*, p. 299) to report on the replies received, I beg to state that out of correspondence emanating from all parts of the country the following plan has been selected as being the most workable:—

Name.—Chemists' Direct Supply Co., Ltd.

Working Capital.—Not less than £10,000 in shares of £5 each, saleable to chemists in business only. One-third part of the nett profits to go as dividend on the original shares and the remainder as bonus to customers in proportion to their purchases in drugs and sundries.

Manufactory in London, with distributing centres in Manchester and Edinburgh.

Objects.—To supply to registered chemists in business only drugs, druggists' sundries, and proprietary medicines for cash or very short credit at manufacturers' cost prices, plus the expenses of their efficient and prompt distribution, thereby ensuring the following advantages:—

(1). This company's drugs would be guaranteed strictly B.P. when so denoted, and if otherwise than B.P. their composition would be stated on the label, so that chemists would know exactly what they

were buying, which is not always the case at present (*e.g.*, mag. cit. eff., and tr. rhei co.).

(2). It is thought that the busy chemist will have less necessity to make his own preparations, knowing full well that his own company is producing them of undoubted quality at the lowest possible prices.

(3). Wholesale houses are not always manufacturers of articles they might make with advantage, and thus the chemist may have to pay several profits before his goods reach him, which would be greatly diminished under this company.

(4). If a large number of chemists combine the company would be larger, and therefore a more economical buyer than private firms.

(5). Proprietary medicines would be supplied to subscribers dealing with the company for drugs and druggists' sundries at manufacturers' lowest prices.

(6). Copyrighted proprietary articles, well put up, and when necessary put up in two styles, to suit rich and poor neighbourhoods, would be brought out by the company and be rigidly protected from cutting. It is thought that these proprietaries, bearing a large profit and being judiciously pushed by means of handbills supplied with them, will in time command a good sale and come into general use, and so largely replace the flood of profitless "patents" now in the market. A chemist would thus have a better selection of profitable proprietaries, augmenting rather than replacing his own, without the risk of the initial expense.

(7). Free delivery of goods.

(8). If this company was successful it would make clear to chemists what could be gained by combination and united effort, and might induce them to support the Pharmaceutical Society better than at present with a view to the improvement of pharmacy by legislation.

From reliable sources it is estimated that if 1000 chemists in business join this company and give it their entire support, their saving in the purchase of drugs and sundries will be about thirty per cent. off what they now pay, and they will also be able to procure their patents at bottom prices. The prices charged by the company, as set forth in their published list, would be those of an average wholesale house, and the usual discounts would be allowed, making a total discount of thirty to forty per cent. I should be glad to see the above scheme criticised, and perhaps some of the chemists' local associations may think it worth discussion.

95, Waller Road, New Cross Gate, S.E.

G. T. COOPER.

May 7, 1896.

ANSWERS.

"LUPULUS."—No harm is likely to be caused by taking it regularly for a few weeks, but, as in the case of other tonics, its beneficial effects will tend to diminish if its use be continued too long, and there would also be risk of gastric derangement.

"NUX VOM."—There is no pharmacy law in the Isle of Man, and anyone may open a shop there as a chemist and druggist.

"ASSOCIATE."—No. 1. *Carex sylvatica*; No. 2. *C. vulgaris*. Please note that specimens of this genus should always be sent in fruit, when identification is required.

OBITUARY.

GREAVES.—On April 20, F. W. Greaves, Chemist and Druggist, late of Ashbourne, (Aged 64)

LINNELL.—On April 6, T. J. Linnell, Chemist and Druggist, Southwark. (Aged 63.)

UPJOHN.—On April 10, F. W. Upjohn, Chemist and Druggist, late Bathurst Street, W. (Aged 53.)

TERRY.—On April 13, Thomas Terry, Chemist and Druggist, Withington. (Aged 58.)

HUTTON.—On April 27, William Hutton, Chemist and Druggist, Portobello. (Aged 41.)

HART.—On April 30, James Hart, Pharmaceutical Chemist, Manchester. (Aged 48.)

YORATH.—On May 3, Thomas Vaughan Yorath, Chemist and Druggist, Cardiff. (Aged 60.) Mr. Yorath was in business before August 1, 1868, and retired about two years ago. He was an Alderman of the Cardiff County Council.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Bindloss, Callis, Heathcote, Henry, Hill, Hudson, Reynolds, Stevens, Stewart.

ALCHEMY AND PHARMACY. THEIR MYSTERY AND ROMANCE.

CHAPTER VIII.

Superstition and its Influence on Medicine.—Love Philtres.

Superstition is a belief in what is wholly opposite to the laws of the physical and moral world and yet supposed to be attainable by supernatural agency.

The words Incantation and Charm seem to have been derived from the ancient practice of curing diseases by poetry and music. Democritus says that many diseases are capable of being cured by the sound of a flute when properly played. Marianus Capellus assures us also that fevers may be cured by suitable songs. Asclepiades actually employed the trumpet for the relief of sciatica, and tells us it is to be continued until the fibres of the part begin to palpitate, when the pain will vanish. What terrible visions might be conjured up if such remedies were used to-day.

The influence of superstition on medicine may be accounted for by the fact, that from the very first, ideas with regard to the action of drugs must have been combined with those concerning supernatural agencies, for the phenomena of Nature in very early times were attributed to spirits. Diseases were supposed to be due to an evil spirit, therefore to cast the disease out was equivalent to curing it, and the means used for this purpose were by no means always ineffective in curing disease.

Incantations and spells were generally used as an addition to a real remedial agent, but the incantations usually got the credit for effecting the cure.

In early times superstition played an important part in the cure of disease, and it prevails to a certain extent to-day. "In the opinion of the ignorant multitude," says Lord Bacon, "witches and impostors have always held a competition with physicians."

There has ever been a peculiar propensity in the human mind to foster a belief in the supernatural, and perhaps more especially in respect to medicine, on account of the obscurity and ignorance with which it was once surrounded. In early times almost every disease was attributed to punishment for evil doing, the working of some demon, or the influence of the stars; hence the use of any article that was strange or rare as a remedy.

"The employment of precious stones for medicinal purposes," writes De Boot, "arises from an Arab superstition which supposed them to be the residence of spirits." They were first used as amulets, and then gradually came to be administered inwardly for various ailments.

"Mystery is the very soul of empiricism," says Paris, "withdraw the veil and the confidence of the patient instantly languishes." A propensity to attribute every ordinary and natural effect to extraordinary and unnatural causes is one of the striking characteristics of medical superstition.

The properties that herbs possessed were attributed by the old physicians to the planets, which were supposed to influence them, and our medical men to this day head their prescriptions with a sign that originally meant an invocation to Jupiter, which is a surviving relic of the old superstitious practice. Another very curious fact with respect to medical superstition is that many of the greatest philosophers were firm believers in it. Lord Bacon is said to have believed in the existence of a panacea that would prolong life beyond its natural term. He considered that the principal cause of death was the action of the external air in drying

and exhausting the body, which he thought might be prevented by nitre; but although he took three grains of his favourite salt every morning for the last thirty years of his life, he died at the age of sixty-six. We have many customs at the present day which are a survival of those days of superstition, and few have any idea of their origin. The mother when she hangs round the neck of her child the plaything known as a coral and bells, little imagines she is perpetuating an ancient superstitious practice. The soothsayers attributed many mystic properties to coral, and it was believed to ward off the evil eye and drive away devils and evil spirits. For this purpose it was suspended from a child's neck as an amulet. Pliny and Dioscorides greatly esteemed the medicinal properties of coral, and Paracelsus recommends that it should be worn around the necks of infants to keep away fits, sorcery, charms, and to serve as an antidote to poisons. The bells usually suspended to it were originally intended to frighten away evil spirits and not to amuse the child alone.

Paris mentions a curious circumstance, that the same superstitious belief should exist among the negroes of the West Indies, who affirm that the colour of coral is always affected by the state of health of the wearer, it becoming paler in disease.

But all the remedies that originated in superstition were not entirely useless. Some, whether by accident or not, had a natural power of efficacy, and led to discoveries of importance. In the time of James I., a powder known as the sympathetic powder of Sir Kenelm Digby had a great reputation for healing wounds. Whenever a wound had been inflicted, this powder was applied to the weapon which had caused it, which was also smeared with ointment and dressed two or three times a day. The wound itself was directed to be brought together and carefully bound up with clean linen rags, but above all to be let alone for seven days, at the end of which time it was generally found to be healed. This was, of course, said to be due to the wonderful properties of the sympathetic powder, instead of the fact of excluding the air from the part and not interfering with nature's own healing powers. The mysterious sympathetic healing powder was afterwards said to be simply calcined green vitriol. The rust of the spear of Telephus, alluded to by Homer as a cure for the wounds which that weapon inflicted, was probably verdigris, and led to the discovery of its use as a surgical dressing.

The cures performed by Royal touch are some of the instances which show the power of faith over desire, or mind over matter. The royal surgeons who introduced the patients to be touched for scrofula, doubtless took care to choose those who had a tendency to recover, and who, if left to nature, would probably have gradually recovered. Boswell says Dr. Johnson, when thirty months old, was taken by his mother to London to be touched by Queen Anne, on the advice of Sir John Floyer, a physician of Litchfield.

From time immemorial the ignorant have had the most unbounded confidence in nauseous remedies, and it would seem as if the nastier and more disgusting the medicines, the greater faith they had in them. The larger the price asked, the more implicit the faith seemed to be. The Collyrium of Danares, a famous quack eye lotion, was sold at Constantinople for £9 a bottle, and the elixirs sold by Paracelsus and Van Helmont brought extortionate prices. The doctrine of Signatories, as it was called, is of very great antiquity. It implied that every natural substance which possesses any medicinal virtues, indicates by an obvious and well-marked external character, the disease for which it is a remedy. Thus the bloodstone was used to stop bleeding, on account of its marks resembling drops of blood. The root of the mandrake, on account of its resemblance to the human form, was used as a remedy for sterility. Turmeric was administered for jaundice, and poppies for diseases of the head. Another belief of the ancients was that all

poisonous bodies possess a powerful attraction for one another, and thus the hair of a mad dog was worn as a charm to prevent hydrophobia, and the foot of the ape was used as a remedy for its bite. On the same principle we are solemnly assured that three scruples of the ashes of a witch, after she has been well and carefully burnt at the stake, is a sure protection against the evil effects of witchcraft.

Many ancient superstitions are so deeply rooted that they find believers among the educated at the present day. Take, for instance, the belief that many people have in the efficacy of red flannel. For sore throat, rheumatism, or swelling, they believe it will cure, when flannel of no other colour will. This belief may be traced to the colour of the cloth often used in incantations, which was always red.

In some parts of the country a wedding ring is still believed to be a universal cure for sore eyes.

A curious superstition is still practised in some parts of Wales for the cure of the complaint called shingles. The term for shingles in Welsh means "The Eagle." It was supposed in ancient times that if a person ate of the flesh of the eagle he would never suffer from shingles, and his direct descendants down to the ninth generation could not contract it, and furthermore had the power transmitted to them of curing others so afflicted by blowing on them.

Love Philtres.

Love philtres were administered for the purpose of inspiring affection or hatred. In very early times they were frequently used, concocted, and sold by the magicians or sorcerers, who often obtained large sums of money in exchange, from amorously inclined gallants or maidens. They were composed of various extraordinary ingredients used in medicine at the time, and were either in the form of a powder, which was to be surreptitiously slipped into an article of food to be swallowed, or in liquid form.

It is recorded that some sorcerers even used the Host, upon which they traced letters of blood. The following it is said were also used in the preparation of philtres:—The entrails of animals, feathers of birds, scales of fishes, parings of nails, powdered loadstones and human blood.

It is little wonder they excited hatred. The *poculum amatorium*, the love philtre of the Romans, and the *philtro* of the Greeks, were venerated with superstitious awe in early times. They became used to such an extent by the former nation under the first Emperors that a degree was promulgated under the Roman criminal law whereby love philtres were deemed as poison, and the punishment inflicted on those using them was very severe. Hairs from a wolf's tail, the bones of the left side of a toad which had been eaten by ants (those of the right side were used to cause hatred), the blood of pigeons, skeletons of snakes, the entrails of animals, and other equally disgusting things were included as ingredients in Roman love philtres.

Pliny states that there were also philtres for quenching love. Thus, if a nest of young swallows is placed in a box and buried, on being dug up after a few days it will be found that some of the birds have died with their beaks closed, while others die as if gasping for breath. The latter were used for exciting love, and the former for producing the opposite effect.

Horace recommends a bone torn from a hungry and voracious dog, and Virgil describes a complete apparatus wherewith a maiden seeks to recover the affections of a faithless lover.

The early Greek and Roman magicians used "hippomanes," which was the lump of flesh found in the head of a colt newly foaled, as an ingredient in their philtres.

About the sixteenth century philtres came to be compounded and sold by the apothecaries, who doubtless derived from them a

lucrative profit. Favourite ingredients with these later practitioners were madragora, cantharides, and vervain, which were supposed to have Satanic properties. They were mixed with other herbs, said to have an aphrodisiac effect.

In Gay's 'Shepherds' Week' reference is thus made to love-philtres:—

"Strait to th' apothecary's shop I went,
And in love powder all my money spent;
Behap what will next Sunday after prayers
When to the ale house Lubberkin repairs,
These flies into his mug I'll throw,
And soon the swain with fervent love shall glow."

"Botanomancy," Ferrand states, "which is done by the noise or crackling that kneeholme, box, or bay leaves make when they are crushed betwixt one's hands or cast into the fire, was of old in use among the Pagans, who were wont to bruise poppy flowers betwixt their hands and by this means thinking to know their loves."

A Charme or an Allay for Love.

If so be a toad be laid
In a sheep-skin newly flaid,
And that ty'd to man 'twill sever
Him and his affections ever.—Herrick's "Hesperides."

The winged ant was another favourite ingredient in love philtres, and was first used by Rhazes, who prepared the winged ant in the form of tincture by maceration in alcohol. This tincture, dropped in the homœopathic manner into wine or mixed with food, was supposed to have a wonderful action in producing symptoms of the tender passion in the coldest hearts. The winged ants alone were used in this preparation, which enjoyed a long reputation, and was subsequently known as "Hoffmann's Water of Magnanimity," and largely used in the seventeenth century as an aphrodisiac.

LESSONS IN PHYSICO-CHEMISTRY.

(Continued from page 305.)

MELTING POINTS AND BOILING POINTS.

Passing on now to other matters, we may next deal with the subject of melting and boiling points. In general, if a solid substance is continuously heated, a point is at length reached at which a change in its state occurs and it becomes liquid. Heat is used up in effecting this change, and consequently the temperature of the substance does not further rise until it has all assumed the liquid state. If the heating is further continued, the temperature of the liquid gradually rises until another definite point is reached, when it assumes the state of vapour. Whenever the substance is thus heated, as long as certain conditions remain the same, these two changes of state occur always at the same two temperatures, and the exact determination of these temperatures is a matter of much importance. Among other purposes served by such a determination, it furnishes a very useful test of the purity of the substance in hand, since the presence of another substance even in very small quantity causes a considerable alteration of the temperatures at which these changes of state occur.

Among the conditions affecting the temperature of melting, or "melting point," of a solid, the pressure upon it at the time of melting exercises a certain influence. As a rule, the liquid that is formed occupies more space than the solid yielding it; in this case, if the pressure on the solid is increased, a higher temperature is required to melt it, and a reduction of pressure leads to melting at a lower temperature. With some substances, notably water, the liquid occupies less space than the solid from which it is formed, and the melting then occurs at a lower temperature when the pressure is increased, and *vice versa*. But in any case,

the influence of pressure on melting point is extremely small, and the alterations due to the ordinary changes of atmospheric pressure are almost infinitesimal and entirely negligible. The conditions that in practice affect the melting point of a solid are its state of aggregation and the rate at which heat is supplied; if the substance is in large pieces and the heat increased rapidly, the temperature may rise considerably above the true melting point before sufficient is melted to be observed. The solid should be finely powdered, and a very little put into a capillary tube which is closed at the lower end, and the powder shaken to the bottom. This tube is then attached to the stem of a thermometer in such a position that the part containing the powder is just level with the middle of the mercury bulb, and the whole is placed in a bath of suitable liquid. The latter may be water, melted paraffin, sulphuric or phosphoric acid, etc., according to the temperature that may be required; sulphuric acid is very generally useful. The vessel for the bath may be a beaker, or large test-tube, etc. It is very convenient to use a double bath consisting of a test-tube fitting loosely

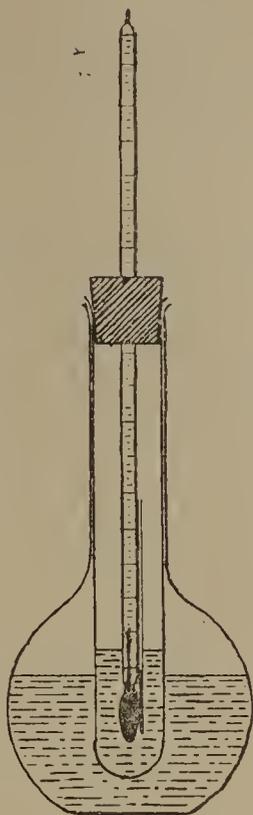

Fig. 8.

in the neck of a flask and not reaching to the bottom, both containing the liquid, as represented in Fig. 8. In the latter case no stirring-rod is necessary, but if a test-tube alone or a beaker is employed, a stirrer should be made by bending a piece of glass rod into a circle, which is turned at right angles to the remaining length (Fig. 9); this fits into the vessel, and is used with an up-and-down motion. The capillary tube containing the substance is easily attached to the thermometer by dipping it into the liquid of the bath and

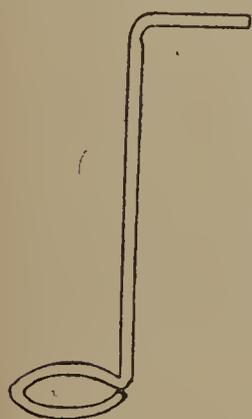

Fig. 9.

laying it against the stem in the right position, or it may be fastened by a rubber or cotton band near its upper end. Whenever practicable the thermometer must be sunk in the liquid to such an extent that the top of the column of mercury when the temperature is at its highest is about a quarter of an inch above the surface of the liquid. The thermometer may be gradually lowered as the temperature rises, since if the top of the mercury is below the surface of the hot liquid some of the mercury will probably distil to a cooler part of the tube. If, on the other hand, much of the mercury column is out of

the liquid, the temperature indicated will be a little too low; the temperature at the middle of the exposed part is then ascertained by a second thermometer, and a correction applied, the amount of which is found from the published tables. The bath is heated very slowly and a constant watch kept on the substance in the capillary tube until it is seen to be melting, when the temperature is accurately read. Whenever possible three determinations with one substance should be made, and if they differ slightly, their mean value taken.

It is often difficult or impossible to fix exact melting points for amorphous substances, as they soften and pass into a semi-fluid and then a fluid state without any sharp point of change. Some other substances are rather apt to sublime without melting; in such cases they can often be melted by heating rather more quickly.

For the determination of the boiling point of a liquid a larger quantity of material is required. To prove the purity of a liquid it is not only necessary that it should boil at a certain temperature, but also that the whole of it should distil without variation of the temperature. The most satisfactory way of determining the boiling point is, therefore, to distil a certain quantity of the liquid; this is best done in an ordinary distilling flask with a side-arm in the neck. The bulb of the thermometer reaches almost to the surface of the liquid, but must not dip below it, and the neck of the flask should be of such a length that the top of the mercury column is only just visible above the cork; if much of the mercury is in that part of the stem above the cork the reading will be too low, and a correction must be applied as mentioned above. The flask should rest on wire gauze, and over the latter is placed a fairly large sheet of asbestos millboard, with a circular piece cut out to allow heating of the bottom of the flask. The object of this is to screen the upper part of the flask from the heat, and so prevent the vapour being heated above the temperature at which it is formed, as would otherwise be the case; neglect of this precaution often causes a considerable error.

THE MAKING OF TABLETS.*

BY FRANK EDEL.

For many years compressed tablets have grown in popularity until they have become an important item in the sales of every pharmacy. They have recommended themselves to the physician because of their accuracy of dosage and convenience, and these are probably the main reasons for their popularity.

The increasing sale of these goods tends, however, to make the pharmacist more and more dependent on the manufacturer, for but few pharmacists make the tablets they sell.

Why is this so? Is there no money in making compressed tablets? Is the preparation of compressed tablets so difficult as to deter any intelligent pharmacist from making them?

The reason why so few pharmacists prepare their tablets is due probably more largely to a lack of information concerning their mode of preparation than to any other cause, for there is nothing about the preparation of compressed tablets which should deter any pharmacist from preparing his own tablets.

As to the question of profit in making them, does any one suppose for an instant that so much capital would be invested in plants devoted to their manufacture if it was not profitable to make them? The writer can say from experience that any intelligent pharmacist can prepare these goods in a first-class manner and as he may need them, and not be compelled to carry in stock the many different kinds now in demand. I have never felt kindly towards the idea of a pharmacist buying supplies that he can make himself. This tendency of modern pharmacists to depend on others for laboratory products that they can make themselves is one of the main reasons for the decreased profits we hear so much about.

If the pharmacist will prepare himself to produce his own tablets and give the physician to understand that he will make any combination that the physician may desire, he will find that the sale of tablets will become a source of more profit than if he lent himself to the sale of the ready-made tablets of the market.

In order to make nice tablets, the substances to be compressed must be carefully prepared. Not only is this necessary, but the machine used to compress them must be kept scrupulously clean, the dies must be smooth and polished and free from rust. With a rough die it is utterly impossible to make smooth tablets, and not

* Copyright, 1896, by the Spatula Publishing Company, and reprinted by special permission.

only is this so, but the material will stick to the dies. The dies should never be cleaned with any hard instrument, but with a damp cloth, and then carefully dried and rubbed with cloth slightly greased with petrolatum. If the machine is to be laid aside, the moulds and die and nickel-plated parts should be covered with petrolatum; this is absolutely necessary in order to prevent rusting.

When the dies become roughened, as they will from constant use, they should be carefully polished and made smooth by means of emery flour and oil. This can best be done in a lathe, but can be done by hand. If done by hand, a piece of wood should be made of such shape as to fit the face of die, and this used to polish with in using the emery flour. It takes more time than working with a lathe, but the work can be nicely done in this manner. The smoother and more perfect the surface of the dies, the less trouble will be had with material adhering to dies and the smoother and more perfect the tablet. It will then be readily seen that too much care cannot be given to the care of the moulds and dies.

While some materials compress readily without any special treatment, this is far from the rule. Some chemicals already in granular form are readily made into tablets; by far the greater number, however, must be specially prepared before they can be successfully compressed. It is necessary to add some adhesive to many substances and combinations before they can be successfully compressed.

The adhesives usually used are powdered acacia, powdered sugar, starch, and glucose. Glucose is only used where it is desired to prepare hard tablets for slow solution in the mouth. Professor Coblenz, in his 'Handbook of Pharmacy,' says that there are few substances which cannot be successfully compressed after being mixed with 5 per cent. powdered acacia and 10 per cent. powdered sugar. My own experience has fully demonstrated to my mind the utility of this as a general formula.

It should be the aim in preparing tablets to make them as soluble as possible. Tablets made with sugar as an adhesive are more soluble than those made with acacia, or even acacia and sugar. Starch is also used to make tablets soluble, but is hardly as advisable as sugar. It has the advantage of taking up a considerable quantity of liquids, and on this account is very useful in such tablets as contain these in such quantities as to be objectionable if made with sugar alone. Powdered acacia should be used in all combinations of a hygroscopic nature.

Some have recommended, in order to ensure more ready disintegration of the tablet, that small quantities of sodium bicarbonate and either tartaric acid or citric acid be worked into the tablet.

While this would increase the solubility of the tablet and be very desirable in some instances, it has the disadvantage that in order to incorporate it the material must have different treatment from regular tablet material in order to prevent the action of the acid and soda before the tablet is made, and then defeat the purpose for which it is added. Again, tablets thus made if not carefully kept from the air do not keep. However, the writer believes that in some tablets which are naturally slow of solution it has much in its favour. It is only intended to use these in very small quantities, not to produce effervescence, but to make the tablet disintegrate by the action of the acid on the soda when taken into the stomach.

It has been found that a fine powder does not compress as nicely nor feed as evenly as a coarse one, and on this account it is necessary to carefully granulate the material to be compressed. This is done by carefully mixing the powder and moistening, then passing through a No. 20 sieve and drying, then passing through a sieve again. Water is generally used to moisten, although alcohol and solution of glucose are sometimes used. The powder must not be moist enough to stick to the sieve. A tinned iron sieve is recommended, but

if it were possible to get a tinned brass sieve it would be much better.

It is necessary to have the granulated material thoroughly dry before compressing. If the granulating has been carefully done and the material well dried, it will often be found unnecessary to add any substance to keep the material from sticking to the dies.

LUBRICANTS.

In the great majority of instances, however, it is necessary to add some substance to the granulated material to prevent the powder from adhering to dies. White vaseline, powdered talcum, and powdered boric acid are the substances usually used. The vaseline is best used as a 2 per cent. solution in ether with an atomiser. The material is granulated and dried, then sprayed with the solution of vaseline and mixed on a paper or stirred with a spatula and dried. It is then passed through the sieve. If powdered talcum is used it should be added to the dry granulated material and stirred with a spatula or mixed on paper, or it can be added to the dried granulated material in a wide-mouthed bottle and mixed by agitation. Not more than three per cent. (of the weight of the granulated material) of powdered talcum should be used.

Boric acid is used in the same manner as talcum, but not more than two per cent. should be used. It is only used in making tablets when a perfect solution in water is desired, as in the case of hypdermic tablets.

Sometimes it is necessary to use both vaseline and talcum, the talcum is then added after the vaseline and not until the powder is dry, when it is mixed as directed above.

In preparing tablets it is a mistake to apply too much pressure, only as much pressure as is absolutely needed should be used. Never try to compress a moist powder, for it will stick to the dies and not be satisfactory. Do not use any more lubricant than is absolutely necessary.

In preparing tablets the materials should be reduced to a very fine powder before mixing. The following formula is representative of a large class of substances and combinations that can be granulated by the addition of sugar as an adhesive:—

Tablets Salol and Phenacetine with Quinine Salicylate.

Salol	250 grs.
Phenacetine.....	250 grs.
Quinine Salicylate	100 grs.

Reduce to a fine powder, add 60 grs. powdered sugar and mix thoroughly; moisten with water, pass through a No. 20 sieve and dry. When dry, lubricate with solution of vaseline and dry; pass through the sieve again. Make 100 tablets. The following tablets are made in the same manner:—

Tablets of Sulphonal.

„ „	Chloralamid.
„ „	Trional.
„ „	Bismuth Salicylate.
„ „	„ Subnitrate.
„ „	„ Subgallate.
„ „	Acetanilide.
„ „	Salicin.
„ „	Salol.
„ „	Quinine Sulphate.
„ „	„ Muriate.
„ „	„ Salicylate, etc.

They may be lubricated with vaseline, but if any trouble is caused by this adhering to dies, a little talcum can be added just before compressing.

(To be continued.)

A DANGEROUS IMPURITY IN HYDROBROMIC ACID.

BY R. C. COWLEY, LIVERPOOL.

A sample of hydrobromic acid was sent to me for examination a few days ago with the information that a clear solution could not be obtained by dissolving quinine sulphate in it.

An examination soon showed the presence of a barium salt. This obviously accounted for the formation of the precipitate with the quinine sulphate. The barium was precipitated as sulphate, and the quantity present was found to correspond to 4.598 grains of barium in the pint.

Compounds of barium are not now often found in hydrobromic acid, but their presence is a source of great danger, even in the small proportion present in the above sample, and they should be rigorously guarded against.

CHROMATIC PHOTOGRAPHY AND RADIOGRAPHY.

BY E. J. WALL.

(Concluded from page 366.)

It has been stated that the bones are opaque to the x -rays, but it must be distinctly understood that this is purely a relative term. There is no proof that any substance is absolutely opaque, and the question of transparency and opacity is to a great extent purely a question of exposure.

The precise action of the x -rays on a photographic plate is not known. That other forces beside visible light can produce a developable image is well known. As early as 1840, Robert Hunt discovered that a coin moderately heated and placed in contact with a film gave a developable image, and the so-called "inductograms" are caused by induced electrical action in the film. Pressure too will act in the same way, and it is only necessary to write in the dark on a film of silver bromide with a round pointed stylus to obtain on development distinct black letters. Many years ago Abney obtained a photograph from the invisible dark radiations of a kettle of boiling water. Röntgen himself is in doubt whether the x -rays actually reduce the silver bromide to the subhaloid or whether they only cause fluorescence in the glass or film itself. In support of the first hypothesis it may be stated that the cathode rays will convert the haloids, not only of silver, but of the alkalies too, to the subhaloid; but in support of the latter hypothesis Dewar's experiments may be quoted to prove that silver bromide itself is capable of fluorescing, and that fluorescence if set up would reduce the haloid to the subhaloid. On the other hand, it seems feasible to suppose that the x -rays might be converted into photo-chemical energy, just as in the same way it is stated, though without proof, that they can be converted into thermic energy.

The practical applications of radiography at present are limited to obtaining images of bones, either healthy, diseased or fractured, *in situ*, and to the detection of abnormal growths, malformations, etc., of the human body.

MM. Girard and Bordas have utilised the x -rays to discover the contents of suspected infernal machines. Buguet and Gascard have applied them to the detection of false gems, for as these are all made of "paste," which on account of its whiteness, hardness, and high index of refraction—being made of lead-glass and lead, either metallic or in the form of salts or compounds—seems to be comparatively opaque to these rays, whilst carbon and most of its compounds are fairly transparent. The suggestion that the x -rays could be used to detect flaws in metal castings, etc., may of course in the future be of value, though at present there are some difficulties in the way.

The latest and one of the most valuable suggestions was that

made by Dr. C. S. Patterson at the recent Camera Club Conference, when he said the rays would be of immense assistance in determining the species of unknown fish and so prevent the wholesale slaughter of young fry which are sometimes extremely difficult to distinguish. Another suggestion—due to Professor Puluj—is the obtaining of casts of the internal structure of dead or living organisms by using the radiograph negatives to print on bichromated gelatin, and in this to cast liquid plaster of Paris.

It is extremely doubtful whether the future of radiography lies in the use of photography, most likely it does not, for presumably a surgeon or physiologist will not trouble to obtain photographs of the internal structures when he can actually see them. The x rays are absolutely invisible to the human eye, and to MM. Rochas and Dariex we are indebted for the reason, which is that the structures of the eye are extremely opaque to them. But whilst we cannot see the x -rays themselves, we can observe their results, as was first done by Professor Röntgen, by using platino-cyanide of barium mixed with gum-water and coated on a screen. Such a screen, with a surrounding tube to keep off side light, and an eyepiece, is the cryptoscope of Professor Salvioni, of Pisa, about which so much fuss was made. Edison uses native calcium tungstate instead of the dearer barium salt. It is obvious that if the x -rays excite fluorescence in any substance we have merely to spread the latter on a flat surface and screen off the x -rays to produce a shadow or absence of fluorescence. By the aid of a fluorescent screen the writer has been able to see distinctly through the body of a child nine years old, and to locate in a girl's foot the presence of a needle which had previously baffled all attempts at finding. In the future the cryptoscope, or fluoroscope as Edison calls it, promises to be most valuable, even if it does not entirely replace for surgical work the use of a photographic plate.

Röntgen has stated within the last few days that all solid bodies can generate x -rays, which only differ in intensity. One of the most striking of all discoveries, which was curiously enough published after Röntgen's first paper, though it had been utilised for some months prior to this, is that of Mr. David E. Packer, of the Astrophysical Station, Birmingham. He attached to the end of a telescope a small camera which had no lens but merely a pin hole of one-twentieth of an inch diameter, and an extension of five inches; at the back of the camera was placed a photographic plate covered with lead foil, absolutely free from holes, and quite light tight. This lead foil is utterly impervious to the ultra violet rays, as well as ordinary light, yet on development magnificent pictures of the solar corona were obtained. In some of these, the originals of which the writer has had an opportunity of examining, the corona is seen to extend to a distance from the sun's edge at least equal in diameter to the sun—that is 860,000 miles, and to be connected with enormous streams of cosmical matter extending right into space. Whether these pictures are due to x -rays or not cannot at present be stated, but the energy, whatever it is, which produces them would seem to have something in common with the x -rays.

In compiling these notes the principle kept in view has been to eliminate all theory and speculation, and when this is done there is very little that is known. There are, however, some experiments which are interesting. Messrs. Atkinson, Pook, and Williams have found that cardboard sometimes retains for from two to eight days the power of giving images when exposed to the x -rays. A plate was placed in a cardboard box, and exposed to the action of the cathode rays, with no result, but the same box used with different objects from two to eight days after gave images of the first set of objects.

Nicola Tesla, one of the most expert and eminent of electricians, has expressed an opinion that in the x -rays we have a stream of material particles—and he also states that under the influence of

the x -rays time seems to pass very quickly, and a feeling of drowsiness is induced.

Professor Batelli is stated to have been able to reflect the x -rays from polished metal parabolas, such as copper and platinum. This, however, is contrary to the experience of others, except that of Jecla, who claims to have succeeded in reflecting the rays.

Professors Rowland and Elihu Thompson, of the United States, contend that the x -rays are anodic rather than cathodic.

There is a big field in connection with the new subject for experimental research, and it is to be hoped that shortly some satisfactory data will be forthcoming, but at present we are in the unfortunate position of being swamped by theory based upon incomplete experiments made by incompetent observers, for everyone in possession of a coil and tube rushes into print and lays down the law and theories, most of which are drawn from ignorant reading of the results. A little patience is probably the best thing at the present moment, but that the discovery of x -rays by Professor Röntgen is, in the language of his fatherland, "epochmachenden," cannot be denied, and is likely to lead to results which are at present unforeseen, and which, as suggested by Lord Kelvin, may entail the complete revision of our theories as regards the closely allied energies of heat, light, and electricity.

PROCEEDINGS UNDER THE PHARMACY ACT.

THE SALE OF KAY'S ESSENCE OF LINSEED.

The Pharmaceutical Society of Great Britain v. Fox.

In this case, which came before His Honour, Mr. Lumley Smith Q.C., at the Westminster County Court on Wednesday last, the Pharmaceutical Society sought to recover a penalty of £5 from the defendant, Charles James Fox, grocer, Warwick Street, Pimlico, S.W., for having sold a compound containing poison, viz., "Kay's Compound Essence," he not being a duly registered chemist and druggist.

Mr. Grey appeared for the Pharmaceutical Society, and Mr. Bonsey appeared on behalf of the defendant.

Case for the Plaintiff.

Mr. Grey, in opening the case, said the action was brought to recover a penalty for the sale of poison contrary to the Pharmacy Act, 1868. All the facts were admitted, and the sole point to be determined was a point of law, viz., whether what the defendant had done came within the exception contained in Section 16 of the Pharmacy Act, 1868. The admitted facts were that the defendant was a grocer living in Warwick Street, Pimlico, that he kept an open shop for retailing, dispensing, and compounding poisons in Warwick Street, and sold on February 13 this year a bottle of Kay's Compound Essence of Linseed, which contains morphine; further, that the defendant is not registered or qualified under the Pharmacy Act, and that he would have to submit to judgment for a penalty under this Act unless he comes within the exceptions of Section 16. On one side of the bottle sold were the words:—

"The success of this remedy has produced many imitations. To prevent disappointment, please note that 'linseed compound' is the trade mark of Kay's compound essence of linseed, aniseed, senega, squill, tolu, etc. It contains a preparation of chloroform and morphine, and is therefore labelled poison."

It was also admitted that Kay's compound essence was patented on May 31, 1873, but owing to the non-payment of fees the patent expired, and became void on May 31, 1876.

Mr. Bonsey: I do not admit the expression "void." I admit that it lapsed.

Mr. Grey said he was giving the words of the Act of Parliament. The following also appeared on the bottle:—

"Kay's Compound Essence follows the Patent No. 1975, and being within the exception contained in Section 16 of the Pharmacy Act, 1868, its sale is free from restriction, but the name and address of the seller must appear hereon."

Then there were other labels, "Kay's Compound Essence" and so on. He did not mean in this case to raise the point whether the preparation followed the specification or not, and for the purpose of this case it might be assumed that it did. He then referred to the provisions of the Act, the object of which had been clearly laid down by many judges to the effect that it forbade the sale of poisons by anyone who has not passed the examinations which he is bound to

do under this Act, and become qualified. It was passed to regulate the sale of poisons, and to amend the Pharmacy Act of 1852. After quoting the preamble, and Sections 1 and 2, Mr. Grey said that the schedule was divided into two parts; one part dealing with those poisons which are most virulent and require special restrictions, and part two dealing with those which are less virulent, such as morphine, and so on. Section 3 of the Act defines "Chemists and Druggists," and Section 10 deals with the registration. But Section 15 was the important one. It says that:—

"Any person who shall sell or keep an open shop for the retailing, dispensing, or compounding poisons . . . shall for every such offence be liable to pay a penalty or sum of five pounds, and the same may be sued for, recovered, and dealt with in the manner provided by the Pharmacy Act."

Then Section 16 says:—

"Nothing hereinbefore contained shall extend to or interfere with the business of any legally qualified apothecary or of any member of the Royal College of Veterinary Surgeons of Great Britain, nor with the making or dealing in patent medicines."

Those were the important words. There was not any definition of patent medicines in the Act.

Mr. Bonsey: I say simply this, that it is a patent medicine within the meaning of the Act, although the patent lapsed by non-payment of fees in 1876.

The Judge: You say once a patent always a patent.

Mr. Bonsey: Yes, that is my point; there is nothing else. This point has never arisen in any of the previous cases.

Mr. Grey agreed that this point had never arisen. In the case of the Pharmaceutical Society v. Piper and Co. the point was whether a proprietary medicine or a secret nostrum, for which Letters Patent have not been taken out, comes within the words: "Nor with the making or dealing in patent medicines."

At this point a prolonged argument took place with regard to the Judge's statement of admission of facts, after which

Mr. Grey proceeded to quote from Mr. Justice Lawrance's judgment in the Piper case, to the effect that he had come to the conclusion that the expression "Patent Medicine" in Section 16 means a medicine protected by Letters Patent under the Great Seal, and, therefore, that the rights reserved under Section 16 did not apply in the case of chlorodyne. Mr. Justice Collins, again, defined what a patent medicine is. He observed that it had been argued that the expression "patent medicine" was a rough way of describing medicines that are dealt with in the same way as patent medicines under the legislation relating to stamps, and that there was evidence before the learned County Court Judge that, at the time of the passing of the Act of 1868, the term "patent medicine" was not confined to what can be technically so described—that is, medicines in respect of which Letters Patent have been granted; but that it meant, broadly speaking, proprietary medicines; and it was contended that the same meaning should be given to it in Section 16. He had come, however, to the conclusion, having regard to the object of the Pharmacy Act and to the provisions of 52 George III., chap. 150, that the expression "patent medicines" in the Act of 1868 should not be made to bear a meaning which would so very greatly enlarge its *primd-facie* meaning—that is, a medicine which is the subject of Letters Patent. Mr. Justice Collins then went on to say that the object of the Act was to deal with the sale of poisons; to regulate their sale and to alter and amend the Pharmacy Act, 1852.

The Judge: The mischief aimed at by that Section does not exist in the case of patent medicines. Anyone can find out the exact ingredients by referring to the specification.

Mr. Grey: That point is dealt with by the Court of Appeal. You will find it referred to in Lord Justice Kay's judgment in the case of the Pharmaceutical Society v. Armstrong in 1894, Queen's Bench Division, page 720. There the subject of the action was Powell's Balsam of Aniseed. The head-note is:—

"The prohibition in Section 15 of the Pharmacy Act, 1868, against the sale of poisons by other than registered chemists is not confined to the sale of the scheduled poisons in their simple state, or of preparations of such poisons, but extends to the sale of a compound containing a scheduled poison as one of its ingredients."

Then on page 726 Lord Justice Kay deals with the same point, and he says:—

"The other argument was that this article was excepted by Section 16, because it was a patent medicine. It was said that in ordinary parlance all proprietary medicines are classed under the head 'patent medicines.' Is that the meaning in this Act of Parliament? In order to construe this Act of Parliament it is material to see how the Legislature has dealt with medicines in other Acts of Parliament, and when we look through the other Acts of Parliament we find a most clear distinction always maintained. Although proprietary and patent medicines are classed together for certain purposes, the language of various Acts of Parliament which impose a stamp duty on medicines mentioned in the schedules shows them to be dealt with as a separate class. On this point I accept what Justice Collins said in the Piper case. The reasons for the exemption seem to me very clear indeed. Where the medicine is, properly speaking, a patent medicine, that is to say, where the exclusive right to make or sell it has been granted to somebody by Letters Patent under the Great Seal—the condition of the patent always is that a specification should be lodged in the Patent Office describing the whole of the ingredients, and the process of manufacture. Therefore, when people buy a patent medicine, they have the means of ascertaining what ingredients are contained in it, and that is one reason, no doubt, for the exemption. Another is this: If a patent of that had been granted, it would have been rather hard to take away from the patentee that which he had been exercising as a right under the authority of the Great Seal, and prevent him from further making and selling, if he were not an authorised person under the Act. For these reasons, I think it is plain that in Section 16 the words 'patent medicine' mean that which they express *prima facie*—medicine the maker or owner of which has obtained Letters Patent for it; the term does not extend, and is not intended to extend, to mere proprietary medicines, or to include a medicine like this, for which the owner or maker has not obtained any patent whatever."

The Judge: The first reason that he gives—about people finding out what was in it—would apply in the present case, as anybody has only got to look at the specification.

Mr. Grey: I rather doubt that would give it if you looked at the specification.

The Judge: The next reason, that it is rather hard to take away from the patentee a right which he has got under the Great Seal, would not apply to this case, because you say he has no right.

Mr. Grey: I say he has no right.

The Judge: What do the other judges say?

Mr. Grey: Lord Justice Smith on page 728 says:—

"But then it is said he is out of the meshes by reason of Section 16 of the Act, which provides that none of the prior Sections shall extend to the case of 'making or dealing in patent medicines,' and it is said that Powell's Balsam of Aniseed is a patent medicine within the meaning of the Act. The first thing one asks is, Where is the patent? And the only answer is, There is no patent. How, then, can it be a patent medicine? It is said it is a proprietary medicine, and that we ought to read Section 16, which exempts patent medicines, and patent medicines only, as exempting patent medicines and proprietary medicines. I certainly should not read the Section in that way myself. The exemption must be read in the manner which the Queen's English dictates, and when the legislation which has taken place before and since this Act of 1868 is looked at, it is abundantly clear that the exception was of patent medicines only, and not of proprietary medicines. Looking at the Statute of 25 George III., chapter 79, section 4, and the next Act of 52 George III., chapter 150, section 2, both prior to this Act of 1868, there is a marked distinction between a patented medicine and a proprietary medicine, which is compounded of secret nostrums. When we come to the Act of 1868, the sole exception made relates to patent medicines, and a few years afterwards another Act, relating to the sale of food and drugs, was passed, in which an exception is made where the food or drug is a proprietary medicine, or one which is the subject of a patent in force."

The Judge: Where does he get those two words "in force"?

Mr. Grey: From the 38 and 39 Victoria, Chapter 63, the Sale of Food and Drugs Act, Section 6—

"A doubt was raised whether there was such a thing as a 'patent medicine,' but the answer was speedily given; a specification was handed up in which it was shown that a patent was taken out for a medicine as late as 1892. In my judgment this case has been brought within the Act."

The Judge: Those words "in force" are important. Section 6 is

"No person shall sell to the prejudice of the purchaser," etc., "where the drug or food is a proprietary medicine, or is the subject of a patent in force."

That is to be used against you to a certain extent, that where it meant to say a patent was in force it would say so.

Mr. Grey: First one must consider, with regard to this Act, there is no doubt that in construing an Act of Parliament the paramount rule is that every statute is to be expounded according to its intent, if you bring all cases within the mischief of the Act. And Lord Coke said that this Act should be dealt with so as to suppress the mischief and advance the remedy.

The Judge: The contrary maxim has been enunciated—that everything imposing a penalty ought to be construed strictly. But Baron Bramwell has said both of them are nonsense.

Mr. Grey said he was quoting from 'Maxwell on Statutes.' He then proceeded to say that Letters Patent are writings of the Queen, sealed by the Great Seal, whereby a person is enabled to do acts and to enjoy privileges which he could not do or enjoy without such authority. That right is a privilege granted by the Crown to the first inventor of any new contrivance, so that he alone should be entitled during a limited period to make those articles according to his own invention. He had also to send in a specification, and it was clear that the object of the specification was to put the public in full possession of the inventor's secret, that is to say, it remained no longer a proprietary article, so that any person might be in a position to avail himself of it when the period had expired.

The Judge: What would the period have been in the ordinary course?

Mr. Grey: If he had kept up his payments it would have been fourteen years from May 31, 1873.

The Judge: You have to consider this: Suppose a man for fourteen years prepared and sold this thing, when the patent expires does the power to sell go back to the people who are qualified to sell it?

Mr. Grey said anybody could sell it. After the fourteen years any person could go and make it according to the specification and sell it. It was open to the public, and after the fourteen years, unless the Pharmacy Act interfered, anybody could sell it. During that fourteen years the patentee could give a licence, and no one could sell the article unless they had a special licence from the patentee. If the latter did not comply with the specification the substance which he sold was not a patent medicine.

The Judge: The theory of this thing is that this matter has been inquired into by the people who have the granting of patents; they have satisfied themselves that it is useful and presumably innocuous; if it were likely to poison the public they would not grant a patent.

Mr. Grey said he was not at all sure about that, as the authorities seemed to accept any patent.

The Judge: We need not trouble about the man not having kept up his payments. Your case broadly is, that when a patent has expired then it ceases to come within Section 16.

Mr. Grey said he did not make any point with regard to the non-payment of fees. His case was that there was no existing patent. Under the Act of 1853, 16 and 17 Victoria, chapter 5, the Messrs. Kay took out their patent and obtained a grant that they should have the exclusive right to sell it. After that Act came the Act of 1868, and if the article in question came within the province of the Pharmacy Act all the liberties and privileges which were given to the patentee would have been derogated, that is to say, he would have been limited in his sale. He could not have sold himself unless he had been qualified, and he could not have sold through anybody else unless he had been qualified. That, Lord Justice Kay said, was one of the reasons why that was put in the Act of Parliament. The reserving words did not extend to a patentee's privileges for any period longer than that limited by the Patent Act, that is to say, after the fourteen years.

The Judge: Have you any more cases to cite?

Mr. Grey: No, sir.

The Judge: Then I understand your point.

Case for the Defence.

Mr. Bonsey said there was just one point on the facts on which Mr. Grey was not quite clear, and that was that the admitted quantity of morphine was one-seventh of a grain. It was said against him that it is a poison, but what was admitted was that the preparation contained one-seventh of a grain, and that but for the exception in Clause 16 the defence must fail. He submitted that this was a patent medicine within the meaning of that Section. He did not know that he need address himself to the point about the patent having lapsed, except to say that the condition imposed by the grant of Letters Patent is merely expressing in language what really happens when the patent expires in the ordinary course of things. The words were these:—

"And in any of the said cases, these our Letters Patent and all liberties and advantages whatsoever hereby granted, shall cease and determine and be void."

That was exactly what happened on the expiration of a patent in the ordinary course of things. The length of time that the protection was given to a person was fixed by the Statute of Monopolies in the reign of James the First, and by that Statute all monopolies were abolished. Then there was a provision in Section 6 which said that to the extent of fourteen years all grants should stand in the position as if the Act had not passed. There was a misconception in Mr. Grey's argument as to what the real nature of a patent is. For a period of fourteen years the grantee of the patent has the exclusive right of making a certain article, and he has the right during that time of preventing other people, by proper legal means, infringing that right to manufacture, but at the expiration of fourteen years he is still the patentee, he has still the right to manufacture under his patent, he does still do so, and sells under his patent, but the only disadvantage or disability under which he is is that he has no longer the exclusive right to do so, and that other people can compete with him. It was a fallacy to say that at the expiration of the fourteen years the patent did not exist.

The Judge: Yon, say a man is alive after he is dead? You, say the patent is alive although it is exhausted?

Mr. Bonsey said the man was still the patentee, and he still manufactured under that patent. It was illustrated in this way; there were cases where injunctions had been applied for to restrain a person from infringing a trade mark which had the word "patent" upon it, and it had been held that it was not a misrepresentation to describe a thing as a patent although the patent has expired, unless you were to go so far as to represent that it was an existing patent and that it was in force, drawing a distinction between the two, and a distinction which has been drawn by the Legislature in subsequent cases. As an illustration he referred to the prior Act of 5 and 6 William IV., cap. 83, an Act to amend the law relating to patents for inventions. There by Section 7 penalties were imposed upon persons who should write or paint or mark upon anything made or sold by them the word "patent." They were restrained by a penalty from putting on any goods the word "patent." Then there was a proviso which says:—

"Provided always that nothing herein contained shall be construed to extend to subject any person to any penalty in respect to stamping or in any way marking the word 'patent' upon anything made for the sole making or vending of which a patent before obtained shall have expired."

The Judge: It says that after the expiration you might, nevertheless, mark it "patent."

Mr. Bonsey said that was so. If a patent was once held, although it had expired, the article might still be marked "patent," showing that the Legislature clearly recognised the distinction between the case of a man never having taken out a patent and the case where a man has a patent which has expired in the ordinary course. That Act was repealed by the Act of 1883. The provision now with regard to that is to be found in Section 105 of the Act of 1883. There it says:—

"Any person who represents that any article sold by him is a patented article when no patent has been granted for the same."

It did not say where no patent is in force at the time.

The Judge: All that comes to is that in those particular cases there has been no penalty on a man who calls a thing a patent when it is not patent. Having been once a patent it says we shall not punish you for calling that a patent still, which otherwise than that clause we should punish you for.

Mr. Bonsey said the inference was that it is still a patent, for that purpose at any rate. Therefore this gentleman would not be liable under that Section for calling it a patent medicine. He thought that was perfectly clear. The real object of the Pharmacy Act was to insure the safety of the public, and prevent their being injured by the sale of poisons by unqualified people. It was argued for the plaintiff that the only reason for excepting a patent is that it would be hard upon a person who takes out a patent to restrict him to the sale of that particular thing by chemists and druggists, and not allow it to be sold by other people. That is to say the Legislature says as long as you like to pay certain fees then you may poison people as much as you like. You may poison them under Letters Patent, if you pay the fees, but if you do not pay those fees you shall not do it.

The Judge: There is that saving clause in the patent that if they find they are poisoning too many people then the patent can be

revoked, and they may be punished because it would be prejudicial to people.

Mr. Bonsey said that was rather an argument in his favour, for they might revoke the patent, and no steps had been taken to revoke this patent. But it was contended that Section 16 was inserted in the Act for the protection of the patentee, because he had paid certain fees and gone to the expense of getting this monopoly. Now that was contrary to the object of the Act, which was the protection of the public, and, therefore, the other reason was the real reason for the exception, namely, that when the article is patented it is made public. Anybody can go and see what it is made of; it is not a secret drug or a secret nostrum, and, therefore, the public is not injured in any way whatever. That was the view, he should submit, taken most distinctly in the cases of the *Pharmaceutical Society v. Piper* and the *Pharmaceutical Society v. Armson*.

The Judge: Let us go by steps as to that, and see how Mr. Justice Lawrance puts it.

Mr. Bonsey said that in both those cases, in arriving at a definition or in attempting to give a definition to the word "patent," the Court laid great stress upon the Stamp Act of the 52nd George III., cap. 150, which was referred to in both those cases, and very fully discussed. In that Stamp Act there is a distinction drawn between a proprietary and patent medicine, and a patent medicine is there given a very wide meaning or wide definition for the purposes for which it was introduced into that Act. Now that Act imposes a stamp duty upon certain things which are specified, a large number being set out in the Schedule; but then it goes on to say:—

"And also all other pills, powders, medicines, etc., wherein the person making or uttering or exposing for sale the same, has, or claims to have, any occult secret of making or preparing the same."

That was one thing—

"or has or claims to have any exclusive right or title for making or preparing the same"—

That was another thing. Then came the important part—

"or which had at any time heretofore been, and now are or shall hereafter be prepared, uttered, vended, or exposed for sale under the authority of any Letters Patent under the Great Seal."

Therefore they imposed the stamp duty upon medicines which were prepared according to a patent that had long expired—

"And which had been or were at that time the subject matter of a patent, or which may hereafter be the subject matter of a patent."

The Judge: It is not quite that; it is "shall have been prepared."

Mr. Bonsey read from the Schedule as follows:—

"Or which had at any time heretofore been and now are or shall hereafter be prepared, uttered, vended, or exposed for sale under the authority of any Letters Patent under the Great Seal."

Somerset House, he said, imposed a duty upon these patent medicines, and the duty once chargeable is always chargeable, even though the patent has expired. If the contention was right that the patent at the expiration of fourteen years absolutely becomes null and void and is no patent at all, he could not understand on what principle they should charge duty as on a patent medicine; but that Act and the description of the patent in the schedule to that Act were very much discussed by the judges in both those cases of the *Pharmaceutical Society v. Piper* and *Armson's* case. Mr. Justice Lawrance spoke of it in the first part of his judgment, where he said the only exception to the prohibition of a person retailing poison is contained in Section 16. And, again, he pointed out that it was argued that whatever chlorodyne might be, whether it was a poison or not, it was at any rate a patent medicine, and therefore the requirements of the Act have no reference to it. The Judge then said, that at first he was impressed with the view that the term "patent medicines" included all the medicines dealt with in the Schedule, but seeing that the distinction was clearly taken in that Statute between proprietary medicines and medicines protected by Letters Patent, he had come to the conclusion on this part of the case that the expression "patent medicine" in Section 16 means a medicine protected by Letters Patent under the Great Seal, and, therefore, that the rights reserved under Section 16 do not apply in the case of chlorodyne. Of course, continued Mr. Bonsey, that was *prima facie* the definition of a patent.

The Judge: Let us stop there for a moment, "patent" means protected by Letters Patent under the Great Seal.

Mr. Bonsey: I suppose that is the *prima-facie* definition of a patent, but they go on further to discuss it.

The Judge: He does put it on the ground that anybody can find out by inquiry.

Mr. Bonsey then quoted Mr. Justice Collins, who said he had come to the conclusion, having regard to the object of the Pharmacy Act, and to the provisions of 52, George III., chapter 150, that the judges ought not to put on the expression "patent medicines" in the Act of 1868 a meaning which would so very greatly enlarge its *prima-facie* meaning, that is a medicine that is the subject of Letters Patent. The Act was intended to regulate the sale of poisons, and to alter and amend the Pharmacy Act of 1852. Broadly speaking, therefore, it dealt with the sale of poisonous drugs, and Mr. Justice Collins asked if there could be anything more dangerous than to allow a medicine which was called a proprietary medicine, but which may contain poison to any amount, to be sold by unqualified persons.

The Judge: Both of those gentlemen treat it as merely a question of publicity. What did the Court of Appeal say?

Mr. Bonsey said the case did not go to the Court of Appeal, but Armson's case did, and the same point was raised. The Master of the Rolls said it was clear to his mind that, construing the exemption according to the ordinary canons of construction, it must be said that the Act applies only to patent medicines, using that term in the sense of medicines for which a patent has been procured under the Great Seal. He did not say there that the patent must be in force or in existence. Then Lord Justice Kay said the reasons for the exemption seemed to him very clear indeed. The same Judge, continuing, said where the medicine was, properly speaking, a patent medicine—that is to say where the exclusive right to make or sell it has been granted to somebody by Letters Patent under the Great Seal—the condition of the patent always is that a specification should be lodged in the Patent Office describing the whole of the ingredients and the process of manufacture. Therefore, when people bought a patent medicine they had the means of ascertaining what ingredients were contained in it, and that was one of the reasons, no doubt, for the exemption. Another reason, according to Lord Justice Kay, was that if a patent of that kind had been granted, it would have been rather hard to take away from the patentee that which he had been exercising as a right under the authority of the Great Seal, and prevent him from further making or selling, if he were not an authorised person under the Act. For those reasons he said he thought it was plain that in Section 16 the words "patent medicine" meant that which they expressed—*prima facie*, medicine, the maker or owner of which had obtained Letters Patent for it.

The Judge: Now the present maker had not Letters Patent, nor the present owner. He had at one time. At the time when this was sold, in February, there was no patent.

Mr. Bonsey said the makers had obtained Letters Patent in 1873. The medicine was made by the same persons who obtained that patent in 1873—by the two Kays. The Lords Justices had pointed out that one strong reason for the exception was that where you have a specification and the thing is once patented, you can go and see what it is made of.

The Judge: Supposing the patent had been revoked under that clause because it was prejudicial, would you nevertheless say it would be a patent medicine?

Mr. Bonsey said revocation would be a different thing. The patent could only be revoked by taking certain proceedings. It used to be done by proceedings by *scire facias*, now it is done by petition. But the Court of Appeal meant that those proceedings might absolutely destroy the patent altogether. The present question, however, was simply as to the patent lapsing in point of time. Then Lord Justice Smith made an observation which he thought was in his favour. He said the exemption must be read in the manner which the Queen's English dictates, and when the legislation, which has taken place before and since this Act of 1868 was looked at, it was abundantly clear that the exception was of patent medicines only and not of proprietary medicines. There was a marked distinction between a patented medicine and a proprietary medicine, and in the Act of 1868 the sole exception made related to patent medicines. In those words a patent was defined for the purposes of this Act, and later, in the Sale of Food and Drugs Act, there was a distinction drawn between proprietary medicines and patent medicines in words which were not found in Section 16 of the Pharmacy Act. It seemed rather an extraordinary proposition that for fourteen

years a man might go on selling a preparation which was prepared according to the Letters Patent, and obtained during that time a large trade all over the country, and the very day after the patent expired anybody who sold one of the articles was liable to a penalty and the man's patent destroyed. The public was not injured a bit more in the fifteenth year than in the fourteen years, because the medicine was prepared under the specification in the same way, and therefore the public was no more in danger at the expiration of the fourteen years than during the existence of the patent.

The Judge: Is there not this reason, that after the patent has expired you have no guarantee that it will be properly concocted? If anybody can make and sell it you run a great risk in putting the ingredients together, whereas so long as it is a patent there is some guarantee that it will be properly done.

Mr. Bonsey: If it is not prepared according to the specification then it is not protected by Letters Patent at all. It is not prepared under the patent.

The Judge: There is much less risk if the patentee prepares it than there is if anybody else prepares it.

Mr. Bonsey: I do not know how that would be.

The Judge: You have "Kay's Compound Essence, manufacturers, Kay Brothers, Limited, Stockport, Great Britain." After the patent expires that might be manufactured by any other Brothers, Limited, and there is no guarantee that the thing is properly made. So long as it is all in one patent there is no legal guarantee, but there is a practical guarantee that the specification will be properly followed.

Mr. Bonsey: I do not know how that may be. Suppose a person after the expiration of a patent were to say he was selling Kay's Compound Essence he would be restrained from doing that. He could not sell it under the same term or the same name.

The Judge: Suppose Kay's name was not on it. Suppose it was "Linseed Compound"?

Mr. Bonsey: Then it would not be under the patent at all.

The Judge: You might have a man up for fraud for obtaining money by false pretences.

Mr. Bonsey: He could not manufacture it as "Kay's Compound Essence" under the patent; he could manufacture something and say that something else was made of the same ingredients, which he could not have done during the fourteen years. You can restrain him from doing that, but after the expiration of fourteen years he could not have sold Kay's Compound Essence, he could have been restrained from doing that. Therefore I do not think the danger is at all increased. If the real reason of the exemption was not that the public had the means of ascertaining what this is composed of, then the only reason is that the Legislature sanctioned the sale of a poison as long as a man took out a patent for it. It is really a short point, though it is an important one, and I do not think I can usefully add anything more upon it.

Judgment.

The Judge: This case, I suppose, will go further. I think the plaintiffs are right. The exception is in favour of the making or dealing in patent medicines. Now this medicine, it is said, is a patented medicine; but then, as Lord Justice Smith said, where is the patent? There was no patent existing at the time when this was sold. I think, with Lord Justice Kay, that a man who gets a patent has certain privileges given him. It would be very hard to say that Letters Patent under the Great Seal give him the exclusive right of making and vending it, and that some other Act of Parliament took it away from him. I think there are many reasons—I need not go through them all—why it should be read as dealing with patents, which in the latter Act would be called the subject of patents in force. There will be judgment for the plaintiffs with costs. I suppose you want leave to appeal?

Mr. Bonsey: Yes, sir.

Mr. Grey: As this is an important case I will ask for a certificate for counsel.

The Judge: Yes.

Mr. Bonsey: Will your Honour give a stay of execution pending appeal.

The Judge: Yes, if there is no undue delay.

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

URANIUM INTENSIFIER.

The best formula for uranium negative intensifier is the following:—

Uranium Nitrate,	
Potassium Ferricyanide, of each	100 grs.
Glacial Acetic Acid	½ oz.
Water, to	10 ozs.

The negative must be absolutely free from hypo. before being soaked in the above. When sufficiently intensified rinse slightly and dry. [Answer to A. E. Hobbes.]

NEGATIVE REDUCER.

The best is Belitzski's:—

Potassium Ferric Oxalate	200 grs.
Sodium Sulphite	200 ,,
Distilled Water	5 ozs.

Dissolve the iron salt, add the sulphite, when dissolved add—

Oxalic Acid (crystals)	75 grs.
------------------------	---------

Shake well till the solution turns green, decant from any undissolved acid, and add—

Hyposulphite of Soda	2½ ozs.
Distilled Water, to make	10 ozs. in all.

This can be applied to the negative immediately it comes from the fixing bath, and may be used over and over again. [Answer to A. E. Hobbes.]

POTASSIUM CHLOROPLATINITE.

This is rather a troublesome salt to make. Dissolve 50 grammes of platonic chloride in 100 C.c. of distilled water, heat to 100° C. and pass a stream of washed sulphurous acid through it till it no longer gives a precipitate with ammonium chloride, allow to stand twenty-four hours and add hot a solution of 23 grammes in 50 C.c. of water, stir, allow to cool, wash and dry crystals. Or place in a glass 24 grammes potassium platonic chloride and 300 C.c. water, 12 grammes potassium acid sulphite and 12 grammes potassium chloride, bring to the boil and allow to boil twenty-five minutes, then allow to cool and pour out into flat dish to crystallise, which takes about two days. [Answer to K. F.]

STICKY FLY PAPER.

Take two parts of foots sugar and one part of beer and heat until dissolved, adding more beer to keep the weight at 3 parts. Heat together birdlime, 5 parts; sesame oil, 3 parts; resin, 5 parts, until a homogeneous mass results; then add the beer mixture while warm. If too thick, thin down with a little more beer. Spread while warm on parchment paper. [Reply to A. E. H.]

FLY GUM.

Bird lime, 5 parts; honey, 2 parts; glycerin, 1 part; warm together to make a uniform mass. [Reply to A. E. H.]

COLOUR FOR SHOW BOTTLES.

It is difficult to advise you unless we know exactly the tint you require. Acid solutions of cochineal are more stable than those containing ammonia. Try the following:—Cochineal, 10 parts; distilled water, 1000 parts; alum, 8 parts; cream of tartar, 8 parts. Boil the above solids well with two successive 500 parts of water and strain: when cold add 6 parts of sulphuric acid. Allow to stand twenty-four hours and filter. The following gives a bright, fast red:—Metallic cobalt, 4 parts; nitric acid, 16 parts; water, 50 parts: dilute the acid with the water and dissolve the cobalt in the mixture, further dilute to 100 parts with water, add 38 parts of strong solution of ammonia and 2 parts of alum, dissolved in 50 parts of water. Make up the whole to 500 parts with distilled water. Another good fast tint is obtained by dissolving a little endbear in water and making faintly acid with sulphuric acid. [Reply to W. L. B.]

PARLIAMENTARY INTELLIGENCE.

SHOPS (EARLY CLOSING) BILL.—The Hon. Lionel Holland (Bow) expresses his opinion of early closing in the following notice, to be moved when the above Bill comes before the House for reconsideration:—

"That this House, while recognising the desirability of shortening the hours of labour of shop assistants, is of opinion that this should be effected by an Act limiting the hours of employment of such assistants in each week."

The electorate of Bromley and Bow comprises a large number of small tradespeople who have a justifiable fear that early closing may mean an early permanent closing for them.

PATENTS AND NOVELTY.—No one perhaps views these two words as exactly synonyms, yet the general public has hitherto regarded the grant of Letters Patent as conveying some official assurance that the article they related to was worth the protection given it. But the general public is wrong, and must record another exploded fallacy. As a matter of fact the Patent Office would seal a patent in respect of a preparation of whisky and water, providing the applicant paid the proper fees and underwent the prescribed procedure. The actions for revocation brought by the Pharmaceutical Society sufficiently exemplify the position of non-intervention taken up by the Patent Office. This state of things recently led Lord Justice Kay to emphatically state as his conviction that there were frequently long and expensive contests about alleged inventions which no human being who was acquainted with the state of knowledge on the subject would think deserving of a patent. Hence he thought it desirable that a functionary should be charged with the duty of examining applications, and rejecting those without novelty. Sir J. Leng (Dundee), who has before interested himself in the business of the Patent Office, drew the attention of the President of the Board of Trade to Lord Kay's dicta, and asked if the suggestions contained therein could be adopted in British Patent Office practice. Mr. Ritchie's answer will be instructive to those who think it a light thing to introduce strict moral rectitude into the conduct of a revenue-producing Department. The right honorable gentleman pointed out that last year there were 25,053 applications for patents, and that an enormous staff would be necessary if the duty of deciding on the novelty of each application were imposed upon the Patent Office. Moreover, even the most eminent authorities differ occasionally as to what constitutes novelty. He was not, therefore, prepared to effect any alteration in the practice of the Patent Office. Of course not; only remember that each applicant pays at least £1 in fees, and the decision of Mr. Ritchie will cause no surprise.

THE COMPANIES BILL.—The Select Committee to which this Bill has been referred has now been constituted. It comprises the Lord Chancellor (Lord Halsbury), Earl of Leven and Melville, Earl of Dudley (Parliamentary Secretary, Board of Trade), Earl of Kimberley, Lord Belper, Lord Hillingdon, Lord Macnaghten, Lord Monckton (Viscount Galway), Lord Farrer, Lord Davey, Lord James, and Lord Aldenham. As before intimated (*ante* p. 374) the Earl of Melville is a member of Melville, Fickus and Company's Bank, and the interest he represents is further strengthened by the co-operation of Lord Hillingdon of Glyn, Mills, Currie and Company, and Lord Aldenham—more familiarly known under his old name of Henry Hucks Gibbs—who is a Director of the Bank of England. Lords Macnaghten and Davey are Lords of Appeal, and may, with Earl Dudley and Lord James, be regarded as official members of the Committee, and the same might be said of Lord Farrer, who formerly discharged important secretarial duties in the Department now presided over by Mr. Ritchie. The *raison d'être* of the Committee would thus seem to be the conservation of banking interests, and the subsequent addition of another banker to the Committee in the person of Lord Wolverton lends support to that view. But this should not discourage the Pharmaceutical Society, for it may be reasonably assumed that a committee so constituted will not find in the amendment proposed by Lord Herschell any principle antagonistic to the well-being of joint-stock banks.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, MAY 16, 1896.

PHARMACEUTICAL REFORM IN GERMANY.

GERMANY has hitherto been regarded as one of the countries where the practice of pharmacy was carried on under peculiarly favourable conditions—the system of limiting the number of pharmacies in proportion to population has prevented competition, the dispensing of medicine has been entirely in the hands of qualified pharmacists and the education of those entering the business has been such as to ensure their occupying a position of social equality with members of the medical profession. But within recent years changes have taken place which have adversely influenced the position of German pharmacists. One result of the system of limitation has been to raise considerably the value of a pharmacist's business, and in some instances this has been done in such a manner as to be regarded by the Government authorities as a public scandal. In addition, there has been, under this system, much difficulty in obtaining a business, and as a result the younger members of the body have not been able to take an independent position so soon as they desired.

The regulation of the practice of pharmacy has consequently been for many years past a subject of anxious consideration by the German Government, and probably not less so by all connected with the business.

The substitution in 1811 of concessions in the place of privileges or charters granted by the State as the authority under which a business was carried on did not materially affect the proprietary interest of the individual to whom a business belonged, and in practice a concession has been as much a piece of saleable property as a privilege. But subsequently a third form of authorisation was introduced—the personal concession—by which individuals obtain from the Government permission to carry on business without having also the power of transferring the business, by sale or otherwise, to another individual. So that when the owner of a business carried on under a personal concession retires or dies, the continuance of the business is entirely subject to the control of the Government.

At the present time there are in Germany 5162 pharmaceutical establishments. Of these 1820 are conducted under the authority of State privileges, 2352 under concessions,

and 764 under personal concessions, only this last-named authority having been granted since 1894. The German Government is now contemplating the establishment of a system throughout the country by which authority to carry on business as a pharmacist or "apotheker" would be granted only by personal concession. By that means it is considered that the sometimes artificially increased prices of pharmacies would be prevented, greater opportunity afforded to the younger qualified men to go into business on their own account, and probably there may also be an expectation that under the new system a reduction in the cost of medicines might be effected.

In regard to this project the owners of pharmacies are naturally opposed to its introduction, and that is also the case with the greater number of those who are still in the position of assistants. One of the chief grounds of objection is that the pharmacist would be to a great extent only a Government official—he would not have power to dispose of his interest in a business and of retiring with advantage. But above all, those who are the possessors of establishments apprehend considerable depreciation of their value, since the Government has so far given no indication that, in abolishing the older systems, any but the holders of privileges would receive compensation. If the concessions were to be abolished without compensation of the present holders, the result would be practically one of confiscation. Even the projects by which it is proposed to provide against that contingency, by a process of redemption, are not altogether satisfactory, because the present owners would have to pay for the provision so made, although their disappropriation would not be so apparent.

Quite recently a commission has been appointed by the German Government to consider the whole subject of regulation of the practice of pharmacy, and it met in the early part of April last. The result of its deliberation does not appear to have been decisive in any direction, but rather to have shown that agreement between the different parties cannot be looked for without the intervention of the Government. Under these conditions the introduction of a legislative measure by the State is awaited with great interest.

THE EARLY LIQUEFACTION OF GASES.

IN view of recent developments, it was a happy thought that led the Alembic Club to re-publish MICHAEL FARADAY'S papers on the liquefaction of gases as an addition to its list of handy reprints. As is well known, the Royal Institution was in FARADAY'S time, as now, foremost in this particular branch of scientific work. Prior, however, to the liquefaction of chlorine by "the prince of experimental philosophers" in 1823, carbonic acid and other gases had probably been liquefied by Count RUMFORD, unknowingly, in 1797; sulphurous acid gas appears next to have been reduced to the liquid form by MONGE and CLOUET; chlorine and sulphurous acid gas were similarly reduced by NORTHMORE in 1805-6, whilst about 1813, BABBAGE seems to have obtained liquid carbon dioxide. It must be acknowledged that a considerable degree of uncertainty exists with regard to all the instances quoted, little or no evidence being available except the bare statements of the investigators. RUMFORD had conducted experiments to determine the force of fired gunpowder, exploding it in cylinders of known diameter and capacity, closed by a valve loaded with a

weight that could be varied at pleasure, and, commenting on his published statements regarding the phenomena he observed, FARADAY remarks that in many of the experiments some of the gases, and especially carbonic acid gas, were probably reduced to the liquid state. MONGE and CLOUET applied cold and pressure simultaneously in their experiments, and FARADAY thought there was no inherent improbability in the accounts that credited them with having succeeded in liquefying sulphurous acid gas. Similarly, he was convinced that NORTHMORE'S and BABBAGE'S results were genuine. In several other recorded cases, however, he showed conclusively either that the means available could not have sufficed to secure the results that were claimed, or that the conditions of the experiments were unquestionably fatal to success.

Chlorine was the first gas definitely liquefied by FARADAY, the desired result being attained by heating in a sealed glass tube crystals of hydrate of chlorine, obtained by exposing moist chlorine to low temperatures. When heated to 100° F. "the substance fused, the tube became filled with a bright yellow atmosphere, and on examination was found to contain two fluid substances." These two fluids were proved to be chlorine and water. Subsequently, DAVY and FARADAY liquefied hydrochloric acid gas, and a few weeks later FARADAY was able to announce the liquefaction of sulphurous acid, sulphuretted hydrogen, carbon dioxide, euchlorine, nitrous oxide, cyanogen, and ammonia. The specific gravities and other properties of the different liquids were ascertained, and definite information was at last placed upon record, such as would enable anyone to repeat the experiments, and so become convinced of the accuracy of the published results. Twenty-two years later, in 1845, further papers on the liquefaction and solidification of bodies generally existing as gases were published by FARADAY. Considerable additions had then been made to this branch of knowledge by THILORIER, who first obtained carbon dioxide in the solid form, and the hope of seeing nitrogen, oxygen, and hydrogen, either as liquid or solid bodies, induced the great English philosopher to renew his investigations on the subject. He did not, indeed, succeed in overcoming the elasticity of the three gases named, but as was generally the case in his researches, other results of the greatest importance were obtained, six substances, usually gaseous, being added to the list of those that could previously be shown in the liquid state, while seven were reduced to the solid form.

The condensing tubes employed by FARADAY were of green bottle glass, and the caps, stop-cocks, and connecting pieces employed were attached to the roughened ends of the tubes by means of a cement composed of resin, beeswax, and red ochre. The pressure in the tubes was often equal to fifty atmospheres, and yet the experimenter enjoyed practically complete immunity from accident or failure. The cooling mixture employed consisted of THILORIER'S mixture of solid carbon dioxide and ether, FARADAY remarking in connection with this that there are "some results producible by cold which no pressure may be able to effect," and that "solidification has not as yet been conferred on a fluid by any degree of pressure." To procure the necessary low temperature the bath of carbon dioxide and ether was put into an air-pump, and the air and gaseous carbon dioxide rapidly removed, a temperature being thus attained which was sixty degrees below that of the bath when in the air, and one hundred

and sixty-six degrees below 0° F. Olefiant gas was easily condensed into a clear, colourless, transparent fluid; hydriodic and hydrobromic acids were obtained both as liquids and solids; fluosilicon, phosphuretted hydrogen, and fluoboron were also liquefied. These were all new results of the liquefaction and solidification of gases, but in addition sulphurous acid, sulphuretted hydrogen, euchlorine, nitrous oxide, and ammonia were obtained as solids. The solidification of cyanogen by BUNSEN, and the liquefaction of arseniuretted hydrogen by DUMAS and SOUBEIRAN were also confirmed. Hydrogen, however, together with oxygen, nitrogen, nitric oxide, carbon monoxide, and coal gas, showed no signs of liquefaction with the pressures and low temperature available.

The last paper quoted contains a statement by FARADAY that so far as his observations justify any conclusion respecting a general law, it would appear that the more volatile a body is, the more rapidly does the force of its vapour increase by further addition of heat, commencing at a given point of pressure for all. Continuing, he says there seems every reason to expect, therefore, that the increasing elasticity is directly as the volatility of the substance, and that by further and more correct observation of the forces, a general law may be deduced, by the aid of which, and only a single observation of the force of any vapour in contact with its fluid, its elasticity at any other temperature may be obtained. Finally, it is observed that the law suggested gives great encouragement to the continuance of those efforts which are directed to the condensation of oxygen, hydrogen, and nitrogen, and that further diminution of temperature and improved apparatus for pressure may very well be expected to produce those bodies in the liquid or solid state. It is a matter of common knowledge how, just fifty years after this forecast was published, the anticipations of FARADAY have been fully realised.

INTERPRETATION OF THE PHARMACY ACT.

By the decision in the case reported on page 386 of this week's Journal another important step has been taken in the construction of the Pharmacy Act, with regard to the position of proprietary medicines containing poison, purporting to be protected under Letters Patent and therefore exempted under Section 16. The article in question is a well-known proprietary medicine, and the case which came before Mr. LUMLEY SMITH, Q.C., on Wednesday, was intended as a test case. As will be seen, the position taken up on behalf of the Pharmaceutical Society is that an article which has been protected under Letters Patent ceases to be exempt under Section 16 of the Pharmacy Act as soon as the patent has expired. No point was made with regard to the non-payment of fees by the patentee, in consequence of which the patent lapsed after being held for a comparatively short period, nor was the question of the validity of the patent raised. On the other side, it was argued that when once Letters Patent have been granted the exemption continues indefinitely, or, to put the matter briefly, "once a patent always a patent." Judgment was given for the Society with costs, but notice of appeal having been entered, comment upon the matter must be deferred for the present.

ANNOTATIONS.

THE SOCIETY'S ANNIVERSARY.—The Annual Dinner of the Members of the Pharmaceutical Society and their friends takes place on Tuesday next, May 19, the place of meeting this year being the handsome new King's Hall at the Holborn Restaurant, London. The President of the Society, Mr. Michael Carteghe, will take the chair at 7 p.m. precisely. On the following day, Wednesday, the 20th inst., the fifty-fifth Annual General Meeting of the Society will be held at 17, Bloomsbury Square, W.C., at twelve noon, to receive the report of the Council and elect the Council and auditors for the ensuing year. Voting papers for the Council Election must be handed in at the meeting by voters personally, if not previously in the Secretary's hands by Monday at latest.

CARELESS ADMINISTRATION OF CHLOROFORM.—In the *Ph. J. Supplement* for April 25, brief particulars were given of a case in which an herbalist, who practised dentistry at Idle, had improperly administered chloroform to a girl who desired to have a broken tooth extracted. He was subsequently arrested on a charge of manslaughter, and at the trial at Leeds on Saturday last, medical evidence was given to show that the necessary precautions had not been taken by defendant, the girl's death being due to asphyxia, caused by the chloroform administered. Mr. Justice Wright, in summing up, told the jury that whatever might be the result of the prosecution it was a perfectly proper one to institute. Supposing a lenient view were taken of the charge, the prosecution would yet have done good in calling attention to the very great danger which necessarily resulted from ignorant persons playing with dangerous medicines and operations. They must not condemn the prisoner because he was not qualified, but must bear in mind that if an unqualified person took upon himself to administer dangerous remedies in a case where qualified help might be had, that person was guilty of manslaughter. The whole question for the jury was—Should the prisoner have used chloroform without knowing more about it? He did not seem to have neglected any precaution he knew of, but should he not have known more? The jury, after finding some difficulty in agreeing, finally announced a verdict of not guilty, and the judge then said he hoped the case would be a warning to all who, without adequate knowledge, performed dangerous operations or administered dangerous drugs. The prisoner had had a very narrow escape, and he deserved punishment, but not so severe as he would have received had the jury convicted him.

THE TECHNICAL EDUCATION OF APPRENTICES.—The Honorary Secretary of the Plymouth, Devonport, Stonehouse and District Chemists' Association—Mr. James Cocks—is endeavouring to obtain a general expression of opinion on this subject, by sending a card to local chemists interested in educational matters, and to headmasters of technical schools, etc., asking for suggestions how an apprentice should take up the various subjects in the pharmaceutical curriculum. It is assumed that the apprentice is sixteen years of age, has passed the Preliminary examination, and is engaged for a term of four years. An attempt to solve the problem here set was made in the students' number of the *Pharmaceutical Journal*, published on September 15, 1894, and the articles that appeared then have since been reprinted in the form of a pamphlet—'Advice to Students'—copies of which can be had by applying to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, W.C. Taking this pamphlet as a basis and working out the necessary details, Mr. Cocks and his friends ought to be able to devise a scheme specially applicable to their own particular district.

THE STELAR THEORY.—In *Science Progress*, A. G. Tansley explains that in the central cylinder of the axes of the great majority of the higher plants an anatomical region of the first rank is now recognised to be co-ordinated with the other great anatomical regions, the cortex and the epidermis. The central cylinder consists of vascular tissue (xylem and phloem) and conjunctive tissue (typically parenchyma), both being separable into distinct strands or regions in a typical case, whilst the innermost layer of cortex, abutting on the cylinder, is also distinguished by special characters. Reduced central cylinders occur in the thin stems of water plants and in other stem structures, the reduction being found to act first on the conjunctive, thus leading to the coalescence of the strands of vascular tissue into a more or less solid cylinder, which is always sharply marked off from the cortex. But there are also stems in which the conjunctive cannot be separated from the adjacent cortical tissue. The central cylinder being called a "stele," all stems with a single cylinder are said to be "monostelic." Most Ferns and Selaginellas, and two genera of Phanerogams, possess in their later formed stems more than one cylinder, each comparable in structure to the single stele of the hypocotyl in such plants. Such stems are known as "polystelic," and the steles in those stems may assume most varied forms, several sometimes even coalescing to form a structure indistinguishable from a single stele. The stele is nevertheless a real and relatively stable type in the arrangement of vascular tissue. In the leaf each strand of vascular tissue is called a "schistostele" or "meristele," as it represents a part only of the stem cylinder, but the meristele of a petiole may simulate a stele. The monostelic type may be assumed to be primitive in vascular plants, and the original stele was probably relatively simple, the primordial stele being represented at the present day by the single sharply defined stele of the embryo, which is maintained in the root and hypocotyl, and passes over in the stem to one of the modern types of structure.

'SCIENCE PROGRESS' for May contains other valuable and suggestive articles, the first being on the past, present, and future water supply of London, by E. Frankland, F.R.S., who considers that the quantity of water derivable from the Thames can be increased from 120 millions of gallons per day to 370 millions, thus providing for the wants of London for fifty or more years to come. Storage of flood water, utilisation of springs, the sinking of deep wells, and more careful filtration, are the means suggested for securing "an ample supply of water which for palatability, wholesomeness, and general excellence will not be surpassed by any supply in the world." Some notes on atomic weights are contributed by Alexander Scott, C. T. Druery mentions some curious facts with regard to aposporous and apogamous ferns, and G. C. Bourne concludes his article on the present position of the cell theory by describing cells as the ultimate vital units—the *Lebonsträger*, or biophors—though they are not the ultimate structural units.

LECTURE ON THE RÖNTGEN RAYS.—A popular lecture on the Röntgen rays will be delivered at New Cross Public Hall, on Thursday next, May 14, at 7.30 p.m., by Dr. Chisholm Williams, assisted by Mr. Leo Atkinson. Photographs will be taken in the Hall—through wood, aluminium, living flesh, etc., etc.—and exhibited during the lecture. By means also of cryptoscopes or fluorescent screens "opaque" bodies, such as purses, boxes, and books will be rendered transparent. It is intended to thoroughly demonstrate the whole subject, from the earliest experiments to the latest developments, including the actual exhaustion of the various forms of vacuum tubes. Tickets (2s. and 1s. each) may be obtained at the Hall on the evening of the lecture, and the proceeds will be devoted to the "Deptford Fund."

ANTITOXIN AND DIPHTHERIA.—In a letter to the *Daily News*, Mr. Lennox Browne refers to Mr. Demetrius C. Boulger's recent communication (see *Ph. J.*, April 25, p. 331) in which it was shown that whereas the mortality from diphtheria in cases treated by antitoxin in one of the Metropolitan Asylums Board's Hospitals, was about 27 per cent. during the first nine months of the year 1895, the death-rate for the last three months of the same year was more than double that figure, exceeding 58 per cent., and was also nearly double the whole mortality in the six hospitals reported upon for the year 1894. Whilst agreeing with Mr. Boulger's inference that the quarterly reports submitted to the Board would probably show a correspondingly increased mortality in all the other hospitals for the last three months of 1895, and consequently an even less satisfactory record for the serum treatment than has been announced, Mr. Lennox Browne is inclined to doubt that the increased mortality is due to a greater malignancy in the type of the disease for the period in which it occurred, and suggests that it is quite reasonable for those who do not admit the benefit of antitoxin to argue that the increased mortality is a direct result of the increased dosage that prevailed during the later months of the year.

THE ANTI-CUTTING MOVEMENT.—The ever active Western Chemists' Association of London will hold a meeting on Wednesday next, May 20, to discuss the anti-cutting movement. The meeting will be held at the Westbourne Restaurant, 1, Craven Road, Paddington, at 9 p.m. precisely, and any chemist in business who is interested in the matter, whether a member of the Association or not, is invited to attend on this occasion.

DRUGS IMPORTED AND EXPORTED IN 1896.—According to the monthly trade supplement in the *Economist*, both the imports and exports of drugs show a marked increase for the first four months of the present year. The gross value imported from January to the end of April was £291,961, against £276,723 during the corresponding period of 1895, and for the month of April alone the figures are £77,811 this year, against £69,869 in 1895. The exports of drugs and medicinal preparations are also satisfactory, as the gross value for the first four months this year amounted to £375,252, against £335,347 last year, and for April, 1896, £88,653, as against £83,815 in 1895. The total value of chemicals and chemical and medicinal preparations exported from January to April, 1896, was £3,062,076, and for the same period during 1895, £2,690,970.

PHILADELPHIA COLLEGE OF PHARMACY.—This College celebrated the seventy-fifth anniversary of its foundation on Wednesday, April 22 last, having been established early in the year 1821. The programme of the proceedings at the anniversary meeting is an exceptionally dainty souvenir of a most interesting occasion. Delicately printed views of the premises occupied at different periods of the existence of the College adorn the pages of the book, and there is also a detailed record of its progress and development. In the list of presidents of the College, by the way, the wicked printer has credited one esteemed individual with great length of years, the third president—Daniel B. Smith—being represented as holding office from 1229 to 1854. The College, it may be observed, last year adopted a three years' course of lectures, with the title of "Doctor in Pharmacy," and the graduating class for 1896 numbers two hundred and twenty-one students. More than fourteen thousand students have matriculated in the Philadelphia College since its foundation, and its continued and increasing success will commend itself to every English-speaking pharmacist who has the best interests of his craft at heart.

PROCEEDINGS OF SOCIETIES.

Chemical Society, May 7.—Mr. A. G. Vernon Harcourt, F.R.S., President, in the chair.—An ordinary meeting was held. A small attendance and a ballot night rarely happen together, but it was certainly so at the last meeting. The first paper selected by the President for reading was that by Dr. W. H. Symons and Mr. F. R. Stephens on "Carbon Dioxide—its Volumetric Determination." Mr. Stephens, who read it, said that the number of papers that had been written on this subject was enormous. The introductory part was devoted to the consideration of processes devised by various authors for the determination of carbon dioxide in the atmosphere, and they were more or less favourably discussed. Volhard's apparatus was useful for rough work. The authors recommend for the collection of samples of air two vacuous litre flasks. Ordinary flasks fitted with rubber-tubing would do. Steam at 20 pounds pressure was blown in for about two minutes until no steam remained on the sides. The tube was then closed and the flask cooled. The sample of air was then collected, the capacity of the flask being previously known. The process is as follows:—An alkaline solution of barium chloride, $\frac{N}{1}$, and sodium hydrate, $\frac{N}{10}$, is introduced into the flask and the rubber tube closed. Then the flask is thoroughly shaken at intervals for half an hour. If the alkaline solution has been in excess the CO_2 will be entirely removed from the sample of air, and the remaining alkali may be titrated directly in the flask with a dilute aqueous solution of acetic acid of known strength, phenol-phthalein being used as the indicator. Acetic acid has been found to give the best results, notwithstanding the fact that at least one worker, quoted by the authors, has condemned its use for this purpose, and an aqueous solution which keeps constant for weeks has been used in preference to an alcoholic solution, which is apparently not so good. Many indicators were tried, and phenol phthalein was selected.

A table of check experiments was drawn on the board, and it seems that the process is quite precise enough for all practical purposes. The following are a few of the figures obtained:—

Alkali.	CO_2 added.	Time.	CO_2 found.
20 C.c.....	18.8	1 hour	19.1
25 C.c.....	18.8	30 minutes	19.0
25 C.c.....	18.8	15 minutes	19.1
	7.5		7.6
	20.0		19.9

Samples of air for examination had been collected by the authors in one of the London police courts, a Salvation Army shelter, Drury Lane Theatre on a Saturday night, and other salubrious quarters, the amount of CO_2 found being stated. It has been said that two cubic feet of CO_2 is given off on burning one foot of gas, but the authors say that only 0.6 cubic foot is yielded.

For the determination of the number of micro-organisms in the air the authors first sterilise the flask by means of superheated steam, and then introduce 10 C.c. of a culture medium containing 15 per cent. of gelatin. Then steam under pressure is blown into the flask in order to displace air. Before the gelatin cools care is taken to have the solution evenly distributed over the lower surface of the flask.

Although several gentlemen spoke after the paper was read, none criticised the process. Professor Ramsay said that CO_2 was not so harmful as was generally supposed, and Mr. David Howard supported that statement, saying that the danger of close atmospheres was really due to foul exhalations. The President seemed to have his doubts about the vacuum being maintained for a month or longer in flasks furnished with indiarubber connections, but Dr. Symons, in his reply, assured him that such connections were absolutely reliable.

As there were no more authors present, the next three papers were read by Professor Dunstan. The first was by R. F. D'Arcy, M.A., "On Certain Views concerning the Condition of the Dissolved Substance in Solutions of Sodium Sulphate." This dealt with the determination of the variations of viscosity of solutions of different strength and temperature. The apparatus for this purpose was a modification of that used by Thorpe and Rodger. Mr. Pickering said that three different hydrates could be obtained from a solution

of one strength, a crystal of one or the other dropped in determining that which would be obtained.

Professor Dunstan then skimmed over the other two papers. "Luteolin" (Part II.), by A. G. Perkin. This colouring body has the composition $C_{15}H_{10}O_6$. Phloroglucin is produced on fusing with alkali. A yellow potassium salt may be obtained from the acetyl derivative. Fisetin, another yellow colouring matter, is a hydroxyluteolin.

"Morin," by Bablich Hermann, Ph.D., and A. G. Perkin. This yellow dye stuff exists in Jackwood. Its composition is $C_{15}H_{10}O_7$, and it bears a close resemblance to luteolin. Phloroglucin and resorcin result on fusion with alkali.

Professor Dunstan, after reading the last two papers, spoke in very complimentary terms of the valuable work done by Mr. Perkin on these yellow bodies. They were substances which, hitherto supposed to be different, were essentially the same.

The following papers were taken as read:—

"Synthesis of Pentacarbon Rings, Part I., Anhydracetone-benzil and its Homologues," by F. R. Japp, F.R.S., and G. D. Lauder, B.Sc.; "Synthesis of Pentacarbon Rings, Part II., Condensation of Benzil with Acetone Dicarboxylic Acid," by F. R. Japp, F.R.S., and G. D. Lauder, B.Sc.; "Reduction of Desyleneacetic Acid, and the Constitution of Zinni Pyroamaric Acid," by F. R. Japp, F.R.S., and G. D. Lauder, B.Sc.; "Electrolysis of Potassium Alloethylic Camphorate, Part II.," by J. Walker, D.Sc., and J. Henderson, B.Sc.

School of Pharmacy Students' Association, May 7.—

Professor Reynolds Green, F.R.S., in the chair.—After the minutes of the previous meeting had been read and confirmed, Mr. A. C. Seward, M.A., gave a most interesting account of "Fossil Plants," illustrating his subject by means of lantern slides. The various methods in which fossils have been produced were briefly described. Attention was drawn to some of the leading forms of fossil plants, and some of the difficulties which are met with in palæo-botanical research were pointed out. A vote of thanks to the lecturer was proposed by Mr. E. M. Holmes, seconded by Professor Greenish, supported by Professor Bretland Farmer, and carried with acclamation. Mr. Seward briefly replied, and the meeting then adjourned.

Society of Chemical Industry (LIVERPOOL SECTION),

May 6—Mr. Eustace Carey in the chair.—With respect to a statement recently published, to the effect that the British alkali trade had of late years decreased to a considerable extent, the Chairman pointed out that it was based on the money values of the products, which was quite misleading, by reason of the lowering of the price in late years. By taking the actual weight of production the figures showed an improvement instead of the reverse. Dr. G. C. Clayton read a paper "Chlorine as a Disinfectant." He detailed a series of experiments conducted on a bacteriological basis with a view to ascertaining the efficiency of chlorine, of bleaching powder, and of sodium hypochlorite. The experiments, carried out in conjunction with Professor Boyce, of University College, gave results distinctly in favour of the use of sodium hypochlorite as a germicide. A paper was also read by Mr. W. J. Orsman on "Colliery Explosions in Dusty Mines," the results of communicated experiments tending to show that carbon monoxide when mixed with coal dust formed a highly dangerous and destructive explosive. The inference to be drawn from this was, he said, that those blasting agents such as gunpowder which produced carbon monoxide on burning, were highly dangerous in their application to coal mining.

Chemists' Assistants' Association, May 7.—

The President, Mr. E. W. Hill, in the chair.—At the annual general meeting of this Association, after the minutes of the previous meeting had been read and confirmed, Messrs. Gilbert, Smith, and Pasco were appointed scrutineers of the voting papers for the election of the Council for 1896-1897, and Messrs. Bellamy and Cooper were selected to audit the balance sheet. The President said he had much pleasure in announcing that there had been a very good and keen competition for the prizes offered by the Association and Messrs. Burroughs, Wellcome and Company for practical work, and after careful deliberation they were awarded to Mr. H. Garnett for his paper, read before the Association on April 16, entitled "The Testing of Lemon Oil" (see *ante*, p. 323). In making this selection the Council wished to say that although they did not guarantee the accuracy of the process, yet the work embodied therein represented good and useful work of a

nature which should be encouraged, and it reflected credit upon the Association and the investigator. He was very glad to find that German chemists did not stand alone in the prosecution of original work on the nature and valuation of essential oils. The paper had already been productive of correspondence in the columns of the trade journals, and he hoped that although it had unfortunately been read at the end of the session, it would stand the test of criticism, and that the author would be encouraged to proceed in the work and endeavour to perfect the process. In the name of the Association he congratulated Mr. Garnett upon his success, his only regret being that owing to a slight delay he was unable to present the medal at that meeting. It would, however, be forwarded in a few days.

Mr. H. Garnett briefly responded, and the Secretary, Mr. R. Glode Guyer, then read the nineteenth

ANNUAL REPORT.

The Council of this Association has much pleasure in submitting to you this, its nineteenth annual report:—

"It regrets to record the loss by death of a staunch supporter and former President, Mr. H. H. Milhouse.

"The Association now numbers 144 members, of whom 41 have been enrolled this session. The vacancies which have been caused by death in the list of Patrons have been successfully filled, making a total of 48.

"The attendance at the ordinary meetings shows a considerable increase on former years, the average being 23, not including the attendance on the occasion of the inspection of Messrs. Idris and Co.'s factory, when 180 members and friends were present.

"As in former years, the papers read before this Association maintain their high standard. Twenty-one papers and notes have been read. The first short paper evening was chiefly devoted to the discussion of dispensing problems. A slight innovation has been made by the visits paid to the two factories. These were distinctly popular and well appreciated.

"The social side of the Association has been greatly developed. In addition to the annual conversazione and dinner, two smoking concerts and a series of three Cinderella dances have been held, which were eminently satisfactory. The annual dinner was held in the King's Hall, Holborn Restaurant, and for the first time in the history of this Association the President occupied the chair.

"The Council has awarded the Association's medal and Messrs. Burroughs and Wellcome's prize to Mr. H. Garnett for his monograph on 'The Testing of Lemon Oil.' It is gratifying to know that this prize was keenly competed for, but at the same time the Council regrets that it was unable to award the essay prize.

"The balance sheet indicates the continued satisfactory financial position of the Association."

In moving the adoption of the report, the President commented briefly upon its satisfactory nature. He remarked that although the statistics showed that there had been a decrease of four in the membership, yet this was not an adverse feature, if it were remembered how the number of assistants in London fluctuated. He was pleased to say that the Cinderellas had been inordinately successful in every way, which fact was greatly due to the energy displayed in their behalf by Mr. H. H. Robins, who had undertaken the management of them. Mr. G. Roe having briefly seconded the motion, it was carried unanimously. The balance sheet was then read by Mr. C. J. Strother, hon. treasurer. He expressed his great satisfaction in having to announce a balance of £83 8s. as against £67 9s. 5½d. last year, which latter was in turn larger than on any previous occasion. This fact showed the sound financial position occupied by the Association. The President moved the adoption of the report, and this was seconded by Mr. C. Morley, who in the course of his remarks advocated the extension of the scope of the Association by the establishment of a chemist's assistants' club, but the President was of opinion that the labour entailed in a scheme of this sort would be far too heavy to render it practicable. Before the motion was put to the meeting Mr. Strother remarked that it had been calculated that every member of the Association got value to the extent of 15s. 4d. in return for the subscription of 5s. Mr. H. H. Robins suggested that, in order to bring the advantages of the Association more prominently before the assistants living in the metropolis, a circular should be issued to everyone whose address could be ascertained, drawing attention to its claims. The President, in answer to this, remarked that at the commencement of the session a letter of this nature was sent to all the metropolitan and suburban chemists, with a request to hand it over to their assistants when read.

After a vote of thanks had been accorded to the auditors on the proposition of the President, seconded by Mr. Strother, Mr. Pasco,

one of the scrutineers, read the report of the Council voting papers. Seventeen members had offered themselves as candidates, fourteen of these being elected. Fifty-nine voting papers were received, one of which was invalid.

The candidates received the undermentioned number of votes:—
C. Morley, 57; R. Melhuish, 56; R. G. Guyer, 53; E. W. Hill, 53; G. Roe, 52; W. Moore, 51; W. G. Crouch, 50; C. J. Strother, 50; H. H. Robins, 49; A. Gunn, 44; Cooper, 36; A. T. Hill, 35; C. E. Robinson, 35; E. A. Umney, 33. The votes for the unsuccessful candidates were: F. R. Stephens, 28; Pearson, 28; W. H. Jones, 25.

The President then gave a brief valedictory address, in the course of which he remarked that he had no suggestions to offer as to new lines to be followed in the future. The sphere of the Association, in his opinion, was quite wide enough; the only thing necessary was that none of the members of the Association should relax their efforts on its behalf. He expressed his thanks to the officers and members for the cordial manner in which they had seconded his efforts.

Mr. R. Melhuish proposed a very hearty vote of thanks to Mr. Hill for the able manner in which he had presided over the business of the Association. In his opinion he had been an ideal President in every detail, and the welfare of the Association had always been his first consideration. Mr. Robins seconded this, and the motion, having been put to the meeting, was carried with acclamation.

Pharmaceutical Chemists' and Apothecaries' Assistants' Association of Ireland, May 8.—Mr. H. Hunt, L.P.S.I., in the chair.—The following paper was read:—

“OUR APPRENTICE,” BY JAMES B. ASHE.

Mr. Ashe said as he had within the last few months turned his back on the apprenticeship stage of pharmacy, he thought it would not be out of place to relate in a short paper his experience of things he had heard and seen during what he might call the budding season of pharmacy. He would divide his subject into three heads, namely, what “our apprentice” was, what he is, and what he ought to be.

In the first place, he would go back as far as the year 1618 and show the kind of work which the apprentice had then to do. Although not required to dip far down into the well of knowledge, yet his lot was far from being a happy one. The compounds then employed in medicine were often of a heterogeneous nature, the mixtures containing from twenty to seventy, or even more, ingredients, and such things were used as crabs' eyes, pearls, oyster shells, and amongst other disgusting preparations included in the formulæ were human skulls, the moss found growing thereon, blind puppies, earthworms, etc. Although the edition of the London Pharmacopœia, published under Sir Hans Sloane in the sixteenth century, had many important alterations, yet such things as earthworms and moss from the human skull still remained, the botanical names of herbal remedies were first added to the pharmaceutical curriculum, and then followed distilled waters, thus ensuring a uniform strength. It would, therefore, be seen that although the apprentice in the time of Queen Anne had very little brain work, yet he more than made up for the deficiency by the amount of mechanical labour called daily into requisition. At that time the apothecary was regarded with awe, and his “science” remained a profound mystery. The apprentice, however, was human enough in some respects. In a street brawl he was sure to be in the midst of it, where his skill in the healing art was a valuable help to those requiring his assistance. Such preparations as hyd. c. crete, pil. hydrarg., etc., always fell to the lot of the apprentice to make, so it might be concluded that his biceps were then more fully developed than in these days. The present-day chemist's apprentice was, he thought, in many cases a complete failure. How many young men were there who voluntarily entered pharmacy as a profession, and of those what induced them to enter the business? From observation and inquiry he found that the great bulk of the apprentices have been obtained through their parents and guardians having chosen pharmacy for them as a compromise between a college course and a profession. The boy on leaving school is “too good” for an office or a shop, and by putting him into a pharmaceutical establishment two birds are killed with the one stone, dignity is satisfied, and the chemist's shop—that half-way house between the college and the counter—recruited by yet another disciple of Galen. The apprentice on the other hand enjoys the novelty of his new calling, believing there is little to be done outside of the mere admixture of drugs and chemicals. From the outside, too, the pharmacy looks very pretty and inviting with its long rows of polished gilt-lettered bottles, while inside the perfume of scents and

aroma of drugs tickle his sensibilities and lead him to the belief that the pharmaceutical apprentice is indeed to be envied. But he is quickly disenchanted when on the first day of his servitude he has to put up seidlitz powders and feels the sting of the acid, and perhaps in the evening if there is a slackness in the compounding room he is initiated into the mysteries of pill making. Rapidly indeed does his ardour cool, and in a short time the gilt is considerably rubbed off the gingerbread. Another reason which often prompts parents to put “young hopeful” to pharmacy is his taste for chemicals, as too often evinced by hopeless attempts at photography with a half-crown camera. He also possesses a treatise known as “The Play Book of Chemistry,” and armed with this volume as a guide, and the backyard as a laboratory, he essays the manufacture of fearful and wonderously bad-smelling “chemicals.”

Of the present-day apprentice foremost may be placed the studious youth. Such a type, said Mr. Ashe, I am told, does exist, but as yet I have not met him. There are very few young men who can conscientiously do a good two hours' uninterrupted study. The studious apprentice is fully alive to the importance and usefulness of his chosen profession, his spare moments are spent to good advantage, and whilst putting up stock his book is open beside him, and chemical equations are his bosom friends. Then we have the easy-going apprentice, whose belief is that everything will work out to his satisfaction. Nothing disturbs his equanimity. Peck-sniff-like he is all peace, and a holy calm pervades him. Give him work and he will do it, as long as he is under observation, but remove the watch and mechanically he wanders to the window, therefrom to study art and nature, animate and otherwise. Draw attention to the neglected work and he attacks it with renewed vigour. This goes on until he is suddenly seized with unwonted energy. He becomes eager to do anything, but as the result of “more haste, less speed” he divides his mass for a dozen into twenty-four pills, makes his six-ounce mixtures wrongly and behaves generally in an extraordinary manner. The secret is out: our apprentice has got a young lady! He had been seen airing her on his evening off duty, and, when taxed with the discovery, acknowledges all, and solicits, in confidence of course, straight hints as to the best place to buy flowers, etc., and invites criticism on the damsel by remarking interrogatively—“Say, Johnny, isn't she a lovely girl?” At this point the crisis may be seen. Now, too, may be seen a remarkable change in his toilet. He leaves business as if he had just emerged from a band-box. He takes a lively interest in the newest styles of neckties and wearing apparel, while his washing bill for collars and cuffs advances by leaps and bounds. He is observed casting furtive glances in the mirror, critically examining the down on his upper lip, and sundry hair washes and moustache promoters found on his dressing-table tell their own tale. The next type is the good-natured, fat, idle apprentice, who harms none but himself. Work and he are sworn enemies, and he will resort to any subterfuge to avoid that enemy. Dickens' Artful Dodger is nothing to him in regard to finding out easy “jobs.” As a rule, however, he is the most obliging fellow in the world, and will go to endless trouble to do a good turn, but—he will not work. I would like to give my opinion as to what the apprentice ought to be. He should begin his pharmaceutical career thoroughly understanding that he is working for a profession, and properly realising what he has to go through before he attains the goal of his ambition. He should possess a good preliminary education, and the entrance examination of the Pharmaceutical Society should be passed before the period of apprenticeship commences, in order that he may have uninterrupted training for his Licence examination. Sufficient opportunities ought to be given for study, as it is not fair to expect a lad after a hard day's work of twelve hours' duration to sit down with a clear intellect and study. I would urge on him the necessity of learning during his apprenticeship not merely the practical, but also the theoretical work of his examination, not leaving it, as is done in many cases, until a few months before the test. Knowledge obtained by the *nulla dies sine versa* is far better and more lasting than the cramming which must of necessity take place if the real work is put off till the eleventh hour. In his private life the apprentice should endeavour to be in every respect the noblest of God's works, a man and a gentleman.

At the conclusion of the paper Mr. Walsh observed that the hours for study allowed by employers were capable of extension. A long day's work took away much of the desire for study from the apprentice. Mr. Hardy concurred, but thought Mr. Ashe's word picture of the apprentice was not lifelike. The types alluded to were such as could be met daily in every large city, but they referred more

directly to the quiet country boy. The city apprentice, as a rule, knew exactly what he was about. Shakespearean pharmacy was not likely to be revived, and the trade was more in touch nowadays with German synthetic remedies than powdered cockroaches or boiled heads. Mr. Hendrick humorously touched on the love-smitten apprentice, and said it was the experience of most of them; like the measles, however, it passed off more or less quickly, according to the severity of the attack. He thought the daily work of the apprentice should not exceed nine hours, and that the period of duty should be between 9 a.m. and 9 p.m., with three hours' interval during this period. There should be no Sunday work for the apprentice, and above all he should not be rushed into work immediately on the completion of his indentures. He deprecated the entrusting of pill-making to the pharmaceutical neophyte, who should get time to look around him. It was a great mistake to allow country apprentices to live outdoors, unless with some relative. The rustic, fresh from the country, and alone in lodgings in a large city, was to be pitied, at present and in the future. An apprentice in a country town was infinitely better off than his metropolitan colleague, unless he had some friends to keep an eye on him. Mr. Ewing disagreed with the writer that the apprentice was a complete failure. If so, why did not the blush arise to the reader's face when he made the statement? He agreed that no apprentice should go to business until the Preliminary examination had been passed. Fortunately for himself, he had undergone the test before he began his apprenticeship, but he had seen young lads reading at night for four hours at a stretch after a tiring day's work, robbing nature of its due, and suffering from want of sleep. It was a disgrace for employers to countenance such a thing, and the remedy was for them not to take apprentices who had not passed the Preliminary examination. No boy ought to be indentured younger than sixteen years of age. Before that period a young man's life was not properly formed, and he was to all purposes a child. He (Mr. Ewing) was in favour of the apprentice roughing it from the beginning; nothing knocked the "cheek" out of the bumptious youth more than a wholesome course of pill pounding or mortar mashing. The evolution of the chemist's apprentice should be gradual. He would divide the period into four years as follows:—The first year simply roughing it, and doing anything he was bidden; the second year he would put him at the counter; the third year advance him to the compounding room; and the fourth and last year might be spent with advantage at general counter and prescription work. The moral condition of the apprentice had not been touched upon at all, and yet this was perhaps the most important point in connection. He would ask, Did the assistant always set the apprentice a good example to follow in everyday life? If the youth were seen going to the dogs, did the assistant—himself a sometime apprentice—put out the saving hand and check the downward course of the boy? Admittedly, there were good, bad, and indifferent amongst all grades of pharmacy, but he feared "Am I my brother's keeper?" was responsible for not a few cases of bad endings to good beginnings. The apprentice imitated the assistant, and the latter should therefore be doubly careful in his acts and words. The moral responsibility was tremendous. With regard to the working hours of the apprentice, there were many masters unaware or forgetful that the Act of Parliament fixed a maximum of eighty-four hours' work, including meal hours, weekly, but what was the fact? The unfortunate apprentices—growing lads and not overstrong in many cases—were obliged to work from 100 to 110 hours weekly. Could it be wondered, then, that so many of these boys broke down not only in their examinations, but in their health? The system prevailing was an outrage on the morality of their profession, and a distinct breach of the law of the land. He trusted that the paper and the discussion arising from it would be fully reported in the trade press, and hoped that the light thus thrown upon the seamy side of the apprentice's life would be productive of good, and perhaps tend to the amelioration of the life of the future chemist's assistant. He had much pleasure in proposing a very hearty vote of thanks to Mr. Ashe, whose paper might be the means of stirring up the masters to a sense of what was due to others as well as to themselves. Mr. Hunt and others, having spoken on the general features of the paper, mentioned that as apprentices had to pay a fee, there were many who would not do porter's work, as included in the "roughing" process, although for their ultimate good, and employers could not insist on such being done. Mr. Hardy said the gradually increasing severity of the Minor examination was an evidence of short sight on the part of those at the head of the English Society, and it was not to be wondered at that

so many were "plucked" from time to time. It was simply putting the cart before the horse. The Society was concentrating its energies on the subjects of examination, and doing nothing to fit the candidates for them. In this respect they in Ireland were much more favourably situated, and with the present men at the helm they would be even more so in future. He failed, however, to see how it could be expected that an apprentice working twelve or thirteen hours per day could possibly prepare the subjects for examination. That they even attempted to do so was evidence not of failure but of success. He advocated a shorter term of apprenticeship and an interval at a college of pharmacy. Mr. Hegarty seconded the vote of thanks to Mr. Ashe, who suitably responded, and the proceedings terminated.

PROPRIETARY ARTICLES TRADE ASSOCIATION

MEETING AT HALIFAX.

At Halifax, on Thursday, May 7, a representative and well-attended meeting was held at the Old Cock Hotel for the advancement of the Proprietary Articles Trade Association. Councillor W. C. Hebden (President of the Halifax Chemists' Association) presided, and among the local members of the profession present were Messrs. James Farr, Jonathan Jessop, G. M. Cobb, J. H. Pilling, W. S. Thompson, J. Swire, H. Bell, H. W. Seely, J. Patchett, J. W. Tiffany, C. H. Fielding, J. R. Comyns (Luddenden Foot), Tom Briggs (Sowerby Bridge), Jos. Rholes (Mirfield), W. Toone (Hipperholme), and D. Hey (Hebden Bridge). The deputation attending included Messrs. W. S. Glyn-Jones (Secretary), W. Simpson (Liebig's Extract of Meat Co.), Frank I. Hoy (Bovril, Ltd.), H. S. Norris (Condal Water Co.), J. E. Garratt (Frog in Your Throat), and S. Norman Pickard and F. H. Taylor (Bradford Chemists' Association).

The Chairman, in his opening remarks, stated that every one of them had had a painful experience of the severity of the "cutting," which had taken place in the retailing of "patent" and proprietary articles. They were all, therefore, interested in any practical remedy that could be found for the solution of the difficulty. He thought that the scheme of Mr. Glyn-Jones was the most feasible that had yet been propounded.

Mr. H. W. Seely read letters regretting inability to attend from Messrs. C. A. Higgins, J. Day (Dewsbury), L. A. Cocker (Ripponden), Smith Ward (Dewsbury), J. Bancroft, Cardwell, and Son (Brighouse), W. Stead (Heckmondwike), W. J. Ward (Conisbro'), J. White (Rotherham), and J. A. Sutcliffe. In his communication, Mr. Higgins wrote that chemists everywhere who were not satisfied with the present state of things ought to support the Association. He could not, he said, understand any one hanging back.

Mr. W. S. Glyn-Jones then, in a concise statement, explained the constitution of the Proprietary Articles Trade Association, and the proposals by which it was intended to achieve the objects in view.

Mr. G. M. Cobb afterwards moved:

"That we, the chemists of Halifax and district, hereby declare our approval of the anti-cutting movement, which we regard as beneficial to the interests of both owners and distributors of proprietary articles. Believing that 'union is strength,' we respectfully advise those proprietors who have not yet joined the defensive combination now being formed in connection with the Proprietary Articles Trade Association, 2, Stonecutter Street, E.C., to lose no time in doing so; and we pledge ourselves to use all honourable means in our power to further the progress of that Association."

Mr. James Farr, in seconding the resolution, maintained that a manufacturer in putting an article on the market was not justified in saying that it was a 1s. 1½d. article if he intended that the retail price should be 1s. He thought that if makers of proprietary medicines were to state distinctly the price they intended their articles to be sold at there would be some hope of the "cutting" system being put an end to. This practice of "cutting" was having a most serious effect on the trade. For some years before he gave up business he was making £120 a year by the sale of proprietary medicines, whilst at the time of his retirement he was not making more than £5. He should be glad to do all he could in order to bring about the accomplishment of the scheme which Mr. Glyn-Jones had placed before them.

Mr. Jonathan Jessop mentioned that he had been retired from business for a number of years. When, however, he was in business, the "cutting" system had to be contended with, and he knew that the evil had been growing stronger and stronger since. It had now been in existence so long that there would be a difficulty, he

feared, in eradicating it. Still, there was no doubt that, by combination, this was possible of accomplishment. He should be pleased to do whatever he could to strengthen the hands of the trade.

Mr. Pickard (Bradford) welcomed the scheme propounded by Mr. Glyn-Jones, not only because of the benefit which he believed it was destined to secure for the trade, but because of the fact that it would enable chemists of different towns to form an acquaintance with one another. He claimed that they should be allowed by the wholesale dealers a margin of profit of at least 20 per cent. It stood to reason that the stores could not afford to keep their establishments open for the sale of proprietary medicines at cost price. What they did was to urge to the customer "So-and-so is a great deal better," and very often they succeeded in substituting something on which they had a good profit. He believed that if the stores were compelled by the manufacturers to sell the articles they supplied at a given price, the public would again give their patronage to the chemists.

The Chairman regarded it as strange that chemists, who prided themselves on being partly professional and partly commercial, but who were distinctly respectable and intellectual, had been almost the last to take up the question of organisation. He believed that if they loyally combined together they could carry the scheme which Mr. Glyn-Jones had placed before them. The benefits derived, moreover, would not stop there, but would go further and further. They now found tailors, drapers, hatters, and all sorts of people engaged in selling these proprietary medicines. But why was it they sold them at cost price? Their object was to gull the public into the belief that because they sold such medicines cheap, therefore everything else in the shop was sold at the same ratio. It was the smartest piece of gulling he knew of, because their only intention was, like the spider and the fly, to get the people into their web, and their loss of profit on the medicines was made up by the extra profits they obtained on other goods. Those people, more than any other class of people, were doing the chemists harm, and it was those people that the combination proposed would most seriously affect. With regard to the question of substitution, he must say that whilst the drug stores were guilty of this practice chemists were equally guilty of the same sin. They endeavoured, to the best of their ability, to induce customers to purchase a preparation of their own in preference to that of the "patent" medicine vendor. It was time, however, that this sort of thing was ended. The interests of the wholesale vendors and themselves, as retail traders were mutual, and that being so, they should do the right thing one to another. What they asked was that the proprietors should allow them to make a profit on the articles they supplied of from 20 to 25 per cent. Of course, they would prefer the 25 per cent., because a fourth was so much easier to reckon. If, however, an arrangement of this kind was come to, it must be on the strict understanding that they would never attempt to substitute for a protected article one of their own. Where a customer came to them for advice, without asking for any of these articles, they would still have a perfect right to endeavour to sell their own goods.

Mr. H. Bell, who looked upon the scheme proposed as a feasible and practicable one, agreed with Mr. Farr that the manufacturer should fix the "face value" of the article he dealt in.

Mr. H. W. Seely observed that the "patent" medicine proprietors had been nursing the stores in the past. They were, however, finding out that, instead of being their greatest friend, they had proved their greatest enemy, in that they put up everything in opposition to the article they supplied. Thus the proprietors were now desirous of again taking up with the chemists. The latter were nevertheless willing, so long as they made amends, to forgive them for the past.

Mr. W. S. Thompson considered that, to prevent "cutting," wholesale dealers should give a guarantee that all retailers selling under full price would be required to forfeit a given sum. They should either do this or consent to allow them 4s. on the turn-over of every dozen 1s. 1½d. articles they sold. The present agitation, he feared, was being a little bit got up by the manufacturers.

Mr. Tom Briggs (Sowerby Bridge): Have you calculated what the profit works out at at 4s. per dozen 1s. 1½d. articles?

Mr. H. Bell pointed out that these were days of education, and said that chemists would have to be content with 15 or 20 per cent. profit, if they wished the manufacturers to support them.

Mr. C. H. Fielding mentioned that the system he had adopted had been that of "cutting the cutters." His object had been to get together a dispensing business, and the trade in proprietary medicines he had allowed to "go hang," as far as he was concerned. There

was a lot of "bunkum" about these proprietary manufacturers. The way they gulled medical men was, to him, really marvellous. Some of the articles advertised he had found in dispensing were not what they were represented to be, and medical men he had communicated with had since refused to use them. The scheme propounded to them that evening had his support.

Mr. J. Swire urged that the agitation would be more likely to be successful if chemists could get the grocers to join with them.

Mr. Glyn-Jones replied on the discussion, pointing out that if chemists were granted 25 per cent. profit on an article they would be much more likely to push it than if they were allowed only 5 per cent. The profit, he maintained, should be regulated a great deal by the question of consumption. Articles of a medicinal character, for example, should bear a greater profit than articles of food, for which there might be twenty times the demand. The suggestion that he was "a dummy" acting the part of the manufacturers in this agitation he emphatically denied. No one who knew the difficulty he had experienced in inducing manufacturers to join would, he knew, make such a suggestion. The fact was that both retailers and manufacturers had something to get by joining the Association. He might say that, as regarded the grocers, they were as anxious for an alteration of the present system as chemists were.

The resolution was then put to the vote, and agreed to unanimously.

On the motion of Mr. W. S. Thompson, seconded by Mr. Brerley, the Executive of the Halifax Chemists' Association was appointed to act as the local executive in connection with the Proprietary Articles Trade Association.

Mr. H. S. Norris moved, and Mr. Frank I. Hoy seconded, a vote of thanks to the Chairman, whose reply brought an encouraging and pleasant meeting to a close.

MEETING AT SHEFFIELD.

A meeting convened by the Proprietary Articles Trade Association was held on Friday, May 8, in the Montgomery Hall, Sheffield. The attendance was fairly numerous. The Association was represented by Messrs. J. E. Garratt (Frog in Your Throat), W. Simpson (Liebig's Extract Company), B. Hirst (Hirst, Brooke and Hirst, Limited), H. S. Norris (Condal Water Company, Limited), C. H. Corbet (Stephen, Smith and Company), and W. S. Glyn-Jones (Secretary). The local pharmacists and dealers were Messrs. S. Cheeves and Son (local agent for Bovril), Greaves and Son (Chesterfield), J. T. Dobb, J. Preston, W. Ward, A. Russell Fox, J. P. Hewitt, C. O. Morrison, T. Dobb, G. Forrest, G. Holmes, C. H. Twelves, J. W. G. Turner, G. Squire, T. Waterhouse, F. Jepson, J. A. Gibson, J. J. Riding (all of Sheffield), and J. Taylor (Woodhouse). Among those who were unable to attend, but who wrote expressing sympathy with the objects of the meeting, were Mr. J. S. Burnell (Sheffield), Mr. G. G. McGibson (Wath), R. Brook (Halifax), Hollingworth Bros. (Barnsley), G. Hodgson (Hemsworth), A. Simpson (Stalybridge), Greaves and Son (Chesterfield), etc.

Mr. A. Russell Fox was elected to the chair, and in his remarks said that, as chemists, all present were naturally interested in this question of cutting prices, and had been for many years. They also naturally desired that something should be done whereby the retailers might secure legitimate profits upon the articles in which they of necessity had to deal. He had come to learn what the Association had to suggest that the trade should do.

Mr. Glyn-Jones then described the aim and objects of the Association which he represented, and its scheme for remedying the cutting evil. At the outset, however, he explained that previous meetings of this character had been held under the auspices of the local associations, and he regretted it was not the case in this instance. The Sheffield Association however, in reply to his communication, stated that as this was a question of prices and their regulation it was not able to take any action in regard to it as a body. Consequently he (Mr. Jones), had been compelled to convene the meeting independently of the Sheffield Association. Mr. Middleton, representing Greaves and Son, moved—

"That this meeting of chemists residing in Sheffield and district, having heard the objects and proposals of the Proprietary Articles Trade Association, considers them worthy of support by chemists generally, and would urge upon all manufacturers and wholesale traders the importance of assisting the movement."

Mr. W. Ward, in seconding, remarked that the proposals of the Association were certainly calculated, if carried out, to benefit all those present, and if anything of the kind suggested could be accom-

plished, he should feel very grateful. He confessed, however, that he could not see the silver lining to the cloud. It seemed to him that the remedy for the grievance lay with the manufacturers, and that retailers could exercise but little influence to coerce or induce them to conform to the scheme which had been laid before them. He was sorry that Mr. Jones had not been able to show that the wholesale houses had made a greater advance in this direction than seemed to be the case. At the present time, when a customer applied for a proprietary medicine and asked the price he was inclined to ask in reply what the customer was prepared to give, or what he had been giving elsewhere.

Mr. J. T. Dobb expressed himself as being in complete accord with the objects of the Association, but saw no hope of their policy being carried out. The wholesale houses were masters of the Association, and he wished the retailers would force them to combine so that they might refuse to supply stores and deal only with the legitimate dealers in proprietary articles.

Mr. J. Preston could not support the resolution because the chemists were being asked to join a nebulous body, which as yet had no mind. No rules had been laid before the meeting, and Yorkshiremen liked to look before they leaped. He also deplored the lack of unity and cohesion among local chemists, as evidenced by the small attendance at the meetings of the local association. He held that the new Association was not true to the principles it advocated, because Mr. Elliman, who had been held up by it as a model, was permitting the sale of his preparation at a shilling per bottle, while the advertised price was 1s. 1½d. His opinion was that in every case proprietary articles should be sold at the advertised price, and no less. He always obtained full prices himself. He claimed that the chemists were an important factor in helping to popularise proprietary medicines, because the public took their opinion upon the medicinal merits of the preparations.

Mr. Morrison expressed a sense of the indebtedness of all the chemists to the deputation, but could not support the resolution until the officials were able to show a better prospect of carrying their objects, and further, if those objects were attained, that the trade would be any better off. He was inclined to predict that if the stores were stopped from selling proprietary medicines they would simply compete with the pharmacists in an equally severe manner in drugs. He looked upon the attempt to put a stop to cutting as merely another species of protection, and in his opinion a man who paid for what he had bought had a perfect right to sell at any price he thought fit. If he saw any prospect of the scheme of the Association being carried out he would heartily support it, but he regarded it as hopeless, and feared that the last state of the chemists would be worse than the first. Competition would be simply transferred to drugs, on which chemists were getting a fair profit, and perhaps they would lose their trade both in drugs and proprietary medicines.

Mr. Twelves heartily supported the resolution.

Mr. Riding took the same side, and urged more combination among chemists.

Mr. Glyn-Jones replied to the speeches in vigorous style. He contended that the objects of the Association were possible if only the retail chemists would unite, and he called upon every person present to help in the work. The smallness of the meeting he regarded as a disgrace to the chemists of Sheffield; many of those who were absent would not even take the trouble to send a post-card expressing sympathy with the movement.

The resolution was carried with only one dissident.

FOREIGN NEWS.

MEDICINE IN SOUTH AFRICA.—A recent issue of the *Cape Times* says that medical men throughout the British South Africa Company's territory are unanimous in their desire to establish a Rhodesian Medical Council, and all that is now wanted to bring about such a desirable result is the sanction of the authorities.

PROPOSED RESTRICTION OF PHARMACIENS IN FRANCE.—The constantly-increasing number of pharmacies in France, and the keen competition to which it has given rise, have rendered pharmacists alive to the fact that protective measures should be adopted tending to restrict their number. With this object a committee was appointed in February last by the "Syndicat Général des Pharmaciens" to study the question, and especially to find some method for the limitation of the number of apprentices. According to the report now published it appears that whereas in 1874, when the profession was lucrative, there were in France 6170 "officines" to a population of 36 millions, *i.e.*, 1 for every 5851 inhabitants, in

1894 for 38 millions there were 8442, or 1 for 4552 inhabitants, and signs were then obvious of declining prosperity. One of the measures suggested by the committee in order to arrest the growing number of new establishments consists in instituting competitive examinations, when a limited number only of pharmaceutical diplomas would be awarded annually, but serious objections would arise in carrying out this project. It was proposed, as a more ready means, and one that would be in the hands of pharmacists themselves, thereby obviating the hazardous process of an appeal to legislation, that local pharmacists should combine and elect a Central Committee in Paris who would be exclusively empowered to authorise the engagement of apprentices. This Central Committee having in its possession the necessary data, supplied by the syndicates in each town, would be able to regulate the number of apprentices according to requirement, taking as basis the official statistics. These show that during the last ten years the Faculties and Schools have qualified an average of 600 pharmaciens, which has been computed to represent 1080 apprentices of one year's standing. It is this number that the Central Committee would endeavour to maintain or diminish, according to expediency. In the event of this proposition being entertained, members of the local syndicates would be requested to bind themselves not to take an apprentice without the sanction of the Central Committee, and not to give certificates of the three years' pupillage unless the whole of that period had been devoted exclusively to the profession.

NEW AMBULANCE STATIONS FOR PARIS.—In accordance with the recommendation contained in a report presented by M. Strauss the Municipal Council has decided to institute four new ambulance stations in Paris. The Director of Municipal Affairs has been charged to present a project for establishing a system of alarms in order to give instant notice of accidents, so that medical assistance may be obtained as speedily as possible. The Council has also requested the Director of the "Assistance Publique" to arrange for the installation of "prompt aid" hospitals, one on each bank of the Seine, or otherwise for the provision of a constant service of surgical aid for these cases in the existing hospitals.

OBITUARY.

SPRINGETT.—On May 5, B. C. W. Springett, Chemist and Druggist, late of Aldeburgh. (Aged 25.)

SYMINGTON.—On May 6, Thomas Symington (of Messrs. T. Symington and Co., Beaverhall Chemical Works) died at his residence, Wardie House, Boswall Road, Trinity, Edinburgh, aged 45 years. Mr. Symington was widely known in connection with the manufacture of essence of coffee (Pyramid brand), in which he had gradually built up a very extensive business. He served his apprenticeship with Messrs. Gardner and Ainslie, of George Street, and about twenty-two years ago purchased the business of Messrs. Scott and Orr, Dundas Street, from Dr. John Nicol. Some years before this the old firm of Pugh and Plew had been amalgamated with that of Scott and Orr. The former seem to have been the first in Scotland to manufacture a coffee essence. In England it seems to have been made by Lea and Perrins as early as 1840. The formula of Pugh and Plew was improved by Dr. John Nicol, and it was brought to its present more perfected state by Mr. Symington, who in 1888 retired altogether from the retail drug business, which became the sole property of his former partner, Mr. J. Innes Fraser. Henceforth Mr. Symington devoted his whole time and energies to his wholesale and manufacturing business at Beaverhall works. About six years ago he had a serious attack of influenza, from which he never wholly recovered. A voyage to Australia in 1890 had a temporary good effect which was short-lived, and for many months he has been almost entirely disabled, and ultimately succumbed to an internal abscess. He leaves a widow but no family. The wholesale business will be continued as before by the remaining partner, who has had entire charge for several years. Mr. Symington became an Associate of the Pharmaceutical Society in 1868, and has been a subscriber to the Benevolent Fund since 1876.

HUGHES.—On May 7, John Hughes, one of the directors of Idris and Co., Limited, died after a brief illness, aged 69 years. He was born at Mold, in Flintshire, and for many years was connected with the York Glass Co., entering the firm of Idris and Co. in the year 1885. Mr. Hughes was a member of the Court of Common Council—where he was very much respected—for about twenty-five years.

CORRESPONDENCE.

THE APPROACHING COUNCIL ELECTION.

Sir,—Can anything be done to arouse a little interest in the election of members to the Council? Continuous grumbling is heard on all sides, and yet when a chance is offered for making a change, if desirable, in the *personnel* of the Council, about one-third or even less of the electorate take the fearful trouble to vote! Are not this eternal apathy, indifference, and want of union amongst us quite sufficient to account for the things which cause the grumbling?

Lowestoft, May 9, 1896.

A. H. HINDE.

Re ILLEGIBLE HANDWRITING.

Sir,—What the doctor meant in the order of which you reproduced facsimile in the *Pharmaceutical Journal* for April 25 (p. 340) was: "Please let bearer have pulv. acid. boracis, ʒss."

Bognor, May 8, 1896.

X.

Sir,—"X's" specimen of "illegible" handwriting (see *Ph. J.*, April 25) I thought fairly easy, and until I saw the attempt of "Boldo" I did not think it needed a reply. I therefore now send my reading:—"Please let groom have pulv. acid. boracis, ʒss."

Plymouth, May 9, 1896.

R. S. LUKE.

Sir,—The order sent you by "X," which appeared in your issue of 25th ult., apparently reads: "Please let groom have pulv. acid. boracis, ʒss."

May 9, 1896.

W. M. S.

Sir,—The order received by your correspondent "X" on April 18 last, and published in the *Journal* of April 25, I read:—"Please let groom have p. ac. borac, ʒss."

Sandown, May 11, 1896.

"YELDEM."

COCAINE IN OINTMENTS.

Sir,—Your correspondent's reply to my queries on above has interested me much, and I feel greatly obliged that, in spite of forebodings, and heedless of my love of badinage—always an unseemly thing in a pharmacist—he has endeavoured to quench my thirst for knowledge, which thirst, however, is not yet slaked. Before passing from the subject, there are one or two points I should like to notice. It is remarkable how much at one I find myself with Mr. Johnston regarding the probable explanation of the decomposition of the alkaloid, as he gives it in his letter of the 13th inst.; but is that gentleman quite at one with himself therein? In his original communication he gave the reason as clear that the alkaloid had been decomposed by the "hot fat," and my query was based thereon. In his reply he has religiously avoided any reference to his former reason, and distorting my question to one disputing the ability of heated lanolin to effect the decomposition, invites me to tilt—Don Quixote-like—against quite revered and reverend authorities. Might I point out to him that they do not support the assertion that the alkaloid was decomposed by the "hot fat," and also that lanolin is not described as a "fat," but as "hydrous" wool fat, and thereby hangs the difference. Such, indeed, must have been apparent to your contributor when he replied to my queries, for he gravely explained his first reason of the decomposition, namely, by the "fat," by showing how it must have been caused by the "water" contained in the "hydrous lanolin." Perhaps he has mistaken my hue and over-estimated the amount of chlorophyll I contain. I am only—

London, April 27, 1896.

P. GREEN.

THE PRELIMINARY EXAMINATION.

Sir,—The cry with us anent the insufficiency of the pharmaceutical Preliminary examination is loud and increasing, and, like the query, "What shall we do with our sons?" getting as familiar. Yet, after all that has been said and written, do you not think, Mr. Editor, that the discussion has been needily restricted to pharmaceutical circles? Why should we not have a conference with some of our leading educationalists in London or in Edinburgh to begin with? We have now got the accommodation, and could easily obtain evidence—yes, and if need be, professorial evidence to certify that scarcely 50 per cent. of the raw material, in the shape of apprentices, supplied from our public schools to pharmacists, will stand the character and tests of the Minor examination owing to lack of elementary education. When we see the *Educational News* and the

Schoolmaster opening up their columns and discussing what to us is an old story, then may we hope that public attention has been drawn to the matter.

Inverness, April 27, 1896.

A. P. S.

APPRENTICES' GRIEVANCES.

Sir,—I would like to call your attention to a pet grievance of mine, and one which I would very much like to see put right. I am at present serving my time in a large retail shop where there are several apprentices. We have to serve an apprenticeship of five years. Now, on several occasions, when an unqualified assistant was wanted for the shop, my master, instead of putting forward one of his apprentices who had been about four years with him, got an outsider, who, in many cases, had only served three years' apprenticeship. These three-year apprenticeships are generally served in small shops and in small towns or villages where little or no real dispensing is done. The putting of these men over us, who have had more experience and who have served a longer time, is manifestly unfair, but, of course, it cannot be helped whilst the terms of apprenticeship are unequal. Cannot a law be made or something done to make it compulsory for all chemists to keep their apprentices at least, say, four years? This would give all an equal chance, and I think it would benefit the apprentices in many ways. Hoping this may catch the eye of someone in a position to set the ball a-rolling,

Glasgow, April 28, 1896.

DRUGGIST.

THE PROPRIETARY ARTICLES TRADE ASSOCIATION.

Sir,—As one of the audience at the recent meeting in Bradford to hear Mr. Glyn-Jones and others on the Proprietary Articles Trade Association and anti-cutting, I should be pleased if you would give space to the following:—

If the co-operation of the retail drug trade is accorded this Association, what length of time will the Association guarantee to support us? Till we create a new and better market for their wares? And will they then, having got another fast hold, turn round and allow us to be in the same position, if not in a worse, than we are now? For my part, I eye the movement as above, and shall not support it; but instead of (as one gentleman said he would do) withdrawing my subscription from the Pharmaceutical Society and giving it to the Association, I shall strengthen it by 5s. to the Benevolent Fund (enclosed herewith, Mr. Editor, which please hand over). If we review the proprietary medicine trade we find that at first these wares were sold through the chemist and druggist, and he foolishly created a market for them instead of exhibiting his skill as a pharmacist in preparing and vending his own specialties. And now we have this burden to bear. A lot was said about substitution, but who commenced it? Why, the cutters, as sharp business men, enticed people into their shop by reduced prices of proprietaries and then substituted their own articles. Again, I do not agree that we substitute. What avail is our training and qualification to practise pharmacy if we are only going to be automatons in buying and vending wares such as proprietaries? And I maintain that we are only upholding our qualification by preparing and selling our own pharmaceutical cod-liver oil or other emulsions in place of Brown's, Smith's or Jones', etc., etc.

Bradford, May 7, 1896.

E. G. ALEXANDER, A.P.S.

ANSWERS.

"H. R."—Probably Schützenberger's book in the International Scientific Series (Kegan Paul) will serve your purpose. The published price is five shillings.

"K. F."—The "lead-pencil-colored" prints are platinotype prints, obtained by printing and development, not by printing out.

A CORRECTION.

CHROMATIC PHOTOGRAPHY AND RADIOGRAPHY.—By the misplacement of an asterisk in last week's *Journal*, it was made to appear that a specially contributed article on "Radiography" was part of a lecture delivered before the Society of Chemical Industry. The foot-note on page 364 referred to the first paragraph only, and the asterisk should therefore have followed the sub-heading "Chromatic Photography," instead of the main heading.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Atkinson, Barrett, Bennett, Clarke, Cocks, Cracknell, Fraser, Griffin, Hinde, Hudson, Jarvis, Kermath, Luke, Roberts, Symons, Thomson.

DETECTION OF THE DIGITALIS GLUCOSIDES AND THEIR PRODUCTS.*

BY H. KILIANI.

The production of colour reactions when some of the digitalis glucosides are dissolved in concentrated sulphuric acid and some oxidising agent, such as bromine, nitric acid, or ferric chloride, is added, has long been known, and statements to that effect are to be found in the papers published by Schmiedeberg. All the references to these reactions agree in recommending the addition of a single drop of a dilute solution of ferric chloride, and they fail to indicate that the intensity—as well as the duration—of the colour produced is very much determined by the proportion of oxidising agent employed.

In a previous communication relating to digitalin, the author pointed out that when this glucoside or digitaligenin is dissolved in ordinary sulphuric acid, a very fine and durable coloration is produced without any further addition, and at that time he was under the impression that this effect might be due to the presence of nitrous compounds in the acid. Subsequently, however, he observed that sulphuric acid did not always have the same effect, and some months ago, having a sample of acid which was particularly suited for producing the colour reaction, he induced one of his assistants to examine it in order to ascertain whether it contained nitrous compounds. The amount was found to be very small, but the acid contained a considerable proportion of ferric salt, and eventually it was found that sulphuric acid mixed with one per cent. of a solution of ferric sulphate† formed an excellent test for identifying the various constituents of digitalis.

By means of this test liquid, digitalin, digitoxin, and digitonin can be very sharply distinguished when in a state of approximative purity, and only minute quantities require to be operated upon. A few fragments of the substance are introduced into a test tube, covered with 4-5 C.c. of the test acid, and stirred with a glass rod until dissolved, when the characteristic reactions described below are produced.

Digitalin becomes immediately coloured intense golden-yellow, and as it dissolves a red colour is developed, which rapidly acquires a violet tint, remaining permanent for several days. With too large a quantity of the glucoside the solution remains red, but on shaking the reddish-violet colour resembling that of the digitalis flower may be seen in a thin layer of the liquid.

Digitaligenin gives a similar colour reaction of greater intensity, that is to say, it can be produced with a much smaller quantity of material.

Digitoxin becomes quite dark coloured on contact with the acid, almost as if carbonised, and then the solution becomes clear, but of a dirty brownish-red colour.

Digitoxigenin does not become dark coloured on contact with the acid, but gradually communicates to it a peculiar red colour, and a very marked fluorescence.

Digitonin and digitogenin do not give any coloration when similar small quantities are operated upon, and even with much larger quantities the acid only acquires a faint yellowish tint.

Although the reaction with digitoxin is the least characteristic of those above described—since many other substances may give a

dirty brownish-red colour when mixed with concentrated sulphuric acid—this deficiency can be made up for by combining with this test that suggested by Keller of dissolving the glucosides in glacial acetic acid, adding one drop of ferric chloride, and then carefully pouring in concentrated sulphuric acid so that it forms a layer underneath the solution. If digitoxin be present, a dark coloration will be produced at the line of contact, and above it a deep blue band in the acetic acid solution. That result, however, is not always very distinct when the directions given by Keller are followed exactly, and the reaction is very much more marked when the acetic acid contains a ferric salt,* and the sulphuric acid containing ferric sulphate is used.

In carrying out the combined test rather larger quantities of the substance must be taken, but three or four-tenths of a milligramme will suffice. When digitoxin is dissolved in 3 or 4 C.c. of the ferruginous acetic acid, and a layer of ferruginous sulphuric acid run below it, there is an immediate production of a dark zone at the line of contact; after about two minutes a blue streak appears above it, gradually expanding until, after thirty minutes, the whole of the acetic solution will have acquired a deep indigo blue colour. Some hours afterwards this colour will have changed to a blue-green, but the sulphuric acid does not become much coloured.

Digitoxigenin does not give this striking reaction, which is referable much more to the saccharine product of the breaking up of digitoxin—digitoxose.†

Under the conditions above described digitalin and digitaligenin only colour the sulphuric acid in the same manner that they do when tested without the use of acetic acid. Consequently it is possible to detect those substances and digitoxin when they are mixed together, for a mixture of the two glucosides will colour the sulphuric acid reddish-violet, and at the same time colour the acetic acid solution indigo blue.

Neither digitonin nor digitogenin give any coloration when submitted to this combined test.

The remarkable delicacy of this test for digitoxin has been the means of enabling the author to modify his former statement as to the absence of digitoxin in the glucoside prepared in the usual manner from digitalis seed. The preparation known as Digitalinum pur. pulv. Germanic did indeed give a negative result when tested with ferruginous acetic acid. If the material from which it was prepared contained digitoxin this substance would be separated in the course of the treatment by Kiliani's method, but the dried residue of the mother liquors did not give any digitoxin reaction. On one occasion some crude digitalin gave a very feeble and uncertain indication of a blue colour when tested by the acetic acid method, so that it may be inferred digitoxin can only be present in very small proportion in the glucoside prepared in the usual manner from digitalis seed.

A glucoside obtainable from the leaves behaves towards ferruginous sulphuric acid exactly as digitalin does, though other circumstances appear to show that they are not identical, and this as well as other points relating to the glucosides of the leaves is now under examination.

In regard to digitoxin there is every reason for the opinion that the substances prepared by Schmiedeberg and by Merck are identical with that to which Kiliani provisionally gave the name of β -digitoxin, and that in future the prefixes α and β may be dispensed with.

* 1 C.c. of the above-mentioned solution of ferric sulphate to 100 C.c. acetic acid.

† A water solution of digitoxose gives no colour with ferric chloride.

* Translated from the *Archiv der Pharmacie*, 234, 273.

† Made by dissolving 5 grammes of ferric sulphate in 100 C.c. water.

PHARMACEUTICAL SOCIETY

MEETING OF THE COUNCIL.

WEDNESDAY, MAY 20, 1896.

Present:

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. JOHN HARRISON, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Corder, Cross, Gostling, Hampson, Hills, Martindale, Newsholme, Savory, Southall and Warren.

Several members were restored to their former status in the Society on payment of the current year's subscription and a nominal fine.

The President announced the receipt from the Board of Examiners in Scotland of a photograph of the Board, and proposed that the thanks of the Council be accorded for it. This was at once agreed to.

The Council arranged the order of business at the Annual Meeting, and then adjourned.

FORTY-FIFTH ANNUAL MEETING.

The President, Mr. Michael Carteighe, took the chair at 12 o'clock, when there was hardly the average attendance.

The Secretary read the notice convening the meeting, and the annual report, which was published in the *Pharmaceutical Journal* for May 9, was taken as read.

The PRESIDENT, in moving the adoption of the report, said, I have no doubt that many of our friends, in looking at the financial statement, may think that we have spent a good deal of money—perhaps even too much, especially during the last year or two. Now I may say, with regard to the last two years, that we have had some expenses in the north connected with the alteration of the premises in Edinburgh, and the construction of the very excellent examination hall and laboratories there. We have had of course to spend a good deal of money and have had to spend all of it, with the exception of £1000, out of the revenue or the balance from previous years. In our financial statement we never take credit for what is owing to us at the end of the year, all that we present is a statement of the money received up to the end of the year, and a statement of what has been expended. If you look critically at the financial statement I think you will find that, substantially, our income was less by about £1100 last year from examination fees, we spent £1150 on the new building in Scotland, in addition to £300 or £400, in the nature of capital expenditure, in keeping laboratories supplied with the necessary scientific apparatus for the proper carrying on of the examinations. There has also been an increased expenditure on account of the Journal, which I will refer to in a few moments, of £1300. This extra expenditure has really been met by the sale of stock, by an advance from the bankers, and by the balance at the end of the previous year. There were a number of things last year on which we spent a good deal of money. We have finished the decoration of No. 16, Bloomsbury Square, and I think I may say we have finished the greater part of what we were called upon to do in Edinburgh. Later on we may have to spend more money on the fittings of the Museum, but with regard to capital expenditure, I think I may say there will be no reason to spend much in the future. Without raising the cry of wolf, or going into too much detail, I think I may say on behalf of my colleagues and myself that we see no reason why, with proper management, we shall not be able to do all we want, conduct our law prosecutions wherever necessary, and carry out all our work without outrunning the constable in future years.

THE 'PHARMACEUTICAL JOURNAL.'

The chief reason of the adverse balance has been the decision of the Council, in the middle of 1895, to increase the size of the *Pharmaceutical Journal*, and to re-model it. That decision was arrived at after the most careful consideration—not, perhaps, without a certain amount of regret on the part of some members of the Society who remembered the Journal in its earliest days,

when it was regarded as a purely scientific journal of Pharmacy. But the view of the Council has been practically the view which was held something like thirty years ago, when I had something to do with it, that it is only fit and right that the Council of this Society should make its official organ acceptable to as large a body of our subscribers as possible. We are endeavouring, I hope successfully, to retain all that is scientific and thoroughly pharmaceutical in the Journal, whilst adding to it other matter, which I know is very much appreciated. It is perfectly well known that members of this Society, and chemists and druggists generally, are not wont to praise. I never heard in this room, after an experience of some thirty years, anyone say anything complimentary about any of the property of this Society—never. Although in a sense we are masonic, that is, we represent a craft, our usage has usually been to damage our own property. In what I am going to say I am not going to make that mistake. I hope you will recognise that your President as Chairman of the Council knows the details of all the business of the Society, knows the value of its respective properties. I am sure that none of you who follow me will say anything which will tend to damage the value of our property—the Journal—a thing given to us in the kindest way by Jacob Bell, made into a weekly journal at the instigation of H. B. Brady and your President thirty years ago, when it was supposed there would not be enough matter to fill a weekly journal, and now made into a journal as large as the medical journals, and capable of affording a mass of information every week. We have sunk, like men of business, a portion of our income for the year—knowing we had not much to spare—in order to make the Journal fulfil the conditions I have named; to make it larger, to keep it the first pharmaceutical journal in the world, and in order that we may have the same claim to the business of advertisements as other journals which have been run on purely trade lines. I may say without fear of contradiction, and without desiring to compliment anybody connected with the Journal, that as at present sent out it is a credit to our body. If the Journal is not useful now, I am afraid it is impossible for us to go very much further. But I may say that, as a matter of business, the expenditure upon the Journal has been wise. As I mentioned just now, the credit for what is due to us never appears in our financial statement; but on the six months' trading under the new régime, from July 1 to December 31, there has been an increase in our income from advertisements which is both interesting and encouraging. It does not come into this account, but will come in this year. I will, therefore, say nothing further on that point than that I, as an individual, have found the Journal to be a good advertising medium. I am now going to give a gratuitous advertisement to the Journal. I know something about advertising: I have been at it for a great many years; and I have tested this Journal in various ways—not by advertising a thing which is universally advertised, where you cannot judge—but I have tested it with special things, and I am perfectly satisfied with the results,—so that if any of you want to make your fortunes, gentlemen, I say advertise in the *Pharmaceutical Journal*. I hope you will accept these remarks; and will recognise that it is not to our interest as members of the Society to have all the details of our work placed before the eyes of everybody else, including our competitors. We are not going to show our hand, we are going to do our best to get some of the business of the country in the *Pharmaceutical Journal*; and if you will leave us alone and trust us, I believe we shall succeed. Speaking generally, I admit we are open to criticism in many ways in regard to the appearance of the accounts; but do not run away with the notion that we had not something in our favour at the end of the year which does not appear on this balance-sheet. The accounts of this Society have been kept on the basis originally devised by Mr. Elias Bremridge, and he was always very fond, as far as possible, of paying everybody to the end of the year, so as to leave no liabilities, an extremely good thing to do; the only thing is that with regard to various forms of business you may be conducting, you pay your money beforehand, and do not get the receipts brought in at the same time. Some of you say, and I have heard it said out of doors, that there is no profit upon the Journal. But you must remember that this Journal is not worked on ordinary business lines. If we were to set against the cost of the Journal some charge for it, as a trading concern would do, you would have to admit that there has been a very distinct profit, and I should be very sorry to have to face an income

tax inspector if he were very troublesome and insisted on going into our accounts, on this particular subject. As a matter of fact, we carry on the Journal for our own purposes—it is sent post free to every person who is entitled to it; therefore when you talk of loss you can only speak of the difference between one side of the account and the other, and you will see an observation to that effect is made in the report. We do not say whether it is loss or gain. The fact is, that the balance, whatever it may be, will and can be reduced probably in future years by increased income from sales and advertisements. I am sure you would be the last persons in the world to say we are not to spend money in giving to those who subscribe to the Society the best kind of journal possible. It is part of our business to do so; added to that the value of the Journal as a means of calling you to arms and getting you to come up to London, support your members, and assist us in getting something through the House of Commons or in stopping something, is very important. You will remember a little encounter we had with the Chancellor of the Exchequer about methylated spirit, how promptly you all responded to my request. We literally deluged the House of Commons with reasons for altering the Chancellor's Budget within something like forty-eight hours—the matter having been initiated in the Journal. Its value, therefore, must be measured in several ways; but in whatever way you measure it I beg to say that the money spent upon it over and above previous years has been spent deliberately. It is a process of sinking of money for future benefit; and the results which I have on the table at the present moment show, on the six months' trading, that the confidence of the Council in making that change has been practically justified.

THE SOCIETY'S HOUSE IN EDINBURGH.

Then with regard to the house in Edinburgh, and the carrying on of the examinations on which we have been spending money, it seems to me we have no right to starve our system of examination. It is our duty under the Statute to examine properly. We charge examination fees, and of course we are bound to have the premises properly equipped with proper apparatus, and all the rest of it.

LAW COSTS.

Now with regard to the law costs. Some of my friends seem to think we are getting extravagant in law. That is about the last charge I should ever have expected to be made against us, because if there is one thing more than another that I understood the members of this Society desired, it was that we should protect the public by efficiently carrying out our Act of Parliament. During the long period I have been your President I think we have developed that process so far that we are, I think, effectually carrying it out. But lest any of you should be unhappy with regard to it, I may say that so long as I am a member of the Council, and assuming the majority of the present members retain that office, I can assure you they will not raise the question of how much money they have got before they go to law. Anybody who breaks the law will be prosecuted, and the provisions of our Act of Parliament will be carried out strictly to the letter. We do not want more money, but if we did I know where to go for it for that particular purpose, and I know there would be no difficulty in getting it. But you must remember that this item of law costs is the balance of a large sum of money. It is not desirable in a public institution like ours to publish details about law costs. It is very undesirable for us to appear before the public in any sense as persecutors of individuals. We are not so. We are a body constituted by an Act of Parliament to see that the law is obeyed, and the question whether we get a penalty without any expense or whether we have to go into court to get that penalty never enters into our minds. If by accident we get penalties without having to go into court, so much the better for us. It gives us a little more money on that side, but even if we have to fight every single case in court, and ordinarily speaking a case in the court in the South will probably cost us from £20 to £30, including getting evidence and things of that sort, the Council will certainly do that. It is possible the time is coming when that may have to be done, because it is obvious that as the Pharmacy Act is better known to other traders there are less infractions than in former years, and therefore we have more difficulty in getting evidence, and there is a disposition perhaps to contest it more freely than formerly. But be that as it may, it will always be the duty of the Council to see that the Act is obeyed at whatever cost. We have, as you know, had some law proceedings with regard to

patents, and this process of revoking a patent is a very expensive one. Some may say, perhaps, "Is the game worth the candle?" We think it is. The effect of our proceedings is to discourage and practically to prevent a number of patents being actually taken out. This Society can never allow patents to be taken out for preparations containing poison without contesting them in a court of law if necessary; it would fail in its duty if it did. You may have seen a report within the last fortnight of a case which may be called, in a sense, a pity, because we have had to go to law, and here we must be prepared, if need be, to spend money. We are going for a very important principle. I do not refer to the proprietors of that preparation. I do not even refer to the preparation—you all know it. It is claimed that it may be sold by anybody, and still worse, that it may be labelled "poison." Here you have therefore a preparation labelled poison thrown broadcast about for dealers to put in their windows, actually making the public believe that poison can be sold by anybody and everybody. That being so, it seemed necessary for the Council to take the opinion of a superior court on the point as to what a patent medicine really is, and we shall have to carry this case, whatever the result may be, to a point where it shall be judicially settled whether, when a substance has been patented and the patent lapses, the rights given to the individual by letters patent shall be practically put into the preparation. The real contention on the other side—once a patent medicine always a patent medicine—means broadly that the Crown having given an individual a certain privilege, he could, after that privilege has lapsed and become void, literally go on claiming the rights of the patentee for the preparation itself. That is a position of things which we feel must be contested, and I am sure you will feel in this case, as in all others, that there is no vindictive action. We have constantly to take legal proceedings against our own members; we may have to do that at any time. I have found it necessary to say in Council—and take this opportunity of repeating it—that the President whoever it is, and the Registrar must do their duty whether the person breaking the law be a member of the Society or not. The safety of the public is the prime object on which we proceed. Consequently if our brethren, members of the Society, will keep branch shops with no registered person in charge they must not be surprised if we have to take proceedings against them. I am sure you will agree with us that it is the right thing to do. There is only one course in fact to take and that is the straight course. I am quite sure that my successor in the presidential chair, whoever he may be, will have the same views on that point as I have myself. Now I want to say a word about title. You will remember most of you that we carried to the Superior Court in Scotland two rather important cases on title. I dare say many of you know that a number of manufacturing chemists, scientific chemists, and what are called professional chemists and analysts, have often complained that we claim an exclusive right to the title of chemist. It has often been said that we have not one. At all events whether we have or have not, we have succeeded in convincing even the Scotch Superior Court, and they have not been disposed to take a very favourable view of the Pharmacy Act, that we have some rights in the matter. We instituted proceedings against two gentlemen in Edinburgh, who carry on very important businesses there as scientific instrument makers and dealers in chemicals, both poisonous and non-poisonous, for scientific purposes. You all know the class of business, and those two gentlemen were men of the highest respectability, we have not a word to say against them; but they protested that they were entitled to use the title of chemist if it were preceded by an adjective, and we have been told that the prosecution of those two gentlemen in Edinburgh was vindictive, that it was a process of persecution, and so on. Now, I want you to understand on what principle we proceed. It is quite certain that no one of us would wish to say to a better educated man than himself who called himself a chemist that he had no right to put that on his card. We do nothing of the sort. We simply take the title of the Act of Parliament; we do not raise the question as to who is a chemist, we never take proceedings against a man for the use of the title unless he keeps an open shop and sells poisons. Now if a man keeps an open shop and sells poisons, and uses the title of chemist with or without an adjective, he is certainly giving the impression to the public that he is registered under this Act, and every reasonable man who calls himself a chemist who is not a pharmacist when that position is put before him accepts it as perfectly equitable. We

have, I admit, in one or two cases, chosen to put the law in motion at the suggestion of public authorities where certain quacks who are professors of certain obnoxious practices do occasionally call themselves chemists, and mix up their preparations in a back room or in a parlour, and in a sense so keep an open shop, but such cases are rare, and practically we have no desire to interfere with the use of the title chemist by the person who uses it in its legitimate sense if he is a professor or practitioner of chemistry. But if he keeps an open shop and sells poisons then we think he ought to be restrained.

THE COMPANIES' BILL.

The last note I have here is with reference to the Companies Bill. I quite feel that some of you may say there was a blue book last year, and we saw, as someone wrote to me, a rattling statement signed Michael Carteighe, which gratified you all, and you may say—what is going to follow? Well, to take the actual blue book itself first. You, gentlemen, have no conception of the tenacity with which the Government Department, in whose house the Committee which was to draft this Bill met from time to time, tried to keep us outside. They tried to prevent our communications actually being considered by the Committee. They suggested that they were irrelevant, and for months it was a species of official hand-to-hand combat with the secretary of that Committee and the officers of the Board of Trade before we could get them to consider our position. We have, I am happy to say succeeded, whatever the results may be, whether they be immediate or remote, at all events we have now in a Government Department a statement of our case by which it has been made intelligible to lawyers and other men of intelligence, as well as pharmacists. It is admitted on all sides that legislation is necessary. But the position taken by those members of the Government who represent Parliament is that an amendment of that Bill is not the right course to adopt for changing the law with regard to such a subject as we and the veterinary surgeons and others wish to have it amended. We say that it is. It is a question of principle whether a mere money payment should convert seven men into a corporate body, and besides allowing them to do certain things positively allow them to use a name which the law says can only be acquired by examination and registration. That affects not only pharmacists but a large number of other people. Our contention is that the Companies Bill is the fitting place to make such a change, because it affects the very form of registrable qualification. You will have noticed that the Bill has been introduced into the House of Lords and referred to a Select Committee. We have as you know had an amendment on the paper. I and others on the joint committee representing the Veterinary Surgeons, the Apothecaries Company, the Dentists, and so on, have all been at work, and we have every hope that we shall be allowed to give personal evidence and explanation before the Select Committee of the House of Lords. If we can get an opportunity of explaining our case we at least are gaining something, for every process of this kind tends to educate people other than pharmacists. That reminds me that in regard to the interpretation of the Pharmacy Act as regards the sale of poisons, the whole of our work for the last few years has been a process of educating the judges. We have been obliged to go on step by step. With regard to many cases as to which some of you said—Why do you not touch them? we did not touch them simply because the President knew what he was about. The judges have to be educated by degrees. There is something almost comical in the way lawyers look on precedents, they are only too happy to find some observation by some other judge or lawyer which relieves them from the necessity of coming to a conclusion themselves. I say it in no boastful spirit, but it is a fact that we have educated the judges, the judges are beginning to understand the Pharmacy Act, and those cases we have not thought fit to bring into court in earlier times were deliberately kept back in order that we might approach the judges under the most favourable conditions. Whether that is a truly moral thing or not I do not know. Before I was President I thought I had some morals, but since I have been President so many of these cases have been left in the hands of the solicitor and the President that I am afraid I have come like a professional lawyer to feel a strong inclination to win my cases. As we suffer many disadvantages I think it is perfectly fair we should take what advantage can be got by the way in which we present our case. I do not think I need detain you further, or I should not allow sufficient time for that amount of heckling which no doubt you desire. I am glad that we have

three or four members of the Society from the other side of the Tweed, who, perhaps, have come to give me the last parting kick. Whether they have or not, I, on behalf of the Council, am very glad to see them. It is desirable that they should come down as much as possible and associate with us and take part in our proceedings. I am sure we have shown to our brethren in Scotland the utmost loyalty and good nature, and all we ask in return from them is that in carrying out their duties there they will not forget the fact that the Society is the Pharmaceutical Society of Great Britain, and that occasionally a meeting has to take place in London.

A GOOD EXAMPLE.

I will conclude by reading something I saw the other day, with regard to an institution not unlike our own, the Institution of Civil Engineers. I do not know any body of men who are so loyal to each other as the Engineers. They have no compulsory powers—they have a charter only; but they are very loyal to each other, and they are very generous—those who make money, to the rest of the body and to their institution; and while it is a fact that if the Government wants an engineer for any particular department it is not bound, and does not consider itself bound, to take a member of that body; still, by promoting education and spending money upon it, the Institution has produced such an effect that to all intents and purposes the members of it have the field to themselves. I have sometimes thought whether we—as a voluntary society—might not have done that. Certainly no Act of Parliament can do so much for any body of men as the individual loyalty of the men themselves, and I feel sorry that in my official capacity it has been my experience to find how ready many of us are to be disloyal to each other. In that process of being disloyal they damage themselves and they damage the body politic. Believe me, gentlemen, that, notwithstanding companies and company trading, the position of the individual is the thing which must be looked to in the future, the mere examination and registration will not be everything for us. The cultivation of all those qualities, including manliness as well as other virtues, is a factor upon which the success of the chemists and druggists depends. In spite of all the opposition that has come, I notice that in large towns and cities where I have been, and in London—there is a healthier tone amongst men, notwithstanding the fact that they have to fight hard—and I am glad to see it. We do not mind fighting hard, but what we object to is fighting unfairly. But it is quite certain, gentlemen, that the cultivation of these attributes must and will produce an effect on the public at large—it is already doing so—even on that class of the community who happen to be in many cases our best customers, but who do not always think too carefully about rights and wrongs—I mean women. They are beginning to understand that a person who is properly qualified is a safer person to dispense their child's medicine than A, B, or C in a store; and I think we shall be able to make them understand by degrees that it is worth a little more to have that security. Who among us, knowing what we do of the expenditure upon our calling, would not, if we were lying sick, rather go to the nearest pharmaceutical chemist for a bottle of physic than to the largest store that ever was? The quotation with which I will conclude, recently appeared in the *Times* as follows:—“The Council's report is of a highly encouraging kind, showing an excellent financial position, with a membership which has increased to a total of nearly 6000, with 816 students. The new buildings are now very nearly complete, and the institution will at length be housed in a manner worthy of its magnificent traditions and growing power. We shall then look for advancement in directions which have been too long neglected. The accumulation of funds can ultimately only promote the decay of an institution of this kind. To apply a portion of those funds to the widening and deepening of experimental knowledge and the prosecution of research, though ending in no technical benefit, will strengthen the scientific sinews of the profession, while adding to its greatness.” I beg to move “That the annual report and statement of accounts as published be received and adopted.”

The VICE-PRESIDENT seconded the resolution, and said he would reserve any remarks he had to make till a later stage, if it were necessary to offer any.

Mr. ATKINSON said: I should like to congratulate the Council on the admirable way in which it has upheld and vindicated the

authority of the Pharmaceutical Society during the past year. It was perhaps more fitting that such an observation should fall from me, because on some former occasions I have felt it my duty to be not quite so complimentary. I know quite well the amount of work that always must be necessitated, and as far as I can gather the legal cases appear on the average to be more than one for each working day; and when we come to consider the amount of evidence that has to be examined and sifted in many cases which have simply not gone beyond the premonitory stage it is a good testimony in itself to the admirable judgment and tact of the Council, and I think it reflects equal honour on the efficiency of the Society. I am very pleased to have an assurance from our President that there will be no relaxation in the vigilance of the Council with regard to these legal proceedings. I say so because I think there has been in certain quarters some apprehension that either such might be the case or that there would be some additional charge made on members of the Society. Of course, this is public work: it is a duty imposed upon the Council for the protection of the public; and there are many who, perhaps, might think that the national exchequer might bear a portion of the cost of a public duty well performed. However, this is a matter, I think, we may safely leave the Council to deal with. But highly as we may estimate the admirable work that has been done, there are, nevertheless, a great many irregularities and illegal practices with which I am afraid the Council is not competent to grapple. I am not going to suggest even that it should do so, because I think there are other methods of dealing with this sort of thing. I am referring now to dispensing as it is done by local practitioners. Who does this dispensing, and how is it done? We know perfectly well; but the public know nothing whatever about it. I heard a gentleman not very long ago lamenting that he had lost the services of his errand boy—who was just sixteen years of age, I think—who had been with him about four years; he said that for the last three years that boy had done the whole of his dispensing, and that was a gentleman who did a very good practice indeed. At an inquest not long ago in the south-eastern district the evidence proved most conclusively that the whole dispensing for the last eight years in one establishment had been done by the cook. One could multiply instances of this kind *ad infinitum*, and if I were asked what was the greatest public danger at the present time, I should have no hesitation in saying that it was the way in which dispensing is carried out by a great many local practitioners. It is an insidious danger; the public know nothing whatever about it, and I say that if you want the dispensing of medicines to go in the proper channel you must make this matter public. You must not be squeamish about it. Pamphlets are cheap, and if you want you can have a sort of pharmaceutical Mr. Jorkins, but you want the thing to be known, and if once the public appreciated their danger, and you arouse a feeling of insecurity, the dispensing of medicines will drift into the hands of those who are competent and qualified to deal with it. We have had a great deal of activity with regard to legal matters, and there has been a good amount of activity in other directions also. Every post seems to bring one circulars connected with anti-cutting chemists, or agreements to be signed that you reserve to yourself 10 per cent. profit or maximum and minimum profits, and all that kind of thing. I do not question the advantage of a certain amount of missionary effort. I do not suppose there is any class of society in England amongst whom missionary effort is perhaps more needed than amongst our own body, but I should like to know that they are preaching the right gospel, and of that I am not quite certain. It is a very significant fact that after allowing the poor chemist to stew in his own juice for ten or twelve years, you now find the manufacturers of proprietary medicines beginning to coquette with him. What does it mean? That they want some more cheap advertisements? Every man must act on his own judgment, but in my opinion the minimum of 10 per cent. is not quite good enough. I think the chemist had better make his own preparations and advertise them accordingly. We are having, and are probably likely to have, a few more doctors to deal with our multiplicity of ailments. If there is any relation between the number of them and the number of physicians, I think the chemist is in rather a bad way. Perhaps he is in a bad way; the chemist and druggist as we knew him twenty-five years ago is gradually becoming a thing of the past. The drug trade, as far as I can judge, seems to be passing into the hands of quite a different class. The new man, who just manages to squeeze through the examination room, must, either on his own account, or

for the benefit of seven or eight other evil spirits, consolidate into a general store business, where he will sell you anything you like, from a mustard leaf to a mousetrap, for 33 per cent. less than any neighbouring chemist. It is very difficult to compete against this kind of thing.

The non-obtrusive, quiet, conscientious chemist is scarcely able to do it, especially when there is absolutely no limit as to veracity or vulgarity on the part of his opponent. I notice that those gentlemen who perhaps are going to do something for the re-habilitation of pharmacy if possible, still appear to harp on a little course of parliamentary treatment. Our record in the past does not seem to me particularly happy so far as legislative tinkering is concerned. Many of our attempts seem to me very much like that leg of mutton which Dr. Johnson described as being ill-bred, ill-fed, and absolutely spoiled in the cooking. I am afraid there is not much likely to accrue to us from any Parliamentary interference. I hold rather strong opinions with regard to Acts of Parliament. I am very much disposed to look upon an Act of Parliament as one of the wiles of Satan. You no sooner get it than you have to begin hunting for some little obscure Section, some nebulous phrase, and whilst spending your time and your money in endeavouring to construe an English sentence, the whole substance falls into the grocery boy's basket. It is not from Parliamentary interference that the greatest results have accrued. Social conditions and commercial conditions arise from other causes, very slight, imperceptible almost, but, nevertheless, you may call it chance, you may call it evolution, or natural causation or what you will, but you cannot stem the current of events. It is by no means improbable that some of these days by a new discovery or a new application of molecular physics the whole thing may be swept into limbo as far as drugs are concerned for the treatment of disease. Who could possibly have foreseen within some thirty-five or forty years ago that when half a dozen men agreed to purchase and divide up a chest of tea that simple action would have revolutionised the whole retail trade throughout the United Kingdom. I am not claiming too much when I say that the effect of that transaction has been felt throughout the habitable globe, and although we, as chemists, were at the time not able to see it would affect us, it would have been something short of miraculous if we had not felt the effect of that kind of thing. We cannot foresee, gentlemen, what there is in the future, but it is to be hoped that your scheme of expansive education will enable the coming man—the pharmacist of the future—to appropriate all the advantages of modern science.

Mr. CAMPKIN: I should like to express my thanks to you, Mr. President, for the admirable address you have just delivered, and I think if our friends in various parts of the country will take the trouble to read it they will see there very much to satisfy them, not only as to the past working of the Society, but the portents, so to speak, for the future. I was rather struck with the remark you made, that it was very unusual to find anyone speaking in complimentary terms of any part of our property or anything connected with the Society, but whatever may have happened in that direction in the past I think the remark will not apply to the work of this year, to the improvement in the Journal, or to the work which you have foreshadowed. I have heard nothing but praise in my travels during the past year with regard to the enlargement of the Journal and the utility likely to arise from it, not only in its scientific aspects, but its commercial aspects also, and certainly, with regard to the Society, I think it never stood higher in the estimate of chemists generally than it does at the present time. There are, perhaps, those who still disagree with that view, and I have occasionally found grumblers amongst my colleagues in the business, but, at the same time many of us think the work has been very considerable in the right direction.

“ No earth-born will
 Could ever trace a faultless line.
 Our truest steps are human still—
 To walk unswerving were divine.”

It is not to be expected that the Council of the Pharmaceutical Society will do quite all that everyone could wish it to do. It cannot probably even guarantee us a good return upon our business, nor could it tell us how to secure it, as you have justly put it, that lies with us individually. But reviewing the work of the Society for the past year, I think it would be difficult for anyone to criticise in an unkindly manner any part of it, because although much has not been published that has been done, no doubt a great deal of work has been done with regard to law

cases and the application of the law for the protection of the public generally, and the chemist generally, which is not apparent on the surface, the results of which only will be proved in years to come. Still a great work has been done in that direction. I will not trouble you on the financial details because they speak for themselves, but one remark was made by Mr. Atkinson with reference to the favourite panacea for all our troubles, namely, Parliamentary action. We are none of us led away with the idea that legislation is in itself a benefit to us; it is only a means to an end. We must have the law on all subjects, but the great secret of success lies in the administration of the law, and in the appreciation of the law by members, and surely there can be no harm in utilising Parliament as a means to such ends as we desire. The result of any Act of Parliament is not apparent until perhaps half a generation has elapsed, and we are now perhaps just feeling some of the deficiencies as well as some of the advantages of the Act of 1868. It may be so, but at the same time that should be no reason for relaxing our efforts in the direction of legislation. I do hope that something will come of the action that has been taken by yourself and the Council as to the amendment of the Companies Act. Who could have predicted that the Limited Liability Act would have had that destructive effect on retail trade that it has? I believe when the Act was passed the idea was that it was only for the purpose of developing great works that could not possibly have been accomplished by private enterprise. Our railways, our shipping, docks, and many other such things, would probably never have been secured except by the operation of the Companies Act, and after that of the Limited Liability Act. But if many of those who promoted it had thought it would eventually be extended to the creation of a number of petty shops, perhaps we might have had the Act amended even before it was too late.

I hope your efforts will be continued in that direction. I noticed in the Journal some time ago that an important amendment had been brought forward by Lord Herschell, and the spirit of that amendment is undoubtedly one that it would be well for us to follow. There are many other points which I hope will be discussed to-day, but I rose mainly for the purpose of expressing the opinion of myself and a number of my friends in various parts of the country, as to the continued usefulness of the Society. There should be one word with us—unity. If we can make the Society united, whether it be by missionary effort or otherwise—and with regard to missionary effort we must not be too particular whether the right creed is preached so long as we are united—we shall become a force, a vital force, a moral force, which even the Legislature will listen to, and then I am sure that as men of experience, like yourself and those by whom you are surrounded at the head of affairs, we shall evolve something that will be to the benefit of pharmacy in the future.

Mr. BARNARD said: I think the report is one of the most satisfactory I have ever seen. When you say that 350 cases of infringement of the Act have been reported to the Council, and in every case dealt with we must feel that the Council is doing some good in the direction of protecting us, the registered men. I should very much like to know how many of those 350 cases led to fines, or promises at least, not to break the Act in future. With regard to the scientific side of the question there is no doubt from the speeches we heard from the presidents of various scientific bodies last night that the Pharmaceutical Society is not only making much progress but is becoming very much recognised and appreciated. But I cannot forget the fact that at the present moment, from the trade side of the question, the chemist and druggist stands in a worse position than he ever did. It cannot be denied that on the one side we have a large number of limited or unlimited companies trading in opposition to us, the registered and recognised, or should be recognised chemists of the country. Then, again, we have another body of men springing up in the East-end of London, men who have not even the capital to form a limited liability company, but who call their shop a drug store. Again, there is another class of men who call themselves a medicine company, dealing as herbalists. All these men oppose and take from us registered men so much of our business that the legitimate chemist and druggist can hardly exist. As for the dispensing of prescriptions, I have been in business in the East-end nearly thirty years, and I can assure you that though they use things we often read about, we very seldom see them. I do hope something will be put in the Companies Bill which will prevent this kind of opposition. I do think that when we read that very broad Section of the Pharmacy Act which says that no man shall call himself a chemist, etc., except he is on the Register, it was never intended that a man should sail as

near the wind as he possibly could, by putting carboys in his window and "drug store" over his house. That is a question which I think the Council should seriously consider, and see if it cannot devise some means to prevent this kind of imitation whereby the public are misled and made to believe that the offender is really a registered chemist and druggist.

Mr. BARRETT (Leamington): Although I have not had the pleasure of hearing your address, the time will doubtless come, judging from the remarks of previous speakers, when I shall learn a great many things from the observations which you, sir, have been good enough to make to the meeting. But we have been learning for some years many things from your mouth; many things you have told us over and over again which I have heard said throughout the country were contemplated to do the chemists of the country good, and not only to do them good, but to teach them the way to get a living. We are told by speakers to-day that by the chemists of the country the Pharmaceutical Society is perhaps looked up to with more respect than it has been in times gone by. I doubt it very much. Perhaps the Pharmaceutical Society may be looked upon with more respect in London. Speaking as a local secretary I find very great difficulty in getting the chemists of the town of Leamington, where you would expect every man to be a member of the Society—and even in Birmingham as well as in the midland counties—I say there is very great difficulty to get the majority of chemists to belong to this Society. They say: "Show us what the Society has done"—they say, "Show us what the Society is going to do for us; and if you can convince us that it will do anything which is likely to help us to get a living, we will join the Society." It might be said without unity—and that is the tale I have to preach—it is impossible to dictate to the Pharmaceutical Society as regards what its policy shall be. The policy, undoubtedly of the Council is the policy of those few that send their subscription and members to represent them. But I sometimes think that even the Council does not always, perhaps, keep in touch with those who are members of the Society in the way that it should do. We have read of the recent attempt—I say, attempt, because everyone must know that the committal of the Companies Bill to the Grand Committee means, at least, for the session at any rate, that there is no passing it. We have read of the attempt to so alter the Bill as to make it illegal for a company to have greater rights than a person. That is the one thing we have been striving for in years past, a step that the Council and the Society have been working for. But how have they been working for it? Do they use all the influence that they can use to bring it about? We see in the Journal that the Parliamentary and Law Committee has reported this and that, but is that using all the influence which the Pharmaceutical Society can use to bring this about? Certainly not. You want greater touch between the Council and your local secretaries all through the country. You want some means of advising the local secretaries as regards the aims you have in view, and the work you are contemplating. You want to go beyond that and to demand that the local secretaries should interview candidates for Parliamentary honours, and obtain from them a promise in favour of altering the Bill. If they will not do that so as to make the Bill just to us—and I have never found a member of Parliament yet who has not said it was unjust—use your influence against him. Place your Council in closer touch with the local secretaries. Let your local secretaries be instructed to see the Parliamentary candidates, and to see whether they are in favour of this alteration. If you do that you will come within measurable distance of getting this alteration. It has been said that some attempt has been made to start a trade association. Do not throw cold water upon it, but come inside and join it. If it does not do what is right come in and alter its policy. I am not a member of the Council of that Society, but I think the policy which it is adopting is one which I have taught for many years in Birmingham. The Council has told you that it can only interfere in matters legal and educational, that it cannot interfere in matters of trade. If so, we must have a trade society like the licensed victuallers and others. Do not grumble at the policy of the society. Come inside, alter the policy if you want it altered, and urge the Society to do for you in matters of trade what the Council of the Society will do for you on the scientific side. It can do science for you, but it want to be in touch with the trade. What is wanted is unity. Let us learn unity from the Grocers' Federation, the Licensed Victuallers' Federation, and from every other federation. The only man you cannot federate is the chemist. If you

will put your shoulders to the wheel in the same way that other traders do we shall soon see a different state of things. A grocer in Leamington, who has been the greatest cutter, is now so sick of cutting that he has joined the Society. Now if they are sick let us come in and join the Society too.

Mr. HYSLOP: There is one paragraph in front of the report that is of so much importance that I feared it would be overlooked, and that is why I rise to have my little say, which will not occupy long. You have spoken in your address of the fact that one wants a "man" in business. One member on my right has referred to the abuse of dispensing by boys and unqualified persons. The only remedy for this, as it seems to me, is that the forthcoming Council should take into their respectful consideration and earnest thought the recommendation from the Scotch Executive—that the Preliminary examination should be increased in "standard and scope." There is much in that which is at the very foundation and root of our future establishment as pharmacists. Allow me to say that I am one of those who believe that the Society has done immense good to chemists. Somebody has just said that his constituents say "Show us the good that the Society has done." My constituents say the same to me, but I can show them the good plainly enough. I have been a member of the Society nearly forty years, and they recognise that I am qualified to speak to them about the work of the Pharmaceutical Society. It is easy to show them the good that has been done, indeed it would be very difficult not to show them. I belong to the grateful ones, whatever else I may or may not be. I believe in two other classes that I have seen, the Amœbæ—they have no backbone, of course—and the sturdy grumblers, who have a backbone with no joint in it. They know not how "to stoop to conquer," and it is these that stand up for things—I will not name them now—things which are being introduced from time to time which lie at the childhood of our Association as chemists, and have nothing to do with the grown-up stature of the pharmacy man. Those that bring novel doctrines forward and quack remedies to heal disorders are, in my opinion, twenty years too late with their remedies, and we as a Pharmaceutical Society must avoid this by paying more respect to the future. If men in business were to stick to their own business and not to go about spreading dissension and tares among the wheat, they would soon find reason to be satisfied with their business, and many would rise to be that sort of man spoken of by Solomon, "Stand before kings, not before mean men." It is easy to attain this good position in the ranks of pharmacy; and having regard to the love of liberty that presides in English breasts, and thanks to the Pharmaceutical Society, which has been the exponent of liberty for so many years, and the sturdy champion that we should gain the rights which belong to us—thanks to them, the advantages can be claimed by us most fully. There are three particulars in which I do trust the Council will before we meet again endeavour, and perhaps succeed, in remodelling the educational list for the Preliminary examination. In my opinion it is deficient in mathematics. A young man will go forth into the world knowing nothing of this but what he calls arithmetic, but it will be found in the course of a very few years that his arithmetic is a burden to him, and at last he throws it off his shoulders, except the little odds and ends which he is obliged to keep about him for trade purposes. The examination should also include algebra and geometry, without which arithmetic is a mere slippery attainment. It is always the same when I get a new assistant. I say to him what is the difference between plus 1 and minus 1? Upon asking the question I find he is minus altogether, and more than that he thinks it does not matter. Then I think that Latin should be supplemented by French so as to make it go down agreeably. With respect to Latin, pronunciation should be insisted upon, and if this were done we should not find young men looking scared when we talk to them about *Pil. aloes sine calomel.* If you say *sine* they are all right, but you say *sine* they do not know where they are. The great thing to teach a young man is to maintain respect among his neighbours, that being the only stable ground on which he can afterwards exercise his profession. I have no doubt whatever of the efficacy of pegging away on the right lines. The issue will be that the cowards—I mean moral cowards—will be squeezed out of the profession, and brave men will be found to take their places, men who can give a reason for their position, and for the stand they make before the public as well as the price they charge for their goods.

Mr. WHITFIELD: It seems to me this meeting is assuming the

character of a missionary meeting. I have a gospel to teach which is of a different character. It is thirty-four years since I was in the torture chamber upstairs, since which time I have not been a very active member of the Society—I have been, I may say, a quiet one, but I have come to-day to this meeting from a sense of duty. I have something to say, and I have been trying to put it into shape. The doctrine I want to teach to-day is just this, we want to have connected with this Society a body of loyal men. Our Chairman has used the term which expressed the matter exactly—we want individual loyalty. How that individual loyalty is to be secured, or rather how it has not been secured in the past, is just what I want to point out. When I was a student some thirty-four years ago I had the pleasure of spending two years in the school, and I left the premises an enthusiastic pharmacist. I was in love with the place and all its associations, and I went from here as I should like men always to go, but I find now the men who go through your School are not enthusiastic, and they are not loyal. There is just one cause to which I largely attribute it. For the last day or two I have been thinking the matter over to see whether I could try and sugar-coat the pill. I want to administer a dose of physic, and I have been trying to see how I could do it nicely. In Yorkshire we are blunt and rude, and I am afraid I must give up the task. I want to put my finger on the blot. In my remarks I do not wish, in criticising the School, to say one word about the lecturers or the professors, but there is one fact to which I would draw attention. Thirty or forty years ago I remember the condition of the Laboratory. At that time the examinations were not compulsory; it was a voluntary matter. Since that time the Society has increased in riches, position, and influence. The School has been increased, but the Laboratory to-day is no better than it was thirty or forty years ago. We, as old students, cannot keep up our enthusiasm; we are not proud of the thing. I have not been up here for a year or two, but when I came up and went in I felt a sense of shame for its out-of-elbow sort of look. Some of its friends may say it is very good; but it is no better than it was thirty-four years ago, and I maintain that it should be. May I go into detail? We have a professor, and we give him a certain sum per annum by way of honorarium. We give him a laboratory rent free, and we allow him to have a private shop there as a laboratory of his own, where space is of value; and not only that, but he is allowed to take all the fees. I do not blame Professor Attfield at all. Personally he is a man who has many friends, and rightly so, but I think we must all agree that he has very commercial instincts, and if the Society put a valuable property in his hand he would have been foolish if he had not made use of it. The men who come up to this School pay their fees, but they get no better instruction here than they get elsewhere—perhaps not so good—and when they leave the School they feel they have paid for all they have got, and they do not go away grateful. They do not feel loyal. Now, do you not feel that as a body of traders you ought to feel ashamed of yourselves in making a bargain of that sort. Is it right that you, as a body of business-men, should put a property of that sort into the hands of a man under that condition? I say it is not. If the money which students pay as fees had been used to extend the laboratory, we should now have a laboratory of which we might be proud. Why should we not go round to other countries and see what can be done in this respect? We have not done that. The men who have passed through the School in the last twenty years have gone away and been lost. If these men had been rightly served in this School—because you get the best men here—they would have gone to all parts of the country, and would have backed you up and benefited you to an immense extent. You have lost the chance; and how the ground lost is to be regained is a problem which I feel is most difficult to solve. I may have been indiscreet in touching upon this matter; but still the fact remains. I cannot go into politics, because I know nothing of pharmaceutical politics, but as a pharmacist who tries to keep up a respectable position, I feel we have lost a chance of making many members of the Society. If we are to have the responsibility, let us send out from this establishment men equipped and trained not merely so as to enable them to get a living, but equipped as thorough pharmacists so that they will be a credit to us. If I have been personal in my remarks in any way I regret it. It has been a matter of pain to me to have touched upon it, but I have brought it up as a matter of duty. I know Professor Attfield has an immense body of friends; but I really think that something ought to be done in the way I have suggested.

Mr. SAVAGE (Brighton): As one who has not attended many of your meetings I may be forgiven for speaking, but I feel to-day we are "A Happy Family," but that we are only representing a very small section of our trade. We are in the happy position of being between the profession generally and traders. We get the kicks on the one hand, and frequently we get a few half-pence on the other. I hope that our new Council will take the matter in hand, and be able to incorporate not only the 3000 or 4000 that are now represented, but the 8000 or 10,000 "Utlanders"—if I may so term them—who are standing aloof. They have no affair with the direction, and they take no active part in the management of the Society. In my own town the most popular chemist—a man whose hand is always in his pocket in case of need—is debarred from taking a place in the Council Chamber, because he was only the managing assistant to one of the leading firms in England in 1868. Is that fair? I say we should only be too happy to return that gentleman to the Council, and he would be an ornament to it. My town is not the only one in this respect. There are many similarly placed. Let the Council be the Upper Chamber, let us have a territorial representation of the chemists throughout the kingdom, and let there also be an Under Chamber. We can then bring such influence to bear that you, sir, will be President, not of a small section, but of one of the best organised societies in the kingdom.

Mr. LOMAS: The few words which I have to say refer to the first paragraph of the report. The President has said that the Council intends to go on prosecuting, and that we are doing good work in this direction; but I do find fault in one respect, and that is that the funds of the Society are being used for the prosecutions. Gentlemen, what are these prosecutions for? Are they for the purpose of obtaining a monopoly for you? Nothing of the kind. They are for the protection of the general public. You have just been called a missionary Society. I say it is no part of your duty to be missionaries and protect the public at large, but that it is the duty of the Government to make good to the Society that loss which the Society incurs in conducting these prosecutions. There is no monopoly in the matter. The Act under which you are prosecutors is passed for the protection of the public, and not for your protection. I have no doubt that if the Treasury was approached in a proper manner the money which you are out of pocket would be returned to you. Let us take it in this way. Suppose the order of things were reversed, and that instead of being out of pocket you were in pocket by the proceedings you would soon have the Exchequer or another department ordering you to pay the balance into such and such a department. You would not be allowed to enrich yourselves at the expense of the prosecutions. If you did you would have the general public down on you. If it cuts that way you have no right to be out of pocket. This Society is not called upon to protect the public, its duty is to protect the members, and to see that no man, unless he is qualified, carries on business as a chemist and druggist. In doing that it does all that is necessary. Outsiders say they will not pay their guinea to the Society for the protection of the public, and I say that they have no right to do it. I contend that we ought to get the money expended on prosecutions refunded. Then it is said that we do not do enough. I agree that we should spend all we can for the good of the Society. I find no fault with that, but I do find fault with it spending money on prosecutions. I will now touch on the one-man company question. I think that the Council deserves the thanks of the Society for the action it has taken. It will be successful in the near future, for the idea that a one-man company should protect five or six persons is so monstrous and contrary to what it should be that I feel certain the Council must in the end be successful.

Mr. CURRIE (Glasgow): Mr. President and gentlemen. In the first place I have to thank you for the very kind reception which we met with on the occasion of the dinner last night, and also at the meeting to-day. This is the first occasion on which I have been present at the Annual Meeting. I made up my mind that I would come this time, not, as you have hinted, to give you a parting kick, or to jump on you, but to let you know that the feeling of Scottish pharmacists towards the Society has undergone a great revolution. The annual report is a very elaborate one, and I have no intention of criticising, but I would draw your attention to one little remark which Mr. Hampson, the Treasurer, made at the meeting of your Council when he referred to Scotland getting so much. I hope, gentlemen, you do not grudge the money which

you have expended. The rooms have been practically completed; they are second to none—they are certainly not second to Bloomsbury Square—and the attendance for educational purposes has increased. I am glad to know that there is a prospect of a larger access of members and associates from Scotland than there has been in the past. For that we have to thank our President, Mr. Carteighe, who on the occasion of his last visit to Scotland was received sometimes very well and sometimes very ill. Be that as it may, after he had been heard speaking everything was in his favour, and those who were against him at the beginning of the meeting have quite gone to the other side at the end of it. I am convinced as years go on that at no very distant date we shall have nearly every chemist in business associated with the Pharmaceutical Society of Great Britain. A great many questions have been mentioned and discussed here referring to prosecutions. Unfortunately in Scotland the prosecutions have not been very gratifying to the Pharmaceutical Society, and still more unfortunately our Scottish judges do not favour our work. I am surprised beyond measure that the remarks which have fallen from the lips of Scottish judges and sheriffs should be allowed to pass without comment. We, in Glasgow, sent a notice to the Council that something should be done to get this matter put right, and I hope that it will receive attention. Another matter is the disposing of unqualified men in surgeries—I refer to keeping open shop business. If you come north you will find in this respect a very serious state of affairs, particularly in Glasgow. No later than last week I had a list of sixty doctors who keep open shop for the sale of drugs and poisons, and in not one of those shops is there a qualified individual—and that only in a very small section of our city. I could give you 300 cases to work upon, in not one of which is there a qualified man. The question of prosecutions in Scotland must be carried on if you are to gain members. We have had the matter discussed over and over again, and we maintain, no matter what may be said to the contrary, that a medical man has no right to have an open shop for sale to the public unless he employs a qualified person. As the question of education has been referred to, I may say that the percentage of failures for a long time has been simply astounding. It is not creditable to the Pharmaceutical Society that it should allow simple examinations like the Preliminary to be gone into time after time so that a man should be able to come up from three to six times to get through such a simple matter, and even then not get through. I say it is not creditable; I go further, and I say this—that if a man fails to pass his examination at the third attempt he should be debarred from passing at all. I would go a step further still, and say that it would be to the interest of the Pharmaceutical Society of Great Britain and to the interests of chemists themselves if it could be made compulsory that the Preliminary examination should be passed before the period of apprenticeship commences. I am delighted to have come to this meeting, and on behalf of my Scottish friends I tender you my hearty thanks for the reception accorded to us.

The PRESIDENT: If no other member has any observation to make I will reply to the gentlemen who have spoken. I may be pardoned if I say that I think the majority of this meeting agree in the main with many of the criticisms that have been made on the report and the condition of pharmacy. It is the duty of the incoming Council to do what it can in the directions indicated. I think the neatest way in which I can deal with your criticism would be this—if you would allow me to say, that all your suggestions shall be considered by the General Purposes Committee, and have the attention they deserve. There is one special thing Mr. Currie referred to, which, perhaps, I may allude to specially. He knows quite well that we have given a great deal of attention to so-called doctors' shops in Glasgow. He also knows quite well that for some time it was held that the doctor was exempt from the provisions of the Act altogether—that is to say, his assistant and his ox and his ass and everything else; and in the early days of my presidential office I had some difficulty in getting my colleagues upon the Council to believe that the exception which applied to medical men only applied to the individuals. It would be a great anomaly if the law had been otherwise. We have to thank some of the Scotch doctors for having carried the case up to the Superior Court in Edinburgh, where we obtained a decision in our favour. Mr. Currie must, I think, point out to his Scottish friends that the difficulties which we have to deal with are considerable in undertaking prosecutions in Glasgow. He knows that the sympathies of the Sheriff appear to go with the boy or girl or woman who is left in charge; and because we cannot hit the medical man he seems to think that it is not a serious offence at all. We do not begrudge the ex-

penditure of money — that question does not enter into consideration at all. Every case is proceeded with on a defined principle, with the amount of seriousness which might involve it being carried to the House of Lords. But the difficulty is this, that if the Sheriff imposes a penalty of a shilling the moral effect on the doctor is almost *nil*. We have received a memorandum on the subject from Mr. Currie, which is under the consideration of the General Purposes Committee; but it is not so easy to move as is suggested, the fact being that the real delinquents are the doctors themselves. I do not hesitate to say that if any member of the colleges in London carried on this business, and attention was called to it, they would be struck off the roll. I did notice that some attempt was made by the medical authorities of Glasgow in that direction, but I do not think they went far enough. If Mr. Currie could manage to influence some of the leading physicians in Glasgow, and temperately put this disgraceful state of things before them in order to see whether they could not help to stop the practice, he would be doing great good. It is perfectly obvious that if we bring the people, half of whom may be boys, before the Sheriff, and the Sheriff practically whitewashes them, the coercive action of the law does nothing to stop the doctor. I am not sure that Mr. Currie could not write a very good article for the Glasgow papers. I commend that form of calling public attention to some of my brethren. Mr. Atkinson referred to the danger of dispensing in close surgeries as distinct from open shops, and that to my mind is a very serious danger. I feel certain that if some of my learned brethren would get an article in the *Nineteenth Century* pointing out the danger, and followed it up by a paper read elsewhere, the moral effect would be extremely great, and it would lead to the subject being considered. The public imagine that the doctor professes to supply medicine. As a matter of fact the doctor wants a fee, and the public think they are getting a visit for 3s. 6d. with the medicine thrown in, but that is not the case. If they knew the danger of having poison dispensed in a close place without the supervision of a medical man, they would be almost as glad as the people in the middle ages to have something between the doctor who wrote potent things for the king and the king who swallowed it. I should not like to be disrespectful to Mr. Lomas, but I really think he was not quite as illogical as some of you thought in his references, though I am afraid we cannot do anything in the direction he says. To quote from a case before us in Scotland, the Procurator-Fiscal actually brought before us officially a serious case of negligence, not only on the part of the person not being registered, but a gross case ending in death, and he asked us whether we ought not to take proceedings against this person under Section 17. Our reply was that the Procurator-Fiscal could do it himself, as we were not the prosecutors. He replied most politely that he could do it, but the money would not be allowed out of the Scottish Exchequer, and that if we undertook to pay the expenses he would undertake the prosecution. I am afraid there is no opportunity at present of getting any Government to give us what is lost out of the public funds. The fines go to the county in many prosecutions we undertake. I prefer in all these cases of carrying out an Act of Parliament to rest our action upon the carrying out the law irrespective of the money. If we carry on this policy we earn the confidence of the public and the respect of the Government department which has to do with us.

The resolution for the adoption of the report was then put, and carried unanimously.

APPOINTMENT OF SCRUTINEERS.

The PRESIDENT then read a list of names of gentlemen who had been nominated to act as scrutineers, and their appointment was unanimously agreed to.

APPOINTMENT OF AUDITORS.

The following gentlemen were appointed to act as auditors:

- BUTT, EDWARD NORTHWAY, 77, Hamilton Terrace, N.W.
- LESCHER, FRANK HARWOOD, 60, Bartholomew Close, E.C.
- STACEY, SAMUEL LLOYD, 22, Great St. Helen's, E.C.
- UMNEY, CHARLES, 50, Southwark Street, S.E.
- YATES, FRANCIS, 64, Park Street, Southwark, S.E.

The PRESIDENT then called attention to the fact that the following registers had been laid upon the table in compliance with the provisions of the Act:—

- Register of Members, Associates, and Students of the Society.
- Register of Pharmaceutical Chemists.
- Register of Apprentices and Students under the Act of 1852.
- Register of Chemists and Druggists under the Act of 1868.

Mr. EWING: Gentlemen, the motion which I rise to move is one which I am sure you will receive with cordiality. It is a vote of thanks to our worthy President and to the members of the Council. I am sure we are all indebted to them for the great attention they have given to their duties, and to the services they have rendered to every person in the trade in this kingdom. In spite of the President's hoarseness I am glad he has been able to discharge his duty to-day with his accustomed vigour and ability. We all hope that he will soon recover his voice to the full. You will cordially endorse what I have further to say—namely, that of all the men who have filled his position, few have equalled and none have excelled him in the devotion he has displayed to the best interests of the Society.

Mr. BARRETT: Gentlemen, I have very great pleasure in seconding the vote of thanks. Although one feels, of course, that you may always possibly find points of difference with the Council, at the same time one is always ready to admit that if we were placed in their position doubtless others would find the same fault with us. It is the duty of everyone to find fault with those in office. Notwithstanding that when gentlemen give up their time to preside over the important duties, such as our President presides over, as well as the members of the Council, I am sure we must all feel that they deserve our best thanks. In the President we have certainly one of those men who are the leading lights not only of pharmacy, but a man who might be a leading light in any position of life which he chose to occupy. The one thing more than another which grieves me is that he has not seen his way to offer himself as a member of the Parliament. Although he does good work in presiding over this Society, I feel that he could do better work for us if he would only grace the House of Commons by his genial presence. I have great pleasure in seconding the vote of thanks.

The resolution was put, and carried unanimously.

The PRESIDENT: Gentlemen, on behalf of the Council, the Vice-President, and myself, I tender you our hearty thanks. I have now to declare this meeting adjourned until 3 o'clock to-morrow, Thursday, to receive the report of the scrutineers.

ADJOURNED GENERAL MEETING.

Thursday, May 21.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The adjourned meeting for receiving the report of the Scrutineers was held on Thursday, May 21.

The Chairman of the Scrutineers, Mr. E. N. Butt, read the following report:—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Fifty-fifth Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:—

Voting papers reported by the Secretary to have been issued	3762
Voting papers received	2173
Voting papers issued, but not returned	1589
Voting papers received	2173
Voting papers disallowed:—	
Informal	6
Received by post too late	85
	91
Voting papers registered	2082

CARTE GHE	1725	PARK	1463
STORRAR	1698	GOSTLING	1459
MARTINDALE	1664	SAVORY	1220
JOHNSTON	1622	BATESON	1171
NEWSHOLME	1608		
CROSS	1594		
SYMES	1586	WARREN	1159
HARRISON	1537	CAMPKIN	1084
HILLS	1520	ARMITAGE	832
CORDER	1514	WILLS	747

EDWARD N. BUTT, *Chairman.*

R. FISHER YOUNG.	P. J. ROBBINS.
HERBERT CRACKNELL.	J. T. SANDELL.
S. A. STURTON.	LEO ATKINSON.
W. PRIOR ROBINSON.	W. L. CURRIE.
J. C. HYSLOP.	WALTER T. COOPER.
HENRY C. BIRCH.	H. N. B. SPINK.
J. H. SHACKLOCK.	T. W. HORSLEY.
A. E. TANNER.	W. H. STICKLAND.
EDWARD B. STAMP.	R. G. GUYER.
D. R. JACKS.	R. FEAYER CLARKE.
R. W. GILES.	

THE NEW COUNCIL.

The PRESIDENT, as Chairman, then declared that the following gentlemen would constitute the Council for the ensuing year:—

ALLEN, CHARLES BOWEN, 20, High Road, Kilburn, London, N.W.
ATKINS, SAMUEL RALPH, Market Place, Salisbury.
BATESON, THOMAS, 23, Stricklandgate, Kendal.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
CARTEIGHE, MICHAEL, 180, New Bond Street, London, W.
CORDER, OCTAVIUS, 31, London Street, Norwich.
CROSS, WILLIAM GOWEN, Mardol, Shrewsbury.
GOSTLING, THOMAS PRESTON, Diss, Norfolk.
GROSE, NICHOLAS MALE, 8, Temple Street, Swansea.
HAMPSON, ROBERT, Norland House, Sevenoaks.
HARRISON, JOHN, 33, Bridge Street, Sunderland.
HILLS, WALTER, 225, Oxford Street, London, W.
JOHNSTON, JOHN, 45, Union Street, Aberdeen.
MARTINDALE, WILLIAM, 10, New Cavendish Street, London, W.
NEWSHOLME, G. T. WILKINSON, 27, High Street, Sheffield.
PARK, CHARLES JAMES, 1, Mutley Plain, Plymouth.
SAVORY, ARTHUR LEDSHAM, 143, New Bond Street, London, N.W.
SOUTHALL, ALFRED, 17, Bull Street, Birmingham.
STORRAR, DAVID, 228, High Street, Kirkealdy.
SYMES, CHARLES, 14, Hardman Street, Liverpool.
YOUNG, JOHN RYMER, 42, Sankey Street, Warrington.

After the report of the Scrutineers had been received, the President moved, and Mr. Martindale seconded, a vote of thanks to the Scrutineers for their labours. This was suitably replied to by Mr. E. N. Butt on behalf of the Scrutineers.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School, and House Committee, held on Thursday, the 14th inst., the Librarian presented the following report of donations:—

To the Library (London).

University College, Liverpool: Calendar, 1895.
King's College Hospital, London Reports, vol. 2, 1894-95.
Mr. Walter Hills, London: Berichte der deutschen chemischen Gesellschaft, 1895.
University of London: Calendar 1896.
Dr. E. Bretschneider, St. Petersburg: Botanicon Sinicum, part 3, 1895.
H.M. Secretary of State for India: Flora of British India, part 21.
Imperial Botanic Garden, St. Petersburg: Acta Horti Petropolitani, tom. 14, fasc. 1.
Radcliffe Library, Oxford: Catalogue of Books added during 1895.

Smithsonian Institution, Washington:

Bolton, Bibliography of Chemistry, 1893.

Mr. E. Andom:

Industrial Explorings In and Around London, 1896.

École supérieure de pharmacie de Paris:

Roques, Recherches sur la cinchonine, 1896.

To the Library (Edinburgh).

Messrs. E. R. Squibb and Sons, Brooklyn, New York:

Ephemeris of Materia Medica, vol. 4, No. 4.

Pharmacy Board of Victoria:

Victoria, Pharmaceutical Register for 1895.

Victoria, Report of the Pharmacy Board for 1895.

Mr. Bertram Prentice, B.Sc., Edinburgh:

On Dimethylacrylic Acid and Antipyrine, 1895.

The following report of donations was presented by the Curator:—

To the Herbarium.

Mr. H. W. Ridley, M.A., Singapore:

Fifty-three specimens of medicinal plants.

PARLIAMENTARY INTELLIGENCE.

THE COMMONS AND RESEARCH.—Mr. Robert Cox (S. Edinburgh) will at the proper time move that the Civil Service estimates be reduced by £100, in respect of scientific investigations. The honourable member is understood to be a member of the firm of J. and G. Cox, gelatin manufacturers, Gorgie Mills.

THE COMPANIES BILL.—No day has yet been fixed for the meeting of the House of Lords Select Committee, to which this Bill has been referred. The House has now risen for the Whitsun recess, and will not again assemble till June 8.

SIR ALBERT ROLLIT, who is fast acquiring a high reputation as an "all-round man," has now turned his attention to educational matters, and has been inquiring whether the Government intends to act upon the report of the Gresham Commission. The Vice-President of the Committee of Council on Education, in reply, has officially announced that a Bill for the re-organisation of the London University on the lines recommended by the Commission is lying in the Privy Council office awaiting the sanction of the Government, and that when that sanction is obtained the Bill will probably be introduced into the House of Lords.

THE SECOND ROYAL COMMISSION ON TUBERCULOSIS, to which reference was made in the Journal for February 29 at the beginning of the Session, has not yet been appointed, and Dr. R. Farquharson, alarmed lest in the nightly parliamentary strife of tongues the subject should meet the fate of the good seed which fell among thorns, is urging the President of the Local Government Board to announce the names of the Commissioners and the terms of the reference.

PUBLICATIONS RECEIVED.

SOUTHALL'S ORGANIC MATERIA MEDICA. Fifth and enlarged edition. By JOHN BARCLAY, B.Sc. Pp. 306. Price 6s. (London: J. and A. Churchill, 7, Great Marlborough Street, W. 1896.) From the Publishers.

LECTURES ON PHARMACOLOGY FOR PRACTITIONERS AND STUDENTS. By Dr. C. BINZ. Translated from the second German edition by ARTHUR C. LATHAM, M.A., M.B. Oxon., M.A. Cantab. Volume I. Pp. 389. (London: The New Sydenham Society. 1895.) From the Council.

LIEBIG AND KOPP'S JAHRESBERICHT FOR 1890. Part 6. Edited by F. FITTICA. (Brunswick: Friedrich Vieweg und Sohn. 1896.) From the Publishers.

CHARCOAL AS A THERAPEUTIC AGENT. By ROBERT B. WILD, M.Sc., M.D. Being the Parkin Prize Essay of the Royal College of Physicians of Edinburgh. Pp. 17. (Manchester: John Heywood. 1896.) From the Author.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, MAY 23, 1896.

THE SOCIETY'S ANNIVERSARY MEETING.

THE proceedings at the annual meeting of members of the Pharmaceutical Society are always interesting, for although their direct influence upon the conduct of affairs may be comparatively slight, they may be regarded as giving expression to opinions prevalent among the community of which the Society is the recognised representative. On some occasions disapproval of the action of the Society's Executive has formed the leading characteristic of the addresses delivered at these meetings, either in discussing the report of the Council or in connection with particular motions brought forward by members. Not unfrequently very unexpected results have taken place, and year by year the advent of the annual meeting is accompanied by a feeling of curiosity and sometimes of anxiety as to what may happen. The meeting this year has not been exceptional in that respect, nor perhaps wanting in the surprise to which it may have given rise. It would be affectation to ignore the circumstance that since the publication of the Council report and the financial statement for the past year, apprehensions have been entertained in some quarters that certain of their details might form the subject of more than ordinary severe criticism. A vague suspicion that there was "something rotten in the state" of the Pharmaceutical Society, appeared to have been conjured up as a warning to Members and Associates of the Society, who were supposed to have placed too implicit confidence in the ability of their elected representatives to conduct affairs and their desire to do so with due regard to the interests of chemists and druggists; probably there were also some who anticipated entertainment from the "heckling" of the Council and the President. The number present at the opening of the meeting was not so large as to afford much indication that such a result might be looked for, but before the termination of the proceedings, the place of meeting was fairly filled.

In moving the adoption of the report, the PRESIDENT, as usual, recapitulated some of the most salient points of the past year's work, and he did so in a manner to leave little for discovery by critical acumen. The fact that the income accruing from the administration of the Pharmacy Act had been reduced while at the same time the prosecution of offenders under the Act has involved an expenditure of a very considerable sum, leaving a balance of several hundreds against the Society, was very plainly pointed out. There was no more reticence in regard to the fact that there has been un-

diminished activity in the steps taken for rendering the Society's premises in London and Edinburgh thoroughly efficient and well adapted to the work of examination with corresponding outlay of money. In matters more immediately connected with the work of the Society as a voluntary body, there has been equal liberality in maintaining the Libraries, Museums, and other educational arrangements, while the outlay on the Society's School has not been much less than a thousand pounds. Then in regard to the Journal—a part of the Society's property which has recently undergone modification in response to a very general desire of the subscribers—the additional expenditure of several hundreds of pounds during the past year was mentioned—not as a circumstance requiring excuse, but as an indication of the thoroughness with which effect has been given to the desires of Members and Associates of the Society.

But this particularisation of the ways in which the Council has deliberately spent more money than has been received as income, did not give rise to any such expressions of disapproval or lamentation as might have been expected if the above-mentioned prognostications had been well founded. On the contrary, the prominent characteristic of this year's meeting has been the unusual complimentary tone adopted by all the speakers in expressing their approval of the work done by the Council, and their sense of the general indebtedness of the trade to those who undertake the laborious work to be conducted in that capacity. The audacious candour with which the PRESIDENT had pointed out all the details of financial deficit and shown that—instead of being portents of impending bankruptcy—they were rather signs of activity which would bear good fruit in the future, met with its due reward in the appreciative response of all the speakers, so that this meeting may be regarded as having reversed the record as to complimentary incapacity to which the PRESIDENT alluded as having been hitherto the habitual attitude of members of the pharmaceutical body. The reports of the proceedings at the Annual Meeting and of the speeches at the Dinner are in themselves so complete that we may dispense with further mention of them in this place. The increased convenience of the fine hall in which the Dinner was held gave general satisfaction, and although the Dinner was comparatively less hilarious than on previous occasions, and perhaps more entitled to be distinguished as what Belgians term a "séance solennelle," it was in every respect a success, and a source of satisfaction to those present. One very pleasing incident of the evening was the receipt of a congratulatory telegram from Mr. DARTON GIBBS, the President of the Midland Pharmaceutical Association, who was at the time presiding over a similar festive meeting at Birmingham (see page 414), where the health of the PRESIDENT and Members of the Pharmaceutical Society was drunk.

THE COUNCIL ELECTION.

THE result of the election for seats on the Pharmaceutical Council for the ensuing twelve months was declared on Thursday afternoon, and full particulars will be found at pages 409 and 410 of this week's Journal. All of the retiring members who offered themselves for re-election retain their seats, except Mr. WILLIAM WARREN, whose rejection implies the loss of a London member, since the three additions to the Council are all country pharmacists—Dr. SYMES, of Liverpool, a well-known former member of Council; Mr. C. J. PARK, of Plymouth; and Mr. THOMAS BATESON, of Kendal.

ANNOTATIONS.

ETHER AS AN ANÆSTHETIC.—Next October fifty years will have elapsed since the first application of ether in surgical operations took place, and in honour of this scientific jubilee, Professor C. Binz, of Bonn, has recently published in Richard Fleischer's *Deutsche Revue* a valuable historical sketch of the successive stages through which that beneficial discovery has gone in various countries.

RÖNTGEN RAYS IN SUNLIGHT.—Attention is recalled by Dr. Phipson to some experiments recorded by him in the *Chemical News* fifteen years ago, upon a white pigment containing zinc sulphide and barium sulphate. Sunlight darkened the compound except when it was covered by sheets of glass, in which case no darkening occurred. At that time Dr. Phipson was disposed to suspect the presence in the compound of a new element, which he provisionally named "Actinium," but he now suggests that the effects noted may have been due to the action of x -rays existing in ordinary sunlight.

THE NATURE OF SMOKELESS POWDER.—In the course of a lecture recently delivered before the Society of Arts, the inventor of the new Maxim powder described it as containing about 90 per cent. pyroxylin possessing a very high degree of nitration, with about 9 per cent. of nitro-glycerin, and from $\frac{1}{2}$ to 1 per cent. of urea. It is perfectly amorphous, and very hard and horn-like, the particles of which it consists being relatively long cylinders, perforated axially with numerous small holes, so that a minimum of burning surface is presented to the initial flame of combustion and a comparatively low initial pressure secured. In burning, the perforations increase in diameter, the combustion surface and consequent evolution of gases being thus greatly extended. The pressure is well maintained, therefore, throughout the bore of the gun, and a maximum of propulsive energy secured to accelerate the velocity of the projectile. The products of combustion of the Maxim powder contain but little carbon dioxide, the pyroxylin giving off carbon monoxide mainly. With a 5-inch breech-loading siege gun this new powder gave a velocity of 2403 foot-seconds, with a pressure of only 30,600 lbs. per square inch, thus improving greatly upon the U.S. Government requirements of a velocity of 1830 foot-seconds, with a maximum pressure of 31,360 lbs. Such high ballistic results have not formerly been obtainable, except with compounds containing from 50 to 70 per cent. of nitro-glycerin.

THE SOURCE AND CONSTITUENTS OF OPOPONAX.—Baur has examined opoponax gum-resin, and concludes, from the plant fragments which it contains, that it is derived from some member of the genus *Balsamodendron*, probably *B. kafal*. The specimen examined and described in the *Archiv der Pharmacie* contained 19 per cent. of resin, 6.5 per cent. of ethereal oil, and 70 per cent. of gum, besides plant fragments. The resin consists of α -panax resin, $C_{32}H_{54}O_4$, soluble in light petroleum ether; β -panax resin, $C_{22}H_{52}O_5$, insoluble in light petroleum ether but soluble in ether; and panax-resinotannol, $C_{34}H_{50}O_8$, insoluble in light petroleum ether, slightly soluble in ether, but dissolving in alcohol, and also, unlike the preceding two, in alkalis. The ethereal oil possibly contained a terpene; the portion of higher boiling point yielded, when hydrolysed, an alcohol, $C_{56}H_{96}O$, boiling at 250° to 255° , and apparently a fatty acid (? butyric). The residue contained "chironol," $C_{28}H_{48}O$, a white crystalline substance, not present in the original substance. The gum-resin also contained an uncrystallisable alkaloid, but no umbelliferone or sulphur.

EUCAINE AS A SUBSTITUTE FOR COCAINE.—Dr. Kiesel, a dental surgeon of Berlin, writing in the *Therapist*, mentions a case in which he injected $\frac{3}{4}$ gr. of cocaine, with the result that the patient was between life and death for an hour and a half. Since that experience he has used eucaine—a substance similar in constitution to cocaine, and having the empirical formula, $C_{19}H_{27}NO_4HCl$ (see *ante*, p. 342). The advantages claimed for eucaine are that the heart is not influenced, that the anæsthesia lasts longer and is more widespread than with cocaine, that the patient can tolerate an injection of 30 grains, that eucaine is not decomposed by boiling, and, finally, that it is cheaper than cocaine.

ADMINISTRATION OF METHYL SALICYLATE BY THE SKIN.—The facility with which the skin can absorb guaiacol has been shown to be very considerable, so that after painting the surface with this substance no less than forty-five grains of it have been recovered from the urine, a much larger dose than could have been introduced into the system by means of the stomach. This fact has led MM. Linossier and Lannois, of Lyons, to try the effect of administering an anti-rheumatic drug—methyl salicylate—in a similar manner, and they have found that it becomes transformed into sodium salicylate in the blood, and is eliminated by the urine in the form of salicylic acid. It can also be detected in considerable quantity in the fæces. The daily elimination takes place in a regular manner during the course of treatment, and no effect is produced on the skin by the applications. The method of application is described in the *Lancet* as very simple, the liquid being spread on the limb by means of a brush, with or without the aid of a medicine dropper, and the part then covered with a layer of oiled silk or other impermeable tissue, over which cotton-wool is fastened, and the whole left undisturbed for four-and-twenty hours. The absorption appears to be retarded by mixing lard or vaselin with the methyl salicylate.

BRITISH MEDICINES USED IN ITALY.—According to Mr. J. Durst, of Naples, quinine is the principal drug ordered in medical prescriptions in Italy, the sulphate, bisulphate, hydrochlorate, and valerianate being the principal salts in general use, whilst of the many qualities in the market Howard's brands are chiefly in favour with medical practitioners, and command the best prices. Iodine is a product of which a large quantity is used, especially in the form of potassium and sodium iodides, of which the best are of British manufacture, and here again Howard's preparations take the first rank. Mercury and zinc compounds, morphine, potassium and sodium bromides, salicylic acid, sodium salicylate, caffeine, cocaine, and pepsin are largely employed. To these may be added boric acid, tannic acid, tartaric acid, alum, sodium bicarbonate, cream of tartar, camphor, gum acacia, potassium chlorate, precipitated chalk, starch powder, magnesium carbonate, and effervescing citrate of magnesia. The latter article is manufactured on a large scale in Italy, though Bishop's preparation is considered the best, and used by all who can afford to pay the higher price which it commands. Many, modern chemical preparations such as antipyrine, phenacetine, dermatol, diuretin, migrainine, sulphonal, and many others command a rapid sale in South Italy; while creosote, guaiacol, and terpin hydrate are in continuous command. Of aromatic essential oils, Mitcham peppermint and lavender occupy the first place, and together with British Indian sandal-wood oil have a large sale, as have also cod-liver oil and oil of turpentine. Since the publication of the first official Italian Pharmacopœia in 1892, extracts and tinctures of the British Pharmacopœia are no longer in demand by Italian chemists, but fluid extracts are still readily saleable. The drugs imported are chiefly calisaya bark, opium, nuxvomica, sarsaparilla, senega root, jalap, and senna leaves, all of these being imported on a large scale.

AUSTRALIAN TOBACCO.—The *Bombay Gazette* points out that Australia threatens to compete with India as a tobacco-producing country, active measures being taken in the island-continent at the present time with a view to the development of the industry. Experimental quantities of tobacco have been grown for a considerable period, and the Melbourne Agricultural Department is of opinion that a highly profitable trade may be built up. To this end the north-eastern districts of Victoria have been inspected by an American expert, who reports that greater care in growing, curing, and grading the tobacco will be necessary to make the plantations repay cultivation. Settlers have accordingly been instructed on those points, and good results may be anticipated. It has also been recommended that the suitability of soil and climate of particular districts for the different classes of tobacco should be carefully ascertained, and that small experimental stations should be established in different parts of the colony for the purpose of making tests with the different varieties of tobacco, and so ascertaining which will best enable growers to realise a profit. By erecting model curing sheds at these stations useful object-lessons could also be given to growers.

INDIAN VERSUS CHINESE OPIUM.—Indian opium costs thirteenpence per ounce at Wenchow, China, whereas the native product can be purchased for sixpence halfpenny per ounce. It is not surprising, therefore, that the import of the former is steadily declining, while the production of the native drug steadily increases. The area under poppy cultivation in the district has increased almost two-fold during the last five years. In spring the river banks are lined with fields of brightly coloured poppies, especially towards the sea coast, where the saline nature of the soil favours their growth. Opium does not interfere with the rice crop, as it is sown in autumn, and it is far more profitable to the farmer than wheat or rape, the usual alternatives of rice. A mou (1 acre equals $6\frac{2}{3}$ mou) of wheat will yield 2 dols., whereas a mou of opium may yield as much as 12 dols. profit to the producer. The output of native opium last year was only fair, owing to heavy rains in the early spring, and amounted to an approximate total of 3,208,266 lbs., valued at £59,583; the retail price has, therefore, slightly gone up. The best opium, according to Acting-Consul Fox, is produced in the districts of Yoching, Suian, and Pingyang, all adjoining the seaboard.

POTASSIUM PERMANGANATE AS AN ANTIDOTE FOR OPIUM.—Experiments conducted by Dr. A. P. Luff demonstrate the selective faculty of potassium permanganate for morphine in the stomach contents, and confirm the conclusions arrived at by Dr. William Moor, of New York, as to the value of the compound as an antidote for opium and morphine poisoning. When the quantity of poison taken is unknown, from eight to ten grains of the permanganate should be administered, dissolved in four to eight ounces of water, and the stomach must afterwards be washed out two or three times at intervals of half an hour, with a weak solution of permanganate. Details of the experiments are published in the *British Medical Journal* for May 16, where also appears a paper on the same subject by Surgeon-Captain F. P. Maynard, who regards the permanganate as being a strictly local antidote. As such it can only act upon opium or morphine with which it comes in contact in the stomach, and can have no effect upon what has already been absorbed. It is not to be expected, therefore, that it will save life where a lethal quantity of the poison has been absorbed, nor can it be regarded as a physiological antidote to opium such as eserine is to atropine.

APOSPOROUS AND APOGAMOUS FERNS.—Ferns usually produce on the back of their fronds multitudinous spores which are formed within minute capsules or sporangia. On germinating, these spores give rise to a leaf-like scale termed the prothallus, upon the lower surface of which sexual organs arise. Within these, in turn, sexual cells are differentiated, and as the result of the fertilisation of one of the female cells or oospheres by a male cell or antherozoid, a new fern plant arises. Thus in normal cases there is a regular alternation of a sexual with a sexless generation. As Mr. C. T. Druery points out in *Science Progress*, however, this is not the only course open to ferns. It has been found that *Aspidium filix mas* may reproduce itself both in the normal fashion and by an apogamous method, simple budding occurring as the result of over-crowding and consequent starvation, which check the formation of archegonia. The young plants are engendered upon precisely the same spots on the prothallus as the sexual ones would occupy. Similar instances have been noted in the case of *Athyrium filix femina*, small whitish bulbils developing on the prothalli, and giving off both fronds and roots when placed in contact with loam. A presumed barren variety of the same plant was found to produce apparent sori which contained no spores, but developed direct into ordinary prothalli when placed under suitable conditions. Further investigation showed that this condition of apospory might also exist in the case of varieties of *Polystichum angulare*, *Lastrea pseudo mas*, and *Scolopendrium vulgare*. It is evident, therefore, that the normal life cycles of certain ferns may be successively shortened, first by the elision of the spore, and then by that of the whole soral apparatus, while De Bary's observations tend to show that in the case of *L. pseudo mas cristata* it is shortened almost to the utmost, the chain being simply sporophore, prothallus, sporophore. But it seems that even the prothallus may be eliminated, as shown by a small plant of *Scolopendrium vulgare*, in which the frond itself acted as the oophore or egg-bearer, and the archegonia and antheridia were generated upon it without the formation of a prothallus proper.

"AN INSTITUT PASTEUR" AT ATHENS.—For the past eighteen months an "Institut Pasteur" for the treatment of hydrophobia by inoculation has been in existence at Athens. During that period more than two hundred cases have been treated, and there has been only one death, the patient in that case having delayed coming up for treatment till fifteen days after being bitten. The establishment consists of twenty-three rooms, and since its existence no person has left Greece for treatment at Paris. Dr. Pampoukis, the Director, was sent in 1886 to study under Dr. Pasteur at Paris, and on his return started a microbiological institute at his own expense, and conducted a series of valuable experiments for the Government. He obtained permission to open an "Institut Pasteur," and did so at his own expense, but he has since been granted an annual allowance by the Athenian municipality, and the Chamber subsequently granted him a yearly subvention, on condition that all persons sent by the authorities should be treated gratuitously.

THE YELLOW COLOURING MATTER OF AUTUMN LEAVES.—According to Staats, the yellow colouring matter extracted from autumnal leaves by boiling alcohol is not identical with phylloxanthin, and it is called by him "autumnixanthin." It gives a reddish-brown precipitate with potash, which dissolves in water or in acids. This potassium compound has been obtained in minute crystals, although autumnixanthin itself has not been obtained in a crystalline condition. When its alcoholic solution is slowly added to boiling hydrochloric acid a red solution is formed.

MIDLAND PHARMACEUTICAL ASSOCIATION.

ANNUAL MEETING.

The annual meeting of the Midland Pharmaceutical Association was held on Tuesday evening, at Mason College, Birmingham, Mr. R. Darton Gibbs presiding. There was only a small attendance of members.

The report of the Council dealt in detail with the work of the year, and stated that in addition to the usual scientific papers, arrangements had been carried out whereby papers on the trade side of their calling had been read. Details were also given of the work of the Trade Committee. The Council having been notified of the formation of the Midland Chemists' Assistants' Association, placed on record its approval of the efforts that the assistants were making to associate themselves for promoting and advancing their interests. The Council was of opinion that the true interests of pharmacists and their assistants were alike, and any results in raising the *esprit de corps* which that work might bring about, were calculated to add to the position and dignity of the future trading members of their body. The past year had brought no relief to the conditions of their calling; the growth of company trading was rapidly extending, owing to the abundance of unprofitably employed capital which was constantly seeking use, and the Council feared that the limits of that development had not yet been seen. General support had been given to the Shop Hours Bill, the Council feeling it desirable in the best interests of the trade that the present long hours of business should be curtailed. The financial statement showed a balance in hand on the year of eight pounds.

The Chairman said that in one of the trade papers, shortly after the last annual meeting, there appeared some disparaging remarks with regard to that Association and the work it did. He knew there was a great deal of work done, and therefore it was rather hard to be told that the work of the Association was of a meagre description. It might be that in his expressions he took rather a gloomy view of the work, but there was nothing to warrant the criticism he had referred to. A new departure had been taken in having the report printed in detail and circulated, so that all the members could see what had been going on during the twelve months. They had departed from the stereotyped forms of previous years, and not only had scientific papers been given, but there had been some interesting and practical discussions on the trade side of their calling. They knew that the chemist's business did not flourish in the same proportion as others, and therefore the Council hoped the work that had been done would assist in some way in finding out the reason why.

Mr. A. Southall moved the adoption of the report and statement of accounts. He did not take a gloomy view of things, and contended that the position of chemists now was better than it was ten years ago. There had been, no doubt, a good deal of unprofitable business done, but the Association was looking after that, and he thought would be able with the chemists in the country to do something to prevent traders selling things at a loss. He thought that local associations had done much to stimulate chemists about the country to give up that sort of bad trade. With regard to the scientific part of their calling, that had certainly improved. The Pharmaceutical Society had done a great deal in the last few years to put down illegal trading. It wanted putting down still more, but the law was rather against the action of the Society in some directions. The Companies Act had been a great drawback to the Pharmaceutical Society doing its proper work, but he imagined the present Government would do something for them in that way, and strengthen their hands so that they might be able to prevent the illegal trading that was going on at the present time.

Mr. Brown seconded the motion, and expressed the opinion that if the Pharmaceutical Society had been the means of compelling paregoric to be labelled "poison," he did not think much of the beneficial character of its action.

Mr. Wheeler (Wolverhampton) supported the motion, and said that it was a pity more support was not given to an association like that. The parent Society laboured under great disadvantages, because it had not the united support of the members of their calling throughout the country in carrying out measures for the welfare of all. If chemists united and gave determined support to the Pharmaceutical Society they would have little cause to complain of its action.

Mr. T. Wakefield also supported the motion, and said that during the last twelve months the Association had shown signs of new life, and if it proceeded on the lines it had followed of late he had no doubt advantages would accrue to them all. If they supported the Pharmaceutical Society as it deserved to be supported, they might urge it to push forward the reforms they desired. Strong action was necessary in the matter of company trading, and the question of doctors dispensing, but they could not expect the Society to move unless chemists gave it their united support.

The report was then approved.

On the motion of Mr. Wakefield a vote of thanks was passed to the Council and officers for their services.

The President, Mr. Jarvis (hon. sec.), and Mr. A. Southall replied.

Subsequently the annual supper was held at the Grand Hotel under the presidency of Mr. Gibbs. In the course of the evening the toast of "The Queen" was honoured, as was also that of "The Lord Mayor of Birmingham," this being the first occasion on which that toast had been submitted to a Birmingham audience, the official information that a Lord Mayoralty had been conferred upon the city having only reached Birmingham during the evening. The health of "The President" was proposed by Mr. C. Thompson, who said that Mr. Gibbs had done much to advance the interests of the Association. The toast was musically honoured, and Mr. Gibbs in responding said that it was gratifying to him to know that after occupying the presidency of the Association for two years they believed he had done something for the craft he loved. He had endeavoured to proceed on broad lines, and if they did not attain to the dignity he wished them they must attribute it to the apathy shown by many of their craft. If they were united and determined there was nothing they desired that they might not get.

The brief speeches were agreeably interspersed with musical and vocal items.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

SUMMER MEETING.

The first of three summer meetings of the Association, arranged by the Committee, was held in the Pharmaceutical Society's Hall, 36, York Place, on Friday, the 8th inst., from 8 to 10 p.m., Mr. J. McBain, President, in the chair. The idea of these meetings is to encourage the study of field botany. Members who have the opportunity are appointed to gather local plants and bring them to the meeting, where they can be practically studied by all the members. There was a good attendance, and, as showing the remarkable nature of the present season, it may be mentioned that specimens of the following plants in flower and several in fruit were shown:—Ranunculaceæ, *Anemone nemorosa*, *Ranunculus ficaria*, *R. acris*, *Caltha palustris*; Cruciferae, *Cardamine pratensis*, *Barbarea vulgaris*; Cistaceæ, *Helianthemum vulgare*; Violaceæ, *Viola canina*, *V. tricolor*, var. *arvensis*; Caryophyllaceæ, *Lychnis diurna*, *Arenaria trinervis*, *Stellaria holostea*; Acoraceæ, *Acer pseudo-platanus*; Geraniaceæ, *Geranium molle*, *G. robertianum*; Oxalidaceæ, *Oxalis acetosella*; Leguminosæ, *Cytisus scoparius*, *Vicia sepium*, *V. sativa*, *V. hirsuta*; Rosaceæ, *Prunus spinosa*, *P. padus*, *Geum rivale*, *Potentilla tormentilla*, *P. fragariastrum*, *Fragaria vesca*, *Alchemilla vulgaris*, *Crataegus oxyacantha*; Grossulariaceæ, *Ribes rubrum*, *R. grossularia*; Saxifragaceæ, *Saxifraga granulata*; Caprifoliaceæ, *Adoxa moschatellina*; Rubiaceæ, *Galium cruciatum*, *Asperula odorata*; Ericaceæ, *Vaccinium myrtillus*; Scrophulariaceæ, *Veronica chamaedrys*; Labiatae, *Lamium album*, *Nepeta glechoma*; Boraginaceæ, *Borago officinalis*, *Myosotis arvensis*; Primulaceæ, *Primula vulgaris*; Euphorbiaceæ, *Mercurialis perennis*; Ulmaceæ, *Ulmus montana*; Salicaceæ, *Salix phylicifolia*; Coniferæ, *Pinus sylvestris*; Liliaceæ, *Hyacinthus non-scriptus*. At 9.15 p.m. Mr. W. B. Cowie gave a demonstration, in which he dwelt more particularly on inflorescences, illustrating his remarks by living plants, and also by a series of diagrams. Mr. Rutherford Hill made some remarks dealing especially with plant names, the early flowering of spring plants owing to stores of nutriment, as seen in the tubercles of *Ranunculus ficaria* and the rhizome of *Anemone nemorosa*, and the structure of flowers in reference to cross-fertilisation and fertilisation by wind and insects. The meeting closed with votes of thanks to Messrs. Hay, Burns, Thompson, Cowie, and Hill for collecting and describing the plants, and to the Chairman.

ANNUAL DINNER OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

The annual dinner of the members and friends of the Pharmaceutical Society was held on Tuesday evening, May 19, in the King's Hall, Holborn Restaurant, London, Mr. Michael Carteighe, President of the Society, in the chair. Amongst those present were:—

Abel, Sir F. Bart., F.R.S. (Secretary and Director Imperial Institute).	Ringer, Professor S. (University College, London).
Bateman, Dr. A. G. (Medical Defence Union).	Roberts, Professor F. T. (University College, London).
Blackwell, S. J. (Master: Salters' Company).	Russell, Dr. W. J. (President: Institute of Chemistry).
Browne, Sir James Crichton, F.R.S. (Treasurer: Royal Institution).	Scott, E. Lionel (Clerk to the Salters' Company).
Currie, W. L. (Vice-Chairman of the Executive: North British Branch).	Simpson, J. F. (President: Royal College Veterinary Surgeons).
Ewing, J. L. (Chairman of the Executive: North British Branch).	Smale, Morton, M.R.C.S. (Dean: London Dental Hospital).
Foster, Professor Michael, F.R.S. (Secretary: Royal Society).	Stevenson, Thomas, M.D. (President: Society of Public Analysts).
Gibbes, F. R. (Master: Society of Apothecaries).	Trimmer, E., M.A. (Secretary: Royal College of Surgeons).
Heath, C. (President: Royal College of Surgeons).	Tyrer, T. (President: Society Chemical Industry).
Hicks, A. Braxton (Coroner for S.W. London).	Upton, J. R. (Clerk to the Society of Apothecaries).

The health of the Queen having been duly proposed and honoured,

"THE MEDICAL PROFESSION."

The VICE-PRESIDENT (Mr. J. Harrison) proposed the Medical Profession. From the earliest times there had always been a class of men who thought themselves qualified to cure disease, and though in early times no doubt medicine was a very rude art, closely allied to ignorance and superstition, still those who practised the art of medicine managed to make themselves of some importance in the communities in which they lived. Since then there had been immense advances made, and medicine was now established upon a scientific basis, and no one recognised that fact more fully than pharmacists, who might claim to have given some aid to the advances of medicine, a claim which medical men would readily admit. While medical men diagnosed disease and prescribed the medicine, the pharmacist prepared the remedy in the most potent and presentable form; and so long as those two functions existed side by side, there was a great future before them both. The time might possibly come when preventive medicine was so much developed, and when sanitary arrangements had become so perfect, that there would be no need of curative medicine, but even then they need not despair, for there would be a large field for their abilities in the preparation of preventive medicine. He would couple with the toast the name of Mr. Christopher Heath, President of the Royal College of Surgeons.

Mr. C. HEATH, in responding, said it seemed somewhat anomalous that the President of the College of Surgeons should be called upon to represent the medical profession, but nevertheless he had much pleasure in undertaking the duty. With regard to the relation of the medical profession to pharmacy, he could only say that he and his professional brethren were much indebted to the chemist, and did not know what they would do if they were left to their own devices. He remembered as a young man writing a prescription—copied, he believed, out of Druitt's 'Vade Mecum'—and forgetting to put in the water, and receiving a polite note from the chemist to whom it was taken pointing out that there was some little deficiency which perhaps he would supply. He was quite sure that they had to thank chemists for preventing them sometimes from committing manslaughter, and certainly from mixing incompatibles. He was sure Dr. Ringer and Dr. Roberts would bear him out in saying that the medical student of to-day knew very little of drugs, and he was sorry to say that such ignorance was in-

creasing. They did not learn, as in the old days of apprenticeship, what the action of drugs was, and sometimes they prescribed things which would turn to a solid mass in the bottle. In the practice of surgery, fortunately, he could corroborate the words of Sir Thomas Watson in an address to the Clinical Society, who said that as he got older he used fewer drugs, and certainly a surgeon did not require a large pharmacopœia. He was sometimes astonished when he met a gentleman in consultation to find the extraordinary drugs he was prescribing—things he had never heard of, though of course he never said so. Last year he ventured to express the hope, as a new pharmacopœia was under weigh, that the strength of laudanum would not be interfered with, and he was happy to say that he believed it would remain as it was, otherwise he had no doubt that the duties of coroners would have been largely increased. Apropos of the Pharmacopœia, he might say that he had that afternoon seen Sir Richard Quain, who asked him to say on his behalf how much he appreciated the labours of the Pharmacopœia Committee of the Pharmaceutical Society. He was sorry to hear from the President that the new pharmacopœia was still in embryo. Of course it was a difficult thing to get through a work of that kind; perhaps it would be better if it were very much curtailed, but in any case he supposed another nine months' gestation would be required, and then he hoped it would be brought forth and would be a credit to its parents. He always kept on his consulting table a little volume with red leaves, which looked like a prayer-book, and no doubt many of his patients thought he was a high churchman, but it was really Martindale's 'Extra Pharmacopœia,' and he must say that he found in that all that he wanted. In conclusion, he would only say that the appreciation of the medical profession by pharmacists was heartily reciprocated.

"SCIENCE."

The PRESIDENT next proposed "Science." He said they were formerly taught that pharmacy, like medicine and surgery, was an art, but by degrees it had been found that the art was based on certain definite principles of a more or less scientific basis. Technical education as applied to pharmacy, meant a study of chemistry, botany, and physics, and the more thorough the knowledge the chemist had of those sciences the more satisfactorily would he discharge his duties both to the medical man and the public. He coupled with the toast the name of Sir J. Crichton Browne, F.R.S., Treasurer of the Royal Institution, who, amongst his numerous other functions, was always engaged in collecting funds for the original scientific work which was carried on in that Institution, on such a grand scale and with such magnificent results.

Sir J. CRICHTON BROWNE said he rose to respond with great diffidence, seeing so many other gentlemen around him on whom the duty might more appropriately have fallen. It was quite right and proper that the Pharmaceutical Society should recognise the claims of science, since it was based upon it, and it had advanced in public estimation in proportion as it became more scientific and less empirical. Its future progress would depend on its keeping abreast of chemical and biological science. John Stuart Mill was once greatly distressed at the thought that a day must come when all the possible combinations of musical notes would be exhausted, and there would be no new music; and so in these lugubrious times they were sometimes told—and even Mr. A. Balfour gave countenance to the idea in his famous book—that science was nearly played out; that she had reached the limit of her possibilities, and that no more great discoveries must be expected. Such a melancholy notion was only one of the symptoms of that deadly pessimism which was creeping through the land; he was much more inclined to adopt quite the opposite and optimistic view, which seemed most reasonable and most in accord with the facts, viz., that science was still in her infancy, that her greatest achievements were yet to come, and that her most brilliant successes in the past were as nothing to the day which should be revealed hereafter. Though science was constantly pushing back the confines of ignorance and darkness there was an ever increasing circumference for further investigation. If there were no more continents or islands on the surface of the earth to discover, there was still the unseen universe, the subtle ether, the invisible rays, which science was concerned with, and in those directions there was a boundless expanse before her. It was only the other day that they had learned about liquid air, about argon, and about the Röntgen rays, with two of which discoveries the Royal Institution had been honourably associated

through the persons of Professor Dewar and Lord Rayleigh, and he thought, therefore, there was no reason to despair as to the future. As to the funds, he was glad to say there was no difficulty—the money simply flowed in. One morning, in Scotland, he opened a letter from America and found a draft for £20,000 from an old confectioner in New York State, who had once attended some lectures in the time of Faraday and was anxious to do something to promote the work; and he had scarcely returned to London when he had a still more munificent donation from Dr. Ludwig Mond, who, in establishing the Davy-Faraday Research Laboratory, which they hoped soon to see opened, had already expended at least £80,000. In practical pharmacy there had been enormous progress in the last quarter of a century, since it had been taken to a great extent out of the hands of the medical profession; the old-fashioned boluses and horrible conglomerations were in great part put aside, and there was a more rational use of the various substances derived from the animal, vegetable, and mineral kingdoms, together with the production of alkaloids, and more recently of animal extracts; in that way pharmacy had kept pace with the advance of medical science, and had given the practitioners of medicine weapons of ever increasing power and precision. Vast as had been the improvements in the armaments and weapons of warfare and destruction, they were able to report parallel improvements in the life-saving apparatus with which they were mainly concerned, and they had not finished yet. Tabloids was not the last word of pharmacy, and if he could believe the announcements which reached him by almost every post, he should conclude that new inventions were being made every ten minutes. But with all his admiration for progress he could not speak disrespectfully of the "old" Pharmacopœia; no doubt it required that revision which it was now undergoing, but he sometimes thought that the statements made as to the uselessness of some of the remedies in it was due to a neglect of those remedies. There was a great deal of good in the "old" Pharmacopœia still, and he trusted that every member of his own profession would always have a competent knowledge of pharmacy as well as of pharmacology, and that pharmacists would not relieve the physician of the art of prescribing. There was no doubt a tendency for prescriptions to run in certain grooves, as was illustrated by a story of the late Sir James Simpson. A lady had come to Edinburgh to consult him, and after returning to her hotel was seized with a misgiving that she might not properly have explained her symptoms, and that Sir James might have given her an unsuitable prescription. She accordingly returned to make sure, but found the great man had left for Inverness. Seeing her agitation, the butler judiciously elicited the cause thereof, and was even favoured with a sight of the prescription, when he at once reassured her, telling her she might take it with perfect safety, as Sir James had "been gie'ing them a' that the day." It was certainly an advantage for a doctor to know that his prescription would come under the eye of a skilled pharmacist, but there was one kind of criticism which he trusted they would not be subject to. He was reading lately that, in the Southern States of America, when the negroes had the misfortune to lose their children they placed on their graves the toys with which they had played during their last illness, and also the unfinished bottles of medicine and the names of the doctors who prescribed them. Whether that custom might be regarded as a touching indication of a belief that pharmacy might be useful even beyond the grave, or as a simple warning to others, he did not pretend to say, but he was quite sure that most medical men would object to that kind of gratuitous advertisement.

"THE PHARMACEUTICAL SOCIETY."

MR. R. A. ROBINSON, in proposing the "Pharmaceutical Society of Great Britain, and the Health of the President," remarked on the innovation introduced into the proceedings by entrusting this toast to a member of the Society rather than to one of the distinguished guests to whose charge it was usually committed. Perhaps it might have been done to save the infliction of a long speech, and at any rate it would have that effect. The Society was founded more than 50 years ago, with four principal objects—the advancement of chemistry and pharmacy, the promotion of a uniform system of education amongst those who practised it, the protection of chemists and druggists, and the practice of benevolence, and there could be no doubt that all those objects had been kept steadily in view, and to a very considerable extent accomplished. Some might perhaps suggest that, with regard to the third object—the

protection of chemists—there might be some doubt, but it was a curious fact that those who thought so were always those who stood outside the Society. There was a large body of men who loyally supported it, but he regretted to say there was an equal number who still held aloof. He ventured to say that if they would but join the Society it was impossible to say what might not be done, either in Parliament or out of it; the one great need was a united front and combined action whenever the occasion arose. Mr. Robinson concluded by a few appropriate observations on the personal appearance and character of the President, which he summed up by saying that he was a man of great energy and capacity, who combined science with commonsense.

The PRESIDENT, in responding, said he thought it was just as well that the toast of the Society should be proposed for once by some one who knew something about it. The Society's motto must necessarily be "Advancement." That was the tendency of the time in every direction, as had been already pointed out, and what the doctor was incapable of doing, not from want of capacity but from the number of other things he had to do, that the chemist had to undertake, and he ought to do it well and thus help in his particular sphere to promote the progress of medicine.

"THE GUESTS."

The PRESIDENT shortly rose again, and proposed "The Guests." After expressing the pleasure which it gave him to see around him so many members of the Society from Scotland and all parts of the kingdom, he coupled with the toast the names of Sir F. Abel, who for many years had been a teacher of chemistry, and was now at the head of the Imperial Institute, where he was establishing a Research Laboratory. This it was hoped would be of great use to all our dependencies and the whole Empire. It would be under the direction of Professor Dunstan and Dr. Russell, one of his old tutors and now the President of the Institute of Chemistry, an Institute which he hoped to see developed until it did for chemical science generally and the educated public at large what the Pharmaceutical Society did in a large measure for pharmacy and pharmacists.

Sir F. ABEL said it was not the first time by many that he had had the honour of responding to this toast, but he felt he was somewhat out of place in doing so, inasmuch as he was one of themselves, having been for some time now an hon. member of the Society. He sympathised heartily with its working, had realised its difficulties, and rejoiced in its success. Men of science were eager to apply their work to practical purposes, and chemists were pre-eminently successful in applying their knowledge for the benefit of mankind. Scientific chemists had always been in thorough sympathy with the Society, and had contributed in some degree to its success, and, he hoped, would continue to do so. His work at the Imperial Institute was closely analogous to that of the Pharmaceutical Society, and he felt himself especially fortunate in securing the assistance of Professor Dunstan. He had had the good fortune to be able to place at the disposal of the Research Laboratory of the Society a good deal of material connected with pharmacy, and their endeavour in the new Laboratory at the Imperial Institute would always be to work in conjunction with the Society for the benefit of the medical profession. In fact, the work of scientific men could never be isolated; every branch of science gradually became more and more intimately blended with other branches, and so he hoped would the work of the Imperial Institute and the Pharmaceutical Society.

Dr. RUSSELL also responded briefly. It was perfectly true, he said, that chemistry was the foundation of pharmacy; and the progress of the latter was due to its followers having known how to avail themselves of the progress of chemistry. With regard to the Institute of which he had the honour to be President, he believed it had a great future before it. Their great object was to increase an accurate knowledge of chemistry, and to spread it over the whole kingdom, and if they succeeded in doing this they would be helping pharmacists to a considerable extent. Whether they obtained Government recognition would depend mainly on themselves. In his opinion they were not in a position to claim it at present, but the work now going on was thoroughly good, and would lead to beneficial results. The class of chemists who did public work had within the last few years very much increased, and he believed the examinations the Institute carried on, and the curriculum insisted on, would result in the formation of a body of thoroughly qualified professional chemists.

NOTES AND FORMULÆ.

MEDICATED GELATIN PENCILS.

The following basis and method is recommended by Montier for the preparation of gelatin crayons:—60 grammes of water and 10 grammes of glycerin are placed in an enamelled dish, and the medicament dissolved in the liquid, which is heated to boiling; to the boiling solution 100 grammes of gelatin is added, with constant stirring to prevent its adhering to the bottom of the vessel. When the water is almost evaporated and the paste flows with difficulty in the capsule, it is run into suitable moulds of gun metal, or into glass tubes previously oiled. The author has devised an ingenious arrangement, in which the tubes are surrounded by a water bath, thus keeping the paste fluid until they are filled. The moulds are then cooled, and the mass withdrawn, trimmed, and exposed to the air to dry for twenty-four hours (*Répert.* [3], vii, 196).

FORMOPYRINE.

By allowing a mixture of aqueous solutions of formaldehyde and antipyrine in equal molecular proportions to stand in contact for eight to ten days, Marcourt has obtained a definite crystalline body, which, when drained on a porous tile and recrystallised from alcohol, is found to contain one molecule of antipyrine and one of formaldehyde. Formopyrine melts at 142° C., is insoluble in cold water, sparingly soluble in hot, insoluble in ether and benzol, soluble in alcohol, chloroform, and acetic acid. It forms stable combinations with acids (*Répert.* [3], vii., 210, after *Bull. de la Soc. Chim.*).

IODOGALLATE OF BISMUTH.

According to Frizzi, this salt may be prepared as follows:—Dissolve with heat 30.4 grammes of bismuth in 100 grammes of equal weight of strong nitric acid and water; add to the solution 500 C.c. of boiling water, and pour into the liquid with constant agitation the following mixture, made hot:—16.6 grammes potassium iodide, 18.8 grammes gallic acid, 300 C.c. distilled water. Collect the precipitate and wash with a cold saturated aqueous solution of gallic acid. Dry at a moderate temperature in dry air. Iodogallate of bismuth forms a greyish-green amorphous odourless powder insoluble in water, alcohol, and ether, soluble in dilute mineral acids and in fixed alkalies. It forms a good antiseptic (*Répert.* [3], vii., 221, after *Bolletino Chimic. Farmaceut.*).

ASSAY OF FILICIC ACID.

An ethereal solution of filicic acid gives on agitation with an aqueous solution of copper acetate a green precipitate of the composition $\text{Cu}_2(\text{C}_{14}\text{H}_{15}\text{O}_5)$. Daccomo and Scocianti suggest this method for the assay of the commercial ethereal extract of male fern, samples of which have given them from 11.8 to 42.5 per cent. of filicic acid. The assay of eight samples of male fern rhizome shows that the drug contains from 1.769 to 2.421 per cent. of this acid. The yield of extract being 10 per cent., a good article should give from 17 to 24 per cent. of filicic acid by this method (*Répert.* [3], vii., 221, after *Boll. Chim. Farm.*).

CRESOCHINE.

Under this name a non-alkaline cresol disinfectant is prepared which is stated to be a neutral combination of tricresyl sulphonate and quinoline with tricresol. It contains 33 per cent. of quinoline and 17 per cent. of tricresyl. It is not caustic and is soluble to the extent of 1 in 25 in water. It is specially indicated as a disinfectant, since, being free from alkali, it does not set free ammonia from nitrogenous organic matter (*Journ. de Pharm.* [6] iii., 497).

DIAPHTHERIN.

Diaphtherin is a new antiseptic in the form of a yellowish powder, which melts at 55° C. and is very soluble in water. It is formed by saturating one molecular equivalent of orthophenolsulphonic acid with two molecular equivalents of orthoxyquinoline. It is employed in surgical practice in aqueous solution, from one half to two per cent. (*Journ. de Pharm. et Chim.* [6], iii., 495).

PHARMACY OF GLYCEROPHOSPHATES.

Syrup of Glycerophosphate of Lime.—Glycerophosphate of lime, 10 grammes; citric acid, 1 gramme; loaf sugar, 610 grammes; distilled water, 340 grammes; dissolve without heat. *Pastilles.*—Glycerophosphate of lime, 15 to 30 centigrammes; cocoa paste, 1 centigramme; for one pastille. *Wine of Iron Glycerophosphate.*—Glycerophosphate of iron, 10 grammes; Madeira, 990 grammes; macerate for twenty-four hours and filter. *Pills.*—Glycerophosphate of iron, 1½ to 3 grammes; powdered rhubarb root, 1½ to 3 grammes; extract of cinchona, 4½ to 4 grammes; mass and divide into 60 pills (*Ann. de Pharm. de Lour.*).

SPRAY FOR APHIS.

Quassia chips, 2 ozs.; water, 1 gallon; boil for fifteen minutes, and then dissolve in the liquid 3 ozs. soft soap. To be used cold. Suitable for roses or apple trees (*Gard. Chron.* [3], xix., 589).

REMEDY FOR CODLIN MOTH ON APPLE TREES.

One lb. Paris green; 1 lb. lime; 250 gallons of water; or better still, equal parts of Bordeaux mixture and Paris green. Used as a spray (*Gard. Chron.* [3], xix., 589).

SPRAY FOR APHIS AND PEAR SUCKER.

Soft soap, 40 ozs.; petroleum, 1 pint; water, 2 to 3 gallons. The soap should be warmed with a little water until it liquefies, then stirred, away from the fire, and the petroleum added. The mixture is then well stirred or agitated with a powerful syringe until it becomes creamy, then dilute with water to 2 or 3 gallons. This is useful against any kind of aphis or suctorial insect (*Gard. Chron.* [3], xix., 589).

DINNER PILLS.

The following, says the *Practitioner*, are two good formulæ:—(No. 1) Extract. aloes aquos., gr. 24; ext. nucis vom., gr. 12; extract. belladonn., gr. 6; sapon. dur., gr. 24. Divide into 24 pills; one to be taken on alternate nights or before dinner. (No. 2) Extract. nucis vom., gr. 2; ext. aloes Barb., gr. 6; extract. rhei, gr. 20. Divide into six pills; one pill daily at dinner-time or directly after.

BISMAL.

Merck has prepared a combination of methylene-digallic acid with hydrated bismuth oxide, in the proportion of four molecules of the former to three of the latter; it forms a soluble bluish-grey powder, giving a reddish-yellow solution with alkalies. Von Oefele considers it a powerful astringent. It is likely to be serviceable in intractable diarrhoea, such as that of tuberculosis (*Journ. de Pharm.*, [6], iii., 297, after *Apoth. Zeit.*).

A PAINLESS VESICANT.

Menthol and chloral hydrate, of each 1 part cacao butter, 2 parts; spermaceti, 4 parts. Mix to form a paste. When spread on a cloth or upon adhesive plaster, and applied to the surface of the skin, this paste acts similarly to cantharides plaster (*Rev. Medico-Pharm.*, iii., 46).

NEW REMEDIES.

[The notes given under this heading embody recent suggestions in therapeutics. They cover both new drugs and preparations, and old ones under new aspects. The word "parts" is used to represent parts by weight, both for solids and liquids.]

THYROID GLAND EXTRACT IN UTERINE FIBROMA.—Tablets of thyroid extract containing 45 centigrammes each, have been given in daily doses of four to eight tablets by Jouin, in cases of uterine fibroma. In three cases so treated he has observed diminution of the hæmorrhage, and in two a partial disappearance of the tumour (*Rev. Gén. de Thérap.*, cxxix.).

SULPHONAL FOR CRAMP.—Fifteen grains of sulphonal taken at bedtime is stated by Andrew to be an excellent preventive of muscular cramp of the legs coming on at night. Seven and a half grains three times a day may be given instead of the larger dose at night if preferred (*Quart. Med. Journ.*, iv., 189).

SIMAROUBA IN DYSENTERY.—For dysentery and summer diarrhœa Ihle recommends the following:—Decoction of simarouba, 340 parts; cognac, 20 parts; mucilage of salep, 20 parts; tincture of opium, 1 part; syrup of orange, 50 parts. A tablespoonful every four hours; a dose of castor oil should precede this treatment (*Dub. Journ. Med. Sci.* [3], No. 289, 64, after *Nouv. Rem.*).

COLCHICUM IN FURUNCULOSIS.—Brocq states that in gouty subjects suffering from boils, but who are neither diabetic nor albuminuric, extract of colchicum in daily doses of three or four centigrammes gives good and sometimes surprising results. (*Brit. Journ. Dermat.*, viii., 35).

COPAIBA OIL IN PSORIASIS.—Abbott Cantrell states that he has obtained very good results from this remedy, which he exhibits in 5 minims doses, in capsules, three times a day. He quotes a case in which a patient was cured of a psoriasis of twelve years' standing in six weeks with this treatment (*Brit. Journ. Dermat.*, viii., 36).

NITRO-GLYCERIN IN SCIATICA.—Troussevitch has cured several obstinate cases of sciatica by giving the following "drops":—Solution of nitro-glycerin (1 per cent.), half a drachm; tincture of capsicum, 1½ drachm; peppermint water, 3 drachms. Five drops thrice daily in a tablespoonful of water for the first three days, then 10 drops thrice daily on the subsequent days (*Pract.*, lvi., 221).

ORPHOL.—β-naphthol bismuth is brought forward, under this not too euphonious name, as an intestinal antiseptic. It contains 26.5 per cent. of β-naphthol and 23.5 per cent. of bismuth. It is given to children in doses of from 2 to 5 grammes, whilst adults are given from 5 to 10 grammes (*Pharm. Post*).

PYROCATECHIN-MONO-ACETATE OF SODIUM IN CONSUMPTION.—A patent has been obtained in the United States for pyrocatechin mono-acetate of sodium, which is said to be a remedy for consumption and loss of appetite, stopping night perspiration, reducing the evening temperature, and in mild cases, destroying the bacillus of the disease. The acid is obtained, according to this invention, by subjecting one molecule of chloracetic acid to the action of one molecule of pyrocatechin in the presence of a carbonate of an alkali, in accordance with a novel process described in the patent.

COMBINATION OF ANTITHERMICS.—Berger and Vogt state that the following combination of synthetic antithermic analgesics is less toxic and more effective therapeutically than the separate ingredients given singly, or than any similar combination which they have tried; antipyrine, 5 grammes; phenacetine, 2 grammes; acetanilide, 1 gramme. Mix, and divide into 16 cachets, each containing 50 centigrammes (*Rev. de Thérap. Med. Chirurg.*, lxiii., 104).

VINEGAR AS AN ANTIDOTE FOR PHENOL.—According to Carleton, vinegar affords a useful palliative to the caustic action of phenol, either upon the skin or on the mucous membrane. External burns dressed with vinegar soon lose the characteristic bleached appearance, and pain is relieved. If the phenol has been swallowed, the patient should drink copious draughts of vinegar and water before the stomach pump is used (*Rev. Med. Pharm.*, iii., 9).

REVIEWS AND NOTICES OF BOOKS.

SOUTHALL'S ORGANIC MATERIA MEDICA. Fifth and Enlarged edition. By JOHN BARCLAY, B.Sc. Pp. 306. Price 6s. (London: J. and A. Churchill, 7, Great Marlborough Street, W. 1896.)

The publication in this country of any new work on materia medica, or new edition of a well-established old one, is a matter of such rare occurrence as to attract special attention. This is more particularly the case with the fifth edition of Southall's 'Materia Medica,' for the work has undergone material alterations that have considerably enhanced its value.

A cursory examination will show that the botanical system of classification has been abandoned, and the usual pharmacognostical arrangement introduced, an alteration that is undoubtedly a step in the right direction, though some pharmacognosists still advocate the former. The number of drugs included has been considerably extended, and with such extension the range of utility of the work has been correspondingly increased.

On reading the work more carefully it will be seen that to each group of drugs an introduction in the form of an outline of the physical and chemical characters common to the group has been prefixed, a welcome and useful addition, not yet general in works on this subject. In the descriptions of the drugs the use of different types has enabled the author to emphasise that which he considers important, and thus bring it more prominently before the reader. Numerous notes in small type appended to the descriptions convey much useful information, and information of a kind that is not generally found in the usual text-books. The matter, especially the chemistry, has been brought up to date, and is presented usually in an agreeable style, the statements being, as a rule, accurate and concise, two qualities the value of which can scarcely be over-estimated.

It may confidently be asserted that in all treatises on pharmacognosy the greatest stress should be laid upon accurate observation and description, as being the only means by which each drug may be recognised and distinguished from all others, like and unlike. This accuracy of observation and description is the foundation stone of true pharmacognosy. Without it no contribution will have the permanent value that is attached in so high a degree to the classical works of Pereira and Hanbury. Nor can any compilation lay claim to reliability unless the information so compiled has been critically examined and sifted in the same spirit. The author of the work now in question does not pretend it to be "anything other than a compilation," and admits that "in the case of those substances included in the British, United States, and Indian Pharmacopœias, the official descriptions found therein are quoted almost verbatim."

In this method of compilation the chief weakness of the work is to be discerned. It has led the author into several errors that a critical examination and comparison of the descriptions with the drugs they represent would have averted. Thus, for example, the margins of witch hazel leaves are not "serrate toothed," but sinuate; coca leaves are not "blunt and emarginate," but provided with a minute horny apiculus, which, however, in many leaves is broken off; nor are Truxillo leaves frequently three times as large as Brazilian (*sic*, ? Bolivian), but the reverse; chiretta does not branch in a "dichotomous," but decussate manner. In some cases the style, too, is far from clear, as, for instance, the introduction to the "barks," in which the botanical and pharmacognostical terms are hopelessly confused.

Notwithstanding these deficiencies, which can easily be remedied in a succeeding edition, the information conveyed is generally accurate, and is conveyed in a manner that will render the work very acceptable to students, to whom it will specially commend itself by the arrangement of the matter, by the concise but not too brief style, and by the systematic enumeration under each drug of the chief adulterations or substitutions and the means by which they may be distinguished.

CORRESPONDENCE.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal should be sent to the Secretary.—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematical names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt. The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

THE SOCIETY AND ITS MEMBERS.

Sir,—One frequently hears of the apathy which characterises the members of the Society with regard to the management of its affairs and the election of its Council. This indifference is occasionally disturbed by some perfervid member's cry that more interest be taken in its affairs. It certainly is very depressing to know that only about one-third of the members register their votes. This means practically that the other two-third are quite content to let things move along as they hitherto have done. One reason for this is that it is quite the exception for our councillors and would-be councillors to state a policy, and consequently the electors have no means of knowing the difference (if any) between the new man and the old. It is satisfactory to note that the issue of an address has not been thought unnecessary by one who is already a member of Council. Another reason for the apathetic attitude adopted by the majority of us is, I think, the impression that prevails that the Annual Meeting of the Society is the only time that criticism may be offered.

For various reasons many of us cannot be present on that occasion, and hence have no opportunity of stating our views. Now, sir, you have said at different times that the *Pharmaceutical Journal* belongs to all those connected with the Society; each one of us has an interest in it. Therefore I think that when anything is done that displeases us or that we are not quite in agreement with, we ought to take advantage of our right and state our opinions in our own official organ. I shall certainly do so in the future when occasion arises to arouse the opinion of members on any matter that appears to me to be open to criticism. If all our members who have grievances would act in the same way we should have a keener interest taken in affairs, and a valuable expression of opinion.

My principal reasons for writing at this time is to take exception to a statement in the Annual Report (*ante*, p. 361). Under the subject of examinations, a quotation is given from the last report of the Government Visitor for England and Wales, in which he states that the examination is "a fair one, and the stringency of the prac-

tical examination in chemistry commendable." This clearly shows that the Visitor must have performed his duties in a very perfunctory manner, or is not conversant with the scope of the Minor syllabus. It is now known that Minor candidates in London have been getting work to do with other than the six pharmacopoeial volumetric solutions. I ask, Why have the syllabus (which was hailed with so much delight) unless it is to be adhered to? It may have been observed that I called attention to this matter at the last meeting of the N.B. Branch Executive, and was informed that we could not discuss it there, though it seemed at one time as if the chairman was not averse to talk the matter over. If we are not to discuss a subject of that kind at a meeting of the so-called governing body in Scotland, where on earth are we to discuss it? I trust in the interests of fair play and justice to the candidates that some attention will be given to this complaint by those in authority, whoever they may be.

Leith, May 16, 1896.

GEORGE COULL.

"AN AGREEMENT THAT LICKS CREATION."

Sir,—Doubtless many of your readers, as well as myself, have received a most extraordinary "Bonus Agreement Note" from Clarke's Night-light Co., and to those who have not I should suggest writing for one without delay. In it they ask you to sign an agreement not to retail their nine hours' pyramid night-lights at less than 7½d. per box, or six boxes for 3s. 7½d.; and on condition you sign this said agreement they will allow a bonus of 6d. per dozen on July 1, 1897, providing the prices have been adhered to. They further say they are doing this with a view to assure the retailer a reasonable profit.

Now, I have only recently received several new price-lists from Sanger's, Newbery's, etc., and from various provincial wholesale houses, and I find each of these quote above goods at 7s. 6d. per doz. net (Sanger's really 7s. 5¾d.) and carriage forward. So that outside London they would cost a retailer, say, at least 7s. 9d. per doz. net when carriage was paid, or, if he signs the agreement, he gets 6d. per dozen bonus, which reduces the cost to 7s. 3d. per doz. net. This firm suggests that he retails them at not less than 7½d., whereby he would get the "reasonable profit" (?) of ¼d. for his trouble. I should like to ask any of your readers, or the firm in question, to point out where the "reasonable profit" comes in?

I consider this remarkable agreement is only for the benefit of the cutter, as he alone can afford to sell at the price, being the only person who can buy direct, and so get a little extra profit. I thought the very object of these anti-cutting agreements was to fix the selling price so that the ordinary retailer (who can only buy from the wholesale houses) can sell at the same price as the cutter, and yet get a "living" and not a "workhouse" profit; but if the above is not a workhouse profit, what is it? This is the most mean and contemptible agreement I ever saw offered to the trader, in fact, "it licks all creation"! If manufacturers of proprietary articles wish to prevent substitution, and to recover the goodwill of the trade, they will only do so by giving a living profit to the retailer for handling their goods, such as Elliman's, Blondeau's, etc., have done, and with such signal success.

Kidderminster, May 11, 1896.

J. T. GRIFFIN.

LIMITED COMPANIES AND THE TITLE "CHEMIST."

Sir,—I think it quite time something is done to prevent limited companies calling themselves "cash chemists" without personal qualification? Why should it be lawful for them to use the title cash chemist any more than it is to use the title cash doctor, cash dentist, or cash lawyer? It seems to me a distinct infringement of the Pharmacy Act? If company pharmacy goes on as it does at present the individual chemist conducting his own business will in the future be a *rara avis*. The only thing is for chemists throughout Great Britain to unite and join the Pharmaceutical Society, thereby strengthening the hands of the Council, which will then be more representative of the whole body and able to approach Parliament for an amendment of the Pharmacy Act with some prospect of success. I think also if Minor men were eligible for membership many more would join the Society, whilst it would be a boon if every chemist and druggist on the Register were exempt from jury service as are dentists.

May 11, 1896.

COUNTRY CHEMIST.

CREAM OF TARTAR.

Sir,—In reply to Mr. M. Conroy's "Note on Cream of Tartar" in your issue of May 2, we must take serious exception to his experience "that cream of tartar containing the amount of calcium sulphate found by Mr. Hill, viz., 4.20 per cent., must have been wilfully adulterated." Mr. Conroy's experience is not wide enough, or he would know that by the precipitation process calcium sulphate is the natural impurity, just as in the crystallisation process, tartrate of lime is the natural impurity. Both are perfectly neutral, useless, and harmless, so far as the consumer is concerned, but both with a little trouble could be removed if our absurd B.P. test were raised to 99 to 100 per cent. as in other countries. What the consumer buys is bitartrate of potassium, and why he should be compelled to take an article containing 92.15 when he can get it 99 to 100 per cent., the editors of the British Pharmacopœia best know. We were the first to raise the trade test to 95 per cent. independent of the B.P., and we hope soon to see it fixed at 99 to 100 per cent.

London, May 12, 1896. KIRKPATRICK, BARR, AND GUTHRIE.

DISPENSERS AND BRICKLAYERS.

Sir,—In Monday's *Telegraph* you could have seen a paragraph stating that "The Secretary of the Bricklayers' Association notified the Works Committee of the County Council that the wages of operative bricklayers were now 10d. per hour, and requesting that the Council's workmen might be given the advance." 10d. per hour = £2 per week = £104 per year. On the same day, in the same paper, appeared an advertisement from the Asylums Committee of the County Council for a qualified dispenser, at the salary of £100 per year. Would it not be as well to advise all desirous of becoming "educated and skilled pharmacists," to join the Operative Bricklayers' Association?

May 13, 1896.

AN E. AND S. P.

DECOMPOSITION IN LITHIA WATER.

Sir,—I shall be glad to have the opinion of readers of the Journal on the decomposition which has taken place in several syphons of lithia water. On drawing a little off into a tumbler there is a very strong odour of sulphuretted hydrogen, and a black, gritty deposit has settled at the bottom of the syphons. Can this be due to the acid used in the formation of the water acting on a badly-made syphon?

Louth, May 16, 1896.

A. BELLAMY.

COCAINE IN OINTMENTS.

Sir,—It is pleasing to me to find that "Mr. P. Green" is in agreement with my proposition at last. If he had not had such a severely logical habit of thinking he need never have been in disagreement, for when I used the expression "hot fat" in that connection it seemed self-evident that the *tout ensemble* was referred to, rather than any one ingredient. However, I suppose we shall have to be more careful in future in the matter of phraseology with such a vigilant logician on the watch ready to give transgressors "beans" and other leguminous delicacies—such as "Green P's," etc..

Brixton, S. W., May 16, 1896.

W. JOHNSTON.

MORPHINE SOLUTIONS.

Sir,—I find the proportions of water and glycerin in the two formulæ, recently published by me (*Ph. J.*, ante, pp. 160 and 180), for ten per cent. solutions of morphine hydrochlorate and acetate are better 7 parts to 1 part (by measure) than 3 to 1. Further, in the case of the hydrochlorate solution, it appears better to substitute citric acid for tartaric acid, in sufficient quantity to keep the salt of morphine dissolved after the solution has been filtered and cooled.

Leicester, May 19, 1896.

G. W. BLYTHE.

ANSWERS TO QUERIES.

SUGAR FOR SYRUPS.—The bulk of the sugar of trade is beet sugar, and it is invariably "blued" and not suited for making medicinal syrups. Pure cane sucrose, "unblued," can be bought of certain manufacturers, and some of the wholesale druggists who take such sugar in quantities keep this pure sucrose in stock, and quote the same in their monthly prices current. [*Reply to W. S. B.*]

SALE OF FOOD AND DRUGS ACT.—Section 3 of the Act stipulates that no person shall sell any article of food mixed with any ingredient or material "so as to render the article injurious to health." In a case such as you mention it would therefore be necessary to

prove that the article treated was injurious to health, which has not yet been done. [*Reply to "LACTIS."*]

TEXT-BOOK OF MATERIA MEDICA.—You cannot do better than procure a copy of the new edition of Southall's 'Organic Materia Medica' (Churchill, 6s.). This is an excellently-arranged work, and well up to date. See review on page 418. [*Reply to "ARBEITER."*]

GILDING ON GLASS.—Use weak isinglass size or pale japanner's gold size thinned with turpentine. The latter is more permanent. [*Reply to A. H. OWEN.*]

WATER ANALYSIS.—Probably sufficient for your purpose may be found in Attfield's 'Chemistry' or Muter's 'Analytical Chemistry,' but a good standard work on the subject is Wanklyn's 'Water Analysis' (Trübner and Co.), the price of which is about five shillings. [*Reply to A. H. G. COGGIN.*]

RECOGNITION OF PLANT.—It is impossible to name the species with certainty in the condition sent. Probably some form of *Salix repens*. [*Reply to "HALDONIA."*]

WORK ON PRESCRIBING.—We are unable to recommend any work on this subject. [*Reply to G. H. W.*]

LIQUOR FERRI DIALYSATUS.—This is a ferric oxychloride, the composition of which varies somewhat according to the temperature, time, and other circumstances attending the saturation of the ferric chloride with the hydrated ferric oxide. Probably the formula $(\text{Fe}_2\text{O}_3)_{10}\text{Fe}_2\text{Cl}_6$ represents the average composition; oxychlorides of iron ranging from $(\text{Fe}_2\text{O}_3)_6\text{Fe}_2\text{Cl}_6$ up to $(\text{Fe}_2\text{O}_3)_{15}\text{Fe}_2\text{Cl}_6$ are stated to exist. The equation for their formation is very simple, each molecule of ferric hydrate combining with the ferric chloride merely gives up three molecules of water. [*Reply to QUÆSTO.*]

ABSORBENT COTTON-WOOL.—Take 100 parts of cotton-wool and boil it for half an hour in 400 parts of water containing $2\frac{1}{2}$ parts of caustic potash. Then wash thoroughly in successive lots of pure water until every trace of alkali is removed, squeeze as dry as possible, and immerse for fifteen or twenty minutes in a 5 per cent. solution of chlorinated lime; rinse once in plenty of clean water, and dip in 400 parts of water acidulated with 3 parts of dilute hydrochloric acid; wash perfectly free from acid and again boil in alkaline solution as above. Finally, rinse free from alkali and dry. [*Reply to C. T. D.*]

UTILISING SPOILED VINEGAR.—The best way to use up your vinegar contaminated with a trace of zinc would be to employ it for liquid blacking. Probably any of the wholesale blacking makers would buy it of you right off, and thus save you any trouble. If you prefer to use it up yourself, try the following recipes:—(a) Treacle, 4 ounces; ivory black, 4 ounces; rape oil, 1 ounce; vinegar, 24 ounces; oil of vitriol, 2 drachms. Mix in the above order. (b) Treacle, 4 ounces; ivory black, 4 ounces; rape oil, $\frac{1}{2}$ ounce; powdered gum arabic, $\frac{1}{4}$ ounce; vinegar, 24 ounces; oil of vitriol, 1 drachm. Mix in above order. [*Reply to W. S.*]

HOLES IN FURNITURE.—The "worm" that is making holes in your furniture is the larva of a small beetle, *Anobium tessellatum*, the perfect insect of which is the well-known "Death Watch," whose amorous ticking signals are the source of superstitious fears among the ignorant. There is only one way to get rid of it, that is to give the articles a good washing with a solution containing corrosive sublimate. The following will answer well:—Corrosive sublimate, 1 ounce; ammonium chloride, 1 ounce; water, 1 pint; glycerin, 1 ounce; methylated spirit, 1 pint. Use with caution and avoid getting any of the liquid upon the fingers. The best way to apply this is with a small "sash tool" or painter's brush; let the furniture be left in the open air, in the sun, after the application. These beetles "prefer darkness rather than light." [*Reply to W. S.*]

TO PREVENT PAINT STICKING TO GLASS.—Probably smearing over the surface of the glass with a little glycerin would prevent the paint from drying on hard. [*Reply to W. S.*]

A CORRECTION.

POTASSIUM CHLOROPLATINITE.—In the first formula for preparing this compound, on page 390 (*Ph. J.*, May 16), the words "of potassium chloride" should have followed the words "a solution of 23 grammes," in the fifth line of the note.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Barker, Bayley, Bellamy, Blinkhorn, Blythe, Coggin, Coull, Cubley, Evans, Forret, Johnstone, Lunan, Mackenzie, Umney.

“THE MONTH.”

Reference was recently made to the fact that M. Ferrand had prepared a number of thiophosphates, corresponding to the general formula M_3PS_3 (*ante*, p. 241). He now describes another series of compounds, corresponding to the formula $M_4P_2S_7$. Copper thiopyrophosphate, $Cu_4P_2S_7$, occurs in violet crystals, which are red by transmitted light. Iron thiopyrophosphate, $Fe_2P_2S_7$, is in small crystalline lamellæ; silver forms a yellow crystalline mass ($Ag_4P_2S_7$); nickel, a dark brown crystalline powder ($Ni_2P_2S_7$); chromium, a black crystalline powder ($Cr_2P_2S_7$); zinc, small needles ($Zn_2P_2S_7$); cadmium, a white crystalline powder ($Cd_2P_2S_7$); mercury, a red crystalline powder ($Hg_4P_2S_7$); lead also forms a reddish crystalline powder ($Pb_2P_2S_7$); and aluminium, a mass of small white needles ($Al_2P_2S_7$). The compounds $Cu_2P_2S_7$ and $Hg_2P_2S_7$ have not so far been obtained. The nickel, chromium, zinc, mercury, and aluminium salts decompose readily in moist air or water; alkalis also attack some of the compounds, and acids practically all of them (*Comp. rend.*, cxxii., 886).

Under this name, diiodo methyl salicylate has been introduced by Dr. A. Arnheim, of Berlin, as a substitute for iodoform, and it is being manufactured by Messrs. Meister, Lucius, and Brüning. It is prepared by the action of iodine upon methyl salicylate, and contains 62.7 per cent. of iodine. It has the form of a white crystalline inodorous powder, melting at $110^\circ C.$, soluble in 10 parts of hot alcohol, readily in ether and in vaseline. Langaard has ascertained that sanoform is not poisonous and that it has other advantages over iodoform (*Pharm. Zeitung*, xli., 320).

This sugar was discovered by Pelouze, in 1852, in the juice of the berries of species of *Pyrus*, after keeping them for more than a year, but very contradictory results have been obtained by chemists who have repeated his experiments, and G. Bertrand has therefore devoted some attention to the subject. It was conclusively proved that the sugar did not exist originally in the juice from the berries of *Pyrus (Sorbus) aucuparia*, *P. intermedia*, and *P. latifolia*, and when the juice was allowed to ferment all the glucose present disappeared and a corresponding quantity of alcohol was formed, but no trace of sorbinose appeared. After the alcoholic fermentation was concluded, however, and the acetic fermentation had commenced, some reddish flies (*Drosophila funebris*, Fabricius, *D. cellaris*, Macquart) were observed to deposit their eggs upon the surface of the liquid, near the edges, and a gelatinous pellicle then formed, upon which numerous larvæ swarmed and subsequently developed into perfect insects. After the lapse of some time the pellicle became greenish in colour. This membrane was found to consist of microbes 2μ to 3μ in length, which appeared to be identical with *Bacterium xylinum*, Brown, and sorbinose was now present in the liquid, having apparently been produced from the sorbite in the juice by the action of the bacteria in the presence of oxygen, the reaction being expressed as follows:— $2C_6H_{14}O_6 + O_2 = 2C_6H_{12}O_6 + 2H_2O$. Once in possession of the special ferment, it is possible to cultivate it either upon the fermented juice of cherries or other fruits, or upon an artificial medium, such as a 1 per cent. peptone solution containing suitable salts and some sorbite (*Comp. rend.*, cxxii., 900).

E. Bourquelot has previously shown that methylsalicylic ether can be extracted from several species of *Polygala* and also from *Monotropa hypopithys*, but he was of opinion that the compound did not naturally exist in

the plants, and has now been able to prove that it is formed in the case of *Monotropa* from a glucoside existing in that plant. The glucoside is accompanied by a ferment capable of decomposing it, and the same ferment has been found in all the plants yielding methylsalicylic ether. After commenting upon the work of Procter, who found, in the bark of *Betula lenta*, a glucoside, gaultherin, and a soluble ferment capable of giving rise to methylsalicylic ether, and that of Schneegans and Gerock, who isolated the glucoside in crystalline form, the author sums up the facts as follows:—1. There is a soluble ferment capable of hydrolysing gaultherin in the roots of *Spiræa ulmaria*, *S. filipendula*, *S. salicifolia*, and *Polygala sp.*, in the bark of *Betula lenta*, the leaves and fruits of *Gaultheria procumbens*, and the petals of *Azalea sp.*; 2. In *Monotropa hypopithys* there exists a glucoside which can be hydrolysed by the same ferment, and is, therefore, probably identical with gaultherin; 3. Neither gaultherin nor the glucoside of *Monotropa* can be hydrolysed by any other known ferment. Schneegans has recently suggested the name “betulase” for the ferment discovered by Procter, but Bourquelot prefers “gaultherase,” as recalling that of the glucoside upon which it acts (*Comp. rend.*, cxxii., 1002).

According to researches carried on by Herr O. Loew (see *Bot. Centralblatt*, vol. lxv., 1896, p. 302), it would appear that asparagin is very often the result of the splitting up of proteids, carbon dioxide being given off at the same time. In many other cases, on the other hand, as in the sugar of the ripe beetroot, asparagin is a synthetic product; it may be formed out of ammonia or nitric acid, and this takes place in barley and maize. Sugar or some substitute for sugar is indispensable for the transformation of asparagin into proteids; this process may take place even in the dark. The sugar need not be formed in the same cells as the asparagin.

E. Gérard has been able to decompose uric acid into urea and ammonium carbonate by the action of micro-organisms. The acid was dissolved in a solution of sodium diphosphate, and the liquid exposed to the air. After four days exposure it was rendered turbid by micro-organisms that had been attracted, and the presence of free ammonia was indicated. Variations in the products of the biochemical action seemed to indicate that if the action were allowed to continue, the urea would in time probably be decomposed, and ammonium carbonate be the sole product (*Comp. rend.*, cxxii., 1019).

P. Cazeneuve finds that the guaiacol carbonate of Heyden, in contact with alcohol saturated with ammonia gas, is converted rapidly in the cold into ordinary urea and guaiacol. As the crystals gradually dissolve in the liquid, the latter assumes a yellowish tint, and then becomes greenish, the process being accelerated by heating to $50^\circ C.$ The urea is obtained in long needles on evaporating the solution, and can be purified by recrystallisation from alcohol (*Comp. rend.*, cxxii., 999).

By passing dry gaseous ammonia into a benzene solution of sulphur dichloride, R. Schenck has obtained a compound of sulphur and nitrogen, having the composition represented by the formula N_4S_4 , and he suggests that it has the constitution shown by the accompanying graphic formula. The characters of the product were found to agree with the statements of previous observers, with the exception of the melting point being $178^\circ C.$, instead of $160^\circ C.$ (*Annalen der Chemie*, 290, 174).

These preparations are recommended by F. Zanardi as useful in making suppositories, by reason of their solubility in fat or oil. The morphine salt is readily obtainable by mixing hot alcoholic solutions of stearic acid and morphine in suitable proportions. It crystallises in brilliant scales, melting at 84° to 86° C. Atropine stearate melts at 120° C., and cocaine stearate at 90° C. (*Bollet. Chim. Farm.*).

Solutions of sodium citro-phosphate are freely sold in the United States as hepatic stimulants and purgatives, and one such solution, known as Citro-Phosphate "Melachol," is claimed to contain 85 grains of the combined sodium phosphate, citric acid, and sodium nitrate in every fluid drachm. Other solutions are said to contain from 60 to 85 grains of sodium phosphate in each fluid drachm, but this is more of the salt than can be retained in solution at ordinary temperatures. W. C. Westcott has investigated the matter, and finds that the product of the following formula corresponds with Melachol in specific gravity, acidity, and amount of phosphoric anhydride:—

Sodium phosphate, cryst.	100 Gm.
Sodium nitrate	2 "
Citric acid	13 "

The substances are triturated together until they liquefy, then enough water is added to make 100 C.c. of solution. Small crystals separate when this solution is cooled to 10° C., but they re-dissolve at 20° (*Am. Journ. Pharm.*, lxxviii., 256).

The fragments of stems and fruits in this substance show that it is derived from a species of *Ferula*. Hohenadel found a sample to contain 56.8 per cent. of resin, 5.8 of ethereal oil, 3.5 of water, 23.3 of gum, and 10.6 per cent. of impurities. The purified resin was yellowish-white, brittle when cold, plastic on warming, and melted at 74.76°. It yielded a sublimate of umbelliferone when heated; and when hydrolysed by boiling with sulphuric acid was decomposed into umbelliferone and sagesinotannol, of which substance it is the ethereal salt. Sagesinotannol, $C_{24}H_{28}O_5$, is a brown body, soluble in alkalis, and yielding a precipitate with ferric chloride; it gives monacetyl and monobenzoyl derivatives, and is oxidised by nitric acid into styphnic acid (trinitroresorcinol). The 56.8 parts of purified resin contains 40 of sagesinotannol, 15.7 parts of combined umbelliferone, and 0.11-0.15 in the free state. The volatile oil contains 9.7 per cent. of sulphur, and probably contains an ester of valeric acid; the bluish fraction, boiling between 210-270, resembles in its absorption spectra the similar bluish or greenish fractions obtained from other umbelliferous gum resins and other sources. The substance contained in it, "azulene," is not, however, present in the original oil, but is formed during fractionation (*Archiv*, ccxxxii., 259).

Professor Pajot records an interesting case of sophistication of colza seeds, grains of a variety of mustard known as sauve, and also of *Brassica juncea* being present, both being artificially coloured with a coating of blue colouring matter, a kind of litmus. To detect the fraud, maceration in water is sufficient, a blue solution being thus afforded which gives with acids a rose coloration, the original tint being restored by alkali. This ingenious sophistication appears to have been carried out in Germany. The artificially coloured seeds are far below the market value of genuine colza seeds, and yield from 10 to 15 per cent. less oil; the oilcake, moreover, could not be honestly employed as a foodstuff for cattle, and is only fit for use as a manure (*Journ. de Pharm.* [6], iii., 434).

In a report on the sisal industry in the Bahamas, Dr. D. Morris, of Kew, states that the sisal fibre derived its commercial name from the Port of Sisal, from which it was originally shipped, though since the completion of the railway to Merida the fibre is now wholly shipped from Progreso. In Yucatan the plant is called "Henequen." There are two sorts, white and green. "Henequen blanco" is the plant known by the aboriginal name of Sacqui. It has a whitish bloom on the leaves, giving them a glaucous colour, and has teeth on the edge of the leaves, and is the product of *Agave rigida*, var. *elongata*. This is the chief plant cultivated in Yucatan. "Henequen verde" is the aboriginal Yaxqui. This has no teeth on the side of the leaves. The colour is a bright green, and the plant is botanically *Agave rigida*, var. *sisalana*. This is the sisal plant of the Bahamas. It yields a fibre which is of value in making ropes, and the sisal industry in the Bahamas is now in a fair way of being established. At present, however, the product does not come into serious competition with any other white-rope fibre, and Dr. Morris is of opinion that attention ought to be directed to the uniform production of a first-class fibre to meet the requirements of the best markets.

The great variation which exists in beechwood creosote from different sources must necessarily entail markedly divergent physiological action. Freyss states in the *Moniteur Scientifique* that in different samples the amount of guaiacol varies from 3 to 30 per cent., and the cresol from 10 to 40 per cent., accompanied by a very variable amount of monophenols. In order to obtain a definite physiological action it is therefore necessary to submit the creosote employed to a critical examination. The author suggests that creosote derived from beechwood should only be employed if it be visibly darkened on prolonged exposure to light, and possesses an agreeable aroma somewhat resembling vanilla. Fractional distillation of the sample should be conducted, treating 100 C.c. in a fractionating flask of 125 C.c. capacity, and the fractions being collected in a graduated receiver. This distillation should be very regular, drop by drop, and should take place between 200 and 220° C. The author finds that the specific gravity of the fraction distilling between 200 and 210°, which contains the greater part of the guaiacol, gives a reliable indication of the amount of that body contained in it. In the samples examined the guaiacol content rose from 10 to 36 per cent., as the specific gravity increased from 1.077 to 1.090. These figures confirm those previously obtained by observers in this country.

The Indian drug "charas" is regarded by the natives as the most potent substance obtainable from *Cannabis sativa*, and an ethereal extract from it has been found by Wood, Spivey, and Easterfield to yield four distinct chemical compounds—a terpene (1.5 per cent.) boiling at 160°-180°; a sesquiterpene (2 per cent.) boiling at 258°-259°; a paraffin (0.15 per cent.) having the formula $C_{29}H_{60}$, and m.p. 63°-64°; and a toxic red oil (33 per cent.) with the composition $C_{18}H_{24}O_2$. This oil has been named "cannabinol." It boils at 265° under a pressure of 20 Mm., and appears to be present in all pharmaceutical preparations of hemp that exert the characteristic effects of the plant. It is a hydroxyl derivative, and has been found by Dr. C. R. Marshall to be extremely active, doses of 0.05 Gm. inducing decided intoxication, followed by sleep. The symptoms produced by it are peculiar to *Cannabis sativa*, and as none of the products of the plant possess this action but cannabinol, he thinks that must be regarded as the active constituent of the plant (*Journ. Chem. Soc.*, lxxix., 529).

According to the latest *Consular Report* the amount of opium imported by steamer during 1895 is larger than in 1894, the values being at 1895 £23,702 for the latter year and £27,389 for 1895.

Opium Imports at Kiungehow. By far the largest quantity of the drug is, however, imported by junk in order to evade the heavy customs and "likin" levies. The value of the import by steamers in 1886, the year before the Opium Convention came into force, was £171,100, and it has diminished every year since then until the one under review, the value in 1894 being only £23,702. The rise in price of the Indian drug accounts partly for the small import in 1894, but practically the diminution is due to the success with which smuggling junks evade the cruisers sent to protect the revenue. It is calculated that about 1000 chests find their way to the island every year without paying the legal duty. Only two captures were made by the cruisers during the year, amounting together to some thirty-three chests. The importation of native opium is said to be on the increase in consequence of the rise in price of the Indian drug.

Tobacco Cultivation in Italy. A good deal of tobacco is grown in Southern Italy, but the growers are very much hampered in their operations by the excise officers, who count not only every plant, but every leaf, thus making their transactions with the growers exceedingly complicated. The present Minister of Finance has taken steps to extend the culture of tobacco in the Nocera district, and plants from Virginia, Kentucky, Sumatra, and other places have been introduced. A school to give theoretical as well as practical instruction in the cultivation and preparation of tobacco is shortly to be established at Nocera, and it is to be hoped, says the British Consul at Naples, that the instruction given there may enable Italy to provide her sons (and daughters) with a less evil-smelling weed than they are compelled by their paternal Government to consume at present. The request for the encouragement of tobacco-growing has long been urged from this province, and it is hoped that the response to it will in a measure relieve the grave agricultural depression from which this wonderfully productive country has been so long suffering.

Toxicity of Scrophularia Nodosa. It is found by Van der Moer (*Nederl. Tijdschr. v. Pharm.*) that aqueous and alcoholic extracts of *Scrophularia nodosa*, or of its seeds, are toxic. Injection of aqueous solutions of such extracts rapidly produces paralytic reaction in frogs, the special symptoms being preceded by a brief period of excitation. The author has obtained from the purified alcoholic extract a yellow amorphous toxic powder, the properties of which resemble the poisons obtained from digitalis.

Oil of Cicuta Maculata. This oil is found by F. P. Stroup to be composed mainly of two fractions, both terpenes, boiling respectively at 177°·5 C. and 179°·5. Two smaller fractions, also terpenes, boil at 181° and 185° respectively, and there are a number of still smaller fractions of undetermined chemical composition, having nearly all the physical characteristics of terpenes of the general formula C₁₀H₁₆. The oil and its fractions are readily soluble in alcohol, acetone, ether, benzol, chloroform, and carbon disulphide, but they are insoluble in water and in glycerin. They react violently with strong nitric acid and quietly with iodine, producing a colourless compound. The net result of the present investigation seems to indicate, therefore, that the oil is simply a mixture of terpenes, with possibly a small trace of an oxygenated compound (*Am. Journ. Pharm.*, lxxviii., 236).

P. Herzberg (*Zopf's Beiträge*, 1895, Heft 5) has studied the development of the seven species into which *Ustilago carbo* is now divided, and classifies them into two groups, according to whether they germinate from a mycele or from a pro-mycele, the latter being simply a form of mycele in which there is an early production of spores. To this latter group belong *Ustilago jensenii*, *U. avenæ*, and *U. perennans*; while *U. hordei* and *U. tritici*, which produce sterile myceles, are formed into a new genus, *Ustilagidium*. In nutrient solutions all the species produce chlamydospores, which again germinate into myceles. Herr O. Brefeld (*Bot. Centralblatt*, vol. lxx., 1896, p. 97) announces the interesting discovery that the parasitic rusts on rice and on *Setaria crus-ardæ*, hitherto known as *Ustilaginoidea oryza* and *U. setaria*, are in reality stages of development of an ascomycetous fungus allied to ergot. This was proved by the cultivation of the so-called uredospores in nutrient solutions, where they gave birth to an abundantly-septated mycele, like the higher fungi, bearing minute conids similar to those of *Pilacre*. The rust of *Setaria* produces true sclerotes. From these sclerotes were obtained peritheces containing true asci, each ascus enclosing eight ascospores. The genus *Ustilaginoidea* must be removed from the Hemibasidii, and must be regarded as a genus of Hypocreaceæ, near to *Tilletia*; the ustilagospores are simply a secondary form of reproductive organ. The small colourless conids which are first of all produced on the mycele are of transient duration, and are succeeded by black spores when the mycele has attained its full development; these the author regards as a kind of chlamydospore.

Crustaceous Lichens. G. Lindau has carried out a series of observations on the morphology and physiology of crustaceous lichens (see *Bot. Centralblatt*, vol. lxx., 1896, p. 60), the following being some of the more important results obtained:—In those forms which live on the bark of trees, there is a portion of the thallus—the basal layer—altogether destitute of gonids, which grows in the interior of the periderm between the layers of cells. In the Hypophloëodæ this layer extends rather deep; in the Epiphloëodæ it is limited to the uppermost strata. A similar structure occurs in the higher lichens, where the hyphæ of the basal layer, which is destitute of gonids, or of the rhizoids, may also penetrate between the cells of the periderm. This portion serves, in the first place, to fix the lichen, possibly also aiding in its nutrition. The growth of the hyphæ is entirely intercellular through the separation of the layers of the periderm; no perforation of the cell-walls ever takes place. There is no direct absorption of cellulose by the hyphæ, but it is possible that cell-walls which have already undergone a change by the action of atmospheric agents may be absorbed. As a lichen-gonid *Trentepohlia umbrina* does not possess, any more than the hyphæ, the power of perforating cell-walls and absorbing cellulose.

Galls. M. Molliard gives a very detailed account of the floral mycoecidia, the galls produced in flowers by the action of parasitic fungi belonging to the Peronosporæ, Uredinæ, and Ustilaginæ, especially in reference to the anatomical disturbances produced in the host-plant. When the same parasite attacks allied species, the results will often be different in the different species. In the vegetative organs of the flower (calyx and corolla), either the nature itself or the distribution of the tissues may be altered. In the sexual organs sterility is not an uncommon result, both in the pollen sacs and in the ovules. The author describes at length the modifications produced by parasitic fungi in a large number of different flowers (*Annales des Sciences Naturelles*, Botanique; new series, i., 67).

Extrafloral Nectaries of Ficus. M. A. Mirabella describes the nectaries found on the leaves of several species of *Ficus*. They agree with one another in their anatomical characters, in their origin which is always from the modification of epidermal cells, and in the nature of their contents. In addition to saccharine substances, which serve largely to attract insects, they contain proteid substances, but no starch. The glands or nectaries make their appearance as small areolæ with well-defined outlines, somewhat depressed, and sometimes covered by a white scurf. Their usual position is the under side of the leaf in the axil of a primary vein, but they also occur on the branches at the base of a leaf-stalk (*Nuovo Giornale Botanico Italiano*, 1895, p. 340).

Monascus purpureus, n.sp. F. Went describes under this name a fungus that produces the pigment known in Java as "ang-quac," which is largely used there for colouring various articles of food, especially a small fish (see *Ph. J.* [4], 1, 211). The pigment, which is imported from China, is of a deep purple colour, and is located in a portion of the thallus, other portions being colourless. It can be completely extracted by chloroform, and was found to be of a very stable character, melting at 50° C., but not being capable of sublimation. It contains carbon, hydrogen, and oxygen, but no nitrogen. The fungus was determined to belong to the *Hemiasci* of Brefeld; it has no true conidia, but produces chlamydospores, which are wanting in the allied genus *Thelelobus* (*Annales des Sciences Naturelles, Botanique*; new series, vol. i, p. 1).

Propagation of the Sugar Cane. Dr. J. H. Wakker points out (see *Bot. Centralblatt*, vol. lxx., 1896, p. 37), that the various cultivated varieties of the sugar cane exhibit gradual degeneration of the sexual organs. The pollen-grains display various degrees of sterility, until the stamens finally disappear altogether. In other varieties this degeneration extends also to the female organs, the ovary being in some cases entirely suppressed. Finally, the inflorescence itself is reduced to a very rudimentary condition. This appears to be the result of the selection by cultivators of those varieties in which the energy is thrown into the production of sugar-producing stems.

Poisonous Australian Plants. J. H. Maiden points out that the mortality of Australian stock is often increased by reason of the impossibility of isolating either the animals or suspected plants. He also refers to the popular notion that certain plants are poisonous to sheep and other animals. *Euphorbium drummondii* is firmly held to be poisonous, but the Government Veterinarian of New South Wales has experimented with it, and concludes that animals eating it are not poisoned but die from indigestion or diseases like anthrax. The plant has not been chemically investigated, nor have the following reputed poisonous Euphorbiaceans plants:—*Beyeria viscosa*, *Phyllanthus lacunarius*, F. v. M., and *Omalanthus* (*Carumbium*) *populifolius*, Grah. *Swainsona greyana*, *S. galegifolia*, *Nicotiana suaveolens*, Lehm., and *Bulbine bulbosa*, Haw., are also popularly known as stock poisons, but there is no satisfactory evidence upon the point. *Crotalaria mitchelli*, Benth., is accused of dangerous properties, and species of *Gastrolobium*, *Oxylobium*, and *Tephrosia* are also in bad repute. There is a great and pressing need for chemical investigation of all these plants. So far, a hygroscopic glucoside, gastrolobin, having a saffron odour, has been found in *G. bilobum*, R. Br., by Rummel, and Guthrie has extracted from *Swainsona galegifolia*, R. Br., an oily body which may or may not be poisonous. Plants of *Macro-*

zamia and *Xanthorrhæa* have been found to produce a disease known as "rickets," and other real or supposed stock-poisons worthy of investigation by chemists are *Stypandra glauca*, R. Br., *Pimelea hæmatostachya*, F. v. M., *P. trichostachya*, Lindl., several species of *Isotoma*, *Lobelia*, *Velleia*, and *Gratiola*. Again, species of *Boronia*, *Frenela* (*Callitris*), *Zygophyllum*, and the ripe fruits of *Petalostigma quadriloculare*, F. v. M., have been used as vermifuges, and chemists could decide whether they are of real use or not (*Agric. Gaz., of N.S. Wales*, vi., 57).

Influence of Condiments on Digestion. The action of condiments when taken with food is not definitely understood, though it is generally understood to be beneficial, as promoting digestion. An observer named Gottlieb has recently confirmed this view to some extent, as the result of experiments on rabbits. A cannula being introduced into the pancreatic duct, pepper or mustard was allowed to pass into the stomach, and the secretion of pancreatic juice was found to increase to three or four times the normal quantity. It appeared more watery than usual, but possessed the same digestive powers as ordinarily.

Composition of Microbes. E. A. de Schweinitz and M. Dorset find that the amount of crude fat in tubercle bacilli (see *Ph. J.* [4], 1, 179) is about 37 per cent. of the weight of the dried germs. The fat, about 3.5 Gm. of which was extracted from the microbes, yielded a hard soap on saponification with sodium hydroxide, and proved to be principally a glyceride of palmitic acid. In addition, it contains a minute amount of the glyceride of a volatile fatty acid, to which tuberculosis cultures owe their characteristic odour, and very small amounts of lauric acid (?) and an acid with an unusually high melting point, having apparently a larger carbon content than any acid previously noted in plants (*Journ. Am. Chem. Soc.*, xviii., 449).

Blood Coagulation. It has been known for some years that peptones, or, more exactly, propeptones, render blood incoagulable by causing the formation in the organism of a substance possessing anti-coagulant properties. C. Delezenne has lately investigated the matter, and finds that this substance is formed exclusively in the liver. It would appear to be either peptone modified by the liver, or a direct product of that organ, the secretion of which is provoked by peptone. The rapidity with which the anti-coagulant effect is produced on administering the peptone, and other facts, seem to indicate that the first hypothesis is more likely than the other. The substance preventing coagulation has not yet been isolated. In solution it resists a temperature of 100° C. for a prolonged period, though access of air causes the liquid to lose its properties rapidly. To preserve it, therefore, for any length of time it is necessary to add a few drops of chloroform, and prevent access of air (*Comp. rend.*, cxxii., 1072).

Rectal Injection of Toxines, etc. P. Gibier finds that in the case of rabbits, dogs, and guinea-pigs rectal injection of relatively large doses of diphtheria and tetanus toxines is not followed by any apparent effect, and does not confer immunity with regard to the effects of those toxines, however often the injection may be repeated. Rectal injection of diphtheria and tetanus antitoxines in very large quantities is likewise incapable of preventing death by minimum doses of the toxines of the two diseases. The rectal mucus appears in any case to retain, and perhaps destroy, the active principles of the toxines and antitoxines. When, by any chance, they are absorbed, they are probably conveyed to the liver and there destroyed (*Comp. rend.*, cxxii., 1075).

It is by no means easy to determine with any great degree of accuracy the temperature at which gelatin masses pass from the solid to the liquid condition, especially when a test-tube, thermometer, and water bath are the means employed, and much time is also occupied in making determinations by the usual method. R. C. Bayley has therefore devised a simple form of apparatus which consists of an oblong water bath holding a considerable quantity of water, and is so constructed that it can be heated by a spirit lamp or Bunsen burner without the hot air or products of combustion reaching the longest side in front. The bottom makes an angle of forty-five degrees with the front, so that the back is not quite half the depth of the front. In the section of the apparatus, as reduced in the illustration, the front is 45 Mm. deep, the back, 20 Mm.; the width of the bath is 25 Mm., and the sloping base measures 35 Mm. from back to front. The length of the bath as shown is apparently about 100 Mm., and a leg is attached at each end of the back, so as to support the sides in a vertical position. A straight line is ruled along the front of the bath an inch from the top, and one or more thermometers are supported inside the bath, with their bulbs parallel to this line. In use the apparatus is laid on its back, and small discs of the gelatin masses to be tested are cast on the front, with their lower edges just upon the line. The discs should be a quarter of an inch thick, and are moulded by pouring the melted gelatin into paper tubes half an inch in diameter, resting upon the front of the bath. When set, the paper is removed and the bath placed erect. Water is then poured in and heated from below, and directly the melting point of one of the discs is reached it begins to slide down the side of the bath. The melting point of one jelly, as ascertained by the usual means, was found to vary between 23° and 25°, the mean being 24°. Six discs of the same jelly were placed on the new apparatus, and all began to move when the nearest thermometer registered 26°. Other experiments gave similar results, the readings being uniformly two degrees higher than the mean of a number of determinations by the ordinary method (*Photographic Journal*, xx., 224).

According to G. le Bon, dark light (*la lumière noire*) possesses several properties resembling those of electricity (*ante*, p. 244). He assumed therefore, that it should be possible to condense the rays on the surface of metallic plates, which they would then traverse and act upon photographic plates placed behind in the dark. Experiments have shown that this hypothesis is based on fact. Thin sheets of copper and lead were placed in photographic printing frames, and one face of each exposed to the light of an electric arc for an hour. They were then placed in darkness for two hours, the sheets of metal removed and their non-exposed faces placed together, with a sensitive plate and the object to be copied between them. After leaving the whole apparatus in darkness for five or six hours, a perfect image of the object appeared on developing the plate, the light condensed upon the outer surface of the copper sheet having apparently traversed the metal and produced the impression on the sensitive film. Care was taken to prevent the effects of heat, contact, or pressure, and it was ascertained that no action took place if the sheets of metal were covered with black paper whilst exposed to light. It is considered that the rays of so-called "dark light" differ entirely from the Röntgen rays and others. The x -rays pass through black paper and organic bodies, but not through most metals, and they are neither reflected nor refracted. On the other hand, the author's experiments prove that radiations from luminous bodies falling upon metallic surfaces cannot traverse black paper nor most cr-

ganic substances, but they pass through many metals and, like electricity, are capable of being condensed and can diffuse themselves on metallic surface. Invisible radiations from fluorescent bodies also differ, having been shown by d'Arsonval and Becquerel to pass through metals and be capable of both refraction or reflection. The radiations given off by certain fishes and animals in the dark somewhat resemble the last-named, but are unable to penetrate metals, especially aluminium (*Comp. rend.*, cxxii., 1054).

W. N. Hartley has determined the composition of a coin by an ingenious adaptation of the methods of spectrographic analysis. The spectrum of the coin was photographed and the metals present first ascertained, after which their relative proportions were arrived at by comparing the photograph with a series of quantitative spectra, in which solutions of known strengths yielded spectra with a certain number of lines of definite length and strength. Alloys were then made to imitate the metal, and photographs of their spectra taken in the same way. The third trial produced an alloy, the spark spectrum of which yielded a photograph identical with that of the coin, a "white" sou of the French Revolution of 1798, the composition being found by the usual methods of analysis to be:—Lead, 13.93 per cent.; copper, 72.35; iron, 0.85; zinc, 12.70. By this novel method of analysis the composition of antique jewellery and coins may easily be determined without injuring them in any degree (*Proc. Chem. Soc.*, 164, 98).

Sicilian Sulphur Industry.

A Reuter's telegram from Rome says that one of the chief questions now engaging the attention of the Italian Cabinet is that of the amelioration of the sulphur industry of Sicily, which is at present in a very depressed condition, owing to the competition of pyrites for the production of sulphuric acid, and the fact of the supply now largely exceeding the demand, not to mention the threatened rivalry of Japanese sulphur. The price has fallen from 140 lire to 60 lire per ton. It is now proposed to abolish the export duty of 20 per cent., which formerly yielded an annual revenue of 3,400,000 lire. In order to make good the deficit thus caused to the revenue, it is proposed to levy a tax of 1 lira per ton on sulphur exported from Sicily, to increase the import duty on barley and white maize from 1.15 lira to 4 lire, and to introduce a statistical fee ranging from 10 centimes per quintal to 10 centimes per ton on imported goods not specified in the treaties of commerce.

C. H. LaWall has devised a simple stirring rod, which enables the operator to note the temperature of a liquid without using a thermometer. A glass tube, 5.5 Mm. in diameter, outside measurement, and 18 Cm. long, is sealed at one end, where it is also bent slightly. The tube is then three-quarters filled with small fragments of beeswax, paraffin, or other substance with the desired melting point, and is then heated until the substance melts and runs together at the bottom. Next fuse the open end of the tube almost entirely, leaving only a capillary orifice to allow of equalisation of pressure. Verify the registration point of the rod by placing it in a beaker of cold water with a thermometer, and gradually raising the temperature until the wax, etc., just melts, and the appliance is then ready for use. By using various kinds of paraffin and wax, singly or mixed, rods can be made, which will indicate a range in temperature from 40° C. to 90°, and they will be found to save much time in manufacturing scale preparations, extracts, and other preparations that require to be kept below a certain temperature during the process of evaporation (*Am. Journ. Pharm.*, lxxviii., 260).

CONSTITUENTS OF LEUCODENDRON CONCINNUM, ETC.

At the Indian and Colonial Exhibition in 1886 a substance was exhibited under the name of proteixine or proteacin, which Meiring Beck had extracted from *Leucodendron concinnum*, a proteaceous plant growing at the Cape (*Ph. J.* [3], xvii, 327, 408). It was a grey crystalline powder of bitter taste like salicin, and was stated to be a febrifuge. The substance was obtained in a pure state by Schuchardt, who presented a specimen to the Society's Museum in 1886 (*Ph. J.* [3], xvii, 755), and Hesse obtained from him a quantity of the leaves from which it was stated to have been extracted, but they proved to be the leaves of the sugar-bush, *Protea mellifera*, yielding a substance of entirely different chemical nature.

E. Merck has now obtained from the leaves of *L. concinnum* a glucoside for which he proposes the name leucoglycodrin, and a crystalline bitter substance (*Berichte uber das Jahr* 1895). The glucoside is obtained by precipitating an alcoholic extract of the leaves with ether after purification with lead acetate. It is a soluble amorphous powder of bitter taste, indefinite melting point, specific rotation of the alcohol solution $[\alpha]_D -40^\circ.25$. The substance dissolves in hot water and separates as a jelly on cooling. It dissolves in concentrated sulphuric acid, with yellow coloration, becoming reddish brown on heating. Analysis and molecular weight determinations led to the formulæ $C_{27}H_{42}O_{10}$ or $C_{27}H_{44}O_{10}$.

The bitter substance, named by Merck leucodrin, resembles salicin; its composition is represented by the formula $C_{15}H_{16}O_8$, and it appears to be identical with the substance to which the name of proteacin was given.

O. Hesse has also investigated this substance* and has adopted the name suggested by Merck in preference to that of proteacin.

By extracting the leaves with ether, treating the ether residue with hot water and lead acetate, separating lead from the clear liquid, evaporating and extracting with ether, leucodrin is obtained in solution, and can be purified by re-crystallisation from alcohol, glacial acetic acid or water. It forms colourless prisms, which melt at $212^\circ C.$, is intensely bitter, readily soluble in hot water, ether, or alcohol, slightly in chloroform or cold water. The water and alcohol solutions are neutral, and they are not coloured by ferric chloride, as has been stated incorrectly. The water solution does not give a precipitate with gold or platinum chlorides, silver nitrate, or lead acetate, but a solution mixed with basic lead acetate gives a copious flocculent precipitate on the addition of some ammonia. Leucodrin is dissolved with yellow coloration by caustic soda, and on the addition of hydrochloric acid it is again precipitated unaltered in a crystalline state. The water solution does not reduce Fehling's solution even after having been boiled with dilute sulphuric acid, but after boiling with the concentrated acid, in which leucodrin dissolves without colouring, there is a reduction.

Analysis gave results suggesting the formula $C_{2n}H_{2n+2n}O$, in which n might vary from 9 to 11. Merck's molecular weight determination pointed to $n=9$ and the formula $C_{18}H_{20}O_9$, which agrees with the analytical data.

By acetylation leucodrin yields a well-defined derivative, triacetyl-leucodrin, $C_{18}H_{17}(C_2H_3O)_3O_9$.

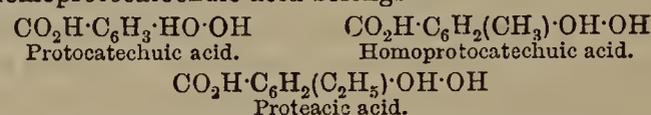

At the March meeting of the Stuttgart Branch of the Society of Applied Chemistry, Dr. Hesse gave an account of the results obtained in this investigation, and showed that *Protea lepidocarpon* contains only a green-coloured resin.

The sugar bush, *Protea mellifera*, is a common plant in South Africa. It blossoms in January and February, the flowers contain a sweet sap, which has suggested the popular name of the plant,

and it is utilised in the production of a kind of confection that is administered in cases of catarrh. This plant does not yield the substance obtained by Meiring Beck, but one that melts 40° below, and Hesse has recently ascertained that this product is hydroquinone, which exists in the leaves to the extent of from 2 to 5 per cent. Associated with it is an acid which has been isolated and studied by Hesse under the name of proteacic acid. It has the form of white granular crystals, which become yellow on exposure to the air, and melt at 187° with evolution of carbonic acid and formation of colourless oily distillate solidifying in crystals, which are not pyrocatechin. The acid dissolves readily in boiling water, is less soluble in cold water, insoluble in benzene or chloroform, but readily soluble in ether. The water solution has a strong acid reaction, decomposing potassium carbonate and neutralising the base. It is coloured greenish by ferric chloride, and the solution, on subsequent addition of potassium carbonate, becomes deep violet blue. Proteacic acid does not reduce Fehling's liquor, but when it is boiled with silver nitrate metallic silver is deposited. By treatment with hydriodic acid, according to Zeisel's method, no alkyl iodide is produced.

Analysis gave results suggesting the formula $C_9H_{10}O_4$. The alkaline compounds of proteacic acid become coloured by oxidation on exposure. The lead salt $(C_9H_8O_4Pb)_2 + PbH_2O_2$ is crystalline and sparingly soluble in acetic acid.

Proteacic acid is therefore the next higher member in the series to which homoprotocatechuic acid belongs—

THE CHEMICAL ANALYSIS OF WATER.*

BY HERBERT A. DAVIES, M.A., B.S.C., F.I.C.

Within the memory of people still living, water analysis was a thing unheard of. If a water supply were reasonably clear, sparkling, and free from bad taste, people asked for nothing more, and those who objected to a well sunk directly beneath a crowded churchyard or surrounded by cess-pools were regarded as eccentric faddists. Cholera and other epidemics which swept away thousands of victims were regarded as visitations of providence to be received in a spirit of humility, and it took a long time to persuade the conservative English mind that a bad water supply and various diseases are cause and effect. It was only after years of persistent teaching of the necessity for pure water that the lesson was learnt, and much of the credit for the vastly improved state of things is due to the many eminent chemists who have devoted their best energies to devising means for distinguishing between good waters and bad. Water analysis is a peculiarly English branch of science. All the standard methods have been devised by English chemists, such as Wanklyn, Frankland, Armstrong, Clark, Tidy, and others, and it is in the English-speaking countries that water analysis is chiefly practised. It is only necessary to consult a Continental work on hygiene to see how very much behind us they are in this respect, and how small a part water analysis plays; the result is seen in the cholera outbreaks at Hamburg, where the water supply was a disgrace to a civilised community.

In the early days of water analysis the examination was confined almost exclusively to the mineral constituents, and according to the amount of the various salts found some rough classification of waters could be made. And even now if we are making an analysis for manufacturers it is the mineral salts which determine the suitability of the water, because if a water is to be used, for example,

* *Annalen der Chemie*, 290, 214.

* Read before the Liverpool Chemists' Association.

in a boiler the presence of organic impurity does not matter, whereas an excess of lime salts will be very injurious.

The first great advance in water analysis occurred about 1867 when Wanklyn, on the one hand, and Frankland and Armstrong on the other, devised their respective processes for estimating the amount of organic matter in water. It is obvious that the suitability of a water from a hygienic point of view can only be decided by determining in some way the amount of organic matter in the water, because whether we regard zymotic diseases as caused by micro-organisms or by some poisonous product of living matter, the cause of the disease will be present in the water as organic matter.

A most deplorable quarrel arose between the originators of the two methods of determining organic matter, and even to this day it breaks out from time to time in the scientific journals. It did much to hinder the advance of the subject, because the abuse and scorn which each lavished on his rival's process caused outsiders to think that both must be worthless. A more serious injury was that in order to magnify the importance of his discovery each of the disputants held that it was only necessary to use his process to get all the information requisite to judge of a water, and that it was almost a waste of time to make any other determinations, and so it came about that relying simply on the one test chemists made very bad blunders, and to this is due much of the contemptuous reference which we hear in certain quarters to mere chemical analysis and its inability to detect pollution. The modern water analyst has been taught by long experience not to rely on any one test, or any half dozen for that matter, but to obtain all the analytical and other data possible, and considering it as a whole, form his decision. I admit that in the past good waters have been condemned and bad waters have been passed as good, but this was not the fault of chemistry, but of the too narrow view which was taken.

To see how far we have advanced from the day when a chemist would confidently pass judgment on a water after determining the free and albuminoid ammonia, I propose to point out the methods adopted by a competent chemist who is called upon to decide about the purity or otherwise of a water. I do not mean to say that the whole of the methods I am about to mention are employed in every case. People cannot expect to get more than they will pay for, but if a complete examination be made it would be on something like the following lines:—

In the first place it is an advantage to have the sample taken by a competent person, who knows what he is about. Every analyst has water sent to him at times in dirty wine bottles or stone jars, which may or may not be clean, sometimes closed with a rotten old cork or even with a plug of paper. If the cork be too small it is easy to remedy that in some people's opinion by wrapping a bit of rag around it, and so on. The first consideration should always be the scrupulous cleanliness of the vessel in which the water is to be carried, and, furthermore, there is generally a certain amount of judgment required to obtain a fair representative sample of the supply in question, avoiding accidental impurities. It is important also to notice the source of the water; if a well, whether it be shallow or deep, whether there be any possible source of pollution near at hand, and so on. It is curious to note how very, very reluctant people are, as a rule, to give any information at all about a sample. They seem to think that the analyst ought to find it out for himself, and that they are being in a manner defrauded if they give him any assistance.

When the sample is taken it is as well to proceed with the analysis without very much delay, because in warm weather especially the organic matter is liable to undergo alteration. Those who are interested in this question will find an interesting series of papers by Professor Liversidge which appeared in the *Chemical*

News not very long ago. The analysis of water may be divided into two parts, a general examination, and an estimation of special constituents. In the general examination we deal first with the colour. At first sight one is inclined to think that water has no colour, but if water be put in a two-foot tube and looked through against a white background, it is surprising to note how well marked a colour there is. Generally speaking, there is a distinct brown colour which to my eye has a decided green tinge. This is due to the vegetable matter dissolved in the water, and when the supply is from a peaty soil, what is known as upland surface water, the colour may be very deep indeed, as peat gives much soluble matter to the water. The London water examiners have a graduated scale of tints, but in an ordinary way it is sufficient to note that there is a light or deep tint as the case may be.

Clearness or turbidity is noted as determining the efficient filtration of the water. When water contains much sewage there is a peculiar opalescent appearance which is very characteristic. The taste and smell are noted, though this does not as a rule give much information, because a badly-polluted well-water is often very palatable. However, if there should be any unpleasant smell it may be taken as almost certain that the water is polluted. It is best to warm the water slightly in an open dish to detect any smell there may be.

The reaction should be noted, that is, whether the water be acid or alkaline. This is best observed with methyl orange. In the great majority of cases a water is alkaline owing to the dissolved carbonate of lime. An acid reaction generally points to pollution with manufacturing waste. In the general examination may be included the microscopical examination of the residue. This should never be rejected, because it often affords most valuable information. The water is allowed to settle for some hours, and then is carefully decanted or syphoned off until about 50 C.c. are left. This is then well shaken round in the bottle, and poured into a conical glass, and again allowed to settle. A drop is then taken with a pipette from the bottom and examined. As there may be anything from micrococci to small fishes, a wide experience in microscopical work is required to enable the observer to come to a right conclusion from what he sees. There are certain organisms which are peculiarly characteristic of sewage pollutions, and others, again, which are only found in pure spring waters. We now come to the special examination, the real chemical analysis of the water. It may be well to point out here the difficulty which sometimes arises owing to the different methods which are adopted to express the results of an analysis. In this country we still adhere, for the most part, to grains per gallon. The practice of using parts per 100,000 is spreading, however, and is, in some respects, preferable, but certain constituents again are expressed as parts per million, and, finally, we have degrees of hardness. It is to be regretted that a uniform system is not adopted, and, in my opinion, it would be better to express everything as parts per 100,000. Of course, any one system can be translated into any of the others, but I have known much confusion arise owing to people getting different sets of figures.

First, the total dissolved matter is estimated by evaporating a known quantity of the water to dryness and weighing the residue. At one time it was thought that the amount of organic matter could be determined by igniting this residue and finding how much weight was lost by the ignition. But if we consider for a moment we can see that, in addition to the organic matter, we also drive off some combined water, also nitrates, and nitrates and carbonates are decomposed, and some chlorides are volatilised, so that it is quite fallacious to consider the loss as organic matter, and this determination is now very rarely made.

The amount of dissolved matter varies enormously, and may commonly range between ten grains to the gallon, and one hundred and fifty. It is impossible to say that any particular number renders a water fit for use or the reverse, because a water may contain a large amount of dissolved salts and yet be very pure organically, and *vice versa*. This consideration applies to most of the constituents. In many popular books on water analysis we see tables divided in three columns giving the amount of the various constituents which render a water safe, usable, and dangerous. Such tables are both worthless and misleading. No particular amount of any constituent renders a water either good or bad. As I pointed out before, we consider the results of an analysis as a whole, and cannot form a proper decision on any one item. We have now to consider the determination of the organic matter, and this is the most discussed portion of water analysis. There are three methods in use, namely, Wanklyn's ammonia process, Frankland's combustion process, and Tidy's permanganate process. As the first mentioned is most generally employed we will consider it first. I may take it, I think, that you are all more or less familiar with the process; half a litre of the water is placed in a clean retort and distilled with carbonate of soda, and the ammonia in the distillate determined with Nessler's solution, alkaline permanganate is then added, and a further quantity of ammonia distils over. This is the albumin oil ammonia. The first lot of ammonia is called free or saline ammonia. It is derived from the ammonium salts in the water, and any urea there may be. The object of adding carbonate of soda is to liberate ammonia from the ammonium salts. It is a curious fact that many books on water analysis omit all mention of the sod. carb., and another mistake which one writer copies from another until it has become accepted as perfectly true is that if the first 50 C.c. of the distillate be tested the amount of ammonia found is two-thirds of the whole quantity of free ammonia. I saw this statement so often that I became suspicious about it, so I tried various samples of water and found it altogether untrue. Yet I have no doubt that many people still calculate in this way instead of determining directly, and I may tell them that their results will always be wrong. The free ammonia in a water is derived from organic matter and is a measure of the amount of organic matter which has undergone change. If sewage or other matter of a like kind gets into water the ordinary putrefactive bacteria decompose the organic matter with formation of ammonia, and the nitrifying organisms further carry on the change, giving rise to nitrous and nitric acid. Therefore, much free ammonia is very strong evidence of sewage contamination. The albuminoid ammonia is derived from the unchanged organic matter, because it has been found that if organic matter, such as white of egg, be boiled with a strongly alkaline solution of potass. permanganate, a great part of the nitrogen in the organic matter is converted into ammonia; therefore free ammonia is a measure of the decomposed organic matter in the water, and albuminoid ammonia is a measure of the unchanged organic matter. Two objections will be at once raised. First, how can you tell how the organic matter is harmless vegetable matter or dangerous animal matter? Well, it is a curious fact that vegetable matter gives rise to very little free ammonia, and a practised hand can also distinguish by the manner in which the albuminoid ammonia comes off. It comes off much more slowly and more regularly. But the most important means of distinguishing them is this: That animal matter is always accompanied by chlorides and nitrates, whereas vegetable matter is not.

The second objection is that although we can tell how much ammonia there is, we do not therefore know how much organic matter there is. The answer is that it does not matter in the least. Long experience has shown that, other things being equal, a certain

amount of free and albuminoid ammonia respectively denote a pure water, while beyond certain limits there has been pollution, and if a water has been polluted by sewage it really does not matter much whether there is an ounce of it or a pound of it in a gallon; the water is equally unfit for use in either case.

The second method of determining the organic matter is Frankland's combustion process. This method is supported by influential analysts, but all the same its days are numbered. It requires elaborate and delicate apparatus, much time, and great skill, but the fatal objection to it is that there are unavoidable sources of error in it which make it quite unreliable. Proof of this has been given lately. It has been shown that when the most eminent chemists analyse the same water their results may differ by more than 100 per cent., and quite a different decision be arrived at. As you are probably aware, the method stated briefly consists in evaporating a large volume of the water to dryness, and then making an organic combustion of the residue with copper oxide. From the amount of CO₂ and N found it is supposed that the amount of organic matter can be calculated, and from their relative amounts whether it is animal or vegetable. It would take too long to explain the various sources of error; it is sufficient to say that nothing but Frankland's great influence and official position keep the process alive. I have never heard of it being adopted outside England, whereas Wanklyn's process is used all over the world. The third method—Tidy's permanganate process—consists simply in measuring the amount of permanganate decomposed by the water. Unfortunately, other substances besides organic matter decompose permanganate, and therefore much reliance cannot be placed upon the results which are obtained by this method.

Closely related to organic matter are chlorides and nitrates. As I pointed out before, nitrates are derived from the oxidation of organic matter by means of the nitrifying organisms which swarm in the upper layers of the soil. Therefore if we find much nitrate in a water it is certain proof that it has been polluted with organic matter, and, moreover, with animal matter. Until recently, it was thought that if the organic matter had been converted into nitrates it was evidence that the water had become so completely oxidised as to be safe, but recent research has shown that under favourable conditions nitrification may go on so rapidly that while nearly all the organic matter is converted, disease germs still retain their vitality. The determination of the amount of chlorine in the form of chlorides is a most valuable guide. Urine and sewage generally contain a large quantity of sodium chloride, and no treatment to which the sewage can be submitted will remove it; therefore the presence of a large quantity of chloride in a water is a most decisive proof of sewage pollution. Of course it must be remembered that in certain cases, *e.g.*, near the sea shore or in places like the Cheshire salt district, there will naturally be a large quantity of chlorides in the water, and in these cases we must rely on the other constituents, but whenever we find more chlorides than the normal amounts, accompanied by nitrates, and high free and albuminoid ammonia, can say with certainty that the water has been polluted by sewage. I am sorry that I have not had time to discuss other points of analysis, such as the detection of poisonous metals, especially lead, hardness estimation, estimation of phosphates, and so on. What I want to do is to impress on you, as far as I can, the fact that water analysis is a difficult and delicate task, calling for trained judgment and long experience. I have been amazed to see the reckless way in which it has been undertaken, and I have known water supplies condemned by people whose training had not gone so far as to teach them how to use a chemical balance properly. Much discredit has been thrown on water analysis in consequence, so that

if I have done no more than led you to think that perhaps it is the chemist who is at fault and not the chemistry I shall be well satisfied.

THE INDIA-RUBBER INDUSTRY IN SOUTH AMERICA.

The world's consumption of india-rubber has been growing so enormously during the past few years that the time does not seem to be far distant when the demand will exceed the supply. Already the difficulty of getting a sufficient quantity of rubber to meet current needs has led consumers to fear that there will be an early famine. One of the chief causes of this heavy increase in consumption is, of course, the employment of the material in the bicycle trade, and long before the limit has been reached in that direction another scope, that may be quite as wide and general, will be opened up in the use of pneumatic tyres upon vehicles of all descriptions. The United States is the largest consumer of india-rubber at the present moment, but that country is run pretty close by Great Britain. The other markets follow a long way behind, but the amount imported by France and Germany is no mean proportion of the trade done in this material.

It is certain that the threatened famine in india-rubber, or, more properly speaking, caoutchouc, would not be so imminent as it now is if the owners of the plantations in West Africa and elsewhere had been a little less reckless in their method of tapping the trees. In order more easily to get at the milky juice it has long been the custom in West Africa, and in some of the South American States, to cut down the trees bodily, so that the collectors only secured one lot of caoutchouc from each tree instead of a large number of periodical yields. The prevalent idea that this policy was justified by the almost unlimited range of forests producing caoutchouc was very soon found to be groundless, and, now that it is too late to have any immediate effect upon the supply, stringent regulations have been made in many countries to prevent the cutting down of trees, and owners are going to a great deal of expense in laying out new plantations, which must, however, take several years before they come to maturity. In the meantime efforts are being made to compensate for these limited supplies by producing artificial india-rubber, and several new processes have lately been brought out in France and Germany, though without as yet producing india-rubber of a suitable quality upon a commercial scale.

The most obvious way of meeting the demand for this material is to give more attention to some of the other rubber-producing trees that are to be found in considerable quantities in South America and elsewhere. At the present moment French capitalists are trying to make profit out of the scarcity of india-rubber by utilising the balata, which for many years past has been employed upon a small scale for a variety of purposes. There are at least two descriptions of balata, the one white and the other red, the latter being known in the English colonies as the "bullet tree," a corruption, no doubt, of the native word "bolletrie." The species being exploited in French Guiana is the *Mimusops balata*, a magnificent tree which is peculiar to all the Guianas. It attains a height of from 90 to 100 feet. The wood is very much sought after for cabinet-making on account of its beautiful colour, while it has also the property of resisting the depredations of insects. These merits are almost fatal to the existence of the tree as a rubber-producer, and in some of the South American States forests are being cut down without any regard to the profit that can be secured by tapping them in an intelligent manner. In Venezuela the tree is also to be found in great abundance, and, in point of fact, it grows very freely in the mountainous districts of the northern States of South America,

Nevertheless, in British Guiana immense forests are found in the low-lying districts of swampy Canje. In a report on the balatas published a little while ago by M. Hayes, a colonising agent, it was said that there was a sufficient expanse of forest in the Guianas to allow of the exploitation of rubber being carried on for centuries. It was, however, necessary that something should be done to prevent the wholesale destruction of the *Mimusops balata*, which would very soon disappear if allowed to be cut down indiscriminately for its wood, and one of the richest and most prolific resources of South America would thus be destroyed. In fact, both in Venezuela and in Dutch Guiana the trees are cut down with a view of collecting as much of the juice as possible, and in French Guiana the same process was for a long time employed. When the trees are thus felled, circular cuts are made every 12 inches, and receptacles are placed underneath to catch the juice. The bark is also sometimes removed from the tree and the juice extracted from it by presses.

In British Guiana it is only allowed to tap the trees without felling them, and a similar restriction is now imposed in the neighbouring French colony. The English method of collecting the rubber is to make horizontal incisions half way round the tree and connect them with a vertical channel to allow of the fluid flowing down into the receptacle, but a better method is said to consist in cutting out rectangular pieces of bark from which the juice is extracted by presses. Alternate rectangles must of course be left on the trunk, and these can be removed at the next tapping, when the exposed parts of the tree are sufficiently healed. To secure perfect vitality in the tree it is preferable to tap it over a third only of its circumference every five years. If properly carried out the collection of balata rubber is a very profitable industry indeed. One traveller in French Guiana, who was accompanied by three men, collected 666 litres of juice in 119 days, which produced on coagulation 360 kilos of rubber. Had the men been able to give their time exclusively to the collection of rubber there is no doubt that the amount would have been doubled or trebled. It is, indeed, estimated that a single balata will supply a kilo. of rubber every year without suffering to any appreciable extent from the tapping. The system usually employed for securing coagulation is to pour the liquid into large shallow pans about four inches deep. A hard crust very soon forms at the surface, and this is removed to allow of another crust forming, and so on until the whole of the juice is solidified. The crusts are then hung on lines to dry. The balata rubber, though perhaps slightly inferior to caoutchouc for certain purposes, and notably as an insulating medium, is yet specially adapted for a great many uses, such as machinery belting, mackintoshes, surgical appliances, etc., and its merits are so far recognised that a considerable trade has grown up during the past two or three years in the Guianas. While the exports of balata rubber from British Guiana in 1881 were only 41,000 lbs., in 1889 they were no less than 363,480 lbs., and though the total fell in 1892-93 to 237,450 lbs., the value has been rapidly increasing, and for the two years named was £20,005. In Dutch Guiana the industry has not been carried on in such a systematic manner. Nevertheless, two American companies are exploiting the balata on a large scale, and are sending the product to the United States. That the industry can be made a very profitable one is seen in the price paid for the rubber, which varies, in Paris, from 3 francs to 8 francs a kilo., according to the quality. It is evident, therefore, that while industrial enterprise is under a cloud in South America, it may be to the interest of capitalists to turn these balata resources to account, the more so as rubber is one of those rare things that are not likely to suffer depreciation to such an extent as to make its production unremunerative.—*South American Journal*,

ORTHOCHROMATIC PHOTOGRAPHY.*

BY CAPT. W. DE W. ABNEY, C.B., F.R.S.

The meaning of orthochromatic photography is the correct rendering of colour on a print, in monochrome, taken from a photographic plate. To photograph pictures so that they are not obviously wrong in colour rendering is the use to which this branch of photography is usually put, and if we can render the colours in a picture properly, we can render any subject. We say that one colour is brighter than another, or more luminous, and we may generalise, and say that one colour has more luminosity than another. It has been said by Helmholtz that he could not picture a method by which a red and a green can be matched for brightness, and yet there is a sort of instinct by which the brightness is judged, and it is this instinct which enables us to get accurate measures of the luminosities of different colours. To judge, however, of the luminosity of colours, we must know the intensity of the light which calls them into being. Thus, a picture in which there was red and green might, under bright illumination, show a particular red, brighter than a particular green, whereas, in a sombre light, the reverse might be the case. Towards evening, the last colours which appear vivid to the eye in pictures in a picture gallery are the blues, the reds disappearing early.

A second difficulty crops up, which is also physiological. If we place a blue-green and a red in juxtaposition in large masses, the blue-green may appear much brighter than when the same colours are presented in small portions. The reason is that, in the centre of the eye we have a yellow dye staining a small central part of the retina, and that shuts off a large proportion of the blue, when the image happens to fall on it, as is the case when the masses are small. When the masses are large the image of the blue falls on the retina beyond this small stained portion, and the full effect of the colour is felt. In a picture, then, it is evident that the luminosity of a small patch of blue will not be the same as it would be if the patch were large. We can imitate what is seen by the retina beneath the yellow spot by using a pale yellow glass over half a patch of blue. Another difficulty is the kind of light used for viewing the colours. If we have blue sky to illuminate the picture, the preponderating blue of this light will show up the blue of a picture more than would be the case if the, comparatively speaking, yellow sunlight, or light from the clouds, were illuminating it. Artists are known to complain of coldness of a picture when viewed in the light from a cloudless sky.

One is often tempted to smile at some art criticisms of colour values in pictures, and it would puzzle a good many of the critics, for instance, to explain what is meant by painting in a high key or a low key, and the difference that exists in colour contrasts in the one kind of painting and in the other. If a few of the laws which underlie a knowledge of colour were more studied, criticism on pictures would be much more valuable than it often at present is. For instance, when a picture is seen through half or more than half closed eyes, the chromatic sense is entirely altered, and the relative values of the different tints are altered. The artist often uses this artifice when painting from nature, and rightly, for he has learnt from experience the kind of light in which his picture will be viewed. But there is no reason for the critic to adopt the same plan in the studio. It is evident, then, that the rendering of the colour in a picture in monochrome with exactness is by no means easy. In this country, at least, the light in which a picture is seen most commonly is sky light, with clouds in the sky. The electric light is a very fine imitation of bright sunlight, and it is quite fair to judge of the luminosity of colours in such a light.

To gain a real knowledge of the colour of pigments, or of light transmitted through transparent bodies, such as glass, we are forced to have recourse to the spectrum, and if we wish to know the orthochromatic value of a photographic plate we must do the same. On throwing the luminosity curve on the screen, it will be seen that in the yellow and yellow-green we have the maximum brightness, and by an artifice we can show how the spectrum in monochrome should be represented. On the screen we have a point from a negative of the spectrum, taken on an ordinary plate. It will be seen that by far the brightest part is that which represents the blue of the spectrum. The yellow has no luminosity to speak of, and the red does not show at all. Early in the seventies Dr. H. M. Vogel, of Berlin, showed that by the addition of certain dyes—fluoresceine principally—the same plate became sensitive to certain rays to which before it was insensitive. Later researches have shown that erythrosine or erzine are effective in rendering yellow green, and that the simple chemical compound cyanine renders a plate sensitive to the yellowish-red as well as to the yellow. How we are to account for this new sensitiveness has been much discussed. Probably the sensitiveness is due to the decomposition, by light, of the dye itself, and the intimate mixture of this product with the sensitive salt gives a mixture on which silver will deposit in exactly the same way as it will on a glass plate on portions which have not been properly cleansed. Dyes which are most effective are those which are most fugitive.

On the screen we have two samples of prints of the spectrum from plates rendered colour-sensitive by means of erythrosine and cyanine. In all these cases there are gaps of insensitiveness in the spectrum. We can reduce the sensitiveness in the blue by means of a coloured screen placed before the plate or in the beam of light falling on it, but you can never get over this difficulty of the gaps. So far there is no plate that I know of which will absolutely fulfil the conditions that have been laid down. But by modifying the screens we can make a compromise which will not be very far from the truth, when we are photographing colours of nature which are not pure colours like the spectrum colours, but which are mixtures from colours from large portions of the spectrum.

First of all we must have a plate which, while sensitive to blue, must also be sensitive to green, some pale yellow, and red, and if there are gaps we must do the best we can to eliminate their effect. If we can photograph correctly the light which is transmitted through a ruby glass, a yellow glass, a green glass, a blue glass, and a white glass, we may take it that any intermediate colours will not be very incorrectly rendered, because each of these coloured glasses transmits a considerable portion of the rays on each side of the colours of the spectrum which most nearly match mine. Thus the red will transmit red and yellow, the yellow-red, yellow and a little green, the green-yellow and blue as well as green, and the blue glass will allow some green, a little red, and a large proportion of blue to pass.

Mr. Ives has shown that an ordinary plate may be made orthochromatic by using coloured screens, but the example he gives of the time of exposure required is not of such a character as makes it appear desirable to use ordinary plates for such a purpose. He gave, I believe, five minutes' exposure with such a screen, when the ordinary exposure was only cap off and on, or say half a second. This would mean a prolongation of the exposure some 600 times. Any plate which, by any amount of exposure, will give a deposit by the red part of the spectrum, may be made orthochromatic, especially if the sensitiveness is gradual. If the sensitiveness to the red is, say, 1000 that of the blue, and the sensitiveness goes gradually down from blue to red, it is only necessary to cut off 999 parts of the blue, and so on for the intermediate colours.

THE TOWN AND GOWN ASSOCIATION, LIMITED.

THE professions have suffered much, and may suffer more, from the working of the Companies Acts, but it is just possible that the development of a novel scheme with which Professor PATRICK GEDDES' name is associated may indicate ways in which the advantages accruing under the Acts may be utilised to the benefit of professional men as much as they have been by the commercial classes of the community. During the past nine years Professor GEDDES has organised and supervised undertakings initiated by him with a view to aiding in the improvement of Edinburgh, and supplying the material conditions of associated and collegiate life, with due regard to the actual conditions and requirements of the Scottish Universities. The beginnings of a University Hall were made by renting and furnishing three small flats, which were entered by seven students on May 1, 1887. Soon, however, it became necessary to take possession of the whole tenement to accommodate the continually increasing number of students, and many houses have been acquired since, but the accommodation at the present time, including twenty family houses or sets of private chambers, is described as being quite inadequate to supply the demand on the part of students and others.

With a view to extending the original scheme and putting it on a wider basis, the Companies Acts have been taken advantage of and the Town and Gown Association, Limited, has been formed to take over Professor Geddes' undertakings, its object being at the same time civic and academic, architectural and educational. On the one hand the Association will concern itself with buildings and sanitation, on the other, with the organisation of residential halls for students and others connected with the universities and with the liberal professions generally. Plans have been drawn for two masses of reconstruction, east and west of New College, thus essentially remodelling the panorama of the Old Town, Edinburgh, viewed from Princes Street. Other improvements have also been made or arranged, so as to throw narrow and noisome closes into spacious open courts, whilst large slum areas are being dealt with by the local authorities, who appear to be co-operating in the desirable object of improving the appearance and hygienic condition of the city, so that

a definite prospect is thus opened up of a cleansed and renewed Old Town. Within this district the work to be taken up by the Association will be seen as an active participation in a renaissance of the historic city, and as the domestic and residential aspect of a general movement.

Altogether one hundred and twenty graduates and undergraduates have been provided for by Professor GEDDES' unaided efforts, but the University numbers nearly three thousand undergraduates, and over a thousand more attend the various extra-mural schools. It is believed also that a large and increasing number of both Scottish and English students are annually lost to the Scottish Universities for lack of the residential conditions, which it is a main object of the Association to supply. It has been proved that the judicious management of a moderate circulating capital in Edinburgh is capable of bringing together undergraduates and graduates so as virtually to constitute a College such as could not be established in smaller university towns without sinking endowments approaching half-a-million sterling. The development of a simple boarding-house, therefore, into a school of "public spirit and individual character," is to supply the plan for the extension and further development of the principle upon a collegiate scale. There are to be both self-governing houses and tutorial houses, in addition to a central building arranged as a centre for the varied student societies and other activities of the University Hall. Professor GEDDES is to join the board of directors, after allotment, as Vice-President, and will also continue his services as manager for some time. It may reasonably be expected, therefore, that success in the past will be repeated in the future, and the enterprise of the Association should benefit its members, whilst improving the University and beautifying the ancient City of Edinburgh. When, it may be asked, will London and its University be similarly benefited?

WHAT IS A PROFESSION?

IN an address delivered at the first annual gathering of the Liverpool Odontological Society, Mr. W. H. WAITE, L.D.S.I., pointed out that several distinctions, having no foundation in reason, have been made between professions and trades—social distinctions, conferring privileges on the first which are denied to the second. The real difference is most simply expressed by observing that, in a trade transaction, the public seek an article, whereas in professional matters an individual is sought. In trade the public can examine the article offered and estimate its value; but in dealing with a profession it is necessary to confide in the individual, having only his reputation and experience for guidance. "In trade the individual is of small consequence, provided the article is genuine; but in a profession the individual is of the first importance—his knowledge, his skill, his character count for everything. In trade, finally, the public can be equally well served at any respectable establishment—the demand and the supply are for the most part uniform. In the professions there is infinite variety; identity is well-nigh impossible, either in the matter requiring attention or in the individuals whose services are sought." The reason the professional man is called professional is because he professes to understand, and to be able to perform, the duties pertaining to his specialty. He has no goods to exhibit for inspection

or competition, but needs to show that he possesses the knowledge, skill, and character he professes. Accordingly, he must be taken very largely on trust, but once his capability is demonstrated "his position is as well assured as anything mortal can be."

EXEMPTIONS FROM THE SHOPS (EARLY CLOSING) BILL.

MR. BANBURY, undismayed by the reception his proposals met with in Grand Committee, intends to make another effort to secure the addition of "pharmaceutical chemist or chemist and druggist or registered druggist" to the Schedule of exempted businesses within the meaning of this Bill. His South Hackney colleague in the House, Mr. T. HERBERT ROBERTSON, wants the exemptions to be made on more generous lines, for in addition to fruiterers, confectioners, and vendors of any article of food ready for consumption (a tremendously wide-reaching reference), he proposes to move that "a chemist or druggist or vendor of medical appliances" shall also have the privilege of figuring in the Schedule. The record of these notices relating to Sir JOHN LUBBOCK'S Bill is of little more than passing interest, for it will be surprising if the respective sponsors are ever called upon by Mr. Speaker this session. Presumably the hopelessness of anything further being done in the way of private members' business is also responsible for the absence of hostile notices against the Shop Assistants Bill.

THE LAW AS TO PROFESSIONAL QUALIFICATION.

THE recent prosecution for manslaughter at Leeds Assizes (see PH. J. Supplement, April 25, p. lxxxv.), and the suggestive remarks of Mr. Justice WRIGHT as to the dangerous results which may arise from allowing ignorant persons to use and practise a skilled profession, have very distinctly raised the question whether, under the present state of the law, the public is sufficiently protected from risk of that kind. In a leading article devoted to a consideration of this question, the *Times* of Thursday last points out that even in regard to the medical profession and the practice of dentistry, the statutory prohibition of the use of titles indicating special kinds of professional qualification is so easily evaded as to have little or no practical value. It is also shown that in addition to that defect, the legislative provision for limiting liability in commercial and industrial undertakings has been misapplied to enable unqualified persons to carry on occupations in which proof of technical qualification is required in the interests of the public. As an illustration of the absurd results that follow, a case is mentioned of a man who in 1879 presented himself for the Preliminary examination of the Pharmaceutical Society, was then rejected and has subsequently come up, on fifteen occasions, without being able to pass. Several penalties have been recovered against this individual for acting as a chemist and druggist and selling poison, but having now converted himself into a company, he is enabled to defy the law providing for the safety of the public and the equitable protection of those who comply with it. In conclusion, the hope is expressed that success will attend the attempt at present being made to remedy this defect by the insertion of a clause in the Companies Bill now before Parliament.

ANNOTATIONS.

CHEMISTS' ASSISTANTS' ASSOCIATION.—The following is the list of officers of the above Association for the session 1896-97:—President, Mr. C. Morley; Vice-Presidents, Mr. G. Roe and Mr. A. Ralph Melhuish; Hon. Vice-President, Mr. E. W. Hill; Hon. Treasurer, Mr. Strother; Hon. Secretaries, Mr. W. Moore (Literary), 17, Bloomsbury Square, W.C., and Mr. C. Robinson, 180, New Bond Street, W.

THE MONTREAL COLLEGE OF PHARMACY was established in 1867 became incorporated in 1879, and has lately been thoroughly remodelled and fitted up with all necessary requirements. The lecture rooms have seats for from 75 to 100 students, and the chemical laboratory has accommodation for more than 60. There are both junior and senior courses, consisting of fifty lectures each, in materia medica, pharmacy, and toxicology, theoretical and practical chemistry, and structural, physiological and systematic botany. Last session 93 students matriculated at the college. The legal examinations for Minor and Major candidates are held twice a year only, a plan that might usefully be adopted in Great Britain; in April they are held at Montreal, after the close of the lecture session, and in October at Quebec. Success at the Minor examination qualifies the candidate as a "certified clerk," and after passing the Major he becomes a "licentiate in pharmacy."

PATENTS.—The thirteenth annual report of the Comptroller General of Patents, Designs, and Trade Marks, besides affording a rich field for the energies of the conscientious statistician, presents features that are of general interest. The Patent Office made a profit during 1895 of nearly £87,000, in spite of heavy expenditure in respect of new buildings. The Chancellor of the Exchequer is doubtless duly grateful for this little addition to the public purse, and would not be disposed to agree to any amendment in patent practice, such as Sir J. Leng advocated a short time ago (see *ante*, p. 390). The applications in respect of patents showed a slight decrease, in respect of designs a marked decrease, and in respect of trade marks an encouraging increase. England and Wales naturally supply the major portion of the applications, then come the United States, with Germany a very close third. Sir Reader Lack gives some interesting tables showing the number of applications for patents during a series of years compared with the number of patents sealed, and those remaining in force during the whole term of fourteen years. As an instance we may take the year 1876. There were in that year 5069 applications, but only 3435 went to the sealing stage, 3367 survived to the third year, 947 to the seventh year, and only 341 to the fourteenth. In 1894 there were 25,386 applications, but only 47.3 per cent. ever proceeded as far as sealing. One gathers from the Comptroller's figures that, as a rule, barely 6 per cent. of sealed patents remain in force for the full term of fourteen years. In fact, the tendency seems to be towards making the procedure of application (which carries provisional protection for nine months) fulfil all the purposes of Letters Patent. The former costs £1, whilst sealing means the expenditure of £3 additional at least, and this may be a potent factor with the commercial man who has "notions."

THE ALUMNI REPORT, published by the Alumni Association of the Philadelphia College of Pharmacy, commemorates the seventy-fifth anniversary of the College by publishing a full report of the proceedings on the occasion of the recent celebration of the anniversary. This, with other matters, renders the May number of the *Report* of exceptional interest.

NOVEL USE FOR OLD FILTERS.—A correspondent of the *Amateur Photographer* suggests the use of a disused filter for keeping a stock solution of sodium hyposulphite ready for use. The crystals are placed in the upper chamber of the filter, which is then filled with water. The solution filters through into the lower compartment gradually, is kept free from dust, and can be drawn off by the tap as required. The same idea will suggest itself to pharmacists as being capable of application in the preparation of other stock solutions, such as certain syraps, mucilages, etc., etc.

THE RÖNTGEN RAYS IN PHARMACY.—Dr. Ferdinand Ranwez has made use of the x -rays to detect mineral substances added to saffron as adulterants. Out of four specimens so examined, only one was found to be pure; another contained 62.13 per cent. of barium sulphate, and a third 11.75 per cent. of that compound, together with a certain proportion of potassium nitrate. The fourth specimen contained 50 per cent. of pure saffron, and the rest consisted of some substitute for that drug, faced with barium sulphate to the extent of 28.6 per cent. The plan adopted was to wrap a gelatino-bromide plate in black paper, place the saffron upon this on the same side as the sensitive film, then allow the rays to act for four minutes, afterwards developing and fixing in the usual manner. The foreign matter is very sharply indicated in the print illustrating the paper, which appears in the *Annales de Pharmacie* for May.

ELECTRICITY AS A REMEDY IN INFECTIOUS DISEASES.—The recent discovery of D'Arsonval and Charrin, that alternating currents of electricity attenuate the poisonous toxins produced during the course of such diseases as diphtheria, causes the Editor of *El Memorandum* to remind his readers of a pamphlet he reviewed some four years since, entitled, "La electricidad y el cólera," written by Señor Rodriguez Merino, an electrician in the posts and telegraphs at Torrelavega. The object of the pamphlet was to air Señor Merino's theory that, electricity being a powerful disinfectant and destroyer of micro-organisms, strong electric currents passed through the bodies of cholera patients might so act on the cholera microbes as to cut short the course of the disease. Though Señor Merino was ridiculed at the time, D'Arsonval's experiments seem to point to there being something in the idea, providing success attends the trials that are being made of attenuating the toxins of diphtheria, as they are produced in the sick person's body.

SOME FINE RADIOGRAPHS.—Mr. Leo Atkinson, who has devoted considerable attention to the "new photography" and recently performed a series of successful experiments to illustrate a lecture on the subject by Dr. Chisholm Williams, has been good enough to send a few examples of his work. These include pictures of human hands, obtained after exposures of three minutes, which show the whole of the bones as clearly as would be possible in a direct photograph of a skeleton. There is also a fine representation of a grass snake under chloroform, showing most clearly the whole of the bony system, besides fine pictures of a mouse and a baby's foot, and two remarkably clear prints of Hippocampus.

APPRECIATION!—The Dublin *Daily Express* of Tuesday last gives several quotations from Chapter VIII. of Mr. Thompson's "Alchemy and Pharmacy," with a pleasant reference to "the attractive series of articles in the *Pharmaceutical Journal*." The articles have also been widely quoted by the *Globe* and other papers.

BORIC ACID POISONING.—From observations of the toxic effect of boric acid, which followed its use as a surgical dressing, as well as for internal administration, in two cases of anthrax, Branthomme (*Répertoire*) concludes that the compound is far from being innocuous. In both cases a marked effect was produced on the skin, red patches of an erysipelatous appearance, or an eczematous aspect, being produced, accompanied by swellings and great thirst. One case recovered rapidly after suspending the boric acid treatment, but the other ultimately succumbed, with every symptom of poisoning.

SALT AS A LUXURY.—The Italian salt monopoly is very injurious in its effects according to Consul Neville-Rolfe. It was proposed recently to increase this tax, but the medical profession rose in rebellion, saying that the tax as it stood was highly detrimental to the public health, and that any increase of it would be unjustifiable, so the project was abandoned. The retail price of the commonest salt is 40 c. per kilo; of kitchen salt, 60 c.; and of table salt, 80 c.; and when its abundance in Italy is considered, it will be seen that the monopoly must necessarily be a very lucrative one. Table salt is very nearly 4*d.* per English lb., a price which would startle our British housekeepers who are accustomed to pay (quality for quality) about 8*d.* a stone for this necessary of human life. So strict is the law of this salt monopoly that one may not take a bucketful of water out of the sea for a bath without an official permit, for fear one should extract salt from it, and although the peasants use seawater to make their bread, they may not take it without paying a tax.

THE CONFERENCE "BLUE LIST" is now being issued to the members, and suggests seventy-two subjects for investigation. Fifty-two of these appeared in the "Blue List" for 1894, published in the *Pharmaceutical Journal* for June 2 and 9 of that year. The additional suggestions refer to the alkaloids of cod-liver oil, kinos, distilled spirit of witch hazel, coca wine, creosote, guaiacol, guncotton, albuminate of iron, aluminium pharmaceutical apparatus, copaiva oleoresin, *Fucus vesiculosus*, digitalis juice, quinine, bismuth subnitrate, the alkaloids of *Lobelia inflata*, jaborandi leaves, the facing of saffron, wool fat, and proximate analyses of *Cactus grandiflora*, *Salix nigra*, *Citrullus colocynthis*, *Catha edulis*, *Ailanthus excelsa*, and *Hemidesmus indicus*.

CRIMINAL POISONING IN HONG KONG.—A lecture on this subject was given at Hong Kong last month before the "Odd Volumes," by Mr. W. E. Crow, Pharmaceutical Chemist and Government Analyst. He confined his remarks for the most part to poisonous agents concerning the use of which, in the colony of Hong Kong, authentic records are in existence. So far as the Chinese are concerned opium in the form of aqueous extract is the only poison used by suicides. Other poisons used for grave offences are but few in number, the chief being aconite, arsenic, *Datura alba*, Nees, and *Gelsemium elegans*. The Chinese know white arsenic as "Pak-Sun-Shek," realgar is Hung-Wong, orpiment is "Tsz-Wong," and a mineral containing arsenic oxide and sulphides is known as "Hung-Sun." Aconite root from various species is indifferently termed "Ts'ó ù," the root of *Gelsemium elegans* is sold under the name of "ú mun kéung," whilst in South China the plant is commonly termed "tün ch'eung ts'ó," and the datura plant is known as "Nun Yeung Fa." Fish have been poisoned by the seeds, freed from oil, of *Camellia oleifera*, "Ch'à tsai ping," or "Ch'à fu." With regard to the importation of morphine into China, Mr. Crow expressed the opinion that China, through her foreign Customs, can effectually stop the traffic if she wills it,

CHEMICAL SOCIETY.

An ordinary meeting was held on May 21, Mr. A. G. Vernon Harcourt, President, in the chair.

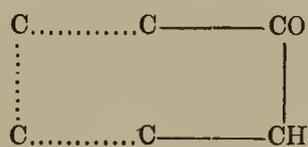

Although the meeting held on this occasion was absolutely devoid of subjects immediately allied to pharmacy, some of the papers were of very great interest indeed, and could not but afford much mental pabulum to the student of organic chemistry. The meeting was a small one, owing, probably, to the unattractiveness of the programme, and by the time the last paper had been read it was still smaller, the audience having diminished almost to the vanishing point.

Dr. F. D. Chattaway, M.A., and Mr. R. C. T. Evans contributed the first paper entitled "The Diphenylbenzenes—I. Metadiphenylbenzene." This is the first paper of a research the authors have undertaken on the products obtained on heating benzene very strongly. It seems that at least two distinct bodies are produced, viz.: metadiphenylbenzene, the subject of the present paper, and paradiphenylbenzene. The former is a colourless body—a hydrocarbon soluble in many of the usual solvents. It melts at 84° C. and boils at 369° C., under a pressure of 766 millimetres.

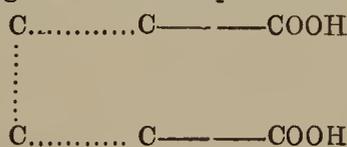

In the discussion there was some controversy as to the action of aluminium chloride on benzene and benzene chloride, Dr. Chattaway saying that no hydrochloric acid is given off with freshly prepared aluminium chloride, whilst Dr. Kipping affirmed that the action was very pronounced.

"Derivatives of Camphoric Acid" was the title of the second paper, which was read by the author, Dr. F. S. Kipping. Before reading it Dr. Kipping was somewhat profuse in his apologies for the absence of experiments. Experiments, he said, he had none, but formulæ he had in abundance, and the black-board fully bore evidence of the truth of this statement.

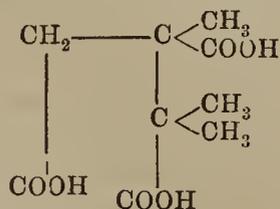

The camphor formulæ are very various, and it is quite clear that no two chemists are in agreement on the question of the constitution of camphor derivatives. Dr. Kipping placed the following upon the board as expressing the constitution of camphor:—

This, on oxidation, gives rise to camphoric acid:—

On further oxidising camphoric acid, camphoronic acid results— $\text{C}_9\text{H}_{14}\text{O}_6$. This is a fatty compound, and that is probably all we know about it. Still further oxidation gives rise to a variety of products—trimethylsuccinic acid, dimethylsuccinic acid, and isobutylsuccinic acid. Dr. Kipping gives the following as the constitution of camphoronic acid:—

The constitution of camphoric acid is very obscure, and no derivatives are known. It appears that the crux of the whole thing lies here, and that if proper derivatives of this body could be obtained, organic chemists will have disposed of a very troublesome problem. Dr. Kipping is endeavouring to obtain halogen derivatives of camphoric acid in order to elucidate the subject if possible.

Some ten or a dozen specimens of products were shown to the Fellows, the most striking being trans-camphotricarboxylic acid, which is in very beautiful hexagonal crystals.

In concluding his paper, Dr. Kipping said that Dr. Collie had a very interesting slide to show. This slide was thrown on the screen, and was, Dr. Collie said, a photograph of two pages of Tiemann's paper on camphor derivatives, published in the *Berichte*, and was really nothing but formulæ. As a slide it was not a success, on

account of its being too small. Dr. Collie said that the experiments which would lead to the composition of camphoric acid were not so successful as one could wish for, and Dr. Kipping, indulging in a little mild invective on the German workers, said that Brett simply turned Tiemann's formula for camphoric acid the wrong way up and called it by his own name.

The third paper was really a sequel to that read by Dr. Kipping, and was entitled, "Some Substances exhibiting Rotatory Power both in the Liquid and Crystalline States," by W. J. Pope. Cis π -camphanic acid is optically active both in solution and in the crystalline state. Matico camphor is laevorotatory in crystalline and amorphous conditions. Trans-camphotricarboxylic acid (the peculiar hexagonal crystals previously referred to) by polarised light does not show true circular polarisation, and this fact Mr. Pope endeavoured at considerable length to explain. Strychnine sulphate resembles this peculiar body in its behaviour to polarised light, and this is due to the overlapping of a number of thin plates.

A whole batch of Fellows filed out of the room as the President was pronouncing the title of the last paper—one of those names which only organic chemistry can boast of—"Dimethoxy-diphenylmethane and some of its Homologues," by J. E. Mackenzie, Ph.D., B.Sc. Dr. Kipping read it in abstract, but the first part was entirely lost in the din of retreating footsteps.

The President, in closing the meeting, congratulated the Society on getting through the whole of the papers submitted for reading.

WESTERN CHEMISTS' ASSOCIATION
(OF LONDON).

THE ANTI-CUTTING MOVEMENT.

A largely attended meeting of this Association was held at the Westbourne Restaurant, Craven Road, on the 20th inst., when Mr. J. C. Hyslop occupied the chair. As it was intended to discuss the anti-cutting movement, any chemist in business interested in the subject—though not a member of the Association—was at liberty to attend on this occasion, and that fact accounted for several strange faces, amongst them being Messrs. C. J. Park (Plymouth), Barrett (Leamington), and W. S. Glyn-Jones (Secretary of the Proprietary Articles Trade Association), etc. At the outset, the President ruled that though outsiders were welcome to speak, it was not reasonable to expect that they should be allowed to vote on a motion.

Mr. Andrews opened the discussion by remarking that the present state of things in regard to the sale of proprietary articles is unsatisfactory—in fact, almost demoralising. As matters now stand, the price printed on the package is almost a danger signal, and the preparations are usually sold at whatever price the public is prepared to pay. The consequences of this state of things are serious, not only to retailers but also to manufacturers, who have at last recognised the demoralising nature of the present state of affairs. The anti-cutting question is therefore one in which every chemist is bound to feel interested. According to the proposals of the Proprietary Articles Trade Association, he understood it was intended that in all cases the price marked on the article by the manufacturer was to be the real selling price. This was a very important point, and he was of opinion that the scheme promulgated deserved earnest consideration, for although not sanguine as to its success, it seemed that, one proprietary article manufacturer having formulated a scheme which worked successfully, there was no reason why a combination should not do so likewise.

Mr. W. S. Glyn-Jones having been invited to speak, said he spoke as a chemist, and not as the Secretary of the Proprietary Articles Trade Association. He proceeded to remark that he was convinced his hearers did not need to be instructed in the workings of the Association of which he was Secretary. It was well, however, to remember that the term "proprietary article" does not necessarily mean "patent medicine" or nostrum, and however much a chemist might be opposed to the schemes of the Association, he would hardly be so hardy as to be willing to give up the sale of such preparations entirely, for they were bound to come into his province in his capacity as a dispenser of prescriptions, and it was advisable that the whole question should be looked at from the point of view of business men. It was absurd to say, as some few did: "Let the whole trade in proprietary articles go, and let us try and keep going on pure dispensing." It was obvious that such a course of action was only possible to a select few among chemists

and it meant starvation to the rank and file. Another point to be remembered was that if chemists do not supply proprietaries, the trade in pure drugs will be damaged, in fact, it has already been damaged by this factor, and the more chemists refuse to look at this important question from a business point of view, so much the more will the drug trade slip away. Chemists cannot afford to despise the questions raised by the Proprietary Articles Trade Association, and he asked those present to give the movement their sympathy and, if possible, support.

The President said it seemed rather ironical that at the last meeting Mr. Parker should have brought forward a motion calling on medical men to desist from prescribing proprietary articles, whilst they were now considering a system which was designed to facilitate the sale of those very articles. It was remarkable that men who came forward to air their fads and hobbies were always twenty years behind the times, and it seemed to him that the proposals of the Proprietary Articles Trade Association were quite impracticable, inasmuch as they were too late in the field. If they had been brought forward twenty years ago there would have been some sense in doing it, but as matters stand, the mischief is done, and the action of the promoters of the Association seemed to greatly resemble sending a fire engine to put out a fire when the house is burnt down. With regard to those who are members of the provisional Council of the Association, Mr. Hyslop remarked that they are nearly all unqualified men. He did not think that it was compatible with a chemist's position that he should interest himself in the proposed schemes of the Association. It was a grocer's question pure and simple, and he was of opinion that the sale of proprietaries had passed out of the hands of chemists, and would never be regained, except those articles which contained scheduled poisons. He concluded by moving:—

"That this Association, in view of the intimate relation subsisting between its members and those of the medical profession—based as that relation is upon a due regard for the public safety—declares it to be inexpedient to facilitate by any means the traffic in proprietary or quack medicines, and that any agreement with grocers, proprietors, or wholesale dealers as to the prices to be charged for the same is out of the question, as being derogatory to the calling and inimical to the welfare of the craft."

Mr. Barrett, in putting forward the other side of the question, said that for many years he had been endeavouring to get together a federation of chemists, which condition was essential to successful reform. The Pharmaceutical Society is debarred by reason of its constitution from taking a part in trade matters, and it behoves chemists to bestir themselves on their own behalf, for it was absurd to expect that Parliament would ever give the sole right of selling drugs to registered chemists. He was of opinion that the resolution which had been proposed by the President was quite out of the question. It was all very well for the select few amongst chemists, who derived the bulk of their income from pure dispensing, to say, "Let the proprietaries go," but what was going to become of the rest of the craft? It seemed to him a hopeful sign that those men who had been first and foremost in acting in a manner conducive to extreme cutting were now most acutely sensible to the advantages of the new movement. The cultivation of the professional side of the pharmacist's calling had been advocated by the Pharmaceutical Society for years, but in his opinion they were worse off to-day than they had ever been before. He hoped that those present would see their way clear to become members of the new Association, so that some satisfactory plan might be arrived at of selling proprietary preparations at a reasonable remuneration to the retailer.

Mr. Hyman said that an important point to be considered was that uniformity of prices would undoubtedly be conducive to a better status for the pharmacist. At present the difference in prices led to comparisons which were very disparaging to the pharmacist.

Mr. W. Johnston said that the President should not have stopped at the names of the manufacturers connected with the Association. All the men engaged in the retail trade who were connected with the movement, were duly qualified, and although perhaps not men of eminence they were men who did their best on behalf of the Association, and that was what was required. It was worth remembering that some time ago a canvass was undertaken of the retail trade, with the result that six per cent. declared themselves in favour of anti-cutting, and he must emphasise the point of previous speakers that it was not fair for the fortunate few who were in a position to be independent of the sale of proprietaries to expect that their views alone of the matter should be considered.

Mr. Cracknell (hon. sec.) next read a letter from Mr. C. B. Allen, in which he particularly regretted his inability to attend the meeting on account of the importance of the question at issue. He would not favour any scheme advanced by the Association which did not secure the full value of articles to the retailer.

Mr. R. H. Parker said that it was impossible to discuss what percentage of profit should be charged on proprietary articles, as what was readily paid in one district could not be obtained in another. No doubt all present were opposed to the principle of cutting. At the same time the prescribing of proprietary articles was to be condemned on obvious grounds. A physician should not prescribe a certain man's preparation where there were several makes of the preparation, but he should leave it to the discretion of the pharmacist to select the best make. It seemed to him that the sale of proprietary articles over the counter as an ordinary business transaction was not attended by so much loss as when they were prescribed. Chemists were intended by their education to be the sole dealers in drugs, and in his opinion a good anti-cutting movement would be one to protect the sale of drugs, for the proposals of the Association seemed more designed to benefit intruders than chemists, and did not attack the principles of cutting. As matters at present stand the manufacturers take all the profits, and it would pay chemists better to let the whole sale of proprietaries slide and devote attention to their own articles.

Mr. Glyn-Jones wished it to be understood that the Association's first aim was to ensure the payment of "face values" for proprietary articles, and, for his part, he would cease to be Secretary to the Association when that condition lapsed. In reply to the arguments that had been brought forward in favour of confining the movement to chemists, he read an extract from a St. Helens newspaper, in which the advertiser—a qualified chemist—made a boast of cutting proprietaries containing poisons.

Mr. Andrews said that one of the most powerful arguments in favour of the movement was that when the conditions were equal, there was no doubt that the public would rather purchase articles of this nature from a chemist than from a grocer.

The President's motion, was then seconded by Mr. Parker, and put to the members of the Western Chemists' Association, only four of whom voted in favour of it. This terminated the meeting, for although an attempt was afterwards made to put forward an amendment, it was ruled out of order.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

EXCURSION TO DUNDEE.

On Thursday, May 21, being the Queen's birthday holiday, the members of this Association, to the number of about fifty, including several ladies, made an excursion to Dundee on the invitation of Professor Patrick Geddes, of University College. The company left Waverley Station, Edinburgh, at 9.35 a.m., and reached Dundee at 11.30, where they were met by Mr. R. Smith, assistant to Professor Geddes, by whom they were conducted over the museum, and then climbed the Law Hill, which commands on one side a complete view of the city of Dundee and the Firth of Tay, with the pretty watering-places of Newport and Tayport on the opposite shore. On the other side the hill gives a fine view of the beautiful Carré of Gowrie and the Siddlaw Hills. A sumptuous luncheon was served in Lamb's Temperance Hotel, at which Mr. James McBain occupied the chair, and had Professor Geddes on his right, and Mr. R. Smith on his left, Professor Geddes' secretary, Miss Ritchie being also present. After luncheon the company proceeded to University College Botanic Garden, where Professor Geddes gave a garden demonstration, in course of which he spoke of the possibilities of town gardening, of the necessity of choosing the right plants and planting them in the right places. No desert, he said, but might blossom; no soil in nature, however poor, but might be made to bloom. In study he insisted upon the necessity of first-hand observation, and of learning only what one wanted to know.

There was a period of the year—during the winter—in which they studied botany, and that indoors, and in which also they made post-mortem examinations and wrote out the result of their studies. Then they projected their winter botany throughout the year, whereas botany was really the science of summer. But it was difficult for people in town to get the impression of the seasonal year. They were apt to miss, for instance, the spring scene of

snowdrop, the scene of crocus, of narcissus, of lilac, and so on. But it was simply by enjoying the spectacle of the flowers that botany was to be learned. One might, he said, laboriously endeavour to get up lines of music by rote, and might even be able to reproduce them from memory, but that would not make one a musician. Botany was one of the subjects which readily lent itself to be learned in this stupid way—without meaning, without even an instrument, or anything else.

The best text-books he believed were books which like 'Flora Feast,' by Walter Crane, had caught the spirit of the subject, and those which taught in relation to the seasons; old books such as Gilbert White's 'Selborne,' and Richard Jeffreys's on to Thoreau's and Thomson's; or books again like 'Through the Fields with Linnæus,' a more important and observant naturalist than any of the present century, with the exception of Darwin. These gave descriptions of the actual world, while all our science back to geography, back to astronomy, was a study of the world through the seasons. He pointed out how in the train from Edinburgh to Dundee one might get not simply a little section of Scottish scenery, but a very large section of the scenery of the world. Any park around them was an example of the southern slopes of the great mountains, of the pastures leading up to the forests in a moderately temperate climate. On the rock-work they had alpine plants, such as made Switzerland the garden of the world. The bits of scenery by the shore, too, were worth noticing, sometimes as at Aberdour Woods the forest sloped down to the sea, or came out into barrennesslike great regions of Northern Russia and of Lapland, the desert of the north. There were the dry regions with the heather, and the wet ones with the willows. In the patch of sand-dunes they had not simply the little landscape they saw but the level shores of northern Europe, just as one coming from Edinburgh and looking up the Forth might see something of the coast of Norway, while the Firth of Tay was the great fiord of the Northern world. And so in one's busy town-life, one had the possibilities of gardening and the possibilities of seeing not only local scenery but the scenery of the world.

Adjourning to the Professor's laboratory, Mr. Smith demonstrated by a simple apparatus the formation of carbon dioxide in the germination of beans and, by another apparatus, the liberation of oxygen by green leaves submerged in water. After attending the ordinary college lecture on botany, the company entered brakes provided by Professor Geddes, and drove by Lochee to Balruddery, the beautiful country seat of Mr. Martin White, M.P., situated about six miles from Dundee. Here they were conducted by the Professor over the hot-houses and through the gardens and grounds, and then walked through the picturesque Den of Balruddery and back to the Conservatory, where tea was served at 6.30 under the superintendence of Mr. Smith and Miss Ritchie. About 8 p.m. the company started to drive back by the Perth road through the village of Invergowrie, and amid the beautiful scenery of the Tay valley, reaching Dundee just in time to catch the 9.10 p.m. train for Edinburgh, where they arrived about 11 p.m. The drive to Balruddery, both going and coming, was enlivened by songs and choruses, and on the Dundee departure platform Mr. McBain proposed a very hearty vote of thanks to Professor Geddes, which was accorded with great enthusiasm and musical honours. Notwithstanding some rain, the day's outing was greatly enjoyed, the splendid hospitality of Professor Geddes being highly spoken of, and Mr. Hay, the Secretary, and his committee deserve hearty acknowledgment of the admirable way in which all the arrangements were carried out.

EDINBURGH PHARMACY ATHLETIC CLUB.

ANNUAL SPORTS.

The fifth annual sports took place in splendid weather, at Powderhall, on Tuesday, May 26, at 6.45 p.m., in presence of a large gathering, among others present being Mr. J. Bowman, President of the Chemists' Trade Association, and Mrs. Bowman. In the 300 yards flat race handicap for apprentice members the first prize was won by Mr. R. Scott, and the second prize by Mr. J. M. Foote. In the 120 yards open flat race handicap, for which 78 entered, the third prize was gained by Mr. G. Somerville, of the Pharmacy Athletic Club. In the half-mile flat race handicap confined to members of the club, R. Scott (Pinkerton, Gibson, and Co.) was first, and A. G. Paterson (Raines, Clarke, and Co.) second. W. J. Walker was first and James Laughton second in the one mile bicycle handicap confined to the trade. In

the 220 yards flat race handicap confined to the trade W. B. Hendry was first, and J. M. Foote second. A new feature of the sports was the final tie of a five-a-side football competition, which fell to be decided between teams representing Duncan, Flockhart and Co. (North Bridge) and Duncan, Flockhart and Co. (Canongate), which resulted in 2 goals and 1 point for the latter to 0 for the former. Mr. Donald Mackenzie (T. and H. Smith and Co.) presided at the presentation of prizes, and in a few words congratulated the club on the successful turn-out. The prizes were then handed to the successful competitors by Miss Smith, and the proceedings closed with a vote of thanks to Mr. Mackenzie for presiding, and three cheers for Miss Smith, which were heartily accorded on the motion of the Honorary Secretary, Mr. J. P. Gibb, to whose exertions the success of the gathering is mainly due.

EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION.

ANNUAL MEETING.

The fourth annual meeting of the Association was held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Friday, May 22, at 9 p.m., Mr. Peter Boa, President, in the chair. The minutes of the last meeting were read and approved, and on the motion of the Hon. Secretary, Mr. Wm. Spence, Howe Street, was elected a member.

The Honorary Secretary (Mr. C. F. Henry) read the annual report and financial statement, from which it appeared that there was now a membership of sixty-five, being an increase of six. Amongst the subjects which had engaged the attention of the Association during the year had been the relationship between prescriber and dispenser, on which an interesting discussion was initiated by the Chairman's opening address. As the result of a communication from the Decimal Association, a petition in favour of two of the three objects aimed at by that Association, namely, the legalising of the metric system of weights and measures for all trade purposes and the introduction of the metric system at an earlier stage in the ordinary school curriculum, had been sent by the Association to a Member of Parliament. The Association had also passed a resolution thanking the Council of the Pharmaceutical Society for the efforts it was making to amend some of the evils of the one-man company system. The Association had also considered and approved generally of Sir John Lubbock's Shop Hours Bill. The label book of the Association now contained 291 specimen labels indicating the decision of the Inland Revenue authorities as to the question of liability to stamp duty. For the first time the Edinburgh Chemists' Ball had been carried through by the Association, and had been a decided success, there being a balance of £4 4s 9d., and the balance of £27 from the former Ball Committee had been handed to the Association. The Association had also given facilities and assisted the Proprietary Articles Trade Association to hold a meeting of the retail drug trade in Edinburgh.

On the motion of the Chairman, seconded by Mr. D. McGlashan, the report was unanimously adopted.

The financial statement showed a balance in favour of the Association of £47 5s. 7d., and on the motion of Mr. Maclaren, seconded by Mr. J. McGlashan, it was unanimously adopted.

Mr. Lunan moved, and it was seconded by Mr. R. J. Macdougall, that a donation of £3 3s. be given to the Benevolent Fund of the Pharmaceutical Society.

Mr. J. T. Coats suggested, and it was unanimously agreed, that £2 2s. be given to the Benevolent Fund and £1 1s. to the Orphan Fund.

Mr. Maclaren then reported for the Committee as to the annual picnic, which, it was suggested, should take the form of a circular tour. It had been arranged to leave Edinburgh (Waverley) at 9 a.m. by train for Craigendoran, which would be reached at 10.35. Then they would take steamer up Loch Long to Arrochar and walk across, two miles, or take 'bus to Tarbet, Loch Lochmond, which would be reached at 1.45. Dinner and tea would be served in the spacious hotel, and they would, about 5 p.m., sail down Loch Lomond to Balloch and reach Edinburgh about 9.23 p.m., travelling by Buchlyvie, Stirling, Alloa, and the Forth Bridge. It was also suggested that members of the Glasgow and West of Scotland Pharmaceutical Association might be invited to join the excursion, and that the tickets should be 10s. 6d. for Edinburgh, and 8s. 6d. for Glasgow.

After some discussion the report was approved of and remitted to the Committee to be carried out.

The following office-bearers were elected for next year:—John Bowman, President; David MacLaren, Vice-President; Claude F. Henry, 1, Brandon Terrace, Secretary and Treasurer; and Messrs. Anderson, Boa, Forret, Glass, R. L. Hendry, D. McGlashan, J. McGlashan, Wylie, Smith, Macpherson, McDougall, and Lunan, as members of Committee.

The meeting closed with votes of thanks to the Pharmaceutical Society, the Ball Committee, and the Chairman.

NOTTINGHAM AND NOTTS. CHEMISTS' ASSOCIATION.

The annual meeting of this Association was held in the Masonic Hall, Nottingham, on Wednesday, May 20. There were present:—Mr. R. Fitzhugh, J. P. (President, in the chair), Mr. T. Mason (Vice-President), Mr. Wilford (Treasurer), Mr. Eberlin (Hon. Secretary), Messrs. Bolton, Beilby, Beverley, Cook, Gell, Lumby, Middleton, R. and W. Widdowson, Jackson, Smith, Adams, etc. The Secretary read his report, which showed the Society to be in a very flourishing condition. The evening meetings held throughout the winter had been well attended, and papers of much interest read. The pharmaceutical classes held at the University College had also been well attended, and the reports of the same were deemed very satisfactory. The election of officers for the ensuing year resulted as follows:—President, Mr. R. Fitzhugh; Vice-President, Mr. A. Middleton; Treasurer, Mr. J. Wilford; Hon. Secretary, Mr. A. Eberlin; Council, Messrs. Bolton, Beilby, Beverley, Cook, Gell, Gascoyne, Mason, and Sergeant. Votes of thanks were accorded to the retiring officers, also to the Pharmaceutical Society for the donation of the *Pharmaceutical Journal*, and the British Pharmaceutical conference for the 'Year-Book of Pharmacy.' Mr. R. Widdowson read an interesting paper on "Legislation in Pharmacy," the discussion on which was postponed to the next meeting.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—The monthly meeting of the Council was held on Wednesday, the 6th instant, at 67, Lower Mount Street, Dublin. The President, Mr. W. H. Wells, Junr., presided, and there were also present the Vice-President (Mr. Downes) and Messrs. Grindley, Beggs, Murray, Evans, Conyngham, Bernard, Whitla, Professor Tichborne, and Kelly.

The President reported what had taken place in connection with the case of the Society *v.* Wilson, of Rathfriland, in which two convictions had been obtained against the defendant, one for selling poison without being qualified to do so, and the other for keeping open shop. The defendant appealed to Newry Sessions, and in the course of five successive adjournments the Judge, after pressing the Society's Counsel as much as he could to accept one penalty and accept a dismissal in the other case, and on one occasion said, "I will upset you if I can," eventually on the last day of the sessions said he would dismiss one of the cases, but that he felt bound by a decision, to which he referred. He (the President) considered such a course of conduct disgraceful. It was not the first time that judges in the north of Ireland had tried to coerce the Society. There was another case to which he wished to refer. In September last a defendant named Noonan appealed to the Privy Council for a reduction of a penalty which had been imposed on him. On November 18 the Privy Council wrote stating that they did not see their way to reduce the penalty. The petty sessions clerk was then written to to collect the penalty, but up to the present the magistrates had refused to sign the necessary warrant for that purpose. Their last statement on the subject was that it would be "signed on the next court day." He thought these matters deserving of the attention of the Lord Chancellor and the Government.

Mr. Murray said the Lord Chancellor had no control over county court judges, but he had over magistrates.

Mr. Haynes said the best course was to put these matters in the hands of some of their Members of Parliament.

Mr. Bernard said that if the warrant for the collection of the penalty in Noonan's case was not signed at once they should apply to the Queen's Bench division for a *mandamus*.

The President called attention to a statement which had been made on oath by a pharmaceutical chemist some months previously, at an inquest on a child in the city, to the effect that he had prescribed for the child. He was asked whether his licence entitled him to prescribe, and he said it did not, but he claimed the right to do so because he had served his time to his father, a qualified medical man. The Coroner said he was aware that it was the habit of pharmaceutical chemists in Dublin to prescribe, and the matter had since been referred to in the *Irish Times* as if that were the case, and by the *Medical Press* as if the responsibility of putting down the practice of "counter prescribing" devolved on the Society and its Council. They had no power whatever, the President said, to do so. None of them had any sympathy with the practice. It could be more effectually dealt with by the Apothecaries' Hall and the other medical bodies.

Professor Tichborne, Mr. Conyngham, and Mr. Murray repudiated the statement that "counter prescribing" was practised by the respectable members of the Society in Dublin or the country. The President said the editor of the *Medical Press* had not been unfair to them in the matter, for, he said, "We are well aware that the most respected members of the Irish Pharmaceutical Society have always discouraged counter prescribing, but neither they nor the Council of the Society have been able to prevent it." Mr. Murray thought a letter ought to be written to the *Medical Press*, contradicting the statement that members of the Society prescribe, but Professor Tichborne said it was sufficient to repudiate it on the part of the Council.

Other business having been disposed of, the Council adjourned.

PHARMACEUTICAL CHEMISTS' AND APOTHECARIES' ASSISTANTS' ASSOCIATION OF IRELAND.—At the last meeting of this Association, Mr. H. Harris read a most interesting paper on "Coca," at the conclusion of which there was some friendly criticism by Messrs. Hardy, Hunt, Ash, and the Chairman, Mr. J. B. Alister, M.P.S.I., followed by a cordial vote of thanks to the writer, who suitably replied. The session is now suspended until the end of August next, as many of the members will be leaving Dublin for the holiday season. A committee meeting will be held to consider the date of adjournment, and also to decide when the winter session will begin.

FOREIGN AND COLONIAL NEWS.

NUISANCE FROM ANIMAL REFUSE.—The attention of the Public Health Council of the Department of the Seine has been called to the nuisance caused by the animal refuse accumulating in the course of the day in the shops of butchers, etc., during the summer months, no less than 25,000 kilos of this animal matter (almost always in a more or less putrid state) being manipulated daily in the neighbouring manufactories at Aubervilliers alone, which largely contributes to produce what is euphoniously termed the "Odours of Paris." It was stated that the disagreeable smells would be efficiently suppressed if the resolution of the Council, passed in October, 1892, were carried into effect. It was then proposed to compel the use by butchers of a 2 per cent. solution of chloride of zinc in which all *débris* would be immersed. This, while preventing putrescence would not interfere with the employment for industrial purposes of this refuse. The following resolution was unanimously adopted:—This Council renews the recommendation made in October, 1892, and insists on the urgency of its realisation, and upon the utility of applying the same to all districts in the Department of the Seine.

DEATH OF M. LEFORT.—The ranks of pharmacy have suffered a severe loss by the death of M. Jules Lefort, which occurred suddenly at Pierrefonds. M. Lefort was born in 1819, and received his diploma of "Pharmacien de 1ere Classe" in 1845, when he commenced business at Ganat (Allier). In 1850 he acquired the well-known Pharmacie Seguin at Paris, and during his business career the title of Lauréat was four times conferred upon him by the Académie de Médecine for original communications of pharmaceutical interest. He retired from business in 1862 in order to devote himself exclusively to scientific researches, and published numerous papers on the various subjects embraced by pharmacy. He was best known, however, by his extensive study of the composition of natural mineral waters, his 'Traité de Chimie Hydrologique' being a standard book of reference. He was successively Vice-President

of the Paris "Société d'Hydrologie Médicale," Président of the Société de Pharmacie et de Chimie, Member of the Académie de Médecine, and he was also named Chevallier of the Legion of Honour.

SECOND INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—On July 2 this Congress will open in Paris. In addition to strictly technical questions the Congress will discuss the analytical processes needed for the guidance of manufacturers and the benefit of the consumer. The proceedings will be conducted in ten sections, and judging from the number and interest of the questions which will be brought up in each, there will be no lack of work. The sections represent such diverse subjects as chemical products, pharmaceutical products, electro-chemistry, colouring matters and dyeing, metallurgy and mining, sugar refining, vintery, brewing and distilling, agricultural chemistry, photography, alimentation, and milk supply. The Association des Chimistes du Sucrierie and de Distillerie, which is organising the Congress, has formed a committee, comprising several members of the French Government and a large number of members of the Institute, together with many of the foremost men of science and industry of France.

NEW BACTERIOLOGICAL LABORATORIES.—The Minister of War has decided to create three new bacteriological laboratories, viz., at Marseilles, Bordeaux, and Rennes. The necessary experts will be appointed from the staffs of the nearest technical establishments already existing.

STERILISATION OF RIVER WATER.—A decision has been arrived at by the Paris Municipal Council concerning the offer made by Baron Tindal to sterilise river water for Paris consumption by his ozone process. This process has already given excellent results in Holland, where water from the Rhine is treated. The inventor proposes to instal, at his own risk, the apparatus necessary to sterilise 5000 cubic metres daily, and guarantees that the water shall be free from all germs, colourless, of natural and agreeable taste, whilst the amount of organic matter shall be reduced at least 30 per cent., and the water shall contain no noxious matter resulting from the method of treatment. The cost is not to exceed 2½ centimes per cubic metre, and the royalty demanded will be 1½ centimes per cubic metre for all water treated during fourteen years for the use of the city of Paris. In the event of the trial being unsuccessful, or of the decision by the experts appointed that the conditions are not duly fulfilled, M. Tindal undertakes that the city shall be freed from all expense, and that the installation shall be displaced and the original works restored at his personal charge. The Council has decided to adopt this system of purification on the conditions stated, with the proviso that M. Tindal shall have no ground for claim in the event of his method being superseded by any other within the term proposed.

THE RÖNTGEN RAYS IN SOUTH AFRICA.—As yet, South African scientists have not been able to put the Röntgen rays to any practical test, although Professor Holm promises the Cape Town Philosophical Society that he will do so shortly. At a recent meeting of the Society Mr. Trotter said he had been experimenting with Dr. Hahn, but, so far, without success. He believed that in time they would be able to produce light without heat, which was now only done by the glow-worm and fire-fly. There were many points in the discovery of far more importance than photography. For instance, he said, they could locate the injury to a limb, and the attention of scientists was now being directed to the velocity of the propagation of these rays and their wave length. Luminous paint, he mentioned, would emit these Röntgen rays when exposed to light or heat.

CAPE COLONY'S NEW MEDICAL BILL.—An announcement was published in a recent issue of the *Cape Colony Government Gazette* to the effect that a Bill is to be brought in to repeal certain sections of the Medical and Pharmacy Act, 1891, and to make other provisions in lieu with regard to the Colonial Medical Council and Colonial Pharmacy Board. Some alterations are proposed in the method of electing members of the Colonial Medical Council and Pharmacy Board, but chemists and druggists will be more particularly concerned with Clause 5, which regulates the conditions under which it is proposed to allow the medical practitioner to act as his own dispenser. The clause is printed below:—

"Every medical practitioner registered under the said Act shall be entitled to practise as an accoucheur and dentist, and may compound and dispense medicines prescribed by himself or any other medical practitioner with

whom he is in partnership or with whom he is professionally associated, either as principal or assistant, upon payment to Government of an annual licence fee of £2 10s. sterling, provided that no medical practitioner shall be required to pay any annual licence fee for merely compounding or dispensing any medicines prescribed by him for and on behalf of the Government. And upon payment by any such medical practitioner of the annual licence fee required by law to be paid by a chemist and druggist (in which case he will not be required to pay the fee before-mentioned in this section), shall be further entitled under such licence or any removal thereof to practise generally as a chemist and druggist, subject to any provisions relating to chemists and druggists contained in the said Act, and provided that he shall not be entitled to dispense medicines prescribed by any medical practitioner with whom he is in partnership or with whom he is professionally associated either as principal or assistant."

Writing in the *Cape Times*, a "Pharmacist" says one of the Bill's chief provisions is to create a whole army of chemists and druggists from the rank and file of the medical profession, not by the imposition of a four years' apprenticeship and a searching examination which pharmacists have to undergo, but by the mere stroke of the pen. What a fuss was made by certain medical men when by a similar legal process their rights were infringed by Parliament in 1891 on the passing of the Act above referred to. He concludes by hoping that chemists throughout the Colony will see that the Bill, which is to be submitted to Parliament during the ensuing session, does not pass the Legislature in its present form, and suggests that meetings of protest be convened in every town towards that end. The proposal is regarded in some quarters as monstrous, and whilst Cape Colony doctors are making great effort to get the Bill passed, the pharmacists see the growing danger of such a measure becoming law, and are strenuously opposing it. The *Cape Times* observes that this is "an attempt on the part of a section of the faculty to obtain the free and unrestrained right to sell medicines—or feeding bottles—as they please, and it will be interesting to see how far public and professional opinion will support them in their endeavour. The prospect is by no means an unalluring one for young and struggling doctors in a country where the Old World prejudice against the counter is a less powerful factor to be reckoned with. But *prima facie*, it certainly seems to press with hardship on pharmacists who have been compelled to pass a stiff examination, from which the medical man will be exempt."

THE CAPE OF GOOD HOPE MEDICAL COUNCIL has just issued its 1895 report, and comments upon the substantial advance made during the past year compared with 1894. Last year there were 62 applications for licences to practise at medicine compared with 39 of 1894. In connection with the subject of the amendment of the present Act, the Council reports that strenuous, but unfortunately again unsuccessful, efforts were made during the past year to secure Parliamentary sanction for those changes which experience has indicated to be necessary, and which have been represented in various reports. To facilitate the preparation of an amending Act the Council has had its proposals drawn up as a Draft Bill, and although duly framed by the Government last year, it was not laid before Parliament, but more than likely will be this season.

CORRESPONDENCE.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal should be sent to the Secretary.—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the Journal, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper, only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematical names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt. The Editor cannot undertake to reply to queries through the post.

THE JOURNAL AND THE SOCIETY'S FINANCIAL STATEMENT.

Sir,—Methinks the Society's financial statement places the Journal in a false light, or rather in a black hole, inasmuch as it is made to bear the whole burden of a debit balance of £2761. Whereas if the number of those to whom it is sent without the credit of any financial return—members, associates, students, honorary and corresponding members of the Society—be taken into account, the sum of the number of half-guineas would exceed the considerable sum of £3000; leaving a surplus and happiness, in the logic of Dickens. The President, in stating that the Journal was sent post free to all connected with the Society, failed to recognise the density of many of us, provincials, who might consider that the word "free" pertained to the postage only, and did not include the Journal also. Of course, this should be known to all the Society's adherents, numbering some 6000; but other trade journals have been weaving hysterical romances and trying to make capital out of the expensiveness of the Society's organ, and I like to play fair.

Glasgow, May 25, 1896.

ALEX. LAING.

THE PHARMACEUTICAL EXAMINATIONS.

Sir,—More than a quarter of a century since I had the audacity to forward a letter to the *Pharmaceutical Journal* expressing in forcible language my feelings of disappointment and disgust at the miserably inadequate arrangements for examining candidates in dispensing and pharmacy existing in 1868. In that letter I traced the wretched state of the arrangements to the "oleaginous complacency" of the Bloomsbury Square "ring," and truly described the dispensing facilities "as equalling in dirtiness and incompleteness those to be found in the most neglected pharmacy in the East End." The letter was not published, but the condition of things was altered. I have waited for more than a year, carefully examining each issue of the Journal, to see if any of the official set at the "Square" had anything to say about the increase in the proportion of rejections of candidates for the Minor examination, and without result. Everything appears to be for the best, to the best of all possible people, at the best of all possible "squares," and really one feels reluctant to disturb the beautiful serenity which still prevails at our superior mutual admiration society. To me this question of rejections appears to be a very serious matter, and worthy of the consideration of all concerned, and it certainly is a question ripe for discussion.

In the first place one cannot help feeling that an examination is faulty which permits men to pass who are hastily and imperfectly prepared, and rejects many who have had adequate practical experience of the business

and have passed at least a complete session at the "Square." I know several cases of both sorts. The following cases appear to me most disquieting. Three men at full age have at different times during the last three years gone to the "Square" for preparation. They all had received an unusual amount of practical experience and had probably dispensed not less than 5000 prescriptions each. They were all of full age, in sound health, worked hard during the whole session, and I am sure no professor could say a word against them. Yet notwithstanding all this they have been rejected from three to five times. I know other cases where men of comparatively little practical experience, supplemented with four months' tuition at a "School," have gone straight through.

This state of things, shown by the proportion of rejections, cannot be satisfactory to anybody, except it be to the Treasurer of the Pharmaceutical Society, and although, after looking through the accounts, I am not without a feeling of sympathy for this official, it does not appear to me to be very high-class finance to depend upon knocking over an increasing number of pharmaceutical ninepins at five guineas a time, to balance accounts which show evidence of want of prudential management.

Now, sir, can any light be thrown on the causes making for this deplorable state of things? I should at once like to state that I desire that the examinations should jointly be a real test of a candidate's fitness to undertake the responsibilities of our calling. But at the outset of our inquiry we ought to know whether the increased proportion of rejections is caused by increased stringency of the examinations or by defective teaching, and I think it must be attributed to the former rather than the latter cause; for although I am not able to say that the teaching methods at the "Square" are perfectly satisfactory, I am prepared to state that the teaching is quite as thorough now as it was when the rejections were only fifty per cent.

In the first place it appears to me important to ask the question, How do the examiners as a body view the responsible duties they have to perform? Do they try to find out what a candidate knows, and whether it would be prudent to entrust him with a certificate, or do they try to find out what a candidate does not know? This is more important than appears on the surface, and an examiner who treats the work of preparation and examination as opposing and antagonistic forces has a very imperfect acquaintance with his real duties.

And may I be permitted to ask this question? Are all the examiners qualified by sufficient knowledge to examine? Is there a single examiner able honestly to examine a candidate in botany as now taught, except the professor who takes charge of this subject? Do the examiners keep strictly to the syllabus? To this question I can give a most positive "no." Instances are not wanting to show that extraneous subjects are dragged in, and although they may not be used to reject a candidate directly, they often unfit him nervously for doing his best and thus lead to the same result.

I know of an altercation that took place at a recent examination as to whether the preparation of syr. ferri iodidi made in a water bath was P.B. or not—the examiner stating it was not, and the candidate (who adopted this method from excess of caution) holding the reverse. Surely this was excess of duty and a pettiness on the part of the examiner. If that examiner were to attempt to prepare syr. ferri iodidi strictly P.B. (as to vessels used) in my shop, he would probably be removed. The second day of the examination, as long as the present conditions last, should be by written papers, as the most difficult part of this second day's business is to work out the personal equation of each examiner. Having once passed the first day a candidate ought not to be expected to go through the practical examination again, and it ought not to be in the power of one examiner on the second day to reject a candidate; the candidate should have the right of appeal. A candidate is sometimes rejected on matters of opinion, not on matters of fact. It is unfair to the candidates to be a long time in the examination rooms waiting to be called; many men have thus become nervously exhausted before the examination is half over.

It is unfair and unnecessary to charge full fees for examinations after the first unsuccessful attempt, and as long as this is the case, and the examination cannot be passed in two steps, the Council must not be surprised to find an opinion prevalent that this is permitted to continue for the value of the shekels it brings to the Society's coffers. There are other matters still untouched, but I must omit them at present, as I should not like to conclude this highly critical contribution without offering some constructive suggestions as to the future.

I would venture to suggest that the examinations should be three in number, as at present:—

1st. Educational, as at present.

2nd. Practical, as first day of Minor examination, qualifying for assistantship under a "Master in Pharmacy."

3rd. Theoretical (written) qualifying as a "Master in Pharmacy" (*Ph. Mag.*), who alone should keep open shop, and then only with his own capital, or capital for which he has the sole responsibility.

Hertford, May 25, 1896.

GEORGE R. DURRANT.

Sir,—It seems generally conceded that the pharmaceutical examinations are unsatisfactory all round. If we commence with the "First" examination, this is really an absurdity as it stands at present, and a totally inadequate test of the school training of the would-be pharmacist. The title should be the old one, the Preliminary examination, and should be fully equivalent to the Medical Preliminary. Until the Society have power to enforce such, I would suggest that the "First" examination be divided into two parts. The examination as it now is might be known as the Preliminary examination, lower grade; and the second part be called the Preliminary examination, higher grade. The papers given should contain for the "lower grade" the present form; and for the "higher grade," which would for a time be optional subjects, the additional papers making the examinations equal to those of the medical preliminaries. This would be appreciated by most candidates. Those who have passed the "lower grade" to be allowed to take the extra subjects required for the higher grade" at any subsequent time and at a reduced fee. The "Minor" examination is known by an absurd title, which is quite an insulting term for an examination requiring considerable study and time to pass it. The term "Minor examination" should be entirely dropped, and a more dignified name used, such as "the qualifying and practising examination," or other suitable term. The present form of this examination is an improvement upon what it was a short time back, but is not stringent enough for a qualifying examination, and certainly requires adding to. It is imperatively necessary in the public interest to prevent "crammed" or book-learned aspirants getting through by mere chance.

The Major examination is not as popular as it ought to be. The title of pharmaceutical chemist given to those passing this examination is not much more than a useless title, and little benefit is in reality obtained by passing it. I think the Minor examination should be practically what the Major is at present, and the Major examination should be more confined to chemistry and analysis, including urinalysis, the detection of poisons, the microscopical examination and culture of disease germs, microscopy, etc. This examination should be more than equal to those required to become a F.I.C., and be such as doctors and the public would have confidence in. A class of trained chemists much needed would thus be created, and a boon conferred on physicians and patients. Botany, etc., should be more stringent in the Minor, and be left out in the Major. The title should be distinctive, such as "The Analytical and Honours Examination of the Pharmaceutical Society," and those passing such might be known as "Analysts and Doctors of Pharmacy." There would thus be created a reliable body of trained men, who would doubtless have preference as public analysts, chemists to public bodies and large works, and be an ever constant inducement to the "Minor man" to study for and to pass the highest examination.

Moss Side, Manchester, May 19, 1896.

P. N. GELSTON.

DECOCTUM CINCHONÆ.

Sir,—If not too late for the new Pharmacopœia I would suggest that the decoctions be ordered for eight ounces instead of a pint. Of course more water must be taken or there will be danger of burning the contents of the pan. This is how I make decoctum cinchonæ—

Red bark, in 20 powder ½ oz.

Distilled water 13 ozs.

Boil for ten minutes in an "open" vessel, stirring with a glass rod for the first five minutes of the boiling period, cool, strain through linen, and pour distilled water over the strainer to make eight ounces.

This would more nearly correspond to the infusions, for by taking 10 ounces of the water we usually obtain about 8 ounces, and decoctions or infusions are mostly ordered in 6 oz. or 8 oz. mixtures, or gargles. It is rarely necessary to make a pint of decoction for one prescription. I do not suggest an open vessel for all decoctions, that of cinchona is especially troublesome, and

should always be made in a fairly large pan. It is generally understood that decoctions and infusions should be made as required, not from So-and-So's liquor or concentrated infusion. I recently dispensed an 8 oz. mixture with 4 oz. inf. cascarillæ, and the patient complained of the intense bitterness of my mixture compared with what had been supplied in another town. The mixture was repeated after some explanation, but it might have ended in my not seeing that client again.

Wolverhampton, May 25, 1896.

J. CLOWER.

THE METHODS OF A FIRM OF TRANSFER AGENTS.

Sir,—In the interests of the trade I enclose you a circular received from Messrs. ——— the transfer agents, and from inquiries made I find similar letters, identical in composition, have been sent to many others. Yesterday, being at Halesworth and Southwold, I found both businesses in each town had been applied for by the gentleman desirous of purchasing a business in those localities. I send, herewith, two copies of Messrs. ———'s letters, and I trust that in addition to this letter you will append one of them.

Stowmarket, May 26, 1896.

GEO. JAS. GOSTLING.

[COPY OF LETTER ENCLOSED.]

London, E.C., May 23, 1896.

G. J. GOSTLING, ESQ.

Dear Sir,—Having a gentleman desirous of purchasing a business in your locality, we have taken the liberty of writing to ask if you would feel disposed to sell yours; we trust you will pardon our asking the question, but if you should feel disposed to sell we shall be pleased to send our client to see you. We make *no charge* unless we introduce a purchaser, and then 5 per cent. on the first £100, and 2½ on the balance of the purchase money. If you will sell, kindly favour us with particulars in the *strictest confidence*; our client can pay cash.

Waiting favour of reply,

Yours faithfully,

———— AND CO.

CORRECTIONS.

MIDLAND PHARMACEUTICAL ASSOCIATION.—Mr. A. C. Weaver of Wolverhampton, points out that his name was misspelt "Wheeler" in the report of the annual meeting of this Association, on page 414. The name was printed as it appeared in the report sent.

THE "SILVER YEN."—In the Journal for March 7, on page 198 it was stated, on the authority of Whitaker's "Almanack," that the Japanese silver yen is equivalent to about 4s. 3d. English money. A Brighton correspondent pointed out at the time that, as a matter of fact the yen is worth only about half that amount, and this is now confirmed by a Shanghai correspondent, to whom we are obliged for the correction.

OBITUARY.

BEESLEY.—On May 15, at West Street, Banbury, Thomas Beesley, Chemist and Druggist. (Aged 78.)

MITCHELL.—On May 12, at Glasgow, William Mitchell, Chemist and Druggist. (Aged 29.)

RIDLEY.—On May 15, at Ipswich, Albert Cowell Ridley, Chemist and Druggist. (Aged 60.)

MEDCALF.—On May 17, Benjamin Medcalf, Pharmaceutical Chemist, of Ware. (Aged 79.) Mr. Medcalf joined the Society in 1842, and has ever since manifested a loyal interest in its affairs.

ALLEN.—On May 20, A. Underwood Allen, Pharmaceutical Chemist, of Lymington. (Aged 74.) Mr. Allen had been a member of the Society for forty-three years.

HOARE.—On May 25, Charles Francis Hoare, Chemist and Druggist of Derby.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs Atkinson, Blythe, Buchanan, Calvert, Coull, Culley, Clower, Durrant, Eberlin, Edgson, Gelston, Guyer, Gostling, Harrison, Hill, Lewis, Llewellyn, Laing, Merck, Naylor, Nightingale, Rowell, Smith, Turner.

Several letters and answers to queries are unavoidably held over until next week.

RUMEX NEPALENSIS, WALL.*

BY DR. O. HESSE.

The roots of this plant are largely employed in Madras and other parts of India for medicinal purposes and for dyeing, on account of astringent properties. Mr. D. Hooper was of opinion that they contain chrysophanic acid, but after Hesse had shown that the chrysophanic acid of *Parmelia parietina* is a substance different from that contained in rhubarb, he requested Hesse to repeat his experiment, and supplied him with a quantity of material for that purpose. The results of the investigation have now been published in Liebig's 'Annalen,' and it appears that the substance present in these roots is not the chrysophanic acid of rhubarb, though closely analogous to it. Hesse suggests for it the name "rumicin," and for two other substances which are associated with it the names "nepalin" and "nepodin."

For the extraction of these constituents the crushed roots were digested with hot ether in a flask fitted with a flux condenser until the ether acquired a deep yellowish-brown colour. On cooling, the liquid crystals were deposited, and a further quantity was obtained on evaporation. This crystalline deposit was then treated with a water solution of potassium carbonate, the dark brown liquor being filtered out of access of air to prevent alteration. On addition of hydrochloric acid in excess, and shaking with ether, nepodin was dissolved, together with some amorphous material, and when the residue undissolved by the potassium carbonate solution was boiled with acetone, rumicin was dissolved, while most of the nepalin was left in the residue.

RUMICIN.—The acetone solution above mentioned deposited on cooling greyish-brown, granular, and laminated crystals, which melted at 182° C. When separated from mother liquor by washing with acetone, they were dissolved with hot benzene, the solution mixed with three or four times its volume of petroleum spirit, boiled for a time, and then filtered to separate a brown flocculent substance. On cooling the solution crystals were deposited, and by re-crystallisation from benzene and petroleum spirit, the substance was sufficiently purified for analysis, which gave results leading to the formula $C_{15}H_{10}O_4$.

Rumicin has the form of yellow laminar crystals of metallic lustre; it dissolves readily in hot alcohol acetone or glacial acetic acid, slightly at the ordinary temperature, readily in chloroform, and scarcely at all in petroleum spirit. It melts at 186°—188° C.; with potash solution it gives a purple-red solution which is gradually decolourised by exposure to the air in consequence of absorption of carbonic acid and separation of the rumicin. With a water solution of potassium carbonate it gives a faint rose colour. Heated with alcoholic potash it dissolves, and on cooling the solution deposits fine purple prisms, which soon become yellow by exposure to the air. Rumicin dissolves in concentrated sulphuric acid, and on addition of water is deposited unaltered in yellow flocks. Heated with hydriodic acid, no alkyl iodide is formed, but a substance identical with that produced under the same conditions from chrysophanic acid—chrysophan-anhydanthron.

The only difference between rumicin and chrysophanic acid appears to be in the melting point. They might be regarded as physical isomers, but as yet Hesse has not succeeded in converting the one into the other.

NEPALIN.—The substance separated as above described may be purified by solution in hot benzene, adding three or four times the volume of petroleum spirit and boiling for some time; a dark

brown flocculent deposit separates, and the clear solution on cooling gives crystals of nepalin, which can be further purified by crystallisation from glacial acetic acid.

Nepalin forms orange-coloured microscopic crystals, melting at 136° C. to a red liquid: it is not volatile and does not contain water of crystallisation. Analysis gives results leading to the formula $C_{17}H_{14}O_4$.

In treatment with acetic anhydride nepalin forms a crystalline acetyl derivative, $C_{17}H_{12}(C_2H_3O)_2O_4$, milky at 181° C.

NEPODYN* may also be purified by treatment with benzene and petroleum spirit. It crystallises in long greenish-yellow prisms, melting at 158° C. Its composition is represented by the formula $C_{18}H_{16}O_4$. The acetyl derivative, $C_{18}H_{14}(C_2H_3O)_2O_4$, crystallises in rhombic plates of a pale yellow colour, and melts at 198° C.

These results show [that *Rumex nepalensis* contains substances quite different from those existing in the allied species of *Rheum* from which rhubarb is derived.† This latter drug contains chrysophanic acid, $C_{15}H_{10}O_4$; emodin, $C_{15}H_{10}O_5$; and rhein, $C_{15}H_{10}O_6$; differing in the relative proportions of oxygen, while the rumex constituents differ in the carbon. The opinion that the rumicin obtained from other varieties of rumex is identical with chrysophanic acid‡ is considered by Hesse to be without sufficient foundation, although the circumstance that rumicin and chrysophanic acid both yield the same product on treatment with hydriodic acid requires further investigation.

THE DETECTION OF COPPER IN VEGETABLE SUBSTANCES.

BY DR. B. H. PAUL AND A. J. COWNLEY.

There is an interesting paper, by Dr. Victor Vedrödi, in the *Chemiker Zeitung* of May 16, on this subject, in which the author questions the accuracy of the method followed by Professor Lehmann for the determination of copper in vegetable substances. Dr. Vedrödi claims to have obtained by his method one hundred times as much copper as that obtained by Lehmann. Considering that an accurate determination of small quantities of copper in vegetable and in alimentary substances generally is of the highest importance, in view of the discrepancies in results which not unfrequently occur in cases of prosecution under the Sale of Food and Drugs Act, these different results of Vedrödi and Lehmann require some consideration. Taking for example Vedrödi's results as to the amount of copper in natural peas, he finds 90 milligrammes and 150 milligrammes per kilo as the minimum and maximum amounts, or, in other words, 0.9 and 1.5 per 10,000, the last figure in many cases representing more than the amount of copper which is used to artificially preserve the colour of green peas, and, as Lehmann points out, Vedrödi's result is ten times as much as Tschirch found in vegetables which had been grown in intensely coppered soil.

Lehmann's method for the determination of copper in vegetables consists in mineralising the vegetable material with concentrated sulphuric acid, and determining the copper colorimetrically, either with ammonia or with ferrocyanide, according to the amount of copper present. Vedrödi, on the other hand, burns the material in a muffle furnace for 8 hours or until mineralised, takes up with hydrochloric acid, passes sulphuretted hydrogen, and burns the pre-

* This name, formed from "Nepal" and "Emodin," is intended to suggest the resemblance to emodin shown by the separation with potassium carbonate from its associates.

† *Pharm. Journ.* [4], i., 325.

‡ v. Than, *Annalen der Chem.*, 107, 324.

* Translated from a paper in the *Annalen der Chemie*, 291, 306.

cupitate to oxide. In both methods there is a liability to error. Lehmann's method is open to the objection that copper is very liable to be left undissolved by the sulphuric acid. In Vedrödi's method it is uncertain that the hydrochloric acid will take out all the copper from the ash constituents; moreover, all that is precipitated by SH_2 is regarded as copper. A very ready and accurate method we have found consists in carbonising about 100 grammes of the material in platinum, extracting the ash with strong hydrochloric acid, filtering through an acid-washed filter, washing the filter with hot water all into a porcelain dish. The residue, which is insoluble in hydrochloric acid, is treated with a few drops of strong nitric acid, then dried and ignited. The ignited mass is treated with strong hydrochloric acid, and the filtered solution is added to the first portion. In this way there is no loss of copper as is likely to occur from the reduction of the copper salt to metallic copper when the carbonisation is being carried out, and its subsequent insolubility in sulphuric and hydrochloric acids, as in Lehmann's and Vedrödi's methods.

The hydrochloric acid solution, after concentrating to about 30 to 40 C.c., is placed in a weighed platinum dish and the copper precipitated by pure zinc. If the deposited copper after weighing is not of a pure copper colour, it is dissolved in a little nitric acid made up to a known quantity, and the copper determined colorimetrically in an ammoniacal solution. In this way the following results showing the amount of copper found in various alimentary substances have been obtained.

	Part of Metallic Copper.	Parts of the Substance.	Parts of Copper in 10,000 of the Substance.
OYSTERS—			
Portuguese	1	in	3,450
Whit-table	1	"	5,500
Dutch	1	"	5,500
Plymouth	1	"	3,300
COCOA—			
Pure Cocoa (free from husk) ..	1	"	21,000
Cocoa containing Sugar and Starch	1	"	17,000
" " " " "	1	"	34,000
BRANDY—			
Sample No. 1	1	"	185,000
" 2	1	"	928,000
" 3	1	"	208,400
" 4	1	"	852,720
WHISKY—			
"	1	"	224,850
PRESERVED PEAS—			
Sample No. 1	1	"	6,980
" 2	1	"	8,770
" 3	1	"	9,020
" 4	1	"	17,500
" 5	1	"	18,420
" 6	1	"	7,140
" 7	1	"	10,520
" 8	1	"	10,520
" 9	1	"	8,000
" 10	1	"	10,520
" 11	1	"	14,280

These results and others show that the amount of copper in preserved peas varies considerably. Some of the samples were also guaranteed not to have been treated with a copper salt.

For comparison with the above results as to the amount of copper found in preserved peas, it may be as well to add Vedrödi's figures as to the amount of copper he found by his method in various vegetable substances:—

	Copper.	
	Parts per ten thousand.	
	Min.	Max.
Winter Wheat	2.5	8.6
Summer Wheat	2.5	3.0
Barley	0.1	0.9
Linseed	1.4	1.9
P. as	0.9	1.5
Mustard Seed	0.9	1.0

So that according to Vedrödi there is more copper naturally present in many vegetable substances than is found in vegetables to which it has been added to preserve their natural colour.

AINU MEDICINAL PLANTS.

(Concluded from page 148.)

Upen (*Seseli libanotis*, Koch, var. *sibirica*, DC.).—This herb has a strong smell and flavour, and is described as a useful medicine for every complaint. It grows in dry places, especially on sandy beaches, and the root is the part used. In times of epidemic diseases it is much sought after by the Ainu on account of its reputation as a preventive of illness, in which it is said to act as a charm. The writer says: "I have often seen the natives chewing it, and found it hanging up in huts to keep off sickness. During a time when small-pox was raging, I saw a dog with some tied to his collar driven round a house." This plant may be taken at any time in place of tea or water and is indeed often preferred; a decoction is usually taken by steeping the herb in hot water and is so taken in cases of severe cold. Some of the old Ainu mix small pieces of the root with their tobacco to improve its flavour.

Yakara-kina or Mo-shiu-kina (*Angelica refracta*, Fr. Schm.).—The plant is found in wet or damp situations. The root-stock is the only part used, and it is generally taken in the form of a decoction by cutting it up in very small pieces, which are put into hot water, and the decoction thus made is drunk, herb and all. It is said to be especially valuable for pains in the stomach, as well as for diseases of the chest. It is sometimes put into soup and eaten as food.

Chima-kina (*Aralia cordata*, Thunb.).—A decoction of the root-stock is used in some parts for washing wounds inflicted by bears and other animals, and after washing, fresh slices are often applied to the wounds.

Oinamat (*Adenocaulon adhaerescens*, Max.).—The leaves, softened by warming at a fire, are generally applied when a person is poisoned by the sumach or *Rhus*.

Noya (*Artemisia vulgaris*, L.).—The stem and leaves are boiled in a pan, and the patient is made to inhale the steam with a cloth covered over his head and the pan until he or she freely perspires. Sometimes in similar affections a decoction of the stems and leaves are drunk. A moxa is also made by pounding the leaves. The plant is considered a charm against evil, especially against disease, and is frequently seen hung up in houses.

Kamui-noya (*Artemisia sacrorum*, Ledeb., var. *latiloba*, Ledeb.).—This particular form of *Artemisia* grows chiefly on rocky cliffs and sometimes on the sandy banks of rivers. It is sub-shrubby in habit, and has a strong medicinal odour. It is largely used in medicine by the Ainu of Kushiro, Kitami, and Teshio.

Makayo (*Petasites japonicus*, Miq.).—A strong decoction of the flower shoots, which are very bitter, is often taken for heavy colds. They are also used sometimes as an article of food.

Seta-korokoni (*Arctium lappa*, L.).—The young leaves, softened by rolling them in the palms of the hands, are applied to skin eruptions; boiled they are also occasionally eaten as food.

Ikema or Penup (*Cynanchum caudatum*, Max.).—This plant is used both for food and medicine. It is said to be good for any complaint, but is a special remedy for small-pox. To wounds of all kinds a thick decoction when applied is said to prevent the formation of pus. Half-cooked roots are said to have an intoxicating effect and to cause loss of all control over the limbs, and to do away with the sensation of the skin. The root is dried and stored up for future use, but it is sometimes taken fresh, either roasted or boiled, and it is said to have a very sweet taste. In time of epidemic sickness the root is chewed in its raw state, and the juice blown from the mouth, sometimes upon and over the afflicted person; sometimes all over the inside of the hut, and through the doors and windows; and sometimes again

round the house, and even whole villages. When so used it is supposed to act as a kind of charm to drive away the demon of sickness; those who use this plant so are generally intoxicated by it. It is also said to be very efficacious as an antidote to poison. As an article of food it is used very sparingly, and always well cooked.

Chiukomau (*Physalis alkekengi*, L.).—The smashed fruits are applied as a poultice for pains in the hips.

Seta-endo (*Elsholtzia cristata*, Willd.).—The decoction of this highly aromatic plant, which is commonly found around the huts of the Ainu, is prescribed to persons suffering from the after-effects of intoxication. It is also used in the place of tea.

Shumnu-hash (*Lindera hypoglauca*, Max.).—Among some Ainu this plant is looked upon as a good remedy for stomach ache, and has a very nice smell and flavour. The wood is broken up fine and boiled, and a dose taken when cool. Sometimes, however, the decoction is poured over rice or millet, and taken. The Japanese names for this plant are Kuromoji or Torikoshiha, the first of which has become somewhat familiar in this country of late in connection with the oil of *Lindera sericea*, Bl., so that the common name seems to be applied to both species.

Ketu-hash (*Daphne chinensis*, Lam., var., *breviflora*).—The whole plant is reputed poisonous, but especially the berries and root. Some Ainu burn the roots to charcoal and reduce them to powder, which is applied to bruises or places where there is any internal pain, but it is never applied to cut wounds.

Ni-haru (*Viscum album*, L.).—The Ainu, like many nations of northern origin, hold the mistletoe in peculiar veneration. They look upon it as a medicine good for almost every disease. It is taken either in food or separately as a decoction. The leaves are used in preference to the berries, the latter being of too sticky a nature for general purposes. Some Ainu have been known to use the mistletoe leaves merely for tea without any reference to their supposed medicinal properties, while others sometimes mix it with their stews. By many of the people the plant is supposed to have the power of making the gardens bear plentifully. For this purpose the leaves are cut up into fine pieces, and after having been prayed over, are sown with the millet and other seeds, a little also being eaten with the food. Barren women have also been known to eat the mistletoe in order to be made to bear children. That mistletoe which grows on willows is supposed to have the greatest efficacy, because the willow is considered by the Ainu a sacred tree.

Kamui-tat (*Betula ermani*, Cham.).—The bark of this species of birch can be peeled off in very thin layers; these papery layers are sometimes pasted over wounds in place of plasters. They are said to possess good healing properties, and to prevent inflammation.

Nitat-kene (*Alnus japonica*, S. et Z.).—A decoction made by steeping the bark of this tree in hot water is said to be good for pains in the stomach. Ainu women take a dose of this medicine immediately after childbirth. It has a very bitter taste.

Ura-susu, or Urai-susu (*Salix multinervis*, Fr. et Sav.).—The fresh bark of this shrubby willow is widely used by the Ainu for application for cut or bruised surfaces. The bark is cut into fine shreds and plunged for a short time in hot water to make it soft. It is then applied to the wound, and is retained there by a bandage. The bark is renewed from time to time.

Yai-ni, or Nup-kurun-ni (*Populus tremula*, L.).—The fresh bark is cut into fine shreds and applied to cut wounds to prevent the formation of pus.

Shungu-unkotuk (*Picea ajanensis*, Fisch.).—The resin of this pine is used by some of the Ainu for applying to cut wounds to hasten their healing.

Nimak-kotuk (*Cremastra nallichiana*, Ldl.).—The root of this

orchid is used as a remedy for toothache; it is merely chewed and then expectorated. It is of a very sticky nature, and clings to the teeth very tenaciously, hence its name "Nimak," teeth, and "kotuk," to adhere to. Sometimes a stiff paste or ointment is made of this plant, and spread over swellings and boils as a remedy, but it is not very much appreciated, and seldom used if other remedies are at hand. A strong glue is made from the roots by pounding them well.

Shuwonte (*Smilax herbacea*, L.).—The application of the softened leaves is said to heal affections of the eyes; they are also applied to skin eruptions and wounds.

Etoruratskip (*Polygonatum giganteum*, Dietr., var. *falcatum*, Maxim.).—A piece of the root-stock is sometimes put into the mouth of a child who suffers from laceration of the tongue and lips, and is allowed to remain there until the pain is relieved.

Pukusa or Hurarui kina (*Allium victorialis*, L.).—This plant is said to be especially useful as a remedy for colds. It is also sometimes to be found hung up in doorways and entrances, and by windows as a charm against epidemic disease.

Surngu-kusuri (*Acorus calamus*, L.).—The root-stock is extensively used by the Ainu as a medicine. A decoction of it is said to cure pains in the stomach caused by drinking bad water or by eating improper food. It is also valuable in colds and head-ache.

Shiu-karush or Kui-karush (*Polyporus officinalis*, Fr.).—This fungus grows upon larch trees, and has a very bitter taste. It is chewed and rubbed into painful places, and is also taken in decoction as a remedy for stomach ache. It comes chiefly from the Kurile Islands, and was greatly prized by the old Japanese doctors.

The foregoing are the chief plants recorded as of medicinal value amongst the Ainu people, who, in the matter of drugs, seem to have a smack of Chinese custom.

SELL YOUR OWN FILLED CAPSULES.

BY EMILE P. FERTE.

The retail pharmacist can just as well as not (and to his profit) sell his own filled capsules of cubeb oil, sandalwood oil, oleoresin copaiba, etc. I use the regular cylindrical shape, having had poor success with the soft, egg-shaped ones.

Procure a well-seasoned board about 1 Cm. thick and make as many holes in it as the number of capsules you wish to fill at one time. It is a good idea to make holes to accommodate the different sizes of capsules, in the same board. Nail a thinner board on one side which is to be the bottom. Have the holes just large enough to hold the capsule without squeezing too hard. Put the empty capsules in the holes and proceed to fill.

Use small (I use 50 C. c.) bottles fitted with the patent stopper-pipette (used as eye-droppers) and keep the oils in them. One pipette-full will fill from three to six capsules, and it can be done without getting any on the outside of the capsule. Do not fill too much. Let the upper part of the meniscus be just below the upper edge of the capsule. To seal, use a camel hair pencil and the following solution:—

Gelatin (Cox's).....	10 grms.
Gum Acacia	50 grms.
Acid Boric.....	1 grm.
Distilled Water q.s. to make.....	100 C.c.

Use slightly warmed (about 40 C.).

I have attained better results with a mixture of gelatin and acacia than with either alone. Experience will teach one just how much to use, which should be sufficient to make a good seal, yet not enough to "slobber." Put the cover on with a spiral motion, pressing gently.—*Spatula*.

THE MAKING OF TABLETS.*

BY FRANK EDEL.

(Concluded from page 384.)

Materials of a hygroscopic nature should be granulated with acacia.

Five-grain Tablets Sodium Salicylate.

Sodium Salicylate	500 grs.
Powdered Acacia	25 grs.

Mix, moisten with water, pass through sieve and dry. Lubricate with vaseline; when dry pass through sieve, and just before compressing add 25 grs. powdered talcum; make 100 tablets.

The bisulphate of quinine is usually preferred to the sulphate for making tablets because of its greater solubility, and also because it needs no preparation for compression other than the lubrication with vaseline and addition of two per cent. talcum.

Headache Tablets.

Acetanilide	300 grs.
Caffeine.....	50 grs.
Sodium Salicylate	400 grs.
Sugar	50 grs.
Acacia.....	25 grs.

Powder freely and mix; then moisten and pass through sieve and dry. Lubricate with vaseline, and when dry pass through sieve again. This makes a good headache cure, for putting up as a remedy to replace the headache cures of the market.

Tablets which contain considerable quantities of extract of liquorice require no additional adhesive added, and should be lubricated with vaseline if necessary.

Granular potassium bromide, iodide, and chlorate, and ammonium chloride are easily compressed without any preparation, requiring also no lubricant.

Tablets can also be made from monobromated camphor, and also of potassium permanganate, by reducing them to granular form so that they will pass through a No. 20 sieve, and compressing.

Tablets containing chemicals which are likely to react on each other in a moist condition are best made by granulating the different materials separately, and then mixing the granulated powders, and compressing. Or, in case the chemicals are insoluble in some liquid, rub them to a fine powder; after granulation, mix thoroughly, and granulate by moistening with some liquid in which neither chemical is soluble. In this way tablets of calomel and sodium bicarbonate are best prepared.

Tablets Calomel and Sodium Bicarbonate.

Calomel.....	100 grs.
Sodium Bicarbonate	100 grs.
Acacia	10 grs.
Powdered Sugar.....	30 grs.

Mix the calomel and 15 grains sugar, moisten and dry. Mix the soda with acacia and balance of sugar, moisten and dry; then rub the two to a fine powder, mix, and granulate by moistening with alcohol, then dry. Make 100 tablets.

Sodium bicarbonate can be made into tablets by granulating with 8 or 10 per cent. powdered acacia. Tablets of charcoal are best made by granulating with 20 per cent. sugar and 5 per cent. acacia moistening thoroughly and carefully drying.

There is a large class of tablets in which the medicinal part constitutes but a small portion of the tablet, the balance being sugar of milk. These are best made by adding a few drops of simple syrup and mixing, then completing the moistening with water. Some, however, prefer to use 10 per cent. of powdered sugar and moisten with water alone.

In tablets containing fluid extracts or tinctures, it is best to add the required amount of liquid to a small amount of starch, mix

thoroughly, and then add sugar of milk to make to required weight. When the amount of tincture is excessive, an equivalent amount of fluid extract should be used, and where even this would be excessive, it is necessary to continuously evaporate it to a soft extract before adding the starch and milk sugar.

If extracts are to be incorporated in tablets, it is handiest to use the powdered extracts, but if these are not at hand the extract should be rubbed to a soft consistency, a suitable starch added and thoroughly mixed, and the proper amount of milk sugar then added, the whole being finally granulated, dried, and compressed.

Throat Tablets.

Oleo-Resin of Cubebs	2½ grs.
Balsam Tolu	20 grs.
Oil Sas-afra	10 min.
Extract Liquorice.....	700 grs.
Powd. Ammonium Chloride.....	250 grs.

If the balsam of tolu is soft, cool with ice and powder by rubbing with a small portion of the ammonium chloride, then add the liquorice and the rest of the ammonium salt and mix, reducing to fine powder; add the cubebs and oil sassafras and mix thoroughly; finally moisten with water and granulate. Make 100 tablets.

This makes a superior tablet for the throat and voice, and can be put up as a special remedy in place of similar proprietary goods largely sold.

The best base for making hypodermic tablets is pure cane sugar. This is much more satisfactory in every way than either dried sodium sulphate or chloride, it is also much more soluble than milk sugar. They are best lubricated with powdered boric acid, using only a small amount, from one to two per cent.

Tablets of creosote are made by adding the creosote to starch, mixing thoroughly, then adding the required amount of milk sugar and granulating.

If it is desired to make effervescent tablets, they can be made in two ways: 1. The material can be prepared exactly as in making effervescent salts, and granulated by moistening with alcohol, then rubbing through a sieve and drying. This should be lubricated if necessary with vaseline.

2. The materials (that is the alkaline and acid parts) can be granulated separately, and when dry the two are mixed by agitation and compressed.

Tablets Lithium Citrate.

Lithium Citrate.....	300 grs.
Sodium Bicarbonate.....	300 grs.
Tartaric Acid	275 grs.
Powdered Sugar.....	275 grs.

These should be all thoroughly dry before mixing, then thoroughly mixed and moistened with alcohol, passed through a No. 20 sieve and dried thoroughly, next passed through a sieve again and made into 100 tablets; or the lithium citrate, 125 grs. sugar and the soda, can be mixed, moistened with water, granulated and dried, and the acid and the rest of sugar mixed, granulated, and dried; the two granulations being finally mixed thoroughly by agitation, passed through the sieve and compressed.

One of these processes must be used if it is desired to add small quantities of acid (citric or tartaric) and alkali to tablets in order to increase their solubility. Tablets containing sulphur are best granulated with both sugar and acacia; if carefully dried they need no lubricant.

Tablets Sulphur (Comp.).

Sulphur	500 grs.
Cream Tartar.....	200 grs.
Extract Ipecac.	1 gr.
Extract Capsicum	1/5 gr.
Acid Arsenious	1/10 gr.

* Copyright, 1896, by the Spatula Publishing Company, and reprinted by special permission.

Bisulph. Calcium	12½ grs.
Powdered Sugar	50 grs.
„ Acacia	50 grs.

Mix and moisten with water, then pass through sieve and dry, finally pass through sieve again. Make 100 tablets.

Tablets Hypophosphites (Comp.).

Calcium Hypophosphite	16 grs.
Potassium „	24 grs.
Manganese „	16 grs.
Iron „	24 grs.
Quinine Hypophosphite	7 grs.
Strjchnine „	1 gr.
Powdered Sugar	40 grs.

Mix the hypophosphites, moisten slightly, and rub to fine powder; add the sugar, mix and moisten carefully, pass through sieve, and dry. Lubricate with vaseline when dry, and pass through sieve again. The above is calculated to make 128 tablets. These can be increased in size by adding more sugar or milk sugar.

If the pharmacist will only use that care that he should use in his every-day work, he will find but little difficulty in preparing any tablet he may wish to. In tablet making, however, as in everything else, a little experience goes a great way in overcoming difficulties.

REVIEWS AND NOTICES OF BOOKS.

CASSELL'S NATURAL HISTORY. Part I. Pp. 76, illustrated. Price 6*d.*
(London: Cassell and Company, Limited. 1896.)

It is truly wonderful what enormous value can nowadays be obtained in encyclopædic works on popular science. The publishers of this work occupy a leading position in such enterprise, but they have probably never excelled the present undertaking, which is to supply a splendidly got-up natural history containing 2500 quarto pages and about 2000 high-class illustrations for thirteen shillings. The first weekly part deals with the man-shaped apes—the gorilla, nschiego mbouvé, koolo-kamba, soko, chimpanzee, orang-utan, gibbon, and siamang, the writer of this section of the work being the editor, Professor P. Martin Duncan, M.B., F.R.S. The matter is well printed on paper of very fair quality, and besides the numerous letterpress illustrations there are full-page engravings and coloured plates, which have been carefully prepared from authentic sources. The text is written in the simplest language possible, and numerous anecdotes serve to render the work interesting as well as instructive.

THE TAX-PAYERS' CASH BOOK. By ALFRED M. SCARF, Fellow of the Society of Accountants and Auditors. Price 2*s.* 6*d.* net (Cloth, 3*s.* 6*d.*). (London: The Income-Tax Adjustment Agency, 12 and 13, Poultry, Cheapside, E.C. 1896.)

There is, without doubt, a real need amongst tax-payers for such a book as this, which embodies an easy system of book-keeping for small trading concerns, with full instructions and examples for ascertaining profit and making returns for Income Tax, as well as preparing accounts in support of an appeal against Income Tax overcharges. The author rightly urges that every retail trader should know the exact amount of his purchases, sales, and expenses, month by month, and that an analysis of the expenses should be made at least once a year, showing the rent, rates and taxes; salaries and wages; carriage of goods; gas and fuel printing and stationery; advertising; stable expenses, repairs, etc., etc. "If, in addition to this, the stock be carefully taken once in each year, there can be no doubt that the comparison which the trader will be able to make of the business done in the various months of the year, and of the expenses under the different headings, will enable him to avoid the evil of overbuying on the one hand and excessive expenditure on the other." Much other perti-

nent advice is also given, and followed by a concise statement of the procedure to be followed in connection with Income Tax payments. Then there are specimen cash accounts for one week, with statements of affairs and forms of trading profit and loss accounts for a year, the rest of the book being taken up with the specially-prepared forms for keeping the weekly accounts. These are well planned for the purpose, being arranged to show full particulars of all private and business receipts and payments, with till and bank accounts, and there is also a space for memoranda. Nothing more simple, and yet accurate, could well be devised, and the cash book can be strongly recommended.

MODERN OPTICAL INSTRUMENTS AND THEIR CONSTRUCTION. By HENRY ORFORD. Pp. 100. Price 3*s.* (?) (London: Whittaker and Co., 2, White Hart Street, Paternoster Square, E.C. 1896.)

According to the preface, the main object of the author has been to place before the reader a descriptive outline of a few of the more popular optical instruments in use. The eye as an optical instrument is first considered, a brief general description being followed by details respecting the iris, retina, crystalline lens, the refraction of the eye, accommodation, and binocular vision. Next in order, the properties and aberrations of lenses are considered, then aberrations of the eye, ophthalmoscopes and their uses, and the various forms of ophthalmoscopes. Retinoscopy, a means of objectively determining the quantity of any error of refraction, has a special chapter devoted to it, as have also spectacles and their selection, illustrated descriptions of various forms of spectacles, stereoscopic projection, the principles of the optical lantern, the stereoscope, and the spectroscope. The book, which is fully illustrated throughout, is written in plain and simple language, and will be found exceedingly useful by students and practising pharmacists. The author is already well known for his work entitled 'Lens Work for Amateurs,' a practical and trustworthy guide to the subject of which it treats, and he cannot fail to add to his reputation by the one now under consideration.

ELEMENTARY INORGANIC CHEMISTRY, THEORETICAL AND PRACTICAL, with a course of chemical analysis and a series of examples in chemical arithmetic, by A. HUMBOLDT SEXTON, F.I.C., F.C.S., etc. Fourth edition. Pp. viii., 366. Price 2*s.* 6*d.* (London: Blackie and Son, Limited, 50, Old Bailey, E.C. 1895.)

This little book is one of that numerous class of works produced for the purpose of enabling a student to pass a particular examination, and in many respects the author has spoiled what might otherwise have been an excellent elementary manual by always keeping in view the fact that he was writing up to an examination schedule, all parts of the subject outside that schedule being carefully avoided. The first few chapters deal with explanations of terms, first principles, and chemical physics, and on the whole the elementary student will find this part a good introduction to general chemistry, but faults are apparent in many places. In discussing the properties of matter, for instance, a good deal is said about weight and the methods of measuring it, but no definition is given of mass. The word mass is not used at all until some ten pages further on in connection with the expansion of bodies, where we are told that "the increase of volume is proportional to the increase of temperature, and to the mass of the substance at 0°." Again, the law of Avogadro is stated without any account of the reasons we have for believing this law to be true. The explanation given of the molecular theory of matter is clear and interesting, and the comparison of the elements to letters and their compounds to syllables and words is probably original and will enable the learner to understand how from so few

elements such an infinite variety of compounds may be obtained. The bulk of the work consists of a more or less systematic course on certain of the elements and their compounds. Many of the chapters on the non-metals are clearly and carefully written, and as full as is desirable in an elementary work, while the summaries at the end of the chapters will be found very useful. But the treatment of the different parts of the subject is most disproportionate. The only metals considered are sodium, potassium, ammonium, calcium, iron, zinc, lead, and copper, and thirteen pages are considered by the author sufficient in which to treat of these substances and their compounds, while the chapters on the non-metallic elements and their compounds occupy 168 pages, one page being devoted to the consideration of argon. Hydrogen is included among the non-metals, and no word is said of the many reasons there are for considering it to be a metal. Carbon, on the other hand, is on page 32 included by inference among the metals, this being evidently due to a slip of the pen.

The second part of the book contains the description of a series of experiments that the student is advised to perform, to illustrate the subjects considered in the first part of the book; the third part deals with chemical arithmetic, and is useful as far as it goes; the fourth part consists of questions on the previous work; and the fifth of an incomplete and unsatisfactory course on qualitative analysis. The sixty or more diagrammatic illustrations with which the work is embellished are distinctly good in principle and execution, and are far more suitable for the purpose than the pictures with which works on chemistry are usually provided.

THE HISTORY OF SURGICAL ANÆSTHESIA. BY H. BELLAMY GARDNER, M.R.C.S., L.R.C.P. Pp. 31. Price 1s. (London: Baillière, Tindall and Cox, 20 and 21, King William Street, Strand. 1896.)

In view of the forthcoming jubilee celebrations of the application of ether in Boston and of chloroform in Edinburgh as anæsthetics, this little book possesses considerable interest, giving as it does an authentic account of the origin and progress of surgical anæsthesia. Quotations are first given from writings by Homer, Herodotus, Dioscorides, Pedanius, Pliny, Galen, Lucian, Hoa-Tho, Cletius, Hugo de Lucca, and others, in which reference is made to the use of various drugs for producing sleep and insensibility to pain. During the middle ages some degree of anæsthesia was probably produced, previous to operation, by means of narcotic drugs or even by inhalation. Compression of the nerve trunks and hypnotism were resorted to later, but it was not until the renaissance of chemical research in the eighteenth century that the discoveries were brought about which have culminated in our knowledge of the anæsthetic agents of the present day. Dr. Michael Morris described some of the effects of sulphuric ether in 1758, Priestley discovered nitrous oxide in 1772, and later Humphrey Davy found that the gas appeared capable of destroying physical pain. Forty years elapsed, however, before this suggestion was put to the practical test by Horace Wells, a dentist of Hertford City, Connecticut, U.S.A., who inhaled some of the gas, and whilst under its influence had a tooth extracted without pain. Subsequently, he used gas successfully among his patients. Dr. Morton, of Boston, one of Wells' pupils, used ether vapour as an anæsthetic in 1846, and in December of that year Mr. Squire administered ether to two patients in University College Hospital, by means of an apparatus he devised for the occasion, while Lister, the famous surgeon, amputated a thigh in one case, and removed an in-growing toe-nail in the other. In November, 1847, Dr. J. Y. Simpson, of Edinburgh, having found ether somewhat irritating to the bronchial mucous membrane, was led to experiment with chloro-

form, which he tried in some thirty cases, and found to possess many advantages over ether. Bichloride of methylene was introduced by Sir Benjamin Ward Richardson in 1877, and strongly advocated by him as an anæsthetic, but has not been used to any great extent. Concerning local anæsthesia, induced by applying cocaine and other substances, the author does not treat, but the numerous facts stated in so limited a space possess a special attraction to everyone interested in the progress of the surgical art and the aid rendered to it by chemistry.

NOTES AND FORMULÆ.

MAGNESIUM PAPER FOR PRODUCING FLASH LIGHT.

Powdered magnesium is sprinkled over impermeable paper covered with starch paste, and dried face to face. After drying, a sheet covered with potassium chlorate is pasted on each side of the first sheet, and another sheet serves as a covering for the whole, which now forms a thick layer which is cut into strips. On lighting the end a brilliant light is obtained. This paper is said to be quite safe and to keep well (*Papier Zeit.*).

RESORCINOL.

Under this name Biélaieff (*Vratch*) describes a compound obtained by melting together at 104-110° C. equal volumes of resorcin and iodoform. The resorcin melts first and slowly combines; the reddish-purple compound when cooled and powdered affords a red-brown powder with a not unpleasant odour, completely soluble in ether, partially dissolved by water. Resorcinol does not possess the caustic action of resorcin, and neither the disagreeable odour nor the toxic action of iodoform. The author advocates the use of resorcinol for dressings in those cases where frequent changes of the bandages are undesirable, and in the case of suppurating wounds where the tissues are markedly disintegrated (*Nouv. Rem.* xii., 8).

PILLS OF SODIUM IODIDE.

Anhydrous sodium iodide, 4 grammes; powdered sugar, 40 centigrammes; distilled water, 1 gramme; powdered starch, 60 centigrammes. Rub the iodide and sugar together, add the water in one lot, mix, add the starch, and mix well. Remove the mass from the mortar while soft and lay it on the pill machine, well dusted with starch powder. Roll quickly and dry in a warm capsule (*Journal de Pharm. d'Anvers*, lii., 18).

PATENT FUMIGATING PASTILLES.

A patent has recently been taken out (Pat. No. 23,210, Nov. 30, 1894, J. Wheeler) for the manufacture of a combustible material for scenting and medicating the atmosphere from the epidermis of the *Betula alba*, or white birch. In order to make it into pastilles or cones for burning it is mixed with ground pumice or fire clay and nitrate of potash. The ground epidermis is also mixed with lobelia, stramonium, tea, and potassium nitrate and chlorate for use in treatment of asthma.

STEARATES OF THE ALKALOIDS.

Zanarch proposes the employment of the stearates of morphine, cocaine, and atropine, which he obtains by dissolving molecular equivalents of these alkaloids, and of stearic acid in alcohol on the water bath, and allowing the stearates so formed to crystallise on cooling out (*Nouv. Rem.* xii., 171., after *Apoth. Zeit.*). Except that these salts exist in a solid form, it is not very evident that they present any marked advantages over the well-known oleates.

PHARMACEUTICAL SOCIETY

MEETING OF THE COUNCIL.

WEDNESDAY, JUNE 3, 1896.

Present :

Messrs. Allen, Atkins, Bateson, Bottle, Carteighe, Corder, Cross, Gostling, Grose, Hampson, Harrison, Hills, Johnston, Martindale, Newsholme, Park, Savory, Southall, Storrar, Symes, and Young.

MR. MICHAEL CARTEIGHE TOOK THE CHAIR.

The minutes of the last monthly meeting and of the special meeting on May 20 were read and confirmed.

NEW MEMBERS OF THE COUNCIL.

Mr. CARTEIGHE, on behalf of the Council, offered a welcome to the newly elected members, Messrs. Bateson, Park, and Symes, and remarked that the principle of territorial representation seemed to be very fairly carried out at present.

LETTERS OF ACKNOWLEDGMENT.

Mr. CARTEIGHE read letters which had been received from Professor Bayley Balfour, Professor Thorpe, and Professor Tschirch, thanking the Council for their election as hon. members, and expressing their appreciation of the honour which had been conferred upon them. A similar letter was read from Professor Planchon, one of the recently elected corresponding members.

ELECTION OF PRESIDENT.

The ballot having been taken in the usual way, Mr. Walter Hills was unanimously elected President, and he accordingly took the chair.

The PRESIDENT thanked the Council for the great honour conferred upon him, which was all the more gratifying as the vote was unanimous. Twenty-three years ago his late uncle, Mr. Thos. Hyde Hills, was elected to the same office, and it was interesting to recall the fact that on that occasion two of the present members of the Council were also present, Mr. Bottle and Mr. Hampson, the former being elected Vice President on the same occasion, and acting as such to his late uncle for three years. It was a great satisfaction to him, as it must be to his colleagues, to still have the benefit of those two gentlemen's experience at the Council table. Since 1873 the duties attaching to the office of President had in no way decreased, and they appeared to him especially weighty when he recollected that he was following one who for fourteen years had presided over the Society with unparalleled ability. No one was more conscious than himself of the many respects in which he was deficient in qualities which his distinguished predecessor possessed, but he relied on the help of his colleagues to fulfil the duties of his office with credit, and trusted that in the course of the next twelve months they would be able together to accomplish something useful, if not heroic, for the common cause.

ELECTION OF VICE-PRESIDENT.

The ballot having been taken,

MR. JOHN HARRISON

was re-elected Vice-President.

The VICE PRESIDENT said that, being the first to speak in the Council following the election of their new President, he ventured to say, as bearing upon their friend's appeal for the support of the Council during his period of office, that he felt such support would be fully and freely accorded him. As for his own re-election to the position of Vice-President, he heartily thanked his brother members of the Council for this renewed mark of their confidence. He accepted the honour in the spirit in which it was proffered, and would only say that the interest he trusted he had shown in the work of the Council during the last twelve months he would endeavour to continue throughout the coming year. If the relations which had hitherto subsisted between the new President and himself should happily be continued during their new relationships it would be to him a source of much happiness.

ELECTION OF TREASURER.

On a ballot being taken, Mr. Robert Hampson was re-elected Treasurer for the ensuing year, and in acknowledging the compliment in a very few words, he said it would be his purpose to retain their funds with the tenacity he hoped he had hitherto exercised,

and he trusted the more they supplied him with the latter the better it would be for the interests of the Society in whose progress they were all so deeply concerned.

THANKS TO THE RETIRING PRESIDENT.

The PRESIDENT said it was his privilege to move :—

That this Council desires to tender its very heartfelt thanks to Mr. Michael Carteighe for the invaluable services he has rendered to the Pharmaceutical Society as President during a term of fourteen years, and to place on record its appreciation of his self-sacrificing devotion and loyalty to the interests of the Society during that period.

He felt sure that they would all agree that no formal resolution could possibly express their feelings of gratitude to Mr. Carteighe for the exceptional services he had rendered during the last fourteen years, and the resolution, though in a few words, came from their hearts. Some few years ago, on the occasion of the presentation of Mr. Carteighe's portrait, he had the opportunity of speaking in some detail of the good work which Mr. Carteighe had effected for the Society's welfare up to that date, and he could only add that since then he had been equally active, as none knew better than his colleagues on the Council. Mr. Carteighe's name had been before the pharmaceutical world for the last thirty years, and there was no need to refer in detail to what he had done; his public work was recorded in the volumes of the *Pharmaceutical Journal* for the last thirty years. During recent years he had been very closely associated with him, and had been somewhat behind the scenes, and he should like to put on record his appreciation of Mr. Carteighe's untiring devotion, of his never-failing and wonderful cheerfulness, of his genial hospitality, of his practical and unostentatious benevolence, and, lastly, of his loyalty to his colleagues. Mr. Carteighe, as they all knew, was a man of exceptional ability and fairly strong will, but he was always ready to recognise and encourage the carefully thought-out opinions of any of his colleagues, and when, as occasionally happened, the views of the majority were not the same as his own, he accepted those views with perfect loyalty. To say more in his presence would not be to his taste, but he might assure him that he carried with him their best wishes, and that they all hoped he would retain for many years the splendid powers of mind and body which he now possessed, and that some at least of those powers would be devoted to the interests of the Pharmaceutical Society.

The VICE-PRESIDENT, in seconding the motion, said he did so with very mingled feelings, because, while recognising the eminent services which Mr. Carteighe had rendered during the last fourteen years and longer to the Society, one felt a certain sense of loss at not seeing him still in the presidential chair. Fourteen years was no inconsiderable portion of a man's lifetime, and to give that time with the profuse liberality with which Mr. Carteighe had placed his abilities at the service of the Society was a sacrifice which none could fully appreciate. Mr. Carteighe was a man who would have risen to the front in any sphere of life, and he felt that they owed him an enormous debt for having so fully and freely placed his great powers at the service of the Society. When the history of the Society for the last twenty years came to be written, one name would stand above every other—the name of the late President—and with regard to the history of the last fourteen years, it would be more prominent still. It was a serious reflection that there were not more than five or six gentlemen present who were members of the Council when Mr. Carteighe was first elected President; in fact he had almost seen a new generation of pharmaceutical councillors grow up, and to a large extent had had to form the opinions and formulate the views of those gentlemen who had been elected since he had succeeded to the chair. It was impossible to find any man who had been more loyal to the Society than Mr. Carteighe had been. In regard to educational work, he had always been in the front rank, and in protecting the interests of those engaged in pharmacy he was always active and willing to go on, whilst in the cause of benevolence no one was more eloquent or more persevering. It was not too much to say that his industry, activity, and energy commanded the admiration of all, whilst his personal qualities compelled their sincere affection. Whilst listening to the observations of the President, it occurred to him that two words would express what they all felt with regard to Mr. Carteighe, viz., genius and geniality. His genius for business they all knew, and his geniality of temperament and never-failing good humour ensured him their personal affection to a degree not often shared by the head of a public assembly. During the last fourteen years several attempts had been made to

obtain larger legislative powers for the Society, and if they had not been successful it was no fault of the late President. Whatever man could do had been done by him, but while man proposed, the disposition of affairs was in higher hands. He was quite sure that had the fates been propitious, Mr. Carteighe would have carried through legislation which would have been satisfactory to them all. Though he was now retiring from the front rank he would always occupy a very prominent position, and he felt sure that he would still assist in the prosecution of the work of the Society, and that when the time came for placing their case before Parliament he would do all he could to assist those who had the matter in hand. He also felt confident that sooner or later he would have the satisfaction of seeing that the bread which he had cast so abundantly on the pharmaceutical waters would bring forth fruit to his own satisfaction and the great advantage of the Society.

Mr. BATESON asked leave to add a word in support of the resolution on behalf of members of the Society outside the Council.

The PRESIDENT said he was sure most, if not all, his colleagues would like to speak to the resolution, but he proposed to commence his duties by being autocratic and putting the motion at once.

The motion having been carried by acclamation,

Mr. CARTEIGHE thanked the President and Vice-President for the too flattering terms in which they had spoken of him. He had now become what Mr. Reynolds called one of the old moons, and ought to put on a certain elderly and stately deportment for the remainder of his term of office as a member of Council; at any rate, he would endeavour to act as became a past President. He could assure his colleagues, one and all, that this expression of their thanks, and the kindness which had always been shown him, not only by the Council, but by the Boards of Examiners, north and south of the Tweed, and by members of the Society in all parts of the country with whom he had come in contact, were very welcome, and had been shown on many occasions in such a practical way, that the debt was really on his side.

STANDING ORDERS.

The standing orders of the Council were re-enacted for the ensuing year.

SECRETARY AND REGISTRAR.

Mr. Richard Bremridge was re-appointed Secretary and Registrar for the ensuing year.

EDITOR AND SUB-EDITOR OF THE JOURNAL.

Dr. B. H. Paul was re-appointed Editor, and Mr. John Humphrey Sub-Editor, of the Journal for the ensuing year.

CURATOR.

Mr. E. M. Holmes was re-appointed Curator of the Society's Museum for the ensuing year.

ASSISTANT-SECRETARY IN SCOTLAND.

Mr. J. R. Hill was re-appointed Assistant-Secretary of the Society in Scotland for the ensuing year.

EXAMINERS FOR THE COUNCIL PRIZES.

Messrs. Frankland, Ransom, and Seward were requested to conduct the examination for the Council Prizes competition in July next.

EXAMINATIONS FOR THE JACOB BELL SCHOLARSHIPS.

Messrs. Lucas, Bascombe, and Pinches were requested to conduct the examinations for the Jacob Bell Memorial and Manchester Scholarships.

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Ellis, John Alfred, King's Cliffe.
Folkard, Montague, York.
Hirst, Thomas, Bosccombe.

Ockwell, Edwin, Crayford.
Place, Edward Bland, Birmingham.
Woollons, Charles Henry F., London.

ELECTION OF ASSOCIATES.

The following, having passed the Minor examination and tendered or paid as "Students" their subscriptions for the current year, were elected "Associates" of the Society:—

Burgham, Harry H., London.
Chandler, Martin William, Swindon.
France, William Henry, Rotherham.
Hill, Richard Barker, Howden.

Smith, Albert George, Liverpool.
Umney, Ernest Albert, Sydenham.
Utley, Luke, Sutton.
Wrothwell, Fredk. J. H., Northallerton

ELECTION OF STUDENTS.

The following, having passed the First examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Alford, Edward, Plymouth.
Bailes, Arthur T., Stockton-on-Tees.
Bailey, Arthur Joseph, Birmingham.
Beardsley, Cyril, Belper.
Bell, Lilian A., Cambridge.
Bull, William Robert W., Bath.
Clarke, W. J., Stockton-on-Tees.
Daykin, Albert Ernest S., Ripley.
Dompé, Donato Onorato, Milan.
Edwards, George N., North Elmham.
Goeh, James Bowles, East Dereham.
Hutchings, Thomas, Launceston.
Jones, David, Kentish Town.

Jones, Henry Lloyd, Abergea.
Kidd, David Bell, Melton Mowbray.
Knight, Richard, Launceston.
Morris, George, Ludlow.
Packer, Frederick Ernest, Norwich.
Powell, Charles W., Middlesbrough.
Redfern, Harry Chaplin, Leek.
Ruff, William, Whitby.
Smith, Walter, West Hartlepool.
Stiles, Percy C. G., St. Ives (Hunts.).
Webb, Walter J., Newcastle-on-Tyne.
Wells, John James, Harrogate.
White, Frederick Ernest, Nunhead.

Wood, Robert John, Driffield.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and the minimum restoration fee of one shilling.

APPOINTMENT OF COMMITTEES.

The Council went into committee to consider the arrangement of the different committees, as the result of which the following arrangements were made:—

Gen. Purposes.—The whole Council to meet on the evening before the meeting of the Council, and at such other times as may be necessary.

Finance.—The President (Mr. Hills), the Vice-President (Mr. Harrison), and Messrs. Allen, Carteighe, Grose, Hampson, Martindale, Newsholme, Park, Savory, and Storrar.

Benevolent Fund.—The President (Mr. Hills), Vice-President (Mr. Harrison), and Messrs. Atkins, Bateson, Bottle, Corder, Cross, Gostling, Johnston, Southall, Symes, and Young.

Library, Museum, School and House.—The President (Mr. Hills), Vice-President (Mr. Harrison), and Messrs. Allen, Atkins, Bottle, Carteighe, Hampson, Martindale, Newsholme, and Savory.

Law and Parliamentary.—The President (Mr. Hills), Vice-President (Mr. Harrison), and Messrs. Allen, Atkins, Bottle, Carteighe, Cross, Hampson, Johnston, Martindale, Park, Savory, Southall, Storrar, Symes, and Young.

Standing Committee to watch Parliamentary Business and take all action thereon in the interests of Chemists and Druggists.—The President (Mr. Hills), Vice-President (Mr. Harrison), and Messrs. Allen, Carteighe, Martindale, and Savory.

Research.—The President (Mr. Hills), Vice-President (Mr. Harrison), and Messrs. Carteighe, Ekin, Martindale, and Dr. Lauder Brunton, Professor Michael Foster, and Professor Edward Frankland.

Evening Meetings.—The staff of the Society's school, the Editor, and the Curator were requested to assist the President and Vice-President in making arrangements for the Society's evening meetings in London.

REPORT OF THE FINANCE COMMITTEE.

The SECRETARY read the report of this Committee, which was of the usual character, and recommended sundry accounts for payment.

Mr. CARTEIGHE, in moving the adoption of this report, said it contained nothing to which special attention need be called. The receipts and payments were of the usual character, and the like observation applied to the Benevolent Fund, to which he might add that they had received from the Secretary to the Edinburgh Chemists' Assistants' Association a guinea to this fund. They had, he was glad to say, now sufficient funds in hand to provide for another orphan. It had always been understood and loyally observed, that canvassing for subscriptions to the Orphan Fund was to be done with the special object in view

of not damaging the Benevolent Fund. It was therefore the more pleasing to reflect that whilst they were educating and maintaining one orphan they had now enough for another. He trusted that this husbanding of their funds might lead not simply to a continuance of the existing subscriptions, but also to a substantial addition to them.

The report was then adopted.

REPORT OF THE BENEVOLENT FUND COMMITTEE.

The report of this Committee recommended grants to the amount of £33 to the following cases:—

An Associate (1841-46) who has had eight previous grants, and who suffers from chronic bronchitis and asthma. (London.)

The widow of a Member and subscriber who has had two previous grants. (Motherwell.)

A sum for the completion of the education of orphans, who have received similar aid during the last four years. (London.)

Three cases were deferred for further information, and one was not entertained.

The VICE-PRESIDENT in moving the adoption of this report said the Committee had seven cases before them the previous day. Of these cases grants were made in three, three were deferred for further information, and one was declined. He thought he might well point to one of those dealt with as an example of the great value of this Fund. One of their grantees on this occasion was a widow left with several children, who had had several previous grants amounting to £50. The result had been that three of the children were now able to provide for themselves, a fourth they hoped would soon be able to do the same, and a fifth would be in a similar position in twelvemonth's time. He trusted that these examples would enable the Council and all concerned in the interests of this Fund to take heart and renewed courage from realising what might follow from enabling their orphans to go out into the world equipped for the battle of life.

Mr. HAMPSON asked to be permitted to add to those observations bearing on the working of the Fund the gratifying intelligence that a letter had been received from the executor of the late Mr. Taylor, of Nottingham, and a former associate in business of the Society, to the effect that he had left them a legacy of £500. This announcement, he hoped, might stimulate others into following so commendable an example. He proposed that a letter of hearty thanks be sent from the Society to the relatives of the deceased, acknowledging his gratifying remembrance of and assistance in the work they were carrying out.

The PRESIDENT, in putting this to the meeting, said he felt it would be carried with cordial unanimity.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

The report of this Committee stated that Professor Attfield's nomination of Mr. C. E. Ashby as demonstrator in the Laboratories was approved, and his appointment until the end of the session was agreed to. The Committee had also appointed Mr. H. L. Lee to act as lecture-room assistant until the end of the present session.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
April	{ Day	359	21	6	15
	{ Evening	98	9	1	5
Circulation of Books.	Total.	Town.	Country.	Carriage paid.	
April	171	91	80	19s. 10d.	

Donations to the Library had been announced (*Pharm. Journ.*, May 23, p. 410), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the under-mentioned works be purchased:—

For the Library in London:—

- Pharmacopœia of Evelina Hospital.
- Wanklyn, Water Analysis, 8th edition.

For the Library in Edinburgh:—

- Wanklyn, Water Analysis, 8th edit'ion.
- Scott, Structural Botany.

Museum.

The Curator's report had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
April	{ Day	369	31	7	15
	{ Evening	24	4	1	1

Donations to the Museum had been received (*Pharm. Journ.*, May 23, p. 410), and the Committee recommended that the usual letter of thanks be sent to the respective donors.

Mr. CARTEIGHE, in moving the adoption of this report, said there was nothing in its details to which attention need be called, and the report was adopted.

THE INAUGURAL ADDRESS.

It was resolved that the selection of a gentleman to deliver the inaugural address at the commencement of the autumn session should be referred to the Library, Museum, School, and House Committee.

THE BURROUGHS SCHOLARSHIP.

Mr. CARTEIGHE announced that the stock for this scholarship had been purchased, namely, £720 in New Zealand Consols, and he said it was necessary to affix the seal of the Society to a form authorising the Bank of England to pay the dividends and the Society's bank to receive them. He moved accordingly, and the motion being put to the meeting, was passed.

GENERAL PURPOSES COMMITTEE.

Mr. CARTEIGHE said that on receipt of the intimation from Professor Dunstan of his acceptance of the position in connection with the Imperial Institute, and resigning his position as Professor in the School and Director of the Research Laboratory, the General Purposes Committee was requested by the Council to consider the relations of the Society to the School and its general education scheme. With this view the Committee appointed a sub-committee of their number, which had had a good many sittings and submitted at the last meeting a short interim report. That interim report was approved by the General Purposes Committee, and afterwards by the Council, and would form part of a complete report to be made later on, when the whole subject had been considered and it could be put in a form suitable for publication. Its chief recommendation was that in future the teaching of chemistry in the Society's School should be entrusted to one person, who should deliver lectures on chemistry and physics, have charge of the educational laboratory, and also be director of the Research Laboratory. The Council, having adopted this report, authorised the Committee to place itself in communication with the present professor of practical chemistry, and accordingly a letter was addressed to him requesting him to favour the Committee with an interview. The result was that on Professor Attfield becoming acquainted with the wishes of the Committee, and as soon as he saw the obvious advantages which would accrue to the School if their proposed arrangement could be carried out, he with very great good nature at once placed his resignation in the hands of the Council. He (Mr. Carteighe) therefore had to report on the part of the General Purposes Committee that two letters had been received from Professor Attfield, one addressed to the Chairman of the Sub-Committee and one to the Council, resigning the position he had held for thirty-four years in the Society's School; and, further, the recommendation of the Committee that a resolution of thanks be passed to the Professor for his services. Such a resolution it would be his pleasure to propose presently. What he would now move was that the report and recommendation of the General Purposes Committee, with reference to the future teaching of chemistry in the Society's School, be received and adopted. He was sure the Council would appreciate the good fortune by which it was enabled to carry out a change of this kind at the earliest possible moment, and to that Professor Attfield's prompt action had contributed in a marked degree. A further recommendation of the Committee was that an advertisement inviting applications for the appointment of a professor to deliver lectures on chemistry and physics, to superintend the practical work in the School Laboratory, and to direct the Society's Research Laboratory, be inserted in such papers as the Sub-Committee think fit, and that it be further empowered to consider and report to the General Purposes Committee on the applications received in reply to such advertisement. The General Purposes

Committee had full confidence in the Sub-Committee which had been appointed, and he had no doubt the Council would adopt the recommendation. Later on it would be the duty of the General Purposes Committee to submit a complete report on the nature of the changes proposed, but he might say that one, which had already received the approval of the Council, was that the Council should take the Laboratory into its own hands, receiving fees and paying the professors, assistants, and demonstrators whatever sums might be determined upon, reverting, in fact, to the plan which was in vogue some years ago. The object of this and other changes, which would be duly reported, was that the School should be placed under the direct control of the Council, which should be able to deal with the fees in such a manner as possibly in some cases to reduce them, and at the same time, perhaps, lengthen the course and give more instruction in the shape of practical work in the Laboratory. The Professor, also, would devote his whole time to the duties of his office. The report recommended that Professor Attfield's resignation be accepted and that steps be taken to advertise for a professor to undertake the work under the new conditions, and obviously it was not possible to deal with the matter as a whole until an arrangement had been made with Professor Attfield.

The motion was seconded by Mr. Martindale, and carried unanimously.

VOTE OF THANKS TO PROFESSOR ATTFIELD.

Mr. CARTEIGHE next moved—

That the cordial thanks of the Council be given to Professor Attfield, F.R.S. for the services he has rendered to the Society during the thirty-four years he has held the distinguished position of Professor of Practical Chemistry in the Society's School. His efforts, while holding numerous honorary offices in promoting pharmaceutical education, and in encouraging good feeling amongst all those engaged in the practice of pharmacy will always be appreciated by the Council and the members and associates of the Society.

Professor Attfield was one of the Society's early pupils. He went from their School as an assistant or demonstrator to Dr. Edward Frankland at St. Bartholomew's, and eventually came back to the Society's School in the position of director of the chemical laboratory. Up to the time of this appointment Dr. Redwood had charge of the chemical laboratory as well as of the lectures, but as he was getting older and was not able to devote so much time to the superintendence of practical chemistry as the then Council thought necessary, Dr. Attfield was appointed director of the laboratory, and subsequently professor of practical chemistry, which position, as he had already observed, he held for thirty-four years. It was very unusual for so young a man as Mr. Attfield then was to be appointed to so responsible a position, but as a fact he was looked upon as one of the rising young men from their School, and especially as being a good teacher and a good organiser; hence his appointment, though so young, to the directorship of the laboratory. His work had been of a varied kind, but probably that which he would prefer to dwell upon, that to which he devoted most of his attention, was his literary and scientific work in connection with his well-known book, and perhaps also his work in connection with the editing of the last Pharmacopœia, its addendum, and the edition now being prepared. Professor Attfield was an extremely good organiser, and a very capable man in many ways, and in saying "good-bye" to him officially they might congratulate themselves on the fact that fortune had smiled upon his efforts in various ways. Although he was retiring from this important position he was only sixty years of age, and happily was in better health than was the case some few years ago. Those who were approaching that age would probably think that it was about the prime of life, and that having done this work for thirty-four years, should he begin again they would hope it might prove free from the cares and routine attaching to teaching, and that for at least another twenty years he might enjoy uninterrupted happiness in such pursuits as he should think fit to follow. Professor Attfield was identified with the Society as one of its honorary members, having been elected some years ago, so that he already possessed the highest honour which it was in the power of the Council to bestow on any distinguished man, and he had all the privileges of an ordinary member, so that, although he would be no longer Professor, he would be in touch with the Society, and would be able to render it important assistance in many ways. They parted with him officially in the belief that he would still retain his interest in the Society, and that they might be able still to avail

themselves of his sterling common-sense and great business capacity in dealing with the affairs of the Society, especially in connection with educational matters. He had known the Professor probably as long as anyone there, though they were all his personal friends and would all join with him in wishing Dr. Attfield and his family all possible welfare and happiness in future.

Mr. HAMPSON, in seconding the motion, said he would not attempt to add to what had been said by Mr. Carteighe. He had always found Professor Attfield a man of great ability and perseverance, and he was sure his long services were appreciated by all members of the Society.

The PRESIDENT said he had asked Mr. Carteighe to take charge of this resolution because he had the subject more at his fingers' ends. It was not from any want of compliment to Professor Attfield, who was a personal friend, and he cordially echoed all that had been said by Mr. Carteighe in moving the resolution. He felt sure that Professor Attfield carried with him the best wishes of the whole Council.

The resolution having been carried unanimously,

Mr. CARTEIGHE said he must apologise for not having referred to the fact that both in his letters and in his interview with the Committee, Professor Attfield distinctly said that if he had been thirty years younger he should have offered himself as a candidate for the new appointment, but under the circumstances he felt it impossible to do so.

LEGAL BUSINESS.

The Council then went into Committee to consider the legal portion of the report, which included the usual letter from the solicitors. On resuming, the report and recommendations were received and adopted, and special resolutions were passed authorising proceedings to be taken against certain persons named.

PARLIAMENTARY INTELLIGENCE.

GRANTS FOR TECHNICAL EDUCATION.—One of the first acts of the House of Commons on assembling after its brief Whitsun recess was to order a return showing the extent to which, and the manner in which, local authorities in the United Kingdom have applied or are applying funds to the purpose of technical education (including science, art, technical and manual instruction) during the years 1894-5 and 1895-6. The return when presented will form a valuable commentary on the various Local Taxation and Technical Instruction Acts passed during recent years, and may furnish material for earnest reflection.

THE GENTLE ART OF OBSTRUCTION.—Few pharmacists would suspect Dr. R. Farquharson, M.P., of obstructive proclivities, but on Tuesday last he apparently found it necessary to vindicate his principles by a sturdy disregard to relevancy. The occasion was the consideration in Committee of the Diseases of Animals Bill, and it is recorded that the Chairman had to call the attention of the Committee to continued irrelevancy on the part of Dr. Farquharson, and to direct the honourable gentleman to discontinue his speech.

LONDON TRADESMEN ON THE SHOPS BILL.—A deputation of metropolitan retail tradesmen, representing drapers, grocers, provision dealers, oil and colourmen, pawnbrokers, watchmakers, hosiers, etc., waited upon members of Parliament interested in the Shops (Early Closing) Bill, in one of the committee rooms of the House of Commons, on Monday night last. Major Dalbiac, the Hon. H. V. Duncombe, Mr. H. S. Samuel, Mr. Money Wigram, and other members of Parliament were present, Major Dalbiac occupying the chair. It was stated that though the deputation was organised by the Voluntary Early Closing Association, it was, nevertheless, a representative body of traders, both with regard to trades and districts. Those represented protested against the Shops (Early Closing) Bill, considering it unworkable, unnecessary, inequitable, and unjust. The Bill was further objected to as being un-English and interfering with adult labour, whilst reference was made to the enormous difficulties which must of necessity arise as to the boundary of any district. It was also urged that London should be entirely excluded from the Bill, one speaker pointing out that the average draper of London now voluntarily gives his assistants forty-five working days holiday per year. Major Dalbiac and the Hon. H. V. Duncombe assured the deputation of their sympathy and support in opposing the Bill.

PHARMACEUTICAL JOURNAL.

LONDON: SATURDAY, JUNE 6, 1896.

THE COUNCIL MEETING.

THERE was a full attendance of members of the newly re-constituted Council last Wednesday, and in accordance with usual custom the chair was taken by Mr. CARTEIGHE. After the minutes of the May meeting had been read and confirmed, letters received from Professor BAYLEY BALFOUR, Professor THORPE, and Professor TSCHIRCH, the recently elected honorary members, were read, expressing their appreciation of the honour conferred. A similar letter of acknowledgment was read from Professor PLANCHON.

In the ballot for the election of PRESIDENT for the ensuing year, the votes were unanimously in favour of Mr. WALTER HILLS, who on taking the chair, and thanking the Council for the honour conferred upon him, expressed his satisfaction that two of the present members of Council, Mr. BOTTLE and Mr. HAMPSON, occupied that position when his late uncle, Mr. THOMAS HYDE HILLS, was elected PRESIDENT twenty-three years ago. Although the duties appertaining to the office of President have become more onerous since that time, and they would be especially so in following a President who has so long occupied the position with unparalleled ability, Mr. HILLS said that he should rely upon receiving the help of his colleagues in his endeavour to fulfil the duties of the office with credit, and to accomplish something useful.

In the ballot for Vice-President, Mr. JOHN HARRISON, was re-elected and, taking advantage of the opportunity thus afforded of speaking on behalf of the Council, expressed the conviction that the support asked by the PRESIDENT would be fully and freely accorded. In thanking the Council for the renewed proof of confidence afforded by their re-electing him, Mr. HARRISON said that his interest in the work of the Council would be as great as heretofore.

Mr. ROBERT HAMPSON was re-elected Treasurer, and in acknowledging this compliment, promised that his tenacity in adhering to the funds should not be relaxed.

The PRESIDENT then moved a resolution of thanks to Mr. CARTEIGHE for the services he has rendered to the Society, adding that although no formal resolution could express their feelings of gratitude for what he had done, he hoped that some at least of his splendid powers of mind and body would continue to be devoted to the Pharmaceutical Society.

In seconding this motion, the Vice-President said that it would be impossible to find anyone more loyal to the Society or more desirous of protecting the interests of those engaged in pharmacy, and he felt confident that sooner or later Mr. CARTEIGHE would have the satisfaction of seeing the bread he has cast so abundantly on the pharmaceutical waters would bring forth fruit to the great advantage of the Society.

Mr. BATESON supported the motion on behalf of members of the Society outside the Council, and on being put by the PRESIDENT, it was carried with acclamation.

Mr. CARTEIGHE, in returning thanks, assured his colleagues that this expression of their thanks was very welcome, and like the kindness he had met with in all parts of the country, it showed that the debt was really on his side.

The Standing Orders of the Council were then re-enacted for the ensuing year. Mr. RICHARD BREMRIDGE was re-appointed Secretary and Registrar; Mr. J. R. HILLS was re-appointed Assistant Secretary in Scotland; and Mr. E. M. HOLMES, Curator of the Society's Museum. As Examiners for the Council prizes, Messrs. FRANKLAND, RANSOM, and SEWARD were appointed, and for conducting the Jacob Bell Scholarship examinations, Messrs. LUCAS, BASCOMBE, and PINCHES.

The additions to the Society comprised fourteen Associates and twenty-seven students.

The report of the Finance Committee was of the usual character, and was adopted on the motion of Mr. CARTEIGHE, who mentioned that a contribution to the Benevolent Fund had been received from the Edinburgh Chemists' Assistants' Association, and that there are now sufficient funds in hand to provide for another orphan.

On the recommendation of the Benevolent Fund Committee, three grants amounting in all to thirty-three pounds were ordered to be paid, and the Vice-President, in moving the adoption of the report of this Committee, pointed out how useful grants from the Fund might be in enabling a widow left with several children to provide for their acquiring a position of independent support.

The PRESIDENT announced that a letter had been received from the executors of the late Mr. TAYLOR, of Nottingham, to the effect that he had left the Benevolent Fund a legacy of five hundred pounds.

The report of the Library, Museum, School, and House Committee contained, in addition to the usual statistics of attendances in the Library and Museum, recommendations as to the appointment of a demonstrator and a lecture assistant. The arrangements relating to the delivery of an inaugural address were referred to this Committee.

On the motion of Mr. CARTEIGHE, it was resolved that the seal of the Society be affixed to a form authorising the payment of dividends on the stock purchased in connection with the Burroughs Scholarship.

Mr. CARTEIGHE then reported the substance of an interim report made by the General Purposes Committee upon the relations of the Society to the School and its general education scheme. The chief recommendation was that the teaching of chemistry should in future be entrusted to one professor, who should also be Director of the Research Laboratory. The resignation of Professor ATFIELD having followed upon his knowledge of the decision come to by the Council, Mr. CARTEIGHE went on to report the recommendation of the Committee that the Professor's resignation be accepted, and he moved that a resolution be passed thanking him for his services, also that an advertisement inviting applications

for the appointment should be published, and that the sub-committee be empowered to consider and report to the General Purposes Committee on applications received. Pending the issue of a complete report on the contemplated changes, Mr. CARTEIGHE mentioned that the Council has already approved of the proposal that it should revert to the plan of paying the professors, assistants, etc. and taking the fees, so that the School should be under the direct control of the Council, the Chemical Professor devoting the whole of his time to the duties of his office. The adoption of these recommendations having been proposed by Mr. CARTEIGHE, and seconded by Mr. MARTINDALE, a resolution was passed to that effect.

Mr. CARTEIGHE then moved that the cordial thanks of the Council be given to Professor ATTFIELD for his services as Professor of Practical Chemistry (see p. 450), reviewing the past work of the Professor, and expressing the hope that the Council would still have the benefit of his assistance in many ways as one of the honorary members of the Society. This motion was carried unanimously.

THE GENERAL MEDICAL COUNCIL AND THE NEW PHARMACOPŒIA.

THE sixtieth session of the General Medical Council was opened on Tuesday afternoon last at the new council room, 299, Oxford Street, London, and after the Registrar had notified the Council that the appointment of Sir RICHARD QUAIN as President terminated on May 26 last, Sir DYCE DUCKWORTH, the Senior Treasurer, was appointed to the chair. Subsequently, it was resolved, on the motion of Sir WILLIAM TURNER, seconded by Mr. WHEELHOUSE—

“That Sir Richard Quain, Bart., be re-elected President of the Medical Council till the expiration of the term for which he has been nominated a member of the Council by the Crown.”

The PRESIDENT, after thanking the Council for his re-election, referred first in his address to the chief features of interest in the history of the Council. He then dealt briefly with the incidents of his “stewardship” since the previous meeting of the Council, and next proceeded to explain what had been done in connection with the revision of the Pharmacopœia. Sir RICHARD observed that whilst progress has been continuous it has necessarily been slow, in consequence of the great care that is being bestowed upon the work. The subjects brought under consideration at the meetings of the Pharmacopœia Committee have been those relating to general construction, omissions and additions, weights and measures, nomenclature, dosage, and the classification of the monographs into ten sections for revision purposes. Four such sections only are as yet in type, two of these have been revised, and two await revision. The Pharmacopœia Committee of the Pharmaceutical Society has also been engaged more or less continuously in replying to the many questions of the Medical Council’s Committee, and has already sent in three reports. It has been decided to introduce the metric system of weights and measures side by side with the imperial system throughout the general text of the Pharmacopœia, and to employ the metric system alone in the paragraphs relating to analysis. Finally, the PRESIDENT stated that, “under present circumstances, to forecast the period at which the new Pharmacopœia will be issued is impossible. In the meantime, it has been found necessary to order five hundred additional copies of the present issue.”

ANNOTATIONS.

DEATH OF SIR J. RUSSELL REYNOLDS.—The failing health which caused Sir John Russell Reynolds to relinquish the post of President of the Royal College of Physicians some two months ago has soon resulted in his death, which occurred on Friday, May 29. Dr. Russell was educated at University College, London, where he obtained three gold medals, and he graduated in the University of London in 1851, when he took the M.B. degree with honours in two sections. Five years later he was elected Fellow of University College, and subsequently Fellow of the Royal College of Physicians and of the Royal Society. He was at one time Holmes Professor of Clinical Medicine, and also succeeded Sir William Jenner as Professor of the Principles and Practice of Medicine. Elected President of the Royal College of Physicians in 1893, in succession to Sir Andrew Clarke, Dr. Reynolds was twice re-elected to that position, and has also acted as President of the British Medical Association. His name appeared in the list of New Year’s honours for 1895, a baronetcy being then conferred on him by the Queen.

DEATH OF SIR GEORGE JOHNSON.—Early in the week a report appeared that Sir George Johnson had a sudden attack of illness, and on Thursday the *Times* announced its fatal termination. Up to Monday last Sir George was engaged in writing on the subject of his treatment of cholera, but on returning from a drive in the afternoon he became unconscious, and remained in a serious condition until his death on Wednesday evening. Sir George was born in 1818, and was throughout his life connected with King’s College Medical School, both as a student and in various prominent positions, contributing largely by his researches and publications to advance the knowledge of diseases. He was made a Fellow of the Royal College of Physicians in 1850, and in 1872 a Fellow of the Royal Society; in 1889 he was appointed a physician extraordinary to the Queen, and in 1892 he received the honour of knighthood.

EUPHORBIIUM AS A CAUSTIC.—A correspondent of the *Lancet* states that the fresh milky juice from the stems of the “common garden euphorbium” is used as a remedy for warts in Normandy, and that he has been able to verify the claims made on its behalf by removing a number of warts from a girl’s hands. According to Dorvault’s ‘L’Officine,’ euphorbium resin enters into the composition of an “everlasting blister,” and is also used in some topical applications for cancer and in veterinary remedies, whilst “aveloz nült,” a cancer specialty, is composed of the same drug. The original aveloz or alvelos was, however, obtained from a Brazilian plant nearly allied to *E. euphorbia anomala*, Salzm. (*Ph. J.* [3], xv., pp. 504, 614. The two species common in English gardens, viz., *E. peplus* and *E. helioscopia*, have long been a popular remedy for warts in England, and the wood spurge, *E. amygdaloides*, is even more acrid than the two species mentioned, so that it has to be used with the utmost caution on persons with abnormally sensitive skin. The exact therapeutical action of the acrid principle present in so many of the genus does not seem to be thoroughly understood, but it appears probable that it might be turned to account in diseases dependent on local deficiency of nerve power, as in leprosy, cancer, and local paralysis, etc., and it is at all events worthy of scientific investigation. It may be worth while recalling the fact that in Brazil the local inflammation caused by alvelos milk is kept within proper bounds by the use of infusion of tobacco (*Ph. J.* [3], xv., p. 245).

THE SILVER YEN.—Referring to the value of the Japanese yen, Mr. William Shepperson writes from Aston Clinton to say that when he was in Japan in 1884-85, it depended much whether paper or silver money was in question. The silver yen is of the same value as the dollar, and varies with the fluctuations of the silver market. Mr. Shepperson visited the Mint, which he describes as a perfect one, at Osaka. This was originally the Hong-Kong Mint, and was purchased from the British. With one exception it was entirely worked by Japanese, and could not possibly have been better managed. Our correspondent possesses several interesting and scarce specimens of the Japanese gold and silver coinage, and also of Corean money, which did not circulate long as it cost more to produce than its face value.

THE POSSIBILITY OF MECHANICAL FLIGHT.—Successful experiments with a flying machine have been performed by Mr. S. P. Langley, Secretary of the Smithsonian Institution, the facts being vouched for by Mr. Alexander Graham Bell, the inventor of the telephone. The aerodrome employed weighed about twenty-five pounds, and measured twelve to fourteen feet from tip to tip, the method of propulsion being by aerial screw propellers, actuated by steam power. In one experiment the aerodrome rose, in the face of the wind, to a height of nearly a hundred feet, and the actual length of flight exceeded three thousand feet, whilst the velocity attained was between twenty and twenty-five miles an hour.

THE KELVIN JUBILEE.—The following programme of the celebrations of the jubilee of Lord Kelvin as Professor of Natural Philosophy in the University of Glasgow has been published in *Nature*:—On the evening of Monday, June 15, at 8.30 p.m., the University will give a conversazione, when there will be an exhibit of Lord Kelvin's inventions. On Tuesday, June 16, addresses will be presented to Lord Kelvin by delegates from home and foreign university bodies, from several of the learned societies of which he is a member, from student delegates from other universities, and from the students and graduates of the University of Glasgow. It is expected that the honorary degree of LL.D. will be conferred on the same day on several of the distinguished foreign visitors. On Tuesday evening, June 16, the city will give a banquet to Lord Kelvin, to which the visitors who have come to do him honour have been invited. On Wednesday, June 17, the senate of the university will invite the visitors of the university staff to sail down the Clyde. The students of the university also invite the student delegates from other universities to a similar trip. Representative scientific men—about fifty in number—from America and the British colonies, and from all the European countries, besides about one hundred and fifty from the United Kingdom, have signified their intention to be present.

PRESCRIBING BY CHEMISTS.—According to the *British Medical Journal* of last week, in answer to a correspondent, "Chemists who prescribe either evade or break the law, and are frequently punished on the prosecution of the Apothecaries' Society or the Medical Defence Union." Without any desire to defend the practice of prescribing by chemists, it may safely be asserted that the latter statement is quite wrong. An isolated case may occur now and again, but so far from chemists being "frequently" punished for the alleged offence, these instances are of very rare occurrence indeed, and it is much to be regretted that an important medical organ should give publicity to such a mis-statement of fact. Moreover, with regard to the first statement in the above reply, prescribing in itself is not a legal offence, the penalty under the Apothecaries Act—the only Statute protecting medical practice—being for acting or practising as an apothecary, which is not the same thing as prescribing.

PHARMACISTS AND THE X-RAYS.—The Leeds correspondent of the *Daily News* has telegraphed to that paper, announcing that a Leeds chemist, Mr. Branson (presumably of the firm of Reynolds and Branson), has announced a new and most interesting development in connection with the Röntgen or x -rays. He now finds no difficulty in penetrating bone as well as flesh by means of the rays, and he is said to have succeeded in taking photographs for surgical purposes, showing the presence of a piece of steel needle in bone. Before this he had revealed the position of a bullet embedded a quarter of an inch in the bone, but until recently had not been able to show anything so diminutive as a needle in bone. The result has been obtained with a new form of tube.

PRODUCTION OF CAOUTCHOUC IN BRAZIL.—The *Bulletin Commercial* states that, according to American statistics, the production of caoutchouc in the province of Para (Brazil), which is constantly on the increase, has doubled in the last twelve years, and quintupled in the last thirty years. The production of 1895 was 13.4 per cent. greater than that of 1894, and 10.2 per cent. greater than that of 1893. The following statement shows the value of the exports in certain years:—

Years.	Value.
1865	£8,243,000
1870	10,528,000
1875	15,144,000
1880	18,889,000
1885	29,310,000
1890	36,300,000
1895	46,363,000

The imports of caoutchouc into the United States have increased in about the same proportion as the exports from Brazil, but in 1895, for the first time, the amount of caoutchouc sent from Para to Europe was greater than that sent to the United States. The increase is specially noticeable in England, France, and Germany, where Para caoutchouc is in great demand.

OPIUM IN CHINA.—The importation of Indian and Persian opium at Foochow still continues to decrease, native opium gradually but surely driving them out of the market. The net import for 1895 was 3563½ chests, as against 3871 in 1894, and 4479 in 1893. Malwa opium realised during the past year 675 to 760 dol.; Patna, 675 to 880 dol.; Benares, 670 to 820 dol.; Persian, 757 to 820 dol. In Foochow, as in other parts of China, the Indian drug is becoming exclusively the luxury of the rich smoker, whilst the coolies satisfy their craving either with Szechuan opium or with the inferior stuff produced in the neighbourhood of Fu Ning.

GROCERS AND THE SALE OF MEDICINES IN FRANCE.—The Paris correspondent of the *Medical Record* recently commented upon the anomaly that grocers in France should be permitted to sell candies and pastilles containing santonin, when the laws regulating the sale of drugs by pharmacists are so stringent. Thus, whilst the pharmacist is forbidden to sell twenty drops of laudanum without a physician's prescription, the grocer may distribute santonin by the pound in the forms specified. That the danger indicated is a real one is shown by the fact that many serious accidents have occurred through such sales by grocers.

THE BRITISH ASSOCIATION, which goes to Toronto next year, is to be invited to visit Bristol in 1898, a suggestion to that effect having been made to the Mayor of the western city by a deputation representing the chief local scientific societies and educational institutions. Sebastian Cabot, who discovered the American mainland in 1497, started on his second voyage from Bristol, his native place, in 1498, and *Nature* thinks a visit to the city in 1898 would be very appropriate, and serve to commemorate the fourth centenary of one of Bristol's greatest citizens.

CHEMICAL SOCIETY.

An extra meeting was held on May 28, Mr. A. G. Vernon Harcourt, F.R.S., President, in the chair, and a large and distinguished audience assembled to hear the Lothar Meyer Memorial Lecture, by Professor P. Phillips Bedson, D.Sc.

LOTHAR MEYER MEMORIAL LECTURE.

The lecturer gave a clear and systematic sketch of the late scientist's life. Lothar Meyer, one of two brothers, commenced life as a student of medicine under very adverse conditions of health, at Oldenburg, graduating there as M.D. Bunsen's reputation attracted him to Heidelberg, where he studied chemistry until 1856. At Königsburg he taught mathematics and physics for a year and a half, and his thesis on the "Action of Carbon Dioxide in the Blood" got him the degree of Ph.D. In 1864 he published his book on 'Moderne Theorien der Chemie.' After a short sojourn at Breslau he undertook the duties of Professor of Forestry at Eberswalde, where he remained for two years. There, however, he had no outlet for his abilities as an investigator, and he naturally wished to get into a more congenial atmosphere. His Professorship in the Polytechnicum at Karlsruhe, where we next find him, was interrupted by failure of health (1874-5). Then, in the hostilities between France and Germany the Polytechnicum became a hospital, and Lothar Meyer became for the time being a surgeon. At the University of Tübingen he was Professor of Chemistry, and had the opportunity of resuming his investigations, his name attracting students from many lands.

In 1887 Lothar Meyer visited this country, and attended the meetings of the British Association in Section B at Manchester, and although he could speak English fluently he addressed the section in German.

In April of last year illness again overtook him, and he died.

Lothar Meyer's publications embraced a variety of subjects. His first was on the condition in which gases exist in the blood, and was published in 1856. His conclusions on this subject are valid at the present day.

At Breslau he wrote a paper on the "Estimation of Carbon Dioxide in the Water of the Springs." Professor Bedson here referred to the recent work of Rayleigh and Ramsay on the subject of the gases evolved from these springs.

At Karlsruhe and Tübingen, Lothar Meyer brought out a long series of publications, and especially may be mentioned his work on the 'Atomic Weights of the Elements.'

A number of tables—the Elements, and the Atomic Weight and Atomic Volumes—were exhibited on the walls, and Professor Bedson pointed out the differences between the weights in the old and new systems.

Lothar Meyer's labours were not all for science. He took much interest in educational matters, and wrote articles on various subjects to magazines. He strongly advocated mathematics and languages for education, and considered that original labour should take the place of examinations. Finally, it was stated that he was a recipient of the Davy Medal of the Royal Society.

Sir Henry Roscoe in a few words proposed a vote of thanks to Professor Bedson for his lecture, and Dr. Gladstone seconded.

Professor Russell, at the request of the President, spoke a few words. He had a clear remembrance of Lothar Meyer as a fellow student, having worked in the next desk to him in Bunsen's Laboratory. He was a thorough good companion.

The President said that at Manchester, at the meeting of the British Association, he had the pleasure of making Lothar Meyer's acquaintance.

Professor Bedson briefly replied, and the proceedings terminated.

APOCODEINE HYDROCHLORIDE AS AN EXPECTORANT, ETC.—
Murrel and Meder agree that apocodeine acts chiefly as an expectorant, while Guinard is followed by Meder in attributing to it a markedly sedative action in maniacal cases. The administration, per os, as well as by subcutaneous injection, gives rise to intestinal peristalsis and produces one or two evacuations. The sedative dose is from 2 to 6 centigrammes either subcutaneously or internally. For internal administration apocodeine hydrochloride, 50 centigrammes; distilled water, 100 grammes; syrup of raspberries, 25 grammes. One half to one teaspoonful for a dose. Or subcutaneously, apocodeine hydrochloride, 20 centigrammes; distilled water, 10 grammes. One Pravaz syringe-ful at a dose (*Intern. Med. Mag.*, v., 129, after *Therapeut. Woch.*).

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, May 28, Mr. E. J. Eastes occupying the chair. After the minutes of the previous meeting had been read and confirmed, Mr. C. E. Ashby read the following "Report on Botany":—

RECENT WORK IN BOTANY.

BY C. E. ASHBY.

The behaviour of the cell-nucleus at different periods in the life of a plant has during recent years been the subject of very minute investigation. You will remember that the nucleus has as its groundwork a modified form of protoplasm, within which lies a coiled thread of linin containing small granules of chromatin. On the occurrence of nuclear division, the thread breaks up into distinct portions containing now conspicuous masses of chromatin embedded as before in linin. These portions of the thread are known as chromosomes. At the next stage of the division each chromosome splits into two halves, one of which passes to each of the daughter nuclei. In the latter the chromosomes again form a thread by uniting end to end. When the daughter-cells divide the process repeats itself, and the thread of linin invariably breaks up into the same number of chromosomes as did the thread in the mother-cell. The nuclei, then, of any individual will all have the same number of chromosomes. It is extremely probable that the chromosomes do not during the process lose their physiological identity, for striking similarity has in some cases been observed between their positions and form at the end of one division and at the commencement of the next. This will be dealt with later. The nuclear thread may be compared to a chain with a definite number of links. Cell-division will then consist in the separation of the links, their splitting in half and the joining of the halves into two fresh chains, each with the same number of links as the original one. Such is the process of cell-division as found in the cells which form the plant body.

In every nucleus of the vegetative parts of the plant the number of chromosomes is the same, but in the spores, and in the generation developed from the spore, half this number is invariably found. There is a particular division of the nucleus which precedes the formation of the spores in which this reduction in number is effected. This is known as the reducing division. The manner in which the reducing division occurs has been more or less satisfactorily traced by several botanists. The chromosomes appear to possess two axes along which division can take place. What we may term vegetative cell division consists in the splitting along the longitudinal axis. Less is known of the reducing division, but careful investigation has proved almost conclusively that it takes place along the transverse axis. It is probably more correct to look upon the bodies which undergo longitudinal splitting, not as single, but as pairs of chromosomes, closely united end to end. Reducing division consists in the separation of these individuals, their distribution to two nuclei, and reunion by their ends into pairs.

These facts afford ample scope for theory. We will first take up the subject from the morphological point of view. Consider the case of a unicellular organism which has not attained sexual differentiation. The very simplest plants we know among the algæ are such. In their single nuclei are enclosed a definite number of chromosomes. The plant is reproduced by mere cell-division, and the daughter nuclei each possess the same number of chromosomes as the original mother-cell. We have abundant evidence to show that progressive development in any direction remained in abeyance as long as the only method of reproduction followed the

asexual or purely vegetative plan. If then the offspring of our plant are to rise in the scale of creation they must develop a sexual mode of reproduction. This might be brought about by one of the daughter-cells, without undergoing any further modification, becoming a gamete and uniting with a similar cell. The product is an individual with twice the original number of chromosomes. All the asexually produced offspring of this cell will now have the double number. If its gametes were to have this number also the individuals of the next generation would have four times the original number, and so in the course of a few generations the number of chromosomes would become infinite. Reduction is necessary at some phase before the coalescence of the gametes in order to prevent this increase. The process has been observed in every class of the vegetable kingdom, but the extreme minuteness of the chromosomes of the cryptogams renders investigation in this group somewhat difficult. We shall find it instructive to examine the process in connection with the life history of a phanerogam. We have seen that the remote ancestors of the phanerogam were asexual plants. These very soon attained sexual differentiation, but at the same time a check was put upon numerical increase, and to compensate for this various asexual reproductive mechanisms were elaborated. Flowering plants, we find, produce spores in great numbers upon the generation which results from the fertilised gamete.

The nuclei of the spores contain only half the number of chromosomes present in the nuclei of the plant which produces the spores. That this reduction in number is of first importance to the plant is evident from its regular and universal occurrence. But it must not be regarded as a process which has gradually been developed and perfected by reason of its utility in the plant's economy. On the contrary, it makes its appearance at the same time as sexuality, to which it is a necessary complement. The reduction in the number of chromosomes really marks the return in the fresh generation to the representative of the primitive form in which the early ancestors of the plant existed. This form, as found in flowering plants, has advanced far up the scale of development. It is no longer unicellular; it has attained sexuality and, in addition, dimorphism, some of the individuals being male and others female. The gametes it bears when they unite give rise to the sporophyte, a generation with the double number of chromosomes in each nucleus, and which must be looked upon as of more recent development than the small gametophyte, for the especial purpose of providing for the sufficient increase in number of the individual.

Passing from the morphological side of the subject we will take it up in its physiological aspects. How is it that a plant shows the same tendencies and characters in all its parts, and that these again are repeated in its offspring? Are these tendencies in some way impressed upon material which pervades the whole plant, and which is transmitted to its offspring? If this be the case, the nucleus is clearly the structure to which this property belongs. This body is found in all living cells, and functions of vital importance take place within it, and furthermore, it is always formed from another nucleus, and on the occurrence of fertilisation the nuclei of the uniting cells completely fuse. We are further led to believe that hereditary characters centre in the chromosomes. These bodies show a definite organised structure; they are constant in number, and divide into equal halves at cell-division, and as we have seen, it is probable that they retain their physiological individuality. The chromosome, then, is regarded as an element of the nucleus charged with all the hereditary characters of the species. In support of this view we find that equal division of the chromosomes, as far as can be ascertained, always takes place, and with it an equal distribution of characteristics. Also Gruber has found

that if a unicellular organism be cut into several portions, one of these, though only containing a fragment of the nucleus, is capable of growth, producing an individual with all the characteristics of the parent. Strasburger has observed that in the division of the pollen mother-cells of *Hemerocallis fulva* single chromosomes not infrequently remain behind in the equatorial plate of the nuclear spindle. These chromosomes induce changes in the surrounding protoplasm, and develop into pollen-grains—usually very small, but still having the characteristics of the species.

It would at first sight appear that a single chromosome in each nucleus would be all sufficient for the transmission of individual characteristics. But should this undergo apparently accidental variation the entire character of the individual might be changed and its chance of life seriously affected. If, instead, a number of chromosomes are present, slight variations in one or two of these will be counterbalanced by the constancy of the greater number, and are not likely to so alter the course of the life of a plant as to unfit it for its environment.

Since the same number of chromosomes are always found in the two gametes between which fertilisation takes place, the two parents would presumably impress their characteristics upon the offspring to an equal extent. Frequently this is the case, but at other times the peculiarities of one parent are more pronounced in the offspring than those of the other, as though the chromosomes of this parent masked to some extent the influence of those of the other in the daughter nuclei. At the reducing division the chromosomes of the nuclei of the mother-cells separate into two groups. These groups contain the same number of chromosomes, but there may be considerable difference in their character. It might so happen that half of the chromosomes from each of the parents of the plant go to each spore, in which case the spores would, in all probability, transmit the characters of the actual plant by which they were produced. Or it might happen that all the chromosomes from one of the parents of the plant went to one spore and all those from the other parent to the other spore. In this case the spores would transmit the characters not of the plant upon which they were formed, but of the two parents of that plant; one spore being exactly like the spores of the female parent and the other like the spores of the male parent. The union of chromosomes in pairs is so complete that it is highly probable that they lose their identity on union. The resultant pair will have characters derived from the two individuals, but the physiological identity of the latter will be lost. The nuclei of hybrids are built up of two kinds of chromosomes, those of one parent differing markedly as a rule in character from those of the other. As a consequence hybrids show a combination of the qualities of the two parents. At the reducing division the chromosomes are re-sorted, as it were, to form the spores. These receive chromosomes representative of each parent in varying numbers, and therefore have characteristics varying between those of the parents. Many of the spores are almost exactly like those of one parent, many closely resemble those of the other, while many have the chromosomes so combined that their characters combine those of both parents.

At the conclusion of the paper a discussion took place to which Mr. H. Brown and the Chairman and Secretary contributed.

The following "Report on Physics" was then read by Mr. T. A. Henry:—

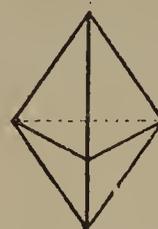

THE RELATION OF CHEMICAL NATURE TO PHYSICAL CONSTANTS.
BY T. A. HENRY.

Although many important and far-reaching discoveries have been made in this branch of science during the past year, I do not think there is anything in the work recorded which would be of

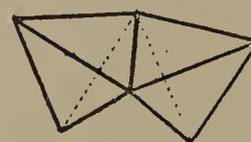

interest to pharmaceutical students, and to the discussion of which we could profitably devote one of our meetings; so that in compiling this report I have written instead a short account of the more recent developments of what is now called physical chemistry. The evidence of this inter-relationship of physical condition and chemical nature presents itself almost at the commencement of one's study of organic chemistry. We find that the physical condition passes from simplicity to complexity as we go up any homologous series of carbon compounds. We have an ideal case in the paraffins; the simplest members of the series are gaseous, and as we pass up the series we come to liquids, viscous liquids, semi-solids, and solids. The physical constants again show the same gradual alteration; beginning with the liquid members we find that for every addition of CH_2 we have a rise, tolerably constant, of about 18° to 20° C. in the temperature of the boiling point. Similarly, the melting points of those solid paraffins, which have been obtained in anything like a pure state, show the same gradual rise. This alteration of constants is what one would expect from purely physical considerations. The conversion of any liquid into a gas involves the rendering latent of a certain amount of energy (supplied in the form of heat), and we would naturally expect that to change a liquid whose molecules are heavy (comparatively speaking) into a gas would involve a greater expenditure of energy than the conversion of a liquid whose molecules are light, that is, other conditions being the same, we would expect a complex substance to have a higher boiling point than a simpler one of the same series.

The whole subject of the inter-relation of the physics and chemistry of substances has absorbed a great deal of attention of late years, chiefly because it is generally recognised that it is in this direction probably that some light will ultimately be shed upon the methods by which complex substances are built up from simpler ones, or even from elementary bodies; but apart from these ultimate considerations, the subject is one of immense interest to every working chemist, for chemistry has secured many new methods of dealing with its problems as the result of physico-chemical research; for instance, the whole subject of stereo-chemistry is founded upon the observation that certain substances have the power of causing rotation of the plane of a ray of polarised light, and you know how far-reaching have been the effects of stereo-chemical considerations. The valuable work carried out by Guye and others on the alteration of rotation amount, due to the substitution of heavy radicals for light ones (without disturbing the general order of the original compound), has resulted in a method of determining the position of the centre of gravity for a great number of substances. The application of this method is simple when the substance contains only one asymmetric carbon atom, but is a little more complicated when we have to deal with substances containing multiple asymmetric carbon. But here, also, the same workers in an ingenious system of experiments, wherein the optical effect of each asymmetric carbon was successively masked, have shown that in such compounds "the total optical effect is the algebraic sum of the optical effects of the several asymmetric carbons," and so the effect of each can be satisfactorily allowed for. There is one ingenious application of physical considerations which may interest you. You know that some of the compounds of acetylene with metals are very explosive, *i.e.*, they are unstable combinations, and we have no chemical method of explaining this, but if we suppose that the binding points of a carbon atom are situated not at the solid angles of a tetrahedron but in the centres of the triangular faces, and we have no grounds for supposing that one position is less likely than the other, we have a complete explanation of this instability, for in the paraffins we should then have two plane faces in contact, in the olefines we should have an edge in contact, and in the acetylene series only a

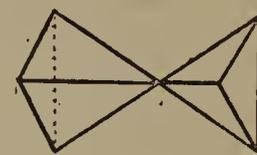

solid angle of each in contact, arrangements which are evidently in a decreasing order of stability; and we reach the limit of stability when we substitute a heavy element like copper for the hydrogen in acetylene, and the result is an explosive compound.

Paraffin.

Olefine.

Acetylene.

Passing now to the consideration of physical constants, we will take first the viscosity co-efficient, upon which constant a good deal of work has been done recently. By the viscosity of a liquid we mean practically its mobility; thus we say a liquid like ether is mobile, while glycerol is viscous. Putting the same thing accurately we should say ether has a low co-efficient of viscosity, while that of glycerol is high. The viscosity of a liquid is an expression for the internal molecular friction of the liquid, and this, again, depends on the mean free space of the constituent molecules. The simplest method of obtaining relative viscosities would be to take two similar pipettes and fill each to the mark, and then allow the liquids to flow out under the action of gravity, and at atmospheric pressure, observing carefully the relative times taken by the two liquids to empty the pipettes. We should then have a ratio expressed in seconds; for various reasons, however, it is more advantageous to have this ratio expressed in pressure units, *i.e.*, in dynes per square centimetre. So that, theoretically, we take a pipette, fill it with a standard liquid, and then allow it to flow out at, say, atmospheric pressure. We then fill the same pipette with the liquid to be investigated and we increase or decrease the pressure upon it until it flows out at the same rate as the standard liquid. For convenience the velocity chosen is unit velocity in the C.G.S. system. We are now in a position to define exactly the "coefficient of viscosity," but experimentally there is still the difficulty of temperature. It is an old observation that viscous liquids become more mobile when heated, that is rise of temperature increases the mean free space of the molecules, and therefore diminishes the viscosity co-efficient. When viscosity co-efficients are determined through a long range of temperatures it is found that on plotting a curve in the usual way for each substance that usually a certain length of each curve for different liquids corresponds to an equal rise of temperature, *i.e.*, for many liquids there exist in this way "temperatures of equal slope," and it is found experimentally that viscosity co-efficients determined at these temperatures show most relationship to chemical nature. There is still to be got over the difficulty of alteration caused by the complexity of the molecule; this is got over by changing "viscosity co-efficient" into "molecular viscosity," which is simply the product of; the molecular weight by the co-efficient of viscosity determined at temperatures of equal slope. Using this constant, the regularities previously mentioned for such constants as the boiling point are found to obtain for viscosity, and it is also found that for the great majority of substances the molecular viscosity can be calculated from fundamental constants expressing the effects of atoms in the molecule, and those due to different atomic groupings. I have devoted some considerable space to the consideration of viscosity, because it does not usually come very much in the way of students. The regularities I have already pointed out to you for the constants we have taken so far are seen again in the observation of the refractive indices of liquids. The

refractive index of a liquid is a ratio expressing the amount of bending which a ray of light undergoes when passing from one transparent substance to another, and is given by the well-known formula $\frac{\text{Sine of angle of incidence}}{\text{Sine of angle of refraction}}$ and is usually represented by the Greek letter μ .

Just as in the case of viscosity there are secondary influences to be got rid of before relationship with chemical nature becomes evident, and these influences are of the same kind as before, and are got rid of in the same way; so that we have as a final expression for "molecular refraction"—

$$\frac{\mu^2 - 1}{\mu^2 + 1} \times \frac{M}{D} \quad \text{where } M = \text{molecular weight.}$$

$$D = \text{density, i.e., weight of unit volume.}$$

An example of the additive character of this constant may be useful, thus for benzene; the molecular refraction from observation is 25.93, while calculating from fundamental constants we get 26.316, an agreement with observation which is remarkably close.

Atomic refraction of singly linked carbon	= 2.365	CH	
" " " doubly " "	= 1.836	CH	
" " " hydrogen atom	= 1.103	CH	
		CH	
For benzene = 3 ethylene unions	= 3 × 1.836 = 5.508		
6 single "	= 6 × 2.365 = 14.190		
6 hydrogens	= 6 × 1.103 = 6.618		
			<u>26.316</u>

Another constant which has been very completely worked out is that of "magnetic rotation of the plane of polarisation."

The first observation on the subject was due to Faraday, who observed that when any transparent liquid (although not optically active) was subjected to the action of a magnetic field it acquired the property of causing rotation of the plane of a polarised ray of light. Dr. Perkin has made this subject his own, and has made observations on a very large number of substances, and his general deductions are similar to those already mentioned for other constants.

Leaving the consideration of physical constants, I should like to conclude the report with a short *résumé* of the relationship of colour to chemical structure. You are, no doubt, all aware that what we call colour is merely the result of the reflection from the coloured substance of light-rays of certain vibration rates, thus we can say that a substance is red because it reflects those portions of white light incident upon it, which vibrate at so many millions per second.

This being so, we should expect to find some evidences of relationship in structure among coloured substances, and this conclusion is supported by observation. Very few coloured substances are found outside the derivatives of such series as benzene, anthracene, naphthalene, etc., so that a nucleus of a special character seems to be essential to the occurrence of colour. It is found again that colourless compounds do not give absorption spectra, but if we begin with a colourless substance having the required fundamental structure, and gradually substitute in that substance certain groups, we find that absorption lines begin to appear at one end of the visible spectrum, and as the substitution of more groups goes on these bands become displaced towards the other end of the spectrum, and if substitution be still continued, the absorption lines begin to pass back again. As the position of the lines in the spectrum changes, the substance changes in colour, and the following table shows how the position of the lines in the spectrum indicates the colour of the substance giving them:—

Position of lines.	Colour of substance.
Violet	Green-yellow.
Indigo	Yellow.
Blue	Orange.
Blue-green	Red.
Green	Purple.

These are, of course, interchangeable, and one list represents the position of absorption lines when the other gives the colour of the substance.

All radicals do not cause a displacement in the same direction, thus, groups like HO, CH₃, COOH, C₆H₅, and the halogens cause a displacement from the "violet" to the "red end," these are known as "batho-chromic groups."

On the other hand, the introduction of such groups as NO₂, NH₂, H causes the reverse displacement, and these groups are "hypso-chromic." A simple series exhibiting this change cannot be prepared, because as the substitution or addition of new groups go on, secondary absorption lines appear, which complicate matters.

In some cases the colour seems to depend on the presence of certain groups, this is well seen in the *azo*-dyes which contain of course the "azo" group, such groups are called "chromophors" or chromogens, and their influence seems to be greater the nearer their position is to the nucleus. The whole subject is of course still in embryo, but there is no doubt that the importance of it from an industrial point of view will be a great incentive to the prosecution of research in this direction. From the work so far accomplished one or two generalisations can be clearly drawn.

1.—That the simplest coloured bodies are those in the green and yellow.

2.—That on the whole complexity of the molecule seems to be necessary to the production of colour.

To the latter generalisation many exceptions will at once occur to you, thus, liquid NO₂ is yellow while the gas is reddish-brown. Iodine in CS₂ is violet, while an ethereal solution is brown, yet determinations of the molecular weight give the same figure in both cases.

The reading of this paper was followed by a discussion in which Messrs. Brown, Tunbridge, and the Chairman took part. The meeting then adjourned.

PROPRIETARY ARTICLES TRADE ASSOCIATION.

MEETING AT CARDIFF.

A meeting of chemists residing in Cardiff and district, was held at the Town Hall, Cardiff, on Thursday, May 28, under the presidency of Mr. J. Munday. There were also present Messrs. A. Tebbutt (Sutton and Company), H. S. Norris (Condal Aerated Water Company), and W. S. Glyn-Jones (Secretary), representing the Proprietary Articles Trade Association, Lloyd (Brigend), H. Spencer Fargher, H. Furnivall, A. Hagon, A. Coleman, R. Mumford, and J. A. Jones (Cardiff), E. W. Harris, and H. Thomas (Merthyr), W. E. Giles, T. P. Garrett, A. Gratte (Newport), D. Arnott (Pontypridd), M. H. Clare (Liebig's Extract Company, Limited), etc.

The Chairman said the meeting had been called by the Proprietary Articles Trade Association to invite full discussion on the advisability of joining the Association or otherwise. Letters of apology and sympathy with the movement having been read from Messrs. Key (Pontypridd), Benjamin (Penarth), T. Davies (Porth), R. Drane, and C. Sanders (Cardiff),

Mr. Glyn-Jones delivered a lengthy address on the aims and objects of the Association, and the advantages to be derived by becoming members. In order to improve the present position of affairs it was necessary for the retail trade to combine, and he expressed a hope that Cardiff would take its share of the work, so that they might go to the manufacturers and wholesale houses with full confidence.

Mr. A. Hagon then proposed the following resolution:—

"That this meeting of chemists residing in Cardiff and neighbourhood pledges itself to support the Proprietary Articles Trade Association, and invites the co-operation of manufacturers in connection with the movement."

For years, he said, the manufacturers had snapped their fingers at the retail trader, but now they were in a position to discuss terms. They could tell the manufacturer that he must consider their interests a little and not expect them to handle his goods for nothing. With regard to the question of profits, he thought they should have a minimum of at least 20 per cent. He believed that was the general feeling throughout the country. He expressed his belief in the powers of the Association, and hoped all those present would join the movement.

Mr. T. P. Garrett seconded the resolution and advocated unity.

Mr. Tebbutt pointed out that the Association had already done a vast amount of good, and said it would be to the interest of them all to support the movement.

Mr. J. A. Jones referred to his practice of refusing to stock an article that he could not sell at a profit, and expressed the opinion that in going to the manufacturer they should not ask for too much profit. He, however, was willing to support the Association in any step it might take.

Mr. Tebbutt pointed out that the Council had fixed upon a minimum profit of 20 to 25 per cent.

Mr. A. Coleman also supported the resolution.

Mr. Arnott pointed out that this Association would do just what the Pharmaceutical Society had failed to accomplish. The Pharmaceutical Society did nothing to increase their profits, or to make it worth their while to carry on business. What the Pharmaceutical Society did not do this Association would take up, and look after their trade interests. For that reason he supported the proposition. He asked whether the grocers were being included, because the great stores and universal providers were their greatest enemies.

Mr. Hagon said the grocers would be only too glad to join them.

The resolution was supported by Mr. Mumford, who welcomed the formation of an association to help to save them from themselves. As retailers they could do nothing, but by combination with the manufacturer and wholesaler they could do everything.

Mr. Lloyd also supported and said that when an article was sold by grocers it ceased to be considered a remedy. He quoted as an instance Eno's fruit salt, which he said was simply looked upon as a pleasant saline which could do no harm.

The Chairman endorsed the opinions of the previous speakers, but pointed out that it was not within the province of the Pharmaceutical Society to look after trade interests. They watched the questions of qualifications and fees, and looked after the sale of poisons.

After a little further discussion the resolution was carried and a vote of thanks to the Chairman and Mr. Glyn-Jones terminated the proceedings. A suggestion was made that local associations should be formed in the various towns in South Wales, with a central association or federation which should meet at Cardiff.

SCOTTISH NEWS.

EDINBURGH PHARMACY ATHLETIC CLUB.—The golfing section held its monthly competition on the Braid Hills Course for the "Dick Handicap Challenge Medal" on Friday and Saturday last. Mr. J. Greig was the winner with the net score of 92.

ABERDEEN PHARMACISTS AND THE AMENDMENT OF THE COMPANIES ACTS.—A deputation from the Aberdeen and North of Scotland Society of Chemists and Druggists, consisting of Mr. John Johnston, President, and Mr. John Cruickshank, Honorary Secretary, waited on Captain Pirie, M.P. for North Aberdeen, in Mr. J. S. Watts' office, on Friday, May 29, and asked his support to Lord Herschell's Amendment to the Companies Bill. The deputation explained that the effect of the Amendment was to prevent companies from selling or dispensing drugs or poisons, unless the same conditions as to qualification which apply to other traders are complied with, and pointed out that under the existing law companies could defy those provisions of the Pharmacy Acts which were designed in the interest of public safety. Captain Pirie expressed himself strongly in favour of the Amendment, and undertook to give it his support when the Bill reaches the House of Commons.

ENGLISH NEWS.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—The following members have been elected as officers of the above Association:—T. C. Clarke (President), H. S. Lawton and R. M. Williams (Vice-Presidents), H. Jessop (Hon. Treasurer), H. M. Bindloss, 17, Bull Street, Birmingham, and J. W. Bland, 8, Corporation Street, Birmingham (Hon. Secretaries).

BOTANICAL RAMBLE.—The second botanical ramble in connection with the Plymouth, Devonport, Stonehouse and District Chemists' Association took place on May 27, Mr. Reade conducting his followers to the neighbourhood of Beer Ferrers (Devon), where several specimens were found. The attendance was not quite equal to the first outing, but the excursion was, nevertheless, equally enjoyable and interesting.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION (JUNIOR SECTION).—The usual monthly meeting was held on May 28 at the Association rooms, Foresters' Hall, Plymouth Octagon. Mr. A. J. Buckley occupied the chair, and there were also present Messrs. E. Hodge, Downing, J. E. Pond, H. J. Reynolds, Treener, Vibert, Osborne, A. T. Darke and others. Mr. R. F. Roper, M.P.S., delivered an able lecture on "Pharmaceutical Testing," and impressed upon his audience the absolute necessity and importance of every pharmacist occasionally testing his chemicals to see that their quality was up to the required standard. He maintained that to apply the test frequently it must be accomplished with as much speed and simplicity as could be brought to bear. He further mentioned that the water of Plymouth, if filtered, was quite as pure as distilled water (*sic*), and that no advantage would accrue to a Plymouth chemist in having a still. Mr. Roper fully explained the use of the specific gravity bottle and tested the s.g. of some tinctures. His explanations regarding the term "melting point" and the use of the hydrometer were very clear. A vote of thanks to the lecturer was proposed by the Chairman and, seconded by Mr. E. A. Hodge. Mr. Roper briefly replied.

DISPENSING OF WORKHOUSE DRUGS.—At a meeting of the Wells (Somerset) Board of Guardians last week, Mr. J. Welch, sen., presiding, the Clerk (Mr. A. G. Russ) said he had written letters to the four medical officers of the Union asking them if they would, at an increased salary, consent to dispense the drugs in future in addition to giving advice. Three out of the four medical officers decidedly disapproved of the proposal, while the fourth only consented to give it a conditional trial. In a discussion that followed, Mrs. Clark and Mr. S. Austin argued in favour of the medical officers being given a sufficient salary to make them properly attentive to the poor. Mr. Hawkins asked, if the proposed system was carried out, whether the doctors would be permitted to make arrangements with chemists for the dispensing of drugs. Mr. J. Welch, jun., thought the Board should adhere to their decision, and that the doctors should be asked to give a definite acceptance or rejection of the proposals by the next meeting of the Board. He moved a resolution to that effect. Mr. G. Slade proposed a modification, which Mr. Welch accepted, but on a division it was decided to refer the question to the General Purposes Committee.

BRISTOL AND THE EARLY CLOSING MOVEMENT.—At a meeting of Bristol shop-assistants and others, presided over by the Right Worshipful the Mayor, on Thursday night, May 28, the following resolution was adopted:—

"That this meeting recognises the grave physical and moral losses to the community resulting from the excessive hours imposed on shop assistants, and urges the citizens of Bristol to support early closing by early shopping, dealing only with shops that are willing to secure reasonable hours by mutual arrangement."

A further resolution was also passed, welcoming Sir John Lubbock's Early Closing Bill as an instalment of much needed reform.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on June 1, Sir James Crichton-Browne, M.D., LL.D., F.R.S., Treasurer and Vice-President, presiding. The following were elected members:—Mr. William Phipson Beale, Q.C., F.G.S., Miss Esther Bright, Mr. Edward Ball Knobel, Treas. R.A.S.

CORRESPONDENCE.

THE SOCIETY AND ITS MEMBERS.

Sir,—Like many others I think it unfortunate that so little interest is taken in the Society's affairs by a great majority of its members. What appears to me even more regrettable, however, is that much of the little interest that is taken is not directed in business-like fashion. I fear that members on the whole simply do not understand the constitution of the Society and the part which individual members may take in causing its functions to be exercised in particular directions. It might be attended with good results if you gave a lecture on procedure occasionally, and had a few questions put to you bearing on points felt to be obscure. It is evident that much of the expression of opinion upon pharmaceutical business is only so much waste of energy. Airing of opinions, even though good in themselves, is not always so creditable as it might be to the persons giving them forth, much depending on the time, place, and manner in which that is done. Mr. George Coull, in writing to the *Journal* (*ante*, p. 419), after referring to what he regards as an injustice in the nature of work set to Minor candidates in London, and to his having been debarred from discussing this subject at a meeting of the North British Branch Executive, puts the following extraordinary question: "If we are not to discuss a subject of that kind at a meeting of the so-called governing body in Scotland, where on earth are we to discuss it?" Why, sir, surely that is about the last place to resort to for such a purpose. The business of the Scottish Executive cannot be to criticise how the Council transacts purely London business, but the Executive's meetings, we must assume, are for the transaction of business connected with the Society in Scotland.

It would be an altogether different matter, though questionable "form," perhaps, were the members of the Scottish Executive collectively—in their non-official capacity, and simply as ordinary members of the Society—to discuss such a question and forward a resolution to the Council, which is the proper authority to deal with it. To my mind the best method would have been for Mr. Coull, as a member of the Society, either to have asked a member of the Council to raise the question in Council or to have applied direct to the Council through Mr. Bremridge. In the event of either of these methods resulting in disappointment to him, he could appeal to the Society at large against the doings of the Council. Business is the end in view not discussion, and surely it is reasonable to suppose the Council would deal with this matter when specifically laid before it without waiting for a preliminary discussion upon it by the Society at large. I would, however, like to see the *Journal* very much more made use of by members than at present; the more we study how to use it and the resources of the Society generally the better will it be for our craft.

Glasgow, May 26, 1896.

J. ANDERSON RUSSELL.

Sir,—As an old chemist I have always looked askance (like many of my brethren) at the Pharmaceutical Society and its doings. Why has it not long since embraced all registered chemists in its fold? Subscriptions would have come in more plentifully, and the funds would not now be so languishing. The Council has hitherto been too exclusive; it alone has created such a gulf between those gentlemen who have gone in for the Major examination and the humbler (may I say it) members of the craft. If all were placed on an equal footing it would be better. What careth the great metropolis or the British public for an M.P.S.G.B.? They are not as a rule such good (commercially speaking) business men as those who have just passed the required standard of qualification. Use your influence to break this terrible barrier, and remember that we all open shop to secure a livelihood for self and family; there should not be such distinctions in this age of enlightenment. To further our interests the Council may easily see its way clear to support the Anti-Cutting League in getting back the full advertised prices of patents and proprietaries, instead of wasting so much annually in prosecutions, etc. The result of such assistance would be in the long run to considerably augment the funds of the Society.

Forest Gate, E., May 27, 1896.

HUGH EDGSON.

CREAM OF TARTAR.

Sir,—Owing to my absence from home on a brief holiday, the *Journal* of the 23rd inst. reached me too late to enable me to reply in your next issue to Messrs. Kirkpatrick, Barr, and Guthrie's letter (*ante*, p. 420). They say that my experience is not wide enough,

or I would know that by the precipitation process calcium sulphate is a natural impurity in cream of tartar. I may here point out that the British Pharmacopœia is our guide, and that it does not recognise what these good people call the precipitation process. Cream of tartar is described in the B.P. as: "An acid salt obtained from the crude tartar which is deposited during the fermentation of grape juice and from the lees of wine." I am aware that the B.P. permits compounds of a definite and known composition to be made by other processes than those described, so long as they "accord with the descriptions and tests given for their identification." See preface to the B.P., fol. xv. Now it has been clearly shown, and the fact is not disputed by Messrs. Kirkpatrick, Barr and Guthrie, that their cream of tartar does not respond to the B.P. test, notwithstanding that it contains 95 per cent. of potassium bitartrate. That is where the shoe pinches, but as they say it is so easy to remove the impurity and thus to make cream of tartar of 100 per cent. purity, I fail to see why they do not make it pure, unless it be for the additional profit it yields by being impure. The whole thing is in a nutshell so far as pharmacists are concerned. Under the Food and Drugs Act, the British Pharmacopœia is invariably taken in courts of justice as the standard for the purity of drugs, and as this particular kind of cream of tartar does not respond to the character and test therein given it is essential to their reputation that pharmacists should give it the cold shoulder.

Liverpool, May 31, 1896.

M. CONROY.

THE PHARMACEUTICAL EXAMINATIONS.

Sir,—Before trying to reply to the letters of Messrs. Durrant and Gelston (not that it is any affair of mine, but that as I know something about the examinations I am interested in any criticisms of them), I took a look at the regulations now in force, and then looked through a book or two to see with whom I had to deal. I find that they are both Minor men, and that it is nearly thirty years since Mr. Durrant passed, and seven since Mr. Gelston got his diploma, so that I think if they went in again next month they would write us very different letters on the subject to those which appeared on Saturday. But in the meantime it would be very useful and interesting to us all if they both, but especially Mr. Durrant, would, instead of finding fault with titles, examiners, examinations, rooms, fees, and everything else, except masters and candidates, tell us what they have done or are doing to promote the education they so strongly advocate. How much time for study do they give or have they given to their apprentices or assistants? Do they keep microscope, burettes, balance, herbarium, etc., for their use, or let them make syr. ferri iod. or ung. hyd. nit., or see that they test and assay their new stocks of hydrocyanic acid or sp. eth. nit.?

The examinations are not perfect, and the examiners are only human, like the rest of us, but their work is very hard and anxious, as it is exceedingly difficult to pass the men who are well up and nervous, and pluck those who are well crammed and have plenty of cheek, and who, if they do get through, do as much harm to the trade as all our other adversaries put together. No; what we seniors ought to do to promote the well-being of the next generation of pharmacists, is each one to encourage and help those apprentices and assistants with whom we come in contact to develop and cultivate a taste for scientific pharmacy. We should teach them not to put themselves on a level with the grocer's or draper's assistants, who are not expected to know much about the goods they sell, but rather to work hard and study all there is to know about everything in the shop, not neglecting the wholesale price and the selling price of mag. sulph. or pulv. glyc. co., but not to let that be the limit of their knowledge, and to take an intelligent scientific interest in everything that comes under their hands. There are plenty of young men up and down the country who are working on these lines, spending their scanty leisure over their books or microscope, or test-tubes or herbarium, instead of wasting it over all sorts of frivolities, which are very pleasant while they last, but don't last long enough to be worthy of more than a passing glance, whereas the man who when young devotes himself to science will take his examinations as they come with a quiet easy mind, and will find his life full of a calm, quiet strength, equally free from bluster and depression, and will unconsciously become one of the leaders of the set in which he finds himself, and will not make the mistake of criticising an examination he knows very little about.

Willingham, Cambs., June 2, 1896.

W. SPENCER TURNER.

"THE METHODS OF A FIRM OF TRANSFER AGENTS."

Sir,—Will you kindly permit us to state that we are the firm of transfer agents referred to by Mr. G. J. Gostling, and that what he describes as a circular was a letter in an envelope, fastened down, and with a penny stamp thereon. Having applications from three clients for a business in the county of Suffolk, we sent the letter, of which you published a copy last week, to about half of the chemists in that county. We certainly cannot see where the interests of the trade are concerned in this matter. If the chemist addressed does not wish to sell his business, he usually says so, or does not answer the letter. The only persons then interested are ourselves, to the extent of the stamp, stationery, and clerk's time.

London, June 1, 1896.

BERDOE AND Co.

MESSRS. ORRIDGE AND COMPANY, the transfer agents, of 32, Ludgate Hill, E.C., write to inform us that the letter reprinted in our last issue did not emanate from them, and that they do not find it necessary to send out such letters; in view, however, of the receipt of Messrs. Berdoe and Company's letter, printed above, there is no need to print their communication.

A CORRECTION.

Sir,—Will you allow me to correct a mistake which appears in your report of the last meeting of the Western Chemists' Association (London). I am represented as saying that six per cent. of retail chemists are in favour of anti-cutting. What I did say—and it is correct—was that over eighty per cent. were in favour of it.

Brixton, S.W., May 30, 1896.

W. JOHNSTON.

PROPOSED TRADE MEETING.

Sir,—I am invited by a well-known manufacturer to sign an agreement not to sell his goods, for which he charges 10s. per dozen, at less than 10s. 6d. per dozen. I have no doubt he expects to derive an advantage by this agreement, but I fail to discover any I shall receive as the retailer, the small fixed price not being worth consideration. I am glad to find manufacturers are beginning to perceive it is not to their interest that their goods are retailed at cost price, and are willing to unite with the retailer for mutual protection. But let the protection be mutual; what is here proposed is certainly not. In order to protect our interests, I propose that a meeting of all chemists in business be held at 17, Bloomsbury Square, and that the Pharmaceutical Council be requested to fix an early date for the same. This, I think, would lead to an active union of the trade, and for this purpose I think Bloomsbury Square is the proper place of meeting.

346, Essex Road, Islington, June 3, 1896. WM. MACGEORGE.

ANSWERS TO QUERIES.

BAKING POWDERS.—Weight for weight, cream of tartar is not cheaper for baking powders than tartaric acid; for the latter having a much stronger neutralising power on the bicarbonate, it goes farther. Cream of tartar is used because it is more slowly soluble, and so causes the more gradual evolution of carbonic acid, which gives a greater porosity and lightness to the mass of dough. [Reply to R. H. R.]

WATER ANALYSIS.—It is impossible to answer your question on the oxygen absorption process unless we know the number of C.c.'s your hypo. solution used up when titrated against the standard permanganate. This solution is very unstable, so that it is always necessary to do a "blank" experiment with pure distilled water. Having found the amount of hypo. equivalent to 10 C.c. of standard permanganate, the water being tested will probably take less, representing the unconsumed oxygen, which number, subtracted from the original quantity taken, will give you the oxygen absorbed. You cannot tell from this process how much "free" and "albuminoid" ammonia is present. Unfortunately, there is often very little accordance between the two methods. All that the oxygen method will do, is to give some idea of the amount of readily oxidisable matter present. You will find an Ehrlenmeyer's flask fitted with a splash trap bulb better than a retort for distilling the ammonias. It is very important to determine the amount of nitrates or nitrites in the class of water you are dealing with. Refer to paper on "Water Analysis" by Millard (*Ph. J.* [3], xviii., 916, 993). [Reply to VANILLA.]

REGISTRATION OF A LABEL.—It is quite possible to protect a label, and not difficult to do so if it bears some distinctive name, signature, device, or word. It is sometimes necessary, however, to disclaim any right to the exclusive use of other matter printed

on the label. Get an application form, costing five shillings, from the local post office, fill it up and send it to the Comptroller, Patent Office, 25, Southampton Buildings, Cursitor Street, Chancery Lane, London, E.C., being careful to attach one of the labels and state what you regard as the essential particular or particulars. If the design is accepted for registration, and there is no opposition to it by other traders, after publication in the *Trade-Marks Journal*, the cost in your case would be about twenty-five shillings.

"ASSOCIATE."—The three specimens sent are:—1, *Carex hirta*; 2, *C. vulpina*; 3, *C. glauca*.

"SECUNDUS."—1, *Ajuga reptans*; 2, *Stellaria holostea*. Please note that specimens will not be named unless the correct name and address of sender accompany them.

TREATMENT OF LEATHER.—Possibly the following glue may suit you; it is largely used for fastening leather at ordinary temperatures, and if well dried, would probably answer at a greater heat:—Take 4 ozs. each of glue and isinglass, just cover them with vinegar, and let soak for twelve hours; then gradually boil, and while boiling add a little tannin until the mass becomes "ropy." Buff off the surfaces of the leather to be joined, and apply the glue while hot. To soften the leather you cannot do better than use what is technically known as "sod oil." This is crude cod-liver oil which has been used in the preparation of chamois leather. You can obtain it from any currier. [Reply to J. C.]

QUALITY OF SAMPLE OF SUGAR.—There is nothing wrong with the sugar you send; we do not find any insoluble white matter, such as you mention. When made into syrup in the B.P. proportions it is perfectly bright. Probably the white deposit you noticed after a time in your syrup bottle was due to the deposition of small crystals of sugar, resulting either from your not having added a little water to make up for that lost by evaporation, or else by storing the syrup in a vessel in which evaporation could take place. Nor do we find any "blue" in your sample. It appears to be of very good quality; you need not fear to use it. [Reply to CUMMINGS BROTHERS.]

TROMMER'S SOLUTION.—This is merely copper carbonate dissolved in excess of sodium carbonate. It is generally made extemporaneously as required by adding an excess of saturated solution of sodium carbonate to a solution of cupric sulphate. [Reply to ASSISTANT.]

THE DETERMINATION OF CAFFEINE IN TEA.

BY A. PETIT AND P. TERRAT.*

When dried tea is treated with chloroform but a small proportion of the caffeine present is removed, in spite of the great solvent power of the liquid for the alkaloid, and it appears to be with the view of obviating this difficulty that certain chemists have recommended the addition of lime or magnesia to remove the caffeine from its natural combination. Commaille, amongst others, makes the tea and magnesia into a stiff paste, which is left to itself for about twenty-four hours, then dried on a water bath, and exhausted with chloroform. This process, however, is far from giving exact and concordant results, as is proved by the accompanying table; in fact, by this process, from tea containing 2.5 per cent. of caffeine, we have obtained only from 0.3 per cent. to 1.2 per cent., according to the conditions of the experiment. There is nothing novel in this observation, however, and experiments by Paul and Cownley,† who made a special study of the subject, seemed to show that magnesia and, more especially, lime possess the property of retaining caffeine when chloroform is used as a solvent. According to those chemists alcohol should be substituted for chloroform, as it does not cause the same difficulty. The employment of alcohol of 80° or 60° has given us very satisfactory results, but with alcohol of 98° there was a very great loss.

To elucidate the question whether caffeine really combines with lime and magnesia or not, we have conducted two assays by Commaille's process, using calcined magnesia, slaked lime, and perfectly dry caffeine, and have been able to recover all the caffeine known to be present. Our results then are not in accord with those obtained by Dr. Paul, who experienced a loss of 27 per cent. with a mixture of caffeine and lime, and a loss of 0.8 per cent. when magnesia was employed.

Combination of the lime or magnesia with the caffeine fails as an explanation of the small yield when chloroform is used for extraction. On the other hand, if the tea be damp, the yield of caffeine is not surpassed by that obtained by any other process. This method, recommended by A. Petit and Legrip,‡ appears to be little known or employed, the probable reason being the existence of a preconceived notion that chloroform cannot completely exhaust a substance containing much water; indeed, it is quite customary to dry such substances before acting upon them either with chloroform or ether. This procedure may be necessary in certain cases but not in the case of tea, in fact the presence of water is indispensable to obtain a good result. The water appears to dissociate the caffeine from its combinations and thus permits the chloroform to exercise its solvent effect properly.

A further proof of the action of water is found in the process of Grandval and Lajoux, who, believing the presence of an alkali to be necessary, and yet wishing to avoid the use of lime or magnesia, substituted ammonia in the proportion of 20 Gm. for 100 Gm. of either of those bases. They prepared a mixture of tea, ammonia, and ether, and percolated it with chloroform, but the results were not better than those obtained by Petit and Legrip's process, and it is evident that the ammonia is unnecessary. By the use of alcohol of 80° and 60° we have obtained almost as good results, but the operation is longer than when chloroform is employed, and it is also more difficult to obtain the caffeine in a pure state.

The following are the details of the Petit and Legrip process:— 25 Gm. of powdered tea is treated with three times its weight of boiling water, and left in contact with it for a quarter of an hour, with occasional agitation. The mixture is next evaporated on a water bath until the tea is just damp and then extracted with chloroform, the percolation being continued until some of the residue left by the chloroform, when dissolved in boiling water and the solution filtered, gives neither precipitate nor opacity on the addition of a solution of tannin. Finally, distil off the chloroform, dissolve the residue in boiling water, filter the solution through paper, wash carefully, and evaporate on a water bath. Usually, the caffeine thus obtained is sufficiently pure to be weighed forthwith.

To remove the chlorophyll, which sometimes impairs the purity of the product, the method followed by Grandval and Lajoux may be adopted: the impure caffeine is dissolved in the cold in 15 C.c. of ten per cent. sulphuric acid, and the solution left for some time before filtration, after which the acid is neutralised with ammonia, and the liquid evaporated. The dry residue is next treated with chloroform, and the chloroform solution evaporated at a very low temperature.

The results stated in the following table demonstrate the effect of the presence of water, the tea used in the experiments containing 2.5 per cent. of caffeine:—

Method Employed.	Caffeine Obtained.	
Dried tea exhausted with anhydrous chloroform	0.18 per cent.	
" " " hydrated "	0.32 "	
" " " boiling "	0.48 "	
Petit and Legrip's process: Moist tea exhausted with chloroform	2.50 "	
Grandval and Lajoux's process: Dried tea and ammonia	2.44 "	
Commaille's process {	After complete desiccation of the mixture	0.30 "
	The mixture being slightly moist.....	1.20 "
	The same, very moist.....	2.50 "
Tea treated with boiling water, dried, and then exhausted with chloroform	0.20 "	
The same, moistened with water before exhausting with chloroform	2.50 "	
Tea, lime, and water mixed into damp paste, dried, and exhausted with chloroform	0.80 "	
The same, moistened with water before exhausting with chloroform	2.47 "	
Dried tea exhausted with alcohol of 98°	0.88 "	
" " " " 80°	2.38 "	
" " " " 60°	2.33 "	
Dried tea and magnesia with alcohol of 98°	0.76 "	
" " " " 80°	2.34 "	
" " " " 60°	2.33 "	
Dried caffeine, 1 Gm., and slaked lime, 4 Gm., made into a paste with water, then dried and exhausted with chloroform	0.997 Gm.	
The same, with magnesia in place of lime.....	0.998 "	

These figures enable us to establish—

1. That magnesia and lime do not enter into combination with caffeine under the conditions of Commaille's process.
2. That lime and magnesia are useless, since by their employment one obtains no more caffeine than in their absence, and, further, they do not serve the purpose for which they have been recommended, since they do not split up the combination or combinations in which the caffeine naturally exists.
3. That, if the Commaille process furnishes variable results, this is not due to the formation of a compound of caffeine with magnesia, which is insoluble in chloroform, but rather to the

* Translated from the *Journal de Pharmacie et de Chimie*, for June 1, 1896.

† *Pharmaceutical Journal* [3], xviii., 417, xxi., 882.

‡ *Bull. de la Soc. Chim.*, 1877, p. 290.

insolubility in that liquid of the combination in which caffeine naturally exists in tea, whence the necessity arises of splitting up this combination with water, magnesia being useless for the purpose.

4. The necessity of operating upon moist tea, since tea treated with water and afterwards dried gives similar results with chloroform to dried tea; during desiccation the previously liberated caffeine again enters into combination.

5. The necessity, if alcohol be employed for extraction, of having it sufficiently dilute, since nearly anhydrous alcohol gives but a very small yield.

ALCHEMY AND PHARMACY. THEIR MYSTERY AND ROMANCE.

BY C. J. S. THOMPSON.

(Concluded from page 382.)

CHAPTER IX.

The Pioneers of Pharmacy.

The operation of distillation was unknown to the ancient Greeks and Romans, although Dioscorides and Pliny describe a process which may be considered that of distillation in its infancy. The process was not known in England until the time of Henry II. To the Arabs we are indebted for the discovery of manna, cassia, senna, and rhubarb, also aromatics, such as musk, nutmeg, mace, and cloves. Blisters were also known and used by the Arabs, who are the first on record to mention sugar, extracted from the cane, and sugar candy, which they called honey of cane.

Rhases and Avicenna were the first physicians to introduce improvements in pharmaceutical preparations. The latter was the first to mention the three mineral acids, and distinguish between the vegetable and mineral alkalies.

In the year 1226, Roger Bacon, a native of Ilchester, in Somersetshire, and a Franciscan Monk, may be said to have laid the foundation of chemical science in Europe. He was excommunicated by Pope Nicholas, and imprisoned for ten years for supposed dealings with the devil. He professed to have discovered an elixir of life, which he affirmed prevented corruption of any constitution and the infirmities of age for many years. Following Bacon at the end of the thirteenth century came Arnould de Villa Nova, who was the first to recommend the distilled spirit of wine impregnated with certain herbs, from which we date our use of tinctures in medicine.

Basil Valentine followed as a pioneer in the administration of metallic medicines; he discovered volatile alkali from sal-ammoniac, and noticed the production of ether from alcohol.

In the year 1493, Paracelsus was born near Zurich, in Switzerland, a man of extraordinary conceit and boldness, but who wrought a greater change and influence in materia medica than any physician since the time of Galen. He travelled all over Europe, and so obtained an extensive knowledge of chemistry and medicine.

This genius of science and quackery, for such Paracelsus must be termed, who scoffed at all the doctrines believed in since the time of Hippocrates, professed to have received his knowledge from the divine being himself. His sheer impudence carried the sympathies of the public with him, and they kissed the skirts of his gown as he passed through the streets, whilst he had among his followers many princes and nobles.

He denounced the apothecaries, who, he said, could only compose insipid syrups and repulsive concoctions, when they have ready to hand at the bottom of their stills, extracts and dyes derived from

the best vegetables and minerals. He disagreed with the doctors also, whose prescriptions he stigmatised as barbarous, and was much against the use of correctives added to pharmaceutical recipes when they had no natural relation to the preparation itself. He believed in the existence of an active principle in plants, which he termed the Ether of Aristotle, that could be isolated and used to avert the various disorders of the human body—an idea which is now the leading spirit in pharmaceutical research. His labours did much to stimulate the practical side of chemistry, and his language was mysterious, as, like other alchemists, he wrapped up all his wisdom and his ignorance in the garb of allegory. He was reported to carry about a familiar spirit in the pommel of a long sword that always hung at his side.

Paracelsus is said to have been the first to use mercury internally; he also employed opium, antimony, and lead largely in his treatment; and he devised a process for the preparation of red oxide of mercury. He was sent for to many of the European Courts, and by the interest of Erasmus was made Professor of Chemistry at Bale, the first chair that was established in Europe. It was here while seated in his chair that, with arrogant impudence, he burnt with great solemnity the writings of Galen and Avicenna, saying that "if God would not impart the secrets of physic, it was not only allowable, but was justifiable, to consult the devil."

He had the greatest contempt for his fellow physicians, and said he had more knowledge in the very down on his bald pate than was in all their writings, and in the buckles of his shoes there was more learning than in Galen and Avicenna, and in his beard more experience than all their universities. The man was a mass of conceit and egotism, yet feared and liked by the people for his boldness.

Latterly he took to drinking heavily, seldom taking off his clothes for many nights together. At length he broke down and the end came at the age of 48, when this singular man died after a few hours' illness at Saltzburg in Austria, a bottle of his boasted panacea for all ills being found in his pocket. He believed the human body to be composed of salt, sulphur and mercury, and that in these "three fast substances" health and disease consist. To give Paracelsus his due, although empiricism and quackery were the chief elements in his career, he swayed an undoubted influence on the medical practice of his time, and with all his egotism did his best to advance the science and art of medicine.

The next pioneer was Van Helmont who flourished some hundred years later. He was the first to notice the existence of gases, also the first to use alum in uterine hæmorrhage, through which he acquired a great reputation.

Little was known of materia medica by the nations of the west from the eighth to the tenth century. The chief cultivation of medicinal herbs took place in the monasteries, each having its own botanical garden, which contributed so much to the progress of medicine. At this time the knowledge of the medicinal value of herbs and roots was much more advanced in the East, and we find that during the reign of Almansour, in the eighth century, a large school was founded at Bagdad, which became a refuge for scientists when exiled from Athens and Alexandria. The works of Aristotle and Galen were translated into Syriac, and the greatest generosity and encouragement were shown to savants who settled there. Before this, the Arabs had considerable knowledge of the use of plants in medicine, and had made some valuable discoveries. Their physicians recommended the use of senna, tamarinds and cassia in place of the violent purgatives used by the Greek doctors, and a number of new plants were introduced by Rhases from India, Persia and Syria. Mesné wrote his treatise on medicine ('De Re edica'), which, on being translated into Latin, was used as a manual in all the schools up to the Renaissance.

Constantine was the first to introduce the most noted Arab works into Europe, himself a writer of no little repute. Then several Arab travellers added to the store of knowledge, among these, Ebor-Taitor, a native of Malaga, travelled in Asia to study plants, and eventually became minister of the Caliph at Cairo.

Otho, of Cremona, in a poem of one thousand five hundred lines, contributed his knowledge of plants, and John, of Milan, in his 'Code of the School of Salerno,' compiled the discoveries in medical botany of a century.

Coming to the twelfth century, scientific progress was not so rapid, yet all the investigation that was made originated in the study of medicine. Most of the monasteries and convents had their botanical gardens and also collections of minerals and animals, which were carefully watched and tended, and the monks and nuns would not only administer to the sick of their own orders, but also to the suffering who claimed their charity. Once lodged there the treatment was good and wholesome, mostly by decoctions of some simple, backed up by good kitchen medicine, quietness, and rest. One or two monks who had special knowledge of herbs were usually allotted to this department. It can then hardly be wondered at, that during the thirteenth and fourteenth centuries most of the record we have of medicine is from works by the brethren of the monasteries. An excellent collection of recipes, comprising also a summary of plants, animals, and minerals was compiled by Hildegard, Abbess of Bingen, called the "Jardin de Santé."

This good lady, like many other abbesses of her time, was much interested in the art of healing. She cultivated her own medicinal plants, and carefully noted down their properties for the use of others, and thus left a valuable record.

In the thirteenth century an advance was made in materia medica by Gilbert and HERNICUS ARVIELL, two Englishmen who travelled through Asia to study plants and their uses. Simon de Cordo, called Simon of Genoa, also took a botanising exploration into Sicily and the islands of the Archipelago, and afterwards wrote a botanic dictionary.

Another eminent botanist of this time was Peter de Crescenzi, a man of good birth and fortune, who was born at Bologna in 1330, and who greatly interested himself in botany and horticulture. His great work, which was translated into several languages, was called 'Opus Rubarium Commodorum.' Contemporary with Peter were three names we must not omit, viz., Vincent de Beauvais, Albertus Magnus, and Arnaud de Villeneuve, who compiled a knowledge of both alchemy, astrology, and physic. Vincent de Beauvais was a dominican monk, and his great work, the 'Speculum Naturale,' is saturated with the superstition of the time. In this book he states 'the mandragora is of the same shape as the human body; the winged

dragon is capable of carrying off an ox, and devouring the same whilst flying." He also describes the scythion lamb, a sort of animal plant which had roots and grew in the ground, and other fearsome creatures, and declared that in Scotland the fruits of certain trees, when they fall into the water, produced the birds called black divers. Villeneuve wrote many treatises on plants and animals, and eventually became teacher of medicine and botany at the University of Paris. He was undoubtedly a man in advance of his time, and boldly declared "that the most solemn mysteries of the Catholic faith could be explained by the teachings of natural history and experimental physics."

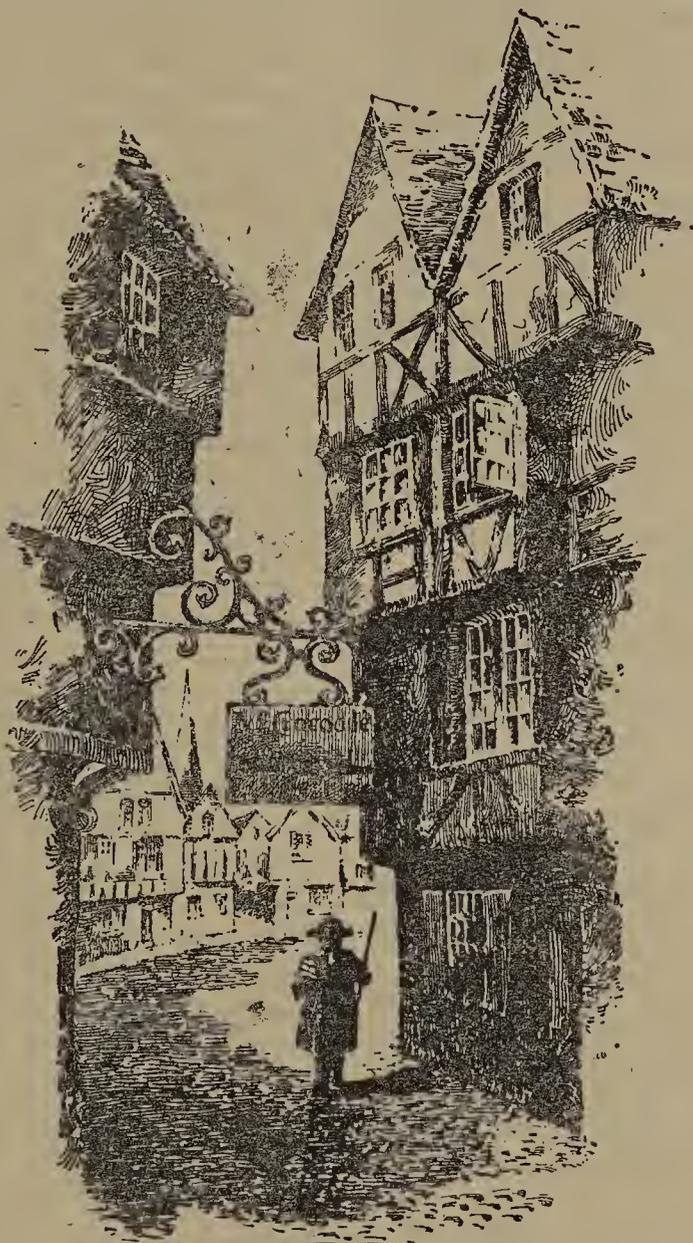

He was therefore accused by the magistrates of sorcery and magic, but he escaped through the special protection of Charles of Anjou into Italy, where he settled for a long time.

The fourteenth century saw little advance in the medical art, but it was enriched by one or two great works. One of these written in Latin by Bartholomew Glanvil, an English monk, was a kind of encyclopædia of immense size, and was called, 'Liber de Proprietatibus Rerum,' and had a great reputation for hundreds of years after.

The advent of printing about the middle of the fifteenth century rapidly spread the knowledge of more recent discoveries throughout Europe, and many large works on botany and herbalism, illustrated with woodcuts, were published at Mayence and Louvain. At Venice many of the works of the old Arab physicians, Avicenna, Mesné, and others were printed and eagerly purchased. The discovery of America in 1492 heralded the introduction of numerous fresh additions materia medica, which were brought to this country by explorers and naturalists.

In the sixteenth century, by the labours and researches of George Agricola, a German, and Conrad Gesner, a Swiss, a considerable advance was made in the knowledge of what was called chemical medicine and botany. Agricola, who was the greatest mineralogist the world had

then seen, explored and spent much time in the mines of Bohemia and Saxony, and thus obtained a practical knowledge of the then known methods of the working of metals. His contemporary, Conrad Gesner, born at Zurich in 1516, has been called the originator of scientific botany, as he was the first to discover a method of recognising each genus and kind by examining the organs of fructification, and in this way discovered 1800 new varieties. A famous physic garden was planted in Paris in the early part of the seventeenth century by Jacques Gohory, an enthusiastic pharmacist, and this garden eventually became part of the Jardin des Plantes. In connection with this garden a school of medicine was founded, the first occupant of the chair of chemistry being William Davisson, a Scotchman, and pre-

AN APOTHECARY'S SHOP. 15TH CENTURY.

decessor to Lefebvre, who afterwards became a chemist at St. James's.

The practice of the teachers at this time was to dictate to their students, and in order to save themselves the trouble of dictating and the students the trouble of writing, which was a very laborious matter in those days, the lecturer would write a book. Such was done by Jean Beguin, who wrote a chemical text-book in 1612, which passed through no fewer than fifty-three editions.

We must also not forget to mention two other pioneers in science of this age, who made important discoveries in botany; they were Matthias of Lille, who eventually settled in England, and Andrew Cesalpin, professor of botany at Pisa. The former first formulated the true principles of classification and arrangement into families, such as the orchids, palms, and mosses, and to the latter belongs the honour of having devised the first system of botany. Having compared the process of generation in animals to the seeds of plants, he distinguished male plants by their stamens, and those which yielded seed as female.

The next era is marked by the publication of the first pharmacopœia at Nuremburg in 1542. "For this act," says Paris, "we are indebted to Valerius Cordus, a young student, who, during a transient visit at that place, accidentally produced a collection of medical receipts which he had selected from the works of the past esteemed writers, and with which the physicians of Nuremburg were so highly pleased, that they urged him to print it for the benefit of the apothecaries, and obtained the sanction of the Senate to the undertaking." To this slight circumstance we owe the institution of pharmacopœias. The first London Pharmacopœia was, however, not published until the reign of James I., in 1618.

Having thus shown how these now almost forgotten pioneers of science laid the foundation stones of the arts of medicine and pharmacy, and how much we owe to their patience and diligence, this series may now be fittingly concluded with a brief reference to the class of medicaments in use in the days of Queen Elizabeth, immediately prior to the differentiation in England of the first pharmacists—the apothecaries—and the beginnings of pharmacy as a separate art.

"A few simples," says Burton, "well prepared and understood are better than such a heap of nonsense, confused compounds, which are in apothecaries' shops ordinarily sold."

For madness and melancholy, wormwood was used. Another remedy was clarified whey, with borage, bugloss, endive, succory, etc., a good draught of which was taken in the morning, fasting. For the spleen and liver, syrups were prescribed composed of borage, thyme, epithyme, hops, scolopendra, fumitory, maiden-hair, and bizantine. These syrups were mixed with distilled water by the apothecaries or stirred into juleps.

Of conserves there were innumerable varieties, and ointments of oil and wax, as well as liniments and plasters of herbs and flowers, well boiled with oil or spirits.

Cataplasms and salves were frequently made of green herbs sodden, pounded, and applied externally.

Gradually as the years have rolled on, the science of chemistry has shed its searching light and unlocked the marvellous resources and products of nature, most of these old relics of the days of superstition and witchcraft have been left behind and forgotten, and it remains only for some old black-lettered tome to tell the story and fill in the background to the picture.

ZINC VALERIANATE IN HAY FEVER.—Dr. Abercrombie has found valerianate of zinc given in three-grain doses in a pill, to be taken immediately after meals, of great service in a troublesome case of hay fever in a neurotic patient: the salt appears to act both as a curative and as a preventive (*B. M. J.*, 1/96, 967).

HOW TO NAME A PLANT.

EXOTIC OR GARDEN PLANTS.*

The season is approaching when inquiries concerning the names of plants are more numerous than usual, and not unfrequently plants are met with which are evidently not indigenous to Britain, but the seeds of which have by some accident become deposited in the most unexpected places, where ballast may have been thrown, or grain, etc., sifted. The difficulty of naming such plants has doubtless been often experienced by amateur botanists, and a brief explanation of the best mode of procedure may be useful to some of our readers.

It may be assumed that after some practice in examining indigenous British plants, the student will have become fairly well acquainted with the general appearance and family peculiarities of the larger and more frequently occurring natural orders, and that he will be able to determine without much difficulty whether any plant that comes under his notice presents the diagnostic characters of any of these orders. If such be not the case, he has to deal with nearly 200 natural orders, and to locate his specimen in its proper position. Supposing he has decided that it belongs to the *Thalamifloræ*, the next step is to ascertain to which of the cohorts or alliances of natural orders under the *Thalamifloræ* section it belongs. The easiest way of doing this is to turn to Warming's 'Handbook of Systematic Botany,' translated by Professor M. C. Potter (Swan, Sonnenschein), p. 580, and taking the cohorts in turn, compare the characters of the ovary, stamens, sepals and mature seeds with the description therein given.†

Having determined the cohort to which the plant belongs, the more difficult task of finding out the natural order remains, and it is useless to attempt this with any hope of success unless well-developed fruit is obtainable, as well as flowers. If these necessary materials can be had, a previous knowledge of the larger and more common natural orders proves of great value. Thus, supposing the plant to belong to *Thalamifloræ*, the ovary being apocarpous, then the plant evidently belongs to the *Ranales* (i.e., *Ranunculales*), and it will be noticed on turning to page 6 of Vol. I. of Bentham's 'Genera Plantarum' that the *Ranunculaceæ* may be used as a peg upon which to hang all the natural orders in the group. Thus the *Dilleniaceæ* have flowers like the *Ranunculaceæ*, but differ in having arillate seeds, and in consisting chiefly of shrubby plants, all the other orders in this cohort having the sepals and petals in three or more rows running more or less into one another. Of these the *Magnoliaceæ* are characterised by an elongated receptacle, the *Calycanthaceæ* by having the receptacles enclosed in the calyx tube (as in the rose) and by the opposite leaves the *Anonaceæ* by the ruminated albumen of the seeds; the *Menispermaceæ* by the small dioecious flowers and (usually) three carpels, and superior micropyle; and the *Berberidaceæ* by the valvate anthers, and usually single carpel (three in polygamous species). The *Nymphaeaceæ* has such characteristic leaves that although on the one hand it resembles the *Ranales* in the apocarpous ovary (*Nelumbium*), and there are plants in the family (*Nuphar*) which ally it to the next cohort, *Parietales*, in which the carpels are

* Articles dealing with the identification of indigenous plants appeared in the last volume of the *Pharmaceutical Journal*, pp. 7 and 226.

† The advantage of using Warming's book is that in the excellent appendix on the classification of plants by Professor Potter, a bird's-eye view of the whole of the classification of the 'Genera Plantarum' is available, whereas in the latter work it is scattered over three large and inconvenient volumes. Moreover, the student will be able to obtain an excellent idea of the divergences of opinion amongst botanists as to the alliances of the groups, from the time of John Ray in 1703 to that of Engler in 1892.

united, and the placentation parietal, there is no difficulty in recognising the plants of the order. The above remarks must be considered merely in the light of giving as briefly as possible the leading differences in these natural orders, and not as a key to be used in determining accurately the natural order. To do that it is necessary to see that the plant agrees with all the characters given in the 'Genera Plantarum,' on pp. vi.-vii., and, if any difficulty is experienced, to refer to the abnormal forms enumerated after the general description under each natural order. When the natural order had been decided upon, the tribe and sub-tribe can be determined in the same way, and then the genus, under which, as a rule, very few diagnostic characters are given, so that if the steps have been carefully followed the determination of the genus is tolerably easy.

To accurately determine the species is a much more difficult matter. If it be a garden plant, there are two or three books which may first be consulted. Of these Nicholson's 'Dictionary of Gardening' is one of the best and most recent. Loudon's 'Encyclopædia' is an old but useful book of reference, and 'The Treasury of Botany' (Longmans) is very useful for giving interesting details concerning the commoner plants of a genus. A list of plants of very recent introduction into horticulture is given every year in the 'Kew Bulletin,' with brief descriptions of the colour of the blossoms, date of flowering, native country, and special characteristics. If the plant does not appear to be given in any of these, the only plan is to take or send it to one of the large national or provincial herbaria, and compare it there with the species of the genus to which it presumably belongs. If the plant has a double flower, and is a purely horticultural variety, the best plan to get it named is to forward a specimen (showing all the characteristic forms of leaf that occur in the plant, with flower and fruit) to one of the leading journals on horticulture for identification.

If the plant be an exotic not in cultivation, the best plan is to inquire at one of our national herbaria the name of the most recent monograph on the genus, and to compare the plant with the descriptions there given. If it does not coincide with any of them it still remains to ascertain whether any new species of the genus have subsequently been described. This may be learnt to within the date of two years back by consulting the index of the 'Botanischer Jahresbericht' (Borntraeger Bros., Berlin).^{*} Unfortunately a list quite up to date of the new plants published every year in all countries cannot apparently be published by our national herbaria, owing to the lack of funds available, since it would occupy the entire time of one clerk to make it out. An annual list of the plants published every year, with the references to the works in which they occur, arranged alphabetically under the natural orders, which might also be arranged alphabetically, would be a great boon to all workers in systematic botany, and would be a saving of valuable time to hundreds of botanists, since there is probably no herbarium in existence which contains a specimen of every known plant. Without available descriptions of new plants it is impossible to say whether any given plant that cannot be found in an herbarium is new or not.

If the above description of the difficulties of naming a plant will render those who send plants to journals to be named a little more careful to enclose specimens in fruit, some little good will have been accomplished, and if it induces them to try and name them for themselves before sending them, the experience will prove very valuable to those who do so, for names learned through the work of others are easily forgotten.

^{*} The 'Index Kewensis' contains the names and references to the descriptions of all flowering plants known up to A.D. 1885.

CHEMICAL VERSUS BACTERIOLOGICAL EXAMINATION OF POTABLE WATER.

BY W. P. MASON.

Apropos of the recent articles upon this question, which have appeared in the English papers, it is noteworthy that there is a growing tendency among physicians and civil engineers to belittle the chemist's opinion regarding the potability of a water, and to pin their faith exclusively upon what the bacteriologist may have to say upon the subject. This feeling is strengthened by the publication of the results of such trials as that undertaken by the London Local Government Board, in which, it will be remembered, water samples purposely inoculated with typhoid germs were sent for analysis to one of England's leading chemists, and were by him pronounced pure.

Those who set special value upon such a "test" of methods as the above, and who consider it quite final as showing the inability of chemistry to detect pollution in a liquid which the bacteriologist would instantly pronounce very foul, should remember that such a sample of water could not be found in practice, and that the very conditions under which it was prepared eliminated the chemical items indicating pollution, while it increased tremendously the signs governing the bacteriological side of the case.

The bacteriologist sought for the Eberth bacillus, and, very naturally, quickly found it in a water purposely sown with a culture of the germ.

The chemist looked for those elements which always occur in sewage-laden water, whether the sewage be from sources of disease or otherwise, and, not finding them, he pronounced the water to be what it really was, free from sewage addition.

Sewage, as it occurs in practice, contains an immense deal of material other than that productive of disease, and it is upon just this comparatively harmless, but constantly present material, that the chemist relies for the indication upon which he bases his opinions.

He is unable to say whether or not a sewage-laden water is disease-bearing on any particular date, for to him all sewage is alike; but he condemns the water, for the reason that, although it may be harmless to-day, it is impossible to predict what may be its condition to-morrow.

Within the week I have been requested to make a bacteriological examination of the water of a certain well, in order to determine if it be affected by neighbouring cesspools.

The physician who made the request was impressed with belief in the paramount value of such an examination and the comparative uselessness of chemical analysis.

I am quite convinced that had I followed his suggestion I should have sought in vain for any specific microbe; but inasmuch as upon chemical analysis I found that the "chlorine" ran twenty-four parts per million, which is about ten times the local "normal," and the "nitric nitrogen" read nine parts per million in place of 0.116, I condemned the water off-hand without going further.

There is simply no comparison between the two methods in question for water problems of this class, and the value of chemistry is still more pronounced in those instances where it is possible to introduce common salt or lithium chloride into a source of suspected pollution, and then look for increased chlorine or presence of lithium in the water of the well. In legal cases touching upon this point of contamination of wells, by cemeteries for instance, the chemical testimony is especially strong.

In the matter of determining the suitability of a stream for city supply, the services of the bacteriologist should be unquestionably secured, but it is doubtful if his report can be considered of more importance than that of the chemist.

Chemical analysis, by comparing the water taken at the site of the proposed intake with that from the same stream above all points of possible pollution, can indicate whether or not up-stream contamination is felt at the lower point; nor is it necessary that the polluting sewage be from pathogenic sources in order that its presence may be recognised.

As Dr. Dupré has pointed out, chemistry in such cases anticipates what may happen in the future, and, by timely advice, may prevent an outbreak of disease, while, on the other hand, the discovery of disease germs in a water is only possible after the water has become infected.

Bacteriology is of especial value, and greatly superior to chemistry for the testing of filters and watching any variation in their efficiency.

For this purpose the simple count of germs per C.c. is most valuable, and differentiation is a secondary matter; for the assumption is a just one, that a filter which will remove the harmless bacteria will take out the objectionable ones as well.

It is very far from my desire to decry the value of bacteriology; but I cannot but feel that, in their enthusiasm over the great triumphs of the new science, the people at large have gone slightly "bacteria mad," and are apt to expect more than can be furnished by the means and information now available.—*Journal of the American Chemical Society.*

BERTHELOT'S CONTRIBUTIONS TO THE HISTORY OF CHEMISTRY.*

BY H. CARRINGTON BOLTON, PH. D.

Marcellin Berthelot, Professor of Chemistry in the Collège de France, Perpetual Secretary of the Academy of Sciences, Senator, Minister of Public Instruction, and recently appointed Minister of Foreign Affairs, known to the scientific world by his masterly researches in synthetical chemistry, has added to these honours that of editing the most important and far-reaching documents pertaining to the history of chemistry ever brought to light.

The six handsome quarto volumes published by him between the years 1887 and 1893 contain the most ancient Greek, Arabic, Syriac, and Latin treatises on alchemy and technical chemistry preserved in the great libraries of the old world. Besides reproducing the original text of these precious manuscripts, these volumes contain complete translations of many treatises, analyses of the contents of others, and critical studies of their mutual relations, their sources and authorship, as well as erudite essays on the chemical knowledge exhibited in them. The six volumes form two distinct works: three of the volumes bear the title 'Collection des anciens Alchimistes Grecs,' and three of them 'La Chimie au moyen âge,' each volume having, moreover, specific sub-titles more exactly indicating its contents.

Not having seen any adequate review of these works in English, I propose in this article to examine their scope, contents, and manner of treatment, as well as to show some of the more important changes resulting from Berthelot's historical studies. The existence of ancient Greek and Arabian manuscripts had long been known; Reuvs, and later Leemans, of Holland, had published summaries of certain papyri preserved in Leyden, more than forty years before, but in such a fragmentary manner as merely to excite curiosity. Ferdinand Hoefer, the French historian of chemistry, and Herman Kopp, the erudite German, had made partial use of some of the manuscripts; but it remained for Berthelot to collect and

compare the diverse copies, to reproduce and translate them for the benefit of students. This he could scarcely have accomplished without the aid of the French Government, both series being "published under the auspices of the Minister of Public Instruction." Government co-operation was brought about through the report made by Berthelot to the "Comité de Travaux Historiques et Scientifiques," and adopted by them in 1884. This report directed attention to the existence of Greek alchemical manuscripts and to the utility of their publication, owing to the great light they throw on the history of natural science, the technology of metals and ceramics, and the history of philosophy in the first centuries of the Christian era.

The difficulties of deciphering, transcribing, and editing Greek, Arabic, Syriac, and Latin manuscripts were prodigious, and Berthelot was fortunate in securing scholars of eminence to assist in the task. In dealing with the Greek papyri, he was aided by Ch. Em. Ruelle, of the Bibliothèque Sainte Geneviève, Paris, and by André Berthelot, son of the editor; the Arabic scholar, Professor Houdas, and the Syriac linguist, Rubens Duval, also contributed their learning, each in his own sphere.

The 'Collection des Alchimistes Grecs' opens with an "Introduction" by Berthelot, which occupies 268 pages; this forms an important contribution to the history of chemistry, based upon a critical study of the ancient treatises; he agrees with other historians in tracing the birth of alchemical ideas to Egyptians, whence they reached Europe through Greeks.

Certain Greco-Egyptian papyri, preserved in Leyden, are of the greatest interest; several of them treat of magical formulæ, incantations, love philtres, dreams, and similar gnostic notions; one of them, known as "Papyrus X," is a treasury of information on metallurgical operations, at so early a period as the third century of the Christian era. It was found in a tomb at Thebes, secured by the Swedish Consul at Alexandria, Anastasi, and presented by him to the Netherlands in 1828. Berthelot conjectures it is one of the ancient Egyptian books on the preparation of gold and silver, which escaped the destruction ordered by Diocletian in 290,—an order issued lest the people using them should grow rich by their art and revolt against the Romans.

This precious document contains one hundred and one chemical and alchemical recipes, followed by ten paragraphs taken from Dioscorides. The recipes are for making alloys to be used in the manufacture of cups, vases, images, and other objects of the goldsmith's art, also processes for soldering metals and superficially colouring them, besides formulæ for making gold and silver links. The text is full of grammatical errors and ignorant spellings, which show the writing to have been the work of an uneducated artisan; the recipes are not arranged in order, several appear in duplicate,—they exhibit no indication of chicanery, although some of the methods are unprofitable. The whole papyrus, in short, is evidently the memorandum-book of a goldsmith (or silversmith) engaged in attempts to imitate gold and silver for fraudulent purposes. Only one author is cited, "Phimenas," who is probably Pammenes, author of recipes occurring also in other manuscripts. The preparation of *asem*, an amalgam of copper and tin, plays a prominent part among the recipes for imitating gold. But time forbids a full analysis of this remarkable manuscript; as a result of Berthelot's careful study of this and analogous treatises, he comes to the conclusion that the doctrines of alchemy concerning the transmutation of metals did not originate in the philosophical views of the constitution of matter, as generally supposed, but in the practical experiments of goldsmiths occupied in making fraudulent substitutes for the precious metals. The "Introduction" contains a chapter on the relations between the metals and the planets, of Chaldean origin,

* Read before the Washington Section of the American Chemical Society, March 12, 1896. From the *Journal of the American Chemical Society.*

and constant occurrence in the early writings, which is illustrated by facsimiles of several manuscript pages. Another chapter is devoted to the figures of apparatus occurring in the treatises of the eleventh to fourteenth centuries; these include water-baths, digestors, aludels, alembics, and a great variety of apparatus for distillation.

The sixth chapter of the Introduction is divided into twelve sections; these deal with several Greek manuscripts, notably those preserved in the libraries of St. Mark, Venice, the Escorial, the Vatican, Rome, Gotha, and in Munich, appertaining to the eleventh to fourteen centuries; of these we note only a few features. At the beginning of the MS. of St. Mark, in one of the earliest of chemical bibliographies, it gives the title of fifty-two treatises, verily not in modern style, yet quite suggestive; among them are the following:—"Emperor Heraclius, eleven chapters on the manufacture of gold." "Justinian, five chapters on the secret art." "Heliodorus, on the divine art." "Theophrastus, verses on this art." "Moses, on the diplosis (doubling) of gold." "Lexicon of the gold-maker, in alphabetical order."

This association of names of Emperors of Rome, Greek classical writers, and the Hebrew law-giver, with chemical and alchemical treatises, is characteristic of the period at which they were compiled, and by no means denotes actual authorship; the names of prominent men were given to the treatises in order to add to the dignity and authority of the writings. This custom prevailed as late as the sixteenth century, and, in certain cases to be noted here after, gave rise to undeserved honours. An entire group of writings have been ascribed to Democritus, giving rise in Egypt to what may be styled the school of Democritus. A certain Zosimus, of Panopolis, is credited with a veritable encyclopædia of the sacred art, a work which occupies ninety pages of Berthelot's volume.

The 'Collection des Alchimistes Grecs' comprises no less than 160 different treatises on the science of Hermes. Many of these are fragmentary in the extreme, extending to only six lines, and even less. All are composed in an archaic, enigmatical style, combining, in one undecipherable medley, chemical terms of obscure meaning, magical formulæ, astrological notions, citations from mythical authors, and mystical allusions to a philosophy long since buried too deep for present resurrection. It is not surprising that commentators early felt the need of lexicons of the sacred art, and such are preserved in these volumes; unfortunately, however, the definitions are no clearer than the words defined; one word was often used for a score of different objects and processes, and a single article was known by a dozen different names. To convey to readers any idea of these extraordinary literary productions by citations is hardly practicable in the space available, for passages lose much when removed from their original settings. The actual chemical knowledge exhibited in these ancient manuscripts is varied, and yet indefinite owing to the numerous obscure expressions; the authors were acquainted with a large number of ores, minerals, earthy substances, and saline bodies, as well as vegetable and animal products, but their ignorance of the mineral acids and their important derivatives limited them to products obtained by aqueous solution, distillation, and the action of heat. Of scientifically classified knowledge there is no trace; the alleged opinions of mythical writers are given as authoritative, and information is imparted in the tedious form of dialogues between philosophers, who remind one of the Scotchman's definition of metaphysicians:—"Poor bodies discussing things of which they know nothing in a language neither of them can understand." Many of the writings contain reverent acknowledgments of the Deity and other evidences of piety. There is a good deal of duplication, arising from the introduction into an essay of passages from another, generally

without acknowledgment. Berthelot remarks incidentally that the term *Philosophers' Stone* does not occur in writings earlier than the seventh century, although the central idea is much more ancient.

Each of the three quarto volumes which constitute Berthelot's *La Chimie au moyen âge* bears an independent title; that of the first volume reads—"Essay on the transmission of the knowledge of Antiquity to the Middle Ages; transmission of Technology; translations of Arabico-Latin treatises, with a new version of the 'Liber Ignium' of Marcus Græcus, and an original edition of the 'Liber Sacerdotum.'"

This volume covers the period from the fall of the Roman Empire to the thirteenth century, thus filling the gap between the ancient Greek alchemists and the Latin writers of the later epoch, a period which had been previously unworked or misunderstood. Berthelot finds that the transmission from the earlier to the later era was accomplished by two agencies; first through the Arabians, who succeeded to the literary and scientific wealth of the Greeks. The Arabic treatises, preserved in the Mohammedan libraries of Spain, were translated into Latin, and thus became for Western nations the sources of their knowledge in medicine, alchemy, mathematics, and philosophy. Some of these translations were collected and printed in the seventeenth century in the works entitled 'Theatrum Chemicum' (5 vols., 1613-22), and 'Bibliotheca Chémica' of Mangetus (2 vols., folio, 1702), and Berthelot discovered in these Arabico-Latin treatises entire passages from the ancient Greek alchemists.

The connection between the Greeks and Arabians was not, however, immediate, but through the Syrians, who were among the first to translate the philosophy and science of the Greeks into an Oriental tongue. These Syriac versions form the subject of the second volume.

A second link between the Greeks and the Latin alchemy was more directly forged, though difficult of recognition; the processes used in industrial arts and metallurgical operations by the Greeks had been adopted by the Latins as early as the time of the Roman Empire, and this chemical technology was preserved through centuries of intellectual degradation to the beginning of the Middle Ages.

The most ancient Latin treatises on chemical technology are the 'Compositiones ad tingenda,' dating from the close of the eighth century, and the 'Mappæ clavicula,' written before the tenth century. These are collections of recipes for industrial processes analogous to those in the Leyden papyrus, and forming links in a chain that extends from that ancient work through the treatises of the Middle Ages to the modern 'Workshop Recipes' and 'Manuels Rorets.' The full title of the 'Compositiones ad tingenda' is as follows: [Translation.]—"Recipes for colouring mosaics, skins, and other objects, for gilding iron, for using minerals, for writing in letters of gold, for soldering metals, and other technical documents." The following are some of the subjects treated:—The colouring of artificial stones used in the manufacture of mosaics; the manufacture of stained glass; the dyeing of skins in purple, green, yellow, and reds; the dyeing of wood, bone, and horn; a list of ores, metals, earths, and metallic oxides, used in jewellery and in painting; a number of recipes for gilding on glass, woods, skins, garments, and the metals. All these topics are treated in barbarous Latin, bordering on a species of jargon; some were originally written in Greek, and copied by ignorant scribes in Latin letters, which shows the influence of Constantinople. In one of the sections on ores the word "vitriol" occurs for the first time, being the eighth century, and in the correct significance of an impure ferrous sulphate. A very rational grouping of substances occurs in this work; the minerals and earths are by themselves; then follow gums, resins

and other products of plants and, thirdly, substances derived from the ocean, such as salt, coral, and mollusks yielding purple dye. A certain receipt for writing in letters of gold is practically identical with one in the Papyrus of Leyden.

A formula for making bronze shows the origin of this name, *De compositio brandisii*, Brindes being a synonym of Brundisium (Brindisi), a town noted in Pliny's days for its metallic mirrors.

A large part of 'Compositiones ad tingenda' is reproduced in the work entitled 'Mappæ clavicula,' of which the earliest known manuscript dates from the tenth century. This latter treatise contains recipes for making gold, for multiplying gold, and imitating the precious metal, closely resembling those of the ancient Greek papyri. In this connection cautions are given to conceal the secrets, and an incantation is prescribed to be used during the operation. Exceeding interest attaches to the fact that the use of the hydrostatic balance in analysis of an alloy is clearly described, for this proves that the knowledge of this instrument did not pass through Arabian channels, and possibly came down direct from Archimedes.

The 'Liber ignium ad comburendos hostes,' by Marcus Græcus is one of the most ancient Latin treatises on Greek fire, dating from the twelfth or thirteenth century, and is probably a translation from an earlier Greek work transmitted through Arabian channels. It deals with instructions for making Greek fire, so-called, phosphorescent materials, fire-proofing substances, and the preparation of fuses and petards, composed in part of saltpetre. Greek fire itself, however, dates from the second century B.C., and phosphorescent stones are named in the much earlier Greek alchemical manuscripts.

Berthelot devotes an interesting chapter to the discovery of alcohol. This product of distillation first appears under the name *aqua ardens*, and the term alcohol in its present signification does not occur before the middle of the fourteenth century; the term *spiritus vini* is also comparatively modern, and *aqua vitæ* seems to have been applied to alcohol for the first time by Arnald de Villanova, who died in 1314. The fact that wine yielded an inflammable substance was, however, already noted by Aristotle, but this body was not isolated. Rhases has been given credit for acquaintance with alcohol, but this is erroneous.

The preparation of alcohol by distilling wine is, however, mentioned in a copy of the 'Mappæ clavicula,' written in the twelfth century, and in the 'Liber ignium' of Marcus Græcus.

In attempting to trace to their origin Latin treatises which claim to be translated from Arabic, Berthelot made the important discovery that they are fraudulent, the Arabic manuscripts having no existence. Thus the chemical works attributed to the Arabian physician Jabir ibn Hayyan (Abu Musâ), commonly called Geber, are shown to be fictitious, and the great reverence paid to him as a pioneer in chemistry has been misplaced. The whole history of chemistry has been falsified by giving credit to the Arabians for knowledge which really belonged to a period five hundred years later.

Yet the historical personage Geber, who lived in the ninth century, left many treatises in Arabic, now preserved in Paris and Leyden, and the translation of these occupy 100 pages of the third volume; they are very different from the works so widely known as Geber's, which are found in Latin, French, German, and English.

In like manner the current alchemical treatises ascribed to Raymond Lully are shown to be fictitious, yet his works on philosophy in the Provençal language are extant.

The pseudo-Arabic works in their Latin form contain, however, traces of the ancient Greek alchemical writings, and to endow them with authority the writers referred the text to mythical personages,

and as these were cited by later authors who did not doubt their genuineness, the pseudo-treatises acquired undeserved renown. Students of alchemy who have been revelling in the works of Morien, Kalid, Zadith, Mary, and the collection of citations entitled 'Turba philosophorum,' are loth to have their antique idols shattered, but this is the fate of every branch of human knowledge when subjected to the modern methods of searching analysis.

The second volume of 'La Chimie au moyen âge' has the sub-title, "Syriac Alchemy, comprising an introduction and several treatises of Syriac and Arabic alchemy from the manuscripts in the British Museum and Cambridge; text, and translation."

The existence of Syriac alchemical manuscripts in the British Museum was pointed out to Berthelot by Professor Richard Gottheil, of Columbia University, New York City. The most important of these, entitled "The Doctrine of Democritus," was translated from Greek between the seventh and ninth centuries. It begins with a charge of self-purification, followed by a key to the symbols used in the manuscript; these signs resemble in part those occurring in the writings of the earlier Greek alchemists. The first section of the "Doctrine" is called "The Preparation of Gold," the second is called "On the Philosophers' Stone," and the succeeding parts contain a collection of recipes, processes with metals, as well as with sulphur, antimony, arsenic and ores, analogous to the Leyden papyrus and the 'Mappæ clavicula.' Rude drawings of apparatus accompany the text. The writer shows acquaintance with a very large number of chemical substances.

The Library of the University of Cambridge possesses a Syriac manuscript, which is a translation of portions of the Greek writings of Zosimus, Democritus, and others. It is similar in character to the preceding.

Volume III. of 'La Chimie au moyen âge' has the sub-title, 'Arabian Alchemy, comprising an historical introduction, the treatises of Crates, el-Habib, Ostanes, and Djâber, from manuscripts in Paris and Leyden; text and translation.'

The Arabic treatises here named are the genuine writings, not the fictitious ones known only in Latin. The first Mohammedan writer on alchemy was Khâled ben Yezid ibn Moaouïa, Prince Omeyyade, who died in 708; he is a historic personage and the reputed teacher of Djâber. Only the titles of his works have come down to us. Djâber, the Geber of the Latins, was, however, the great master of the art and enjoyed the highest reputation throughout the Middle Ages; he is credited with 500 treatises, an Oriental exaggeration. Six of these are here collected and translated. They exhibit evidence of Moslem faith on the part of the author; he shows familiarity with the hydrostatic balance, with many species of minerals (of which an ingenious classification is given), and he discourses on the changes in volume produced by heat and by cold; at the same time he admits using allegorical and obscure language in all his works. There is no reference to the mineral acids, to nitrate of silver, and other chemicals that Geber is supposed to have known. Perhaps the most clever passage in his works is the following from the 'Book of Mercy':—

"I saw that persons engaged in attempts to manufacture gold and silver were working ignorantly and by wrong methods; I then perceived that they were divided into two categories, the dupers and the duped. I had pity for both of them."

Berthelot's superb volumes comprise more than 2600 pages, and much of the contents defies review. Besides these original documents he has published two works dealing in more popular style with the periods of alchemy and Middle Age chemistry. These are entitled: 'les Origines de l'alchimie' (1885), and 'Introduction à l'étude de la chimie des anciens et du moyen âge'

(1889) the latter is largely reprinted in the quarto volumes; all are charmingly written, well illustrated, and well indexed.

Berthelot had extraordinary qualifications for the task and enjoyed unrivalled opportunities; the result is a magnificent contribution to the history of chemistry, of the utmost interest to the chemical student as well as to the philosopher.

LAVENDER AND ITS CULTIVATION.

BY F. S. CLIFFORD.

Old England with all its historical memories flood upon us when the refreshing odour of lavender greets our smelling faculties. The climate of England appears to be better adapted to the perfect development of this fine old favourite perfume than any other on the globe.

"In each bright drop there is a spell,
'Tis from the soil we love so well,
From English gardens won."

Various authors say that the sense of smell is the sense of imagination. As it has before been stated, how wonderful is the mind, that one who has learned to distinguish and name odours can recall many hundreds by name through the sense of smell. There is no doubt that pleasant perfumes exercise a cheering influence on the mind, and easily and indelibly become associated with remembrances. Sounds and scents share alike the property of refreshing the memory, and place vividly before our minds scenes of our past life, an effect which Thomas Moore beautifully illustrates in his "Lalla Rookh":—

"The young Arab, haunted by the smell
Of her own mountain flowers as by a spell,
The sweet Elcaya, and that courteous tree,
Which bows to all who seek its canopy,
Sees called up round her by the magic scents,
The well, the camels, and her father's tents,
Sighs for the home she left with little pain,
And wishes e'en its sorrows back again."

Tennyson expresses the same feeling in his "Dream of Fair Women":—

"The smells of violets hidden in the green,
Poured back into my empty soul and frame
The times when I remember to have been
Joyful and free from blame."

Criton, Hippocrates, and other ancient doctors classed perfumes among medicines and prescribed them for many diseases, especially for those of a nervous kind. Pliny also attributed therapeutic properties to various aromatic substances, and some perfumes are still used in modern medicines. Who would think of depriving the sick or well of flowers or of forbidding their use?

When perfumes are rightly and discriminatingly used, as they should be, how do they differ, except in favour of the perfumes? For it is true that some particular kinds of flowers if left in a sleeping-apartment all night, will sometimes cause headache and sickness, but this proceeds not from the diffusion of their aroma, but from the carbonic acid which they evolve during the night. If a perfume extracted from the same kind of flowers were left open under the same circumstances no evil effect would arise from it.

Discarding, however, all curative pretensions for perfumes, I think it right at the same time to combat the doctrines of some who hold that they are injurious to health. I have never heard or knew of a case where anyone was seriously harmed by their use in large quantities or by continual use.

It can be proven that the use of perfumes in moderation is beneficial than otherwise, and in cases of epidemic they have been known to render important service, both as curatives and preventives, were it only to the four thieves, who, by means of their famous

aromatic vinegar, were enabled to rob half of the population of Marseilles at the time of the great plague, without any fear of infection.

We have also seen the benefits of the employment of perfumes in our own times, when small-pox, cholera, and contagious diseases were prevalent in our land. As for health, we only ask that those who are constantly engaged in handling and manufacturing perfumery be observed, and that their physical condition be compared with that of any other class of manufacturers or professional men. The cultivation of flowers for the manufacture of perfumes also gives out-of-door employment to thousands.

One great benefit in the use of perfumes is that it tends to cleanliness, and "Cleanliness is akin to Godliness." Almost compelling one to notice when they are breathing a vitiated air, or associated with filth. The nose educated is a true monitor. To the "unlearned" nose all odours are alike, but when tutored, either for pleasure or profit, no member of the body is more sensitive.

Lavender is a native of Persia, the Canaries, Barbary, and the south of Europe, from the last of which it is said to have been first brought to England, where, finding a congenial soil, and being cultivated, it yields an otto very far superior to that produced from its original place of growth.

Lavender is grown to an enormous extent at Mitcham, in Surrey, and at Hitchin, in Hertfordshire, England. Very large quantities are also grown in France, that grown upon Mont Blanc being the finest.

Who will be the first to experiment with the growth of lavender in the United States? Surely some part of our wonderful country will be found to be the most favourable place in which to cultivate it to perfection. Thirty-five hundred lavender plants can be grown on an acre of ground if the plants are placed three feet apart and four feet between the rows. An acre of plants yields about fifty pounds of otto of lavender.—*Spatula*.

CAMPHOR.

Camphor is not the exclusive product of any one natural order, genus, or species; but what is more remarkable, of closely allied species of camphor-yielding genera—one species possesses the secretion, while no trace of it is found in another. Although several kinds of camphor are articles of commerce, little, if any, reaches this country, save that obtained from *Cinnamomum camphora* (*Camphora officinarum*), a member of the laurel family, and of the same genus as the tree whose bark furnishes the spice called cinnamon. Like many other natural products of which scientific research has multiplied the applications, camphor is becoming dearer and scarcer, and the question has arisen, How is the supply to be maintained equal to the demand? The bulk of the camphor imported into Europe comes from Japan and Formosa, and comparatively little from China. This is the product of *Cinnamomum camphora*, and Dr. E. Grasmann has published* an interesting account of this tree, both from a scientific and commercial standpoint. He has rather overweighted his article with second-hand information respecting laurels generally and those of Japan in particular, which, as might be expected, is inaccurate in some details. Disregarding these, we find much that is interesting concerning the camphor tree itself, which is one of the noblest objects in the forests of eastern sub-tropical Asia. It attains gigantic dimensions, surpassing all other trees of the Japanese forests, at least in girth of trunk if not in total height. Dr. Grasmann gives

* 'Der Kampherbaum. Mittheilungen der deutschen Gesellschaft für Natur- und Völkerkunde Ostasiens in Tōkiō,' vi., pp. 277-315, with illustrations. 1895. Reprinted from *Nature*.

the recorded dimensions of various notable trees, but what is more to the point, he also gives measurements made by himself. A tree in the neighbourhood of the town of Miyazaki, Oyodomura, measured in 1894, was 14.80 metres in circumference at 1.30 M. from the ground, or 4.48 M. in diameter, and it was 35 M. high.

There is an illustration of this giant reproduced from a photograph. Concerning the distribution of the camphor tree in Japan, the author states that it grows naturally in Kinshin up to about 34° lat., and scattered in favourable situations some 2° farther north, the extreme limit being 36° 24'. It is abundant in the island of Formosa, and also occurs in the Tsusima and Luchu groups. On the mainland of China, according to Dr. Grasmann, it inhabits the coast region from Cochin-China to the mouth of the Yangtzekiang, and it may be added that it is now known to extend westwards at least as far as Ichang in the central province of Hupeh. From Dr. A. Henry's notes accompanying his specimens in the Kew Herbarium, it appears that the wood is in great request, but no camphor is extracted; and Consul Playfair reported the same from Pakhoi, Kwangtung, in 1883. Indeed the camphor industry would seem to be at present very limited in China, although the tree is common and widely spread. The little that is exported is mostly from the province of Fokien, but the amount is increasing in the same measure as the production is decreasing in Japan. In the latter country something has been done to maintain the supply, but Dr. Grasmann holds that the present rate of planting is wholly inadequate. He urges the importance of increasing the plantations to the greatest possible extent, inasmuch as every part of the tree is useful, from the roots to the young shoots and leaves. Even the fruit is employed in the preparation of tallow. In Formosa camphor distilling has been carried on in the most recklessly extravagant manner imaginable. It is suggested that Japanese rule in the island may put a stop to such disastrous waste.

With regard to the increasing price of camphor, it has been stated in various publications that this is due to its being used in the manufacture of smokeless powder. In reply to inquiries on this point, Sir Frederick Abel wrote to the Director of Kew in November last as follows:—

"Any increase of demand, involving a rise in the price of camphor, is not due to its application as a constituent of smokeless powder. That material was used in the earliest days of the manufacture of a successful smokeless powder for artillery and small arms; but its employment was soon demonstrated to be attended with serious practical disadvantages, and its application for the purpose can therefore not be said to have been other than experimental, and of no great importance, even at that time, as affecting the market value of camphor. This substance, has, however, been used extensively for many years past, and no doubt in continually increasing quantities, for the conversion of collodion cotton into the material known as celluloid, which is applied to the manufacture of imitation ivory, tortoiseshell, horn, and a great variety of purposes."

As Dr. Grasmann observes, the greatest enemy of the camphor tree is man, and in Japan large trees are eventually killed through the felonious nocturnal grubbing of their roots. Some birds are fond of the fruit and seed, and the caterpillar of *Papilio sarpedon* feeds on the leaves; but, except to young plants, they cause comparatively little damage. Apart from the wanton destruction of trees, the probability of the supply of camphor being maintained is seriously diminished by the fact that the tree grows but slowly in its early years. At the same time it colonises freely, and is now naturalised in several countries, notably in Madagascar, where, according to Dr. Meller, in a note accompanying a specimen in the Kew Her-

barium, it was abundant as long ago as 1862, and was much used for building purposes.

Next in point of importance in producing camphor is *Dryobalanops aromatica*, a tree belonging to the Dipterocarpeæ, and inhabiting Borneo and Sumatra. The formula of ordinary camphor is $C_{10}H_{16}$; of Borneo camphor, $C_{10}H_{18}O$; and the latter can be artificially prepared from the former. Borneo camphor is deposited in clefts and hollows of the wood, and has simply to be taken out; but it is comparatively rare, and exceedingly dear, bringing eighty times more, according to Grasmann, than ordinary camphor. Nearly the whole production is imported into China, where it is esteemed beyond the ordinary camphor, and used as incense.

Blumea balsamifera (Compositæ), a shrubby plant exceedingly common in tropical Asia, yields a kind of camphor by distillation. Hainan is the principal seat of the industry, but the crude article is refined at Canton, whence there is an annual export of about 10,000 pounds. No doubt this source of camphor could be much more extensively utilised.

Members of various other natural orders, notably the Labiatae, yield essential oils of the same composition, and having the same properties, as camphor. Menthol is an example.

PHARMACEUTICAL SOCIETY.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 10th inst., the Librarian presented the following report of donations:—

To the Library (London).

School of Pharmacy Students' Association:

Papers read, 1894-95, vol. 21.

New South Wales Department of Agriculture:

Agricultural Gazette, 1891-93, vols. 2-4.

Pharmaceutical Society of New South Wales:

New South Wales Pharmacy Board Register, 1896.

Herr E. Dieterich, Helfenberg:

Helfenberger Annalen, 1895.

Prof. A. Tschirch, Bern:

Pamphlets on various subjects.

Mr. John Barclay, B.Sc., Birmingham:

Southall's Organic Materia Medica, 5th ed., 1893.

Royal Institution of Great Britain:

List of Members, etc., 1895.

Proceedings, no. 89, 1896.

American Pharmaceutical Association:

National Formulary, revised ed., 1896.

To the Library (Edinburgh).

American Pharmaceutical Association:

National Formulary, revised ed., 1896.

Royal Society of Edinburgh:

Proceedings, vol. 20, 1893-95.

Indian Meteorological Memoirs, by J. Eliot, M.A., vol. 7; vol. 8, part I. 1894-95.

The following report of donations was presented by the Curator:—

To the Museum.

Mr. G. H. Hawtayne, C.M.G., F.R.G.S., Administrator-General British Guiana:

Specimen of the pods of *Mucuna pruriens*.

Messrs. T. Christy and Co., London:

Three specimens of medicinal products from Curaçao.

Messrs. Wright, Layman, and Umney, London:

Specimen of spurious jaborandi.

The Smithsonian Institution, Washington, U.S.A.:

Report of the U.S. National Museum, 1893.

To the Herbarium.

Dr. Geo. King, M.B., LL.D., C.I.E., etc., Superintendent Botanical Gardens, Calcutta:

Flowering and fruiting specimens of *Microstemon officinalis*.

Mr. H. N. Ridley, M.A., F.L.S., Director Botanical Gardens, Singapore:

Specimen of *Alyxia lucida*.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, JUNE 13, 1896.

THE WORKING OF THE SALE OF FOOD AND DRUGS ACT.

THE evidence given before the Select Committee appointed to inquire into the working of the Acts of Parliament relating to adulteration, has in various ways given definite expression to the belief that considerable amendments will be necessary for effectually repressing adulteration, without at the same time inflicting hardship or unduly interfering with trade. The report of the Second Committee, which sat during this year, has still to be published, and it may be expected that the advantage of thoroughness may result from the long duration of the inquiry and from the opportunity which has been given for statements of opinion on all sides. In the present state of parliamentary affairs there is probably but small prospect of amended legislation on this subject during the current session, but some brief indication of the results arrived at may be useful meanwhile.

It has been shown that the initial machinery of the Food and Drugs Acts was faulty, because if the local authorities of any district declined to come under the provisions of the Acts, or were indisposed to work them to prevent adulteration, there was no central authority possessed of the power to compel them to do their duty to the community in protecting the consumer. Even after the principal Act had been in operation twenty years it was shown that the food of a population of about three millions was not protected, the Act either not having been put in force or no samples taken for analysis. This defect must be remedied without delay, and there is reason to expect that the Committee will recommend that the Act be made compulsory instead of permissive as at present. Complaints were common that the inspectors' purchases were made from small rather than large tradesmen, from ignorant shopkeepers not knowing the law. Hence for mutual protection certain manufacturers of proprietary articles, such as cocoa and mustard, stated that to safeguard such customers they had been compelled to modify the sizes of their packages, so that the smallest quantity usually required should be sold in an unbroken packet labelled in conformity with the law, and not taken from a bulk quantity to be labelled by the seller, as has been the practice till recently.

Representatives from such branches of trade as the milk, butter, and lard industries, where the natural variations of composition are marked, or where changes occur by keeping, spoke strongly of the expense which had been incurred in defending actions brought against them for adulteration. Many analysts have not yet realised what an adulterated article really is, and consequently attempts have been made to fix arbitrary standards of purity and to work up to an average quality instead of conforming to the provisions of the Act. The illegality of such a course is well illustrated by the recent case of *HEWITT v. TAYLOR*, better known as the "Mossley Milk Case," tried in the Court of Appeal before Lords Justices LINDLEY and KAY. It was contended that because the non-fatty solids of a milk were 7.98 per cent., and the analyst had certified that upwards of six parts of water had been added to every 100 parts of the milk, the defendant should be convicted on the analysts' certificate. The defendant, however, satisfied the magistrates that the milk was, when sold, in the same condition as when milked from the cow, and they dismissed the case. The Lords Justices upheld the magistrate's decision.

A representative of the lard refiners mentioned four cases which occurred in the year 1895, in which the local analysts, whose names were given, had pronounced the lard sent out by his firm to be adulterated. In the interest of his customers the cases were defended, and all were dismissed. The cost of the defence amounted to £425, but the costs allowed reached the insignificant sum of £15, leaving £410 as expenses out of pocket, in addition to the loss of time and injury done to the business by such proceedings.

One of the most striking indications of the defective nature of the present Acts is the conflict between public analysts and the chemical officers of the Board of Inland Revenue appointed to act as referees in cases of dispute. In the absence of any sufficient definition of what constitutes adulteration, differences of opinion have arisen which have been in many instances perplexing to magistrates, and have hindered the just administration of the law. The friction which has existed between the analysts and referees, since they were appointed in 1875, assumed, as was natural, an acute form when Mr. HEHNER, as the representative of the public analysts, gave evidence. He claimed for the public analysts that their methods of analysis were the best of their kind, and that the improvements in food analysis were mainly due to the original work duly recorded in the *Analyst*, which "is a mine of information to which every analyst in this or other countries goes." The charges made by other witnesses as to the unsatisfactory work of some analysts were represented as beneath notice, and even the lard cases above referred to were not explained.

The evidence given was considered by the PRESIDENT as challenging the competency of the Court of Appeal, and in the end rebutting evidence was allowed. It was then contended that the detection of the adulteration of articles such as tea, coffee, pepper, spirits, arrowroot, vinegar, and other products on which a duty had been imposed, had been in existence long before there was an Adulteration Act, and that in the case of milk and butter, but especially milk, reliable methods of analysis had been in force shortly after the passing of the Act, and that the natural variation in the composition of milk and butter were at the same time investigated. The pages of the *Analyst* were referred to, and quotations made from it to show that in 1885, ten years after the Act had been in operation, a special committee of public

analysts, selected by their colleagues for their expertness in milk analysis, could not examine the same milk under the most favourable conditions without varying from each other in the non-fatty solids and fat as much as seven-tenths of one per cent., and that when attempting to estimate the quantity of water which had been purposely added to a sample of milk, whose composition was known to them, they were compelled to abandon the figures they had obtained as representing "solids not fat," and "fat," and rely on the "total solids" for their results. In the case of butter, reference was made to the writings of the Public Analysts' representative, where it was stated that the average percentage of insoluble fatty acids in butter was 85.85, that three years later the average was 87.3, and that the lowness of the first results was due to "loss by spurting" in the evaporating basin. Much evidence of a similar kind was given.

THE CONFERENCE AT LIVERPOOL.

THE time of meeting of the British Pharmaceutical Conference is rapidly approaching once more, and the provisional arrangements made by the local committee at Liverpool were explained by Mr. WARDLEWORTH at a meeting of the Executive Committee, held on June 3. Briefly, the proposed arrangements and approximate times are as follows (see page 476):—

Monday, July 27.	{ 8.30 p.m.—Reception by the President (Mr. Wm. Martindale) at the Walker Art Gallery.
Tuesday, July 28.	{ 10.0 a.m.—Address by the President, followed by Sessions of Conference.
	{ 1.15 p.m.—Luncheon at the Adelphi Hotel, followed by Sessions of Conference.
	{ 4.0 p.m.—Cruise on the Mersey, and visit to the Manchester Ship Canal.
Wednesday, July 29.	{ 10.0 a.m.—Resumption of Sessions of Conference.
	{ 4.0 p.m.—Visit to the Watch Factory at Prescott.
	{ 8.30 p.m.—Smoking and Drawing-Room Concerts at the Adelphi Hotel.
Thursday, July 30.	{ 9.0 a.m.—Excursion to Hawarden, Eaton Hall, and Chester.

There is good reason to believe that exceptional efforts will be made locally to render the meeting of 1896 a memorable one, and it is common knowledge that the pharmacists of Liverpool, who usually work so well together, are fully capable of making a success of anything of the sort they take in hand. It may also be noted here that the arrangements for reporting the proceedings in the *Pharmaceutical Journal* will be somewhat modified this year, the intention being to publish a full report, including all the papers read, in the number for August 1. Members who find themselves unable to attend the meeting will, therefore, be able to read a full account of the proceedings in the Journal before the company assembled at Liverpool has dispersed.

With regard to the place of meeting for 1897, we understand that it will probably be still further north than Liverpool, as Scotland is likely once more to have an opportunity of displaying her unsurpassed capacity for entertaining public bodies. At the Liverpool meeting an invitation to the members of Conference to assemble at Glasgow the following year, will be given on behalf of the pharmacists of that city and district, by Mr. W. L. CURRIE, President of the Glasgow and West of Scotland Pharmaceutical Association, and it may well be imagined that few will complain if the invitation should be as cordially accepted as it will be given.

ANNOTATIONS.

THE SALE OF POISONOUS PREPARATIONS BY UNQUALIFIED PERSONS.—The *Patent Medicines Journal*, referring to the action of the Pharmaceutical Society in fulfilling its statutory duties with regard to the sale of poisons, thinks "there will have to be an end one of these fine days to the pretence that all these prosecutions are instituted in the interests and for the 'protection of the public,'" as "it is a hollow cry at best," and "why not admit that the real main-spring is the determination of the chemists to protect themselves?" It might be imagined from this petty outburst that the Society was on its trial before our contemporary and had been pleading justification. But surely there is no necessity for the Society, as a legally constituted body, to excuse itself for doing what the law requires of it, and perhaps if the readers of the *Patent Medicines Journal* would in like manner seek to keep within the letter of the law, there would be little need for the publication of rash assertions about "harassing respectable people who are engaged in a respectable manner of earning a living." Perhaps, too, the *Patent Medicines Journal* might then find its occupation gone, and the energies of its staff be devoted to more promising labours?

GERMAN CHEMICAL INDUSTRY.—According to the Consular Report on the trade of Mannheim for 1895, a number of newly-invented pharmaceutical products were offered during the year, some of which are expected to prove valuable, but it is complained that most of them had been introduced before being properly tried. Trade in quinine recovered towards the end of the year, after being rather dull, whilst cocaine was in good demand throughout the year, though at prices that left little or no profit. Salicylic and gallic acids fell greatly by reason of fresh competition or dissolution of conventions, and the sale of alcohol preparations was considerably affected by the continued changes in the fiscal impost. Export prices for such products were purely speculative, as the manufacturers were quite uncertain whether drawback to the full amount would be allowed. The new tax is said to demand a fresh revision of the import duties on alcohol preparations, since as things are, both foreign countries and the chemical factories in the free port of Hamburg can alike manufacture such products cheaper than Germany itself.

PHARMACIES IN DENMARK.—The number of pharmacies in Denmark is so limited that it is possible to indicate their position very clearly on a map of the country of moderate size, as has been done by H. J. Moller in his 'Kort over Danmarks Apotheker.' There are 88 "personal" pharmacies (*Personligt Apotheksprivilegium*), the licence to conduct which is not transferable, and lapses with the death of the owner or his widow. Unless the widow is herself legally qualified, she must have a qualified apotheker in charge. Then, there are also 81 "real" pharmacies (*Reelt Apotheksprivilegium*), which may be conveyed by the owners to others, and seven branch pharmacies (*Hjælpeapothek*). Denmark also boasts of 160 physicians (*Distribuerende Læge*), who are permitted to sell medicines, 11 others (*Dispenserende Læge*), who may dispense their own medicines but not keep open pharmacies, and 10 retailers of medicines other than poisons or potent drugs and preparations, who must not dispense (*Haandkøbsudsalg af Medicamenter ved Ikke Apothekere*). The neighbourhood of Copenhagen is naturally best served from a pharmaceutical point of view, whilst Iceland is the abode of four apothekers only—three "personal" and one "real."

ELECTION OF EXECUTIVE OF THE NORTH BRITISH BRANCH.—Voting papers for the election of members of the North British Branch Executive have been issued, and must be returned by Thursday next, June 18. The list of persons eligible and willing for election includes twenty-three names, the whole of the members of the retiring Executive standing for re-election, except Messrs. Adam Gibson and John Nesbit, whilst the following eight new candidates offer themselves:—

Aitken, Robert, 73, Princes Street, Edinburgh.
 Baker, William Charles, 13, Dundas Street, Edinburgh.
 Dunlop, Thomas, 181, Albert Road, Pollokshields, Glasgow.
 McKellar, Arthur, 69, South Portland Street, Glasgow.
 Mackenzie, James, 45, Forroth Road, Edinburgh.
 McLaren, David, 42, South Clerk Street, Edinburgh.
 Macpherson, Colin Allen, 97, Dalry Road, Edinburgh.
 Mitchell, Donald, 30, Union Street, Inverness.

The result of the election will be announced on Friday, June 19, at a meeting of the Members and Associates in Business of the Pharmaceutical Society, residing in Scotland, and the Chairman's statement will be made at the same meeting.

ABERDEEN CHEMISTS' ANNUAL PICNIC.—At the last meeting of the Aberdeen and North of Scotland Society of Chemists and Druggists, the Secretary reported that the arrangements for the annual picnic were now completed. It has been arranged to go on Wednesday, July 1, by train to Aboyne, and from there, by kind permission of Sir William Cunliffe Brooks, Bart., of Glen-Tana, the company will drive to the top of the Forest of Glen-Tana, where a stay of two hours will be made to allow any who care to ascend Mount Keen (2305 feet). On a clear day a very extensive view to the south can be obtained from the summit, and the drive through the Forest is one of the finest on Dæside. Any member of the craft spending holidays in the neighbourhood, and wishing to join the excursion, should communicate with the Secretary, Mr. J. Cruickshank, 42, George Street, Aberdeen, as early as possible.

EDINBURGH CHEMISTS' ANNUAL EXCURSION.—We are requested to announce that the annual excursion of the Edinburgh District Chemists' Trade Association will take place on Wednesday next, June 17, when Loch Long and Loch Lomond will be visited. Full particulars and tickets (Edinburgh, 10s. 6d. each, Glasgow, 8s. 6d. each, including dinner and tea at Tarbet Hotel) may be obtained from the Hon. Secretary, Mr. C. F. Henry, 1, Brandon Terrace, Edinburgh, and any friends in the trade on the line of route, or at present sojourning in the district, will be heartily welcomed.

ANÆSTHETICS IN OPERATIONS ON THE THROAT, NOSE, AND EAR.—On May 22 last, at the Central London Throat and Ear Hospital, a post-graduate lecture on "Anæsthetics for Operations on the Throat, Nose, and Ear" was delivered by Mr. W. G. Holloway, B.A., M.D., Camb., Assistant-Surgeon to the Hospital, and brother of Mr. C. T. Holloway, A.P.S. The advantages in such operations of nitrous oxide gas, either alone or combined with ether, were pointed out and confirmed by a table recording 4500 successful administrations. The upright position was advocated as being the safest and most convenient both to operator and patient. Chloroform was deprecated as being dangerous in operations on the upper air passages, and unnecessary for short surgical procedures where nitrous oxide gas was sufficient to produce anæsthesia. The lecture was illustrated by photographic lantern slides specially prepared by the lecturer.

THE RÖNTGEN RAYS IN BOTANY.—Experiments with the Röntgen rays have been conducted at the University Extension College, Reading, and a brief report on the results obtained in botanical work appears in *Nature* for June 4. Mr. G. J. Burch there states that by suitably arranging the exposure and development, it has been found possible to show the ovules inside the ovary in an unopened bud, the seeds within a seed vessel, and even the veins upon the white petal of a flower. Apparently these results are due to refraction and reflection of the rays when the incidence is sufficiently oblique. Similar indications are visible in a photograph of a fish's eye prepared by Mr. Yetts, in which there is a narrow dark shadow that can only be due to internal total reflection, whilst the feathers are seen in a picture of a bird by Mr. Soper, and a print of a foot, developed by Mr. Herbert, shows the fabric of the stocking.

TWO KINDS OF X-RAYS.—Some phenomena observed by Mr. T. C. Porter, of Eton College, and also reported in *Nature*, seem to indicate that the rays to which attention was first directed by Professor Röntgen, are of two kinds. To one kind, designated x_1 , flesh is fairly transparent, and bone opaque, but to the others, distinguished as x_2 , flesh seems nearly if not quite as opaque as bone. Under ordinary circumstances, in the cold, most of the rays emitted from an excited tube are x_1 , but if the tube be heated the proportion of those is diminished, and more of x_2 are emitted. Wood and paper seem fairly transparent to the x_2 -rays, but glass is very opaque, and aluminium much more opaque than to the x_1 -rays. It is possible that the x_2 -rays may be related to the x_1 in the same kind of way that red is related to violet light.

DOCTORS' SHOPS IN ENGLAND, managed by unqualified individuals, do not perhaps constitute so great an evil as in the sister kingdom, but such do exist, as was shown at an inquest held at Sheffield on Saturday last. A spring-knife cutler, who had been somewhat addicted to drink and had also suffered from paralysis, purchased a quantity of laudanum at the shop belonging to Mr. Walter Mitchell, Sharrow Lane. This he drank, and death was the result. Mr. Mitchell, though a chemist and druggist, and as such fully entitled to keep open shop for the sale of poisons, is also a licentiate of the Society of Apothecaries, London, and his name appears on the 'Medical Register.' His brother, Thomas Mitchell, who is not registered as a chemist and druggist, stated at the inquest that he managed the shop and sold the laudanum during the proprietor's absence. He also pleaded ignorance of the fact that he had broken the law by so doing, but the jury considered that he had acted wrongly in selling the poison, and the coroner said that if any proceedings were taken, the Pharmaceutical Society would initiate them. The position of the proprietor of the shop, it may be observed, is hardly consistent with the principles that should guide him, either as a registered chemist or as a medical practitioner.

VACANCY OF THE PROFESSORSHIP OF CHEMISTRY.—As announced in the advertising columns of this and other journals this week, the Professorship of Chemistry in the Pharmaceutical Society's School of Pharmacy is now vacant, and applications are invited to be sent together with not more than six testimonials to the Secretary and Registrar, on or before Tuesday, 23rd inst. The Professor will be required to give his whole time to the duties of the chair, and will have charge of all the lectures and practical instruction given in the subject during the session, lasting from October to July. Full particulars may be had on application to Mr. Richard Bremridge, Secretary and Registrar, 17, Bloomsbury Square, W.C. It is specially noted that personal canvassing by candidates will be considered to be a disqualification.

REVIEWS AND NOTICES OF BOOKS.

A MANUAL OF PHARMACOLOGY AND THERAPEUTICS. By DR. WILLIAM MURRELL, Physician and Lecturer to Westminster Hospital. Pp. 657. Price 16s. 6d. (London: Baillière, Tindall, and Cox, King William Street, Strand. 1896.)

Dr. Murrell is so well known both as a physician and a therapist, that his work is sure to command attention. The physiological action of drugs and their practical uses are explained concisely, clearly, and correctly. The author has also managed to make the subject interesting; this is a great achievement, and is sure to find favour with students.

The omission of lists of pharmacopœial preparations no doubt makes the book more pleasant to read, but it certainly prevents it from being a complete and comprehensive text-book for the student, who is told by the author that "it is not worth while trying to remember the preparations of opium. There are only twenty of them, and they practically remember themselves." Dr. Murrell must be a man of some humour; for instance, in his description of the watering-places, he tells us that "Sandgate lives on the reputation of a past landslip and the promise of future improvements."

Speaking of the impurities of opium, we are told that "bullets and cow's dung are at a premium in opium-producing countries." The article on aconite is extremely important; Dr. Murrell lays stress on the great variability of the strength and composition of aconitine. The English aconitine is at least seventeen times as active as the German, the French being intermediate in power. There are many preparations of aconitine sold; Merck's is twenty to thirty times as active as that of Friedländer, whilst Petit's is eight times as active as Merck's. It appears that persons have been poisoned by the substitution of one preparation for another.

Antipyrin, or phenazonum, which is now so frequently prescribed, is not a drug that Dr. Murrell likes. He writes that "after small doses the symptoms not infrequently observed are epigastric pain, nausea, and vomiting, followed by weakness of the pulse, hurried respiration, and cyanosis. In some cases there is persistent sneezing, with lachrymation, and a flow of mucus from the nostrils. After larger doses the symptoms observed are intense headache, persistent vertigo, loss of memory, confusion of ideas, and deafness." It may safely be said that the general experience of the medical profession will scarcely confirm this statement, but nevertheless the warning is valuable.

At the end of the book is found a list of useful prescriptions, and also a dietary and recipes for preparing food for those in sickness and in health, describing not only the preparation of beef-tea and jellies, but also such dishes as devilled lobster and baked pork and beans.

CHEMICAL TECHNOLOGY. Edited by C. E. GROVES, F.R.S., and W. THORP, B.Sc. Vol. II.: Lighting. (London: J. and A. Churchill.)

Probably in no department of technology is the indication of progress more strikingly manifest than in the matter of "Lighting," and we have here the first instalment of the history of that subject in a well-illustrated volume of 400 pages, preparatory to the final consideration of "Gas and Electric Lighting, Lighthouse Illumination, and Photometry," which is promised at an early date in the next forthcoming issue.

The authors of the present treatise are Messrs. Dent, McArthur, Field, Redwood, and Louis, each taking the department for which he is specially qualified, and the subjects covered include Fats and Oils, Stearine Industry, Candle Manufacture, the Petroleum Industry and Lamps, and Miners' Safety Lamps. Taking these in the order mentioned Mr. W. Y. Dent devotes forty-five pages to the

description of the physical properties, processes for extraction, and modes of testing oils and animal fats, taking account only of those which are suitable for illuminants. The next section, Stearine, by Mr. J. McArthur, describes the methods of treatment (saponification and super-heated steam distillation) resorted to by De Milly, in France, and George F. Wilson, F.R.S., in this country, and enumerates the successive attempts directed to the preparation of fatty acids of higher fusion point, with saving of the glycerin. The apparatus for cold and hot pressing of the resulting fatty bodies is further illustrated, and the process of conversion of oleic into palmitic acid described.

There is a flavour of ancient history about the next article on Candle Manufacture, by the Messrs. Field, but the reader eventually finds in the narrative a clear account, with some admirable illustrations, of the latest and most approved forms of candle-making machinery. The chronology is certainly well told, and it is curious to note how in 1852, when bismuth was cheap, this metal and its corresponding nitrate were extensively employed for making Palmer's "Metallic Wick" and candles which did not require snuffing.

Section IV.: The Petroleum Industry, by Mr. Boverton Redwood, being an important division of the subject, is treated of very fully, reaching the length of 150 pages. There are maps of the districts and tables of statistics showing how widely distributed are these oil wells over the face of the globe. The United States and Canada, Russia, Hungary, India, Assam and Burmah, China and Japan all come in for extended notice; besides the shale oil beds of North Britain, Trinidad pitch, ozokerite, and natural gas. The drilling and boring plant, receptacles for storage and transport, distilling apparatus, etc., are fully described; and so enormous is the yield of the world's petroleum that it is easy to see how for a long time to come this product (refined kerosene) must continue to be the "poor man's candle." Reference is made incidentally to the light oils (petroleum naphtha), paraffin, and vaselin products; also to certain residues used as lubricants. The average constitution of the different sorts of burning oil, the modes of refining, and apparatus employed are very fully set out, the latter forming the subject of numerous illustrations.

The transition to Lamps, also by Mr. Redwood, is appropriate, and here we find ninety pages full of interesting matter and beautiful engravings, the details ranging from the elaborate Carcel lamp to the flaring lucigen. Oil gas, air-gas machines and carburettors, Railway and Ships' Lights form a kind of supplement to this chapter.

Finally, Section VI., covering fifty pages, is descriptive of Miners' Safety Lamps, and Professor Clowes's recent experiments with his Fire-Damp Indicator here find a record. The authors, Messrs. Boverton Redwood and D. A. Louis, seem to have got together every known kind of safety lamp, and from statistics it appears that the favourite nowadays is Marsaut's lamp or the Clanny, with glass cylinder fitted with two or three concentric upper cones of wire gauze protected by a strong metal covering or "bonnet." The lamp now seems to be generally provided by the miners, and not, as formerly, by the colliery proprietors.

It only remains to be said that the style of production of the work before us is eminently satisfactory, the printing and paper are good, and the illustrations excellent. The authors have spared no pains in bringing up to date the accounts of the several branches of technology entrusted to them, as will be seen by the formidable array of authorities quoted in the preface; and not only are the current sources of information laid under contribution, but a vast amount of extra professional or special papers brought under survey, including British and foreign government reports, transactions of learned societies, and especially those of mining and

engineering institutes, Cantor lectures, patent specifications, etc. For those engaged in technical teaching as well as pupils entering upon advanced courses of study, the volume ought to prove invaluable; and, in the rare cases of specialists demanding more than is here described, the numerous foot-notes and references to further sources of definite or local information and statistics will supply all that is needed to meet the case of what may fitly be termed extraordinary requirements, so that really nothing seems to have been omitted from the careful compilation which the editors have succeeded in placing before their readers in the work now under review.

LECTURES ON PHARMACOLOGY FOR PRACTITIONERS AND STUDENTS.

By Dr. C. BINZ, Director of the Pharmacological Institute in the University of Bonn. Translated from the second German edition by ARTHUR C. LATHAM, M.A., M.B. Vol. I. (London, 1895: The New Sydenham Society.)

It is with great pleasure that the appearance of an English translation of Professor Binz's admirable lectures on pharmacology is welcomed. In their original language they are well known and highly appreciated by many readers in this country, and the present excellent translation will do much to extend their usefulness. They possess a special interest in that they show us the matured opinions not only of a well-known teacher, but also of an investigator to whose experimental work we owe much of our knowledge of the precise actions of many important drugs.

Professor Binz defines pharmacology as "the scientific investigation—with reference specially to the requirements of the physician—of such substances as are contained in the official pharmacopœias of various countries, and are employed in the treatment of disease." He therefore attaches to it a much wider meaning than is usually understood in this country, and includes not only an account of the action and uses of each drug, but also its mode of preparation, composition, and tests; in fact, all that we usually understand as *materia medica*.

Only the first volume is published as yet, but this contains a large number of the more important drugs, including the anæsthetics, opium, the compounds of iodine, alcohol, the belladonna group, the digitalis group, strychnine, cocaine, ergot, the ammonium salts, the essential oils, and others of minor importance.

A clinical classification is adopted, not because it is free from faults, but "because it leads to the creation of a natural system, the ultimate aim of pharmacology being to provide for clinical needs." The pharmaceutical and chemical details are in most cases subsidiary to the account of the actions and uses of each drug; the toxicology and the treatment of poisoning is fairly given. All through the volume special prominence is afforded to such properties of drugs as are capable of experimental demonstration; many experiments are described in detail, and a number of diagrams are introduced to illustrate the effect of drugs on pulse, heart, or respiration. It is impossible to criticise fully all the chapters of the book. There are, however, a few points that may be noted as especially illustrating the marked differences which exist between the methods of using drugs here and in Germany. In the group of narcotics are found many drugs, such as the iodides and the nitrites, which one is not usually accustomed to consider under that head; on the other hand alcohol is not included as a narcotic. The *spiritus ætheris nitrosi* is, however, described with ether and not with the nitrites, and it is stated that the nitrite action is not produced by its administration in the usual doses; its reputed diuretic action is mentioned, but no reference is made to its diaphoretic properties. The account of the nitrite of amyl is full, but the other nitrites are disposed of very summarily. Sodium

nitrite is stated to be not suitable for practical purposes as it readily decomposes in the stomach, and "it will be well to regard it as a substance which simply serves to illustrate and explain the general action of the nitrites." Of nitroglycerin it is stated that "the only practical way of prescribing it is in small tabloids which are prepared with chocolate and gum arabic"; apparently the author is unacquainted with the liquor trinitrinæ, or similar solutions of nitroglycerin.

In connection with morphine, a short account is given of the chemical properties and constitution of vegetable alkaloids. The description of opium and morphine hardly seems adequate to the importance of these drugs. A reference is made to the frequency of poisoning by morphine in England and America compared to Germany, and credit is given to "the strict and very salutary laws which exist in Germany with regard to pharmacy, and prevent such a frightful abuse."

For hypodermic use Professor Binz prefers a one per cent. solution of morphine, and the doses he recommends are considerably smaller than the doses generally given in England. It is almost generally recognised that the *injection morphinæ hypodermica*, B.P., is too concentrated for general use, and probably favours the administration of an unnecessarily large dose; a reduction to a 1 in 20 solution would be a decided improvement in the forthcoming Pharmacopœia. Codeine is said to be superseded in practice by *codeinum phosphoricum*.

In describing squill its expectorant action is not even mentioned: it is said to be popularly used as a diuretic, but not often prescribed by physicians. Zinc salts are treated of as acting on the nervous system, and though vomiting is given as a symptom of zinc poisoning, no mention is made of the therapeutic employment of zinc salts as emetics.

Colchicum is said to be not often prescribed in Germany, and considerable doubt exists as to its efficacy in relieving the pains of gout and rheumatism, because it is almost always given with opium. It would appear from the context that Professor Binz does not clearly distinguish between rheumatism and gout, as he states that in sodium salicylate, antipyrine and similar medicines, we possess remedies more efficacious and safer than *colchicum*.

Alcohol is very fully treated as to its action upon the temperature, the heart, and the process of digestion; the position of alcohol as a food is insisted upon. Very little is given as to the effect of alcohol upon the brain and nervous system, and paralysis is not mentioned as one of the results of chronic alcoholism. An interesting statement supported by experiments is that "alcohol in large doses increases in an extraordinary manner the power of resistance to septic poison."

The translator has added useful explanatory notes, which might have been extended with advantage; for example, "Hoffmann's anodyne" is given as the synonym of "*spiritus ætheris*," without any note that the German Pharmacopœia differs from the British in not containing the *spirit ætheris co.*, which more nearly corresponds to the original Hoffmann's anodyne. Other instances where explanation is required might easily be quoted.

Many interesting historical details are given, and a number of cases are also graphically described; these were selected because they presented many of the conditions of a scientific experiment, and they undoubtedly add much to the interest of the subject. Professor Binz's style of writing is clear and graphic, and the translator is to be congratulated upon the success with which he has rendered it into excellent English. It must be pointed out, however, that the addition of an index to the volume would have rendered reference easier, and saved much time in looking up any required subject.

BRITISH PHARMACEUTICAL CONFERENCE.

MEETING OF THE EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held at 16, Bloomsbury Square, on Wednesday, June 3, at 3.30 p.m.

Present:—Mr. Wm. Martindale (President), in the chair, Messrs. Atkins, Attfield, and Carteighe (Vice-Presidents), Messrs. Bird, Holmes, and Symes, Mr. Wardleworth (Hon. Local Secretary), Messrs. Naylor and Ransom (Hon. General Secretaries), and Mr. Nightingale (Assistant Secretary).

The Secretaries announced that letters had been received from Messrs. Groves, Umney, Ewing, Wells, Coull, Conroy, Martin, Moss, Farr, and Wright, regretting their inability to be present.

The minutes of the previous meeting were read and confirmed.

Mr. Wardleworth, on behalf of the Local Committee, presented a draft programme of the local arrangements in connection with the Liverpool meeting. It is intended that the Reception by the President shall be held on Monday evening, July 27, at the Walker Art Gallery. The opening meeting of the Conference will be held at University College on the following morning, when the President will deliver his address and the reading and discussion of papers will be commenced. Luncheon will be provided at 1.15 p.m., on this and the following day, at the Adelphi Hotel, which will be the headquarters of the Conference. The business will be resumed at 2 p.m. and at 4 o'clock it is intended to take a cruise on the Mersey, visiting the entrance to the Manchester Ship Canal, and passing the docks to the mouth of the river. Business will be resumed at 10 a.m. on Wednesday, and at the conclusion of the sittings in the afternoon it is proposed to drive to the watch factory at Prescott. The usual smoking concert will be held at the Adelphi Hotel in the evening, and a drawing-room will be arranged to take place at the same time. Thursday will be devoted to the excursion, when it is intended to cross the river and visit various places of interest, including Hawarden, Eaton Hall, and Chester.

It was moved, seconded, and carried unanimously:—

That the programme as submitted be accepted, and that the best thanks of the meeting be accorded to Mr. Wardleworth for his kindness in coming from Liverpool to give details of the suggested arrangements.

The place of meeting for 1897 was considered, and it was announced that an invitation would probably be received at the Liverpool meeting. A list of officers for the ensuing year was drafted for recommendation to the general meeting. Thirty-four gentlemen, having been nominated, were elected to membership.

CHEMICAL SOCIETY.

An ordinary meeting was held on June 4, Mr. A. G. Vernon Harcourt, F.R.S., President, in the chair.

Before proceeding to the business of the evening, Professor Dunstan announced that an address had been presented to Cannizzaro on the occasion of his 70th birthday. This eminent scientist has been a Fellow of the Chemical Society since 1862, and had delivered the Faraday Lecture in 1872. The address which was read to the meeting by Professor Dunstan was dated June, 1896, and was signed by the President, Treasurer, and the Secretaries.

Dr. W. H. Perkin, F.R.S., read his paper on "The Magnetic Rotation of Organic Substances, with Especial Reference to Benzenoid Compounds."

The original object of this research was to study the magnetic rotation of bodies of the aromatic series. As results accumulated, it was found that there was peculiar behaviour in the case of bodies of this and of the fatty series. About two hundred substances had been examined, and the present paper was a brief account of the more striking results Dr. Perkin had obtained.

The apparatus used for the investigation was the same form as that used by the author in 1884, when this work was first undertaken.

Photographs and drawings of the elaborate apparatus were thrown on the screen by the electric lantern, and were fully explained by Dr. Perkin. The arrangement roughly consists of an electro-magnet between the pole pieces of which the body to be examined is placed. The polariser and analyser, which are on different stands, are placed at a certain distance from the back ends of the pole pieces. The observations are made by the sodium flame, a special piece of apparatus being required for maintaining this flame satisfactorily. The glass tube employed for holding the substance to be examined

is shaped thus \perp , the perpendicular piece being used as a sort of funnel to fill the tube.

Dr. Perkin had taken particular care to have all the substances examined perfectly pure, and in this particular alone the paper should be of especial value.

After Dr. Perkin had very fully explained the apparatus, a long series of tables of the numbers he had obtained for the magnetic rotation of the various substances examined was shown on the screen. The effect of temperature was noted, and it appears that each class of compounds has its own temperature difference. The influence of the nitrogen group is most remarkable, the magnetic rotation always being lowered, and of all the compounds examined the amines were found to yield the most striking results. The effect of displacing hydrogen by phenyl and other groups was gone into at some length by the author. Incidentally he mentioned that dimethylaniline hydrochloride was generally considered not to be crystalline, but Dr. Perkin had found that it was crystalline. The magnetic rotation of aniline is reduced by hydrochloric acid.

Dr. Perkin took something like two hours to read his paper, and though exceedingly interesting in many respects, it grew somewhat monotonous from the incessant repetition of dry figures.

Several gentlemen present spoke in very complimentary terms of the plodding perseverance Dr. Perkin had shown in collecting the material for his paper, and a vote of thanks was duly proposed to him.

The President stated that the paper entitled "Note on Santalal and Some of its Derivatives," by Alfred C. Chapman and H. S. Burgess, would be postponed until the next meeting on the 18th.

The paper on "Mono-nitro Guaiacol," by Professor Meldola, F.R.S., was taken as read.

PHARMACEUTICAL CHEMISTS' AND APOTHECARIES' ASSISTANTS' ASSOCIATION OF IRELAND.

At Dublin on the 3rd inst, a committee meeting of the above Association was held at 51, Heytesbury Street, Mr. James B. Alistair, M.P.S.I. (President), in the chair. The following were present:—Messrs. H. Hunt, Ewing, Parker, Payne, D. O'Sullivan, Walsh, and W. J. Hardy (Hon.-Secretary). A concise and very satisfactory statement of receipts and expenditure during the past session was submitted by the Honorary Treasurer (Mr. W. B. Payne), who said that out of close on 100 who had joined the Association since its formation in August, some eighty were in good standing. Several valued members had left the city, but this he was glad to say had not terminated their connection with the body. Since they had started a sum of over £20 had been received in respect of subscriptions, and after meeting all claims and demands in full, there remained on hand a balance of £5 6s. 8d., irrespective of the subscriptions for the current half, which, if added to the balance on hand, would more than double the credit balance. During the early part of the session the very heavy item of rent for the premises in the "X. L." Café was obliged to be met, and were it not for the kind grant of the Society's rooms to hold their meetings, they would not be so well off. It was unfortunate they did not earlier ask the Council for the accommodation, but it was better late than never, and the little experience of roughing it on their own account would enable them the better to appreciate the excellent quarters now assigned to their use. An inspection was made of the list of membership, and several names were expunged by reason of continued absence or non-payment of subscriptions. A resolution was formally passed suspending the bi-monthly meetings of the Association during the summer months, and the Secretary was directed to acquaint the general body of members accordingly. A circular to that effect was drawn up and ordered to be printed for circulation. It was arranged to hold meetings of the Committee at stated intervals towards the close of the summer for the purpose of revising the rules and preparing a syllabus of lectures, papers to be read, etc., during the winter months, those concerned to be notified beforehand in writing. The President and Hon. Secretary spoke in felicitous terms of the strides made by the Association, which numbered among its honoured and honorary members the names of some of the most prominent physicians and pharmacists in the city. Hopes having been expressed that the coming winter's session would prove a record one, the proceedings terminated.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

At a meeting of this Association held during the present session, a convenient form of apparatus for the extraction of drugs by hot or cold solvents was exhibited and described, as follows :—

NEW EXTRACTION APPARATUS.

BY J. H. HOSEASON,

Assistant Lecturer on Pharmacy, Owens College, Manchester.

The apparatus consists essentially of a jacketed copper percolator tinned internally, of a tubular condenser. The lid of the percolator is fitted air tight by a vulcanised rubber band inserted between the rims and secured by clamps. The screws at A and B (Fig. 1), are of the same size, so that the tubular condenser can be attached at either position.

For the purpose of extraction the apparatus is arranged as in Figs. 1 and 2. The tubular condenser is attached to A by a nut, the joint being rendered secure by the insertion of a thin rubber or cork washer. To B is fitted a block tin tube G, connecting the

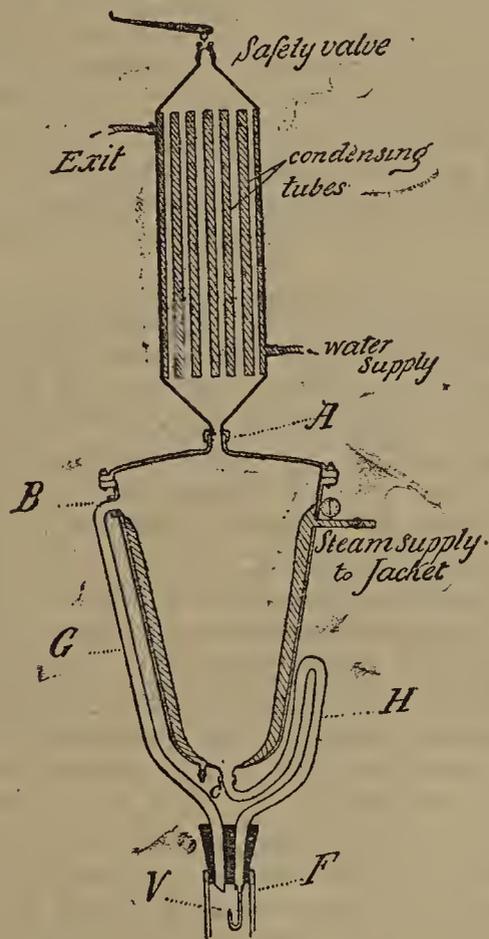

FIG. 1.

percolator with the receiving flask F, and from C a syphon tube H, also of block tin, passes into the neck of the flask F. The lower end of the syphon tube H is fitted with a downward acting glass valve, V, to prevent the hot vapours ascending this tube. The following details give the principal dimensions of the apparatus :—

Condenser tubes (length)	18 ins.
Diameter of condenser	6½ "
Total length of condenser	26 "
Depth of percolator (from level B to bottom)	20 "
Inside diameter of percolator at the same level.....	14 "
Inside diameter of bottom of percolator	6 "

The centre of the side tube G at B is 1½ inch below the lid rim. Practically a rise of 6 inches has been found sufficient in the syphon tube H.

The percolator is prepared for use by placing a thin layer of absorbent cotton at the bottom and covering that with a sheet of thick filter paper; the powdered drug is then carefully and evenly packed in.

A sufficiency of menstruum (alcohol 50 to 60 per cent., ether or ligroin 40 to 50 per cent. in proportion to the weight of drug employed) is now added and maceration allowed to proceed for twenty-four hours, A being closed by a screw cap.

On application of an air force pump at A the first percolate may be obtained without the aid of heat; by adding a quantity of fresh menstruum, equal in volume to that already driven over, this process may be repeated if considered necessary.

To thoroughly exhaust the marc add another equal portion of solvent, placing three-quarters of the volume in the percolator and the remainder in the receiving flask F. The condenser is now to be attached to A, and heat applied to the flask F by a suitable steam or water bath. During the first few minutes the heated air

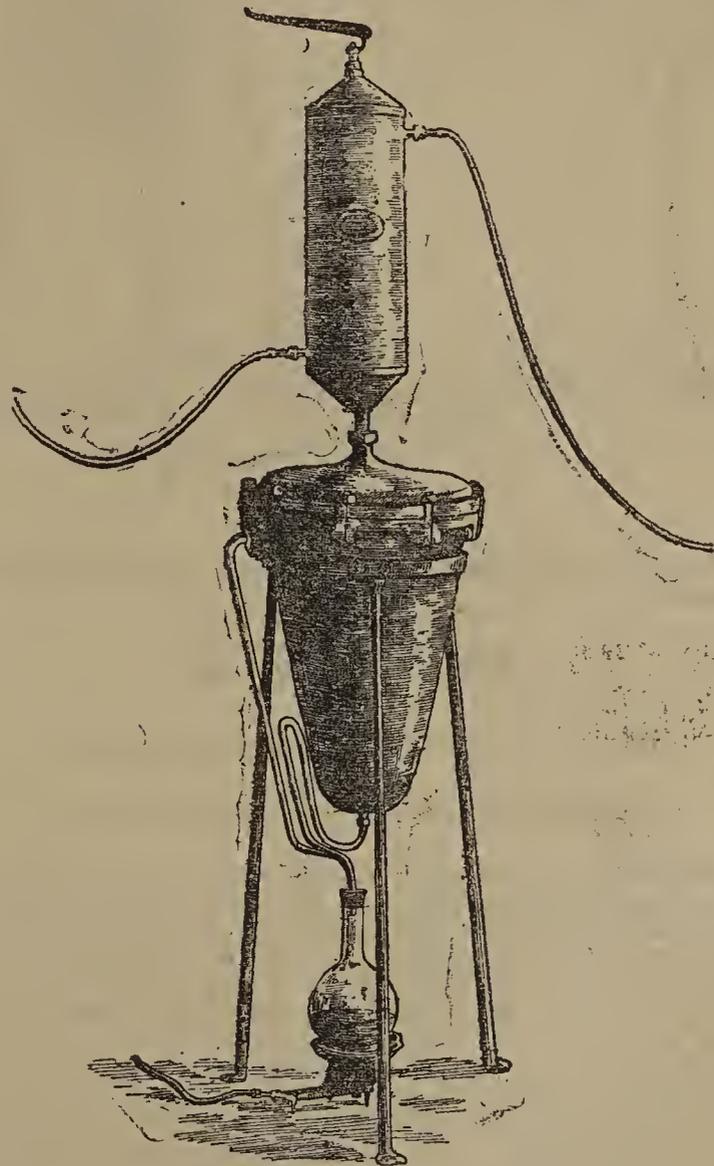

FIG. 2.

contained in the apparatus should be allowed to escape by opening the safety valve. The solvent having been raised to the boiling point, the vapours will pass up the tube G into the top portion of the percolator, and be rapidly liquefied by the condenser. Percolation will begin and the process become continuous.

The boiling point of the solvent will be lowered, as the apparatus necessarily works under reduced pressure.

After extraction has been completed the condenser is removed, and pressure by an air force applied at A to remove as much of the solvent as possible. To recover the remainder, remove the side tubes G and H, close A and C by screw caps, and apply the condenser to B (Fig. 3). On passing steam or hot water into the jacket, distillation will shortly take place.

The use of such an apparatus is indicated where drugs have to be exhausted by volatile solvents; especially in plant analysis is this the case. It effects a great saving in solvent by preventing evaporation, and does away with the necessity of transferring the drug from percolator to still. By attaching an exhaust pump the apparatus can be used as a vacuum pan. It will adapt itself to many other pharmaceutical operations, e.g., preparation of syrups,

infusions, waters, hot filtration, simple maceration, percolation, etc., etc. It may be used for the extraction of drugs by hot solvents when necessary (by keeping the percolator jacket steam

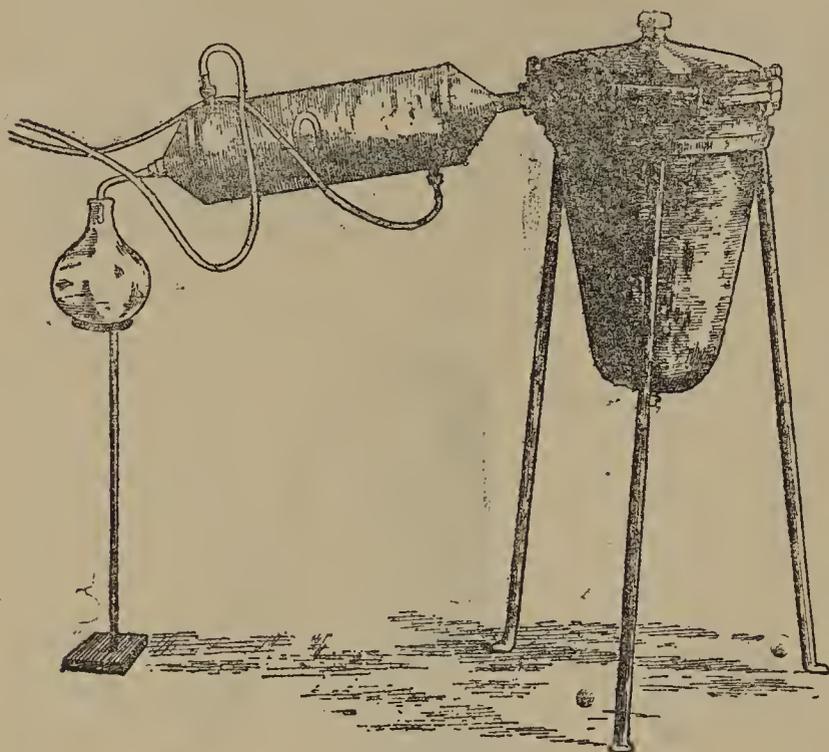

FIG. 3.

or water heated), although this process is not a desirable one as a general rule.

LEGAL REPORTS.

CASE UNDER THE COMPANIES ACT.

THE CHEMISTS' ASSOCIATION, LIMITED.

A petition for the winding up of this company came before Mr. Justice Romer on Monday, June 8. Mr. Eve, Q.C., who appeared for the petitioner, Jos. Beecham, said it was a creditors' petition for a compulsory order, or, in the alternative, for a winding-up under supervision. There was a voluntary winding-up pending, and Mr. Farwell, Q.C., who appeared for the company, had agreed with him that if a supervision order were made, the present voluntary liquidator would retire in favour of some independent gentleman, to be agreed upon, out of three or four names which had been submitted. The real object was to ensure the interests of the unsecured creditors being protected.—Mr. Justice Romer made the supervision order, referring it to Chambers to appoint a fresh liquidator, when he should see that a proper person was appointed.—Mr. Jenkins, for other creditors, supported the petition.

CASE UNDER THE SALE OF FOOD AND DRUGS ACT.

DEFICIENT SPIRIT OF NITROUS ETHER.

At Sittingbourne Petty Sessions, on Monday, April 6, William George Saffrey, of Sheerness, described as a chemist, but not registered as such, was summoned under the Sale of Food and Drugs Act, with selling spirit of nitrous ether, not of the nature and quality demanded.—Defendant said he was guilty of selling the article, not knowing that it was as described in the charge.—Police-constable Cook, stationed at Sittingbourne, deposed to going to defendant's shop on February 24, acting under instructions from Superintendent Capps, and purchasing four ounces of spirit of nitrous ether. Defendant served him, and he paid defendant one shilling. He then informed defendant that he had purchased the article for the purpose of being analysed by the public analyst.—Superintendent Capps stated that he went into the defendant's shop and received the spirit which had been purchased by the previous witness. He told defendant

that it would be analysed by Dr. Adams, of Maidstone. The analyst's certificate was to the effect that the article was adulterated, because it was deficient in nitrous ether to the extent of 44 per cent.—Defendant informed the magistrates that the article came into his possession by mistake, he having ordered the proper article from the traveller of a firm, who, however, sent the wrong kind. He had had it since January 4, and produced a letter from the firm mentioned to show that his statement was correct. This was handed to the magistrates, but the Chairman said it was not evidence.—After some consultation on the Bench, the Chairman said there must be a conviction. The magistrates could not overlook the fact that there was a deficiency of 44 per cent. of nitrous ether, and defendant would be fined £1, including costs.

PARLIAMENTARY NOTES AND NEWS.

PARLIAMENTARY PROCEDURE.—Mr. Sydney Gedge has given notice of a new Standing Order with the object of saving time in taking Divisions of the House of Commons. He proposes that the "Ayes" or "Noes" shall, in succession, hold up their hands, and that, if the Speaker or Chairman declares that the Ayes or Noes have it by a large majority, his decision shall be conclusive; while, failing such a declaration, the Division will take place in the ordinary way. In case the Speaker or Chairman declares the judgment of the House, any member who desires to have his vote recorded may write his name and the word "Aye" or "No" on a card, which he will deposit in a box under care of the Sergeant at Arms, the vote so signified to be printed in the Division Lists.

THE COMMERCIAL INTERESTS OF THE EMPIRE constitute a sonorous and effective text for election addresses, but those interests do not always commend themselves to honourable gentlemen after they have passed triumphantly the ordeal of the polls. Sir Joseph Leese (Accrington), however, is not to be included in the list of those who morally degenerate after election, or he would not have asked the Secretary of State for India the other night to interest himself about rhea fibre. It appears that a certain Professor Bilderbeck Gomess has recently discovered an effective and economic process for treating the fibre and rendering it available for manufacture into fabrics. Presumably the professor has overcome the difficulty hitherto experienced of decorticating and cleaning without injury the fibre from the green stems. Sir J. Leese, whose constituency is chiefly engaged in textile industries, recognising the importance of the alleged discovery, both to Indian agriculture and to Lancashire manufactures, asked that inquiries might be made with a view to developing the production of the fibre. But Lord George Hamilton could not be induced to exhibit any interest, and he replied to the effect that he knew nothing of the discovery, but that if it was of commercial value, no doubt it would receive attention from those specially interested in the subject. No official inquiries would however be made. This answer is in marked contrast with the active efforts made by Lord Mayo's administration in 1869 to stimulate the invention of a satisfactory method of cleaning the fibre. It might interest the honourable member for Accrington to learn that despite official indifference here the Government of India is keenly alive to the importance of developing the economic products of the Empire, and that an official committee of experts is at the present moment engaged in considering the practicability and utility of encouraging the extended cultivation of indigenous medicinal plants. One of the members of that committee, Dr. George Watt, C.I.E., an honorary member of the Society, has, in his 'Dictionary of Economic Products of India,' brought together all that was known at the time of publication concerning rhea fibre.

THE COMPANIES BILL.—The Select Committee of the House of Lords appointed to consider the Companies Bill was expected to meet on Friday. It is believed that the Government will not offer any opposition to the amendment proposed by Lord Herschell, and there is ground for hope that the Bill may leave the Upper House with the desired clause incorporated among its provisions. Its subsequent fate, however, appears to be no longer in doubt, for it is futile to imagine that the Government will willingly add another official measure to the burden of business under which the House of Commons and the Ministerial Party are already groaning.

Under such circumstances it will be wise for pharmaceutical associations which may have contemplated memorialising local members of Parliament on the subject, to husband their strength and reserve their efforts until the fitting moment arrives and the signal is given for concerted action.

VACCINATION has been rather a prominent topic of late outside the House, hence Sir William Priestley was quite opportune in signalling his return, as member for the Universities of Edinburgh and St. Andrews, by asking Mr. Chaplin to arrange a uniform system of direct vaccination from calf to arm when calf lymph was employed. The chief of the Local Government Board, though no expert on the subject, fully realised the importance attached in medical circles to the direct calf to arm system, but was much more impressed by the consideration that meeting the wishes of his honourable friend would involve an entirely new organisation and a very large expenditure of public money. Sir William Priestley was also reminded that the Royal Commission on Vaccination was now engaged in compiling the result of its six years' deliberations, and would probably have something to say on the matter.

THE SECOND COMMISSION ON TUBERCULOSIS is at last in process of formation, and the President of the Local Government Board, urged by the interrogations of Dr. Farquharson and Mr. Lees Knowles, has intimated that he will shortly be in a position to announce the names of those who will constitute the Commission. Replying to Mr. Knowles, Mr. Chaplin disclosed the full terms of reference to the Commission. They are: (a) To inquire and report as to what administrative procedures are available and would be desirable for controlling the danger to man through the use as food of the meat and milk (with the products thereof) of tuberculous animals; and (b) what are the considerations which should govern the action of the responsible authorities in condemning or not condemning for purposes of food supplies, animal carcasses or meat exhibiting any stage of tuberculosis. The Commission will have something very much like a "wholesale order" in dealing with the work allotted to it. The whole subject is surrounded with difficulties, but in the interest of the public health it is to be hoped that they may be surmounted.

EXIT EARLY CLOSING.—An unpropitious fate and an unsympathetic Ministry have willed that the Shops (Early Closing) Bill and the Shop Assistants' (Half Holiday) Bill shall take their places with the vast and increasing crowd of measures for which the subsequent proceedings of Parliament this Session will possess no interest. Though the Shops Bill is deferred till Friday the 12th and its rival till Monday the 15th instant, it is a mere matter of form, and the Bills are as dead as the hopes of their supporters.

OBITUARY.

- BROWN.—On May 27, Edwin Brown, Chemist and Druggist, late of Liverpool. (Aged 44.)
- LA TROBE.—On May 29, Henry La Trobe, Chemist and Druggist, Bristol. (Aged 54.)
- TOLLEY.—On May 31, W. A. Tolley, Chemist and Druggist, late of East Barnet. (Aged 55.)

PUBLICATION RECEIVED.

A MANUAL OF BOTANY. By J. REYNOLDS GREEN, Sc.D., F.R.S. Vol. II. Classification and Physiology. Pp. 541. Price 10s. (London: J. and A. Churchill, 7, Great Marlborough Street. 1896.) From the Publishers.

WILKINSON'S OINTMENT IN ECZEMA.—In the obstinate inveterate forms of eczema, Lassar extols the application of Wilkinson's ointment, originally introduced as a remedy for scabies. This is composed of sulphur; ol. rusci, aa, 4 parts; cretæ preparat., 1 part; sapon. moll., paraffin. moll., aa, 8 parts (*Brit. Journ. Derm.*, viii., 185).

CORRESPONDENCE.

THE SOCIETY AND ITS MEMBERS.

Sir,—It must have been exceedingly gratifying to official minds to see the severe reprimand that was attempted to be administered to unhappy me in this week's Journal, an admonition characterised by such spontaneity, and from the second city of the Empire too. I think the title you gave the letter was rather a misnomer though, it would have been a better description had it been entitled "The Society and Two Members" or "Mr. J. Anderson Russell v. Mr. George Coull."

I am sorry I cannot congratulate Mr. J. Anderson Russell on his contribution to the discussion now going on, because it has neither breadth nor depth. He gets hold of one point, and that a subsidiary one, and makes it his text, namely, what he calls the "extraordinary" question which I asked in my previous letter to you. Then with an assumption of superiority decidedly refreshing, but which I rather resent, he proceeds to give me certain advice as to what I ought to have done under the circumstances.

The first question that strikes one is the motive Mr. Russell had in writing his letter, because he quite misses the point of mine, which was, as I distinctly stated, to publicly call attention to a statement in the Annual Report to which I took exception, not as he calls it, "to what I regard as an injustice to Minor candidates in London," but to what actually is a manifest injustice, and is admitted to be so by all with whom I have conversed about it. And I may here remark that the Council has been remiss in its duty in permitting such a thing to occur at all. If Mr. Russell does not consider it unjust, I am sorry for his standard of ethics.

He then refers to my being debarred (harsh word) from discussing this subject at a meeting of Executive, and to the fact that I put the already mentioned "extraordinary" question. Then comes the statement that "the business of the Scottish Executive cannot be to criticise how the Council transacts purely London business, but the Executive's meetings, we must assume, are for the transaction of business connected with the Society in Scotland." Now this sentence contains the crux of the whole question, and on its correct interpretation rests the value of Mr. Russell's letter, apart from the personal criticism of myself and my methods. My contention is that the examinations, in whichever division of the kingdom they are conducted, cannot be said to be either purely London or purely Edinburgh, they are the examinations of the Pharmaceutical Society of Great Britain. And if, as it appears, we can discuss the First examination and send a resolution to the Council on that subject, why may we not similarly discuss the other examinations? Some of our young men go to London to be examined, and many Englishmen come to Edinburgh. Therefore I think we are quite within our rights in asking a question on the subject.

I am reasoning this out on the assumption that my question did refer to the London examinations, in order to show that my position is not so untenable as it is thought to be. But I am afraid Mr. Russell has not referred to the report of the Meeting of Executive at which my original question was put (*ante*, p. 336); he will there find that the question had reference to the Edinburgh examinations. Hence there was no necessity for your correspondent writing you at all. I think it is Lord Salisbury who gives his political opponents the advice, "Verify your references," and I would seriously commend the same to Mr. Russell's careful consideration. With regard to the advice about writing to a member of Council to raise the matter at a Council meeting, I am obliged to him for it, but there is no necessity to do so when one can raise it oneself. It would probably be referred to some committee, and that is not what is wanted; we want, as men sometimes do, light.

If Mr. Russell has read the history of the Society aright, he will know that it is this concealment of things that gives men a dislike to the Society and has done an incalculable amount of harm. The more openly matters are managed the more interest will be taken in the affairs of the Society. It might be argued (adopting the above advice) that a Member of Parliament ought not publicly to put a question which is of great importance to his constituents and the public at large, but should write privately to a Secretary of State for information.

Another of Mr. Russell's fallacious statements I cannot allow to pass without notice, namely, "Business is the end in view not discussion." That sentence to the unthinking sounds extremely well, but when it is analysed how illogical it is. For how can business be done without discussion unless the business proposed by one

member be accepted without demur? and if that is done then Councils and Executives are superfluties.

In conclusion, sir, to ease Mr. Russell's mind, I may publicly state that there is no member of Executive I hold in higher esteem than our worthy Chairman, and, further, that my loyalty to the Pharmaceutical Society is undoubted, having become connected with it as a Student of the Society before my apprenticeship began.

I should be sorry if the healthy discussion now going on should degenerate into a personal squabble, and, so far as I am concerned (in the language of diplomacy), the incident may be considered closed.

Leith, June 6, 1896.

GEORGE COULL.

THE PROPRIETARY ARTICLES TRADE ASSOCIATION.

Sir,—I beg you would correct the report of my remarks at the Cardiff meeting of Proprietary Articles Trade Association which appears in the *Pharmaceutical Journal* of this date. It contains a glaring misrepresentation of what I said. My allusion to the Pharmaceutical Society was to this effect, that this Association would do just what the Pharmaceutical Society had been blamed for not doing, and that it would form the complement of the Society. In this allusion I was referring to the usual criticisms which one hears from non-supporters of the Society. As a local secretary it would have been ridiculous for me to have made such statements as are attributed to me. I have always considered that it was outside the province of our Society to take up the question of prices. I further stated that the very persons who had blamed the Society for not looking after our trade interests were the ones who refused to take advantage of what it had done in the matter of proprietaries containing poisons by joining to obtain better prices for these articles. Injustice to myself I trust you will rectify these statements.

Pontypridd, June 6, 1896.

D. ARNOTT.

* * * Though the reporter might perhaps have made a happier choice of words, the general impression conveyed by his report of Mr. Arnett's remarks seems to be the same as that given by the above letter.—[*Ed. Pharm. Journal.*]

THE JAPANESE YEN.

Sir,—I think your note on this subject requires a little explanation. In the days referred to there was a very active ring of money-changers—and there may be now—whose business it was to get a living out of the variable exchange, and their system was to collect in, say, the month of June, all the paper currency—yen-satsu—they could possibly lay their hands on, so that paper was at a premium; then out it would come from the said money-changers, and, silver easy, they commenced to apply the same treatment conversely to the coin, and frequently with greater success than in the case of paper, which was not too strong or secure in the minds of many in those days; and so it was, the value of the paper and silver yen rose and fell at the will or caprice of these said money-changers or financiers.

Aston Clinton, Bucks, June 5, 1896. WILLIAM SHEPPERSON.

INCOME TAX OVERCHARGES.

Sir,—If instead of paying income tax for which they are not legally liable and then grumbling, taxpayers would be more prompt taking action, there would be fewer complaints as to the manner in which the Acts are administered. It is not sufficiently realised how large a measure of relief is to be obtained by taking a little trouble at the right time. Will you permit us to briefly refer to a few of the various grounds on which taxpayers can obtain relief? Persons whose incomes from all sources for the year 1895-6 did not exceed £160 are entitled to exemption, and those whose incomes did not exceed £500 to considerable abatements. Claims for exemption or abatement may with few exceptions still be made in respect of the years 1893-4 and 1894-5, even when the income is said to be "free of income tax," while in many cases claims can also be made in respect of life insurance premiums. The amount recoverable for the three years named may amount to upwards of £20 on an income under £400 per annum. A wife's income derived from a profession, employment, or vocation, where the joint income did not exceed £500 for 1894-5 or 1895-6, is to be dealt with separately, the effect of which may be to give two abatements off the joint income, when the tax recoverable for 1894-5 and 1895-6 would amount to £21 6s. 8d. Persons engaged in business whose average profits for the three years ending 1895-6 were less than the amount upon which they paid tax may make a claim on the ground of diminution of profits, and in this connection farmers should note that claims under Schedule B. must be lodged before July 6 next. A loss in business or farming can be set off against income from any other source. The time for making

appeals is limited, and it is of the utmost importance to remember that there is no time better than the present for appealing, as by doing so at once not only can repayment of tax overpaid be obtained, but the assessment for the ensuing year 1896-7 will also be settled at the same time. If any of your readers are in doubt as to whether they can make a claim we shall be pleased to tell them, if they will send us full particulars of their incomes and a stamped directed envelope for reply.

THE INCOME-TAX ADJUSTMENT AGENCY.

12 and 13, Poultry, London, E.C., June 10, 1896.

CREAM OF TARTAR.

Sir,—Mr. Conroy's letter is only a further condemnation of the present B.P. test, and has already been answered by Mr. Alfred H. Allen's (Sheffield) able paper before the Society of Public Analysts. This will no doubt hasten the alteration of the B.P. standard, but in the meantime we will cheerfully defend any action under the Food and Drugs Act for supplying cream of tartar containing three per cent. more potass. bitart. than required by the B.P. We have already had the matter decided in our favour in three police courts, and the more we are prosecuted the more the present ridiculous standard will be exposed.

London, June 10, 1896. KIRKPATRICK, BARR, AND GUTHRIE.

ANSWERS TO QUERIES.

BOTANICAL SPECIMEN.—The specimen you send is a proliferous growth of some grass. It is impossible to name it with certainty unless an entire plant is sent. [*Reply to W. F.*]

PYROCATECHIN MONOACETATE OF SODIUM.—Probably you will be able to obtain this from Merck's agent, F. Boehm, 16, Jewry Street, E.C., if the article is yet on the market. [*Reply to J. T.*]

MURCELL'S SOLUTION.—We have, so far, failed to trace this anywhere. Can it be a corruption of Mutzel's solution or mixture given as a liver stimulant in hepatic obstruction? This is composed of neutral tartrate of potash, 10 parts; extract of gentian and extract of centaury, of each 10 parts; water, 250 parts. Dose: A dessert-spoonful. [*Reply to ASSISTANT.*]

DISPENSING QUERY.—You do not state the volume of the mixture of glycerin and water you used; the only definite quantity you give is for the tartaric acid. It is quite possible that the morphine was altered in some way by prolonged heating, particularly if you boiled it. The alkaloid is very liable to change in the presence of free acid (see *Ph. J.* [3], xvi., 654). If you send us some of the separated crystals perhaps we can tell you what they are. The neutral tartrate is by far the best salt to use for strong solutions of morphine. [*Reply to G. W. B.*]

HOW TO BECOME A SANITARY INSPECTOR.—Examinations intended to enable persons desirous of becoming Inspectors of Nuisances to prove their competency are conducted by the Sanitary Institute, Margaret Street, London, W., and the Local Government Board accepts the certificates of that body as proof of the fitness of those holding them. Candidates must be of full age, and the fee payable for the examination if held in London is three guineas, whilst a guinea extra is charged when an examination is held at Plymouth, Birmingham, Newcastle, or other provincial centre. The subjects of examination are elementary physics and chemistry; local conditions; water; materials and construction; air, lighting, and warming; drainage, sewage, and sanitary appliances; and sanitary law. Apply to the Secretary of the Institute for a copy of the syllabus and particulars of the course of special lectures and demonstrations conducted in the Parkes Museum. [*Reply to "RUMEX."*]

TONING AND FIXING SOLUTION.—A cheap and efficient toning and fixing solution without lead salts is the following:—

Hyposulphite of Soda	4 ozs.
Aluminium Sulphocyanide	30 grs.
Salt	60 grs.
Chloride of Gold	2½ grs.
Water	to 20 ozs.

The prints should be well washed prior to immersion in this bath, and the above quantity is sufficient for a full sheet of paper 17½ × 24 inches. The reason why lead salts are objected to in those baths containing lead, alum, and acid salts is that although the baths tone well in most cases the toning is entirely due to the so-called sulphur toning. This is really the formation of sub-sulphide of silver, which is not a stable salt, hence such prints are not permanent but quickly fade and turn yellow. A combined toning and fixing bath "without lead and alum salts or acid" ought to be a good line now, as a good deal of attention has been directed to this question of late. [*Reply to HYDROQUINONE.*]

SENNA AND ITS ADULTERANTS.*

A MICROGRAPHIC STUDY.

BY E. LATOUR.

The medicinal importance of senna leaflets, and the numerous sophistications to which they are subject, have induced the author to study their anatomical structure, and also that of the leaves and leaflets which are most frequently mixed with the drug, in the hope of being able to find some sure means of detecting these foreign admixtures. This is of especial importance in view of the possibility of the presence of the leaves of *Coriaria myrtifolia* or other dangerous species. The use of the microscope is the most valuable means available for the purpose, other methods of determination being so frequently inapplicable. Thus, in cases where the specimen consists of minute fragments only, or where the principles naturally contained in the drug have undergone considerable change, the anatomical elements are yet often found completely preserved. Independently of the chemical and organoleptic characters, therefore, the purity of the specimen and the nature of possible impurities may be detected by macroscopic characters (as revealed to the naked eye or disclosed by means of a hand-lens), or by the more minute anatomical characteristics, which are only distinguishable by the use of a microscope. The object of the present article is to deal exclusively with the last named.

STRUCTURE OF LEAFLETS OF SENNA (*Cassia* sp.).

Senna is the product of several species in the natural order Leguminosæ (Cæsalpineæ), including *Cassia acutifolia*, Del., *C. angustifolia*, Wahl., *C. obovata*, Collad, *C. lenitiva*, Bisch., and their

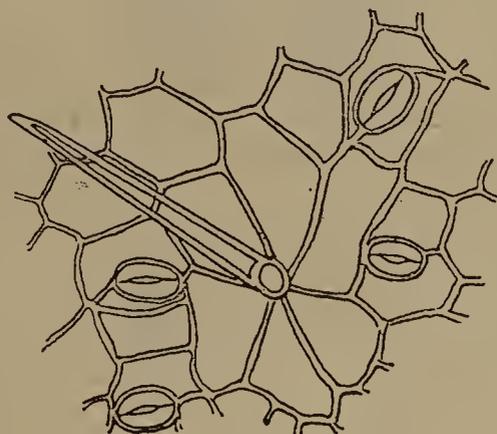

Fig. 1.—*Cassia obovata*, Collad. Upper epidermis of leaflet, showing unicellular hair and stomata with simple outlines. (x 300.)

different varieties. There is little difference between the upper and lower epidermis of senna leaflets. The cells are irregularly polygonal with thin walls, and there are numerous stomata, which are each in contact with two to four cells. There are also numerous unicellular hairs on the epidermis, which

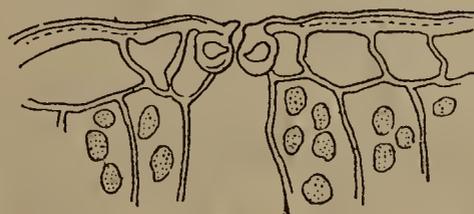

Fig. 2.—*Cassia obovata*, Collad. Section of stoma in upper epidermis of leaflet. (x 400.)

are deciduous, leaving as they detach themselves a base having the appearance of an annular pad, around which the neighbouring cells seem to radiate. In *Cassia obovata* (Figs. 1 and

2) the stomata are situated on a level with the surface, and their outline appears simple under the microscope; other sennas have the

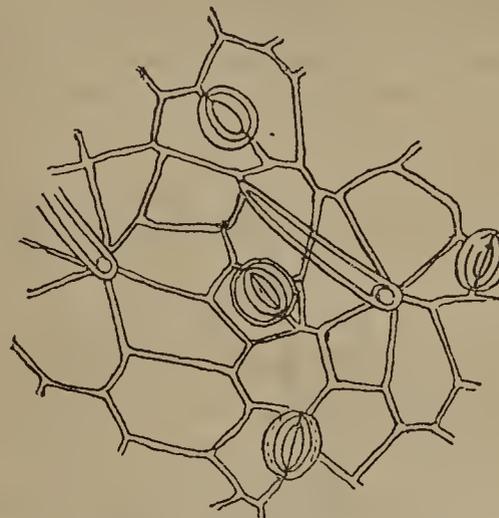

Fig. 3.—*Cassia acutifolia*, Del. Upper epidermis of leaflet, showing unicellular hairs, and stomata with doubled outlines. (x 300.)

stomata placed below the surface, and also with doubled outlines (Figs. 3 and 4). The parenchyma, which is protected by an epidermis covered with a stout cuticle, is divided into three

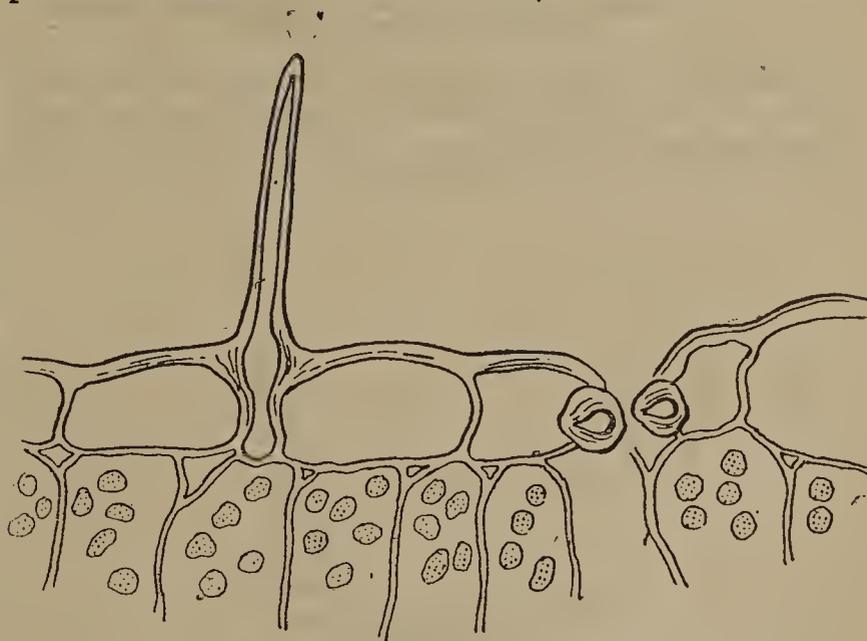

Fig. 4.—*Cassia acutifolia*, Del. Section of lower epidermis of leaflet, showing a stoma, a hair, and a portion of the palisade tissue. (x 385.)

layers, the uppermost and lowest consisting of palisade tissue, whilst between these there is a zone of very small, rounded, parenchymatous cells. Stellate crystals of calcium oxalate are seen

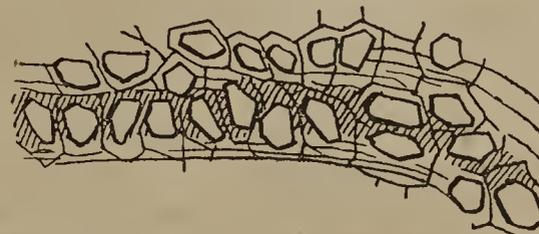

Fig. 5.—Fragment of senna leaflet, showing vein surrounded by cells containing crystals. (x 400.)

here and there throughout the parenchyma, and prismatic crystals of similar composition occur singly in cells which unite to form sheaths around the principal veins (Fig. 5). The endodermis is not coloured by sodium hypochlorite.

STRUCTURE OF POSSIBLE ADULTERANTS OF SENNA.

Other leaves or leaflets that have been found mixed with senna are those of *Coriaria myrtifolia*, L., *Solenostemma argel*, Haynè,

*. Translated from *L'Union Pharmaceutique* for May 15, 1896.

Vaccinium vitis-idaea, L., *Colutea arborescens*, L., *Globularia alypum*,
Tephrosia apollinea, De C., and *Cassia marilandica*, L.

1. *Leaves of Coriaria myrtifolia*, L.

The cells of the lower epidermis of these leaves are about a third larger than those of the upper epidermis. The cells are irregularly polygonal, with thin walls, and the stomata have elliptical

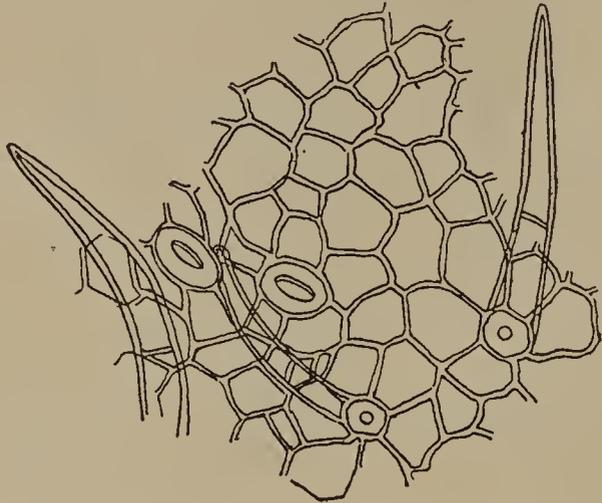

Fig. 6.—*Solenostemma argel*, Hayne. Leaf epidermis, showing stomata and multicellular hairs. (x 400.)

apertures, whilst each is accompanied by two cells placed symmetrically and finely wrinkled. Hairs are wanting. The leaf parenchyma consists in the middle of loosely-joined, rounded cells, and there are two rows of palisade cells adjoining the lower

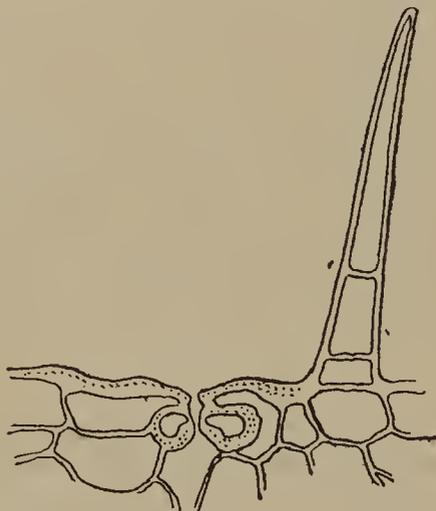

Fig. 7.—*Solenostemma argel*, Hayne. Section of stoma, and a multicellular hair on epidermis of leaf. (x 400.)

epidermis, but only one row adjoining the upper epidermis. The endodermis, which is clearly defined and consists of large cells, is coloured yellowish-brown by sodium hypochlorite.

2. *Leaves of Solenostemma argel*, Hayne.

The upper and lower epidermis of argel leaves are almost alike, being formed of very thin polygonal cells (Figs. 6 and 7). The not very numerous stomata have very large apertures and are bordered by five to seven cells each. The hairs are numerous and multicellular. The leaf is characterised by its double zone of palisade cells, its very limited spongy parenchyma, and by the presence of sphaero-crystals (Figs. 8 and 9) and secretion cells (Figs. 8 and 10). The median vein is large.

3. *Leaves of Vaccinium vitis-idaea*, L.

The upper epidermis of these leaves consists of polygonal cells with thick and sinuous walls, and is characterised by the lack

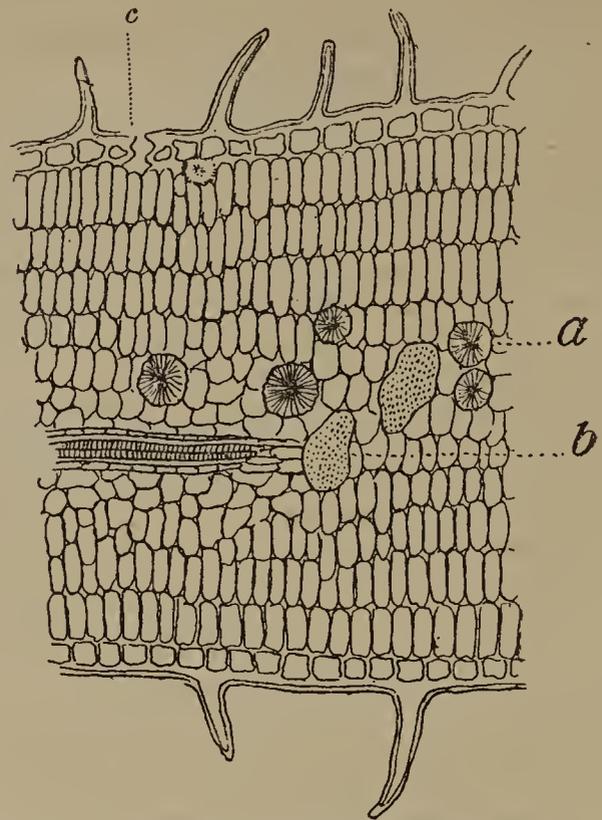

Fig. 8.—*Solenostemma argel*, Hayne. Transverse section of leaf, showing sphaero-crystals, a, secreting cells, b, and stoma, c. (x 10.)
of stomata, hairs, and glands (Fig. 11). The cells of the lower

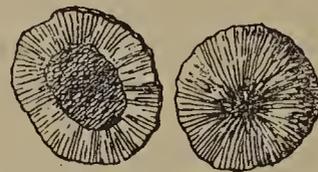

Fig. 9.—Two isolated sphaero-crystals (x 80)
epidermis are smaller, and on this side of the leaf there are numer-

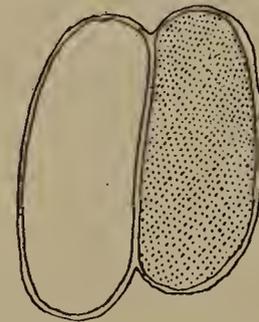

Fig. 10.—Two isolated secreting cells, one of which has lost its resinous contents. (x 800.)
ous small stomata, each surrounded by four or five cells, as well

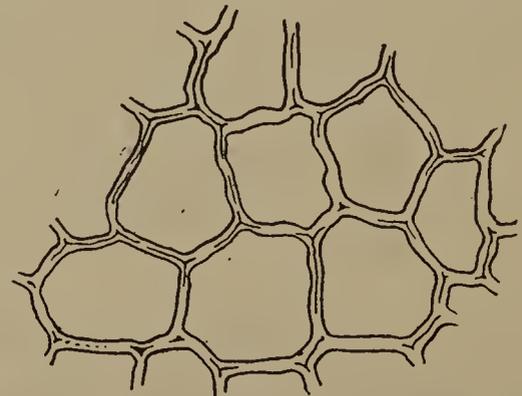

Fig. 11.—*Vaccinium vitis-idaea*, L. Upper epidermis of leaf, showing sinuous-walled cells. (x 400.)
as multicellular glands (Fig. 12). There are only two zones in the internal tissue of the leaf, one of palisade cells and the other of spongy parenchyma, and the edge of the leaf is traversed by a

bundle of fibres. The fibro-vascular bundles in the veins are also

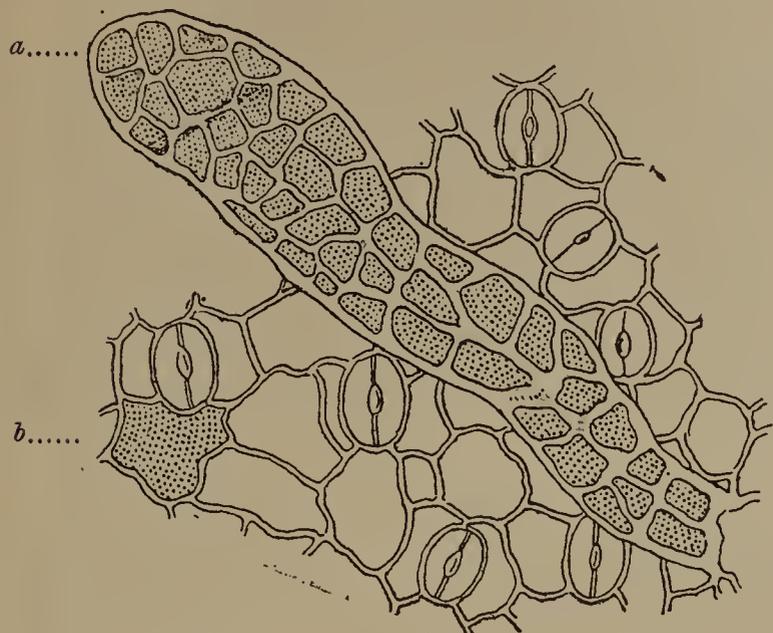

Fig. 12.—*Vaccinium vitis-idaea*, L. Lower epidermis of leaf, showing stomata, a large glandular hair, *a*, and an epidermal cell containing resinoid matter, *b*. (x 400.)

covered by a mass of pericyclic fibres on their upper and lower surfaces.

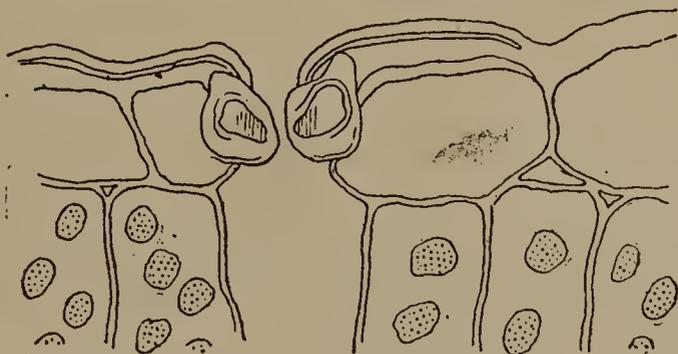

Fig. 13.—*Colutea arborescens*, L. Transverse section of leaf, showing stoma, cuticle, and epidermal cells. (x 800.)

4. Leaves of *Colutea arborescens*, L.

The leaves of *Colutea arborescens* have an upper epidermis consist-

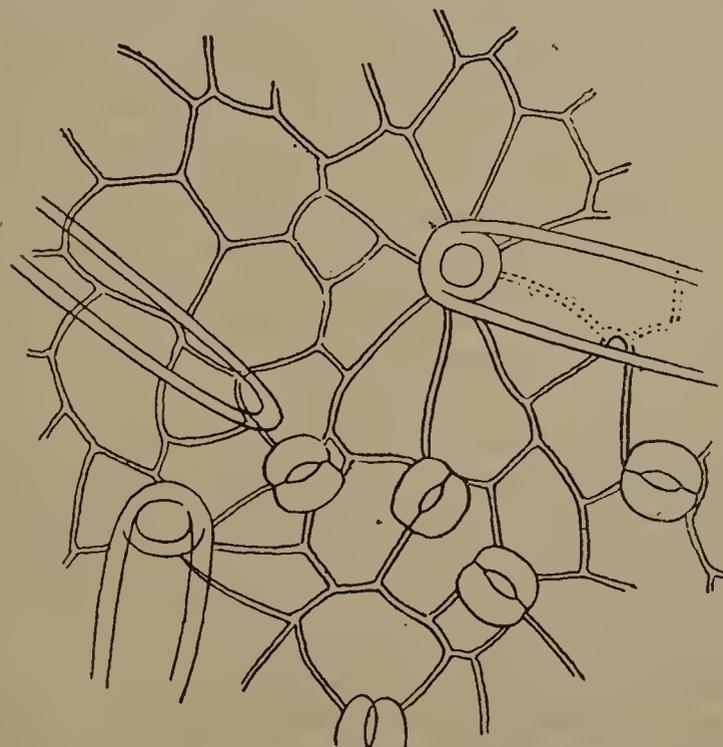

Fig. 14.—*Colutea arborescens*, L. Lower epidermis of leaf, showing stomata and unicellular hairs. (x 400)

ing of irregularly polygonal cells which have thin and sinuous walls. Hairs are wanting and stomata very rare. On the lower surface (Figs. 13 and 14), however, there are numerous small stomata with elliptical openings, each being surrounded by four or five cells. The long unicellular hairs are also abundant, and generally narrow at the base. The parenchyma presents no special features.

5. Leaves of *Globularia alypum*, L.

These leaves have the epidermis alike on both sides, consisting of irregularly polygonal cells with very thick walls, and containing

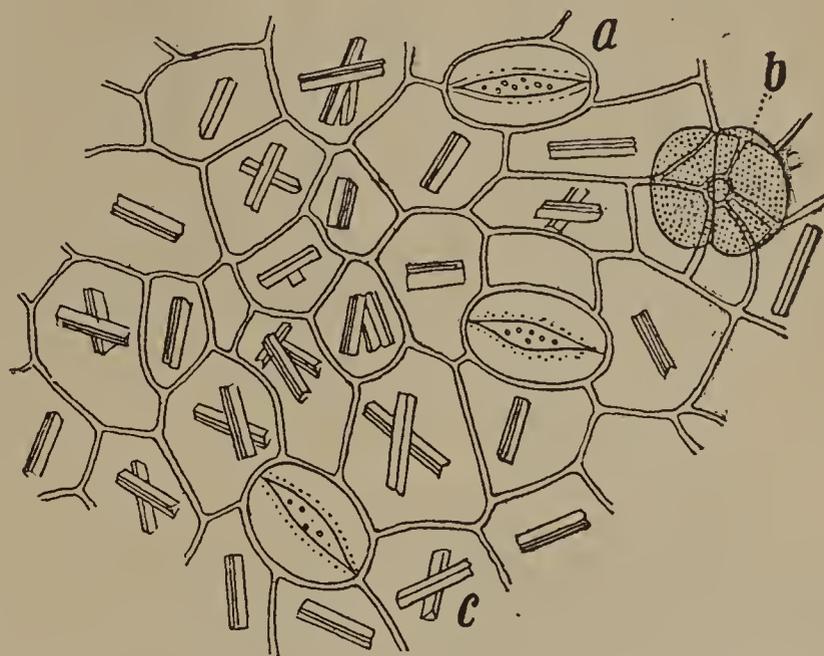

Fig. 15.—*Globularia alypum*, L. Lower epidermis of leaf, showing stomata, *a*, bicapitate gland, *b*, and crystals of calcium oxalate, *c*. (x 400.)

prismatic crystals of calcium oxalate (Fig. 15). The numerous stomata are surrounded by two to five cells each, and have elongated apertures. The leaves bear bicapitate glands but no hairs, and the parenchyma is homogeneous with but few interspaces.

6. Leaflets of *Tephrosia apollinea*, De C.

The epidermis is much alike on both sides of these leaflets, being formed of the usual irregularly polygonal cells, and the numerous stomata with large apertures are surrounded by several cells. The hairs (Fig. 16) are multicellular, long, and numerous, and the

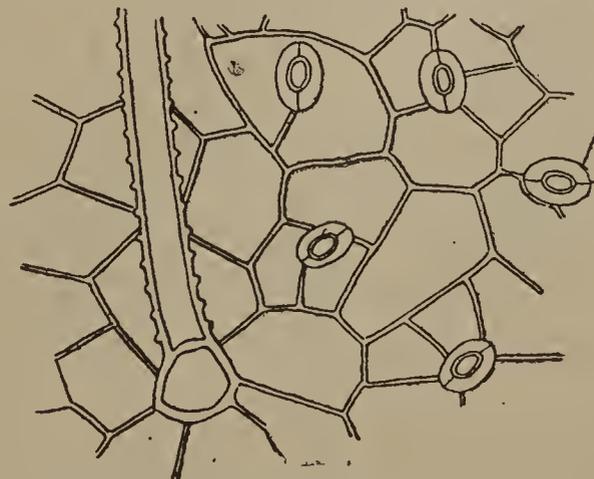

Fig. 16.—*Tephrosia apollinea*, De C. Lower epidermis of leaf, showing stomata and multicellular hair. (x 400.)

parenchyma is normal. The median vein is triangular, projects at the base, and diminishes towards the opposite extremity. It is

protected by a fibrous cover surrounded like the secondary veins by a sheath of cells containing crystals of calcium oxalate.

7. *Leaflets of Cassia marilandica*, L.

Large, sinuous cells and the absence of stomata characterise the upper epidermis of the leaflets of *Cassia marilandica*, whilst the lower epidermis differs in possessing stomata with small, elliptical

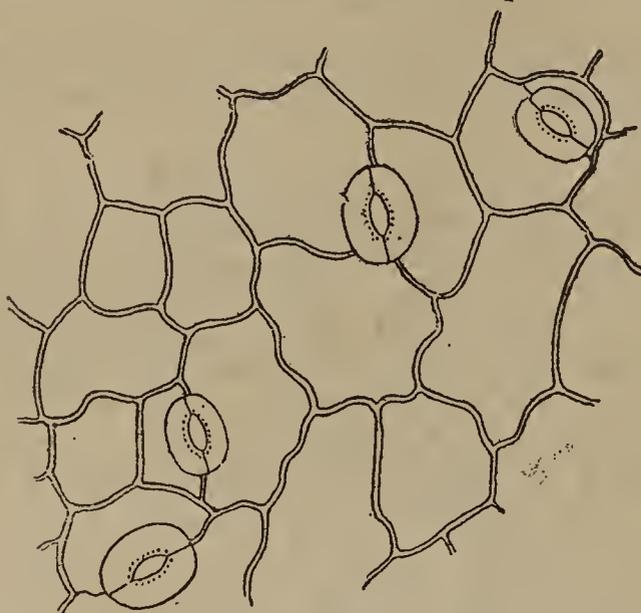

Fig. 17.—*Cassia marilandica*, L. Lower epidermis of leaflet, showing stomata. (x 400.)

apertures (Fig. 17). Hairs are lacking in both cases, the leaflet has but one row of palisade cells, and the spongy parenchyma is very loosely connected (Fig. 18).

TO DETERMINE WHETHER SENNA IS ADULTERATED.

The specimen to be determined, whether entire or not, is carefully picked over, and suspected pieces are placed on one side. The latter are then examined under the microscope after decoloration with sodium hypochlorite. It is well, however, to test with ferric

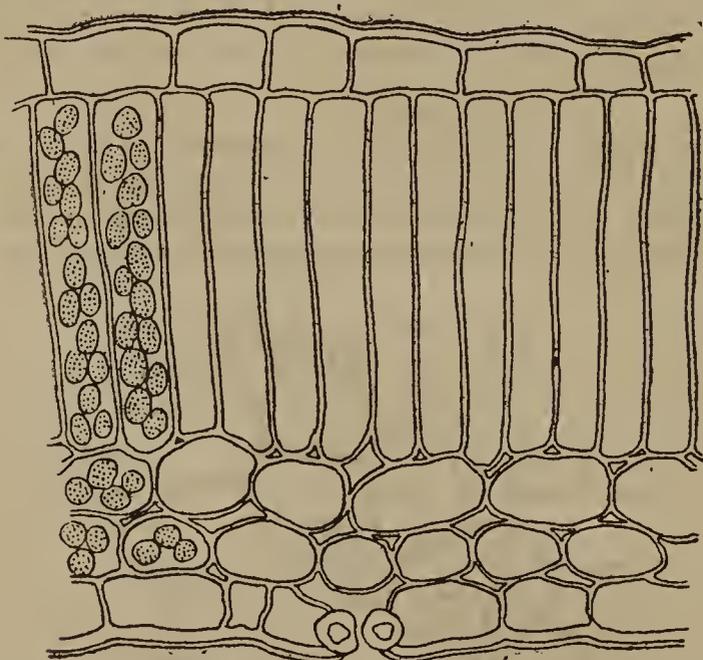

Fig. 18.—*Cassia marilandica*, L. Transverse section of leaflet, showing stomatal epidermal cells, palisade tissue, and spongy parenchyma. (x 400.)

chloride previously, as this gives a precipitate in the case of leaves from *Coriaria* and *Vaccinium*. The microscopic examination of specimens in the state of powder is an extremely delicate operation, but the clearly-defined characters of the principal substances used to adulterate senna readily enable us to determine the nature of any falsification.

NOTES AND FORMULÆ.

QUINOSOL: A NEW ANTISEPTIC.

Quinosol is a neutral compound of oxyquinoline, which readily liberates that body in the nascent condition, when it possesses very active antiseptic properties. Quinosol is readily soluble in water, has a slight, not unpleasant, odour, and is entirely non-toxic. A solution of 1 in 4000 prevents the development of staphylococcus. Kossman has employed this body largely as a substitute for phenol and for sublimate; no toxic action or eruption has been produced; when used as a dusting powder it is free from irritating or caustic action. The only inconvenience found with it is the yellow stain which it leaves on linen and on the hands of the surgeon. This, however, is easily removable by water (*Nouv. Rem.* xii., 132, after *Vratch*).

PYROCATECHIN AS A PHOTOGRAPHIC DEVELOPER.

Pyrocatechin is said to possess the following advantages as a developer:—its delicacy is equal to pyrogallol, the solution only alters very slowly on exposure to air, and is much more stable than hydroquinone, eikonogen, etc. The colour of negatives is very favourable to printing, which proceeds more rapidly than with other developers. It gives brilliant prints without hardness. It does not fog the plates. It does not stain the fingers. The same bath will develop several plates. The following are the principal solutions:—Solution A: Water, 1 ounce; sodium sulphite, 20 grains; pyrocatechin, 10 grains. Solution B: Water, 1 ounce; potassium carbonate, 100 grains. For use in ordinary exposures, equal parts of A, B, and water. For under-exposed plates, take one part A to two parts B. For plates that have had a timed exposure, the following one-solution developer is recommended:—Water, 2 ounces; sodium sulphite, 25 grains; sodium carbonate, 50 grains; pyrocatechin, 10 grains. To bring out contrasts, a two per cent. boric acid solution is recommended instead of bromide (*West. Drugg.*, xviii., 11).

GELATIN BOUGIES OF ALUM AND TANNIN.

Macerate 5 parts of gelatin in 35 parts of water for fifteen minutes, then add 10 parts glycerin, warm until the gelatin is dissolved and the liquid has evaporated to 40 parts. This may be rapidly and conveniently done in a capsule on an iron plate over a gas jet. To the hot mass add a warm solution of 8 parts of alum in 25 parts of water. This addition causes the gelatin to coagulate, but on continued heating, it again liquefies. Evaporate to 64 parts and strain. The mass then contains 12½ parts per cent. of alum. In a similar manner tannin may be combined with a gelatin basis by adding a solution of tannin in glycerin, 1 in 5, to the hot mass; the coagulated mass also, in this instance, becomes liquid again. The water is driven off and the liquid run into moulds. By this method perfectly transparent bougies are obtained (*Journ. de Pharm. d'Anvers*, lii., 19, after *Neder. Sijdschrift*).

ARTEMISIN.

According to Merck, artemisin, $C_{15}H_{18}O_4$, is obtained from the last mother liquors in the manufacture of santonin from the seeds of *Artemisia maritima*. It is freed from santonin by re-crystallisation from chloroform, being deposited combined with one molecule of the solvent which is evolved at 90°. It melts at 200°, gradually turns yellow in the air, and is more readily soluble in water, and in dilute alcohol than santonin. When heated with soda 10 parts, and water 40 parts, a fugitive carmine-red colour is produced, and like santonin it gives the same colour with alcoholic soda. Artemisin is apparently a hydroxy-santonin (*Journ. Chem. Soc.*, lxx., 60, after *Chem. Centr.*).

THE PHARMACEUTICAL CHEMICAL INSTITUTE AT MARBURG.

BY W. HARRISON MARTINDALE.

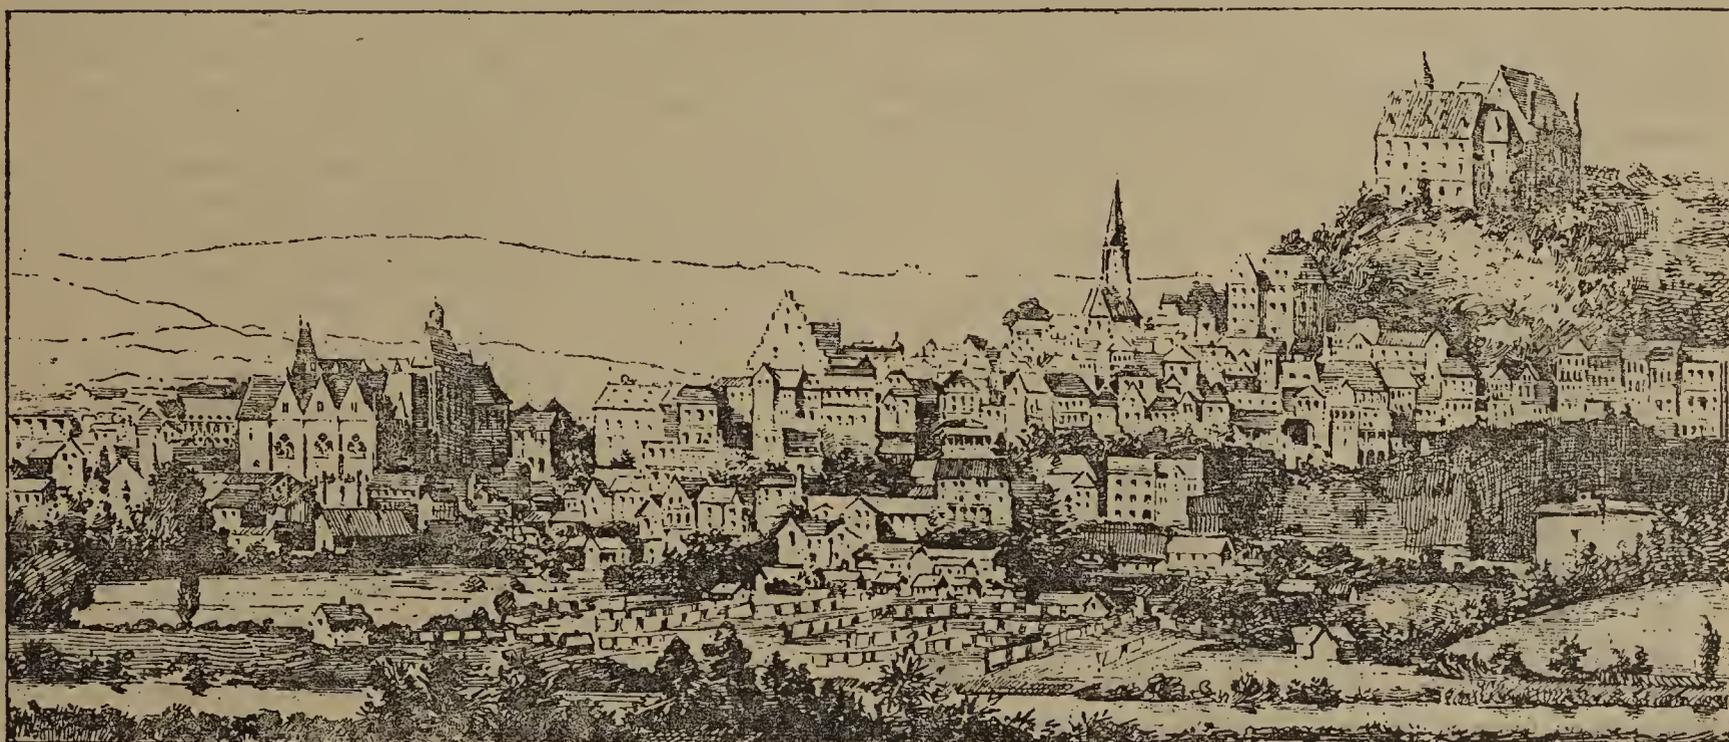

The University of Marburg, which is attended by about a thousand students, consists of the University building proper, together with numerous "instituts" working in complete union with the University in different quarters of the town. The present article embodies a description of one only of these institutes, the Pharmaceutische Institut, presided over by Professor Ernst Schmidt.

Passing up the avenue of acacias in the Ketzlerbach, we reach the Marbacherweg, also shaded with the same delicate foliage, and leaving the Anatomical and Dentistry Institutes on the right and left, we arrive at the Pharmaceutische Institut, surrounded by its garden, where trailing *Ampelopsis* does its best to hide the sternness of the portals. On entering the stone-paved hall we are sure to be greeted by some friendly "Assistent," who will not fail to recognise us as *Ausländer*s, and with the inimitable bow will conduct us to the sanctum of the professor. No one can be in the presence of Herr Geheimrath Professor Ernst Schmidt, without being impressed

The lecture-table is particularly ingenious in construction, besides being fitted with numerous gas and water connections, a portion can be lifted off, and reveals a white porcelain pneumatic trough, about a metre square, for gas collecting.

When a particularly stinking or fuming experiment is to be shown during the lecture a square glass shade with sliding door stands on a certain spot on the table, and should a Bunsen burner be introduced into the box (and the door naturally left ajar for the gas tube), the uninitiated wonder why no smell nor fumes escape into the air. The chicanery consists of an aperture in the table, over which the box stands, connected with an underground draught tube passing into a chimney.

The balance room and library is used mostly by the more advanced students, *i.e.*, not before their third semester. The balances are ten in number, standing on two sides of a long table—extremely good instruments—all weighing and calculations being carried to the fourth place in decimals. The balances are labelled, and set apart for "Assistenten," "Doctoranden," fourth and third semester men. A Mohr's specific gravity balance, polariscopes

GENERAL VIEW OF MARBURG.—The University is the large building on the left.

with his genial manner, his physique, his swinging gait (which carried him, it is said, over Crimea's battle-fields), his essentially "chemist's face," often beaming into a smile, with keen dark eyes behind the orthodox gold-rimmed spectacles, and when we hear his lecture in the auditorium we wonder whether he has acquired his voice by instilling the principles of "organic and inorganic" alternately each semester into the brains of two thousand odd students during the last five and twenty years. "Der alte Herr" celebrated his jubilee the year before last, and still we often hear of the great festivities on that occasion. The Institut consists of the professor's sanctum and private laboratory, auditorium, balance room, and library, four laboratories for first, second, third, fourth, and higher semester men respectively, volumetric analysis room, four sulphuretted hydrogen rooms, combustion room, extraction room, baracke-janitor's store-room and house, chemical collection, stock-rooms, etc.

THE LECTURE ROOM AND LIBRARY.

The auditorium is capable of seating a hundred students, and has a lecture-table some ten metres long, and black-boards sliding up and down forming doors to cupboards for reagent bottles on the wall behind the lecture-table.

spectroscopes, microscope, refractometer, saccharimeter, and other instruments are also ready for use.

THE LABORATORIES.

The laboratories are large, well-illuminated rooms, kept in "state" order and cleanliness, the second and fourth semester in the basement, the first on the ground, and the third semester on the first floor; in each thirty to thirty-five students on an average are at work, with the exception of the fourth semester, where the number is variable; the room is capable of accommodating eighteen "Practicanten." The benches and fittings in the laboratories are of carved oak, which from time to time is rubbed with "boiled oil" to preserve the same. Each student has on an average one and a half to two square metres of table room—varying, of course, with the kind of work he is doing—under which are his cupboards and drawers; each is provided with a separate tier of shelves above, and reagents in stoppered bottles with black enamelled lettering on white ground.

The second semester men have a balance-room to themselves. The volumetric analysis room adjoins that of the third semester, as this branch is a feature of the third semester study. All apparatus must be locked away before leaving, or a fine of 6*d.* is imposed for

every article found—this ensures the above-mentioned order, but naturally only refers to the first, second, and third semester students; throwing a match or a bit of paper on the floor is similarly punished.

The sulphuretted hydrogen in the different rooms set apart for it is generated from modified pieces of Kipp's generating apparatus, the delivery tube consisting of a pipe supported horizontally upon the wall, with a large number of smaller tubes branching at regular intervals at right angles from it, each being provided with a separate tap; these tubes are connected by means of rubber tubing with a row of wash-bottles on a shelf beneath, and the student brings his solution and his own glass delivery tube and finishes his H_2S work in the H_2S room. For leaving an H_2S tap on or bringing anything smelling of H_2S into a laboratory, the fine is 6*d*.

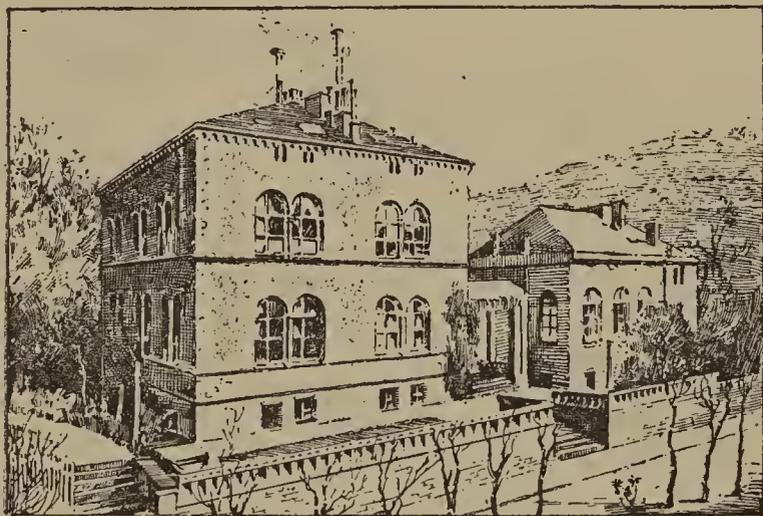

The consumption of sulphide of iron per annum is half a ton.

The combustion room in the basement has a blow-pipe and three ovens for organic elementary analysis.

The extraction room, also in the basement, is fitted with a Soxhlet extraction apparatus, drying cupboard, steam-pans, still for ethereal solutions, etc., for working drugs *en gros*.

The "Baracke" is an outhouse whither those ambitious in smell-producing are banished.

The chemical collection contains some hundreds of organic and inorganic specimens, the majority of which have been prepared by

PHARMACEUTICAL INSTITUTE, MARBURG.—The building on the right is connected with the main building by corridors, and contains the Auditorium, with the second semester laboratory in the basement.

the students working on their *arbeit* thesis for their "Dr." degree, and by those working *preparatif* in the fourth semester.

THE DAY'S WORK.

The day's work consists in attending lectures and practical work in the laboratory. The lectures in the summer semester commence with botany by Professor Meyer at seven, and those in the winter at eight. The Botanical Institute stands in the Botanical Garden in the town, in which peasant-women are employed in keeping the extensive collection of plants in order. The lectures last one hour each, although in the majority of cases the "academical quarter" comes into force and the professor enters at a quarter after the hour, the students rising until he has taken up his position at the reading-desk. Clapping or stamping is never resorted to during a lecture, except at the beginning of the first lecture and the end of the last lecture of the semester. The botany lecture over, the students must then climb the hill to the Physikalische Institut, where at 8.15 Professor Melde lectures on "Experimentalphysik"—mechanics and optics in the summer, and magnetism, electricity, and heat in the winter semester. This large new building, crowned with an astronomical observatory, is beautifully fitted within and provided with electric light. At 9.15 they are in time for Professor Schmidt's

lectures on inorganic chemistry in summer, and the organic branch in the winter at the Pharmaceutical Chemical Institute. Each professor has his "lecture-assistant" present at his lecture, and in the case of Professor Schmidt, the assistant's day is entirely employed in preparing the experiments for the lectures. In his first lecture Professor Schmidt exhorts the men to attend regularly, and explains that the aim of his lecture will be to discriminate between the cardinal points of the subject and the matter of secondary importance. This results in the students bringing their "Schmidts" (Ausführliche's 'Lehrbuch der Chemie für Pharmaceuten,' etc., I. Anorganische Theil; II. Organische Theil) with them, and marking the margins of the same during the lecture. This is a great improvement on the old note-taking system, as with the latter the student loses everything he has not written down, and cannot rely upon what he has written. Everything is explained with minute precision, the Professor's dry humour being proverbial and greatly appreciated.

Other lectures which the student attends are Professor Schmidt's "Toxicology," one day a week in the winter semester, and the "Chemical Examination of Drugs and Medicines," one day a week, extending through three semesters; Professor Meyer's "Chosen Points from the Physiology and Biology of Plants," and "Microscopical Practical Work"; Professor Kohl's "Classification of the Angiosperms and Gymnosperms, with Special Consideration of Medicinal Plants," and the same professor's personally conducted botanical excursions in the vicinity of Marburg on Saturdays. These take place almost entirely in the afternoons during the week.

At the conclusion of Professor Schmidt's morning lecture at ten o'clock the students work in their respective laboratories until one o'clock, under the direction of the assistant in charge of each. During this time the professor makes a daily visitation of the laboratories, and questions each student as to his work and his results. His memory in this respect is remarkable, and his friendly chaff when a first semester student finds lead that should be barium usually takes the form of "pseudo-lead, which in ordinary life one chooses to designate barium."

In the first semester the work consists of analysing mixtures of salts, at first few and simple, and gradually increasing in number and difficulty. When the student has gained sufficient proficiency in this he may receive qualitative mineral and qualitative inorganic toxicological analyses in flour, milk, meat, beer, etc. A student is expected to complete twenty-five qualitative analyses, but it is no great difficulty to complete twice the number in the time.

In the second he commences qualitative analysis, receiving solutions of copper, zinc, mercury, nickel, and other salts. He gives in his result the amount of the salt in question that he finds to the assistant, who then signifies in his note-book whether the result is satisfactory or not. This note-book is handed to the professor on entering the laboratory for his daily round. The student further determines the chemical composition of samples of such salts as calcium phosphate and barium chloride, etc., and still continues with qualitative mixtures, minerals, and toxicologicals.

In the third semester he carries out "separations," quantitative analyses of mixtures of salts; for example, zinc sulphate and nickel chloride, and quantitative toxicologicals (with one and more inorganic poisons), and still keeps himself in practice with qualitative analyses as before. In the volumetric work the students have to keep the room supplied with the stock volumetric solutions, and they are instructed in the handling of Mohr's as well as Guy Lussac's burettes, the latter being the greater favourites with the Professor. All the official volumetric analyses are carried out by each student.

In the fourth semester—usually after passing the "Staats Examen"—he busies himself with analysis of foods of all descriptions—milk,

butter, tea, chocolate, water, wine, etc., etc., and at the same time may prepare inorganic and organic compounds, but the student may choose his course of work.

THE STATE EXAMINATION AND THE PH.D. EXAMINATIONS.

The State Examinations take place during the holidays and last six to seven weeks, during which the student has inorganic and organic compounds to prepare in somewhat large quantities, receives qualitative, quantitative, toxicological and volumetric analyses and is examined *vivâ voce* and in writing in chemistry, analysis of drugs, and other subjects. Pharmacy, it will be noted, is not included in the qualifying examination (Staats-Examen), but has a place, however, in the assistants' examination (Gehülfer-Examen). For the "Doctor" degree six semesters' study is requisite, and the student is examined in one subject as principal subject (usually chemistry), and two others as secondary ones (usually botany and physics), besides being sounded in philosophy.

On passing an examination the newly-born Herr Reichs-Apotheker or Herr Doctor Phil. invites his friends to give him a "Hu ja ja Fahrt," which consists in their driving round the town with him in an open landau at evening (owners keep special vehicles for the purpose!) yelling "Dem Candidaten Hu ja ja, hurah, hurah, hurah!"—and there we will leave him!

TOILET PREPARATIONS.*

BY FRANK EDEL.

Among the articles meeting with steady sale in every pharmacy are tooth powders and pastes, as well as liquid preparations for the same purpose. These have a regular and constant sale, and I believe that a large proportion of such demand can be easily supplied with products of the pharmacist's own manufacture. Lately the demand seems to favour paste dentifrices, but these preparations are easily prepared. In putting up this class of preparations, as in putting up all special preparations, the pharmacist should see to it, first, that he has a meritorious formula; second, that the product of such formula be put up in nice style. It is impossible to make anything but a very limited sale on any preparation unless the preparation has merit. If it has, when once used it will be used again, and perhaps recommended to others. If it has not, its use will be limited.

It is a fact—which every pharmacist has seen demonstrated many times—that a nice, neat package goes a great way toward selling any preparation. My own observation has impressed these facts on my mind time and time again. The houses which make a business of manufacturing druggists' glassware have given the matter of containers for both liquid and powder preparations for the teeth attention, and several nice styles of bottles are now in the market designed especially for this class of preparation, so that now it is only a matter of choice with the pharmacist as to what style of bottle he will use.

A good liquid preparation for the teeth can be made by the following formula. For the want of a better name let us call it—

English Impearling Fluid.

Fl. Extr. Soap Tree Bark	2 ozs.
Glycerin	4 ozs.
Alcohol	4 ozs.
Water	q.s. to make 1 pint.
Oil Cloves	4 drops.
Oil Wintergreen	3 drops.
Tr. Cudbear to colour.	

Mix.

Or it can be made from the ground soap tree bark by percolation. It can be easily and cheaply prepared, and furnishes a preparation very similar in appearance and taste to the most popular preparations on the market. If it is desired to flavour it

similar to the preparations sold as imitations of the popular anti-septic "Listerine," it can be flavoured with eucalyptol and thymol in place of the flavours given above.

Par Excellence Tooth Powder.

Precipitated Chalk	2 lbs.
Prepared Chalk	2 lbs.
Powd. Sugar Milk	1½ lb.
Borax	½ lb.
Powd. Orris Root	1 lb.

Mix thoroughly and colour with carmine if so desired. This powder can be flavoured with oil of wintergreen or oil of rose as preferred. In mixing the carmine with powder it is better to dissolve it in a small amount of ammonia and mix with a small amount of the chalk first, and then incorporate with the balance of powder. This will be found an efficient and at the same time a cheap tooth powder.

After experimenting with many of the published formulæ for making tooth paste, with but little satisfaction, I came to the conclusion that the trouble was not so much in the powders used as in the liquid that was incorporated to make the same into paste form. After some considerable experiment the following liquid was found to give good results:—

Glycerin	2 parts.
Water	1 pint.
Gelatin	1 oz.

Macerate the gelatin in water until soft, then heat to dissolve, add the glycerin, and mix thoroughly. This was found very satisfactory for the purposes given above.

Imperial Tooth Paste.

Prepared Chalk	2 lbs.
Precipitated Chalk	2 lbs.
Powd. Sugar	1 lb.
Powd. Carb. Magnesia	½ lb.
Powd. Borax	4 ozs.
Carmine	q.s.
Oil Wintergreen or Oil Rose	q.s.

Mix the powders, and, if desired, colour as recommended above; then add the flavours and mix thoroughly; next gradually add the above liquid, mixing carefully in a mortar until the product is a paste of the proper consistency. It will be found difficult to get rid of the lumps entirely by mixing in a mortar, but this can be easily done by running the paste through a paint-mill. Such mills are not expensive, and aside from their use in making tooth paste as above, are very valuable in preparing such ointments as ointment of zinc oxide. The paste when made must be immediately put in jars or in collapsible tubes. The popular English pastes are put up in jars, while those made in this country are generally put up in tubes.

Some years ago it was customary to mix a small quantity of powdered myrrh with tooth powder or paste. This gives the powder, to my mind, a disagreeable taste, and has no advantage as a cleanser over those not containing it. Likewise the tendency now seems to be against soaps being incorporated into paste or powders. Soap is in no way advantageous in such preparations, and to me seems very disagreeable.

If it is desired to flavour the paste to meet the ideas of some who are advocating flavours as mentioned above in connection with the formula for English impearling fluid, eucalyptol and thymol can be used in place of the oils as recommended above. In either case it is well, however, to use a small portion of oil of wintergreen.

To those who have had no experience in filling collapsible tubes with tooth paste or toilet creams, I would say that I have found nothing so handy as a large-barrelled metal syringe. Remove the pipe and fill the barrel with paste, then force the given quantity into the tube, and close with a broad pair of pincers (which are furnished by the manufacturers for that purpose). It only requires a little ingenuity, however, to improvise pincers that will close the tubes nicely, and any tinsmith can make a suitable apparatus for filling the tubes.

* Reprinted from the *Spatula*.

An Elegant Cold Cream.

Glycerin	6 ozs.
Lanolin	1½ oz.
Petrolatum, White	4½ ozs.

Mix the lanolin and petrolatum and then incorporate the glycerin, flavour with oil of rose or oil of ylang-ylang, and put up in jars or collapsible tubes. This is the finest preparation of its kind I have ever seen. It is easily made and keeps perfectly.

What has been said in regard to putting up preparations for the teeth is equally true of toilet preparations in general, viz., first, be assured that you have a good formula and then put it up in nice style.

There is no lack of formulæ for colognes, but not one out of every dozen will be found worth anything. Some years ago, I remember seeing a formula recommended as similar to a very popular cologne. The writer of the article said that this cologne owed its peculiarity to the oil of Canada snake-root, and then proceeded to recommend a formula which called for the oil in such quantity as to drown every other odour and make a cologne having no resemblance to the one he said it resembled.

It is not the purpose of this article to propose formulæ imitating standard goods on the market, but rather to recommend such as in my own hands have proved satisfactory in every way. The following formula yields a musk cologne that is at once elegant and lasting, and will be found the equal of any on the market:—

German Cologne.

Oil Bergamot.....	1½ oz.
„ Lavender Flowers.....	½ oz.
„ Lemon	2 drs.
„ Asarum.....	1 dr.
„ Sandal, Best	1 dr.
„ Rose Geranium	1 dr.
„ Neroli, Bigarade	15 min.
„ Patchouly.....	20 min.
Fl. Extr. Orris Florentine.....	1½ oz.
Tr. Musk (1 dr. to pint).....	6 ozs.
Tr. Storax (1 part storax, 9 parts alcohol)	1 oz.
Alcohol Deodorised	80 ozs.

Mix and allow to stand one month or more and filter.

In making the above, as in all other colognes, only the best oils should be used. The above is in reality an extract for preparing a perfume, and does not come under the head of cologne proper. It is, however, an excellent preparation, strong and lasting, and will give general satisfaction.

Where the cologne is to be used as an aqua cologne for bath and other purposes, the following will be found excellent:—

Cologne Par Excellence.

Oil Bergamot	8 ozs.
„ Lemon	6 ozs.
„ Cinnamon Ceylon	2½ drs.
„ Cloves	2½ drs.
„ Neroli	5 drs.
Alcoholic Extr. Jasmine.....	6 drs.
Oil Rosemary Flowers.....	4 ozs.
„ Lavender	6 drs.
Benzoic Acid	2½ drs.
Musk	10 grs.
Alcohol	4 gals.
Water	1 gal.

Mix and allow to macerate a long time. This, I consider, the finest cologne of the kind I have ever seen.

The following formula yields an excellent preparation:—

Toilet Cream.

Blanched Sweet Almonds.....	2 oz.
Borax	30 grs.
Sweet Almond Oil	½ oz.
Quince Seed	1 oz.
Alcohol	4 ozs.
Dist. Water q.s. to make	32 ozs.

Rub the almonds to a smooth paste with a portion of the water; next add the balance of water gradually (making an emulsion of almonds); then strain and add the quince seed; let stand with frequent agitation for twelve hours and strain; then dissolve borax in 1 oz. water, add the oil and shake and mix with the mucilage of

quince seed, add alcohol and shake; finally flavour with oil of rose or oil of ylang ylang. This yields an elegant milk-white toilet cream that is an excellent emollient and dries quickly, or, if it is desired, one ounce of glycerin can be added in place of the oil and borax. If it is too thick it can be thinned by adding more emulsion of almonds.

Witch Hazel Toilet Cream.

Quince Seed	1 oz.
Glycerin	1 oz.
Dist. Ext. Witch Hazel.....	1 qt.
Alcohol	2 oz.
Borax	15 grs.

Mix the glycerin, quince seed and the extract, and let stand, with frequent agitation, for twelve hours; then strain and add the borax dissolved in small quantity of water and add alcohol gradually.

Violet Powder.

French Chalk.....	1 lb.
Powd. Orris Root.....	1½ lb.
Corn Starch	5 lbs.

Mix thoroughly and perfume with oil orris dissolved in alcohol if the orris root does not give odour enough. The above yields a very excellent dusting powder.

Par Excellent Face Powder.

Precipitated Chalk	23 ozs.
French Chalk	24 ozs.
Bismuth Sub-carbonate.....	7 ozs.
Zinc Oxide C. P.	17 ozs.
Corn Starch	30 ozs.

Perfume with Oil of Rose to suit.

This makes a very excellent face powder. If it is desired to make it a flesh colour, it may be coloured with carmine.

Superior Bay Rum.

Oil Bay.....	¾ oz.
Oil Orange	¼ oz.
Alcohol.....	3 pts.
Water	3 pts.
Precipitated Phos. Calcium.....	q.s.

Mix the oils and alcohol, add the calcium and shake; then add water and shake thoroughly and filter. Colour with 90 proof rectified Jamaica rum, or with slight amount of caramel.

Violet Water.

Extr. Violet	16 ozs.
„ Cassia	8 ozs.
Tr. Orris Root	16 ozs.
Tr. Musk.....	½ oz.
Extr. Rose.....	1 oz.
Extr. Jasmine	10 ozs.
Alcohol, Deodorised.....	9 pts.
Water	1 pt.

Mix and allow to stand at least one month. In making these toilet waters only the best orris should be used. The extracts ordered are the alcoholic extracts of the flower pomades, and not the perfume usually sold under similar names. Only the best deodorised alcohol should be used in the work.

CHEMISTS AS LEADERS.

BY PETER TOWNSEND AUSTEN.

The historians of human development speak of the Stone Age, the Bronze Age, the Iron Age, and other ages, meaning thereby the successive periods of human activity that have been characterised by the use of these materials. The most fitting term to apply to the period which began between fifty and a hundred years ago, and whose development is yearly more rapid and more wonderful, would be "The Chemical Age."

In the past, while what was called philosophy marked a high mental activity, much of it was a form of thought based almost entirely on abstract speculation, for the study of matter and its changes was almost unknown. Instead of the exact observation of material objects and their behaviour under varying conditions, and the study of the phenomena of Nature, all kinds of imaginative trains of thought were evolved, and speculations, often baseless, were put forward with little idea as to whether they were supported

or not by facts. Even when facts were observed, they were often distorted in order to make them accord with the false or visionary philosophy of the day. But when the delicate balance was invented, and the weights of the different kinds of matter could be exactly determined, and their changes followed with precision, the great principle of the indestructibility of matter was established, and the schools of abstract philosophy suffered an overturn. Instead of the observed fact being subservient to the speculation, the observed fact became dominant, and speculative philosophy retained its value only so far as it accorded with and explained, or amplified by inference, the fact.

All this bears directly upon the conditions of modern competitive life. For instance, men, first of all, must obtain food. To obtain it from weaker communities by force or robbery could be successful only for a time, as the producers were either exterminated or they gave up so unprofitable an industry. The food-supply of mankind depends on the application of a knowledge of the principles involved in plant growth. The basis of this knowledge is chemistry. It was not really until 1840 that it was demonstrated by the great chemist, Liebig, that plants, like animals, feed. They take certain kinds of nutriment out of the soil, and soon exhaust it. Soon they fall to grow. Liebig showed that if these nutritive substances were put back into the soil, the plants would keep on growing, and that there was no limit to the productiveness of the earth, when properly nourished as chemical science indicated. Malthus stated that the population must be restricted, else it would exceed the food supply. Liebig showed that the production of food stuffs, made possible by the application of chemical science, was so immense that such a danger is not to be feared. Chemical knowledge has rendered it possible to make several blades of grass grow where there was only one. Liebig then investigated live stock, and proved that, though animals eat many kinds of food, the food owed its value to a few definite nutritive elements that are found in greater or less amounts in all foods; and that the animals, though seemingly widely different in physiological nature, were composed essentially of the same substances. Thus the raising of live stock and the production of dairy products were placed upon a scientific basis. Agriculture began to employ scientific methods, and the cost of raising plants and animals was greatly reduced.

It is not always easy to appreciate at first glance the far-reaching effect of a chemical discovery. The introduction of the hot blast in the manufacture of iron increased the production of pig iron. The invention by Bessemer of the converter method of making steel practically revolutionised the manufacturing industry of the whole world. What cheap steel means to humanity could not be told in a large volume. The invention of the basic process for treating phosphatic iron ores by Thomas and Gilchrist made it possible to produce steel from ores existing in immense quantities and hitherto entirely worthless. And, strange to say, phosphorus, the "iron master's curse," is now obtained as a phosphatic slag, which is a most valuable fertiliser for the farmer. The chemist turned the bane of England's iron industry into a blessing to England's agriculture. Weldon utilised the waste product in the manufacture of chlorine, so that it could be used over and over again. In turn was reduced the price of bleach, of bleached white cotton and of white paper. Books were made cheaper. Education was cheapened. The waste tars of the gas manufacture under the skilful hands of a host of chemists are now the basis of an immense industry. They produce brilliant dyes, perfumes, antiseptics, medicaments, and what not. The astonishing development of chemical knowledge has assisted in the evolution of electricity, the commercial future of which is incalculable. The study of life has been taken up, and by the aid of the colossal genius of Pasteur, disease

in plants, animals, and men is checked and avoided, thousands of lives are yearly saved, and the tenure of human existence is far stronger than it was half a century ago. These modern advances in chemical science and their applications have taken place so quietly, although irresistibly, that the average individual does not appreciate the part they are playing; nor can we estimate the still greater part they are to play. Another striking instance of the results of chemical research is the development on the one side of explosives, and on the other of hard and tough steel. Without the assistance of the chemist war would be monotonous.

The stability of a community lies in its independence. Its independence is based on its productiveness. Manufacturing consists in changing one kind of form of matter into some other kind of form. It is easy to understand, therefore, that chemistry, the science that studies the changes in the identity of matter, underlies the manufacturing arts. Hence the industrial status of a nation may be fairly estimated by the condition of its chemical knowledge. It is fair to hold that the country that has the best chemists will in the long run be the most prosperous and the most powerful. It will have at the lowest cost the best food, the best clothing, the best manufactured materials, the fewest wastes and unutilised forms of matter, the best guns, the strongest explosives, the most resistant armour. Its inhabitants will make the best use of their country's resources; they will be the most healthy, the most free from disease; they will oppose the least resistance to favourable evolution; they will be the most thrifty and the least dependent on other nations. The education of its people in chemistry and the physical sciences is the most paying investment that a country can make. Competition to-day between nations is essentially a competition in the science and applications of chemistry.

It is fair to assume, also, that if men who have devoted their lives to the study and practice of chemical science, and who hence must have the clearest understanding of all men of the true relations existing both between material things and between material things and humanity, also possess the mental calibre that may enable them to be men of affairs, they ought to be especially successful in executive positions. Such an assumption is supported by the fact that the number of responsible positions, at first sight quite unconnected with chemistry, which at present are filled by chemists, or men who have received a thorough training, is large. This shows, not that the chemist is an unusual kind of man, but that a chemical education may make a man unusually efficient. Perhaps as striking an illustration of this as any is the increasing number of chemists in charge of large educational institutions. There is no position in which a man may more powerfully and so lastingly influence man than that of the head of a large school or college.

The Marquis of Salisbury, Prime Minister of England, is a chemist, and spends much of his spare time in his finely-appointed laboratory. And France recently placed in the most intricate and difficult of positions, that of Minister of Foreign Affairs, her most eminent chemist, Berthelot.

These are signs of the time—indications of the chemical age that the world has now entered into, and in which it is destined to remain for many years to come. It will be interesting to watch the course of the two great nations which are now under the guidance of chemists, bearing in mind that Germany is now the home of chemistry, nor forgetting that Russia's advance in chemistry during the last quarter of a century may fairly be called phenomenal. In this connection, too, it may be pertinent to ask what has become of all the clever and earnest young Japanese chemists who have been studying at the leading educational centres of Europe and America during the last few years?—*North American Review*.

REVIEWS AND NOTICES OF BOOKS.

A MANUAL OF BOTANY. Vol. II. Classification and Physiology. By J. REYNOLDS GREEN, Sc.D., F.R.S., F.L.S. Small 8vo, pp. i.-xi. ; 1-541. Price 10s. (London: J. and A. Churchill. 1896.)

This volume completes the sixth edition of the work hitherto known as Bentley's 'Manual of Botany,' but which, in consequence of the great alterations that have been made in nearly every chapter, except in the part on systematic botany, is now practically Green's rather than Bentley's 'Manual.'

The present volume is divided into two parts, devoted respectively to Classification and Physiology.

Comparatively few alterations have been made in the first part. The majority of those natural orders which have been reduced to tribes in Bentham and Hooker's 'Genera Plantarum,' such as Tropæolaceæ, Oxalidaceæ, and Limnanthaceæ, under Geraniaceæ, have been retained (possibly to avoid any alteration of the useful analysis of the natural orders that is given at the end of each sub-class), but their position in the 'Genera Plantarum' is indicated in each instance. Continental arrangements of the natural orders of plants do not fit in with the works on systematic botany published in this country, and for this reason it is well that Professor Green has retained the British arrangement, since the work will serve better than most others as an introduction to the numerous colonial and other Floras published in this country.

With few exceptions, the terminology has been rendered more uniform by the use of the termination "*aceæ*" to distinguish natural orders, thus aiding the memory of the student by conveying a definite idea. The division of the vegetable kingdom into four groups, viz., Thallophyta, Bryophyta, Pteridophyta and Spermophyta is another instance of this. The substitution of the word Spermophyta instead of Phanerogamia has the advantage of rendering the nomenclature uniform, whilst expressing more correctly the leading feature of the group than the word "Anthophyta," of A. Braun.

The arrangement of the natural orders in cohorts according to the plan of 'Genera Plantarum' is a decided gain, as is also the bird's-eye view of the cohorts and their characters given on p. 224. It is, however, to be regretted that the concession made to evolutionists, of altering the relative position of the sub-classes (beginning with Monochlamydeæ, and ending with Corollifloræ), makes the arrangement of the natural orders less useful for subsequent work in systematic botany; for all botanists have sooner or later to be systematists as well as biologists and histologists. Here and there a few short notes on the relationships of the different natural orders are given, but a comprehensive view of the reasons for grouping the natural orders into alliances or cohorts is wanting, and this is a feature that may well be dealt with in a future edition.

Economic botany has practically been removed from the manual, and space thereby economised. In fact, this branch of the subject has grown so much of late years as to require a volume to itself. 'The Treasury of Botany' and Boulger's work on economic botany should, however, be a help to those, and probably they are many, who regarded this as one of the most useful features of the late Professor Bentley's 'Manual.'

The physiology of plants is, as is well-known, Professor Green's special branch of the subject, and here he is evidently quite at home. This part of the work has been practically rewritten in the peculiarly lucid style characteristic of the author, and probably no better account embodying all the recent discoveries in this branch of the science could be found in the English language. It is satisfactory to feel that the student has now a useful manual of botany by an English botanist, which is brought up to date and not merely a translation of a German work, as so many of the recent text-books have been, at least to a considerable extent.

One novel but very useful feature which deserves notice is the glossarial character of the general index, explanations of the meaning of the terms being added wherever they can be briefly given.

It will be gathered from the above remarks that the book is well adapted to the requirements of botanical students in general, and pharmaceutical students in particular. Its handy size, clear type, and numerous well-printed illustrations make it even more suitable in this respect than it would be otherwise, and Professor Green is congratulated on the conclusion of a difficult and yet necessary task.

PARLIAMENTARY NOTES AND NEWS.

ANTI-BLOCKING SCHEMES.—Almost every private member who has been a victim of the pressure of Government business or the tactics of Her Majesty's Opposition is ready to express the opinion that Parliamentary procedure needs amendment. In addition to the proposals of Sir Albert Rollit, Sir Edward Clarke, and Mr. Gedge, to which allusion has been made in these columns, it has been recommended that a new Standing Order shall be adopted by the House with a view to preventing to some extent the present waste of legislative energy. The proposed order, which has been approved by a Committee of the House, substitutes for the present method of death by inanition the more scientific process of suspended animation, but with a sure and certain hope of re-awakening in the next session of the same Parliament. A member in charge of a measure which has reached, say, the Committee stage, and finds further progress hopeless, may, by giving proper notice, move "that further proceedings of such Bill be suspended until the next session." And no amendment would be permitted to such motion. If the motion is carried, the private member, relieved of further anxiety, would have leisure to attend to the needs of his party instead of saying hard things about the Government. In the ensuing session, any member whose name "backed" the Bill could claim to move "that the resolution of the previous session be read." Thereupon the Speaker would read the resolution and call upon the member to present the Bill in the form in which it stood when suspended. On the motion being carried, the Bill would be printed and would renew its Parliamentary course with increased prospects of ultimate success. Legislation on the instalment system does not perhaps strike one as being very dignified, and it may open the door to certain evils, but the formulation of such a scheme by a Committee of the House indicates the congested state of public business and the recognition of the need for some means of rescuing really good measures from an undeserved oblivion. Perhaps even a Pharmacy Bill might be possible if the proposed order becomes incorporated in the standing orders!

A WINTER SESSION.—Since the above scheme has been made public in the columns of the *Times*, another device for the conservation of parliamentary energies has emanated from the First Lord of the Treasury, and it has the advantage over all other proposals in that it has received official sanction, and will actually be put into practice. Briefly it may be summed up in the words "Winter Session." The Government intend to proceed steadily with official business till August 14, and to then suspend further proceedings till January 13, from which date till March, Parliament will sit to finish off (if possible) the Education Bill and other outstanding items of the Government programme. Such an arrangement must not be regarded as furnishing additional chances for the advancement of private members' Bills, or as rendering it possible that the House of Commons may be able to consider the Companies Bill from the Lords, but it is a distinct advance towards the "carrying-over" principle embodied in the embryo standing order above alluded to.

THE SELECT COMMITTEE of the House of Lords on the Companies Bill held its first meeting on Friday, 12th instant, when the Lord Chancellor was appointed Chairman, and preliminaries as to procedure were discussed. It was decided that the Committee should take evidence on the points dealt with in the Bill, but the question as to whether such evidence should be made public or not was deferred until the next meeting, which is fixed for Friday the 19th instant, at 12 noon.

THE REPORT OF THE ADULTERATION COMMITTEE is in draft, and will be considered at the Committee meeting on the 25th inst. Hence its communication to the House may be shortly expected. According to the *Times*, the report, when it does appear, will contain recommendations in favour of the establishment of a Board of Reference to decide such questions as food standards, and to which also would be referred all questions of adulteration. In fact, it will suggest the enlargement of the Court of Appeal at Somerset House, and not the setting up of a separate body. This announcement is not over-lucid, and one may be excused some anxiety as to the constitution of a Board which is apparently to exercise judicial as well as technical functions.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, JUNE 20, 1896.

PHARMACOPŒIA STANDARDS.

Now that the revision of the national Pharmacopœia is in progress and there is a probability that, in connection with that work, additional provision may be made for standardising drugs and medicinal preparations, a convenient opportunity is afforded for considering the suggestion that the official definitions of the British Pharmacopœia should be applied as standards for the purposes of the Sale of Food and Drugs Acts. A further reason for directing attention to this matter is to be found in the contemplated amendment of the law relating to adulteration which has been for some time past the subject of inquiry by a Select Committee of the House of Commons. The suggestion above mentioned appears to involve the assumption of analogy between the conditions under which drugs or medicinal preparations are supplied to the public and those obtaining in the sale of ordinary food commodities. It also ignores the fact that, while legislative provision had been made for securing the purity and fitness of drugs and medicines long before the passing of the Act relating to adulteration of food, the special qualification of persons engaged in pharmacy and the statutory obligations imposed upon them by the Pharmacy Act serve as guarantees for the articles they supply, which have no analogies in ordinary trade.

Bearing in mind the fact that the predominant object of the issue of a British Pharmacopœia was "to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined," there can be no reasonable doubt as to the moral obligation binding pharmacists to observe the descriptions by which articles of the *materia medica* are officially defined and to be guided by the directions indicating what the medicines of the Pharmacopœia are intended to be. Any degree of uncertainty that may have existed as to the legal obligation in this respect was very positively removed by the Pharmacy Act, 1868, which defines the persons entitled to call themselves chemists and druggists and makes the compounding of medicines of the British Pharmacopœia—except according to the formularies

of the said Pharmacopœia—an offence punishable under the Act.

The obligation thus imposed upon pharmacists is so evident and so reasonably appropriate to the position they occupy that to question, from that point of view, the feasibility of maintaining Pharmacopœia standards would justly be considered a retrograde proceeding. Naturally no such attempt has been made; but, on the contrary, the prevailing tendency has been to extend and amplify the definition of medicines, in regard to their composition and strength, by introducing improved methods of preparation and testing. In this way pharmacists have contributed largely to advance the object of the Pharmacopœia, and within recent years the pages of this Journal have furnished abundant evidence of their endeavours to secure greater uniformity and precision. For these several reasons it appears generally unnecessary and undesirable that the procedure required for preventing adulteration of food materials should be extended to the supply of drugs and medicinal preparations. There are, moreover, special reasons for this conclusion. Certain Pharmacopœia articles present practical difficulties by their liability to undergo change, even when prepared in strict conformity with official formulæ. After some lapse of time the strength of such articles may fall more or less below the respective standards of the Pharmacopœia. In the case of other articles the adoption of high standards of quality may render their production impracticable or unnecessarily expensive.

The attempt to make Pharmacopœia standards the criterion of the nature, substance, and quality of articles in the administration of the Food and Drugs Acts appears therefore to be open to objection, for the adoption of that course, while likely to lead to harsh and even unjust application of the law in the case of articles subject to alteration, might be an obstacle to improvement in the official standards. Moreover, the decision of questions as to whether any deviations from Pharmacopœia standards are to be regarded and dealt with as offences, involving liability to fine and imprisonment, requires more special acquaintance with pharmaceutical matters than is to be expected from officials charged with administration of the law suitable for repressing the grosser forms of adulteration which are practised with articles of food.

The subject has recently been dealt with from this extra pharmaceutical point of view by Professor J. U. LLOYD in a paper read before the Philadelphia College of Pharmacy. Having regard to the conditions which have been called into existence by legislative enactments in regard to adulteration, he points out that if the Pharmacopœia standards for medicinal articles were adopted as legal standards for the purposes of those enactments the very thoroughness and precision of the United States Pharmacopœia—which is largely of the pharmacist's own making—might involve hardship on those it was intended to aid. He shows that while the purity of some Pharmacopœia articles is very minutely defined they are often administered by physicians in quantities measured by that arbitrary standard the teaspoonful, so that the dose may vary to the extent of fifty per cent., more or less than is intended. As examples of articles which begin to change immediately they are made and continue to alter with greater or less rapidity, according to circumstance, Professor LLOYD instances liquor sodæ chlorinatæ, liq. plumb. subacet., acidum sulphurosum, aqua ammon. fort., spiritus ammoniæ and aqua ammoniæ. He gives

analytical determinations of their rate of alteration, showing that these articles must necessarily deviate from the Pharmacopœia standards, and that the question as to permissible latitude requires to be considered by competent authorities. In the case of liq. ferri subsulph. and liq. ferri tersulph., the tests prescribed in the U.S.P. may be construed to demand the total absence of any excess of nitric acid and of ferrous salt—conditions which, if practicable, are not easy to secure. Chlorinated lime and sulphurated lime are mentioned as examples of commercial articles which are generally different in strength from the standards specified in the Pharmacopœia. Caustic potash and soda also in most instances contain less than the specified 90 per cent. of the Pharmacopœia.

In putting forward this view Professor LLOYD is careful to explain that he does not suggest any countenance of adulteration, sophistication, ignorance, or carelessness of manipulation, but merely a plea for liberality and confidence in the professional integrity of qualified pharmacists. He also urges as a matter of justice to the officers whose duty it is to enforce the adulteration law that they should not be required to apply it to medicines. In commenting upon the paper the Editor of the *American Journal of Pharmacy* remarks that, while it furnishes much food for thought, the author does not in any way exaggerate the difficulties which beset the pharmacist. The fact that laws regulating the practice of pharmacy have generally been found satisfactory when their administration has been in the hands of practical pharmacists is pointed out as furnishing the safest guide to a settlement of the question raised by Professor LLOYD.

INTERPRETATION OF THE PHARMACY ACT.

THE hearing of the appeal in the case of the Pharmaceutical Society *v.* Fox has not been long deferred, and Justices CAVE and WILLS seem to have been of opinion, when the case came before them on Saturday last, that the matter in dispute was not one requiring profound consideration. It will be remembered that the point raised was whether the owner of a medicinal preparation that has at one time been protected by Letters Patent retains his special privileges with regard to protection when the patent has been allowed to lapse. Mr. Fox, the nominal defendant and appellant in this case, argued that the preparation in question—Kay's Compound Essence of Linseed—having once been protected by Letters Patent, had thus been removed permanently from the scope of the Pharmacy Act, 1868. According to the appellant, the fact that the patent is no longer existent counts for nothing, since "once a patent always a patent." Justices CAVE and WILLS, however, showed little inclination to accept this view of the matter, and without calling upon counsel for the Pharmaceutical Society to reply to the arguments of Mr. BONSEY, they affirmed the decision of the County Court Judge, holding that a patented article is one for which Letters Patent still exist, and not one which has been the subject of an expired or lapsed patent. The *Standard* puts the whole matter in a nutshell by the pertinent suggestion that "when an ordinary article—not coming within the scope of the Pharmacy Act—ceases to be the subject of a patent, anyone may manufacture and, roughly speaking, sell it. If this rule were held to be applicable to medicines containing poisons, the results would be most undesirable. The

guarantees which the maintenance of the patent provided would be gone. It would be the easiest thing in the world for unqualified persons to pay the trifling preliminary fee for a patent on some popular medicine, containing poison, which they had invented, and then, on the earliest possible occasion, let the patent drop. In this way we should have the flood-gates opened to the very mischief which the Pharmacy Act was designed to prevent."

These remarks as well as those made by the Judges during the hearing of the appeal are indicative of a growing appreciation of the real object and public utility of the Pharmacy Act. They serve to show that the risks attending the unregulated sale of poisons and potent medicinal preparations by persons wholly ignorant of their nature and possible effects, are becoming so much better known and understood, that it may be expected there will be, in future, greater regard for the salutary provisions of the Act, and more consideration shown for the services rendered by properly qualified pharmacists. As an immediate result of the decision in the case of the Pharmaceutical Society *v.* Fox, Messrs. KAY BROTHERS, Limited, of Stockport, direct attention to the fact that Kay's Compound Essence of Linseed can only be sold by persons on the Register of Chemists and Druggists, and they request all unregistered vendors of proprietary medicines to return their unsold stocks of that preparation to the wholesale dealers from whom they were obtained. Wholesale dealers are also requested to return their stocks for re-labelling or exchange.

THE FUNCTION OF CALCIUM IN PLANTS.

IN 1875, J. BOEHM arrived at the conclusion that one of the functions of calcium in plants is to aid in the conduction of carbohydrates. Subsequently, A. F. W. SCHIMPER showed that oxalic acid is a bye-product in the building up of proteids in plants which normally contain crystals of calcium oxalate, and that, in the absence of calcium, acid potassium oxalate accumulates in the leaves and buds, and acts as a poison. He concluded, therefore, that the use of calcium is to combine with and neutralise this poisonous salt. Sugar, however, was proved to travel in leaves containing no appreciable amount of calcium, and carbohydrates were found sometimes to travel from the seeds up the stem of the seedling without any corresponding emigration of calcium. P. GROOM (*Annals of Botany*) now suggests that acid potassium oxalate retards the action of diastase on starch, and that the first effect of the salt on the assimilating tissues is the accumulation of starch, owing to an arrest of the change of the carbohydrate into sugar. The second effect, as the soluble oxalate accumulates, is the retardation of the manufacture of starch, and hence probably of the assimilation of carbon, whilst the last effect is the death of the protoplasm. GROOM's researches, therefore, confirm SCHIMPER's discovery, that the evil effects of a lack of calcium are to be attributed to the accumulation of acid potassium oxalate in plants which normally contain calcium oxalate. They may also be regarded as complementary in showing that, in the absence of calcium, there is a stoppage of the conduction of those carbohydrates only which have entered into the condition of starch. Part of the carbon assimilated by plants never enters into the starch condition, and it is clear, therefore, why growth is not at once arrested in shoots or seedlings deprived of calcium.

ANNOTATIONS.

THE KELVIN JUBILEE.—The ceremonials in commemoration of the jubilee of Lord Kelvin, as Professor of Natural Philosophy in Glasgow University, commenced on Monday last and have been a wonderful success. The presentation of addresses of congratulation was quite a serious business, so numerous were they, and the list of eminent guests was a very long one. At the banquet held on Tuesday evening, Lord Kelvin, in responding to the toast with which his name was coupled, said that he did not feel pride on the occasion, but rather he saw the great kindness of his scientific comrades and of all his friends in crediting him for so much. He thought the word "failure" characterised his most strenuous efforts for the advancement of science during fifty-five years, as he knew no more of electric and magnetic force, or of the relation between ether, electricity, and ponderable matter, or of chemical affinity, than he knew and tried to teach in his first session as professor. In the pursuit of science, however, inborn necessity to make the effort saves the naturalist from being wholly miserable, and there were splendid compensations for philosophical failures in the admirable discoveries by observation and experiment on the properties of matter, and also in the exquisitely beneficent applications of science to the use of mankind with which the past fifty years have so abounded.

AMERICAN PHARMACEUTICAL ASSOCIATION.—The ever-welcome bulky volume of the Proceedings of this Association has once more come to hand, the occasion of its publication being the forty-third annual meeting held at Denver, Colorado, last August. At the time of this meeting the Association numbered 1548 members, and its income for the year ending July 1, 1895, amounted to nearly \$7000. The report of the meeting occupies 468 pages, and the annual report on the progress of pharmacy, by Henry Kraemer, brings the number up to 1115; then there is the long list of members and an excellent index, followed by the latest revised edition of the 'National Formulary,' which alone fills more than 200 pages. The list of queries published by the Section on Scientific Papers (see p. 494) may prove useful in view of the approaching Conference of British pharmacists at Liverpool.

THE RÖNTGEN RAYS have now, it is stated, been proved of use for the purpose of medical diagnosis, experiments at Berlin with fluorescent screens having enabled Professors Du Bois Reymond and Grumnach to discern clearly the pathological conditions of the heart, lungs, stomach, etc., in living subjects. The shadow cast by the lungs of a man who had once suffered from pulmonary hæmorrhage revealed the presence of calcifications of formerly tuberculous parts as dark spots, and similar dark points indicated calcification in the heart of another person. Healthy tissues, on the other hand, were transparent to the rays.

'SCIENCE PROGRESS' for June begins with a long and comprehensive article on "The Growth of our Knowledge of Helium," by J. Norman Lockyer, C.B., F.R.S. Commencing with the discovery of the line D_3 , in 1868, and of other unknown lines in 1869, the author then proceeds to deal with Dr. Hillebrand's researches on uraninite, D_3 and other unknown lines in nebulae, photographic results during the solar eclipse of 1893, and the recent discovery of a terrestrial source of helium. Other communications are on "Insular Floras" (Part VI.A), by W. B. Hemsley, F.R.S.; "The Present Position of the Cell-Theory" (concluded), by G. C. Bourne, M.A.; and "The Hereditary Transmission of Micro-Organisms," by Dr. G. A. Buckmaster.

THE NEW NATIONAL FORMULARY.—The Committee responsible for the publication of this 'Formulary' complains that demands have been too common for the inclusion of working formulæ for preparations sold under fanciful trade names. It is satisfactory to note that the Committee did not consider it within the scope of its duties to devise and construct formulæ for such preparations. "On the other hand, preparations for which working formulas were suggested to the Committee were uniformly subjected to critical experiment, and their formulas embodied in the revised 'Formulary.'" The weights and measures of the metric system are exclusively used in this revised 'Formulary,' and they have been adjusted, whenever practicable, so as to make 1000 grammes or cubic centimetres of the finished product.

"PHOTOGRAPHING THOUGHT" is the heading given by the *Standard* to a letter from its Paris correspondent, which he begins by remarking that "it may be rash to pronounce that anything is beyond the photographer's art." It appears that a Dr. Baraduc has just made a communication to the Academy of Sciences, in which he affirms that he has succeeded in photographing thought, producing at the same time numerous photographs in proof of his assertion. The method of procedure is for a person to enter a dark-room, place his hand on a photographic plate, and think intently of the object the image of which he wishes to see produced. The photographs that were shown are described as being mostly very cloudy, though a few were comparatively distinct "representing the features of persons and the outlines of things." Dr. Baraduc is also said to claim the ability to produce a photographic image at a great distance. In support of this he relates how a Dr. Istrate, who was going to Campana, declared that a portrait of himself would appear on a photographic plate in the possession of a friend at Bucharest. The friend went to bed with sensitive plates at his head and feet, whilst Dr. Istrate, before going to sleep at Campana, "willed" that his image should appear on his friend's plate (whether at the head or foot of the bed is not stated). According to Dr. Baraduc the marvel was accomplished, the plate on development revealing "a kind of luminous spot" in the midst of which can be traced the profile of a man. Many people were inclined, at the outset, to doubt the early reports of Röntgen's discovery, but more will be sceptical on this occasion, and perhaps with better reason.

THE PROFITS OF PHARMACY.—Pharmaceutical chemists in London will doubtless be surprised to learn from the *Manchester Evening News* what enormous profits they have realised owing to the recent spell of hot weather. The London correspondent of the newspaper in question speaks of an extraordinary trade in drinks having been developed by pharmaceutical chemists, all the available assistants in many shops having been occupied without intermission during the hot weather of last week in dispensing "iced lemon syrup and saline" at the rate of twopence per glass. One chemist admitted to this trusting and doubtless veracious correspondent that his net profits on the week from this source alone exceeded £100. But whilst rejoicing in the presumed displacement of alcoholic liquors by chemists' draughts, the writer of this sensational paragraph sees possible evil in "the rage for acid drinks, even when nominally neutralised by an alkaline addition," and thinks "it is greatly to be desired that some simple and categorical pronouncement should be made by a physician of unimpeachable repute." The suggestion, however, that milk, corrected if necessary by the slightest admixture of lime or soda water, is the proper drink in any weather for people of any age, is hardly likely to meet with general acceptance in these days of microbe scares. Even pharmacists, with their special knowledge, are likely to prefer iced claret cup.

PHOTO-MICROGRAPHS OF IRON AND STEEL.—A series of very accurate photo-micrographs have been taken by Mr. F. Andrews, F.R.S., under a high magnifying power, to illustrate the minute flaws in iron, steel, and other metals and alloys. These flaws occur sometimes in very considerable numbers, sufficient to influence seriously the deterioration by fatigue of railway axles, tyres and rails, propeller shafts, and other parts of machinery subject to severe strains and performing important duties. These photo-micrographs are obtained by highly polishing and etching small sections, such as may be easily cut from spare portions of the article to be tested, and the photographs obtained form most reliable vouchers of the real quality of the material before final application to its intended purpose.

INVERNESS CHEMISTS AND THE COMPANIES BILL.—The Inverness Chemists' Association recently deputed Messrs. Macleod and Junor to prepare and send a memorial to Sir Robert Finlay, the Solicitor-General for England, expressing the views of the chemists and druggists of his constituency—the Inverness burghs—on the pharmaceutical aspect of the Companies Bill, and referring especially to Lord Herschell's amendment. In his reply the Solicitor-General speaks of the very important and influential memorial he has received, and assures the memorialists that, when the Bill reaches the House of Commons, their views will have his most careful consideration. He also states that the point raised is one which has long been familiar to him, and that he is thoroughly sensible of its importance.

ONE OF THE MISSING LINKS between man and the higher apes appears to have been discovered in Java by Dr. Eugène Dubois, when, some eighteen months ago, he found the remains of the creature to which he gave the name of *Pithecanthropus erectus*. Professor Virchow, Sir W. H. Flower, Sir W. Turner, and Professor O. C. Marsh have examined the specimens, and the result of careful study is summed up in the statement that the animal belonged to the Pliocene period, and represented a form intermediate between man and the higher apes. This discovery is described in the *American Journal of Science* as an event of the first importance to the world of science.

THE REMUNERATION OF DISPENSERS.—A Coventry correspondent directs attention to the fact that the Committee of a local hospital is advertising for a dispenser possessing the Minor qualification, who must be prepared to undertake the whole of the dispensing for both in and out patients, and to keep a register of patients, devoting his whole time to the duties of his office for the magnificent salary of seventy pounds per annum. If, as he suggests, the dispenser is not furnished with board and lodging in addition to the painfully inadequate salary mentioned, this is a much worse case than that referred to in the *Journal* recently (*ante*, p. 420), where the Asylums Committee of the London County Council offered a salary of one hundred pounds per annum for a qualified dispenser. But the question that naturally suggests itself, in connection with such scandalous evidence of non-appreciation of the value of pharmaceutical training, is—what are registered men about to accept positions at such salaries? The fact that small salaries are so openly and so frequently offered seems to indicate that they find ready acceptance, and so long as this is the case it is hopeless to expect the public estimate of a dispenser's duties to rank very high. The weeding-out of the numerous black sheep in Pharmacy seems a necessary as well as a desirable operation.

AMERICAN PHARMACEUTICAL ASSOCIATION.

SECTION ON SCIENTIFIC PAPERS.

Queries.

1. *Sanguinaria*.—The liquid preparations slowly deposit a precipitate upon the sides of the containers. Can a menstruum be devised which will hold permanently in solution the soluble constituents?

2. *Gelatin Capsules*.—What general rule should be adopted in compounding prescriptions ordering gelatin capsules? When should the ingredients be dispensed in dry powder, and when is it preferable to form them into a mass?

3. *Ichthyol*.—Ichthyol is now being used internally, dissolved in water and other media. A palatable form of administration is wanted.

4. *Salol and Acetanilid* are given usually in powder form. Cannot formulæ for therapeutically unobjectionable liquid preparations of the same be devised?

5. *Salicylic Acid*.—It has been alleged that the synthetic salicylic acid now in the market occasionally shows the presence of salol. Is this statement correct, and if so, to what extent?

6. *Formalin*.—A 40 per cent. solution of formaldehyde under that name is attracting much attention as an antiseptic and deodoriser. A good practical formula for its preparation by the retail pharmacists is wanted.

7. *Kamala*.—It is supposed that rosin is the active constituent. Investigation recommended. Is a tincture advisable?

8. <i>Pyrethrum Carneum</i> .	} Insect Powder. Can it not be used as a medicine? On what depend their insecticide properties?
" <i>Roseum</i> .	
" <i>Cinerariaefolium</i> .	

9. *Veronica Officinalis* is used largely as a house remedy for pectoral complaints and skin diseases. Is there any alkaloid or other active principle in the plant to warrant such use?

10. *Viscum Album (Mistletoe)* is used by practitioners to arrest post-partum and other uterine hemorrhages. Investigation invited.

11. *Pichurim Beans*.—What are they? Various descriptions of their oils are given by different investigators.

12. *Strophanthus Seeds*.—A determination of the active principles in the seeds of commerce, their nature, quantity, and mode of valuation.

13. *Pareira*.—Pareira is a valuable diuretic and tonic drug. Buxine has been found in it, but this can hardly be the important principle. What is it?

14. *Rhus*.—What is the really potent principle of the Rhus group? Is it a volatile acid as claimed by Maisch, or is it a substance resembling cardol?

15. *Tannin*.—At what season of the year should the tannin drugs be gathered? What relation does the amount of tannin present bear to that of starch? Does the tannin increase as the starch decreases? Or, is this true of some drugs but not of others?

16. *Cypripedium*.—There appears to be a poisonous principle producing effects similar to those of *Rhus toxicodendron*, in the glandular hairs of some cypripediums, particularly *C. spectabile*. What is this principle?

17. *Iris*.—The rhizomes of many species of iris abound in starch, as the species that furnish the orris root of commerce, but the rhizomes of *Iris versicolor* and of the *Iris pseudo-acorus* do not turn blue with iodine solution. What is the carbohydrate present?

18. *Veratrum*.—By what means may the rhizomes of *Veratrum album* best be distinguished from those of *Veratrum viride*? Some method is desirable by means of which this may be done easily and with certainty.

19. *Aconites*.—The different aconites are very liable to be confounded. In the case of drugs so potent it is exceedingly important that the structure of each specie liable to be gathered or sold for the officinal should be carefully described. Someone should undertake the task of the thorough investigation of the microscopical structure of all the species.

20. *Pepsin Test*.—A discussion of the variable results obtained in the tests.

21. *Cotton-seed Oil*.—A review of the tests for its presence as an adulterant in other fixed oils.

22. *Cod-liver Oil*.—Are the official tests sufficient to distinguish a pure cod-liver oil? If not, what additional ones should be adopted?

23. *Methyl Acetate*.—Write a paper on the possible use of methyl acetate as a solvent in pharmacy.

24. *Sodium Bisulphite*.—The sodium bisulphite of commerce is rarely found more than one-fourth the strength required by the U.S. Pharmacopœia. Is the official standard too high, or does this salt rapidly deteriorate on keeping?

25. *Terpeneless Volatile Oils* are now articles of commerce. Are they liable to deteriorate on keeping? How much stronger are they than ordinary volatile oils?

26. *Lard Oil*.—Lard oil appears to be grossly adulterated. Is it possible to obtain lard oil in the open market of the standard of purity of the U.S. Pharmacopœia?

27. *Guaiacol*.—Commercial guaiacol varies in purity from 50 to 90 per cent. according to Dr. Squibbs. Cannot some process be devised for its assay and purification, if necessary?

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, June 11, Mr. H. A. D. Jowett, Vice-President, in the chair. After the minutes of the previous meeting had been read and confirmed, a paper on "Gold Mining in the Transvaal," by Mr. H. T. Durant, was read, in the author's absence, by the Secretary. The paper was commented on by Mr. Tunbridge and the Chairman, and the Secretary was asked to convey the thanks of the meeting to Mr. Durant.

A report on "Organic Chemistry" was then read by Mr. H. Brown, which dealt with Featon's work on a new dibasic acid obtained by the oxidation of tartaric acid, and with recent work on the celluloses. The report was followed by a discussion, to which Messrs. Henry, Tunbridge, and the Chairman contributed. Mr. Brown briefly replied, and the meeting then adjourned.

BOTANICAL EXCURSIONS.

SHEFFIELD COLLEGE OF PHARMACY.

On Monday, the 15th inst., the students of the Sheffield College of Pharmacy had a most interesting botanical excursion to Castleton. Train was taken to Hope, and thence the party walked through the pastures to Castleton. Some thirty or forty good specimens were obtained, illustrating the flora of the district. After a most enjoyable repast at the Bull's Head, the party left Hope by the 9.15 train for Sheffield. Castleton, which is situate sixteen miles from Sheffield, boasts not only of its Blue John mines and extraordinary caverns, but also the ruins of the old castle of the Peverils, so familiar to the readers of Sir W. Scott's 'Peveril of the Peak.'

GLASGOW AND WEST OF SCOTLAND SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

On Saturday the 13th inst., the students attending the Glasgow and West of Scotland School of Pharmacy, accompanied by the principal, had a botanical ramble to the Glasgow water reservoirs, about nine miles distant from the city. The party took 'bus to Milngavie and then proceeded round the reservoirs in search of wild flowers. A great number of plants were collected belonging to the following natural orders:—Ranunculaceæ, Caryophyllaceæ, Cruciferae, Umbelliferae, Rosaceæ, Leguminosæ, Compositæ, Labiatae, Scrophulariaceæ, Urticaceæ, Caprifoliaceæ, Plantaginaceæ, Ericaceæ, Boraginaceæ, Euphorbiaceæ, Polygonaceæ, and a number of Cryptogams.

LITHIUM BITARTRATE IN SUPPURATING GINGIVITIS.—This salt, known also as "tartarolithine," which exists as a white powder soluble in water, is employed by American physicians in the treatment of suppurating gingivitis of gouty origin. It is given in doses of 30 centigrammes, dissolved in aerated water (*Nov. Rem.*, xii. 205).

PROCEEDINGS UNDER THE PHARMACY ACT.

APPEAL IN THE KAY'S ESSENCE OF LINSEED CASE.

Pharmaceutical Society of Great Britain v. Fow.

In the High Court of Justice, Queen's Bench Division, on Saturday, June 13, 1896, before Mr. Justice Cave and Mr. Justice Wills, an appeal from a decision of His Honour Mr. Lumley Smith, Q.C., was heard.

Mr. Bonsey, in opening the case for the appellant, said: My Lords, I appear for the appellant in this case, which is an appeal by the defendant in an action brought in the Westminster County Court by the Pharmaceutical Society to recover a penalty of £5 under the Pharmacy Act for selling an article which contained poison, the defendant not being a chemist.

Mr. Justice Cave: Which is the Act.

Mr. Bonsey: It is the 31st and 32nd Vic. c. 131, the Pharmacy Act of 1868. Section 15 provides that every person who shall sell, etc. [Reads the Section.]

Mr. Justice Cave: What is the point here—whether the thing was a poison?

Mr. Bonsey: The point is simply whether this is a patent medicine within the meaning of Section 16, which confers an exemption in the making or dealing in patent medicines. [Reads the Section.] The question is whether the article which was sold was a patent medicine within the meaning of that Section. The facts are simply these: On May 31, 1873, Letters Patent were granted to a chemist at Stockport for the manufacture of a medicine which is called Kay's Compound Essence of Linseed, and ever since 1873 it has been manufactured by him, and sold by chemists and shopkeepers generally. In 1876, three years after the patent had been granted, the patent lapsed, in consequence of the fees not having been paid. As your Lordships know, certain fees have to be paid at stated times, and I think under the Act which was in force then a fee of £50 had to be paid at the expiration of three years; the not having been paid the patent lapsed. The question in this case really is whether the words "patent medicine" in Section 16 apply to a medicine for which a patent has been obtained, although the patent has expired. No distinction is drawn between a patent having lapsed and it having expired at the end of fourteen years, or the period for which the patent has been granted.

Mr. Justice Wills: Is this an ordinary patent under the Patent Act?

Mr. Bonsey: Yes, my Lord. The contention of my learned friend is this. I understand he will admit that during the three years before the patent lapsed this would have been protected by Section 16, but inasmuch as the patent is not now, so to speak, in force, Section 16 has no application at all. The result would be, if my friend's contention is correct, that Letters Patent might be granted to a man for the manufacture of a medicine like this, or of any other kind. He might for fourteen years manufacture that, and anybody might sell it; it need not be sold by a chemist. It could be sold without any restriction, but then the day after the expiration of that fourteen years it could not be sold by anyone but a registered chemist.

Mr. Justice Cave: The notion, of course, is to protect a patentee in the enjoyment of his patent rights. That is part of the inducement to take out a patent, by which it no longer becomes a trade secret, but the manufacture is known to the world, although they cannot manufacture it as long as the patent rights last, and inasmuch as that would be of little value if he could not also license other people to sell it, the protection is extended to his licencees too. But the moment that is over the reason is gone.

Mr. Bonsey: I submit not, my Lord.

Mr. Justice Cave: Anybody might manufacture and sell it. It is no longer confined to the patentee.

Mr. Bonsey: Yes, my Lord, anybody might manufacture and sell it, but having regard to the object of this Act, and other Acts to which I shall call attention, I submit that when the Act speaks here of a patent medicine it means a medicine for which a patent has at any time been granted.

Mr. Justice Wills: Why should a poison which enters into a patent medicine be sold by anybody and everybody when poison cannot generally be sold? I do not understand that at all.

Mr. Bonsey: My Lord, the object of the Pharmacy Act, 1868, as stated in the preamble, is this: "Whereas it is expedient for the safety of the public that persons keeping open shop," and so on. The

object is the safety of the public. Can it be said that for a period of fourteen years the Crown will grant a licence to a man to sell a thing which is a danger to the public; that as long as he pays his fees he may endanger the safety of the public and sell it?

Mr. Justice Wills: I do not understand the connection between the two—the fact of a dangerous thing being patented, and that rendering it not a source of danger to the public—I do not understand that theory of the Act.

Mr. Bonsey: The distinction, I think, is this, that if a medicine has been patented the public are protected, and they do not require to be protected by this Act—for this reason: before a patent can be granted it has to be examined—a specification has to be lodged, the proper authorities examine it and if they are of opinion that the article to be patented is dangerous or injurious to the public, the patent would be refused. And still further, the whole of the ingredients are disclosed in the specification, so that anybody, by paying a very small sum, can go and ascertain for himself what the ingredients of that particular compound may be. Therefore, where a medicine has once been the subject of Letters Patent, there is sufficient protection without the restriction imposed by this Act of Parliament. The Legislature has in different Statutes drawn a distinction between a patent and a patent in force, to use an expression which has been used by the Legislature in another Act; and even in the Patent Acts a distinction has been drawn between a thing which is the subject of an existing patent and a thing which is the subject of a patent that has expired. To illustrate what I mean, may I draw your Lordships' attention to an old Act which was in force up to the time of the last Patent Act of 1883, and was repealed by that Act, though the substance of it has been re-enacted in a section of a later Act. By 5 and 6 William IV. c. 83, sec. 7, there is a penalty of £5 imposed on persons who mark any goods with the word "patent," but the proviso to that section is in these words: "Provided always that nothing herein contained shall be construed to extend to subject any person to any penalty in respect of stamping or in any way marking the word 'patent' on anything, for the sole making or rendering of which a patent before obtained shall have expired." There the Legislature draws the distinction; a man may mark a thing and describe it as a patent, although the patent has expired, and he is not liable to any penalty at all. Therefore I contend my friend is wrong in saying, as probably he will say and as he said in the court below, that when you find the word "patent" in a Statute like that it means a patent in force.

Now, my Lords, I have a strong illustration of this distinction in a very recent case with regard to an Act analogous to this Pharmacy Act, viz., the Sale of Food and Drugs Act.

Mr. Justice Wills: An observation occurs to me that goes a good way against your argument—it is that so long as a thing really is a patent you know what it consists of, but the moment it ceases to be a patent there is no security whatever, that what is known under the name of the patented article is really the same thing.

Mr. Bonsey: With regard to that point, my Lord, there is in this case no evidence; in this case the facts are admitted.

Mr. Justice Wills; I assume it is in fact the same, but I say there is no security for it. It has been pointed out, in one of the cases, by one of the Lords Justices that there is some security to the public by reason of the patent—not, as you suggest, that the Crown would refuse to grant the patent if they thought it not a wise compound for a man's inside, but because the mode of compounding and so on was all known, and, therefore, there might be security. But the moment the patent has expired there is no security of that kind; anything might be sold under the name of the patent.

Mr. Bonsey: I cannot for the moment see the distinction, my Lord, for this reason; if during the fourteen years the patent is in force a man likes to be fraudulent and does not manufacture the article according to the specification, it would not be a medicine prepared according to that specification.

Mr. Justice Cave: He has an interest to prevent that.

Mr. Bonsey: You go and look at the specification, and you assume it is prepared according to it. If that is not done, it is not within his patent, and so if it is manufactured by anybody else afterwards, unless it is manufactured according to the specification, it would not be within the protection. Of course, a patent medicine is a somewhat complicated matter, but take the case of a very simple machine which might be the subject of a patent. If anybody manufactured that afterwards according to the specification of the original patent, there would be no difficulty whatever in seeing whether it was or was not still a machine or article under the particular patent which had some time before been

granted. With regard to this Section 6 of the Sale of Food and Drugs Act, it says no person shall sell to the prejudice of the purchaser certain articles of food or any drug which is not of the nature and substance demanded, and then there is the exception, "Where the drug or food is a proprietary medicine, or is the subject of a patent in force." There, my Lord, in a very similar Act the Legislature has used the words, "a patent in force," but there are no words of that kind in the Pharmacy Act, 1868.

Now, my Lord, although this point has not been decided it has been considered in two cases. The first case is *Pharmaceutical Society v. Piper* in 1893, Queen's Bench Division, 686, and the question was raised whether the words "patent medicine" in Section 16 include a proprietary medicine that is not a patent medicine at all, but is commonly termed a patent medicine by the public. There Mr. Justice Collins, at page 698, after drawing attention to the point and discussing the question whether a proprietary medicine was a patent medicine, says, "That mischief does not exist in the case of patent medicines, for anyone can find out the exact ingredients used in them. The case is altogether different to those which are merely the subject of some proprietary right." As I read the judgment of the learned judge, that is his view of the reason why there should be the exemption in Section 16; but it was more fully dealt with in a subsequent case in the Court of Appeal of the *Pharmaceutical Society v. Armson* in 1894, Q.B.D., 720. The same point was taken in that case, that a patent medicine in Section 16 includes a proprietary medicine. Lord Esher deals with it at page 724: "When we find the Act of Parliament, or Acts of Parliament, which have been dealing with this very subject matter distinguishing between proprietary medicines, secret medicines, and patent medicines, and when you come to this Pharmacy Act and find that it has in terms dealt with only one of those phraseologies, viz., patent medicines, it is clear to my mind that, construing this Act of Parliament according to ordinary canons of construction, you must say that it applies only to patent medicines, using the term in the sense of medicines which have procured a patent under the Great Seal." Then Lord Justice Kay, at page 726, says "The other argument was that it was excepted by Section 16 because it was a patent medicine." Then he says: "The reasons for that exemption seem to me very clear indeed. Where the medicine is, properly speaking, a patent medicine, that is to say, where the exclusive right to make or sell it has been granted to somebody under Letters Patent under the Great Seal, the condition of the patent always is that a specification is lodged in the Patent Office describing the whole of the ingredients and the process of manufacture. Without that no patent could be obtained: without that any patent would be void. Therefore, when people buy a patent medicine they have the means of ascertaining what ingredients are contained in that patent medicine, and that is one reason, no doubt, for the exemption." Then he gives another reason—"if, before this Act of Parliament which we have to construe, a patent of that kind had been granted, it would give to the patentee the exclusive right of making and selling the patented article and it would have been rather hard by this Act of Parliament to take away from him that which he had been exercising as a right (under the authority of the Great Seal) and to prevent him from further making or selling if he were not an authorised person under the Act." Now, my Lords, just to deal with that reason which has been given by the learned Lord Justice I would say that it would be hard to take away from a person that which had been granted to him. I should have thought if that had been the object of the exemption it would have been said that the Act did not apply to the dealing in patent medicines for which Letters Patent had at that time been granted. But I fail to understand why, while the Legislature in imposing restrictions on the sale of certain things for the protection of the public, should also permit, after that, any person to take out a patent and sell the same thing under letters patent for fourteen years without restriction, if it be a danger to the public. Therefore, with very great respect to the Lord Justice, I think the first reason which he gives for this exemption in Section 16, is the real one, because, if the object had been merely to prevent hardship accruing to persons who then had patents it could have been worded in a different way. Lord Justice Smith also deals with this point at page 728, and says: "The exemption must of course be read in the manner which the Queen's English dictates and when the legislation which has taken place, before and since this Act of 1868 which we are dealing with, is looked at, it is abundantly clear that for some express purpose the limitation and the exception were put in patent medicines, and only patent medicines, because if you begin

with the Statute of 25, Geo. III., sec. 4, and then take the next Act of 52, Geo. III., c. 150, sec. 2, both prior to this Act of 1868, there is a distinction between a patented medicine and what I should call a proprietary medicine, that is, a medicine which is compounded of secret nostrums. When you come to the Act of 1868, the sole exception made relates to patent medicines. Then a few years afterwards—seven years—another Act is passed, in which the exception is made where the food or drug is a proprietary medicine, which this Powell's balsam of aniseed is, or is the subject of, a patent in force." Now, my Lords, those Statutes to which the learned Judge refers are the Stamp Acts: the last Stamp Act is 52, Geo. III., c. 150 and certainly in that Act a large number of these proprietary medicines are set out in the Schedule, and then it goes on to say: "And also pills, powders, preparations, etc., which heretofore have been, now are, or shall hereafter be prepared, uttered, vended, or exposed for sale under the authority of Letters Patent under the Great Seal," so that any medicine which has at any time been the subject of Letters Patent is subject to the duty imposed by this Act: in point of fact and in practice stamp duty is always imposed and exacted after the expiration of Letters Patent, that is, after the expiration of fourteen years, and, my Lords, that provision in the Act of Geo. III. is very largely referred to and discussed in both these cases of Piper and Armson. I think it had great weight with the Court in both those cases, because where you had the Legislature providing that a medicine which has at any time been the subject of a patent should be liable to stamp duty, although that patent has expired, of course it deals with the patent both during the time of the fourteen years and after the expiration of the fourteen years exactly on the same footing. If a man is to suffer the burden imposed upon him by the Legislature of paying the stamp duty, one fails to see why he should not get the advantage that is also given to him as the owner of a patent medicine within the meaning of Section 16. There is no other case that I know of in which this question has been discussed at all, except those two. I contend that when the judgments in Armson's case are looked at, although it is true this exact point did not arise, yet the learned judges there have clearly expressed their opinion that the reason why this exemption occurs in Section 16 is because the public are perfectly protected as long as the medicine is prepared according to the Letters Patent. Your Lordships will observe that in the last case Lord Justice Kay used the expression: "When the medicine is, properly speaking, a patent medicine, that is to say, where the exclusive right to make or sell it has been granted to somebody." Therefore I submit that as long as the medicine is prepared according to the patent which has been granted, it is within the exception. In this case it is manufactured and prepared by Messrs. Kay, the original patentees. There is no question raised in this case upon that. It was put by my learned friend that there would be a difference in the case of the medicine being prepared not only by the original patentee, but also by any one after the patent had expired. I think that is the point which your Lordship referred to a few moments ago when your Lordship suggested that although the public might be protected during the fourteen years, they would not be protected after that, because anybody could manufacture. The question there would be in every case—was this prepared according to the specification; and in this case there being no question about it having been prepared by the original patentee under his Letters Patent, the only question here is, whether the fact that the patent lapsed in 1876 prevents him taking advantage of Section 16. As I pointed out at first, if my friend's contention be correct then this great hardship accrues to the person who is the owner of the patent. For fourteen years he manufactures this article and it gets into the hands of a large number of shopkeepers and storekeepers of all kinds throughout the country: then the day after the expiration of the fourteen years every one of these people commits an offence, and is liable to a penalty of £5, to be sued for by the Pharmaceutical Society if he happens to have one bottle of this medicine in his shop for sale and although he may know nothing whatever about the patent having lapsed. The sole object of the Pharmacy Act is the safety of the public; but these questions raised upon it are really trade questions. For twenty years this medicine has been manufactured by Messrs. Kay and sold without objection on the part of the Pharmaceutical Society. There has been every opportunity of ascertaining what it is made of from the specification, but now after twenty years the Society has thought fit to impeach the right to sell it. The object, of course, is that the sale of all these proprietary and patent medicines, of which there has been an enormous increase

within the last few years, should be kept in the hands of chemists and druggists. It would really be a disadvantage to the public if they were not able to obtain harmless preparations of this kind, which are useful and beneficial, at the grocers' and village stores or other convenient places. Having regard to the decisions, I cannot contend in this court that the fact of there being only one-third of a grain of morphia among the numerous ingredients in this bottle of medicine, suffices to remove it from within the Statute. I allude to it simply to point out that in interpreting this Act of Parliament the only thing to regard is the safety of the public, to see that the object of the Act is satisfied and that no undue restriction should be placed upon any trade, or no undue inconvenience imposed upon the poorer members of the community, who are not able always to consult a medical man and get prescriptions like those who are better off. When one sees that there is an exemption put in the Act itself, I respectfully contend that a very liberal interpretation, at any rate, ought to be put on that Section. It is perfectly apparent that more safeguards exist in the case of a patent medicine than in the case of a proprietary medicine that is sold by a chemist and druggist. It really is that when once a patent has been granted Section 16 applies.

Mr. Justice Wills: Your argument is, "once a patent always a patent" for the purpose of this Act.

Mr. Bonsey: Yes, my Lord.

Mr. Justice Wills: That statement seems to me almost to answer itself.

Mr. Bonsey: I submit not. There is no magic in or exclusive definition of the word "patent." You must deal with it having regard to the subject matter of the Act of Parliament.

Mr. Justice Wills: The thing is not a patent article after the patent has expired.

Mr. Bonsey: It is no misdescription to call it a patent. There are many cases in which it has been held that a person has a right to call a thing a patent even after the patent has expired. Those questions have arisen where actions have been brought to restrain manufacturers from infringing trademarks, or selling their goods so as to represent them as the goods of other people and the Courts have always said that as long as you do not represent that the patent is actually in force you have a perfect right to call a thing patent if letters patent have at one time been granted for it. If any authority is needed for that there is the case of *Chevin v. Walker* in 5 Ch. Div., p. 850. That was an action brought to obtain an injunction to restrain the defendant from describing a filter as patent; it appears that in 1862 a patent had been granted, but, exactly as in this case, it had lapsed at the expiration of three years by reason of the non-payment of the fees, and one of the questions there discussed was whether the plaintiff, who was the patentee, had any right to come and complain of the other party describing his filter as patent because his patent was not in force, and it was held that as long as the plaintiff merely described it as patent, but did not indicate that the patent was in force, there was no misdescription at all, and he had a perfect right to do what he did. Take as an illustration the case of patent leather. That is a term which is commonly used, and it is no misdescription to call a pair of boots "patent leather boots," although, as a matter of fact, no patent is existing at the present time. I contend that you cannot give merely one meaning to the word "patent" wherever you may happen to meet with it in any Act of Parliament, especially having regard to the fact that in two different Acts of Parliament you find it differently used and described. In the Sale of Food and Drugs Act it is dealt with as being during the time the patent is in force. I should merely like to add in connection with a matter I was referring to a few moments ago that, when you are considering whether the public are protected sufficiently, if the Letters Patent have once been granted, they are a great deal more protected than they are in the case of what is called a proprietary medicine—a secret preparation which may be sold by any chemist in this country, who does not know what it is composed of at all, while in this case any member of the public or any chemist can go and ascertain. Therefore I say in a case where Letters Patent have once been granted, although the patent may have lapsed, or may have expired in the ordinary way, there is far more protection to the public than there is in the case of a proprietary medicine of which no one knows what the ingredients are. To put my argument very shortly it is that in Section 16 the words "patent medicine" mean a medicine for which Letters Patent have been granted, because when you regard the object of the Act of Parliament adequate safeguard is provided for the public. That

could only have been the object for which it was put in. If not, then one must admit the Legislature to have said: That if you like to pay fees and take out a patent you may endanger the public by so doing for fourteen years, but we will not allow you to do it for any longer term than fourteen years. I cannot suggest that the Legislature should have enacted anything of that description, therefore I say that the fact of Letters Patent having been granted is apparently a sufficient protection to the public and that the 16th Section ought to be so construed. There is no other point raised in this case. We admitted the facts, but this point is of some importance, not only in this case, but in others, and we wish to have it decided.

Judgment.

Mr. Justice Cave: We need not trouble you, Mr. Grey. I am of opinion that the learned County Court Judge was clearly right in this case. The language of the Act is unmistakable. It speaks of making or dealing in patent medicines, and this preparation could not be said to be a patent medicine. The argument that Mr. Bonsey has addressed to us might properly be addressed to the Legislature, to induce them to make a change in the law; but cannot be accepted by the Court: as the Law now stands it is perfectly clear that the appeal must be dismissed.

Mr. Justice Wills: I am of the same opinion. I have no particular wish to enter into a speculation as to why patent medicines were excepted. The reasons which seem to have been suggested by the various Courts that have dealt with the matter are not perhaps altogether satisfactory. Perhaps no satisfactory reason can be given; but so far as has been suggested there seems to me no reason at all for departing from the obvious natural meaning to be attached to the words in the Act of Parliament. Two reasons have been suggested why patent medicines should be exempted from the provisions of the Act; one is that their composition can be ascertained. As long as the patent exists there is some sort of security as to that, but as soon as the patent is thrown open to the world the patented article, if it is of any value at all, is pretty sure to be produced in a cheaper form, and still go by the same name. Another reason given was that the patent having conferred upon the owner of the patent a right to sell unconditionally, and to be the sole vendor during the period of the patent, viz., fourteen years, it is not to be supposed that the patentee himself cannot sell because he is not a licensed chemist. If that is part of the reason for this enactment, it clearly does not apply to the case of a non-existing patent. Mr. Bonsey's argument may be summed up by saying, for the purposes of this Act, once a patent always a patent, but I think that statement answers itself. It seems to me a patent medicine is a medicine for which there is a patent, not one for which there has been a patent.

Mr. Grey: I understand, my Lords, the appeal will be dismissed with costs?

Mr. Justice Cave: Yes.

Mr. Bonsey: Will your Lordships give leave to appeal?

Mr. Justice Cave: No, Mr. Bonsey, it is too clear.

Mr. Bonsey: Does your Lordship think it is too clear, having regard to the way in which the point was discussed in the other case?

Mr. Justice Cave: We have heard this case argued, and decline to give leave to appeal.

SALE OF POISON BY AN UNREGISTERED ASSISTANT.

Pharmaceutical Society of Great Britain v. Sinclair.

At the Greenwich County Court, before His Honour Judge Bristowe, on the 12th instant, the defendant, John Sinclair, was sued for a penalty of £5 incurred by him in selling poison contrary to the provisions of the Pharmacy Act, 1868.

Mr. T. R. Grey, instructed by Messrs. Flux, Thompson and Flux, appeared for the Society, and defendant appeared in person.

Mr. Grey said it was an action for a penalty under Section 15 of the Pharmacy Act, 1868, which was an Act to regulate the sale of poison, and he referred to the Sections of the Statute bearing on the case. The authority which dealt with the question in this case was the case of the Pharmaceutical Society v. Wheeldon. In that case the defendant was not a chemist and druggist but simply an assistant to a registered chemist, and it was on all fours with the present case. The defendant was an unqualified man employed as an assistant at 85, Clifton Hill, New Cross, where he sold to a witness, who would be called, some laudanum, which was a poison included in the Schedule to the Act.

His Honour (to defendant): What is your defence?

Defendant: According to the Act I am not the seller.

His Honour: I will interpret that.

Mr. John Partridge, examined by Mr. Grey: On March 4 last I went to 85, Clifton Hill, New Cross. I purchased twopennyworth of laudanum and twopennyworth of soap liniment. I was served by defendant, who was alone in the shop.

Mr. E. J. Easles, examined by Mr. Grey: I am an analyst. I received the bottle produced from Mr. Partridge. I analysed its contents, and found it to contain a preparation of opium. I found half a grain of morphine to be present; that would be equivalent to rather more than one-seventh of an ounce of laudanum of British Pharmacopœia strength.

His Honour (to defendant): What have you got to say? Did you sell this poison?

Defendant: Yes, as an assistant.

His Honour: Here is a case in which it is decided that an unregistered chemist's assistant, who in the absence of his master sells any poison or preparation containing a poison, is liable to a penalty under Section 15 of the Pharmacy Act, notwithstanding that he effects such sale on behalf of his master, and that his master is duly registered.

Defendant: I did not sell apart from the jurisdiction of my master.

His Honour: I cannot help that.

Defendant: You will find in one section that the seller is defined to be the person on whose behalf the sale is made. I say that section clearly defines who is considered to be the seller.

Mr. Grey: Defendant is referring to Section 17, in which for the purposes of that section only a special definition is given—this action is under Section 15.

His Honour: The High Court has decided the point in a case on all fours with this. There is no defence. I must find a verdict for the plaintiffs.

Judgment for plaintiffs with costs.

ILLEGAL SALE OF WINSLOW'S SOOTHING SYRUP.

Pharmaceutical Society of Great Britain v. Brade.

At the Blackpool County Court, before His Honour Judge Coventry, on the 17th instant, the defendant, Thomas S. Brade, was sued for two penalties of £5 each, incurred by him in selling poison contrary to the provisions of the Pharmacy Act, 1868.

Mr. R. E. Vaughan Williams, instructed by Messrs. Flux, Thompson and Flux, appeared for the Society, and defendant did not appear.

Mr. Vaughan Williams stated that the action was brought by the Council of the Pharmaceutical Society, which was charged with enforcing the provisions of the Pharmacy Act, and the defendant, who was an unqualified person, was charged with having on two occasions sold Winslow's soothing syrup, a compound which contains morphine. The proceedings were taken with the object of stopping the sale of poisons by unqualified persons on behalf of limited companies. The penalties were incurred on January 18 and February 1 last by defendant, when he was an assistant to a company called Gaulter and Co., Limited, carrying on its business at 6, West Street, Fleetwood. Most of the shares in that company being held by Mrs. Gaulter, it might be termed a one-woman company. So far as could be ascertained, its business was carried on without any qualified chemist being engaged therein. It, therefore, became the Society's duty to enforce the law against the unregistered assistant, and there was authority supporting the present claim. He should prove the facts and, upon the Statute and decision in Wheeldon's case, ask for a conviction.

Arthur Foulds, examined by Mr. Vaughan Williams: On January 18 last I went to 6, West Street, Fleetwood. The name at the shop was Gaulter and Co., Limited. I purchased a bottle of Winslow's soothing syrup. I was served by Thomas Brade; he was the only

person in charge of the shop. I went again on February 1 last. Defendant sold to me another bottle of Winslow's soothing syrup.

Harry Moon, examined by Mr. Vaughan Williams: The bottles produced were handed to me by Mr. Foulds, enclosed in their wrappers and fastened up.

Ernest J. Eastes, examined by Mr. Vaughan Williams: I am an analyst and Fellow of the Institute of Chemistry. I analysed the contents of the two bottles produced; the one marked January 18 contained one-sixteenth of a grain of morphine and the other one-eleventh of a grain. Morphine is the chief toxic ingredient of opium, and is an exceedingly dangerous poison, especially to infants.

His Honour: Is it necessary to prove quantity?

Mr. Williams: No, I think not; any appreciable quantity is sufficient. I put in the Register, which by the Statute is made evidence, and the absence of defendant's name therefrom is evidence that he is not a chemist and druggist.

His Honour: You said that in the other case the person selling was the one liable.

Mr. Williams: Yes; that is the decision in Wheeldon's case.

His Honour: Then you say in effect that only qualified chemists may sell poison?

Mr. Williams: Yes.

His Honour: I have no option to inflict a smaller penalty.

Mr. Williams; No; and there is a further provision that provides for full costs.

His Honour: I give judgment for the plaintiffs for the two penalties and costs.

POISONING CASES AND INQUESTS.

DEATH FROM AN OVERDOSE OF MORPHINE.—Mr. Luxmore Drew held an inquest on Saturday last, at the Kensington Town Hall, with reference to the death of Professor John Henry Middleton, aged 49, the Director of Art at South Kensington Museum, who died from morphine poisoning. The evidence of the widow and others was to the effect that the deceased had suffered from nervousness during the past three years, and was greatly depressed because he thought he would never get well. He had not slept well for four months and his appetite was gone. He had been in the habit of taking hypodermic injections of morphine three times a day and death appeared to be due to an overdose.—Mr. T. H. Keer, a pharmaceutical chemist, of Bruton Street, said the deceased had bought morphine from him for twenty-two years, and witness had sold him as many as twenty-four bottles at a time. The jury were unanimously of opinion that death was due to misadventure.

A CORONER ON THE SALE OF LAUDANUM.—At an inquest held at Loughborough on May 27, before Mr. Deane, relative to the death of John Henry Smith, labourer, of Sibley, who had died from laudanum poisoning, the evidence revealed that Smith purchased sixpennyworth of laudanum from William Stevenson, chemist, Sheepshed, after having failed to purchase a shillingsworth from a grocer, and swallowed it.—The Coroner said if Mr. Stevenson put his name and address on the bottle, and also a label indicating its contents as poison, he complied with the law as it at present stood, though he and many other coroners who had dealt with cases of opium poisoning would be glad to see a change in that law. Laudanum was not in the list of poisons, purchasers of which had to state for what they were required, and to give their names and addresses; but he would be glad if the Legislature would transfer laudanum to that list, for he believed that those who wanted to use it for a legitimate purpose would not object to go through the formalities.—A verdict of death by poison taken while the deceased was of unsound mind, was returned.

SULPHURIC ACID IN MISTAKE FOR MEDICINE.—Mr. T. R. Finlay, editor of the *Paisley and Renfrewshire Gazette*, died in Paisley Infirmary on Saturday, June 6, under sad circumstances. Of late Mr. Finlay has been in bad health and was taking medicine. Before leaving his residence on Friday he went to take his medicine and accidentally drank some strong sulphuric acid. He was badly burned in the mouth and throat and the tissues of the stomach, and succumbed to his injuries.

CORRESPONDENCE.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

A PHOTOGRAPHIC QUERY.

Sir,—I note in the *Ph. J.* "Annotations" for May 23 a reference to (p. 412) experiments recorded by Dr. Phipson in the *Chemical News* upon a white pigment containing zinc sulphide and barium sulphate, sunlight having darkened the compound and suggesting *x*-rays existing in ordinary sunlight. I had a curious experience. A lady in my dwelling house was being photographed sitting at a small round table in the act of pouring out a cup of tea from a large silver-plated teapot held steadily upwards directly in front of her. When the photograph was developed no trace of the teapot was visible, but the lace and ornaments on her dress, which were directly behind the teapot were as plainly seen in the photo as if no teapot had been held in front of them. The sun was strong, and the window opposite to which she was sitting had a southern aspect, and was receiving the full rays of the sun. This appears to me to be a case in point, where *x*-rays were existent in ordinary sunlight. I should be pleased if some of your chemical expert correspondents would explain this fact in your columns, as it seems extraordinary to me.

Edinburgh, June 10, 1896.

J. K. NICOL.

MURCELL'S SOLUTION.

Sir,—In your issue of the 13th inst. there appears under "Answers to Queries" (p. 480) a reference to "Murcell's solution." If it is *en règle* for a reader to contribute a suggestion, may I be permitted to instance "Monsel's solution" (liq. ferri persulph.), the hæmodynamic, as perhaps intended?

Liverpool, June 16, 1896.

GEORGE DANBURY.

THE PHARMACEUTICAL EXAMINATIONS.

Sir,—With regard to the personal matter between Mr. Coull and Mr. Anderson I have little to do, but in examinations I take a lively interest. In the first place, I think they might be re-arranged with advantage. I quite agree with Mr. Coull and the Edinburgh Executive that the present Preliminary is a delusion, and the sooner it is amended the better. The advice which you gave students in the educational number of the Journal to take the London Matriculation instead of the Pharmaceutical Preliminary is most sensible, and I advise all would-be apprentices to take either that or the science entrance examination of the nearest university or college. With regard to the second examination, I would have it purely theoretical, very much on the lines of the present Bell Scholarship examination, and to take place at the close of apprenticeship; the subjects to be (1) Latin, with special reference to pharmacy and medicine as contained in such books as Ince's 'Latin Grammar of Pharmacy,' and Pereira's 'Selecta à Prescriptis.' (2) The doses and

galenical preparations of the B.P. and the poisons law. (3) An elementary knowledge of chemistry, both inorganic and organic, botany and physics, such as the Science and Art Department's elementary courses cover. There ought to be no difficulty in getting up these without attendance at a school of pharmacy, as elementary science classes are scattered all over the country now. One cannot but notice the splendid start which his scholarship examination gives the Bell scholar over his less fortunate fellow students, many of whom begin the course without even the most rudimentary knowledge of chemistry, without admitting the advantage such an intermediate examination would have. The third examination to be passed at twenty-one, and to be the qualifying examination. The subjects to be practical dispensing and pharmacy, but no theoretical, the B.P. being allowed; materia medica and practical histology as at present for the Major; chemistry and botany, ditto, or on the lines of the Intermediate Science Examination.

With regard to the practical chemistry examination, I would strike out the nitrogen combustion and the preparation of the organic substances. No retail chemist ever determines the amount of nitrogen in his caffeine, or wishes to make aniline, unless for amusement. Such things form a necessary part in a course of organic chemistry, and the synthetic work done both in the inorganic and organic side is, in my opinion, one of the best features in the practical course at the "Square," but they ought not to form a necessary part of the exam. There are other things of more practical use to the retail chemist, and I venture to say that a thorough knowledge of analysis—gravimetric, volumetric and qualitative; the recognition by chemical means of all substances used in medicine and the thorough examination of the same (whether balsams, resins, or synthetic remedies), for impurities—both by official and unofficial methods, where the latter may possess distinct advantages—is of far more importance to the pharmacist and would of itself be a sufficient examination. Such a course would necessitate a year's attendance at a school of pharmacy. This ought to be the *ultima thule* of the pharmacist. If he wish to go farther let him take the B.Sc. degree. He would have passed the necessary preliminary, and his qualifying examination would enable him to take the Intermediate Science Examination with very little extra trouble. Another year at a recognised university or college would give him his B.Sc., and I venture to say there would be many chemists' assistants who would go on to that. There is only one other thing I wish to say, and that is to endorse the suggestion that a candidate who has obtained 70 per cent. in any subject be held to have passed in that subject. It seems really too hard to pluck a candidate in all the subjects because he fails to please in, say, botany, a subject which possibly he has no natural liking for. It is most disheartening, and I have on more than one occasion been touched to sympathy for a student who has been so treated after a conscientious session's work. The fee for his second appearance need not necessarily be altered. Hoping the above suggestions may help towards a thorough discussion of the subject,
London, June 15, 1896. MAJOR.

THE SOCIETY'S LIBRARY—A SUGGESTION.

Sir,—May I suggest the advisability of the Society having duplicates of certain works which are wanted for reference? For instance, I have been waiting since May 7 for a copy of Cripp's 'Pharmacy,' and am now informed by the Librarian that it will be another week before I can have it.

27, Great Tower Street, E.C., June 11, 1896. ISAAC HARTNESS.

ANSWERS TO QUERIES.

[Queries addressed to the "Editorial Department, 17, Bloomsbury Square, W.C.," will be replied to in the Journal as early as possible after receipt, but the Editor cannot undertake to reply to them through the post, nor is it always possible to publish answers the same week. Questions on different subjects should be written on separate slips of paper, each of which should bear the sender's name or initials. Readers requiring working formulæ for special preparations, and intimating their wants to the Editor, will be assisted as far as may be practicable. The word "parts," when used in formulæ, invariably indicates parts by weight.]

PREVENTIVE OF FERMENTATION.—Alcohol and chloroform are the best and safest preservatives of infusions. See Mr. Edmund White's paper on this subject, published in the *Pharmaceutical Journal* for February 24, 1894. In the same paper you will find a description of a method of preventing fermentation in infusions

and other preparations by a simple process of sterilisation. [Reply to APPRENTICE.]

AQUEOUS SOLUTION OF HYPO.—Sodium hyposulphite in a solution at all concentrated will keep good for months, but in hot weather, particularly if exposed to the air, it will begin to develop a growth of mycelium. [Reply to J. HICKING]

REDDENING OF AMMONIUM SULPHOCYANIDE.—R. E. Liesegang pointed out that a concentrated solution of ammonium sulphocyanide turns deep red on exposure to sunlight and air, but this colour is bleached again if the solution is placed in the dark ('Photo. Archiv., xxxiv.,' pp. 145, 177). He gives no reason for this, but as this salt can be prepared by direct union between carbon disulphide and ammonium hydroxide, thus

it is quite possible that the NH_4CnS splits up in the presence of air and moisture, forming a red salt of the same colour as the original solution. It is not fit to use for photographic work in this state. [Reply to J. HICKING.]

QUALIFICATION AS ANALYTICAL CHEMIST.—The best qualification for this purpose is that conferred by the Institute of Chemistry. Write to the Secretary, 30, Bloomsbury Square, London, W.C., for particulars regarding regulations for admission to membership. [Reply to R. WOOD.]

STRENGTH OF AMMONIA WATER.—There is no rule for determining this. The simplest plan is to refer to the tables in Watt's 'Dictionary of Chemistry,' and other standard works. Ammonia water of s.g. 0.979 at $\frac{15^\circ\text{C.}}{4^\circ\text{C.}}$ in air, contains 5 per cent. of NH_3 ; that of s.g. 0.959 = 10 per cent.; of s.g. 0.942 = 15 per cent.; of s.g. 0.925 = 20 per cent.; of s.g. 0.909 = 25 per cent.; and that of s.g. 0.895 = 30 per cent. of NH_3 .—[Reply to J. H. PEARCE.]

ACTION OF LYSIDINE.—This base is a powerful solvent of uric acid, and it has been recommended in cases of acute gout and uric acid diathesis generally. It has also been used in the treatment of Bright's disease. [Reply to W. B. HOILE.]

APPOINTMENT AS DISPENSER.—We are not aware that there is any demand for dispensers on passenger steamers or in the merchant service. [Reply to MARE.]

FILLING SYPHONS.—"The best way of filling siphons with Lithia Water, B.P.," or any other aerated water, is to use a machine specially made for the purpose. Instructions for using such machines are always supplied by the makers. [Reply to "H. S."]

TONING AND FIXING SOLUTION.—Yes, it was a printer's error. The correct formula is—

Sodium Hyposulphite	4 ozs.
Ammonium Sulphocyanide	30 grs.
Sodium Chloride.....	60 grs.
Gold Chloride	2½ grs.
Water	to 20 ozs.

We are making inquiries in the other matter you refer to. Meanwhile, have you seen Hardwick's 'Manual of Photographic Chemistry'? [Reply to HYDROQUINONE]

PUBLISHERS' NOTICE.

CASES FOR BINDING.

CASES for binding the half year's numbers (one volume) of the *Pharmaceutical Journal* are now ready. Cloth, gilt lettered, price 1/3, post free.

APPLICATIONS should be sent, accompanied by remittance, to the *Pharmaceutical Journal* Office, 5, Serle Street, Lincoln's Inn, W.C.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs, Bennett, Bird, Blythe, Christy, Clague, Cottman, Coull, Danbury, Dyson, Ferrall, Foster, Greaves, Grier, Hardy, Heanley, Herman, Hill, Hoile, Hooper, Ingham, Jaffe, Junor, Mackie, MacHardy, Martindale, Morris, Newbury, Pattison, Pearce, Robb, Robson, Russell, Saunders, Shacklock, Shepperton, Slater, Street, Stroud, Summers, Tomlison, Turner, Wall, Wallace, Whitehead, Wood, and Wright.

“THE MONTH.”

Action of Diastase.

T. B. Osborne and G. F. Campbell have made several hundred trials with the object of determining precisely the influence of certain conditions upon the action of diastase, such as the age of the diastase solution and the presence of sodium chloride, disodium orthophosphate, tripotassium orthophosphate, orthophosphoric acid, acetic acid, or citric acid, in systematically varied quantities. In the case of citric acid, the minutest quantities always depressed or destroyed diastasic action, but in the majority of instances no such uniform results were attainable as would lead to safe conclusions in regard to the circumstances that insure a high degree of diastasic activity. The purer the diastase is made the more sensitive it appears to external conditions, so that the determination of the maltose-producing power of the ferment thus becomes of uncertain value, and perhaps fails to furnish a safe criterion of the purity of the enzyme. A great influence on the activity of the diastase appears to be exerted by the addition of various substances to its solution, and it would thus seem that the proteid is not the only factor involved in the amyolytic action of the ferment. It is not at all improbable, therefore, that attempts to purify diastase result in the removal of some substance that favours, or is essential to, its action, and that the enzyme itself may be feeble in its operation through the absence or deficiency of some accessory substance. Thus, in many cases, the presence of sodium chloride increases the diastasic action several fold, and the results of extended experience tend to strengthen the belief that albumin is an essential factor in such action. Of all the preparations made, none from which albumin was absent showed amyolytic power, and those containing most albumin were most active, whilst it has been found possible to judge of the diastasic power of a preparation by heating a portion of its solution to 65° C. and observing the amount of coagulum formed (*Journ. Am. Chem. Soc.*, xviii., 536).

Acetylene and Pyrophori.

H. Moissan and C. Moureu find that iron, nickel, and cobalt pyrophori, prepared by reducing the respective metals by hydrogen at the lowest temperature possible, will decompose acetylene in the cold with incandescence and the production of carbon, hydrogen, and carbides. The decomposition appears to be the result of a similar physical phenomenon to that observed in the case of platinum black, being due to the porosity of the metals (*Comp. rend.*, cxxii., 1240).

Glycero- Phosphoric Acid.

Delage and Gaillard recommend the following method of preparation: Phosphoric acid (60 per cent.) is mixed in a flask with one and a half parts of glycerin; the mixture produces a rise of temperature from 15° to 25° C. The flask is fitted with a thermometer and gas tube, and the contents very gradually heated up to 120° C., when the mixture begins to boil and acquires a yellow colour. On continuing the application of heat, the temperature rises rapidly; at 160° the liquid becomes brownish-yellow, and at 170°–190° dark brown and syrupy, acrolein vapour being given off. The flask is then allowed to cool, and the translucent gelatinous mass is rubbed in small portions with precipitated calcium carbonate and water until carbonic acid gas is no longer evolved. After neutralisation the mixture is left for six hours, and then filtered to separate calcium phosphate and a resinous substance. The filtrate, which is clear and slightly yellow, is next mixed with half its volume of alcohol (90 per cent.), which throws down a flocculent precipitate of calcium glycerophosphate. This is collected on a

filter, washed with alcohol, dissolved in water, again precipitated by addition of alcohol, collected and dried at a low temperature over quicklime or pumice stone saturated with oil of vitriol. The calcium salt thus obtained is a white crystalline powder, soluble in 10 parts of cold water, and less soluble in hot water. Another salt of glycerophosphoric acid is formed simultaneously, which is not precipitated by alcohol, and on evaporating its solution it separates as a flocculent gelatinous mass (*Nouv. Remèd.*, 1896, 8, p. 217).

Oxidising Soluble Ferments.

G. Bertrand states that the colour changes produced on exposure of the juice of beetroot, potato tubers, and other vegetables to the air are due to the oxidation of tyrosin under the influence of a soluble ferment, which he proposes to call “tyrosinase.” This ferment belongs to a class to which he has applied the generic name “oxydase,” and is found naturally associated with tyrosin in numerous instances, as in the beetroot, dahlia, etc., whilst also occurring in several fungi not containing tyrosin. The author compares it with laccase, the only oxidising soluble ferment previously known (see *Ph. J.* [3], xxv., 754), which causes the latex of the Tonquin lacquer tree to become insoluble when exposed to air, but is without effect on tyrosin (*Comp. rend.*, cxxii., 1215).

Galactochloral, Arabibromal, and Levulochloral.

In a further addition to his communications treating of the compounds of various sugars with chloral, to which he has applied the general name “chloraloses,” M. Hanriot states that galactose combines readily with chloral when the mixture is warmed for an hour at 100° C., in the presence of hydrochloric acid. On purification, by heating with water and subsequent cooling, β -galactochloral, $C_6H_{11}Cl_3O_6$, separated in crystals melting at 202°. The mother liquor retained a certain amount of the compound, together with a crystalline compound recognised as α -galactochloral, but the latter could not be isolated in a state of purity. The β -galactochloral is almost entirely insoluble in water and in ether, but soluble in methylic alcohol. When its potassic solution is treated with benzoyl chloride, tribenzoylgalactochloral, $C_6H_8Cl_3O_6(C_7H_5O)_3$, is formed, crystallising in long needles, which melt at 141° and are soluble in alcohol, methylic alcohol, or benzin, but only slightly soluble in ether. Bromal was found to give similar results to chloral, but the bromaloses are less stable and less easily obtained than the chloraloses. With arabinose, however, bromal yielded small crystals (m. p. 210°) of arabibromal, $C_7H_9Br_3O_5$, which is slightly soluble in boiling water, but otherwise insoluble, and is decomposed on prolonged boiling of the alcoholic solution. Levulochloral, $C_6H_{11}Cl_3O_6$, was obtained in crystals melting at 228°. It is soluble in cold water, more so in boiling water or alcohol, but only slightly soluble in ether (*Comp. rend.*, cxxii., 1127).

Uranium and its Properties.

H. Becquerel showed some months ago that the salts of uranium emit radiations possessing properties some of which are comparable to those of Röntgen's x -rays. In a recent paper he gives further details, and states that he has also experimented with metallic uranium, in the state of powder, and finds that it possesses the same power in a more marked degree, this being the first case recorded of a metal possessing what may be termed invisible phosphorescence. According to H. Moissan, uranium can easily be obtained in the metallic state by decomposing the double fluoride of uranium and sodium, either by means of metallic sodium or by electrolysis; or better, it may be readily produced by reducing uranium oxide by means of carbon, in the electric furnace. All three methods furnish good results, and as much as 15 Kg. of the metal has thus been prepared for recent

investigations. It is stated that uranium can be obtained in crystals, and that the pure metal has properties closely resembling those of iron, especially as regards filing, carbureting, tempering, and oxidising. It combines with oxygen, however, with even greater facility than iron, and in fine powder slowly decomposes water in the cold. The action of uranium upon the hydracids is also more energetic than is that of iron, and the metal possesses a great affinity for nitrogen, but does not affect the magnetic needle. Moreover, it is much more volatile than iron in the electric furnace (*Comp. rend.*, cxxii., 1086 and 1088).

This alkaloid, obtained from *Anhalonium williamsi* by Heffter, has recently been found useful as a soporific. Trials made by Jolly in one of the Berlin hospitals show that when administered in the dose of 6 centigrammes it rapidly produces sleep which lasts for several hours, and without producing any objectionable effects. When injected the dose is from 2 to 4 centigrammes. The composition of pellotine is represented by the formula $C_{13}H_{19}NO_3$.

T. B. Osborne and G. F. Campbell have examined the proteids of malt. The specimen examined contained "bynedestin," a globulin which is not precipitated by saturating its solutions with sodium chloride, and but partly precipitated by saturating with magnesium sulphate; "leucosin," an albumin identical in composition with the leucosin found in wheat, rye, and barley; a protoproteose readily precipitated from aqueous solutions by adding an equal weight of alcohol, and a similar compound which was less readily precipitated; also a deuteroproteose, a heteroproteose, and "bynin" and another proteid. Both of these proteids were insoluble in water and saline solutions, but only the last was insoluble in alcohol. The following table shows the proportions of the various proteids in the malt investigated:—

Proteid, insoluble in salt solution and in alcohol.....	3.80	per cent.
Bynin, soluble in dilute alcohol	1.25	"
Bynedestin, leucosin, and proteoses } soluble in water and salt solution. }	Coagulable .. 1.50 Uncoagulable 1.29	" "
	7.84	"

From the results of the investigation it is inferred that the proteids of barley undergo extensive changes during germination, without acquiring, or before acquiring, the properties of proteoses; also that hordein disappears, being replaced by an alcohol-soluble proteid of entirely different composition, whilst edestin is similarly replaced by a new globulin. The albumin, on the other hand, is unchanged in character and increased in quantity. It is further noted that the proteids replacing the hordein and edestin are much richer in carbon and poorer in nitrogen (*Journ. Am. Chem. Soc.*, xviii., 542).

This is the name of a very remarkable dye-stuff, which has been known for some years and has recently been examined by F. W. Richardson and H. E. Aykroyd. It is obtained by fusing organic substances—such as starch, cellulose, sawdust, blood, horn, feathers, etc.—with alkaline sulphides, sodium polysulphide being preferred; and it was believed by the inventors to constitute an organic sulphide. The dye occurs in black, porous, hygroscopic lumps, quickly alterable on exposure to the air, and it dissolves readily in cold water, giving a black solution which develops brownish colours by aerial oxidation. By using with it salt, sodium bisulphite, potassium bichromate, or copper and iron sulphates, shades of colour varying from pale grey to brownish-black may be obtained. On investigation, the pure dye-stuff was separated from the "cachou" as a black powder, insoluble in water, alcohol, ether, and acids, but soluble in hot

solutions of caustic soda or potash. Experiments proved that both furfurool and thiophene will yield the dye when heated with sodium polysulphide, and the authors therefore term the dye principle trithiophenic acid. Attention is directed to the fact that the reaction ensuing when polysulphides are fused with organic bodies serves as a distinctive test for tetramethenyl and other "cachou"-forming groups in compounds (*Journ. Soc. Chem. Ind.*, xv., 328).

M. Cazeneuve shows that these two fuchsines behave in a different manner in the presence of alcohol containing aldehydes. If a few cubic centimetres of an aqueous solution of a salt of rosaniline (1 in 1000) be decolorised by means of sulphurous acid, a violet coloration is produced on adding alcohol containing formal or ethylic aldehyde. In the case of acid fuchsine S., however, under similar conditions, the violet coloration is not produced, but a rose tint like that of the original solution diluted. This is more distinct in proportion as the alcohol contains less aldehyde. The addition of hydrochloric acid does not modify the result in the latter case, but it intensifies the coloration produced by the salts of ordinary rosaniline. To show the difference between the effects produced by the two compounds, it is suggested that the solutions used should be prepared as follows:—Solution of fuchsine or fuchsine S. (1 in 1000), 30 C.c.; solution of sodium bisulphite (34° B), 3 C.c.; water, 200 C.c. (*Journ. de Pharm.* [6], iii., 595).

C. H. La Wall has experimented with various methods for the assay of sanguinaria and its preparations, digesting them for a given length of time with certain solvents, in the presence of excess of ammonia, and subsequently separating the alkaloid by the use of an immiscible solvent. Thus, in experiments 1, 2, and 4, 10 grammes of the drug in No. 50 powder was macerated for four hours with 10 grammes of aqua ammonia and 100 grammes of (1) a mixture of ether, 3 vols., chloroform, 1 vol.; (2) ether; and (4) petroleum spirit. In experiment, No. 3, the same quantity of drug was treated with 100 C.c. of Prollius' fluid, by Lyon's general assay process. The results obtained were as represented in the following table:—

Process used.	Solvent used for Second Extraction.	Alkaloid obtained.	Colour.
No. 1	Chloroform, 3 vols.; ether, 1	4.86 per cent.	White
" 2	Ether	5.12 "	"
" 3	Chloroform, 3 vols.; ether, 1	6.06 "	Dark
" 4	Same as with No. 3	1.48 "	White

A combination of processes Nos. 1 and 4 was then tried, and it was thus found that the petroleum spirit exerts a solvent action upon a portion only of the alkaloid present, giving constant results with the same sample. Subsequent extraction of the residue with the light chloroform ether used in experiment No. 1 resulted in removal of the remaining alkaloid, and gave results for total extraction agreeing within a small fraction of 1 per cent. A careful assay of the drug by the petroleum spirit process yielded 1.68 per cent. of alkaloid, and as a fluid extract prepared from the same sample by the U.S.P. process was found to contain 1.67 per cent. of alkaloid when similarly assayed, it appears probable that the U.S.P. process thoroughly exhausts the drug. No difference could be observed in the alkaloid extracted by petroleum spirit and that subsequently extracted from the residue by chloroform ether, but the author is of opinion that the petroleum spirit process, since uniform results are given by it, may be used for standardisation. The average alkaloidal content of commercial sanguinaria by this process is given as 1.5 per cent. (*Am. Journ. Pharm.*, lxviii., 305).

**Opium
in
Japan.**

The British Consul at Tainan reports that the Japanese have now prohibited the importation of opium by foreigners, intending apparently to control the trade themselves. Only 1712 cwts. of foreign opium were imported during 1895, as against 2378 cwt. in the preceding year, and of the total import 94 per cent. was Persian. Chinese opium was imported to the extent of 57 cwts. only. With the object of preventing suffering and possible death, which might ensue in some cases were the supply of the drug to be suddenly cut off, the drug is still to be administered in limited quantities to confirmed smokers, but only when medical men certify that it is a necessity. The practical outcome of this Japanese legislation, it is pointed out, will probably be that the consumption of opium in Japan will be restricted in quantity, and the trade in the drug become a Government monopoly (*Foreign Office Annual Series*, No. 1733, p. 3).

**American
Beeswax.**

E. Dieterich publishes the results of his examination of several samples presenting marked deviation in character from normal beeswax. The specific gravity was in all instances higher than that of normal wax (0.960), and ranged from 0.9629 to 0.9677. The melting point was in most instances also higher than that of normal wax (63°·5 C.), ranging from 64° to 68°·5 C., that of one sample being 63° C. While the ratio of the acid number to the ester number in normal wax is 1:3.75, in the samples examined it ranged from 1:3.8 to 1:4.6, indicating an addition of Japan wax or Carnuba wax. Judging from the melting point of these samples, addition of paraffin appears to be excluded, as it would reduce the melting point below that of normal wax. The borax test also gave results indicating addition of vegetable wax. One of the samples also appeared to contain an artificial colouring ingredient (*Pharm. Centralh.*, xxxvii., 378).

**Prussic Acid
in
Plants.**

The results of Dr. M. Treub's investigation of the formation and distribution of hydrocyanic acid in *Pangium edule* show that the acid is one of the earliest nitrogenous products of assimilation in the plant. Both in the cortex and pith special cells rich in the acid were found, and it could also be detected in the pericycle, as well as in the parenchyma cells of the leaves, and in the flowers and fruits. The phloem provides the channel along which the acid is conveyed, after being formed in the leaves, and the special cells containing hydrocyanic acid in the young plant subsequently become proteid stores. The presence of carbohydrates and the supply of nitrates from the soil are essential conditions of the formation of the acid (*Annals of the Buitenzorg Bot. Garden*, xiii., i., and *Bot. Zeit.* 1896, 102).

**Röntgen Rays
in
Germination.**

A. Schober has experimented on the effect of the x -rays on the germination of the oat. He concludes that they differ from ordinary light-rays in this respect among others, that they have no power of producing heliotropic curvatures, even in organs so sensitive to light as the axis of a young seedling (*Ber. Deutsch. Bot. Gesellschaft*, 1896, p. 108).

G. Bertrand and A. Malèvre have found pectase in five species of Cryptogams examined, and in about forty species of flowering plants belonging to widely separated families; the only negative results obtained being with conifers. The amount of this diastase present varies with the species, and with the part of the plant. It was found in the root, stem, leaves, flowers, and fruit, but most abundantly in the leaves. A mode of obtaining pectase

in a pure state from the leaves of clover or lucerne is described, consisting essentially in dissolving in chloroform, and then precipitating by alcohol, when it separates as a white powder (*Morot's Journal de Botanique*, 1896, p. 37).

**The Acid
Excretion of
Roots.**

F. Czapek has investigated the nature of the acid substances contained in the fluid excreted from the roots of a number of plants. Among inorganic bases potassium was found to be invariably present, magnesium very often, calcium only rarely. Small quantities of chlorides were often found, phosphates invariably; and the acid reaction was due to the presence of primary potassium phosphate. Of organic acids, formic was often present in the form of potassium formate; oxalic acid occurred only in the hyacinth, and then only in the form of primary potassium phosphate. The corrosive action of the roots of plants on mineral substances is due, in all cases, to carbon dioxide (*Ber. Deutsch. Bot. Gesellschaft*, 1896, p. 29).

**Remarkable
Instance of
Proterandry.**

J. Daveau describes an example of proterandry extending over a whole year in the case of a palm belonging to the genus *Kentia* or *Howea* growing in the Botanic Garden at Lisbon. The flowers are grouped in clusters within the spadix, and each cluster consists of three flowers, two male and one female; but the female flower is only in a very rudimentary condition when the male flowers are mature and discharging their pollen. In this condition it remains through the autumn and winter, and expands only at the same period in the next summer, when it is pollinated by male flowers in other newly-formed inflorescences.

**Some New
Preservative
Solutions.**

J. Amaun recommends the use of the following preparations for the preservation of mosses and green Algæ:—1. *Lactophenol*; 20 grammes of crystallised phenol, 40 of lactic acid of sp. gr. 1.21, 40 of pure glycerin of sp. gr. 1.25, 20 of distilled water; this preparation combines the clearing properties of phenol and that of restoring the softness and turgescence of the tissues of dried algæ possessed by lactic acid. 2. *Cupric lactophenol*; 2 Gm. crystallised copper bichloride, 2 Gm. crystallised copper binacetate, 96 Gm. lactophenol; this may replace lactophenol where it is necessary to preserve the green colour of the specimen, and 10 per cent. of it added to the water in which the Algæ are found will serve as a fixing agent. 3. *Lactophenol cupric solution*; 0.2 Gm. crystallised copper bichloride, 0.2 Gm. crystallised copper binacetate, dissolve in 95 Gm. distilled water, and add 5 Gm. lactophenol; specially good for Desmidiæ, Palmellaceæ, and filamentous Algæ, which do not undergo any change of form or colour in it. 4. *Lactophenol gelatin*; 8 Gm. white gelatin, 44 Gm. distilled water, and after two hours add 38 Gm. pure glycerin of 1.25 sp. gr., then add 10 Gm. lactophenol; a very good substitute for Canada balsam, but must not be used for preparations coloured with aniline dyes, only with those coloured by hæmatoxylin or carmine. 5. *Cupric lactophenol gelatin* is like the last, but prepared with cupric lactophenol; in this the form and colour of the chromatophores are well preserved. 6. *Lactophenol gum*; 38 Gm. white gum arabic, wash rapidly in running water, and add 50 Gm. freshly-boiled distilled water, then add 6 Gm. glucose and 6 Gm. lactophenol, mix and filter; good for mounting rapidly all kinds of vegetable preparations, especially mosses. 7. *Styrasin*; dissolve 100 grammes of pure styrax in 200 C.c. of chloroform, filter, and transfer the solution in small quantities into a flask containing one litre of ordinary petroleum spirit, allow to deposit for twenty-four hours, decant, and evaporate the solution in the sun; a syrupy, resinous solution is thus obtained with the index of refraction 1.60–1.64 specially adapted for diatoms. 8. *Biniiodide of mercury*

glycerin; obtained by dissolving mercury biniodide in pure glycerin in the presence of potassium iodide; a liquid is obtained with the index of refraction 1.80. M. Amaun finds the best cement for preparation made with these media is amber or dammar varnish, to which 2 per cent. of boiled linseed oil has been added (*Morot's Journal de Botanique*, June 1, 1896).

G. Roux and A. Trillat have conducted experiments in disinfection under practical conditions, in enclosed spaces of capacity varying from 70 to 1400 cubic metres, with the fumes of formic aldehyde produced by a special oxidising apparatus or by the "autoclave formogène." They found that pathogenic germs could thus be absolutely destroyed when freely exposed to the aldehyde, and that the dust in the air and on the walls of rooms was at the same time thoroughly sterilised. The action of the aldehyde appears to be exercised immediately and simultaneously in all parts of an enclosed space. Care must be taken in employing this process to avoid the escape of the aldehydic fumes, on account of their irritating properties, but there is no risk from the formation of carbon monoxide. Dr. F. J. Bosc has experimented in the same direction, and fully confirms the above results, showing that even *Bacillus tuberculosis* can be destroyed, either in the dry or moist state, by the aldehyde fumes. He suggests that all objects to be disinfected should be as fully exposed to the fumes as possible, and that after disinfection free currents of air should be admitted for a quarter of an hour before the room is entered, and the windows then be left open. After thoroughly ventilating for two days, all traces of the formaldehyde odour will have disappeared, and it will be found that objects in the room are uninjured as regards their structure and colour (*Ann. de l'Inst. Pasteur*, x., 283 and 299).

It appears probable that the Röntgen *x*-rays will prove of greater use in dentistry than in surgery, indeed—as F. Harrison points out—the methods only need simplifying to enable dentists to observe in their patients what was only possible until recently in the dead subject. The genesis of the teeth, the construction of artificial crowns, the anomalies of roots, the difficult eruption of wisdom teeth, and many other conditions of organs which are enveloped in tissue that is opaque under ordinary conditions, are said to become visible by the illumination of the *x*-rays, and reproductions of photographs taken with a Newton's tube, which are used to illustrate the article, afford satisfactory proof of the statement. For practical purposes, of course, a cryptoscope will be found simpler in use and more generally satisfactory than the photographic process, and Mr. Harrison proposes to experiment with an apparatus of that description (*Journ. Brit. Dent. Assoc.*, xvii., 343).

C. F. Cross and E. J. Bevan have examined this product, the preparation of which from cotton takes place in the following stages: (1) The cotton is nitrated and dissolved in ether-alcohol; (2) the viscous solution of cellulose nitrate is drawn through fine orifices of glass, and precipitated by water or solidified by evaporation of the solvent, the process being continuous so that a fine thread is formed; (3) the threads having been thrown or twisted together to form the compound thread or textile yarn, this is next denitrated by resolving the nitric ester. The resulting cellulose thread retains its form and lustre, and constitutes the artificial silk known commercially as lustru-cellulose. Cross and Bevan have definitely proved that the denitration of the nitrate yarn is complete in regard to the removal of the nitric groups (NO_3), the lustru-cellulose containing only 0.19 per cent. of

nitrogen. They also find that the cellulose residue reverts to the normal molecular condition of the original on denitration, and that no oxy-cellulose results from the cycle of operations. The new artificial silk is therefore regarded as being substantially a normal cellulose, and its use involves no possible risk from explosion or excessive inflammability (*Journ. Soc. Chem. Ind.*, xv., 317).

Dr. Chas. Rice says the methods now almost exclusively employed in the principal public hospitals of New York city for sterilising catgut for surgical purposes, are the following three:—(1) Maceration in oil of juniper and subsequent boiling with alcohol of 94 per cent., then transferring to and keeping in chloroform saturated with mercury biniodide; (2) The same as No. 1, except that the maceration in oil of juniper is omitted; (3) Simple maceration for at least 48 hours in chloroform saturated with mercury biniodide, the strings being left in the solution until required for use. Chloroform is the most satisfactory solvent of the fatty matters in catgut, and complete sterility is effected by saturating the chloroform with mercury biniodide. The best, smooth musical strings should be used, and under ordinary circumstances five sizes are sufficient—violin D, A, and E, and first and second banjo strings. As an additional precaution, it is deemed advisable to subject them to a preliminary sterilisation, by boiling them with enough alcohol of 94 per cent. to keep them covered, in a large wide-mouthed Erlenmeyer flask. To the neck of the flask should be fitted an upright condenser, and the apparatus is set upon a steam bath and boiling maintained for an hour. Then, immediately on removing the strings, they must be transferred to the biniodised chloroform, which should be of the strength of 1 in 1000 (*Alumni Journal, New York College of Pharmacy*).

A new method of making and finishing wax-cells for microscopical purposes is described by M. Pflaum, who has found them answer every demand, whether for fluid or dry mounting, during several years that he has used them in his own work. Rings of asphalt and benzol cement are first drawn upon the cleaned glass slides, and allowed to set thoroughly. A mixture of equal parts of wax (? beeswax) and paraffin is then melted, and with this cells of the required depth are raised upon the asphalt rings by means of a turntable. The wax cell-walls are immediately well covered with asphalt cement, special care being taken to cover the inner and outer edges nearest the glass, so that the wax is entirely enclosed by the cement. Cells thus produced are said to be capable of resisting any change of temperature and to be especially suitable for glycerin mounts. When an object has been placed in position within one of the cells, a very thin ring of the melted wax is run round the edge and a cover-glass at once pressed firmly down on it. Fasten the cover-glass with a ring of shellac in alcohol, and after that is thoroughly dry finish with zinc white or other suitable varnish, being careful to avoid any in which benzol is the solvent (*Amer. Monthly Micros. Journ.*, xvii., 63).

At a recent meeting of the Liverpool Section of the Society of Chemical Industry, Mr. Douglas Herman drew attention to the beneficial effects of the administration of oxygen gas to persons suffering from the influence of noxious gases. This is an occurrence not infrequent in chemical factories where the workmen have to enter flues or chambers in which chemical processes have been carried out. As pointed out by the author, what is wanted in such cases is an immediate supply of fresh oxygen to the lungs, and this is most easily provided from a cylinder of compressed oxygen, either by a tube con-

Oxygen Gas as a Restorative.

veying a gentle stream being placed in the patient's mouth while the lips are held tightly round the tube, or by the tube being inserted in one nostril while the other is compressed. A respirator may also be used, covering both mouth and nose. Mr. Herman states that several lives have been saved at works where oxygen has been employed in this way at his suggestion, and he recommends that a cylinder of oxygen gas should always be kept in readiness at places where poisonous gases are likely to be produced and affect the workpeople. In the case of drowned persons, oxygen inhalation has also been found useful, and it might with advantage be kept in readiness at police stations, Royal Humane Society stations, etc., as is now done in France (*Journal Soc. Chem. Ind.*, xv., 247).

A satisfactory picro-carmine, yielding a solution

A Stable Picro-Carmine Solution. that has been proved to keep good for five years is made as follows:—Pure carmine is dissolved in a mixture of ammonia water, 1 part by volume and water, 4 parts, care being taken to keep the carmine in slight excess. After standing for two days, filter the solution and expose it until a precipitate begins to form, protecting it from dust meanwhile. Again filter, and add concentrated solution of picric acid (? to excess), then agitate and set aside for twenty-four hours, when a third filtration must be followed by the addition of 1 part of chloral hydrate to every 1000 parts of solution. At the end of a week filter for the last time and immediately bottle off in small glass-stoppered vials (*National Druggist*, xxvi., 176).

On the basis of experiments made for the

Pepsin Digestion. purpose of ascertaining in what manner the action of pepsin is retarded by wine, Hermann-Peters has come to the conclusion that wine is not a suitable medium for the administration of pepsin. The retarding effect is produced not only by the alcohol present in wine, but also by the acid tartrate present. Tartaric acid does not itself interfere with the action of pepsin, but it cannot be substituted in place of hydrochloric acid, the presence of which is an essential condition of digestion by pepsin, and the presence of acid tartrate in wine is prejudicial, because it neutralises hydrochloric acid, setting free tartaric, so that pepsin wine will contain no free hydrochloric acid (*Berichte der Pharm. Gesellsch.*, iv., 258).

According to *Engineering*, acetylene is being

Acetylene as a Tram-car Illuminant. tried as an illuminant on the Paris tram-cars. The generator, containing calcium carbide and water, is placed on the rear-platform under the steps, and weighs, when charged, only 27 lbs. It is said to be capable of producing 35 cubic feet of the gas, the illuminating power of which is estimated at fifteen times that of ordinary coal gas. The lighting is said to be very efficient, it being possible to read a paper in any part of the car, and the cost, so far as the experiments have yet gone, works out at less than that of lighting by petroleum, but as the car has only been in use a few weeks, it is not yet possible to give definite figures.

The use of sodium chloride as an aid to the

Sodium Chloride as an Iodine Solvent. solution of iodine in water is recommended by Muller (*Méd. Nouv.*), more particularly when the solution is intended for internal use. For example, to produce a local effect on the pharynx, he adds to the water used half to one per cent. of sodium chloride, and the following is suggested as a suitable prescription:—Tincture of iodine, 1 to 2 Gm.; sodium chloride, 2 Gm.; distilled water, 200 Gm. The tincture of iodine is that of the 'Codex Medicamentarius,' and is made by dissolving 10 Gm. of iodine in 120 Gm. of strong alcohol.

WILLIAM BUCKLAND.

Since Buckland's death in 1856, a new era of scientific thought and work has been in progress. Darwin's "Origin of Species," which ushered in the modern methods of biological research, appeared in 1859, and laid the foundation for a completely new series of generalisations, which have become so familiar to us that it is only by an effort that an approximately just estimate can be formed of the attainments and conclusions of the men who worked previous to that epoch.

Buckland was so commanding a figure in the science of his day that his biography can hardly fail to benefit the mind in assisting it to apprehend more clearly the evolution of scientific ideas. Mrs. Gordon, Dean Buckland's daughter, has recently written his life.* She gives, with an attempt at chronological order, an account of some of the most interesting facts in a life, which, while devoid of excitement, was full of incident and novelty. What purpose is served, however, by the long—the very long—excerpts from Buckland's writings, which have been incorporated with the biography proper, is not plain. The glimpses which are obtained of the man himself reveal him as full of buoyancy and good humour, but the impression produced by a first reading of this volume is a rather depressing one. The long quotations are dispiriting. If biographical details helped in any way to elucidate the writings, their quotation would be pardonable, but such is not the case. Having made this little protest, it is only just to add that in other respects the "Life" is admirable.

William Buckland was born at Axminster in 1784. From his early childhood his father was in the habit of taking him for walks in the lias quarries in the neighbourhood, collecting ammonites and other shells. When thirteen years of age he was sent to a grammar school at Tiverton, and a year later he was successful in obtaining a nomination to Winchester. Here as a boy, he says, he became familiar "with the chalk formation, from the fact of the pathway to the playground on St. Catherine's Hill passing close to large chalk pits, which abounded with sponges and other fossils, and from the practice of digging field-mice from their holes in the surface of the chalk."

He was elected scholar of Corpus Christi College, Oxford, in 1801, and he immediately turned his attention to the study of the science of which he was to become so masterly an exponent. "In my early residence at Oxford," he himself says, "I took my first lesson in field geology in a walk to Shotover Hill with Broderip, who knew much of fossil shells and sponges from Mr. Townsend, the friend and fellow-labourer of William Smith, 'The Father of English Geology.' The fruits of my first walk with Mr. Broderip formed the nucleus of my own collection for my own cabinet, which in forty years expanded into the large amount which I have placed in the Oxford geological museum." After taking his B.A. in 1804, he added to his income by giving tuition to private pupils. He was thus enabled to indulge in his favourite studies, and, with the aid of the income derived from his scholarship, continued them throughout his forty-five years' residence at Oxford.

In 1809 he was admitted into Holy Orders, and in the same year was elected Fellow of his college. It was not, however, until he was appointed to the Deanery of Westminster in 1845, that his connection with the Church resulted in work at all commensurate with his geological and agricultural labours.

The study of geology was undertaken in thorough earnest by Buckland when twenty-four years of age. He explored the chalk hills of Berks, Wilts, Dorset, and a large part of Devon. He made a tour through the centre and north of England, and in 1813 he

* 'The Life and Correspondence of William Buckland, D.D., F.R.S.' (John Murray, London, 1894).

accompanied his friend, W. Conybeare, into Ireland. The latter journey furnished the material for his first important paper, written in collaboration with Conybeare, "On the Coasts of the North of Ireland." His excursions were not confined to his native land, but were speedily extended to the Continent, the first being undertaken in 1816 into Germany with John Conybeare and Greenough. From Weimar he wrote, "We saw Goethe, and at Freyberg visited Werner, who gave us a grand supper, and talked learnedly of his books and music, and anything but geology."

Intense enthusiasm, keen observation, and unflinching good spirits were well-marked traits in Buckland's character. The two latter features are well exemplified in the following extract from a letter, which has a slight historical value for pharmacists, because it indicates how temporary mydriasis was produced by the use of belladonna before atropine had been isolated. He says, "I am sorry to inform you that all my movements have been deranged, and my plans thwarted by an accident that befell me a month ago near Sidmouth, from the falling of an ignited spark of iron from my hammer into the cornea of my eye, which I did not discover to be fixed there till some days after, when it began to oxydate. The result has been a series of five or six operations to cut out the minute rusty fragments, and a degree of inflammation which has prevented me from reading or writing during the last three weeks. I am happy to say the cause of injury is now totally removed, and in a few days I shall again take wing for Oxford. As I like always to extract all possible good out of the evil that befalls me, I have learned two curious facts in physiology from my oculist at Exeter. First, that he once drew a tooth out of a patient's eye (literally an eye-tooth), growing between the bony orbit and ball of the eye, and I have seen the specimen. Second, that the belladonna leaf has the singular and useful property, if laid on the eyelid, of causing a great expansion of the pupil and iris, which is of the highest service in cutting for cataracts, to render visible the inner chamber of the eye and, in cases of diseased pupils, by drawing the iris backwards in every direction, preserves it from contact with the central injury."
