But we know too little of the natural course of disease. The other day we were told of a case in which a pericardial friction-sound in rheumatic fever, evidently from recent inflammation, disappeared under mercurial treatment. But this did not produce much impression, as we had seen the same result take place in a like case where the patient had had a saline mixture only. Besides, in both these patients, there may have been more disease remaining than the stethoscope would tell us. We heard Dr. Jenner recently impress on his class the importance of being aware that a murmur might appear when a patient was getting well from rheumatic fever. An inexperienced Practitioner might, he said, put this down to a relapse of an attack of the endocarditis; but really it was due to contraction of lymph, which had been effused into the valve during the acute stage of the disease. To give mercury in such a case would be to prescribe for a sound. We require, then, when collecting facts as to rheumatic fever, to know how the heart was months after the patient left the Hospital. Besides, in pericarditis, for instance, as Dr. Gairdner has clearly pointed out,^(a) we want more evidence as to inflammation of the pericardium than as to stethoscope sounds. We must be sure that the heart was healthy to begin with; our treatment must be definite as well as "vigorous," and we should examine the organ carefully months after the patient left us apparently well.

SATURDAY, FEBRUARY 27.

SIR GEORGE GREY'S AMENDED ACT.

THE announcement, by Sir George Grey, that it was "the intention of her Majesty's Government to propose an amendment" of the Insane Prisoners Act, gave universal satisfaction, as affording a hope that we might thereby gain some compensation for the lamentable miscarriage of justice in the Townley case. Probably, some simple-minded lovers of "the true and just" hoped for even more than this. They may have reasoned—"the whole law relating to criminal insanity is felt by all to be in a most unsatisfactory state; there are no great and engrossing subjects of domestic policy to absorb the time and energies of Government and Parliament; while the consideration of criminal insanity, in some degree, will be forced upon them by this Act: surely, then, we may look for some large and statesmanlike measure of legislation on the subject."

Well, the Home Office has been in labour on the matter; and what has it brought forth? We cannot make use of the well-known classical quotation on the occasion; for the entire absence of any grandeur or loftiness of conception in the present "superior clerk" of that department of the Government, would render that degree of comparison between parent and bantling ludicrous; but if the throes of parturition are in any measure proportioned to the product, the friends and admirers of Sir George Grey may, at any rate, feel assured that his health and strength have not undergone any severe strain.

The proposed legislation is confined to the amendment of Act 3 and 4 Vict., cap. 54; and what does the amendment amount to? The certificate of insanity is to be signed "by two or more of the visiting justices," instead of "by any two justices," and "by two Physicians or Surgeons selected by them," instead of "by any two Physicians or Surgeons;" and on the receipt of such certificate, the Secretary of State "may, if he think fit," direct further inquiry into the case before directing the removal of the prisoner, while the present Act only provides that "it shall be lawful" for him to order such removal at once. The amended Act is to apply to England alone, so that there will be "one law in operation in England, another in Scotland, and another in Ireland." It seems a very sorry piece of patchwork legislation; but it was foolish to hope for more. We must suppose that Sir George Grey approved of the present Act, or it would have been amended long ere this; and as legislation on the matter has only been forced from him by popular indignation, it is natural that he should do as little as possible, and should make the amended Act as like as possible to the present one. Still, the amendments are improvements; and we are taught that we ought to be thankful for even the smallest mercies, though it is scarcely to his civil governors that an Englishman looks for such teaching.

How the amended law is to be set in action does not appear

on the face of it. Sir George Grey says, "by those who have to act;" but the phrase, "if any person . . . shall appear to be insane," is precisely the same in both Acts, and we know that in Townley's case the Act was set in motion by his own solicitor. That the justices shall be "two or more of the visiting justices," may be an improvement on the "any two justices," but certainly a very infinitesimal one, for the visiting justices do not appear to be appointed on account of any other fitness than the propinquity of residence to the gaol. That the required "two Physicians and Surgeons" should be selected by the visiting justices, instead of by the friends or solicitor of the prisoner, is a decided change for the better; though it cannot be said that any assurance is thereby given that these gentlemen shall be selected on account of their possessing any experience of insanity, or any special skill in the diagnosis of mental disease, or in unravelling complex and difficult points of evidence, nor is any safeguard given against their being men ruled by special theories of insanity or moral depravity.

We do not learn what is to be the form of the certificate. The present Act simply states that "it shall be duly certified by such justices and such Physicians and Surgeons that such person is insane;" but as it is required that ordinary certificates of lunacy shall state the symptoms on which the diagnosis had been formed, we must suppose that the words "duly certified" mean that the certificate shall be framed like the ordinary legal certificate of insanity; it would be an injustice to Sir George Grey to imagine that it need be only "a deliberate and recorded opinion," without containing the grounds on which that opinion had been arrived at.

We allow, then, that Sir George Grey's Amendment Act will be better than the Act 3 and 4 Vict.; but, at the same time, we think that this mode of determining as to the sanity or insanity of a condemned criminal is inadequate and wrong. It will, we believe, be generally felt that it is not fit or just that such an inquiry should be committed to a private tribunal composed of two or more justices, and two Medical men of their selection. Publicity is the very genius of English justice, and it is imperative that it should be afforded as far as possible under all circumstances. Questions of insanity are, perhaps, not always best tried by ordinary juries; and in the case of a prisoner condemned to death, and after conviction reputed insane, what is called the true English mode of trial by judge and jury would probably be too slow and cumbersome a means of arriving at the truth. The examination ought, we think, to be entrusted to a commission appointed by Government, and their report should be made public, whatever their decision may be. And, we believe further, that the commission ought to consist of Medical men eminent for their experience and knowledge of insanity—the very subject, that is, about which the inquiry has to be made. The opinions expressed in the House of Commons during the debates on Sir George Grey's bill on the unfitness of Medical Practitioners to deal with this question, would be amusing, were not the matter one of such vital importance. Some members would permit of a mixed commission, composed of Medical men and lawyers, while others would not admit Medical men at all; and the latest and most pregnant proofs of the soundness of these opinions are the reports of the two commissioners in Townley's case;—the first from a mixed commission, having been a hesitating compromise, which left the matter pretty much where it was before; while the second, composed of Medical men only, was so clear, logical, decided, and scientific, that it satisfied every one, and removed all the doubt and confusion which had gathered round the case.

As to the machinery by which Government should be moved to appoint a commission, we are inclined to think that a statement from the governor and Surgeon of the gaol, that such and such a convict had become insane, would meet all requirements.

It is greatly to be regretted that Government has not seen fit to take the opportunity of amending the law generally as

regards criminal insanity, and of making it more consonant with the knowledge, science, and humanity of the age; and we cannot but hope that Sir Fitzroy Kelly, or some equally competent private member of Parliament, may bring in a bill to supply the neglect of her Majesty's Ministers.

We cannot now discuss the question of how Medical science may be best employed to elicit the truth in cases where insanity may be pleaded; but we would direct our readers' attention to an able and temperate pamphlet on "Insanity and Crime," lately put forth by the Editors of the *Journal of Mental Science*, in which they will find some very judicious and admirable remarks on the subject.

THE WEEK.

THE DEATH-RATE OF MANCHESTER.

THE Manchester and Salford Sanitary Association has issued a very able report on the public health of those towns during the last quarter of 1863. During that quarter the deaths were at the rate of 31.2 per 1000 per annum of the living. Of 3286 deaths, 1622, or nearly one-half, were of children under five. The births during the quarter were 3973. There, as elsewhere, high mortality means children's mortality. Scarlet fever was the most fatal of epidemic diseases. The author of the report believes that the history of this epidemic proves that the fever spreads by gradual propagation amongst the people; and that it has no connection with the exhalations emitted from decomposing animal and vegetable matter. On this last point, we doubt if the writer takes the whole facts into consideration; but the question is too large to be discussed now. One point he justly insists on, which is likely not to be controverted,—the necessity of providing fever wards or other means of isolating persons labouring under this disease, so as to check the diffusion of the poison.

THE ARMY MEDICAL DEPARTMENT.

THE Medical department of the Army has now come to a dead lock for want of candidates. At the recent competitive examination, we understand that some forty-eight candidates only presented themselves, and that of these thirty-seven were considered competent. This, together with the fact, that of the thirty-three successful candidates in the August examination, whose names we published last week, three only were educated at the metropolitan Medical Schools, is sufficient evidence that the service has lost all attraction for the best class of English Medical students. It is needless to remark upon the striking contrast afforded in the number of candidates for the Medical service of the army compared with all other branches of Government employment, for in the latter there is never any lack of applicants of a high order. The forlorn condition to which the service has been reduced by the suicidal policy pursued since the granting of the original Warrant has received the last confirmation required. The authorities, in their necessity, have determined to abrogate the existing rules as to age and qualification. Another examination for commissions is to be held at Chelsea Hospital on March 21 next, and all legally qualified men under 30 years of age will be admitted to it if physically competent. By a singular retribution, the want of Medical officers is now principally felt in India, the very country where they have been most unfairly treated, to which, in spite of promises to the contrary, the provisions of the original Warrant have never been extended, and where, at the present moment, the Assistant-Surgeon is relatively worse off as regards emolument, when his expenses are taken into account, than anywhere else in the British Empire. The humiliating strait to which the Department is reduced would furnish a fitting epitaph for the late Indian Warrant strangled in its birth. As the present condition of things cannot go on without claiming the interference of Parliament, we would suggest the kind of changes required in the Medical service to raise it from its present condition to one of

efficiency and popularity:—1. An earlier retirement—say at twenty or twenty-one years—which would necessitate a more rapid promotion from the rank of Assistant-Surgeon. 2. An increase of pay for the rank of Surgeon. 3. The extension of the original Warrant to, or the promulgation of a new liberal Warrant for, India. 4. Changes in the internal management of the Department, and the position and duties of the Army Surgeon in the minor matters of extras, recruiting, branding soldiers, etc. Were a liberal and conciliatory course taken by those in power, the Department might even now regain the short-lived popularity which it acquired on the promulgation of the Warrant of 1858.

THE ALEXANDRA PARK AND THE REGENT-STREET TUNNEL.

We have before us two schemes for public edifices, which are the very opposites of each other in every respect. One is for erecting a huge arcade—or tunnel, as it would better be called—between Bond-street and Regent-street. The obvious objection to such a place is, that it cuts off the free circulation of air through the neighbourhood; it creates a number of shops and residences of the most unwholesome description; and it provides a sickly place of resort for town loungers, liable to be perverted to the worst purposes. The bill for legalising this intrusion was rejected in the House of Lords on Monday night. The other is the Alexandra Park—a scheme for transplanting the late International Exhibition building, with such improvements as would make it difficult for the original architect to recognise his offspring—to a high and breezy hill in the north of London. There health and morality, which always wait upon honest out-of-door recreation, will be fostered. There will be facilities for cricket, gymnastics, horticulture, music, and every other rational kind of amusement. A great gap will be filled up for the north Londoners, who at present are sadly deficient in places of public resort; and in the midst of the prevailing rage for brick and mortar, a magnificent park will be preserved for the public health and recreation.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE IV.—FEBRUARY 9.

The structure of the brain deserves a most careful consideration in connexion with the subject of the present course of lectures, as many of the characters of the groups of the Mammalia have been based upon it. The form of the brain can only be studied upon specimens hardened *in situ*, or from casts of the interior of the cranial cavity, as it immediately loses its shape and the relative situation of its component parts on removal from the body. A series of casts of the cranial cavity of different races of men and various animals have lately been added to the College Museum. Foremost among the morphological characters of the human brain may be given its great relative size; though its form varies much, as a general rule the cerebrum is highest in the parietal region; it covers and projects beyond the cerebellum posteriorly, and it covers and projects beyond the olfactory lobes anteriorly; it has a very slight supra-orbital excavation, which is in relation to the slight projection of the roof of the orbits into the cavity of the skull, and the supra-cerebellar excavation is not deep.

The entire encephalon is capable of division into three principal parts:—1. The fore-brain, consisting of the olfactory lobes, the cerebral hemispheres, and parts surrounding the third ventricle; 2. The mid-brain, the corpora-quadrigemina, and the crura-cerebri; 3. The hind-brain, the cerebellum, pons Varolii, and medulla oblongata. Of these the first and last are further divisible into segments. The segments of the fore-brain may be called—1. Olfactory; 2. Hemispherical; 3. Thalamary. Those of the hind brain are—1. Cerebellar; 2. Oblongate. The mid-brain does not need further subdivision.

The olfactory segment in man is extremely small, and has

no internal cavity. The characters of the large and important hemispherical segment requires very careful study; each hemisphere is generally divided into three lobes, but the boundaries of these are very vague. A better division is that of Gratiolet, whose work on the "Cerebral Convulsions of Man and the Primates" is the best that has been written on the subject. He divides the external surface of the hemisphere into five lobes, which are called—1. Frontal; 2. Parietal; 3. Temporal; 4. Occipital, and 5. Central; the last is the "island of Reil," placed at the bottom of the fissure of Sylvius. The surface of the hemispheres is covered with a labyrinth of elevations and fissures—*gyri* and *sulci*, as they are technically called. Although at first sight looking most confused, careful attention will detect order, and they can be without difficulty arranged and named, as has been done by Gratiolet, in the following way:—In the first place there are certain fundamental sulci; of these the most important is the well-known fissure of Sylvius. In front of this, on the upper and lateral part of the brain, is a deep, well-marked, and exceedingly constant transverse sulcus, called the fissure of Rolando; this is bounded both in front and behind by two large convolutions, which run nearly transversely, passing slightly backwards at their upper end; these are the antero-parietal and postero-parietal gyri. With the exception of these two, all the gyri of the outer side of the hemisphere run more or less in the longitudinal direction. They are easily remembered—being three on each lobe, and placed in tiers one above the other. On the frontal lobe are the infero-frontal, medio-frontal, and the supero-frontal; on the temporal lobe, the antero-temporal, medio-temporal, and postero-temporal; on the occipital lobe, the infero-occipital, medio-occipital, and super-occipital. Bounding the upper extremity of the Sylvian fissure is an arched convolution called the angular gyrus; and connecting the postero-parietal, angular, and temporal gyri with the occipital are a series of small convolutions called the annectent gyri; they usually bridge over a fissure which occasionally exists, called the external perpendicular sulcus.

Upon the inner surface of the hemisphere, or that which is turned towards its fellow, are certain well-marked and important fissures. Between the upper surface of the corpus callosum and the margin of the hemisphere is one running in the longitudinal direction, the calloso-marginal. On the posterior part is a deep and constant fissure, also longitudinal, called the calcarine; and above this, and placed more vertically, the internal perpendicular. Below the calcarine, and running down towards the bottom of the temporal lobe, is the collateral sulcus; and close to the posterior margin of the ventricular aperture is a deep sulcus, the dentate, containing within it a small convolution commonly called the "fascia dentata." The principal gyri on the inner side of the hemisphere are the callosal, marginal, uncinatæ, and the quadrate lobule. Certain of these external markings have very definite relations to internal portions of the cerebrum.

Each hemisphere has within it a great cavity—the lateral ventricle—which has prolongations, or cornua, extending in three different directions, anterior, middle, and posterior. The whole cavity has a remarkable relation to the corpus striatum, being, as it were, curled round it; so that this body forms the floor of the middle part of the ventricle, but the roof of its posterior and outer portion. The corpus striatum, in fact, is an outgrowth from the middle of the base of the hemisphere, and forms the axis around which the whole is developed. It is also in close relation externally with the central lobe, anteriorly and below with the substantia perforata antica, and internally with a smooth space below the beak of the corpus callosum, which might be called the "substantia lævis." In the descending corner of the lateral ventricle is an elevation corresponding to the dentate sulcus, called the hippocampus major; in the posterior corner is the hippocampus minor, or calcar avis, corresponding with the calcarine sulcus; and between the two is placed the eminentia collateralis, or pes accessorius, corresponding to the collateral sulcus.

THE PROPOSED ENLARGEMENT OF THE LONDON HOSPITAL.

THE Building Committee of the London Hospital have issued a valuable report on a proposed plan for enlarging their institution, which we would print *in extenso* if we had the space. Their receiving-rooms are too small for comfort, or even decency.

"The space allotted for all classes of in-patients is so limited, that the following evils may be noted as immediate results:—

"Only the worst cases can be received. These swell the mortality of the Hospital, and keep out cases far more capable of relief. Governors are thus subject to frequent annoyance from rejection of cases; patients suffer from repeated disappointments, prolonged anxiety, and unavoidable expense; wards are so overcrowded, that not only is the cubic space hitherto apportioned for each patient materially reduced, and the chances of individual benefit so far lessened, but the general economy of the Hospital (involving the arrangements and duties of Medical officers, nurses, and servants, and facilities for cleansing and ordinary repairs) is virtually set at nought—instability and uncertainty prevailing in every department.

"In the out-patient department increased space is most urgently required. Proper ventilation, facility of classification, convenience of Medical and Surgical treatment, and of subsequent dispensing and dressing, together with a decent and proper amount of comfort for the poor, during their lengthened detention in the waiting halls, are all things to be desired in the out-patient department.

"Inability to provide sleeping accommodation for night nurses is subversive of that control which the Hospital should have over the movements of this important class of servants; it materially lowers the standard of the women who can be obtained for night duty in the wards, and lessens their efficiency while engaged in that duty.

"The Hospital has been twice increased as to accommodation for patients, without any provision being made for the largely increased resident staff; and from this cause great inconveniences are experienced. Officers cannot be located so suitably for their work as they ought to be, and no apartment can be allotted for a waiting-room, consulting-room, or extra bed-room, however urgently required."

The Committee say, with regard to the proposed enlargement, that—

"Space for about seventy additional beds is given in the ward arrangements of the proposed new buildings, such beds being intended to be allotted for children, Physicians' male and female patients, obstetric cases, and for male and female Hebrew patients, and their general establishment,—the removal of these cases from the old portion of the building, leaving vacancies where they are most required, and capable of immediate and economical adaptation.

"The Building Committee learn from the surveyor that the maximum cost of the new building will be about £21,000, and that of the requisite alterations of the old about £4,000. This estimate, however, it is believed, will more than cover every possible contingency.

"The following facts are worthy of note:—

"1st. That under similar circumstances, in 1843, when the last enlargement of the building came into operation, *an immediate decrease of mortality was the result*. It fell at once from 10 per cent. to 8, and ultimately as low as 6 per cent. It has now again gone up as high as $8\frac{3}{4}$ per cent.

"2nd. That between the enlargement of the Hospital in 1830 and that in 1840, the patients had only increased from 8419 to 12,812; while between 1840 and 1863, the increase has been from 12,812 to 30,009.

"And lastly, That while the funded property of the Hospital is now £241,000, in 1840 it was only £194,000 (including £1200 per annum terminable in twenty years).

"The Building Committee would only further urge, believing it to be within the scope of their instructions, *that the establishment must not continue to be worked, as at present, upon its present basis*. The entire system is one of undue pressure, subversive of sanitary arrangements, inconvenient to the Professional staff, unfair towards the patients and the servants of the Hospital, and delusive as regards the advantages offered to governors and the public. Either certain portions of the Hospital must be definitely closed to further admissions—an evil much to be deprecated, and a regulation, moreover, which cannot apply to accidents, whether coming as in- or out-

patients—or the wants of the vast population surrounding the Hospital must be more adequately met; and the Building Committee are not without a reasonable expectation that the requirements of this charity, genuine and legitimate as they are, will not be disregarded when duly made known to its supporters and the public generally."

We can only express our belief that the sacrifice of a tenth of the funded property will be a very cheap price to pay for improvements such as these which the Committee wisely desire to attain.

THE MEDICAL PROFESSION AND CERTIFICATES OF LUNACY.

THE very difficult and unenviable position in which the Medical Practitioner is placed when called on to sign a certificate of lunacy, has been illustrated by so many instances during the past year or two, that the subject has necessarily become one uppermost in the minds of all who have the interests of the Profession at heart. The law imposes the duty of signing such certificates on the Physician or Surgeon, and rightly so, for he belongs to the only class of the community whose education and training qualify them for the exercise of that power. But it not only gives him no protection in the performance of the duty, but visits him with heavy penalties in case of abuse or error. We are quite alive to the necessity of guarding the public from an improper exercise of the power reposed in the Profession, but we hold that no Medical Practitioner should suffer for mere mistake. We are glad to see that the College of Physicians of Edinburgh has taken the initiative in this matter; and we trust that their efforts to secure the immunity of the certifier in cases where neither wilful error nor carelessness are proved, will meet with powerful support from the other Medical corporations and from the Medical Council.

At an extraordinary meeting of the Royal College of Physicians of Edinburgh, held on February 19, 1864, the following resolutions were moved, seconded, and unanimously agreed to:—

"1. That the Royal College of Physicians of Edinburgh recognises it to be its duty, in accordance with its original charter (1681), to promote Medical science, and also to protect the interests of the Medical Profession and of the public; and that, accordingly, the College has endeavoured, on various occasions, to establish a sound relation between the Profession and the public in the matter of certificates in lunacy.

"2. That the duty of signing certificates in lunacy is one at all times painful and disagreeable, and one peculiarly liable to bring the Medical man discharging it into collision with the patient or his friends; and therefore one, of which, were it practicable, the College feels satisfied the Profession would gladly be relieved.

"3. That the duty of signing certificates in lunacy appears, nevertheless, to the College, indispensable as a part of Medical practice; and that both the public interest and the welfare of the insane themselves require that it shall be performed as freely as is consistent with proper securities against abuse.

"4. That the peculiarity of the position of Medical men in signing such certificates is, that they are thereby brought in contact with persons who are not in full possession of their senses, and who, even after their discharge from an asylum, frequently retain a prejudiced or revengeful feeling against those by whom they were placed under treatment.

"5. That the Royal College of Physicians approves of every reasonable security being given to patients and their friends, in regard to confinement in asylums, and therefore was in favour of Section XXXVIII. of the Lunacy Act (Vict. 20 and 21, cap. 71), which provides that, 'If any person shall grant any such certificate or statement as aforesaid without having seen and carefully examined the person to whom it relates, at the time and in the manner specified in such certificate, with a view to ascertain the condition of such person to the best of his knowledge and power, he shall be guilty of an offence, and shall for every such offence be liable in a penalty not exceeding £50; and if any person shall wilfully and falsely grant any such certificate, to the effect of any person being a lunatic, the person so granting such certificate shall be guilty of an offence, and for every such offence be liable in a penalty not exceeding £300, or be liable to imprisonment for any period not exceeding twelve months.' Prosecutions for these

offences would be undertaken by a public prosecutor, who may be supposed to act without prejudice in the matter.

"6. That the Royal College of Physicians has repeatedly endeavoured, during the progress of recent legislation in lunacy, to secure the introduction into bills before Parliament, of clauses extending to Medical men some protection, unless in cases where they have signed certificates in lunacy without 'probable cause.'

"7. That the Royal College of Physicians is still of opinion that the legislature, which imposes by statute on Medical men the duty of signing certificates in lunacy, is bound to give them some protection in honestly endeavouring to discharge that duty. The College therefore instructs the Council to spare no efforts to secure the introduction of a clause affording some protection, into any measure which may be brought before Parliament during the present Session."

PARLIAMENTARY.

ON Thursday, February 18, in the House of Commons, Lord Naas wished to ask the right hon. gentleman the Chief Secretary for Ireland a question with regard to the extraordinary correspondence published in the newspapers as having taken place between Sir R. Kane, Dr. Bullen, and the Irish Government. Had the annual report of the President of the Queen's College, Cork, for the present year, yet been presented to her Majesty, or laid upon the table of the House? Did that report contain the whole of the correspondence which had taken place between those gentlemen and the Irish Government; and if not, would the right hon. gentleman have the kindness to produce the entire correspondence?

Sir R. Peel said the report of the President had been presented yesterday, and laid upon the table of the House. Some other correspondence had taken place, not between Sir R. Kane and the Irish Government, but between the Inspector-General of Constabulary and Dr. Cullen (laughter)—he meant to say Dr. Bullen; and there would be no objection to produce it if the noble lord wished.

Lord Naas: Am I to understand that that correspondence was published in the newspapers before it was presented to her Majesty?

Sir R. Peel: The correspondence was not published by the authority of the Irish Government. It did, I am sorry to say, appear in the newspapers before the report was laid on the table of this House.

Sir G. Grey asked leave to introduce a bill, founded on certain recommendations of the Commissioners who were appointed to inquire into the operation of the Acts under which sentences of penal servitude may be passed. In the opening of his speech he adverted to some points of a general character, referred to in the report of the Commissioners. The first of these was the statistics of crime. He said that, notwithstanding the increase of crime which had taken place in England and Ireland during the two years previous to the appointment of the Commission, and the prevalence of robbery with violence in the metropolis towards the end of 1862, there had been, during the last twenty years, a considerable diminution of crime, although, during the latter portion of that period, transportation had been almost discontinued, and the population had greatly increased. With respect to the numbers of robberies with violence in the metropolis, in the last six months of 1862, there were fifty-two cases, while, in the last six months of 1863, there were only twenty-six cases. Sir G. Grey attributed this diminution, not to the law by which corporal punishment is now inflicted for this crime, but to the fact, that the gang of persons by whom he believes it was chiefly perpetrated have been all apprehended and brought to justice. The next point he noticed was the treatment of prisoners sentenced to penal servitude, which, he contended, on the evidence of the Commissioners, was not of that lenient character that had been asserted. He quoted the following passages from the Report:—

"A very general impression appears to prevail that the system pursued in these prisons is not of a sufficiently penal character. It has been said that but little work is done by the convicts; that their diet is excessive; that they receive unnecessary indulgences; that their material condition is, in many respects, better than that of free labourers; and that, consequently, the punishment cannot be severely felt. We consider that, upon the whole, this impression is erroneous. The life of the prisoners is extremely monotonous. Having been used, in most cases, to constant change and excitement, they are debarred from all pleasures and amusements; they

are compelled to pass their time in a dull, unvarying routine of distasteful labour; and, at the close of each day's work, they return to the cheerless solitude of their cells. The work which they get through is, no doubt, less than what a regard for their own interest induces free workmen to perform, but the labour is by no means light, as we shall show more fully presently; and, considering the previous habits and character of the convicts, and that they are working under compulsion, there can be no doubt that it is much disliked by them."

Further on in the Report the Commissioners said:—

"We doubt whether any great augmentation of severity in the treatment of convicts during their punishment is practicable, especially when we consider that the imprisonment lasts, in many cases, for several years. The prolongation of sentences must, we think, be chiefly trusted to for increasing the fears entertained of penal servitude by the criminal classes."

With regard to the amount of labour performed by the convicts, the testimony of the commissioners proved that it was as much as could be reasonably expected from men without previous training and practice, and not working under the stimulus of remunerative wages. The recommendations in the Report of the Commissioners were of two classes. The first related to matters of administrative detail; the second to matters which rendered an alteration of the law necessary. The first recommendation of this class was, that sentences of penal servitude should not be for a shorter period than seven years, and the Government entirely concurred in the opinion that short sentences should be abolished. With the foregoing recommendation another was connected, that certain of the male convicts should be sent to Australia. Although the Commissioners were, in his opinion, fully justified in making this suggestion, it had awakened so much alarm and opposition in those colonies, that her Majesty's Government thought that, under all the circumstances, it would be undesirable, for the sake of a remote advantage (while asserting the undoubted right of the Crown), to enter into a contest with the colonies, and to insist on doing what was distasteful to them. On the whole, the Government, in declining to act upon this recommendation, thought it expedient to adopt in the bill five years as the minimum term of a sentence of penal servitude. Another recommendation in favour of remissions of parts of sentences, as a reward for good conduct, had been dissented from by the Lord Chief Justice, but he thought the preponderance of the evidence was in favour of the principle; the Government, therefore, thought that it would not be expedient to alter the existing practice of granting licenses, revocable in cases of misconduct. Another recommendation in the Report related to the consequences that should attach to a breach of a license, and Sir George stated the conditions which the bill would annex to the grant of licenses. He explained, in conclusion, some of the minor details of the bill.

After a long discussion on the question of transportation to the Australian colonies, and on that of licenses or tickets-of-leave, permission was given to introduce the bill.

Leave was given to Mr. W. Ewart to bring in a bill to render permissive the use of the metric system of weights and measures in this country. The bill was read a first time.

On Friday, February 19, in the House of Commons, Mr. W. Ewart gave notice that on the first opportunity after Easter he would make a motion for the repeal of the punishment of death.

On the motion of Lord Hotham, an address to the Crown was agreed to for a copy of any letter or memorandum (other than the memorandum dated Horse Guards, February, 1863, now upon the table of the House, Parliamentary Paper No. 406 of Session 1863), signed by the Adjutant-General of the Forces, and addressed to the Commander-in-Chief in India, between the 18th day of December, 1862, and the 1st day of June, 1863, in which his Royal Highness the Field Marshal Commanding-in-Chief is stated to have modified his opinion on the remarks of Sir Hugh Rose on Dr. Turnbull, Surgeon of the 6th or Inniskillen Dragoons; and an address was also adopted for a copy of an order or memorandum, dated Horse Guards, January 14, 1864, and signed by the Military Secretary to his Royal Highness the Field Marshal Commanding-in-Chief, on the subject of the late court-martial on Lieutenant-Colonel Crawley, 6th Dragoons.

The House went into Committee on the Insane Prisoners Act Amendment Bill.

On clause 2,

Mr. G. Hardy said that if the word "death" in the second

line of the second clause were omitted, it would have the effect of raising the question which he was anxious to discuss. The operation of the bill ought to be confined to the period between conviction and execution; and, if it were intended by the Government to deal with the question of insanity either at the time the offence was committed, or at the subsequent period of arraignment, that end ought to be attained by some different machinery. He did not think that any inquiry consequent upon the certificate of the visiting justices ought to be by a jury. A jury required the direction of a leading mind, and he was far from being satisfied that they were easily directed to a right conclusion. In a pamphlet by Dr. Hood it was stated that, in the six years from 1852 to 1858, 120 persons were tried for murder or attempts to murder, or for acts of personal violence, and were acquitted on the ground of insanity. Of that number, seventy-nine were received into Bethlehem Hospital, and in several instances they exhibited no symptoms of insanity during their residence in the asylum. That showed the way in which juries acquitted prisoners where there was no ground for saying they were insane; and the risk would be greater if their decision in favour of sanity was to be immediately followed by the punishment of death. He thought that when a man had been convicted by a jury of his countrymen, he should be dealt with as a State prisoner, and that the State should undertake the charge of investigating the condition of his mind. When the visiting justices certified that a prisoner had become insane, commissioners should be sent to call such witnesses as they deemed fit, and upon their report the Secretary of State should act, without any responsibility attaching to him. The mode which he should propose in a subsequent amendment, of sending three commissioners, not more than one of whom should be of the Medical Profession, was better than that of a jury, which was suggested in the amendment of his hon. friend. He begged to move the omission of the word "death" in line 12 of the clause.

Mr. Neate suggested that it should rest with the governor of the gaol, as well as the visiting justices, to put the machinery of the law in motion. In many respects the governor was a better person to exercise the power than visiting justices, who were frequently selected merely on account of their near residence to the gaol. In his opinion, the law with regard to insanity was very unsatisfactory. In the eye of the law, normal and habitual insanity was no defence whatever. The question considered was, whether the prisoner was insane at the time the act was committed and in reference to the circumstances under which it was committed. The inquiry should be, not whether a prisoner had become insane since his conviction, but whether he was habitually and normally insane, which was, and ought to be, a sufficient ground to exempt him from punishment.

Mr. Macdonough approved the amendment of his hon. friend. He thought that the matter in question ought not to be committed to visiting justices, and that a commission would be a much better mode of instructing the Secretary of State. The commissioners ought not to be Medical men, but should have the power of taking the evidence of Physicians and experts if they thought necessary.

Sir G. Grey said he had considered the amendment of the hon. gentleman very carefully, but he had failed to satisfy himself that it would be an improvement. Suppose a man charged with a capital crime, but not yet put upon his trial. If the amendment were adopted, the very day before his trial he might be examined by two visiting justices and two Medical men, and the Secretary of State would be bound to act upon their report. The hon. member proposed, not that there should be a representation by the visiting justices of a prisoner's insanity, but that they should certify to the fact of his insanity. This would be the only instance in which two laymen, as distinguished from Medical men, had been proposed to be employed to certify the existence of insanity. There were cases in which two Medical men might sign, and others in which visiting justices and Medical men might jointly sign, but none in which laymen were to sign alone. To that extent the hon. gentleman proposed an innovation on the existing law, because, although the opinion of laymen in cases of insanity was of value, it ought not, in his opinion, to be entirely unconnected from that of Medical men. He had sent down a commission very much like that proposed by the hon. gentleman to inquire into Townley's case. It was composed of two laymen, members of the lunacy commission, and one Medical man, and what was the result? They produced a report which was evidently a compromise. If the present bill had then been the law, with the hon. gentleman's amendment, the certificate of

this commission would have been final, the Secretary of State would have had no discretion, and he must have transferred Townley to a lunatic asylum. He thought it would be better that there should be a certificate from the visiting justices and the Medical men, and that the Secretary of State, being thus put in motion, should appoint those persons whom he thought best qualified to examine the prisoner and report to him. The course pointed out by the hon. gentleman was open to great objection, and he could not give it his assent.

Lord R. Cecil said that the right hon. gentleman, in objecting to put prisoners under sentence of death in a different position to other prisoners, had failed to notice the peculiar state of public opinion with regard to these prisoners. Among a small section of the public there was a strong opinion against the punishment of death, and that feeling was entertained so vehemently that no scruples would prevent some people who shared it from putting into work all the machinery which might exist for the purpose of saving a criminal from his fate. It was necessary, therefore, to treat the position of these prisoners as exceptional, and to take special precautions to prevent people signing their names to statements which they did not believe, for the sake of getting them off. The weak point of every such tribunal as that proposed was, that it would consist more or less of Medical men, and the Medical and legal theories of insanity entirely differed from each other. He was convinced that we should never arrive at a proper condition of the law, and never relieve the Secretary of State of the constant obloquy cast on him, except by having recourse to the ancient and tried system of trial by jury.

Mr. Neate said, that in a conversation he had had with Dr. Forbes Winslow that morning, that distinguished Physician told him that he had lately subjected three patients under his care, all hopeless and incurable lunatics, to the test laid down by Baron Martin—that they should know the nature of an offence, and the legal consequences which would flow from it, and all three of them had given such answers as would have placed their lives in jeopardy. "If you were to shoot a man with a pistol, what would be done to you?" was the question he put; and one answered that he should be hung, the second that he should be hung here, but guillotined in France, and the third said that he should be hung only that he was a lunatic. Nothing could rescue us from a continued difference between the present state of the law and common sense and humanity, but an inquiry which would reconcile all the conflicting views on the subject.

Mr. Hardy said if there was any error in the administration of justice, it was rather on the side of acquittals on the ground of insanity than improper conviction of lunatics. (Hear.) This bill should be confined to questions arising after conviction. It would be much better that Medical men should be called in as witnesses than as judges. Both theoretically and practically, the Medical man would take a very different view from what a jury or barrister would take. But what the House had practically to decide on was this, whether a man under sentence of death should be treated in the same way as a man under sentence of a few weeks' imprisonment or penal servitude. Should there not be, once for all, an investigation into his sanity, and with as little delay as possible? If a judge and jury were to be called in, it could not be done promptly enough, for the judges might be otherwise engaged. For these reasons he had come to the conclusion that it was necessary that commissioners should be sent down forthwith, and should certify to the Secretary of State. What he wished the Committee to determine now was, whether the word "death" being struck out of the clause the investigation should be by judge and jury or by a commission?

Mr. M. Smith supported the proposition of a jury. If the inquiry were not so conducted, it would be better to leave the whole responsibility to the Secretary of State.

Sir G. Grey believed that if the question of the sanity of a prisoner under sentence of death must be submitted to a jury, before whom, of course, lawyers on both sides would appear, so much delay would occur that it would become impossible to carry out the capital sentence; and he entirely agreed with the hon. and learned member for Leominster that the adoption of such a plan would only be affording the means of evading the execution of the law. With regard to the proposition before the House, he thought it was right, in the first instance, to require a solemn declaration from the visiting justices and Medical men of the insanity of the prisoner, and then the Secretary of State, on his own responsibility, which he could not shrink from, would take that course which he deemed best calculated to satisfy the requirements of the case. With

regard to the observation that the words, "if it should appear," might mean "if it should appear to anybody," he wished to say that he believed there was no doubt that the true construction of those words was that the matter in question must appear to the persons who were to act.

Mr. Hunt wished to know whether, after the present bill was passed, the law would be in any better position than before? He did not believe the public would be satisfied if they saw the deliberate decision of judge and jury reversed by the certificate of four gentlemen, however respectable or conscientious, who had held a private hole-and-corner investigation. (Hear, hear.) The question was, whether or not the prisoner had become insane since he was tried?

Sir G. Grey: No; since he committed the crime.

Mr. Hunt demurred to that. He understood that the whole of the prisoner's career would be brought under the notice of the jury up to the time of the trial. It seemed to him that, under this bill, if a prisoner under sentence of death could only persuade the Surgeon of the gaol that he was mad, he would save his life; for the Surgeon was bound to bring the matter before the justices, and his opinion would be sure to have almost irresistible weight with the latter. As to the other Medical evidence, one of the mad-doctors would probably be called in, and he looked with great suspicion on their testimony. Dr. Winslow had based his opinion of Townley's insanity on his perverted moral sense, but in that case every great criminal must be insane. He did not desire to cast any reflection on Dr. Winslow, who was said to have refused a fee for his evidence, and who, no doubt, gave it conscientiously. The fact was, the Doctors in the department of Medical science themselves ran mad in regard to the question of insanity. He doubted whether there was a single gentleman in the House who would successfully come out of the ordeal of an examination by them, and should not like to try the experiment himself. For the sake of the Home Secretary, his duties in this matter ought to be precisely defined. He thought there ought to be a distinction between the cases of prisoners under sentence of death and those under lighter sentences, because in the former case there were much stronger motives for imposition, which demanded greater precautions. He hoped the right hon. gentleman would consent to exempt prisoners condemned to death from the operation of the bill; and, however he provided for that class, he trusted there would be a full public inquiry.

After some remarks from Sir C. O'Loughlen,

The Committee then divided, when there voted—

For the amendment	32
Against it	26
Majority	—6

The word "death" was, therefore, retained.

Mr. Hunt regretted that the important discussion which had just taken place had not occurred in the presence of a greater number of members. Considering the small majority by which it had been decided to retain the word "death" in the clause, and considering also that some of those who had voted in that majority had not heard the discussion, but had come in to vote, he would urge upon the hon. member for Truro or the hon. member for Leominster to raise the question again upon the report, in order that the House might have an opportunity of reviewing its decision.

The clause was then agreed to, as were also clauses 2, 3, and 4.

Mr. G. Langton moved the insertion of a clause, placing the charge for the maintenance of insane prisoners upon the common fund of the Union.

Sir G. Grey assented to the proposal, which was then agreed to, and the House resumed.

On the motion of Mr. Bruce, leave was given to bring in the following bills:—Bill for the amendment of the law relating to the importation of diseased cattle and unwholesome meat; and a bill to make further provision for the prevention of infectious diseases among cattle.

The bills were subsequently introduced and read a first time.

On the motion of Mr. Villiers, the select committee to inquire into the administration of the relief of the poor under the orders, rules, and regulations issued by the Poor Law Commissioners and the Poor Law Board, pursuant to the provisions of the Poor Law Amendment Act, and into the operation of the laws relating to the relief of the poor, was reappointed.

On Tuesday, February 3, a discussion on the present system of treating convicts under sentence of penal servitude, followed on a motion by Lord Salisbury for the number of

that class of prisoners confined in gaols, other than Government prisons, in 1862 and 1863. The returns were ordered.

In the House of Commons, in answer to a question by Sir J. C. Jervoise, in reference to the vaccination of sheep,—

Mr. Lowe said: The experiments in vaccinating sheep concluded last Michaelmas; and I am sorry to say the result is exceedingly unsatisfactory. I am also sorry to say that the report is not yet ready to be laid before Parliament. As I am not able to produce the report, I may state its general effect. The experiments that have been made are of two kinds. One has consisted in vaccinating sheep with lymph taken from the human subject; and this has succeeded in some measure. The sheep took the disease, though in an irregular and abnormal form; but when we came to test the value of that vaccination, we found that the sheep took the virus, either by inoculation or in the natural manner, from other sheep; so that vaccination thus accomplished appears to be futile. The next plan was to inoculate cows with matter taken from sheep, in order, if possible, to produce a vaccine disease in cows, which would stand in the same relation to sheep as cow-pox does to the human subject. But we entirely failed in producing that disease; and, therefore, the result of the experiments was altogether unsatisfactory.

On the motion of Mr. S. Fitzgerald (in the absence of Mr. Arthur Mills), an address to the Crown was agreed to for a return showing the expenses occasioned by the court-martial on Lieutenant-Colonel Crawley, distinguishing the proportions to be defrayed from Imperial and Indian revenues respectively.

Mr. Hibbert called attention to the demoralising effects of public executions. He dwelt upon the arguments ordinarily urged against public executions—the disorderly assemblages they collected, the disgraceful scenes that sometimes took place on those occasions, their failure as examples upon the criminal population, and their brutalising effect upon the lower classes. He proposed that capital punishments should not be made a barbarous spectacle in public, but be inflicted as in Germany, America, and Australia. He concluded by moving for papers.

After some observations by Mr. Hadfield,

Sir G. Grey said this question had been brought before the House by a gentleman no longer a member of the House, who had brought in a bill to substitute private for public executions; but he failed to convince the House that it was safe or expedient to adopt the measure. After a passing allusion to the execution on Monday of five men—not Englishmen, but foreigners—for a barbarous murder, under circumstances which led the perpetrators to expect impunity, he contended that Mr. Hibbert was wrong in supposing that public executions had no deterring effect and that they failed as examples, and he insisted on the evils which would attend the mode of execution he had proposed to substitute for them. He hoped the House would not be induced to accede to Mr. Hibbert's views; he was not prepared to consent to any alteration of the law.

Alderman Sidney complained of the recent execution, insisting that the culprits should have been sent to the outports.

Lord H. Lennox, while he agreed with Sir G. Grey, described and animadverted upon certain disgraceful scenes at the late execution.

After a short discussion, the motion was withdrawn.

Sir G. Grey moved that the report on the Insane Prisoners Act Amendment Bill be agreed to.

Mr. Hunt said that when the bill was in committee he had stated that "Dr. Forbes Winslow had based his opinion of Townley's insanity chiefly on his extraordinarily perverted moral sense." It had been represented to him that this was not a correct statement of Dr. F. Winslow's theory of the case, which was that there was great moral obliquity in Townley, and with this a mental aberration; and, viewing these conjoint conditions, Dr. Forbes Winslow came to the conclusion that he was not of sound intellect. He (Mr. Hunt) did not see much variance between this correction and what he had himself stated, but he was anxious not, in any degree, to misrepresent Dr. Forbes Winslow to the House. He protested against moral obliquity being taken into consideration at all in estimating the sanity or insanity of a prisoner. (Hear, hear.)

The report was then agreed to.

On Wednesday, February 24, the House of Commons went into committee on the Malt for Cattle Bill. The discussion turned principally on the propriety of repealing or diminish-

ing the malt tax, and not on the scientific question of the value of malt as a cattle food.

The Insane Prisoners' Act Amendment Bill was read a third time and passed.

THE BITTERNESS OF DEATH.

THE late execution of five pirates at the Old Bailey has inflicted a very painful wound on society, and has caused the propriety of capital punishment to be questioned in many a mind which heretofore acquiesced in it without suspicion. For our own parts, we hold to the doctrine that life may be taken in self-defence and in vindication of Law; hence, that war is justifiable for adequate cause, and likewise the execution of criminals who have taken or attempted to take human life. Nevertheless, there are great "searchings of heart" in the matter. Many of those who approve of the punishment of death, disapprove of public executions; and for ourselves, having once witnessed an execution in a country town, we can say, that the appalling part of the scene to us was not the death of the criminal, but the crowds of young persons of both sexes, who came trooping in from the neighbouring villages to the *Hang Fair*, as it was called, and who came to that as they would to a prize fight. To us it seems that the idea of any moral benefit to such spectators must be founded on ignorance or hypocrisy. Cruelty has its fascinations even more than lust has; and it is the gratification of the lowest animal passion, rather than the seeking a high moral lesson, which, as we affirm, animates most of the spectators at an execution, and especially the women. We will not dwell on the circumstance, that these pirates belonged to a low, uneducated, brutalised class, and one whose brutality is ingrained by the treatment they too often receive—let us hope that the next ship captain convicted of cruelty may be hanged too. But, we may remark, that the most appalling part of this horrible tragedy is not the conduct of the mob, nor the struggles of the dying, but the too faithful account which the *Times* gives of the mental agonies of the poor wretches as they were being prepared for the scaffold. Here is the true bitterness of death; here lies the fascination to the lookers-on. Of Watto, it is said that—

"He looked perfectly resigned and subdued as the hangman drew the straps and buckles rigidly around. When it was done, he asked for the turnkey who had watched over him since his conviction, and when he at once came forward, tried to shake hands with him and kiss him on the cheek. But the gaoler, almost shuddering, drew back from the salute, and then, and then only, did the wretched young man seem abashed and cast down beneath the ignominy of his position; nor did the explanation of his clergyman, that such farewells between men were not customary in England, seem at all to relieve the confusion and despondency with which he retired slowly to his cell. The next to step forth from his room was Lopez—the adviser of all the murders, the determined perpetrator of at least one—the worst-looking in countenance, and to the very moment of his death the most defiant in gesture and in bearing of them all. Not for a second did his mere swagger, if we may use such a term at such a time, impose on those accustomed to see really brave men going to their death. So unsteady was he, that every movement, even the least the hangman made to buckle the straps around him, threatened to tilt him over; his fingers were almost buckled in the way the hands were clasped together; his eyes sought every face with an anxious, dreadful glance; his lips trembled, though he tried almost incessantly to wet them with his parched tongue; but in vain. Duranno, who so cruelly assassinated the mate, was the next to come out, and he, like the two that followed him, were what are called Manilla men—that is to say, they were born in the East, and spoke indifferent Spanish. They were all, however, of the pure Tartar type—flat nosed, small eyed, with low, retreating foreheads, and heads thickly covered with masses of lank black hair, like those of the North American Indians. Duranno was the first who showed signs of fear. Watto was resigned; Lopez was defiant; but Duranno seemed blanched by his fear to a dull clayey hue, that was worse to look upon than the pallor of death itself. Still, though his lips kept

shivering, and his eyes reeled, he seemed to bear up till the hangman removed the sailor's necktie, and undid the collar of his shirt. Then the death that was so near seemed to come upon him in all its bitterness, and he crept together with his limbs, and spoke a few words, in almost piteous tones, to the Roman Catholic clergyman who was with him. Blanco was even worse than this. Large beyond all the rest in stature, an overmatch for almost all the others in mere brute strength, the man who had taken the most conspicuous and relentless part in all the murders, who had struck down the mate, and boasted of having thrown him while praying for mercy into the sea, who had stabbed the captain in his sleep, and beaten the captain's brother till his very corpse was shapeless, came out from his cell as if the very agony of death was on him, so strongly did he show his fear. He seemed helpless as he was being pinioned, and sighed heavily. He, like Duranno, shuddered as his neckerchief was removed, but seemed gratified that two little copper crucifixes, which he wore round his neck, were allowed to remain. He kept trying to wet his lips with his tongue, and rolling his eyes up above him on every side, looking, as it seemed to those around, for the scaffold on which he was to die. Leone, or Lyons, as he was called, was the last to come. Without any show of fear, but with much of sorrow, he stepped into the corridor and was pinioned, looking, as he showed himself throughout, a resigned, and apparently deeply repentant man. He said that he quite admitted the justice of his punishment, but until then he had never seen how wicked his crime had been, or how deserving it was of death. All the prisoners have stated to the sheriffs since their condemnation, that they would never have been driven into mutiny and murder had they not been nearly starved and kept on a pint of water a-day while in the tropics. After such statements it seems incumbent on the owners of the ship *Flowery Land* to prove how she was victualled and watered for her voyage to China, and what was the actual provision made for the crew, almost the last of whom died yesterday.

"When they had actually come to the gibbet, Duranno and Blanco leant back faint, and the others seemed to listen with dreadful faces, now looking up to where the clang of the bell came down upon them, then glancing with quivering lips through the passage which just let in the daylight and the noise of the crowd. Scarcely a minute was thus passed when the hangman returned and hurried out with young Watto. Perhaps at the sight of his comrade in guilt thus borne away, perhaps at the sound of the mob without, Duranno turned pale and faint, and asked for water. Water and brandy both were brought, and Duranno and Blanco both drank a little of the spirit raw, and were then hurried off. Lopez was called next, but as he rose there was a half shout, half scream from the crowd outside, for Blanco, the most powerful of all the murderers, and supposed to have been the most hardened, had fainted with the rope round his neck, and was, in fact, hanging till the warders ran back to fetch a chair, in which the wretched man was propped up till the drop fell. Lopez and Leone now remained alone on the bench, Lopez careless as usual, though quiet—Leone resigned, and apparently absorbed in thought and prayer. Again Lopez was told to rise, but again there was a delay, of which he took advantage to ask for something to drink. Water was put to his mouth, but he spat it out, and turned away his head, though the feverish eagerness with which he swallowed some brandy was awful to behold. Then he rose, and as he stood hearing the bell toll his desperate spirit at last gave way, and his eyes filled with tears, which he tried in vain to raise his pinioned hands to wipe away. Then he, too, went out with a light, jaunty step, and was almost immediately followed by Leone. There was deep silence now within and without the gaol. In another instant there was a heavy sound, and all turned away, while the gibbet creaked audibly, for the five murderers hung dying side by side. There was a dreadful pause inside for a minute or two, during which all spoke in whispers, as if in a sick chamber. Then the creaking ceased, and the hangman came slouching in, and his return was taken as a sign that all was quiet now."

The common remark is, that Englishmen would have showed more "game." Even in the case of the bravest and most innocent man, some signs escape of the agony within. The unfortunate Major André, "when waiting near the gallows, evinced some nervousness, putting his foot on a stone, and rolling it, and making an effort to swallow, as if checking an hysterical affection of the throat." These, however, were but

the slight reactions of natural infirmity, and he died praying those about him to bear witness that he met his fate like a brave man.(a)

FROM ABROAD—NEW ILLUSTRATION OF THE ANTIQUITY OF MAN—ACTION OF OXYGEN ON THE ECONOMY—M. BOUDIN'S CANDIDATURE AT THE ACADEMY OF MEDICINE.

MM. MILNE-EDWARDS and Lartet recently gave an account to the French Academy of Sciences of some interesting results as regards the antiquity of man derived from their visit to the Cave of Bruniquel, just discovered in the South of France. This natural grotto has evidently long served as the habitation of men unacquainted with the use of iron or bronze, but who possessed great skill in working bones by means of stone utensils. Within its precincts has been found an enormous quantity of the bones of reindeer, oxen, and horses, mingled with a multitude of objects of primitive industry and remains of several human skeletons. Of course, the co-existence of these objects in the same stratum is no proof in itself that man was the contemporary of the animals in question; for a convulsion of nature occurring at a period when the reindeer had ceased to inhabit temperate Europe might have brought objects of very different ages pell-mell together. But upon one of the worked bones, found at a considerable depth below the surface of the cave, were cut the outlines of the heads of a horse and of a reindeer, both perfectly distinguishable. Whatever may be the date of this sculpture, it must have been performed when the inhabitants of Bruniquel were familiar with the reindeer as a habitant of the temperate regions of Europe; and, therefore, it constitutes a proof of the existence of man in Gaul prior to its disappearance from these regions. All zoologists are agreed that such disappearance and the retreat of the reindeer to the circumpolar regions took place at an epoch anterior to historical periods; and, therefore, the Cave of Bruniquel must have been inhabited by man at an epoch prior to any of which history or tradition furnishes any account.

Having shown, in their former communication to the Academy of Sciences, that the chief effects of oxygen, employed experimentally on animals, is the production of great turgescence of the vascular system, unaccompanied by inflammation, MM. Demarquay and Leconte next relate the results of their investigations into its action upon man. In the first place, when applied locally to the surfaces of wounds, by the aid of special apparatus in caoutchouc, it induces a slight sense of heat and tingling, but no pain. After a few hours the suppuration becomes diminished in quantity and consistency, and the granulations assume a greyish colour, and seem less in size; but after the oxygen has been removed they again become red and turgescence; and if the applications be repeated for some hours at a time, several days in succession, a more or less vivid inflammation of the wound is induced. One remarkable effect of the oxygen, however, is the rapid manner in which it modifies the inflammatory or congestive redness which surrounds wounds. Through this property, the redness surrounding ulcers of the limbs, and the injection of the skin persisting after eczema, have been effectually removed. The bladder and tunica vaginalis have been injected with oxygen without inconvenience, hydrocele, in one instance, undergoing cure afterwards. The most interesting result of these researches is the action of oxygen when inhaled. The authors, their pupils, and their friends have been able to inspire a dose of from twenty to thirty litres without any inconvenience; and no accident has arisen from its use by a great number of patients during more than six months. Daily inhalations of twenty to forty litres during a month or six weeks have given rise to only a slight warmth of the fauces or chest, sometimes accompanied by a little intoxication or headache. In most persons, the pulse at first increases in number, but in some it becomes slower; and in general the inhalation is followed

by an increase of strength and appetite—of the latter sometimes to a remarkable degree. Patients exhausted by prolonged disease, however, do not undergo these modifications. Those who have wounds, either recent or old, after a few days' inhalation, find them become red and turgid, and suppurating more freely. This peculiarity explains the results obtained in phthisis by Chaptal and Fourcroy. Patients arrived at the third stage of that disease at first derived great benefit from the inhalations, but the inflammatory symptoms soon becoming more intense, with abundant expectoration and more frequent cough, death followed. It may be questioned how far this would have been the issue had the oxygen been inspired at an early period of the disease. These general conclusions are arrived at by MM. Demarquay and Leconte:—1. Oxygen applied to wounds, whether recent or old, causes little pain, but ultimately gives rise to a more or less vivid reaction. 2. It may be injected into the mucous or serous cavities without ill effects. 3. It may be inhaled in doses of 20 to 40 litres at one time daily, without inducing any accident. 4. Its essential property is to increase the strength, stimulate the assimilatory powers, and develop the appetite.

The list of candidates, arranged according to merit, presented to the Paris Academy of Medicine by the Section of Hygiene, in order that a new member of this section might be chosen, gave rise to warm altercations in the secret committee of the Academy, and caused the greatest surprise out of doors. The order of the presentation was—1. M. Delpech; 2. M. Dutrouleau; 3. M. Boudin, etc. All who were aware of M. Boudin's long-continued labours in the cause of public hygiene, and Medical statistics, and geography, and which have secured him an European reputation, naturally expected to find him heading the list, and came to the conclusion that causes other than the scientific claims of the candidates must have given rise to this strange marshalling. And it turns out that a curious motive has here been in operation. M. Boudin, it seems, is a believer in some of the extraordinary pretensions of animal magnetism, and the relegation of his name to the position it occupies was intended as a mark of academical disapprobation. Great as our regret and surprise may be that a man so long habituated to the habits of exact inquiry should countenance the delusions here reprobated, we cannot but protest, in the name of the rights of free inquiry, against this species of ostracism sought to be set up. It is not denied, even by those who oppose him, that his merits as a hygienist far transcend those of any other candidate at the disposal of the Academy; and it cannot be admitted that any views he may entertain respecting magnetism can militate against his efficiency as a member of an academy, in which men of any conceivable opinion upon every possible subject appropriately find their place.

THE RIBERI PRIZE.—The Royal Academy of Medicine of Turin announces that this prize (the most magnificent in money value in existence) of 20,000 lire—nearly £1000—will be adjudged to the author of the best work, whether in manuscript or published, which has been produced during the three years from the 1st of January, 1862, to the 31st December, 1864. Any subject in Medicine and Surgery may be chosen, the preference to be given to such work as exhibits a truly important progress in Medical science. The manuscripts or books must be written in Italian, Latin, or French, and of these last two copies must be forwarded. All works, which will become the property of the Academy, are to be delivered, free of expense, to Dr. Marchiandi, Secretary to the Academy, before the 31st of December; and their authors are requested to indicate the portions to which they most particularly wish to draw the attention of the Academy.

PREVENTING THE "TURNING" OF MILK.—A simple and effectual preventive of that disagreeable occurrence, so frequent in summer, "turning" of milk, is found in the addition of one gramme (fifteen grains) of bicarbonate of soda to each litre (about a quart) of milk. This does not affect the taste of the milk, while it facilitates its digestion. It constitutes the only means of preserving the milk employed by one of the large Paris milk establishments.

(a) Irving's "Life of Washington," vol. iv., p. 153.

SECOND IMPRESSIONS OF THE BRITISH PHARMACOPŒIA.

By A CHEMIST.

THE British Pharmacopœia has now been long enough before the Profession to undergo a candid and deliberate examination, and the result is a universal feeling of intense disappointment. In the elaborate criticisms to which it has been subjected—mostly by persons who have wished to give as favourable a view of it as is consistent with the claims of scientific truth and justice—so many errors, omissions, trivialities, and other faults have been pointed out, that when looked at in its more general aspect, in relation to the interests of the healing art and its professors, and the safety of the public, we are compelled to conclude that the Medical Council will have no other course open to them than to withdraw it as speedily as possible from circulation.

The production of a Pharmacopœia has occupied the Medical Council five years—no insignificant proportion of the active life of a Practitioner; and if we attach any importance to the declaration of the preface, they entered upon their task with a feeling of solemn responsibility, even approaching to awe. To the common reader, especially to one versed in the mysteries of compilation, the difficulties which they detail with great gravity appear simply ridiculous. They speak of numerous researches in chemistry, pharmacy, and natural history, and into the value of old and new remedies, carried on with the complex machinery of a “committee;” but of any results of these researches we find but a faint trace in the work itself. All the chemistry, botany, and natural history we can discover may be found in the hand-books of these several sciences, familiar to the loosest reader; and an ordinary compiler would scarcely earn his salt who should occupy five months in putting the matter together. The law of copyright was another “cause of delay,” obliging the Council to apply to the Legislature for an Act to secure it; and never was an Act granted to a corporate body more improperly. In the 444 pages of which the work consists, we defy any one to point out a single page of original matter. We are not told, however, that the Council attempted to include in the Act a prohibition under a penalty even to make a quotation. Prefixed we find ostentatiously set forth two sections of the said Act, which, let all concerned take notice, neither convey a copyright worth a farthing nor impart any legal authority to the work itself. We believe that every scrap of the Pharmacopœia may be printed, with a little acumen as to the form, without infringing the copyright. But it is not worth the trouble. There is another and a graver matter demanding attention. The Council, having expended the incredible sum of £6000 in the compilation, and willing to throw the odium of a gross act of injustice on to other shoulders, make the Lords of her Majesty’s Treasury fix the price to be paid for the work; and the said Lords, knowing, as they must needs know, the *wealth* of the Profession and of chemists, have made it half-a-guinea, thus mulcting a limited although large class of somewhere about £30,000 for the benefit of a small corporate body. Why not act in a fair spirit of trading, and let a publisher take the book and charge for it in some proportion to its cost? The trick, however, it must be allowed, is an ingenious one; and we may conjecture that its author or authors may be familiar with the esoteric principles of railway boards in the halcyon days of the “railway king.” We doubt if the British Legislature ever before taxed in such a manner a section of the community for the benefit of a few persons.

To turn to the book itself, as the Profession waited five tedious years for a work worthy of its reputation for learning and science, perhaps expectations were formed not having any very reasonable basis. That a corporate body framed like the Medical Council should be able to produce a work of the kind as satisfactorily as a single accomplished individual, ought not to have been expected. It would not be difficult to point out many such Physicians, Surgeons, or pharmacutists who could have compiled a really good and unexceptionable pharmacopœia. There is an inherent incapacity in a large board to proceed with harmony in prosecuting such a task. Differences of opinion arise which are irreconcilable, except by mutual concessions fatal to the value of the results; and the more trivial the matter under discussion, the more obstinately men adhere to their private opinions. This is strikingly illustrated in the case before us. The question was mooted,

whether or not any change should be introduced into the weights and measures in use in pharmacy? Numerous meetings were held and long discussions passed on this very simple and indifferent matter. The issue was, by a lucky but narrow preponderance of common sense, the adoption of imperial weights and measures,—those, in fact, used in all other arts and every branch of commerce. Even this triumph, however, must be marked by an absurdity—the abolition of the terms and signs for scruples and drachms, so useful as an abbreviation of twenty grains and sixty grains.

Finding themselves entrusted with the duty, under the Medical Act of 1858, of framing a British Pharmacopœia, the Council entered upon their task with views and an aim and purpose extremely narrow, and, as it appears, altogether erroneous. The ideal of an imperial Pharmacopœia entertained by the Profession generally was a work comprising a very complete list of substances, whether natural or artificial, employed as remedies within the limits of the British Empire, with clear and definite instructions for distinguishing the substances enumerated—either botanically or chemically; and, further, prescriptions or processes for preparing or compounding such substances in forms suited for use. To a certain extent, and in a limited degree, these purposes have been attempted; but, having no defined end in view, men often make out their deficiencies by haphazard and luck.

It has always been a subject of regret that the several Pharmacopœias of the three kingdoms were the production, not of the collected and collated experience of practical men in Ireland, Scotland, and England, but of small *coteries* in the respective Colleges. Nevertheless, we had, at least, the benefit of three sources of information. The Medical Council seem, so far as we can trace any aim in the Pharmacopœia, to have considered their business to begin and end when they had reconciled or adjusted the discrepancies and differences of the three old Pharmacopœias.

It is quite true that it was a crying and palpable evil to have medicines, on the use of which human life often depended, and designated by the same names, of such various degrees of strength, in the three provinces, that a prescription written in London might be a dangerous poison if prepared in Edinburgh or Dublin. But the redress and removal of this perilous discrepancy was but one, and that, perhaps, not the most important, purpose of an imperial work. In our opinion, this narrow and mistaken primary aim of the Council has vitiated the whole work.

For whom, and to what use is the British Pharmacopœia intended? We cannot discover. To take the most limited view of it, should we not anticipate that it would contain the desired account of remedial agents employed in their practice by the Physicians of the metropolis? In reality, it notices little more than half of them. On examining the files of prescriptions at the establishment of a pharmaceutical chemist, at the west-end of town, where, if anywhere, the practice of the leading Physicians will be represented, nearly 40 per cent. contained ingredients not found in the Pharmacopœia.

In the crowded eastern, southern, and northern districts and suburbs, we will venture to assert the proportion of substances in daily use, not noticed in the Pharmacopœia, will be found far greater.

If we further consider the provinces, colonies, and dependencies of the British Empire, we must conclude that this pretentious work scarcely contains one-third of the known remedies employed in the treatment of diseases.

The Medical Council have taken a very low estimate indeed of the resources of the healing art. We are familiar with a general scepticism respecting the power and efficacy of medicines professed by many persons; but we will venture to say it is by those whose experience is very limited, and that those who are daily brought into contact with disease and suffering, and are called upon to treat any considerable number of patients, entertain no such doubts. We have reason to believe the members of the Council are not sceptics. It may, perhaps, be an error on the other side, but we hold it to be more philosophical to assert, that the healing art will not reach the perfection of which it is susceptible until the action of every substance, whether produced by nature or art, upon the human constitution is accurately known.

Botanists tell us there are 200,000 species of plants recognised and described. The British Pharmacopœia enumerates 126 whence material is derived for the treatment of diseases. Of these, about forty are either common articles of diet—wheat, barley, raisins, etc.; flavouring matter—lavender, dill, cinna-

mon; or merely colouring substances—sandal wood, the red poppy, and the like, leaving about eighty-six plants as being, according to the Medical Council, the total amount of substances useful as remedies to be derived from the whole vegetable kingdom. We cannot object to this if they are all of which they know the use; but how partial a guide is the Pharmacopœia, and how little claim can it have as a legally-authorized exponent of therapeutics!

In the recently-issued Pharmacopœia of the United States of America, the number of plants laid under contribution for remedies is 258. In seeking for the causes of this strange discrepancy between the two works, we cannot discover any essential difference in the physiological and pathological doctrines professed in the two countries; but we find a very palpable difference in the manner in which the respective Pharmacopœias were compiled. The United States' Pharmacopœia is revised every ten years by a committee of delegates from, not only the Colleges, but all the societies existing for the promotion and intercommunication of Medical knowledge. In the intervals, a standing committee of Practitioners and pharmacutists receive, from any person and every quarter, information of new discoveries or improved processes for preparing medicines. They appear to examine and sift thoroughly and carefully testimonies respecting alleged remedial virtues of plants and artificially-prepared substances, and, when the evidence in their favour preponderates, admit them into the official list. We well know how easily mistakes are made on this subject—how apt men are to believe, on slight and insufficient grounds, they have discovered valuable remedies—and how necessary it is to bring to the test of repeated experience, in different hands, in various places, and many times, facts advanced by individuals.

If, in a decennial revision of a pharmacopœia, there are not found many things to admit, a few to reject, and alterations of processes to be described, the science of therapeutics must be indeed stagnant. The last editions of the Edinburgh, Dublin, and London Pharmacopœias bear the dates respectively of 1841, 1850, and 1851—the most recent being thirteen years', the oldest twenty-three years' old. What, then, has been accomplished in these long periods? If represented by the British Pharmacopœia, we find (confining our remarks at present to the vegetable kingdom) eight new plants introduced—Arnica, Bael, Bebeeru, Cusso, Kamela, Santonica, Pomegranate, and Podophyllum.

Four of the eight are considered to be remedies for tapeworm. Without much research, probably twenty substances might have been enumerated with an equal claim to the same properties.

Of Bebeeru, and its alkaloid Beberia, it may be observed that it was long ago introduced as an antiperiodic—as a substitute for quinia. Its nauseous taste and uncertain action has long since almost banished it from practice; and a long list of antiperiodics might be given, for the power of which far more testimony could be adduced than for this plant. On the medicinal virtues of Arnica, the evidence is most conflicting: whilst some say, "The sovereignest thing on earth for an inward bruise" is Arnica, others dispute this, and maintain that all its alleged effects are due to the spirit of wine—the vehicle of the tincture.

The only plant of indisputable value which the Medical Council recognise as a contribution to the list of therapeutic agents during twenty-three years, is Podophyllum. It is the introduction of Podophyllum, and the retention of several old remedies which are almost, if not altogether, abandoned in practice, which encourages the hope expressed above, that the Council is not wholly composed of Medical sceptics. But we naturally inquire if the action of Podophyllum as a chologogue is recognised, why exclude other plants extensively in use, and having a reputation for a similar action—Iris Versicolor, Leptandra Virginica? If the Prunus Laurocerasus is worthy of adoption from the Ph. Edin. as a natural source of amygdaline transformable into prussic acid, why not Prunus Virginiana? Why reject Cimicifuga Racemosa, now found in every shop, and so highly commended by Dr. Simpson, the introducer of chloroform? If Digitalis remains for its action on the heart, why refuse Veratrum Viride? The physiological action of this last is powerful, definite, and constant, and we have witnessed beneficial results in enlarged heart, with dropsy, from its careful use, which nothing else could possibly have effected. Lactuca has been ejected, apparently on the vague and unsatisfactory statement of Dr. Garrod, that he had tried it in coughs without benefit. We ask in what coughs? Because the testimony of Dr. Duncan, supported

by numbers of Medical men and verified by popular opinion, proves that in *some* coughs it is an effective and most valuable calmative. Professor Donovan considers hyoseyamus to be almost, if not altogether, inert. The truth is, that all so-called narcotics, soporifics, sedatives—except Opium and its alkaloids—have special actions; and a careful discrimination of symptoms, and choice of the right calmative agent, enables us to relieve suffering with promptness and certainty. We need more vegetable calmatives; and he would render a great service to practical therapeutics who would extend our list, and discriminate the special applications of each. Again, the Pharmacopœia has one parturient—Ergot, but in practice many are recognised. And thus we might proceed; but space would fail us to expose the omissions and shortcomings of the British Pharmacopœia as compared with the information really possessed by British Practitioners.

(To be continued.)

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF STAFFORD.

THE town of Stafford is presumed by some historians to have been originally built on an island. Plott, who, in the year 1676, published a very quaint and amusing volume, called the "History of Stafford," now an extremely rare book, gives a classical account of the "beginnings" of the town. In the narrative there is probably a nucleus of truth mixed with a more than common measure of amusing traditional fiction. The island on which the town was raised was anciently, he tells us, called Bethnei.

"It began first to be inhabited by St. Bertelline, the son of the king of this country (Kenred, King of Mercia), about the year 705 A.D. Bertelline was scholar to St. Guthlac, with whom he tarried until his death; after which, although now unknown to his father, he begged this island of him, where he led a hermit's life for divers years, till disturbed by some who envied his happiness, when he removed into some desert mountainous places, where he ended his life, leaving Bethnei to others, who afterwards built it, and called it Stafford, there being a shallow place in the river hereabout that could easily be passed by the help of a *staff* only."

Plott adds that the first castle was built by Elfreda, daughter of Alfred the Great, Queen of Mercia. She built the castle on the north of the river Sow, about the year 916. The present castle was built afterwards by Ranulf, or Ralph, the first Earl of Stafford.

We trace no other satisfactory account of the history of the town until the time of the Conquest; then we find it to be a large place, with a castle, burgesses, and bailiffs. William, with his well-known predilections for Norman rule, gave command of the castle to one of his followers, Robert de Toner, and added thereto a barony, which remained until the reign of Richard III., when it ceased for the time, with the political martyrdom of Humphrey de Stafford, Duke of Buckingham.

Like all other towns of importance, Stafford was originally fortified, and entrance to it was only possible by the usual four gates. During the Parliamentary wars in May of the year 1643, the fortifications were destroyed by Sir William Brereton, and an order was issued on December 22nd of the same year for the demolition of the castle. Modern Stafford may be said to have risen from that period; for after that the walls were never rebuilt, and the town extended untrammelled by fortifications, gateway, or moat. There is still, at a distance of about one mile from the town, an unfinished castle, recently founded on the ruins of that destroyed by the Parliamentary army, and forming a very conspicuous object, not wanting in effect. The district in which the town stands is low and damp; and a river, the Sow, runs near the town. During the months of winter, and after heavy falls of rain, the whole town is often flooded, and sometimes it remains so for eight or ten days; but the water soon disappears when the overflow ceases.

The appearance of the town is not inviting. The entire absence of any systematic plan of drainage leading to open drains in every street, the dull and narrow character of the streets themselves, the presence, in the main street, of two or three thoroughly old-fashioned English houses, with their overhanging, carved, and peaked frontages, and the true unartistic modern brick house, tend to give a motley character of old

and good, and new and bad architecture, which is singularly striking.

If any sanitarian exquisite wishes specially to be con-founded in his notions of modern progress and civilisation, he should go to Stafford on a very wet day, when a cattle fair is being holden. He can get the account of the fair from any almanack, and he may perchance obtain a prophecy of the weather from the clerk of that department, Admiral Fitzroy. I, for one, had the felicity, without any previous inquiry, of dropping into the town at the fortunate moment,—a pelting wet day, a cattle fair, no drainage, and no market-place for penning the lowing herds! It was a sight not to be seen without remembrance; the streets and pavements were actually monopolised by the bovines. The animals stood with their noses at the doors of the houses, as though they had knocked, had sent in their cards, and were only waiting for the order to walk upstairs. Fighting my way down a quiet street, tacking sometimes to the bow and sometimes to the stern of the impediments in the way, and going on tiptoe the while, to avoid other consequences, I met Pepper's Ghost (which had been figuring the night before at the "Lyceum"), borne along in agony by the smallest possible boy, who, for reasons best known to himself, had the largest cross of sticking-plaster I ever saw in my life on the bridge of his nose. The ghost evidently was astounded, and unhappy; it was only 125 miles from its own home in the Polytechnic, still the change was too much for it. It would have vanished, but its bearer, of the Excelsior type, held it too firmly, and carried it straightway towards the gaol, whither it seemed to enter, and appeared no more. Joking apart, it is absolutely sickening to see the town of Stafford on a cattle fair day; it is physically and positively unwholesome; and how the respectable inhabitants can tolerate having their door-steps turned into sale-blocks, and their pavements into manure heaps, is incomprehensible.

A good trade is carried on at Stafford, the chief manufacture being shoe-making. This last-named branch of industry has long been the "staple" of the town; and a good story relating to it is told of Sheridan, who was in his day member for Stafford. At one of his election dinners he gave as a toast, "May the manufactures of Stafford be trodden under foot by all the world." Within the last year, factories for the shoe trade have been introduced, and sewing machines; and, as a result, the process of working in private houses at the "stall" has greatly declined. The change has led to some curious modifications in the health of the operatives, of which more in the proper place. In addition to the shoe business, the hat-making business is a rather important branch; once, indeed, this department of industry was first on the list, but of late it has declined. Strikes amongst the operatives are exceedingly common in the town, and are often sustained for long periods, leading to great privation and distress. The frequent recurrence of these strikes has led to the detriment of the Stafford trade, and to the establishment of centres of industry in other towns. Worse still even, the manufacturers located in Stafford have been led to open extensive branches in other places, simply because they dare not trust to their own operatives for the sudden or urgent accomplishment of large orders. The number of shoemakers in Stafford over 20 years of age, in the year 1861, was 1546 males, and 434 females.

THE STAFFORD COUNTY INFIRMARY.

The Stafford County Infirmary was completed in the year 1766. It is a plain building, with a straight frontage, and is three stories high, exclusive of the basement. It is situated at the northern extremity of the town, and faces the east. At the back is a garden,—which has recently been well-arranged, for the use of the convalescents, by the House-Surgeon, Mr. Greaves,—and, beyond, meadow lands, through which runs the river Sow. The meadow lands enclose large beds of peat, and are often extensively flooded. The external appearance of the building is plain and heavy, and its position is not promising. The walls are of brick. On the left side or wing a fever Hospital is attached; this fever department is connected with the general Hospital by a passage in the basement.

INTERNAL ARRANGEMENTS.

The number of wards for ordinary cases in the general Hospital is twelve; seven of these are for male, and five for female cases. There are two large day wards, for the use of patients who can leave their beds and sit up during the day; and two wards, one for males, another for females, set apart specially for accidents. As a general rule, the Medical and the Surgical cases are separated and classified. In the fever

house there are four wards, two for males and two for females. The Hospital, altogether, is capable of holding 120 beds; and two extra rooms, called the "chapel wards," can be used at times when there is great demand for admissions.

The cubic space is, nominally, very limited, viz., 800 cubic feet per bed. It is to be observed, however, that the full complement of patients is rarely in the house, seventy being about the average; hence the cubic space *actually* allowed, per patient, is liberal—not less, probably, than 1500 cubic feet.

The ventilation of the Hospital is imperfect. In the original construction an attempt was made at an artificial system of ventilation. Around the wards at the upper part—behind, in fact, the cornice—there was constructed a small horizontal shaft, having openings into the wards, and communicating on each side of the chimney with ascending shafts, which passed upwards with, or by the side of, the chimney, but not communicating with it by any opening. In practice, this attempt at ventilation has proved a failure, the air showing a tendency to descend into the ward, instead of making its escape upwards and outwards, as was intended. The result is, that in most cases the openings into the wards are closed up, and ventilation by the window is alone depended on. This, too, is not possibly effective, seeing that the position and construction of the windows do not allow of the direct transit of air across the wards. In nearly every instance when I was passing through the Hospital, there was a close, musty, characteristic, bad-air-Hospital odour. In ventilating, the windows are opened from above. The *warming* is everywhere carried out by means of open fire-grates. The grates are badly constructed, and are so fixed, that the radiation of heat into the wards must needs be extremely limited, and the useless loss of fuel considerable.

Water is abundantly furnished to the whole of the building by the action of a steam-engine.

The cleaning of the floors is by the dry process, and as the floor-boards are of oak, this method of cleansing answers well. Washing and wet scrubbing of floors is performed not more than three times a-year; for the rest, dry rubbing and bees'-wax polish suffices. There cannot be a doubt that, by this plan, much trouble is saved and much annoyance; but it is not, after all, without its disadvantages. In the first place, the waxed floor is exceedingly slippery, and some practice in walking upon it is necessary before the proceeding is safe. To patients who are not strong or steady on their limbs, this is naturally a great drawback. In the next place, as I learned from Mr. Greaves, there is this objection to the polished floor, in the Surgical wards particularly, that blood or other similar fluid falling on the floor leaves a deep, dirty stain, for the removal of which it is necessary to wash the spot with water, to scrub, and to repolish. For this reason, in the Surgical wards, on one floor on the men's side, as well as in the accident wards, Mr. Greaves has introduced the method—first applied, I believe, in England in the Northampton Infirmary—of washing the floors, and afterwards of polishing them with hot Calais sand and the brush. The floor, very cleanly polished, is thus left free from danger and trouble. It is not slippery, but, on the contrary, gives a good hold to the feet, while it shows no deep stain when blood or dark fluids are spilt upon it.

The walls of the Hospital within are painted, shoulder high, of a light-brown, or rather, pale lead-colour; above that they are limewashed. This obtains throughout—except in the fever wards, some of which are painted green; ornamentation, art in any shape there is none—not a picture, not a flower. In the corridor of the fever wards there is a trellis-work for plants, and in summer, I believe, some plants are trained over it, but this is all. To meet the eyes of the sick there are a few of the ordinary Hospital bills,—admonitions, confessions, promises,—which, however good in their way and intention, do but surfeit and nauseate when carried beyond reason: no picture, no flower, and no colours but white and brown. To lie for weeks in that gloom would surely of itself be worse suffering than that arising from diseases, under a happier sky.

The bedsteads are of iron, and there are no curtains, except in two of the wards, where light head curtains are permitted. The bedding consists of a straw mattress and a horsehair mattress. The horsehair, when it is dirty, is cleaned and used again; the straw is destroyed when it is considered unwholesome; the tick is purified, and new straw is introduced.

DIET OF THE HOSPITAL.

The diet of the Hospital is explained in the subjoined table. It will be seen that a liberal proportion of plain food is allowed, and that alcoholics are excluded altogether. The quantity of tea

is excessive, and can hardly be found to answer in every case. Why, in the dietaries of Hospitals, coffee should be excluded is one of those curious and absurd conventional usages for which it is impossible to assign a reason. Think of a quart of

tea a-day for an anæmic girl, hysterical, sleepless, flatulent, always ready for a good cry, and within an ace of becoming a medium! A quart of tea a-day for her! Poor Quashee, it's too bad by two halves.

Staffordshire General Infirmary Diet Table.

MEALS.	FULL.	ORDINARY.	MILK.	LOW.	EXTRA DIET.
Breakfast.....	1 pint of tea, with $\frac{1}{4}$ pint of milk.	1 pint of tea, with $\frac{1}{4}$ pint of milk.	1 pint of tea, with $\frac{1}{4}$ pint of milk.	1 pint of tea, with $\frac{1}{4}$ pint of milk.	1 pint of tea, with $\frac{1}{4}$ pint of milk.
Dinner	5 oz. of meat. $\frac{1}{2}$ lb. of potatoes.	3 oz. of meat. 1 pint of broth, with vegetables. $\frac{1}{2}$ lb. of potatoes.	Two days $1\frac{1}{2}$ pint of rice milk. Two days 12 oz. of pudding. Three days $\frac{1}{2}$ lb. of bread pudding, or 12 oz. of rice pudding.	1 pint of broth, and 6 oz. of rice or bread pudding.	
Tea, at 4 p.m. . .	Tea, 1 pint, with milk (for women).	Tea, 1 pint, with milk (for women).	1 pint of tea, with milk.	1 pint of tea, with milk.	1 pint of tea, with milk.
Supper	Milk and gruel (alternate nights).	Milk and gruel (alternate nights).	$\frac{1}{2}$ pint of milk.	1 pint of gruel.	$\frac{1}{2}$ pint of milk.
Daily allowance to each Patient	1 pint of tea (for men). 2 pints of tea (for women). 12 oz. of bread. 5 oz. of meat. $\frac{1}{2}$ lb. of potatoes. $\frac{1}{4}$ lb. of butter (per week).	1 pint of tea (for men). 2 pints of tea (for women). 12 oz. of bread. 1 pint of broth, with vegetables. 3 oz. of meat. $\frac{1}{2}$ lb. of potatoes. $\frac{1}{4}$ lb. of butter (per week).	12 oz. of bread. 2 pints of tea. $1\frac{1}{2}$ pint of milk. Rice. $\frac{1}{4}$ lb. of butter (per week).	2 pints of tea. 12 oz. of bread. 1 pint of broth, and 6 oz. of rice or bread pudding. $\frac{1}{4}$ lb. of butter (per week).	2 pints of tea. 12 oz. of bread. 1 pint of milk. $\frac{1}{4}$ lb. of butter (per week).

The meat to be roast four days, and boiled three days (Sunday to be one of the boiled).
Extras to be specially ordered:—Arrowroot, mutton chops, beef-tea, fish, eggs, egg pudding, jelly, porter, ale and beer, wine, or spirits.
Each Patient, on admission, to be placed on ordinary diet until a diet is ordered by the Physician or Surgeon.

I cannot omit to notice a defect in the management of this Hospital of a singular kind, considering the position of the town of Stafford. The patients are made to drink all their gruels, soups, and similar liquids from metallic vessels, made of tin or of tinned iron. To the stranger the use of these vessels appears both slovenly and unwholesome; it is impossible to keep cups and basins of the kind properly clean, and there is a commonness about the proceeding which is pitiable. Is it possible that at the door of the potteries of England, and, I may say, of the world, many years will have to pass away before the governors of a Hospital for the sick will allow earthenware to replace base metals on the invalid's table? On the ground of expense, there can be no kind of hesitation; so that the explanation of the existing fact must be, that there is want of thought, and its attendant, a bad economy.

USE OF ALCOHOLICS.

I have pointed out that in the ordinary dietary of the Hospital there is no allowance of any alcoholic fluid; but as an extra, alcohol in any form can be ordered by the Medical staff. Practically, this plan is found to answer well wherever it is tried; and, as it saves an immense sum annually, it is gaining favour amongst the governing bodies of Hospitals generally. In the Stafford Hospital, during the year 1863, the total value of alcoholics consumed amounted only to £148 5s.; the items being, for beer, £61 2s.; for porter, £25; and for wines and spirits, £62 5s. The number of patients admitted in the year was 586, and the average duration of each patient in Hospital may be taken as of five weeks' duration. The result is that, of beer and porter, at a cost of twopence a pint, the average amount allowed per patient is half a pint a day; while the amount of wine and spirits must be less than the third of an ounce. In matter of temperance, the Stafford Hospital is superior to that of Lynn; and the fact is still more remarkable when it is remembered that there are four wards in the former for the reception of cases of fever, and in the latter not a solitary fever bed.

RULES FOR ADMISSION OF PATIENTS.

For every guinea subscribed annually, or for every twenty guineas subscribed as a donation, a subscriber or benefactor is entitled to recommend one in-patient and two out-patients (or six out-patients) within the year; subscribers of half a guinea are entitled to recommend two out-patients annually.

All persons who recommend patients having no parochial settlement in the county are considered responsible to the charity for any expenses which may be unavoidably incurred in burying such patients in case of death, or in their removal after being discharged. This rule is peculiar to the Stafford Hospital.

No patient is admitted into the Infirmary whose case may

be equally relieved, with regard to advice and medicines, as an out-patient.

Fever patients are admitted on any day of the week, and are charged as in-patients against the privilege of the person who recommends them. All persons entitled to recommend patients are at liberty to send fever patients into the Infirmary at any time upon payment of one guinea with each; and the same permission is given to unions and parishes subscribing, on the payment of three guineas by the former and one guinea and a-half by the latter, with every such patient.

No patients with sore legs are admitted unless the examining Surgeon considers there is a probability of their being cured, or decidedly relieved, in two months. No woman far advanced in pregnancy, no child under seven years of age (except in extraordinary cases), no lunatic, no person having convulsive fits, or suffering solely from itch, or any complaint that is judged incurable, or in a dying condition, is admitted as an in-patient; or, if inadvertently admitted, is suffered to continue.

COST OF EACH PATIENT.

In the year 1863 patients to the number of 596 were admitted into the Hospital, the daily average being $51\frac{3}{4}$. The number of out-patients was 1179. After dividing fairly the expenses for drugs amongst all the patients (in and out), and deducting these expenses from the out-patients, the cost of each in-patient (every item of Hospital expenditure being taken in) averaged about £4 3s. 9d. per case. But in this calculation is included the large sum of £486 8s. 11d. for repairs of Hospital, furniture, stationery, etc., which, although necessarily incidental to every establishment, cannot properly be understood as defining the actual average expenditure of each patient. The amount for repairs deducted, the average cost of each in-patient is reduced to the sum of £2 19s. 9 $\frac{1}{2}$ d. during the year 1863. The average cost of each out-patient in 1863 was 2s. 11 $\frac{1}{4}$ d.. Economy in Hospital management could not, I think, proceed further; and the authorities may point to the fact as some excuse for the internal condition of their institution.

PRACTICE OF THE HOSPITAL.

PREVAILING DISEASES OF THE HOSPITAL.

Acute diseases are rarely admitted. On the Physician's side, scrofula, Bright's disease of the kidneys, phthisis, rheumatic affections, and anæmia are common. Ague is now scarcely ever met with, but neuralgia is exceedingly prevalent; it is, in fact, the leading Medical disease. Chest affections of the chronic type, other than consumption, are prevalent. On the Surgical side the diseases are also, in the main, of the chronic form. Cases of stone are exceedingly rare—so rare, that lithotomy is practised not more than once in three years.

Bronchocele, which here is classed as a Surgical disease, is common.

OPERATIONS.

The statistics of operations performed in the Hospital were very imperfectly kept until the last two years. In that period, however, Mr. Greaves has tabulated them carefully, with the results. The number of operations performed annually amounts to about forty, but only twenty of these are capital operations. This is a fair average of operations for the past five years.

CHLOROFORM.

The administration of chloroform is entrusted to the House-Surgeon, who attends exclusively to the effects of the narcotic. The method of administration is very simple: a pad of lint is fixed on a small sheet of gutta-percha sheeting. The chloroform is poured on the lint, and the sheet is held obliquely over the nose, so that the patient obtains a full supply of air from beneath. Narcotisation is induced rather slowly. The above has been the plan adopted in nearly every case; but, for a short time, Snow's inhaler was brought into requisition; it soon, however, fell into disfavour, as too complicated and cumbersome. No death has ever occurred from chloroform in the Stafford Hospital. The number of administrations have been at least 750.

MORTALITY.

By Dr. Farr's method of calculation, in the year 1861 the general mortality of the Hospital was at the rate of 36.36 per cent., a mortality extremely low, when compared with other Hospitals—the Royal Infirmary at Manchester, for instance, where it was 130.69 per cent. In the year 1863, on the same basis of calculation, the mortality has been greater than in 1861—viz., 47.00 per cent.

The Surgical mortality has of late years been very low. At one time pyæmia and erysipelas were severe, and caused many deaths, but they have not appeared recently. In the years 1862-1863, the following capital operations were performed with the results named:—

Operations from April 3, 1862, to September 11, 1863.

Sex.	Age.	Operation.	Result.
Male	45	Excision of upper jaw.	Recovered.
Male.	25	Amputation of leg.	Recovered.
Male.	19	Amputation of part of foot.	Recovered.
Male.	60	Removal of steatomatous tumour of head.	Recovered.
Male.	48	Amputation of leg.	Recovered.
Male.	21	Amputation of arm near shoulder after accident.	Recovered.
Female.	40	Cancer of breast.	Recovered.
Male.	18	Amputation of leg after accident.	Died.
Female.	11	Excision of elbow-joint.	Recovered.
Male.	45	Amputation of foot (Chopart).	Recovered.
Male.	9	Amputation of leg.	Recovered.
Male.	22	Amputation of foot (Pirigof).	Recovered.
Male.	44	Removal of lower lip; cancer.	Recovered.
Female.	50	Amputation of breast.	Recovered.
Female.	47	Amputation of breast.	Recovered.
Male.	68	Amputation of fore-arm after accident.	Recovered.
Female.	28	Excision of knee-joint.	Recovered.
Female.	29	Amputation of thigh.	Recovered.
Female.	26	Amputation of part of hand.	Recovered.
Female.	28	Removal of loose cartilage from knee-joint.	Recovered.
Male.	35	Amputation of one leg after compound comminuted fracture of both legs.	Death from shock (immediate).
Male.	57	Removal of large tumour from knee-joint.	Recovered.

This mortality after Surgical operations is most satisfactory. In the two cases that ended fatally, the deaths could hardly be attributed to the operations, for in both instances there was no rallying from the shock of the accidents; but, including these cases, the mortality is only 9.09 per cent. The success may be accounted for by the absence of epidemics, the large allowance of air, the small number of operations performed, the impossibility of contagion from dissecting-room poison, and the very temperate use of alcoholics. I shall dwell at greater length on this subject of mortality in my next paper.

(To be continued.)

PROPOSED NEW HOSPITAL FOR THE NORTH-EAST OF LONDON.—A meeting of influential gentlemen residing in this district was held at the residence of Dr. Grainger Tandy, of Spital-square, on Thursday week, for the purpose of promoting the above object; the Rev. T. S. Evans, Vicar of Shoreditch, in the chair. The necessity of such an institution was clearly demonstrated—there being no Hospital provision for a district containing 300,000 or 400,000 inhabitants. Resolutions were adopted declaratory of these facts, and pledging the meeting to establish such a Hospital, and a committee formed for carrying out the objects of the meeting.

REVIEWS.

On Australasian Climates, and their Influence in the Prevention and Arrest of Pulmonary Consumption. By S. DOUGAN BIRD, M.D., L.R.C.P.L., Physician to the Benevolent Asylum, Melbourne, etc., etc. London: Longmans. 1863. 8vo. Pp. 165.

A PHYSICIAN who is able to tell us a history of mortal disease arrested in his own person, and hope restored when it had apparently taken final leave of him, has a strong claim to be heard when he relates the means by which this was effected, and may be effected for other sufferers. Nor will the reader who takes up Dr. Bird's book with this feeling experience the sense of disappointment and disgust which often awaits the student who has opened a work with a promising title, only to find that its contents do not justify the author's pre-fatory flourishes.

Dr. Bird's personal experience is interesting; for consumption had declared itself unquestionably in his case by profuse hæmoptysis, rapid wasting of flesh, and alterations of the respiratory sounds, which were pronounced on high authority to be certainly indicative of tubercle. European travel having failed to do more than arrest the most troublesome symptoms, a voyage to Australia was tried, and "in six months the patient gained sixteen pounds in weight, lost all his symptoms, and remains at the present time in excellent health;" that is, more than two years from this favourable change in his condition. Encouraged by this result, and by many others of a similar character which he has seen follow the adoption of Australia as a residence by phthisical patients, Dr. Bird proceeds to analyse the causes of this apparently favourable influence of the climate.

The work commences with a chapter on the "Principles of Modern Treatment in Phthisis," which, though simple and brief, contains the pith of all that can be said upon the general question. The author justly remarks, that with regard to that item of treatment which consists in change of climate, a narrow and partial view is too often taken by Physicians—namely, the view which regards such change merely as a means of escaping from the severity of an English winter. If nothing more than this is to be effected by foreign travel, but little can be expected from it beyond the delay of the fatal issue of consumption; for it is, in fact, but the treatment of symptoms. What is required is, an alteration in the whole regimen, and in all the habits—in the physical and the moral atmosphere. To take but one of the greatest physical desiderata for a cure—free and thorough oxygenation—that is a condition nowhere to be obtained in perfection but in places exposed either to the upper layers of the atmosphere, as mountain countries, or to the winds sweeping from the sea, as in places not too far removed from the shore, or upon the sea itself. But mountain air has often far too irritant a quality to suit the delicacy of the phthisical patient; to live upon the sea perpetually is not convenient; while the various European littorals have many objectionable points. The Western coast of Europe, and our islands in particular, are exposed to the influences of the Gulf stream, which brings with it masses of warm vapour, that condense to fog and rain, and thus deprive us, to a large extent, of the physical and moral benefits of sunlight. The Mediterranean coasts of France, on the other hand, have an often intolerably dry and irritating atmosphere. Italy, in its northern portion, is exposed in winter to rain, fogs, and keen, irritating winds: in its southern portion the climate is constantly relaxing and depressing: and what may be said of Italy may be said in general terms of Greece. One European littoral there is—the eastern seaboard of Spain—which, from its mild, equable, and marine, but, at the same time, sunny and bracing climate, is a perfect winter residence; but this is ineligible in summer from the oppressive heats; and the same remarks apply to Syria, Egypt, and Algeria. Such, briefly, is the case theoretically made out against Europe, physically considered. On the part of the Australian continent, it is urged, that its coasts offer conditions of climate which ensure the constant ozonation of their atmosphere in a high degree; while, at the same time, it must contain sufficient moisture, for the prevailing winds are those that sweep over a vast expanse of ocean. And, on the other hand, the absence of high mountain ranges prevents the defect of gloomy, clouded skies. The mean yearly temperature of Melbourne is about the same as that of Montpellier, Marseilles, Nice, Pau, Genoa, and Florence, but the mean range of the seasons is far less than in these localities.

Dr. Bird urges, therefore, that the consumptive European who determines to seek health in Australia will have the double benefit of a long sea-voyage—itsself a powerful remedial agent—and of arriving, at its termination, in a country whose climate is the best suited of any in the world for his permanent re-establishment in health. He adds several considerations which are highly important. The complete severance, necessarily for a long period, from the business cares which are left behind in England; the youthful “hopefulness” which is the prevailing feature of the marvellous colony to which he goes—a hopefulness which is inherent both in its natural scenery and in the character of its thriving population; and last, not least, the *homeish* look of things, so soothing and cheering to all invalids—all these cannot fail to aid most materially in the work of cure.

But all theoretical arguments to prove that Australia *ought* to be an eligible residence for a phthisical patient are of insignificant importance in comparison with the facts adduced by Dr. Bird to prove that it actually *is so*: these last are far more striking than we were prepared to find them. “In short (to put the matter in the author’s words), seven persons die of consumption here (in Melbourne and its suburbs), while twenty die in England out of every hundred (of the total mortality), though we are far more liable to the disease as regards *age* and *sex*, and equally so as regards *race* and *occupation*.” And if the whole colony of Victoria be taken into consideration, the probability is, that not more than 5 or 4.5 per cent. of the whole mortality is due to consumption. The author attributes this extremely favourable result not only to the sunny, dry, and exhilarating atmosphere, but to the rapidity and completeness with which the vital processes are performed under its stimulating influence, and the large appetite for food thus created, which the prosperity of the colony permits its inhabitants to satisfy.

Zymotic diseases, principally manifesting themselves during the hot season, appear to be the scourge of Melbourne; and the author states confidently, that the entire absence of drainage is almost entirely to blame for this source of mortality. If this be the case, as seems *à priori* likely enough, it would seem that the mortality of Melbourne ought, as soon as this nuisance is done away with, to sink to a pitch extraordinarily low in the conditions of city life. Endemic disease, on the other hand, is but slightly prevalent in Australia, owing to the dry and ozoniferous character of the air.

Such is the gist of Dr. Bird’s more important observations: for all matters of detail, as to the different parts of Australia which are appropriate to different classes of patients, and as to the sort of cases for which the moist climate of New Zealand is preferable, we refer our readers to the work itself. They will also find interesting details of the arrest of tubercular disease, even when suffering had proceeded to a considerable length, in several cases, under the influence of the invigorating climate of Australia.

There may be, as Dr. Bird himself confesses, some shade of partiality in the warmth with which he speaks of the benefits of an Australian residence to phthisical patients. Nothing, however, can destroy the value of the positive statistical facts which he adduces; and he is entitled to our thanks for having opened up the subject of Australasian climates in their Medical bearings more fully than it has yet been done. Moreover, the book is pleasantly, even elegantly, written; and it is a real *edition de luxe* to such readers as love a clear type, a not too bulky volume, and a variety of topics, lightly and pleasantly touched upon, to relieve the more serious subject-matter of a scientific work. Above all, a certain air of common sense in dealing with pathological questions, not too common, unhappily, among writers upon these subjects, has struck us as distinguishing the book in a high degree. We recommend it to the study of every member of our Profession.

POOR DOCTORS.—“As to medicines and Medical attendance, is it likely that the one underpaid doctor can, out of his salary, provide the various medicines that are required for his patients? All who visit workhouses know well how frequently the ‘house medicine’ and the ‘house pill’ are made to do duty for many different ailments, and how the chronic and supposed incurable cases are left to take care of themselves. That the workhouses are in reality our Hospitals for incurables, is a fact that ought to be continually impressed upon the public mind, because it is not as yet realised, and few ask the question, what becomes of all the thousands who are annually discharged from our Hospitals.”—*Journal of the Workhouse Visiting Society.*

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL REFORM.
LETTER FROM MR. RICHARD GRIFFIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I shall feel obliged for space for the annexed letter, which will inform the Poor-law Medical officers that the select committee on poor relief have been reappointed, and now I trust we shall have such resolutions passed as will induce Parliament to amend the laws relating to the Medical relief of the poor. Since last July I have only received the following subscriptions:—W. Smith, Bromsgrove, 5s.; C. C. Claremont, St. Pancras, 10s. 6d.; W. H. Pilkington, Blackburn, £1; Medical officers, Rotherham, £1. I need scarcely say, that having already expended over £20 more than I have received, it cannot be expected of me to take any very active measures unless the Poor-law Medical officers will come forward in the same liberal manner which they did some three or four years since. The select committee must, I feel sure, recommend something; but a mere recommendation will do nothing unless we place ourselves in a position to compel its being carried out. You are probably aware that a milk-and-water superannuation bill has been put in circulation amongst the guardians by the Poor-law Board; and although it is only a permissive, and not a compulsory measure, the guardians have in many unions objected to it, and so they will to any bill that may be sent them; therefore, if the Poor-law Board desire to shelve a measure, they have only to send it to the guardians for their opinion, and the affair is at once settled. The registrars throughout the kingdom have lately been in correspondence, and are endeavouring to obtain one shilling for each vaccination registration instead of the threepence now paid. I wish them success; but I think when their measure comes forward we ought to get a clause inserted that our one shilling and sixpence for vaccination should be increased; but, unless we have a fund in hand of at least £100, we can do nothing.

I am, &c. RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, February 23.

“12, Royal-terrace, Weymouth, Feb. 22, 1864.

“Sir,—I have the honour to forward you, by railway, evidence on the Medical relief of the poor, supported by an extensive series of tables, which I respectfully beg you will lay before the select committee on poor relief, which, I perceive by the newspapers, has been re-appointed. The evidence which I now submit to the notice of the committee will, I feel confident, convince them that the evidence laid by me before them in 1861 is substantially correct, and that the evidence of Mr. Cane in April, 1862, in respect thereof, is most incorrect, and tends to conclusions which, if uncontradicted, must mislead the committee, and prevent them coming to a right decision on the question. I will give you an instance of the errors committed by Mr. Cane, who says:—‘In 1858 there were 3307 Medical officers, and in 1861, 3479;’ whereas at this moment there are not more than 3102, or thereabouts, Mr. Cane having confounded the Medical districts and appointments with officers.

“Mr. Cane says (3887):—‘In 1840 the Medical relief was £151,781, and in 1861, £238,222.’ (3839.) ‘It has been constantly and largely increasing up to last year;’ but he omits to inform the committee that, since 1840, the area and population of the places brought into account has largely increased, and that, in reality, the main increase in the payment arises from the formation of new unions, and the addition of extra parochial places to the old unions, parishes, and incorporations. Mr. Cane has thought fit to impugn my figures, but I can assure the committee they are, in the main, correct. A few places, no doubt, are erroneously spelt,—Retford, for instance—which Mr. Cane has most unfairly commented on, although he must have known the place referred to was Thetford; for, had I meant Retford, I should have called it by its right name—East Retford—and not have dropped part of the name, as Mr. Cane has done. These quotations will prove how little his evidence is to be relied on. I, therefore, respectfully trust the select committee will admit my evidence in refutation of that of Mr. Cane’s, not only in justice to myself, but to the large body of Medical officers I have the honour to represent, and, I may add, in justice to the poor; for I feel confident that if the reforms advocated by me, be fairly carried

out, much good will accrue to the poor, and ultimate benefit to the ratepayers. There is one point I wish should be brought before the committee, which is, the establishment of dispensaries in all populous places, and that the drugs should be found by the Poor-law Board; and in thinly-populated places, where Dispensaries could not be established, an allowance—say 2s. per case—should be paid to the Medical officers for drugs. In payment, I would advise that the money now voted by Parliament for half the salaries should be applied to this purpose, the guardians being compelled to pay a sum not less than 2s. per case in towns as salary, with mileage in addition in country places.

"I have the honour to be, Sir,

"Your most obedient servant,

"RICHARD GRIFFIN.

"The Right Hon. C. P. Villiers, M.P., Chairman
Select Committee Poor Relief."

HOSPITAL MORTALITY.

LETTER FROM DR. W. FARR.

[To the Editor of the Medical Times and Gazette.]

SIR,—The subjoined extract from the appendix to the Registrar-General's Twenty-fourth Report, expresses briefly the results of some of the information which has been collected at the General Register Office respecting Hospitals.

Dr. Bristowe will see that I agree with him when he says that the question whether Hospitals, and especially large Hospitals, "benefit mankind directly," deserves "the fullest investigation."

In my opinion the skill of country Practitioners and the fame of the Medical officers of county Hospitals is underrated in London, and I speak from seven years' experience in country, London, and Paris Hospitals. But with all the admitted advantages which patients derive from the Medical skill of the large London Hospitals, is the mortality of the same class of cases lower in their wards than in the wards of small Hospitals, and in the cottages and lodgings of the poor? Dr. Bristowe, I have been informed, is engaged officially on an inquiry into the subject, and will, I have no doubt, do his utmost to conduct it with skill, care, and impartiality, so as to "test" the assertion, that sanitary condition has no influence on Hospital cases. Dr. Murchison's facts will necessarily rivet his attention.

I regret to find that Miss Nightingale's Anonymous Critic and I still differ as to the true method of deducing the rate of mortality; and that even after your skilful diversion and defence which followed my letter—giving an advantage to his cause of two to one—his wrath is still raging too angrily to justify me in attempting to reason with him. My letter is "confused," "violent," "a queer composition;" and the method of dividing the deaths by the bed-population of Hospitals is "an arithmetical flight of fancy," "a gross misuse of figures," leading to conclusions which he "utterly disbelieves!" This style of argument does not appear to require any reply. And as a method of mathematical demonstration, that of Euclid is preferable.

After all, reviewers are mortals like ourselves, who, for the moment, occupy the calm seats of judges, against whose decisions any one has, with your permission, the right to appeal to the supreme court which your readers constitute; and who, I must add, will only have the whole case fairly before them, when they have read Miss Nightingale's book as well as its reviewer's article.

I am, &c.

February 20.

W. FARR.

EXTRACT FROM DR. FARR'S LETTER TO THE REGISTRAR-GENERAL.—APPENDIX TO REGISTRAR-GENERAL'S TWENTY-FOURTH REPORT.

"Public Institutions.

"The great majority of the people of England live in detached dwellings; and a certain number reside in barracks, asylums, workhouses, Hospitals, lunatic asylums, and prisons, or in public institutions, as they have been called, of various kinds.

"The mortality of the inmates of some of these institutions is, for various reasons, much above the average; so the inmates having been returned at the Census, it was thought right to pick out the principal institutions in which the mortality was likely to be so great as to affect the mortality of the sub-district in which the institution is situated.

"The list has been compiled on this principle, and does not

include a great number of institutions of various kinds. It includes all the principal Hospitals and workhouses.

"The Commissioners in Lunacy, the Inspectors of Prisons, and the Poor-law Commissioners publish in their annual reports accounts of the respective institutions which come under their cognisance. The statistics of the Hospitals of the country are not given at all, or are not given upon a uniform plan. Miss Nightingale, who perceived all the importance of

"Table XIV.—England: Public Institutions.

England.	Number of Inmates on April 8, 1861.	Deaths in the year 1861.			Annual Rate of Mortality per Cent.
		Persons.	Males.	Females.	
In 853 Public Institutions	154,602	32,437	19,137	13,300	20.98
„ 690 Workhouses.	119,984	22,785	12,822	9,963	18.99
„ 106 Hospitals	12,709	7,227	4,950	2,277	56.87
„ 57 Lunatic Asylums.	21,909	2,425	1,365	1,060	11.07

this information, suggested that the Hospital statistics should be collected in forms, of which the members of the Statistical Congress in London approved; (a) and if the Hospital boards carry out the plan, they will place the Hospital statistics on a level with those of the other institutions of the country.

"The number of institutions in the Table XIV. is 853, which held 154,602 inmates on the day of the Census, exclusive of the officers and servants. 32,437 inmates died in the year; and, assuming that the average is represented by the enumerated population, the mortality was at the rate of 20.98 per cent., or 210 per 1000; while the mortality of the population of all England was at the rate of 22 in 1000, or 2.163 per cent.

"The mortality in these institutions was ten times as high as the mortality in the population generally.

"The annual rate of mortality in the lunatic asylums was at the rate of 11 per cent.; in the workhouses, 19 per cent.; and in the Hospitals, 57 per cent.

"With respect to Hospitals, then, while the annual mortality of the general population was 2.16 per cent., the mortality of their inmates was at the rate of 56.87 per cent., or 26 times as high. The inmates of Hospitals are, it is scarcely necessary to say, all suffering from diseases which tend, generally, to increase the risk of death.

"The Hospitals are filled by a succession of inmates, who remain for a time varying from a day to a month, or a year; and the mortality is often given as so many deaths per cent. on the cases treated. The mean term of treatment varies in different Hospitals; in many it averages 36.5 days, or the tenth part of a year. Assuming that term of treatment to be applicable, the mortality of the cases in these Hospitals was 5.687 per cent. in 36.5 days; or the Hospitals, to every 100 beds occupied, had nearly 57 deaths annually.

"Hospitals enable the charity of the country to supply the sick with skilful Medical advice upon the cheapest terms, and this has led to the establishment of the institution upon the voluntary principle in every county. An eminent Physician or a Surgeon can visit his patients in a short time as they lie in the same or in contiguous wards; and he often consents to attend them without any fee or salary. The collection of the sick under one roof conduces also to economy in the nursing department, in the kitchen as well as domestic service, and in the pharmacy, as the drugs can be purchased and dispensed at a cheap rate. A resident Medical officer can attend to all the urgent cases.

"Table XV.—Principal General Hospitals in England and Wales, 1861. (Special Hospitals are excluded from this Table.)

	Number of Hospitals.	In-mates.	Average Number of Inmates in each Hospital.	Deaths.	Mortality per Cent.
Total Hospitals	80	8535	107	6220	72.88
Hospitals containing—					
300 inmates & upwards	5	2090	418	2101	100.53
200 and under 300	4	913	230	838	91.78
100 and under 200	22	2898	132	2041	70.43
Under 100	49	2634	54	1240	47.08

"The cost of the building is generally so great as to make the lodging much dearer than the best cottage accommodation.

(a) English Programme of International Congress, pp. 63-65. See also Report of the Proceedings.

"One great evil has often counterbalanced all the advantages. The collection of a number of persons, exceeding those of an ordinary family, under one roof, has hitherto always had a tendency to increase the dangers of disease; for several diseases are, like fire and ferments, diffusible. The danger is increased when all the inmates are sick, for their breath and excretions spread through the wards. The dangers, too, are likely to increase in a faster ratio than the numbers, and the patients are less likely to recover health in the sickly atmosphere of a large building in a city than in pure country air.

"These institutions were, accordingly, at one time, infested by Hospital gangrene, and by erysipelas; the lying-in Hospitals were depopulated by fever (metria); infants perished by hundreds in the Foundling Hospitals; and even in the present day patients often die of Hospital pyæmia, so frustrating the hopes of the skilful Surgeon.

"It must be stated that nothing can scarcely be worse than the ventilation and all the arrangements of the old Hospitals.

"The classes of cases which are admitted into particular Hospitals, and the reasons for which patients are discharged, differ largely, so that the investigation of the effects of Hospital air, and of treatment in the various establishments, requires great care and skill. It is so important, however, that it should be undertaken for the sake of the sick, and for the sake of Medical science.

"A careful comparison of the duration and of the rate of mortality of certain well-defined diseases in Hospitals and in private practice would settle the question.

"In the meantime, it is evident from the tables that the mortality of the sick who are treated in the large general Hospitals of large towns is twice as great as the mortality of the sick who are treated in small Hospitals in small towns.

"It remains to be seen whether the mortality in small Hospitals is not twice as great as the mortality of the same diseases in patients who are treated in clean cottages.

"Should this turn out to be the case, the means of realising the advantages of the Hospital system, without its disadvantages, will then be sought and probably found, as the problem is not insoluble."

THE NEW COUNTY HOSPITAL AT WINCHESTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your last number contains a letter on the subject of the above-named Hospital. The plans for the new building are therein said to have been concocted by three personages,—1. "Miss Nightingale;" 2. "An architect named Butterfield;" 3. "A domineering baronet of the neighbourhood." Permit me to say a few words in reply.

1. The lady alone is treated leniently. Her only crime appears to be that of forming one of such a wicked triumvirate.

2. The architect is criticised in most slashing style. He is described as "only known to the writer as a defacer of fine old churches, and a builder of ugly new ones." He is charged with "never having built a Hospital before," and, worse than all, with giving a "strictly ecclesiastical character to the design."

On the first count opinions may differ. A writer in the *Times*, a few years ago, stated that Mr. Butterfield's work showed more original genius in design than that of any other architect of the day.

On the second count, it must be remembered that Hospitals, not being as plentiful as churches, have not yet attracted a special class of architects. I am not aware that the more recently built Hospitals are so perfect in their arrangements as to give their architects a pre-eminent claim to employment in the erection of new ones.

On the third count, I venture to offer the opinion, that, if a religious tone can be given to our Hospitals, without the sacrifice of important features (among which cheerfulness should be included), a great point would be gained. Nor am I frightened at the prospect of the nurses becoming converted into sisters of charity in consequence of the "conventual effect" of their dormitories. In short, I believe that if the internal arrangements of the projected Hospital are nearly as perfect as are the internal arrangements of Mr. Butterfield's churches, the county of Hampshire will have good reason to be proud of their Hospital, notwithstanding the epithet of the "streaky-bacon style" applied to its exterior.

3. The baronet fares but little better than the architect. If a landowner happens to take an intense interest in a county charity, and devotes much time, labour, and acumen in

mastering its details and requirements, it is probable he may acquire some influence with his neighbours. Even if a would-be manager of the charity should call him "domineering," he could afford to put up with the abuse. And probably he would be forgiven if, in the exercise of his judgment, he slighted the opinion of disappointed persons, or of the "careless one" who signs himself "Epicuri de Grege Porcus."

I am, &c.

F.R.C.S.

THE RELATIVE MORTALITY IN LONDON AND COUNTRY HOSPITALS.

LETTER FROM MR. T. HOLMES.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Richardson, in some communications which he made to your Journal on January 9 and on January 16, relative to the Norfolk and Norwich Hospital, and which are intended as the commencement of a "Medical History of England," made the following statements:—

1. That the average mortality after cases of lithotomy in metropolitan Hospitals is 50 per cent. or more.—See your number for January 9, p. 42.

2. That the difference between this rate and the rate of mortality after the same class of cases in the Norwich Hospital (calculated at one in seven, or say 15 per cent.) is due to the difference in the air of London and Norwich.—*Ibid.*, p. 43.

3. That the rate of mortality over all the Surgical cases in the Norwich Hospital in 1862 was 2.5 per cent.—*Med. Times*, January 16, p. 67.

4. That only one case of pyæmia had been registered in that Hospital during the last seven years.—*Ibid.*, p. 67.

The first statement was disputed by Mr. Thompson in a letter published in your number for January 16. To this letter Dr. Richardson promised to return an answer after he had finished his series of papers on Norwich and Lynn; though, as the statement was a merely arithmetical one, and must have been based on some document, which could as easily have been produced in five minutes as in five weeks, it is difficult to see why he should not have answered Mr. Thompson at once. At any rate, Dr. Richardson's papers on the above subject came to an end last week, and still no evidence of the truth of this statement is produced.

In the same number I called in question both the two first statements of Dr. Richardson; but to this letter of mine no answer has appeared, and no evidence has been adduced in support of Dr. Richardson's opinion on the subject. It is peculiarly important that such evidence, if it exists, should be produced at the present time in relation to the very serious question which is now pending before the Court of Chancery, with reference to the new site of St. Thomas's Hospital—a question on which Dr. Richardson is known to have given evidence, embodying the views which he propounded in his paper on the Norwich Hospital. Now, if Dr. Richardson is convinced that these views are correct, he ought, in justice to the numerous Medical witnesses on the other side who think otherwise, to produce the facts on which alone such views can be supported; and, if his data are impugned, he ought not to delay the attempt to verify them until this important question shall have been settled. If, on the other hand, Dr. Richardson is convinced that he was mistaken in his facts, and hasty in his inferences, it is hardly candid in him to put himself before the Profession as supporting opinions which he knew to be erroneous.

As to Dr. Richardson's third and fourth statements quoted above, I believe he is in possession of evidence, based on documents from the Hospital itself, proving to him that they misrepresent the facts of the case.

I think, therefore, that we, who are interested in discovering the truth on this important question of the relative salubrity of town and country Hospitals, in order to apply it to the practical business of the day, have a right to ask Dr. Richardson to state distinctly whether he adheres to the four statements which I have quoted above. I am, &c. T. HOLMES.

22, Queen-street, Mayfair, London, W., February 20.

P.S.—I had written the above when my attention was called to a letter, signed "M.D.," and inserted in small type at the end of your paper of to-day's date, to which I may, perhaps, be allowed to say a few words in reply, though neither its matter nor manner render it much worth an answer. Allow me, in the first place, to disclaim any zeal about the "good repute" of my brethren in London. The question is

merely one of facts, and cannot in any manner touch anybody's reputation, unless it could be shown (what Dr. Richardson, certainly, never asserted) that the excess of mortality which he alleged to take place in London is caused by errors of practice—an assertion destructive of his whole line of argument, which is intended to show that the alleged difference is caused by the air of London. The sentence which your correspondent professes not to understand is, surely, very simple. Country Hospitals receive a different class of cases on the Medical side, chiefly because they exclude infectious diseases; while all the large metropolitan general Hospitals, except the London Hospital, receive them; and, on the Surgical side, because acute Surgical cases and grave accidents are more rare. Of course, in speaking of "country Hospitals," I could not be supposed to have such an institution as the Leeds Infirmary in view, nor any of the other Hospitals of great manufacturing cities, which are not country Hospitals in any sense of the term, and where the Surgical cases are usually as acute as at metropolitan Hospitals, while the nature of the Medical cases varies, according to the regulations of the Hospital. In saying that the cases received at a country Hospital are of quite a different kind from those received at a London Hospital, I am merely stating a fact which I thought was notorious, but which can, at least, be easily verified by any one who will take the trouble of doing so. I do not, of course, mean, as your correspondent represents, that individual cases of Surgical injury are different in London and the country; but that cases of disease or injury, which in London would be considered too chronic or too trivial to give a title to admission, are received in great numbers at country Infirmarys, and that it is to this fact that the difference in the death-rates is mainly due. In saying that the Hospitals in London "receive a more severe class of cases, and treat them with a success little inferior to that obtained in the milder cases treated in country Hospitals," I was thinking chiefly of operative cases, especially amputations. I believe that in Hospitals in rural districts the injuries for which amputation is performed are generally of a less severe nature, the diseases are more generally of the chronic type, and the patients are, as a rule, more healthy and less dissipated. I think that I can adduce reasonably strong grounds for each of these assertions, and those grounds will very shortly be laid before the Profession. But, if I am in error, I shall be very glad to be convinced of it. It is a mere question of fact, rather difficult to settle from the evidence before us, and in which no one's feelings need be in the least concerned. I have not intended to speak disrespectfully of Dr. Richardson; and, if I characterised his assertion about lithotomy in London as an "enormous error," it was merely because I know of no other term to describe what I believe to be a misstatement of an arithmetical proposition in the ratio of more than 3 to 1.

OBITUARY.

DR. HEADLAM.

DR. HEADLAM, M.D., uncle of the Right Hon. T. E. Headlam, M.P., Judge Advocate-General, died at Newcastle-upon-Tyne on the 18th, in the eighty-sixth year of his age. His death is attributed entirely to his advanced years, as he expired without any disease, and in full possession of his faculties. He was a native of Gateshead, practised with great success in early life in the north of England as a Physician, and took an active part in the social and political reforms of the country up to within a few years of his death. He was early appointed a justice of the peace for the borough of Newcastle, and was twice elected mayor for that town, once in 1838, and again in 1846.

UNIVERSITY COLLEGE HOSPITAL.—Mr. Charles Dickens has consented to preside at the annual dinner of this institution, announced to be held at Willis's Rooms on an early day in April.

CONSUMPTION OF VICHY WATER.—The consumption of this alkaline water has assumed in France, and especially in Paris, gigantic proportions. In 1863, there were despatched from Vichy 1,460,000 bottles; and 180,000 baths were administered. Paris alone received 900,000 bottles. Since the 18th January, the public has been allowed free access to these as to the other Medical waters in France, without the intervention of Medical Inspectors of Mineral Waters heretofore necessary.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 18, 1864:—

Edward Carpenter, St. Thomas's Hospital.

The following gentlemen, also on the same day, passed their First Examination:—

Griffith Griffith, University College; George William Rigden, University College; William Bell, King's College; Edmund Farrington Boulton, King's College; M. S. W. Wilson, King's College; Alexander Clement Rayner, Charing-cross Hospital; Francis Henry Wickham Taylor, St. Thomas's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ABSOLOM, GEORGE W., M.D. Edin., has been appointed Visiting Surgeon to the Perth County and City Infirmary.
ALLEN, F. C., L.D.S.R.C.S. Eng., has been elected Surgeon-Dentist to the West Kent General Hospital, Maidstone.
BULL, HENRY G., M.D. Edin., has been appointed Physician to the Hereford General Infirmary.
HALL, CORNELIUS S., M.R.C.S. Eng., has been appointed Surgeon to the Carlisle Dispensary.
HEMMING, CHARLES, M.D. St. And., has been elected Coroner for the Borough of Abingdon.
HICKS, ROBERT, M.R.C.S. Eng., has been appointed Surgeon to the Seamen's Infirmary, Ramsgate.
KELLETT, EDWARD, M.D. Edin., has been re-elected Medical Officer for the Workhouse of the Kells Union, Meath.
LYELL, H., M.R.C.S. Eng., has been elected Medical Officer for St. Olave's Union, Southwark.
MACLAGAN, THOMAS J., M.D., has been appointed Medical Superintendent of the Dundee Royal Infirmary.
MASON, THOMAS P., M.B. Lond., has been elected Physician to McCreer's Hospital, Dublin.
REED, S. CARTWRIGHT, M.D., has been elected Medical Officer to the South District of the West London Union.
RYAN, RICHARD S., L.R.C.P. Edin., has been elected Second Medical Officer for the Workhouse of the Callan Union, Co. Kilkenny.

DEATHS.

DAVIS, HENRY ROBERT, M.D. Edin., at 12, Addison-road North, Notting-hill, W., on February 16.
FRASER, J. T., M.D., Assistant-Surgeon Madras Establishment, at Malacca, on January 3.
GRANGER, FREDERIC, M.B. Cantab., at Musgrave-place, Exeter, on January 4, aged 73.
HEADLAM, THOMAS E., M.D. Edin., at Newcastle-on-Tyne, on February 18, aged 86.
INNES, JOHN S., L.R.C.S. Edin., at Garnfaeh, Nantyglo, Monmouthshire, on December 20, aged 47.
LUCAS, T., M.D., J.P., at Rochford Town, Co. Cork, on January 22, aged 75.
MARTIN, G. M., Surgeon, at Spennymoor, Durham, on December 12, aged 38.
MATHER, MATHEW, M.D. Glasg., at Annfield-place, Glasgow, on December 25.
NATHAN, LEWIS H., M.R.C.S. Eng., of Great Ducie-street, Strangeways, Manchester, on January 17, aged 65.
NICOLLE, Dr., at St. Martin's, Jersey, recently.
O'BRIEN, GEORGE W., M.D. Glasg., of Bellevue, Ennis, Ireland, on December 2.
ROSE, Dr. HENRY, the distinguished Professor of Analytical Chemistry at the University of Berlin, died on January 28, in the 68th year of his age. He produced more than 200 memoirs on inorganic chemistry; and his "Treatise on Chemical Analysis" went through six editions, and was frequently translated.
SHORLAND, THOMAS, L.S.A., of High-street, Alderney, on December 18.

UNIVERSITY INTELLIGENCE.—Cambridge, February 22, 1864. An examination for four minor scholarships will be held in Downing College on Monday, May 30 next, and the two following days, and will begin at 9 a.m. on Monday. The examination will be chiefly in classics and elementary mathematics, but some weight will be given to proficiency in French and German. Two additional papers will be set, one on moral philosophy in connexion with the principles of Jurisprudence, the other on the elements of the natural sciences in connexion with Medicine; and in awarding two of these scholarships considerable importance will be attached to any special proficiency in the legal or in the Medical subject. Foundation scholars will, by the same examination, be elected from among the undergraduates of the College. Persons who have not been entered at any College in the University, or who have not resided one entire term in any such College, are eligible to these minor scholarships, which will be of the

value of £40 per annum, and tenable for two years, or until their holders are elected to foundation scholarships. No one elected minor scholar will receive any emoluments until he has commenced residence as a student of the College. Satisfactory testimonials as to their moral character must be sent to the master by all candidates for these minor scholarships, on or before Wednesday, May 25.

THE BRITISH PHARMACOPŒIA.—By some singular misadventure, one of the sheets in some of the copies of the British Pharmacopœia (sheet T, pp. 273—288) has been wrongly printed, so that the pages do not run consecutively. It is not a mere wrong folding or paging, but a misprinting, that nothing but cancelling the sheet can rectify.

THE MUSEUM OF THE LATE PROFESSOR SCHROEDER VAN DER KOLK.—We regret to learn that, owing to a fresh domestic affliction, necessitating a change of family arrangements, the splendid physiological, pathological, and ethnological museum of the late Professor Schroeder Van der Kolk will be disposed of much below its value. We have before us a *résumé* in Latin of the detailed catalogue belonging to the museum, and from this list it appears that this important collection, the result of the life-long labour of a master, contains, exclusively of the ethnological section, 770 pathological, and 337 physiological specimens. Respecting the nature, condition, etc., of the collection, we extract the following from a notice in French prefixed by the editors, Professors P. Harting and G. J. Loncq, of the University of Utrecht, to the list just mentioned: "The most interesting part consists of long series of pathological preparations of the different organs of the human body, which are so complementary one to the other, as to represent the different phases of the same disease. Another and smaller part is composed of physiological preparations. In the great majority the blood-vessels of both categories of preparations are injected with coloured substances. Lastly, a small number of skulls and skeletons of various nations complete the collection. Among the latter there are two skeletons of negroes which deserve special attention. All these objects are in a state of excellent preservation. With the exception of the greater part of those relating to diseases of the bones, and of a few others, the anatomical preparations are all preserved in spirit of wine." If we are rightly informed, the entire collection would be disposed of, under the circumstances, for about £500.

DANGEROUS LAMP OILS.—At the meeting of the Association of Medical Officers of Health, held on Saturday last, at the Scottish Corporation-hall, a paper was read on the recent petroleum accidents and on the ready detection of dangerous lamp oils. It was shown that these accidents had invariably resulted from the employment of oils capable of being ignited at a very low temperature, in many cases even below the standard of the Petroleum Act, one very severe accident being traced to the employment of an oil giving off inflammable vapour at a temperature below the freezing point of water. The author of the paper, Mr. Tegetmeier, exhibited a very easy and practical mode of detecting dangerous oils. Two teacupfuls of boiling water and one of cold water (at the ordinary temperature of a sitting-room) were mixed together in a small basin; a cupful of the water was then taken, and a teaspoonful of the oil to be tested poured on its surface; in a few seconds a light was applied to the oil. The dangerous oils, those capable of igniting below 128 degrees, immediately took fire, whereas it was shown to be impossible to ignite those which were of a safe and non-explosive character. In the conversation that ensued, Drs. Letheby, Lankester, and R. D. Thomson took part, and the desirability of raising the standard of the Petroleum Act from 100 to 125 degrees was discussed, many accidents, some of a fatal character, having arisen from the employment of oils having a higher inflaming point than 100 degrees Fahrenheit.

BOOKS RECEIVED.

Journal of the Workhouse Visiting Society. January, 1864. London: Longman and Co.

* * This record of a praiseworthy association notices the difficulty of combining law and charity—legal machinery to repel idleness and pauperism with kindness and sympathy. It acknowledges the underpaying of the Medical officers. Altogether it contains more subjects of interest than would be expected from its title.

Report of the Limehouse District of the Medical Officer of Health. 1863.

* * Calls attention to the excessive mortality in the eastern districts of London, which the writer refers to "more imperfect and inefficient ventilation," generating typhus, and intensifying other diseases. The western districts of the metropolis are compared with his own, and are

accredited with a larger proportion of consumption, and nearly as high an infant mortality. Strangely, as it seems to us, no reference is made to the different social status of the inhabitants. The other matter is mainly of local character.

Proofs of the Non-Existence of a Specific Ethetic Disease. By David MacLoughlin, M.D. London: John Churchill and Sons. 1864.

* * The writer is of opinion that "no Medical Practitioner who is acquainted with Medical science, and who respects himself, can at the bedside point out what are the pathognomonic symptoms of a primary syphilitic ulcer on the genitals, or on any other part of the body." He, therefore, addresses the Secretary of State for War, as "this so-called syphilitic disease" has never been scientifically studied by the Army Medical Department. He adopts the euphuism, "injury," for syphilis, the existence of which he denies.

The Dublin Quarterly Journal of Medical Science. February, 1864. Dublin: Fannin and Co.

* * Mr. Porter's Contributions to Operative Surgery; Notes on the Climate of the Swiss Alps, by Dr. Weber; Dr. McDonnell's Observations on Bromide of Potassium in Epilepsy; with other contributions on iridectomy, amputation at the ankle-joint, treatment of anthrax by pressure, and valuable clinical records, give great interest to this number. There is a long list of reviews and proceedings of several learned bodies, from one of which we laid an extract before our readers last week.

On the Diseases of Women. By Fleetwood Churchill, M.D. Fifth Edition. Dublin: Fannin and Co. 1864.

The Roman, or Turkish Bath. By James Lawrie, M.D. Edinburgh: Maclachlan and Stewart. 1864.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Mr. T. E. Amyot is thanked for his note and the enclosed article. *Inquirer*.—Churchill's or West's "Diseases of Women."

Dr. J. E. Smyth.—The Government Annuities Bill does not contain the proposed provision of superannuation allowance for Poor-law Medical officers.

An Appeal.—The sudden and unexpected death of Mr. W. S. Partridge, of High-street, Bordesley, Birmingham, who had honourably practised as a Surgeon in that neighbourhood for twenty-four years, leaving a widow and thirteen children almost deprived of the common necessaries of life, calls upon his numerous friends to do all in their power to alleviate their distress. With this object, a committee, composed of the under-mentioned gentlemen, has been formed for the collection and receipt of subscriptions, to be applied for the benefit of the family in such a way as shall be determined upon by three trustees, to be nominated by the committee. The committee earnestly appeal to the benevolent for their assistance in carrying out the object they have in view. Subscriptions will be thankfully received by Dr. Bell Fletcher (the Treasurer), any member of the committee, by Mr. E. F. Mason, 67, New-street, Birmingham (the Honorary Secretary), at the Office of the *Daily Gazette*, or by Messrs. Attwood, Spooner, and Co.

The Alleged Neglect of Prisoners by the Government of the Southern States.—Some weeks back an account of the neglect of Federal prisoners by the South was inserted in this Journal. In contradiction of that statement the following paragraph from the *Weekly Despatch* has been sent us by a correspondent:—

"The Richmond correspondent of the *Atlanta Appeal* describes a recent visit to the Hotel de Libby. He found the passages and ante-rooms of the prison piled up with boxes and bales of clothing and provisions, which had just been received from the North by flag of truce. Upon ascending to the upper storeys of the building occupied by the prisoners he saw the greatest profusion of comforts and luxuries in the way of *provant* that even a riotous imagination could conceive. Hams, smoked beef, Bologna sausages hung from the rafters; tin cans of potted meat, oysters, sardines, green peas, etc., were arranged on shelving against the walls; while the finest pippins rolled along the floors. Immense packages of new publications, sets of chessmen, backgammon boxes, etc., which had apparently just been opened for distribution, proved that the Yankees did not intend their unhappy brethren should die of *ennui*. The prisoners themselves were variously occupied, some lying at full length on the floor, deeply involved in the tragic incidents of Miss Braddon's novels; others playing whist and euehre, or deeply pondering the gambits; others asleep; others again eating their dinners. Bigadier-General Niel Dow was lapping up the soup furnished by the prison cook with evident satisfaction. One man only was reading the Bible. All looked in fine health, and seemed remarkably cheerful. Major Turner informed the writer that several of the officers of the highest rank had handed him a statement, which they had voluntarily drawn up, denying in the fullest and strongest manner the infamous lies about Confederate cruelty which have recently been circulated at the North."

SIR WM. BROWNE, M.D.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me to correct one error in Dr. Richardson's interesting Medical History of Lynn:—Sir William Browne, M.D., was not, as is there stated, the son of Dr. Edward Browne, nor, to the best of my belief, the grandson of Sir Thomas Browne, M.D., of Norwich. Dr. Edward Browne, who, at the time of his death—August 28, 1708—was President of the Royal College of Physicians, left but one son and one daughter: the former, Thomas Browne, M.D., a Fellow of the College of Physicians, died in 1710, aged 36, and was buried in the church of Northfleet, near Gravesend. Sir William Browne, M.D., the eccentric Physician of Lynn, was the son of a Physician, was born in the county of Durham in 1692, and would appear not to have been of the same family as the distinguished Norwich Physician, the author of the "Religio Medici."

I am, &c.

40, Finsbury-square.

W. MUNK, M.D., F.S.A.

THE DIMINUTION OF THE MAORIE RACE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having seen your observations upon Dr. Tukcs' "Medical Notes on New Zealand," and your selection of his observations; and while I bear testimony to their point and correctness, you must permit me to declare that there are other and more certain causes which will lead to the destruction of the Maorie race than those mentioned by Dr. Tukcs, if they are allowed to continue much longer. The great curse of the Maorie people is their tribal condition. Setting aside the injustice of the lazy and indolent sharing equally in the production of the soil and all other of God's blessings with the good and industrious—a fact that stops anything like individual improvement—there is a species of communism among the soxes which is rapidly deteriorating the race, and must eventually lead to its extinction. At almost all the native villages indiscriminate intercourse at the earliest ages is common among the boys and girls of the tribe. The natural result is that women become barren, like the prostitutes of the cities of Europe; when they grow up and are married, they have few or no children. In the earlier ages of the race illicit intercourse was punished by death; but in the present transition state of the Maorie race, the Christian dispensation affords but a moral restraint, which is ill-appreciated by the semi-savage. Hence, if the Maories continue to enjoy their tribal rights, and be independent of British rule and British precept, they must become speedily extinct.

The Maorie war which is now waging will be the saviour of the Maorie race if it ends in the removal of this tribal condition, which prevents improvement and tends to destruction,—if it places the semi-savage in the position of a British free man;—if, while it gives him all the rights and advantages, it shall make him amenable to all its duties, it will at once advance him in the scale of the human family, and give him an opportunity of improvement in every point of view. Such is the desire of the British race in New Zealand; and, should this war accomplish such a result, the improvement of the colony will be more rapid and important than ever fell to the lot of any British colony.

I am, &c. S. J. STRATFORD, M.R.C.S. Eng.

Auckland, New Zealand, December 4, 1863.

ON TRICHINÆ MORBUS.

BY ADOLPHE WAHLTUCH, M.D., L.R.C.P. LOND.

THE Trichinæ Morbus having lately attracted the attention of the Medical Profession, as well as of the laity, it seems to me to be a matter of special importance to note all the facts which bear relation to it, and to spread the knowledge of them to the widest extent.

The tragedy of Hettstädt, where, at a dinner party, numbers, who had partaken of fresh sausages, became victims to the poison of Trichinæ, supplies us with the following striking observations:—Of those who, at dinner, used a Red-wine, the greater number of cases soon terminated fatally; of those who drank a Rhine-wine or Beer, this fatal termination was somewhat postponed; while of those who indulged in Spirits, none were affected by the disease. A similar sad catastrophe is reported from Wiesbaden, where, at a wedding-breakfast, in which about twenty persons took part, several of the guests became diseased, but recovered; whilst the young couple, whose union they were met to solemnise, soon perished from the fell effects of this poison.

Dr. Tümgel, of Hamburgh, narrates a poisoning by pork, whereby, in 1851, several persons were affected, while three of the number died. Judging from the recorded symptoms, he comes to the conclusion that these were cases of Trichinæ Morbus.

Dr. Kopp also records several cases of poisoning by sausages, which he lays down to Trichinæ Morbus from the fact, that the symptoms of disease made their appearance not before the end of the second week after the use of the suspected food, which had been but once partaken of. Fish-poison likewise deserves our attention, in so far as the sturgeon has injurious effects only if used in a raw state, and never if cooked. This statement would lead to the idea of parasites swallowed, which may live and generate symptoms of disease in the human body.

Dr. Fiedler experimented on live rabbits, and found that the migration of embryos to the muscles begins on the tenth day after their introduction into the body, that it is at the highest point on the thirteenth to the fifteenth day, but lasts to the thirtieth and the thirty-fourth day. The "incapsulation" of the Trichinæ begins towards the end of the fourth week; the "incalcination" is scarcely complete before the ninth to the twelfth month. All his therapeutical experiments had a negative result: he tried Oil of Turpentine, Glycerine, Camala, Extr. Filicis Maris, Kali Pyronitricum, Acetum Pyrolignosum,—but all in vain; all purgatives were unsuccessful. The Trichinæ die at 50° Reaum. (144½° Fahr.). Professor Langenbeck, of Hanover, found Trichinæ in the earthworm (*Lumbricus terrestris*); he is of opinion that the Trichina is nothing else but the well-known *Ascaris minutissima*. As a prophylactic measure, he advises that swine should be fed only in yards with a close, well-rammed pavement. Geese, ducks, etc., are free from the disease, as they swallow and likewise eject the earthworm whole.

In my opinion the Trichinæ seem long ago to have selected man as one of their victims, but have remained latent or unobserved by the Profession, until their ravages became wholesale massacres. The noxious influence of unsound meat and fish has been acknowledged in all ages; and Medical sanitary rules for the prevention of their use are adopted everywhere. As the Trichinæ die at a temperature not less than 144½° Fahr., I should consider it advisable totally to avoid the use of raw meat or fish, and to subject it to a higher temperature and for long enough to assure its being well-done throughout. If the *Lumbricus terrestris* is indeed the primitive bearer of the Trichinæ, special attention should be

paid to the feeding of animals; and though it is not always possible to prevent the admixture of earthworms with their food, nevertheless a relative prophylactic measure is preferable to none at all; the very absence of success in therapeutical experiments must increase the necessity for prophylaxis.

29. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital 1½ p.m.; Samaritan Hospital, 2½ p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures on Physiology.—Lecture II.—The Evolution of Carbonic Acid by the Lungs and Skin, and other Phenomena of Expiration and Excretion, under the Influence of various Agencies. By Edward Smith, M.D., F.R.S., F.R.C.P. PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

March 1. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. A. R. Wallace, Esq., F.L.S. "On the Origin of the Races of Men with Reference to the Theory of Natural Selection."

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Life."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8 p.m. Anniversary Meeting. ST. MARY'S HOSPITAL MEDICAL SCHOOL, 8 p.m. Dr. Graily Hewitt, "Clinical Conference in Midwifery."

2. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Dr. Tyler Smith, "Cases of Ovariectomy," and Papers by Mr. Squire and others.

3. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Mr. Weeden Cooke, "On the Tumours Affecting the Female Breast."

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Life."

4. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of the Council.

ROYAL INSTITUTION, 8 p.m. Professor Stokes, Sec.R.S., "On the Discrimination of Organic Bodies."

WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Practical Evening, for the Narration of Cases and the Exhibition of Specimens.

ORIGINAL LECTURES.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians: Physician to King's College Hospital.

LECTURE IV., FEBRUARY 5.

MR. PRESIDENT,—Before commencing my Lecture I will draw your attention to some fine specimens of *Cannabis Indica*, with its extract and tincture, also of the active principle, digitalin, which were not present on Wednesday when I was discussing the value of these substances. To-day, I shall speak of other introductions into the British Pharmacopœia, and shall first draw your attention to certain resins either obtained from drugs already officinal or newly introduced. These are,—the Resin of Jalap, the Resin of Scammony, and the Resin of Podophyllum, known more commonly at the present time as Jalapine, Scammonine, and Podophylline. Of the first I need only state that it constitutes the active part of jalap, of which it forms from 12 to 15 per cent., and hence the dose of the resin, compared with that of jalap, should be in the inverse ratio.

Scammony itself, the dried milky exudation of the root of the plant, consists chiefly of a resinous matter; in good Scammony the amount of resin should be about 80 per cent., but, as found in commerce, it is a most variable drug, from the adulterations to which it is subjected. I believe that about two tons of Scammony are annually sent to Europe, and it is the object of 2000 men in Asiatic Turkey to adulterate it in the most advantageous manner. Hence it was not uncommon to extract the resin from the Commercial Scammony, and use it in this form.

Scammony Resin is now ordered to be made from Scammony Root by means of Rectified Spirit, and when thus prepared differs in some respects from the Scammony itself, more especially in its odour. Scammony has a disagreeable, musty odour, arising probably from fermentation having taken place in the juice before becoming dry, and butyric and other acids thus formed; but the root itself, as you may perceive from the specimen, has a fragrant smell, and hence Resin prepared directly from it participates in that odour.

As to the physiological and therapeutic action of this resin, I may tell you that numerous clinical observations have been made with it both by Dr. Farre and myself, which have already been published, and the result of which was, that Scammony Resin made from the root is quite equal to the best Virgin Scammony: it was tried by itself, and likewise in combination with other purgatives, as in the compound Extract of Colocynth. Should it be practicable to ensure a supply of the root, it cannot but prove of advantage to have the Resin made in this country, as we should then be free from the possibility of its being adulterated abroad. The *Mistura Scammonia* is ordered to be made with the Resin, rubbed up with milk, and it is optional to use either the Resin or Scammony itself in the preparation of the compound Extract of Colocynth.

I should mention that the same option is extended to *Confectio Scammonia*, or Confection of Scammony, contained in the British Pharmacopœia.

The dose of Resin of Scammony is much the same as that of the best Scammony.

The third Resin is that obtained from the root of the plant called *Podophyllum peltatum*, belonging to the natural order *Ranunculaceæ*, and growing in North America. The characters, both of the root and Resin, will be seen in the specimens; they are fully described in the Pharmacopœia, but I have neither necessity nor time to detail them here.

This Resin, under the name of Podophylline, has of late been

extensively employed in this country, and various are the opinions as to its value as a therapeutic agent. From some personal experience in its use, and from what I have been able to gather from the observations of several Physicians, I have formed the following opinion of its action:—

1. Resin of Podophyllum is a powerful purgative.

2. It often produces actions from the bowels containing abundance of biliary matter, but this is probably more from its causing an emptying of the gall bladder, than from its augmenting the secretion of this fluid. I state this from noticing the fact that when many evacuations were caused by it, the latter were rather of a serous or mucous than bilious character.

3. That it often, when administered in large doses, causes much griping and depression.

4. That it is better to give it in conjunction with other purgatives than to trust to it alone for the cathartic effect.

5. That when thus combined it assists the action of the purgative, and often enables one pill to take the place of two or more.

6. That its griping properties can be much mitigated by combination with small doses of Belladonna or Henbane Extract.

7. That it is a valuable addition to the *Materia Medica*, and often capable of replacing mercurials as a cholagogue purgative.

The doses of Podophyllum Resin vary from a quarter of a grain to half or even one grain.

With the exception of the changes of nomenclature in the mercurial preparations which we spoke of in our last Lecture, no extensive alterations have been made.

In the first place, the Red Sulphuret or Cinnabar, termed, in the London Pharmacopœia, *Hydrargyri Bisulphuretum*, has been omitted; this is used occasionally as a colouring ingredient, but chiefly for the purposes of fumigation; for the former object it is worse than useless, and for the latter, its place can be well supplied by the Red Oxide, which is more readily volatilised.

Hydrargyri Iodidum Rubrum, or the Red Iodide of Mercury, has been introduced. All I need state concerning this salt is, that it consists of single equivalents of mercury and iodine, and that its composition is represented by the symbol, HgI (the equivalent weight of mercury being taken at 100); that it stands in the same relation to the green iodide of the metal, as corrosive sublimate does to calomel; and, lastly, that an ointment of the salt, containing sixteen grains to the ounce of simple ointment, is ordered to be prepared.

The dose of the salt is from one-twelfth to a quarter of a grain, larger than that of corrosive sublimate, as the amount of mercury is much smaller, from the equivalent of iodine being so high. The ointment should be used with some caution, on account of its irritant properties.

In relation to the administration of the Iodides of Mercury, it may be well to recall to your minds the powerful influence of iodine preparations in modifying the action of mercurials, or in causing, under certain circumstances, the development of the symptoms of the metal, and probably these considerations may apply to the difference of action of the iodides when compared with other salts of the same metal.

For many years before M. Melsen had published his researches upon this subject, I had seen from time to time patients who exhibited all the symptoms of mercurialisation from the exhibition of iodide of potassium. It had also been noticed in works on *Materia Medica* that the iodide occasionally produces effects similar to mercury. No explanation, however, was offered of the occurrence of such symptoms. It can be shown conclusively that when mercury is administered for any length of time it becomes in part deposited in the tissues in an insoluble form. In explanation of this, it may be stated that some of the salts of this metal, as the corrosive sublimate, form a very slightly soluble compound with albumen; and there is likewise evidence that mercury at times is reduced to a metallic form within the body, occasionally giving rise to suppuration and necrosis, and it has even been found after death in the liquid state in the heads of the bones. M. Melsen has shown most conclusively that the administration of iodide of potassium to patients in whom mercury is thus retained, has the power of setting the metal free, of rendering it soluble, and thus of bringing it back into the blood, and of again inducing all the symptoms of mercurialisation.

About two years since, I had a patient under my care, in whom the power of the Iodide of Potassium in thus reinduc-

ing mercurial action, was beautifully illustrated. The following are the details:—

A young man was admitted into the Hospital suffering from a tubercular skin affection and ulcerated throat of a syphilitic nature. He was first placed under the influence of Iodide of Potassium, commencing with five-grain doses, and afterwards increased to ten grains, and given three times a-day. No physiological symptoms were induced, and the disease did not appear to be influenced by the treatment. Calomel, in grain doses, was next administered, and full salivation was induced; and along with this both the throat and skin rapidly improved, and, after a short time, became nearly well. The Mercury was then discontinued, and the symptoms of the metal gradually subsided, and at last entirely disappeared. When we were fully assured that such was the case, Iodide of Potassium was again prescribed, in ten-grain doses; but within forty-eight hours mercurialisation had returned in such intensity that the salt had to be discontinued: with its omission, the symptoms ceased, but returned again, in a slighter degree, on the patient resuming the iodide. After a time, he was able to take the full dose with impunity, probably from the mercury having been eliminated from the body.

The simultaneous administration of mercury and iodine is productive of peculiar effects; and it is most probable that the same may occur, at least in some degree, when the Iodides of Mercury are introduced into the system.

Hydrargyri Nitratæ Liquor is another introduction into the Pharmacopœia of this country. It is a strong solution of the Nitrate of Mercury—a salt corresponding to the Corrosive Sublimate, Hg,NO_5 , and has been employed as a powerful caustic in cancerous affections. Its application has sometimes been followed by absorption of the metal and the production of mercurialisation: hence some care is required in its use. It is applied to the diseased part by means of a camel's hair brush.

In the preparations containing alcohol, ether, and similar bodies, some rather important alterations will be found in the British Pharmacopœia. These I will now try and explain. Rectified Spirit, Proof Spirit, Sherry Wine, and Chloroform remain practically the same as before, the term Chloroformum being substituted for Chloroformyl; Spiritus Vini Gallici, or French Brandy, is omitted; Ether is ordered of lower specific gravity—viz., 0.735, instead of 0.750—and hence it contains less spirit and water; Oleum Æthereum, or Ethereal Oil, has been omitted; and Spiritus Ætheris Nitrosi considerably modified; and lastly, Spiritus Pyroxylicus has been introduced. First, with regard to the omission of Ethereal Oil, which was supposed to form an important ingredient in Spiritus Ætheris Compositus, or the old Hoffman's Anodyne. It has been omitted, I believe, mainly for the following reasons:—

1. Although imagined to be more antispasmodic in its properties than ether, no clinical observations had proved that such was the case.

2. It is a most expensive preparation when properly prepared, and one very liable to undergo decomposition.

3. It is not only extensively adulterated, but not unfrequently other compounds are substituted for it.

Under these circumstances it was considered desirable that the ethereal oil should be altogether abandoned, and hence the former Compound Spirit of Ether is designated simply Spiritus Ætheris, and contains one part by volume of the Ether of the Pharmacopœia to two parts of Rectified Spirit.

There is only one remark needed with regard to Chloroform—namely, that a preparation, Spiritus Chloroformis, or Spirit of Chloroform, is introduced to substitute the so-called Chloric Ether so largely employed in practice at the present day. The name Chloric Ether is very erroneously applied to the preparation, as it is only a mixture of Chloroform and Rectified Spirit, and has no possible relation to the true Chloric Ether or Chloride of Ethyle, as will be seen by the formula on the board—

Chloroform— $\text{C}_2\text{H,Cl}_3$ —Trichloride of Formyl.

Chloric Ether— $\text{C}_4\text{H}_5\text{,Cl}$ —Chloride of Ethyl.

The so-called chloric ether hitherto employed in Medicine has varied very greatly in strength. At some establishments one part of chloroform by volume was dissolved in six parts of rectified spirit: at others the compound did not contain more than one part of chloroform in nineteen of spirit. In the British Pharmacopœia a correct nomenclature is employed, where the preparation is named Spiritus Chloroformi, and a definite composition is given—namely, one part by volume of chloroform to nineteen parts of spirit: it contains, therefore, one

part in twenty. This strength was selected as yielding a preparation from which the chloroform is not precipitated, even when it is mixed with water containing much saline matter dissolved in it.

We have next to allude to the Spiritus Ætheris Nitrosi, or Spirits of Nitrous Ether, called in the London Pharmacopœia Spiritus Ætheris Nitrici. As its name indicates, it should consist of a solution of true nitrous ether in spirit, but the London preparation is in this respect very faulty. It is made by distilling a mixture of nitric acid and rectified spirit, and, as a result, we have a spirit holding in solution scarcely any nitrous ether or nitrite of ethyle, but other compounds, especially aldehyde, which, by keeping, is gradually acidified into acetic acid; it is, therefore, a preparation having but little relation to the name it bears, and probably not very potent as a remedial agent. I am assured that, as found in the shops, it often contains less than 1 per cent. of the nitrous ether. In the British Pharmacopœia a new, and, I trust, greatly improved, process has been introduced: a salt, the Nitrite of Soda, is placed in the Appendix, with the method and process for its manufacture from the nitrate of the same base; this salt is then distilled with a mixture of rectified spirit and sulphuric acid. The nitrous acid, liberated by the action of the sulphuric acid, unites directly with the ether of a portion of the alcohol, forming nitrite of ethyle, which distils over with the undecomposed spirit, and forms the Pharmacopœia compound—Ætheris Nitrosi Spiritus, or Spirit of Nitrous Ether. Tests are given in the Materia Medica to ascertain the presence of the Nitrite of Ether, and, when properly prepared, it contains between 5 and 6 per cent. of this body. We shall now, therefore, have an opportunity of ascertaining if nitrous ether possesses any well-marked valuable properties as a diuretic—a point which, hitherto, in this country, we have been unable to determine, on account of the very small amount of the compound contained in our Pharmacopœia preparation. In the formula on the board you will observe the composition of the various compounds which I have referred to in speaking of this preparation; and on the table the preparation itself.

Nitrate of Soda = NaO,NO_5 .

Nitrite of Soda = NaO,NO_3 .

Nitrite of Ethyle, or true Nitrous Ether = $\text{C}_4\text{H}_5\text{O,NO}_3$.

Aldehyde = $\text{C}_2\text{H}_4\text{O} + \text{HO}$.

Acetic Acid = $\text{C}_4\text{H}_7\text{O}_3 + \text{HO}$.

I have, lastly, to refer to the introduction of Spiritus Pyroxylicus Rectificatus, or the Rectified Pyroxylic Spirit, into the British Pharmacopœia. It is defined to be hydrated oxide of methyle, with about 10 per cent. of water, a product of the distillation of wood. Before proceeding to discuss the properties of this body, I must impress upon you the necessity of separating it in your minds entirely from the Methylated Spirit which is now so largely used in this country in manufacture, and which is not subject to the excise duty imposed on other spirit. The so-termed Methylated Alcohol is ordinary rectified spirit, to which one-fortieth of methylated alcohol has been added—an addition which is supposed to render it quite unfit for use as a beverage. It is a fact much to be regretted that some druggists have made certain Pharmacopœia preparations with this adulterated spirit, instead of the Rectified Spirit of the Pharmacopœia. The Aromatic Spirits of Ammonia, Spirits of Nitrous Ether, and even tinctures have been thus prepared. Such a practice, on every ground, cannot be too much deprecated. The Pyroxylic Spirit of the Pharmacopœia differs altogether from this—it is Wood Spirit Alcohol, free from most of the strong and nauseous compounds which contaminate the crude article employed in adulterating Rectified Spirit, and has a composition which you will observe on the board, and be enabled to compare it with ordinary or Ethylic Alcohol:—

Wood, or Methylic Alcohol—Hydrated } = $\text{C}_2\text{H}_3\text{O} + \text{HO}$.

Oxide of Methyle } = $\text{C}_4\text{H}_5\text{O} + \text{HO}$.

Ethylic Alcohol—Hydrated Oxide of } = $\text{C}_2\text{H}_3\text{O}_3 + \text{HO}$.

Ethyle. } = $\text{C}_4\text{H}_5\text{O}_3 + \text{HO}$.

By oxidation, Methylic Alcohol yields } = $\text{C}_2\text{H}_3\text{O}_3 + \text{HO}$.

Formic Acid } = $\text{C}_4\text{H}_5\text{O}_3 + \text{HO}$.

By oxidation, Ethylic Alcohol yields } = $\text{C}_4\text{H}_5\text{O}_3 + \text{HO}$.

Acetic Acid } = $\text{C}_4\text{H}_5\text{O}_3 + \text{HO}$.

On the table you will see the two bodies just alluded to, and, in addition, a specimen of Methylic Acid, which is remarkably free from impurities, and which has been recently prepared by a new process.

The question of greatest moment to us in relation to this subject is this—Has Methylic alcohol any valuable medicinal properties? It has been employed as a sedative, and has been

asserted to be useful as such, in allaying sickness in certain forms of gastric disturbance; it has also been employed to check cough and expectoration in phthisis and bronchitis. Personally I have had but very slight experience of its efficacy, but I cannot help being strongly impressed with the idea that where it has proved efficacious its value has depended rather on the contained impurities than on the true Methylic alcohol, of which it is chiefly composed.

The impurities are usually high hydrocarbons more or less allied to creosote, and we are all aware that in some forms, both of stomach and pulmonary affections, this substance is very useful. I question (although I do so with some diffidence) whether an absolutely pure Methylic alcohol, which has no more odour than Ethylic alcohol, would be found to produce physiological or therapeutic effects appreciably differing from those of an equal quantity of common spirit. To demonstrate this, however, we must have recourse to clinical observation. I do not think I should be wrong in stating that the many reasons which exist against the employment of this substance altogether in Medicine caused some of the Committee to object greatly to its introduction into the British Pharmacopœia.

(To be continued.)

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

LECTURE II.

(Continued from page 196.)

INFLUENCE OF DISEASE ON THE DAILY EXCRETION OF
URINARY SOLIDS.

Disease exerts a marked influence over the urinary solids, its most general effect being rather to diminish than augment them. In cases of anæmia and chlorosis, for example, the diminution is sometimes very considerable. The twenty-four hours' urine of M. L., aged 30 (Hospital case), suffering from anæmia, consequent on hyper-lactation, contained—

Total Solids.		Organic.		Inorganic.	
grammes.	grains.	grammes.	grains.	grammes.	grains.
34.89	= 540.79	26.63	= 412.76	8.26	= 128.03

Lest some may suppose that in this case the diminution in the amount of urinary solids may have been due to a diminished supply of food, I shall quote another case from private practice, about which there can be no doubt. This lady was also suffering from anæmia, and being of the same size, and nearly the same age (32) as the preceding, it may be taken as a parallel case. Her diet was of the most nourishing description. Turtle, and other nutritive soups, well-cooked fresh meats, and three or four glasses of wine daily. Notwithstanding this, the twenty-four hours' urine yielded on analysis only—

Total Solids.		Organic.		Inorganic.	
grammes.	grains.	grammes.	grains.	grammes.	grains.
32.64	= 505.92	24.98	= 387.19	7.6	= 117.80

being even less than the Hospital case.

I have now to quote an example of an increase of the urinary solids as the effect of disease. The most interesting case of this kind which has fallen under my personal observation is that of a gentleman aged 43, of very high literary attainments. He had enjoyed perfect health till within eighteen months before I saw him, when, after great and continued mental exertion, he was seized with intense frontal headache, and violent palpitation of the heart; so much so, that he had to resign his appointment, and desist from all mental labour. When brought to me by Dr. King, he was suffering from other symptoms in addition to the above, the most distressing of which were, pain from the hips downwards, with shooting, burning sensations in the soles and upper part of the feet. He had also pricking, burning sensations in the wrists and hands, and to such an extent did these annoy him, that they

prevented his ever enjoying a comfortable night's rest. On analysis, his twenty-four hours' urine was found to contain a very great excess of solid matter; and this, too, in spite of his taking very little food, in consequence of his suffering from dyspepsia. Under treatment, a marked diminution of the urinary solids took place, and with it a corresponding improvement in health. The twenty-four hours' urine was analysed on three separate occasions, with the following results:—

	Total Solids.		Organic.		Inorganic.	
	grammes.	grains.	grammes.	grains.	grammes.	grains.
March 19	80.67	= 1250.38	57.42	= 890.01	23.25	= 360.37
„ 31	71.61	= 1109.95	49.22	= 762.91	21.39	= 331.54
April 22	63.24	= 980.22	47.82	= 741.21	15.42	= 239.01

At the time of the last analysis the patient was very much improved.

The quantity of solids daily excreted may, in certain diseases, be far greater than even the above.

In cases of diabetes, for instance, the amount of solid matter may be enormously increased—not merely on account of the presence of sugar, but also on account of several of the urinary ingredients being augmented. Here is the analysis of the urine of a gentleman, aged 57, who suffered for six years from diabetes. I quote it, not because it is the most striking example I could give, but because it happens to be the first that has come to hand, and because I shall have afterwards to refer to the case when on the subject of treatment:—

	Total Solids.		Organic.		Inorganic.	
	grms.	grains.	grms.	grains.	grms.	grains.
24 hours' urine . .	276.21	= 4281.25	256.60	= 3977.30	19.60	= 303.80

I might go on quoting many more such examples; but these are sufficient for the present purpose. I shall, therefore, turn to the important question,—What effect have remedies in controlling the elimination of solids by the kidneys?

EFFECT OF REMEDIES ON THE URINARY SOLIDS.

There are certain remedies which have a powerful effect in reducing, and certain others which have an equal effect in augmenting the urinary solids. First, as regards those remedies which reduce them. Nearly all belong to the narcotic group; and the most active are opium, morphia, conia, hyoscyamus, and Indian hemp. As one and all of these, from their specific action on the nervous system, are occasionally counter-indicated, it fortunately happens that we have another group of remedies of an entirely opposite neurotic character, which also have the power of diminishing the elimination of solid matter by the kidneys. The most powerful of these, I believe, is the citrate of quinine and iron, and next to it the ammonio-citrate of iron in combination with quassia—two remedies which, as was before seen, have also the property of diminishing, in certain cases, the amount of liquid excreted by the kidneys.

Those medicines which, on the other hand, increase the solids are digitalis, atropine, and colchicum—indeed, it is possible that the chief benefit derived from the use of these remedies in certain diseases arises from this action. In gout, for example, both immediately before and during the paroxysm, the urinary solids are said to be diminished; whereas, as soon as the paroxysm begins to subside, they are said to increase, and the more rapid the increase the quicker appears to be the convalescence of the patient. Now, it so happens that both the carbonate of potash and colchicum, which, as is well known, are useful remedies in the majority of cases of gout, increase the elimination of solid matter by the kidneys.

There are yet other substances which, although not usually classed under the head of medicines, nevertheless merit our attention. These are alcohol, wine, and beer—all of which influence the daily amount of solids passed by the kidneys. Thus, Böcker found that alcohol and beer lessen the quantity, while white Rhine wine (Niersteiner) augments it. Here, then, we see that in the treatment of disease we can even select our stimulants so as to further the effects of our other remedies.

INORGANIC SALTS.

It must have been observed that I have hitherto spoken of the urinary solids as a whole, notwithstanding that they consist, as you are aware, of two parts, an organic and an inorganic. I have purposely done so in order to save time; for, as a rule, what influences the one influences the other. There are, however, certain exceptions to it, with which I must now make you acquainted.

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

From the preceding tables you will have learned that the organic is usually greatly in excess of the inorganic matter; and, although this is the case at all periods of life, yet the relative proportion varies with the age. Thus, it will be seen by the subjoined table, that while a child aged eighteen months passes for every pound of its weight only one-third more organic matter than the adult, it excretes no less than three times more inorganic salts:—

Solids per lb. of Bodily Weight in Twenty-four Hours' Urine.

	Total Solids.		Organic.		Inorganic.	
	grammes.	grains.	grammes.	grains.	grammes.	grains.
Girl aged 18 mths	0.58	= 8.99	0.33	= 5.11	0.24	= 3.72
Mother aged 27 yrs	0.31	= 4.80	0.23	= 3.56	0.08	= 1.24

The excess is here still seen to be in favour of the organic; and even in disease this rule holds good. There is, however, one remarkable exception to it, which, as far as I am aware, has not been noticed by other observers. And this is the more surprising, seeing that not only is the relationship altered, but actually reversed, the inorganic preponderating over the organic ingredients of the urine. The most striking illustration that I can give of this most important fact is in albuminuria, and I think that I cannot do better than quote the one cited in a memoir "On the Blood and Urine of Pregnancy," published conjointly by Gegenbaur and myself in Scanzoni's "Beiträge" for 1854. The case was that of a woman, aged thirty-nine, the analysis of whose urine yielded the following results:—

In the 24 hours' Urine.	26 days before Delivery.		14 days before Delivery.		7 days after Delivery.	
	c. c.	oz.	c. c.	oz.	c. c.	oz.
Water	1169	= 37.7	1668	= 53.8	1792	= 57.8
	grms.	grains.	grms.	grains.	grms.	grains.
Organic solids	16.37	= 253.73	21.67	= 335.88	27.69	= 429.19
Inorganic salts	28.88	= 447.64	26.70	= 413.85	31.01	= 480.65

Here it is seen that the inorganic ingredients preponderated over the organic on the twenty-sixth day before delivery as seven to four, on the fourteenth day as nine to seven, and on the seventh day after delivery, when the albuminuria was already beginning to diminish, as ten to nine.

DETERMINATION OF THE WATER AND SOLIDS.

Having ascertained the exact quantity of urine passed in the twenty-four hours, we can form a rough estimate of the amount of solids it contains by multiplying the last two figures of the specific gravity by 2.33. Thus, in the case of a urine of 1020 specific gravity, if the 20 were multiplied by 2.33, the result would be—the solids in 1000 cubic centimetres of urine $20 \times 2.33 = 46.6$ grammes.

If, instead, however, of 1000, 1250 cubic centimetres of urine were passed in the twenty-four hours, an additional "simple proportion" calculation would be required to ascertain the total amount. Thus, if 1000 cubic centimetres of urine contained 46.6 grammes of solids, 1250 cubic centimetres would contain 58.25; the calculation being to multiply 46.6 by 1250, and divide by 1000.

$$\frac{46.6 \times 1250}{1000} = 58.25 \text{ grammes.}$$

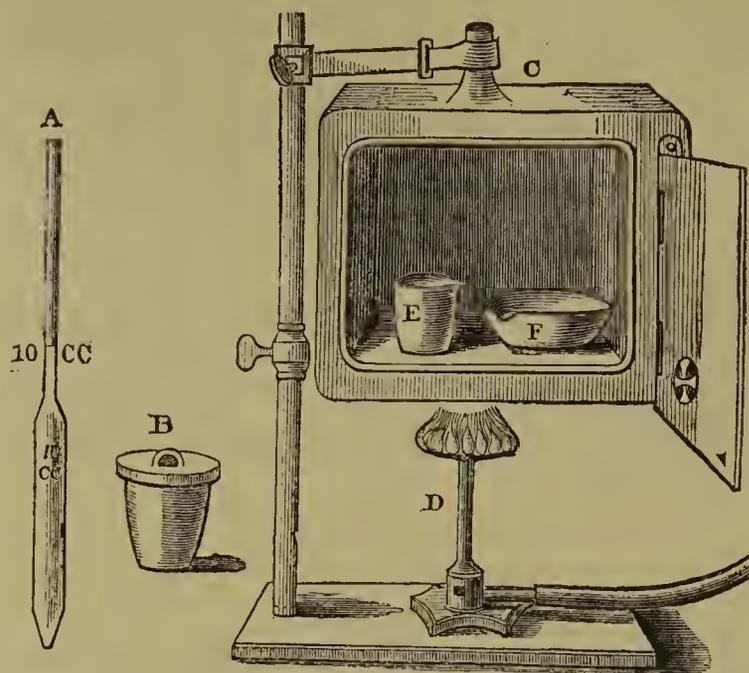

Again, if instead of 1250 cubic centimetres of urine being passed, there were only 800 cubic centimetres, the calculation would still be made on precisely the same principles.

$$\frac{46.6 \times 800}{1000} = 37.28$$

Although this method does very well when we merely wish to have a rough guess at the amount of solids passed in the twenty-four hours, and it might even be sufficiently exact for ordinary clinical purposes if the specific gravity of the urine were carefully taken with a correct apparatus—the pick-nometer (Fig. 3, E), for example; yet it is found to be inadequate for scientific purposes, and, therefore, it is necessary to proceed as follows:—Twenty cubic centimetres of urine are exactly measured off in a graduated pipette (Fig. 6, A), put into a clean porcelain crucible of known weight, and again weighed to ascertain the weight of the urine it contains, should that not have been previously done in finding its exact specific gravity. (I generally use the pick-nometer as the measure, and thereby make one weighing do for both.) The uncovered capsule (Fig. 6, E) is now placed in a close water-bath, heated to 100° C. (212° F.), and kept there until the aqueous part of the urine is all driven off. When such is the case, the crucible will cease to lose weight. (The drying is

further insured by placing the capsule for a short time under an air-pump.) The difference between the capsule when first weighed and in its now dry state gives the quantity of water

FIG. 6.

in twenty cubic centimetres of urine. If the patient chance to have passed 1000 cubic centimetres in the twenty-four hours, all that is required is to multiply the loss of water by fifty, and the result is the total amount of water in the twenty-four hours' urine.

Next, as regards the solids, the weight of the brown residue now remaining in the crucible is the weight of the solids in 20 cubic centimetres of urine; and supposing, as we have just said, 1000 cubic centimetres of urine were passed, and the residue weighed 0.6 grammes, the calculation would be:—Multiply 1000 by 0.6, and divide by 20, the amount of urine employed in the analysis—

$$\frac{1000 \times 0.6}{20} = 30$$

30 grammes, or 465 grains in the twenty-four hours. The calculation might be simplified by multiplying 0.6 by 50.

Lastly, to ascertain the amount of inorganic salts. This is done by placing the crucible containing the urinary solids over the flame of a spirit-lamp until all the organic matter is destroyed, and there remains nothing but the inorganic ash of the 20 cubic centimetres of urine. (e) The capsule is now allowed to cool, and again weighed, when the weight of its contents will represent the amount of inorganic salts in the 20 cubic centimetres of urine. Suppose, for example, that they weigh 0.3, the calculation would be—

$$\frac{1000 \times 0.3}{20} = 15$$

15 grammes, or 232.5 grains of inorganic substance in the twenty-four hours' urine.

DEATH OF DR. JOHN JACOB, OF MARYBOROUGH.—With grief we have to record the death of this distinguished member of our Profession, and to express on the part of our brethren the regret they must entertain for the severe loss they have suffered by the lamentable event. His eminence as a provincial practitioner, his high character for independence as a member of our body, and his unflinching honesty, won for him a position in public estimation which cannot fail to sustain the reputation of those who are engaged in the pursuits to which he was specially devoted. He had been for some years in a precarious state of health from excessive labour in the discharge of his public duties, and has, in fact, fallen a victim to that spirit of determination and energetic devotion to the service in which he was engaged for which he was so remarkable. On a future occasion we hope to enter more largely into some detail as to the part he has taken in Medical affairs.—*Dublin Medical Press.*

(e) In order to get the ash perfectly white, it is necessary to add either a few drops of nitric acid, or a fragment of the nitrate of ammonia to the charred mass, and again expose the crucible to a red heat.

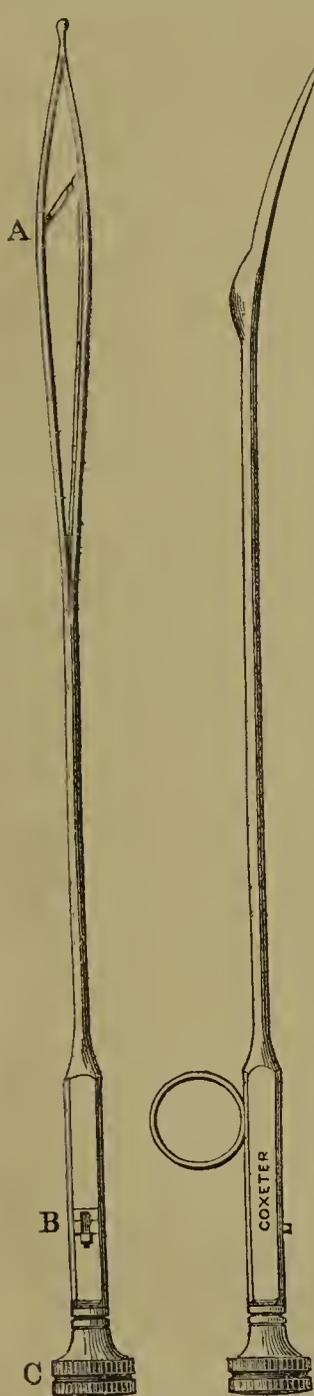

ORIGINAL COMMUNICATIONS.

NOTICE OF AN INSTRUMENT FOR DILATING THE CANAL OF THE CERVIX UTERI.

By WM. O. PILESTLEY, M.D.,

Professor of Obstetric Medicine in King's College, London.

MR. COXETER, of Grafton-street, has recently made, under my direction, a dilator for the os and cervix uteri, which I have found very convenient and effective, and which may be serviceable in the hands of other Practitioners. The instrument

consists of two blades in lateral apposition, united at their extremities, and again about five inches lower down, being un-united in the interval. The form is that of an uterine sound. A projection two and a-half inches from the point indicates the length of the uterine cavity, and the finger can ascertain by its position how far the instrument has passed into the womb. The mechanism is borrowed from Mr. Henry Thompson's dilator for the male urethra. A small cross-bar, forming a lever, lies between the un-united portion of the blades at A, and this is made to assume a position more or less horizontal by means of a wire passed through the stem of the instrument, which is worked up and down by means of a screw (C) attached to the handle. An index at B shows how far the blades are separated in the progress of dilatation, and a ring is fixed to the under side for the insertion of the fourth or fifth finger of the left hand, to steady the instrument, while the finger and thumb of the same hand are employed in turning the screw. In this way the right hand is free to guide the point of the sound in the necessary direction, and to keep it *in situ* during the expansion.

The advantages possessed by this form of dilator are,—that it can be fashioned very small for extreme instances of contraction, where it would be very difficult to pass in a sponge-tent; and, although the flexibility of the uterine sound is not consistent with its mechanism, yet it can be made of any curve required. The dilatation produced is lateral, gradual, and progressive, without necessarily being so forcible as

to rupture tissue, and there is little tendency in the instrument during the separation of the blades to work itself downwards and withdraw from the os uteri.

Further, the whole cervical canal, including the os uteri internum, can be widened by this instrument, but its greatest power of expansion corresponds to the os uteri externum, where dilatation is most required.

The instruments previously in use have lacked some of the advantages mentioned, and have thus been less useful. Among others, I possess a dilator employed by the late Dr. Edward Rigby, constructed like a pair of polypus forceps, with the blades terminating in a long and slender duckbill, for insertion into the os uteri. The instrument could not be passed into an os uteri much contracted; moreover, in any case I have attempted to use it, I have not succeeded in penetrating within the os uteri beyond half an inch, and it has slipped out of the orifice directly separation of the blades was

attempted. An ingenious instrument was exhibited by M. Mathieu, of Paris, in the late Industrial Exhibition. This, also, I have employed; but it has the disadvantage of dilating in an antero-posterior direction, and in practice tends to withdraw from the canal of the cervix instead of stretching the contracted parts. This last objection also applies to those exhibited by Charrière. I do not propose here to discuss the propriety of dilating the os uteri, or to point out the instances in which dilatation should be attempted. I think it is generally admitted that cases occasionally occur in which this treatment may be pursued with advantage if it can be carried out effectually; and my own experience leads me to believe that gradual dilatation is more likely to be followed by permanent widening of the cervical canal than the more forcible and rapid distention produced by a sponge-tent.

Lastly, I may be permitted to remark that the relief experienced in some cases of dysmenorrhœa after dilatation of the cervical canal is not always apparently in proportion to the amount of previous contraction as determined by the easy or difficult introduction of the uterine sound in the menstrual interval. There are, I believe, patients to be relieved by dilatation who have no marked contraction of the orifice, but who suffer pain because the menstrual fluid is secreted more rapidly in the uterine cavity than it can escape through a cervical canal of ordinary calibre, or else, it may be, have the aperture narrowed for the time being by spasmodic contraction of the orifice such as takes place in spasmodic stricture of the urethra in the male.

I have been informed at Mr. Coxeter's that, some time ago, another practitioner had ordered Mr. Thompson's urethra dilator, without the modifications I have suggested, but with the view of employing it for dilatation of the os uteri. I have not been able to ascertain this gentleman's name; but as this short paper is simply to notice a useful instrument, and not to put forth a claim to priority, it is of little consequence.

DIGITALIS IN CARDIAC DISEASE.

By DAVID H. STIRLING, M.D.

As the action of digitalis upon the heart is now being investigated anew by various Physicians, I beg to send you the following notes of cases treated by that drug. They are condensed from notes taken while the cases were under treatment:—

Mrs. F., aged 69, consulted me about six years ago, when suffering from an attack of "breathlessness," with cough, which she attributed to bronchitis. She had no symptoms of bronchitis, but the heart's action was irregular and weak. No cardiac murmurs or other sign of structural change. Under the most simple treatment,—rest, mustard cataplasms over the region of the heart, and a glass or two of wine daily, she rapidly recovered.

Similar attacks recurred from time to time, each one more difficult to combat than the preceding. In the autumn of 1862, after a rather severe attack, there remained more or less irregularity of cardiac action, and slight breathlessness on going upstairs. In March last a most severe attack of dyspnoea came on suddenly during the night. I found her propped up in bed, afraid to move or speak. She complained of severe pain across the front of the chest, retched frequently, at times so severe as, along with the painfully-laborious breathing, to threaten almost instant death. The pulse at the wrist was almost imperceptible; cardiac action so tumultuous as to render it difficult to distinguish between the first and second sounds; both sounds sharper than natural; no cardiac murmurs; face bedewed with cold sweat; feet and legs cold. Chlorodyne gave temporary relief; brandy was given freely, and hot bottles applied to the extremities. In about an hour the immediately-dangerous symptoms were overcome.

Next day she was able to bear a short stethoscopic examination, which revealed considerable disease of right lung, as evidenced by comparative dulness over the lower half of the right side; bronchial breathing in upper half of lung; respiratory sounds in lower half heard only on attempting to take a deep inspiration. Extensive congestion was present, and clearly traceable to impeded circulation. Cough with hæmoptysis came on, and all food was refused or rejected. The urine became scanty, not albuminous; legs œdematous; ascites followed; rest in bed became impossible, and the case seemed altogether hopeless. Stimulants, diuretics, counter-irritation of all kinds over chest and back were perseveringly used, but

without success. This state of matters continued for nearly three weeks, when, anxiously pondering what course to follow, Dr. Handfield Jones' cases fortunately came to my recollection, and I at once prescribed digitalis. Ten drops of the tincture were given every four hours. The relief was so great that from a state of absolute agony she enjoyed comparative quiet in less than three days. The heart's action became daily stronger, as indicated by less tumultuous action and slower pulse. Calm breathing, cessation of hæmoptysis, gradual removal of ascites, and œdema of legs, followed, and convalescence was established. The medicine was continued for a fortnight longer in ten-drop doses thrice daily. The lung gradually recovered, but slight comparative dulness and less distinct respiratory sounds over affected part remained. During last summer she suffered several times from a recurrence of her former symptoms. On each occasion digitalis was immediately given, with the effect of removing all pain and difficulty of breathing after two or three doses.

Mrs. S. suffered from general anasarca during pregnancy. I learned this for the first time when called to attend her in her confinement. Slight post-partum hæmorrhage left her weak, and she made a slow and imperfect recovery. Some weeks after I had left off attendance I was again called, and found her in a state of extreme weakness, propped up in bed, and breathing hurriedly. The pallor of surface was something remarkable; she seemed to have no red blood in her body; there was general anasarca, and short hacking cough. On examination I found irregular cardiac action, first sound scarcely heard anywhere, second sound very sharp at base, pulse about 170 when it could be counted, urine scanty, but quality normal. Weak cardiac action seemed the alone cause of her sufferings. Strong soups and wine ordered; ten drops of tincture of digitalis to be taken every four hours. In two days she felt greatly better; heart's action became stronger; when patient lay perfectly quiet there was no irregularity; the first sound was now distinctly heard, and dyspnœa gone. Iron was added to the digitalis, and rapid improvement followed. Some weeks later the heart's action again failed, pulse rose, dyspnœa returned, and a sense of sinking was complained of. The digitalis was resumed, and all these symptoms disappeared in a day or two.

Mrs. Y., aged 44 years, had long suffered from disease of the heart, according to her husband's account; the symptoms complained of being, palpitation on walking smartly, on going upstairs, or after any excitement; occasional swelling of the legs, and sometimes cough. I found her sitting in a chair, propped up with pillows, breathing rapidly; face of a purplish hue, and cold; tongue cold; pulse at wrist imperceptible; great œdema of legs; could not move without bringing on a "fit of breathing." Arcus senilis very marked. On examining the chest, I found the heart beating in a most extraordinary manner: the organ seemed to fill out and press upon the ear, then making one or two attempts at contraction, both sounds very feeble, it would suddenly thump against the ear and recede so much, that the stethoscope could with difficulty be kept applied. No cardiac murmurs; no bronchitic complication; stomach very irritable, even cold water rejected; thirst great; to have tea spoonfuls of strong beef-tea, wine and brandy in same quantities frequently, and ten-drop doses of tr. digitalis every four hours. Next day I was informed (the patient lived some miles in the country) that she could not take the stimulants, and that the medicine had been rejected twice. Ordered to take five-drop doses of the digitalis, slowly sipped from a glass of water, during a quarter of an hour; to be repeated as formerly. The irritability of stomach ceased, and in two days ten-drop doses were given, without any discomfort. A few drops of tr. of nux vomica were tried with each dose, but without good effect. In a few days more she was able to be downstairs during great part of the day, and enjoyed comparative quiet during the night. Improvement in this case was partial, and of short duration. A second severe attack came on, was again greatly relieved by digitalis, but rest in the horizontal posture became from this time impossible. I saw her on three different occasions, each time observing a marked change for the worse. The medicine was discontinued, and tonics, stimulants, and counter-irritation employed, as before the trial and failure of the digitalis, but without any good result. Anasarca increased, dyspnœa became constant, and death followed most painful sufferings in a few weeks. Why this case resisted the treatment so successful in the others I cannot say; it seemed as hopeful as the others, and promised well at first.

I have made trial of digitalis in several cases of mitral regurgitation, but cannot speak favourably of its effects.

From my experience of the action of digitalis in cardiac disease, I am satisfied that we have in that drug a most valuable agent in cases of enfeebled heart without valvular complications. Its action on the organ appears direct and rapid, and no bad effects seem to follow its prolonged use. As it is of vast consequence that we should become acquainted with the range of action of this and other active medicinal agents in disease, I trust digitalis will obtain a fair and extended trial in cases of enfeebled cardiac action. Iron given in combination with it, as in Case 2, seems to act well, but the iron can only be of use in improving the quality of the blood. Alone it fails; along with the "specific" it is of value. In Case 3 I tried nux vomica in combination, in hopes of improving the tone of the stomach, but I am satisfied the practice was wrong, and likely to interfere with the action of the other medicine. The disorder of stomach in these cases is clearly due to sympathetic irritation, to be remedied by removing the primary affection.

Perth.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

LONDON HOSPITAL.

NOTES ON LARYNGOSCOPY.

ON a recent occasion, in bringing some cases of laryngeal disease under the notice of the students, Dr. Morell Mackenzie made some preliminary remarks on the importance of the laryngoscope in diagnosis. The application of remedies with precision to the interior of the larynx was always a delicate, and frequently a difficult, operation; and it required that the eye should be constantly practised and the hand habitually exercised; but, "for the purposes of diagnosis, a little care and average manual dexterity were," Dr. Mackenzie observed, "alone necessary." He insisted on the great injury which might result from mistaking functional for structural disease, and remarked, "that, though such an error, no doubt, frequently occurred in former times, there was no excuse for it now."

Loss of function, independent of structural disease, might depend on some peculiar condition of the "nerve-force," or it might be due to extrinsic disease—that is to say, to pressure applied to the pneumogastric nerve or its branches. It was very necessary to recognise this fact, because it had a very important bearing both on the treatment and the prognosis. "Fortunately, it was easy," Dr. Mackenzie said, "to diagnose between these two conditions; for, whilst in true functional aphonia the vocal cords were always both equally affected, in cases where the loss of voice was due to pressure on the pneumogastric or recurrent nerves, the paralysis was almost invariably unilateral." In true functional aphonia, the vocal cords sometimes scarcely moved at all in phonation, whilst at others they appeared to approximate perfectly. The fact, however, that in functional aphonia the two cords always acted equally, afforded a point for differential diagnosis between the two diseased states now under consideration. It was only when the pressure was applied to the recurrent nerves in their passage between the trachea and œsophagus, that both nerves were at all likely to be affected at the same time. This sometimes occurred in malignant stricture of the œsophagus, and Dr. Mackenzie said that he had met with a few such cases; but in this disease there were other symptoms which clearly indicated its true character. When one vocal cord remained immovably fixed, it was necessary to make a very careful examination of the chest, as there was every reason to fear the existence of a thoracic tumour. To this we have already drawn attention in our Hospital Reports January 9, where a case, under the care of Dr. George Johnson, in King's College Hospital, is recorded, in which he found the laryngoscope was of the utmost use in determining the existence of an aneurism of the aorta, and also another case in which an examination by Dr. Mackenzie gave similar evidence. In the following number, Dr. Gairdner, of Glasgow, gave particulars of a case in which laryngoscopy helped in the diagnosis of a thoracic tumour. As an important feature in diagnosis where the laryngoscope could not be used, Dr. Mackenzie observed, that "in true

functional aphonia the cough is almost invariably natural—that is to say, it *sounds* perfectly. In aphonia due to pressure on a nerve, the cough has always a peculiar metallic ringing sound. In simple functional aphonia, the voice is generally completely suppressed, and the patient can only whisper: in unilateral paralysis, the voice is seldom suppressed, but the patient speaks in a shrill, painful voice.”

In cases where there is an absence of symmetry; where the vocal cords do not appear to diverge from their point of insertion at the same angle; where the glottic opening inclines to one side or the other; or where one capitulum Santorini appears to be at a higher level than the other, it is very desirable to introduce the laryngeal mirror, first with one hand and then with the other. An unsymmetrical appearance in the larynx is sometimes produced by an unsymmetrical position of the mirror, and one hand will be found to correct the mistakes of the other. Dr. Mackenzie observed that it was not his intention to give a systematic account of diseases of the larynx; but he hoped that the patients now brought under notice would illustrate some of the more common pathological conditions met with in practice.

SYPHILIS.

When a patient once became affected with constitutional syphilis, he was very liable to affections of the larynx. The morbid condition might be a mere catarrhal congestion; but it might be a violent inflammatory process, leading to rapid ulceration and extensive loss of substance. There might be an œdema or a new formation; but there were two conditions, one of which was quite pathognomonic, and the other very characteristic of syphilis. These were (1) mucous tubercles or condylomata, and (2) syphilitic stenosis, from chronic thickening of the mucous and sub-mucous tissues.

Case 1.—*Syphilitic Condylomata of the Larynx.*

Henry P., aged 24, suffering from hoarseness and cough. Six months before he had had a hard chancre, and since his body had been covered by a roseolar eruption. In the beginning of December he caught cold, and became very hoarse. With the laryngoscope, some soft, whitish, irregular elevations of the mucous membrane were seen on the inter-cartilaginous portions of the vocal cords. The rest of the mucous membrane was brightly congested, and contrasted strongly with the pale condylomata. Dr. Mackenzie considered this a typical case of secondary disease of the larynx. According to Gerhardt and Roth, this condition was very common in constitutional syphilis; but in Dr. Mackenzie's experience it occurred less frequently in London than it appeared to do at Tübingen. As regards local treatment, Dr. Mackenzie observed that he had found a solution of bichloride of mercury (gr. j., ad. ℥j.) very effective, if applied freely every day. Nitrate of silver answered very well, but it was more disagreeable to the patient. The cases reported by Gerhardt and Roth in *Virchow's Archiv.* had been treated with mercury, administered internally, so as to produce its specific action. This plan was certainly strictly in accordance with the doctrines of M. Ricord, but Dr. Mackenzie had not always found it necessary to employ constitutional treatment.

Case 2.—*Syphilitic Stenosis of the Larynx, treated by the Administration of Iodide of Potassium.*

Patrick B., aged 43, applied for relief on account of loss of voice and shortness of breath.

Twenty years ago he had had a primary sore, and since then ulcers had formed on different parts of the body, which had left numerous scars. He caught cold two years ago, and lost his voice at that time; latterly he had found his breath very short, and was unable to do any work requiring the least exertion. The laryngoscope showed that the diameter of the laryngeal canal was greatly diminished by the immense thickening of its walls. The surface of the mucous membrane was not of a brighter red colour than in the normal condition. This was not an instance of inflammatory tumefaction, but a case in which an exudation had been slowly taking place for a long time, and gradually undergoing organisation. The induration was general, but the true cords were less affected than the other parts, with the exception of the epiglottis, which was quite healthy. The right false cord was so much enlarged that it almost eclipsed the true one below it, and on phonation only allowed a small portion of the free edge to be seen. These cases did not often yield to local treatment, as the exudation generally underwent a higher degree of development, and seemed to possess a greater vitality than was commonly imagined. Fortunately the effect of iodide of potassium was

highly satisfactory in syphilitic stenosis. In this case absorption had already begun to take place under the use of this drug. The respiration was less embarrassed, and the action of the vocal cords more free. Nitrate of silver had been applied both in the solid form and in solution, but no effect had been produced by this agent.

Case 3.—*Syphilitic Stenosis treated with a "Pulverised Solution" of Perchloride of Iron.*

This case was very similar to the last. Mary Anne S., aged about 35, was sent to Dr. Mackenzie by Dr. Tilbury Fox. She seemed to have been suffering from constitutional syphilis for a long time, and said that she had been under Mr. Dunn, at the Farringdon Dispensary, almost continuously for the last five years. She had lately left the Westminster Hospital; and when she applied to Dr. Mackenzie, on December 22, she was suffering from severe stridulous breathing, complete aphonia, and a constant croupy cough. A laryngoscopic examination showed great thickening of the false cords and of the ary-epiglottidean folds and mucous membrane over the arytenoid cartilages. She had a great objection to having her throat "burnt," as she said that that always made it worse. Under these circumstances, Dr. Mackenzie caused her to inhale a "pulverised solution" of iron (gr. v., ad. ℥j.). This treatment produced the most satisfactory results. At the end of a week there was no cough nor stridor, and the patient was able to speak in her natural voice. Iodide of potassium was given at the same time; but as she had been taking this medicine for some months, Dr. Mackenzie considered that the great improvement was due to the local action of the iron. It was seldom that these cases were influenced by local remedies, and this was a remarkable exception. Though, however, the patient considered herself cured, there was, of course, a certain amount of induration remaining, and a tendency to the return of a more acute inflammation would no doubt remain for some time.

These cases of syphilitic stenosis were not to be confounded with those where the narrowing depended on the contraction of cicatrices after ulceration. In the cases now under consideration there was very little tendency to ulceration; and the narrowing, as already stated, depended on the organisation of an exudation beneath the mucous membrane. Syphilitic stenosis was essentially a tertiary phenomenon.

PHTHISIS.

The remarks which had been made with reference to syphilis applied in some measure to tubercular disease of the larynx; that is to say, that in patients affected with pulmonary phthisis the pathological process in the larynx varied greatly as regards site, character, and course. Thickening of the mucous and sub-mucous tissues was the most common laryngoscopic feature, and ulceration seemed rarely to take place till after there had been considerable deposit. In the absence of syphilis, Dr. Mackenzie considered that great thickening of the tissues at the upper opening of the larynx was very characteristic of phthisis. In these cases, two large, round, pyriform, or oblong tumours were often seen forming the posterior half of the laryngeal image. An exudation took place into the areolar tissue; and when the exudation was confined to the immediate vicinity of the capitula Santorini, instead of seeing these little tubercles surmounting the arytenoid cartilages, their place was occupied by two round tumours, looking like the half sections of marbles. When the ary-epiglottidean folds were involved, the tumours were of a pyriform shape, the small end of the pear being formed by the epiglottic extremity of the ary-epiglottidean folds; and when the false cords were also affected, they often formed, with the ary-epiglottidean folds and the mucous membrane over the arytenoids, two large oval tumours, one on each side. Both sides were not always equally affected, but it often happened that they were so. In the following case there were no physical signs of phthisis, "yet there was no doubt," Dr. Mackenzie said, "that the disease was of a tubercular character."

Case 4.—*Laryngeal Phthisis.*

James G., aged 24, suffering from complete aphonia and slight dysphagia. He states that he was quite well till nine months ago, when he took cold and became hoarse. After three months the voice became entirely suppressed, and has remained in that condition since then. There was no trace of lung disease, but the laryngoscope showed two large round tumours in the arytenoid region. The tumours were formed of the thickened tissues around the capitula Santorini; they

were about the size of the half segments of cherries, and were of a bright red colour. Rather below, and to the outer side of the normal position of the right capitulum Santorini, a small yellow speck was seen. It appeared to be beneath the mucous membrane, and did not project at all. It was difficult, in cases of this sort, to tell whether the appearance was due to the presence of pus or tubercular deposit beneath the mucous membrane, or whether the yellow speck was the displaced cartilage, shining beneath the membrane. The false cords were congested, and it was only possible to see just the inner edges of the true cords, which were noticed to be very irregular and jagged. This patient had never had syphilis; and Dr. Mackenzie said that, from the appearance of the larynx, he was able to diagnose phthisis, notwithstanding that the stethoscope gave no signs of that disease. The patient had been under treatment for some time, and various local remedies and constitutional measures had been resorted to, but without any effect. The prognosis was very unfavourable.

NEW FORMATIONS.

The morbid growths most commonly found in the larynx were undoubtedly of epithelial character. These pathological productions were analogous to the warts which form on the common integument, but the relative proportion of their histological elements was slightly modified by their growth from a mucous surface. In warts on the skin there is a greater development of epithelial scales, whilst on the mucous membrane the minute blood-vessels and papillæ are more numerous. On the mucous surfaces, therefore, they are softer and more easily torn away from their connexions. This was an important and highly satisfactory fact as regards treatment, for the morbid growths were far more easily removed than would be the case if they were as dense as those on the common integument. It had been well remarked by Dr. Czermak, that small growths on the vocal cords often destroy the voice more completely than larger ones; for, whilst small excrescences got in between the cords, and prevented that degree of approximation which was essential to the due production of sound, the larger tumours sprouted up into the laryngeal cavity, and thus caused less interference with the action of the cords. There was another curious and interesting fact in connexion with the effect which morbid growths in the larynx exercised on the vocal function; this was, that "when there is a small growth in close proximity with the vocal cords, the aphonia or hoarseness which is present is sometimes only indirectly caused by the growth." The loss of function, though of course dependent on physical causes, is not due to direct mechanical influences. The cause of the dysphonia may be a superinduced congestion of the vocal cords, or it may be that the innervation of the part suffers in some way from the presence of the morbid growth. "Now it is not uncommon," Dr. Mackenzie observed, "in various diseases, for Physicians to prove or support a diagnosis by the subsequent results of treatment. This method could no doubt sometimes be relied upon; and when a previous diagnosis was found to dovetail nicely with the subsequent course of the disease, the former certainly obtained some confirmation. But there were cases where such a process of reasoning would lead to a very fallacious conclusion, and the following was a good example of this kind":—

Case 5.—Laryngeal Excrescence—Aphonia—The Voice Restored without Removal of the Growth.

Charlotte B., aged 35, suffering from aphonia. This patient first applied to Dr. Mackenzie at the London Hospital in November, 1861. At that time she had had complete loss of voice for two years; and, when examined with the laryngoscope, an irregular warty growth, about the size of a pea, was seen on the anterior surface of the right arytenoid cartilage; it was just above the level of the vocal cords, but its lower surface appeared to touch the right true cord. Both the true cords were congested. The aphonia was thought to depend on the presence of the growth in the larynx, and strong solutions of nitrate of silver were applied to it. At the end of three weeks the voice was restored, but the growth had not undergone the slightest alteration in appearance. General reasoning would have led one to believe that the voice was restored because the tumour was removed, but the fact was quite otherwise. The patient retained her voice perfectly till the autumn of 1863, when she caught cold and became aphonic. She applied to Dr. Mackenzie in December, 1863; and he found, on comparing the laryngoscopic appearances as they then presented, with a

drawing he had taken in November, 1861, that the laryngeal growth had not undergone the slightest alteration. Dr. Mackenzie adopted the same treatment as he had employed in 1861, with the same result; the voice was restored, but the morbid growth remained *in statu quo*.

Case 6.—Laryngeal Growth Removed with Curved Forceps—The Voice Restored after Five Years of Aphonia.

Margaret L., aged 43. This patient stated that, in March, 1858, she caught cold, and lost her voice. From that time till October, 1863, she had never been able to speak above a whisper. The laryngoscope revealed an excrescence rather larger than a pea on the posterior extremity of the right true vocal cord. At the third sitting, Dr. Mackenzie succeeded in seizing the growth with some curved forceps, and bringing it away. Dr. Andrew Clark had kindly examined it with the microscope, and he pronounced it to be a simple wart. The epithelium was of the scaly variety. The voice was restored, but it was of a rather deeper tone than was common in women. A small, but distinct white depression at the posterior extremity of the right vocal cord indicated the situation of the wound caused by the evulsion of the growth.

METROPOLITAN FREE HOSPITAL.

BROMIDE OF POTASSIUM IN SOME FORMS OF INFANTILE CONVULSIONS—CASES AND CLINICAL REMARKS.

(Cases under the care of Dr. JAMES JONES.)

E. P., aged 10 months, a female, pale, with a prominent forehead, and rather large abdomen. Supported solely by the breast; cut four central incisors with diarrhæa, but no convulsions. The upper lateral incisors are now protruding the gums, which are swollen and tender; fontanelle depressed; bowels rather costive; was seized with a violent paroxysm of convulsions; urine pale and abundant. After a few hours had a second attack of equal severity. A Medical man who was consulted incised the gums freely, gave some brisk cathartics, and ordered hot baths, with cold lotions to the head to be used in the event of a return of convulsions; but the paroxysms continued to recur at irregular intervals. On the third day the child was brought to the Hospital. Dr. Jones prescribed a mixture of bromide of potassium in doses of two grains, with ammonia and camphor mixture every six hours. About two hours after the first dose the child had a paroxysm of convulsions, but of a much milder kind, after which there was no relapse.

S. B., aged 11 months, a male, a tall, thin child, with skin and hair remarkably fair, was taking, in addition to the breast milk, a teacupful of Oswego corn flour pap night and morning; cut all the incisor teeth without any apparent suffering or derangement of the health. Upper bicuspid are protruding the gums, which are much inflamed and swollen. Had been much frightened, being violently shaken by a girl who had charge of him. Fontanelle depressed; pupils small; aversion from light. Convulsions came on about 11 o'clock p.m. during sleep, and continued for ten minutes. A hot bath was given, and the gums were freely incised. The convulsions ceased for two days, but returned the third day, with increased severity. Dr. Jones prescribed two grains of bromide of potassium to be repeated every four hours. There was no return of convulsions, and the child soon lost the aspect of fear and distress which previously were well marked.

J. G., aged 2 years and 3 months, a well-developed boy, but anæmic, very timid, and with peculiarly restless eyes, dentition complete, three days before his first attendance was seized with convulsions of a very severe type, which continued to recur at irregular intervals twice or three times a-day. A dose of calomel was given, followed by castor oil and turpentine, but with no improvement. No worms were discharged. Bromide of potassium was then given in doses of three grains every six hours. The first day of this treatment there was one rather violent paroxysm of convulsions and another less severe, after which they entirely ceased. The bromide was continued in progressively diminished doses for ten days, after which he took the perchloride of iron in small doses. He was brought as an out-patient for two months. He appeared at the end of that time in perfect health.

I have taken these three cases as typical of a form of infantile convulsions commonly met with in large towns and crowded localities. However much these little patients may differ in aspect or appearance, there is one pathological con-

dition common to all—viz., hyperæsthesia of the nerve centres, coupled with anæmia and complete absence of all symptoms of inflammation. There is an aspect of timidity and an expression of anxiety highly characteristic. The child often talks or mutters in his sleep. He seems to dream a good deal, often starts up frightened, and is apt to wet the bed. The urine is pale and copious, the tongue clean, the pulse is weak and irregular in number, the fontanelle, if still existing, is *always* depressed. The appetite is generally good, often ravenous; the bowels sluggish. It is of great importance to distinguish between these cases and those of a sthenic type and arising from encephalic inflammation. If depletory measures be employed, such as leeching, frequent purging, antimony or calomel in repeated doses, the little patient grows rapidly worse, the convulsions recur with increased severity and frequency. Such treatment adds to the morbid sensitiveness of the nerve centres. If, on the other hand, means be adopted which tend to support the strength and to calm the excessive irritability of the nerve centres, the convulsions cease. Opium is often of great service in these cases. It has been condemned by many as an uncertain medicine in convulsions, but it is only so when given indiscriminately. In the cases under consideration it proves very useful, but it should be used with much caution if the diagnosis be imperfect. But my chief purpose in making these remarks is to draw your attention to the action of the bromide of potassium in these cases. It appears to have a powerful sedative effect on the morbidly irritable nerve centres; its power in controlling reflex excitement of the voluntary muscles is very remarkable. This property is well exemplified by the experiments of my friend, Dr. Gibb, who has used it successfully to diminish the spasmodic action of the muscles of the pharynx on the application of the laryngeal mirror. I have now tried it in many cases of infantile convulsions of the type indicated by the cases I have brought under notice with very good results. Its effect is rapid, one or two doses being often sufficient to arrest the tendency to convulsion. From the rapidity of its action it would seem to be a direct sedative either to the cerebro-spinal centres or to the vasomotor nerves, probably to both. As an eliminant it is much inferior to the iodides, whereas the latter have much less claim to the character of sedative.

Medical Times and Gazette.

SATURDAY, MARCH 5.

SHALL THE DRUGGISTS HAVE A CHARTER?

Most of our readers are aware of the existence of a respectable, but somewhat dreary journal, yclept the *Pharmaceutical*, which circulates amongst that portion of the chemists and druggists owning allegiance to the Pharmaceutical Society. This serial is principally devoted to a discussion of matters pertaining to Pharmacy, and we are very willing to admit that, despite the heaviness which of necessity cleaves to such a subject, the *Pharmaceutical Journal* is useful, although not entertaining, in its day and generation. But it has besides another object. It is the organ of that portion of "the trade" who are dissatisfied with their public and social *status*, who wish to cast the sober business shell, and to start into new life in the butterfly hues of a profession. They are longing for examinations, licenses,

the exclusive possession of the name "chemist and druggist," a State protection from competition with all unqualified drug vendors, and a severance of their body from the contaminating alliance with the drysalter and oilman. As may be supposed, our recent article on the "Proposed Legislation for Chemists and Druggists" has aroused the ire of our respectable contemporary. For ourselves, we confess that we wrote, not to support the dignity of the owners of those pretty red and blue solutions which impart such cheerfulness to our street prospects on a winter's evening, but in the interests of the great Medical Profession, of which the chemists and druggists form no part.

The *Medical Times and Gazette* is charged with being a dissentient from the principle that dispensers of medicine should possess competent knowledge. We simply deny the allegation. We hold that dispensers of medicine should possess competent knowledge of *dispensing*, just as other tradesmen should be acquainted with their several callings. But we say that the competency of the chemist and druggist is to be judged by the public, and not by the State, and that not only is there no necessity for any other tribunal than the former, but that the introduction of State interference in the matter is a direct contravention of acknowledged commercial principles. We repeat that there is nothing in the business of the chemist and druggist which elevates it from the rank of the other better class of trades. To become an expert dispenser of medicines it is only necessary that a lad should have an ordinary education at a third-class grammar school, and an apprenticeship to a competent master for a moderate length of time.

But the Pharmaceutical Journalist puts the matter on a very different footing. He considers that it is necessary for dispensers to exercise a "supervising care" (*sic*) over the prescriptions of Physicians, in order that patients may not be killed by the blunders of the writers. Really, we think that the College of Physicians would wish to express their grateful thanks to this champion of the spatula, but, at the same time, to politely inform him that they would rather their prescriptions were dispensed as they wrote them. Of this the chemist may be certain, that if any one is killed by the prescription of a Physician, the penalty of the law will certainly not fall on the dispenser, if his duty be accurately performed; but on the prescriber. No one doubts that chemists should be a well-educated body of men,—a body well skilled in their trade and the knowledge it requires. But of this the public and the Medical Profession are the only necessary judges. And that they do form an adequate judgment the position and business of such houses as Allen's, Savory and Moore's, Bell's, Morson's, Bullock's, Squire's, Corbyn's, and a dozen others we could name, prove. If, however, any chemist or druggist requires a testimonial of proficiency as a passport to business, the Pharmaceutical Society's certificate is within his reach.

We are not in the least ashamed to avow that we look on this subject through the medium of the interests of our own Profession. We do not wish to see in every village an inferior kind of Practitioner. We are not desirous that the precedent of the Apothecaries' Act should be followed over again; (a) that

(a) At a special meeting of the Council of the Pharmaceutical Society, February 26, 1864, the following requisition, duly signed, was submitted to the Council:—

"To the President, Vice-President, and Council of the Pharmaceutical Society of Great Britain.

"Gentlemen,—We, the undersigned, believing that it is highly desirable for the protection of the public that all future chemists and druggists should undergo a *due professional examination before commencing business*, hereby request you to convene a general meeting of the members of our Society, for the purpose of considering the expediency of an immediate application to Parliament for an amended Pharmacy Act, by which (*following the precedent of the Apothecaries' Act*) the legitimate interests of those already in business should be protected, and proper provisions made for rendering the examinations of future chemists by your Board a compulsory instead of an optional proceeding."

In compliance with the above requisition, it was Resolved—"That a special general meeting of the members of the Society be held on Thursday, the 17th March, at twelve o'clock precisely, and that the notice convening the said meeting, with the names of the requisitionists, be announced in the ensuing number of the Journal."—*Pharmaceutical Journal*, March 1.

Medical Practitioners should be starved out, as a highly-learned and accomplished body of men—*laudati et argentes*—to be referred to in emergencies, whilst the lucrative part of Medicine, *i.e.*, the daily and hourly relief of bodily ailments, falls into the hands of the chemists and druggists. Give the chemist and druggist a new Professional character, and the counter practice which he already carries on must increase enormously. Who is to hinder him from visiting? Suppose, some fifteen years hence, in a country village, a respectable, well-educated druggist, who has been long established, and *knows the action of medicines*, who holds a legal diploma as a Pharmaceutist, and a young Surgeon, the only Medical Practitioner in the village, the latter perhaps not known, and wanting some of those graces of manner and appearance which are an easy passport through the world. Where would public confidence be placed? If in a case of emergency the chemist were sent for, where is the law that would prevent his going? Would public opinion sanction repressive measures? We leave these questions to be answered by the common sense of the Medical Profession.

We are quite aware that some of the promoters of this movement amongst the chemists and druggists profess to disclaim all intention of passing into the domain of the Medical Practitioner, and repudiate the practice of prescribing over the counter. But we have one question to ask on this point—In how many druggists' shops in London at the present time would a customer, who asked for "something to cure a cough," be referred and recommended to pay a fee to a Physician? Or suppose a mamma, applying to know whether a little "chalk mixture" would not be a proper thing to give baby—from how many chemists would she get the answer, "Madam, I do not prescribe, I only dispense?"

It is urged that the proposed legislative interference is for the protection of the public. We simply ask, are the public in danger now? Would a certificate of competency be any safeguard that no blunders should ever be made in the shop of the possessor?

We acknowledge the division of labour, and we are most ready to express our gratitude for the additions made to our knowledge by the Pharmaceutical Society. We say to them most cordially—"Go on and prosper in the study of the sciences which may throw light upon your avocation." But we, writing in the interests of Medicine, are not so bereft of sense but to see that in districts where the Medical man is paid by his physic, where the only remuneration given for his professional services is the profit contingent on the medicine supplied, to elevate the druggist is to place the public (whose protection is so sacred) in the hands of a *mere* tradesman, who is utterly ignorant of diagnosis. The Surgeon and Apothecary in general practice combines some trade, just as the attorney does who charges per sheet for documents; his trade, however, is subordinate and incidental. But be this as it may, we know country Hospital Surgeons in very large practice, men of science and general accomplishment, first-rate operators and practitioners, who make almost the whole of a large income by supplying their own medicine:—very derogatory, doubtless, but a fact. We English do not make perfect constitutions on paper, to which afterwards facts may be adjusted, but we take the facts first and adjust our constitution to them. And it is a fact that a large portion of the public will neither pay fees nor for attendance alone.

On the same principles which regulate physic, and in which we acquiesce for ourselves, we say to the chemist and druggist, Go on; study; make yourselves as much philosophers as you can. But except in large towns and in the case of a very few chemists in the best parts of London, you can't live on your legitimate business; and you know it. You would starve on the dispensing of prescriptions and the mere sale of drugs. You add to this the sale of patent medicines; you cover your counter with bills of "antibilious pills" for "indigestion and all complaints arising from liver derangement," or of "pectoral pills, for the

cure of asthma, bronchitis, and consumption;" and you can't live then. You must sell perfumery, toothbrushes, and all sorts of sundries for the toilette and the sick room; and in smaller places you must add grocery, oils, paint, &c. Carry on your business and improve it as much as you please by becoming educated and scientific men; but do not suppose that we, having the interests of the country Practitioner at heart, can be indifferent to the prospect of seeing our Profession deluged by the influx of your whole body. As a legalised Profession, the law gives us a certain amount of protection—some of us care for it; some do not—but we see clearly enough that, if the druggist is to add to his business by taking the position of the Medical Practitioner, the sooner the Medical Practitioner takes to the sale of perfumery and cattle medicines the less likely will he be to go into the Insolvent Debtors' Court. To bring in *a trade*, as another privileged body, with a privileged title, would be an injustice to the Medical Profession, and an outrage on the recognised principles of political economy.

THE WEEK.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE V.—FEBRUARY 11.

IN this Lecture the description of the structure of the human brain was continued. On the inner surface of the cerebral hemisphere is an aperture leading from the third ventricle into the cavity within the hemisphere; this is the foramen of Monro. The aperture is prolonged backwards as a cleft (in the undisturbed condition of the parts closed by membranes), which constitutes the lateral portion of the so-called "great transverse fissure of the brain." The lower boundary of this cleft is a thin white band called the *tænia semicircularis*. Above and in front of the opening is a portion of the inner wall of the hemisphere, closing the lateral ventricle towards the middle line, which may be called the "septal area." The free, inferior margin of this area, which is thickened, constitutes the body and posterior crus of the fornix. Besides the anterior pillars of the fornix (small white bands passing down to the corpora albicantia, behind the anterior commissure), there are numerous longitudinal fibres passing forwards from the fornix in the septal area, above and in front of the anterior commissure; these may be called the "pre-commissural" fibres; they are less developed in Man than in the lower Mammals. The upper part of the septal area is very thin, constituting the "septum lucidum," which may also be described as the part of the inner wall of the hemisphere situated immediately above the anterior part of the fornix and the pre-commissural fibres. The corpus callosum is a great mass of transverse fibres, running from the inner wall of one hemisphere to that of the other, above the longitudinal fibres of the septal area, and forming the roof of the inter-hemispherical cavity or fifth ventricle, and also on each side the roof of the lateral ventricles. In Man this great transverse commissure is exceedingly large; it reaches back so far as to cover the corpora quadrigemina, and almost to touch the cerebellum. Its hinder part is called the splenium, and is very much thickened, containing commissural fibres, not only of the part of the hemisphere immediately opposite to it, but those from all the posterior portions; the middle part, of great length in Man, is the proper corpus; the front part makes a strong bend, the genu; the part that is reflected underneath being called the rostrum. From the latter a delicate layer, the rostral lamina, passes to the upper part of the anterior commissure, though it is doubtful whether it consists of true cerebral matter.

The principal characteristics of the cerebral hemispheres of Man are, their vast size in proportion to the other parts of the encephalon and to the nerves which arise from them; the large size of the frontal lobe, the sulcus which separates this region from the parietal being situated far back; the charac-

teristic form of the central lobe or insula, somewhat V shaped, and divided vertically by a deep fissure, each half further subdivided by radiating sulci into a number of folds; the great development of the annectent gyri, which usually leads to the entire obliteration of the external perpendicular fissure, and to the extreme reduction of the occipital lobe; and the great obliquity of the fissure of Sylvius. On the internal surface of the hemisphere may specially be noted in the human brain, the obliquity of the internal perpendicular fissure, the downward direction of the hinder part of the calcarine fissure, the proportionate smallness of the uncinat gyrus, the thinness of the septal region, and the great size of the corpus callosum, particularly the large development of the genu, rostrum and rostral lamina.

The thalamary segment of the brain is formed by the optic thalamus on each side, prolonged below into the infundibulum and pituitary body. Its roof is formed by the velum interpositum. The anterior boundary is an almost perpendicular wall, passing down from the anterior commissure to the optic commissure, called the lamina terminalis. The optic commissure itself forms part of the inferior and anterior boundary of the third ventricle, which is the cavity of this segment. The anterior descending pillars of the fornix also belong to the thalamary segment. The mid-brain consists above of the corpora quadrigemina, below of the crura cerebri; the "iter a tertio ad quartum ventriculum" is its ventricle. In the hind brain, the great development and anterior convexity of the pons, and absence of corpora trapezoidea are characteristic of Man, as is also the small size of the flocculus and of the vermis, as compared with the lateral parts of the cerebellum.

A sketch of the modifications which the human brain undergoes during its development will render intelligible, and afford useful material for comparison with, many of the permanent conditions of this organ in the lower vertebrates. In its earliest condition, the embryo has, on its upper surface, a groove, called the "primitive groove." This becomes widened in front; and from this part the future brain commences, in a cellular substance, originally in strict continuity with the epidermal layer of the embryo. In the anterior widened portion of the groove, three dilatations take place, one behind the other. The lips of the groove growing up unite in the middle line; so that a tube is formed with three vesications— anterior, middle, and posterior—corresponding with the three primary divisions of the brain before given. In the course of development, a bending of the whole takes place, the middle vesicle being at the top of the bend. From the sides of the anterior vesicle, grow out two hollow bags, which rapidly enlarge and eventually become the cerebral hemispheres. From the front of these, another prolongation, at first also hollow, forms the olfactory segment; while the remaining part of the primitive anterior vesicle becomes the thalamary segment. The growth of the hemispheres so far transcends that of the other segments, that they soon cover them all; and at the fifth and sixth month actually project further beyond the cerebellum than they do in a later period of life. From the floor of the great cavity in the hemisphere, the corpus striatum grows up, and forms an axis, around which the whole hemisphere becomes curved; so that what was at first the hinder becomes the lowermost part. On the inner surface, the original aperture of communication with the primitive segment, from which the hemisphere is an offshoot, becomes the foramen of Monro; from the upper border of the aperture, the fornix is formed; and from its inferior border, the tania semicircularis. On the hemispherical side of the latter, grows up the corpus striatum; on the other side, the optic thalamus. On the external surface of the hemisphere, a space is formed corresponding to the outer surface of the corpus striatum. This is the future central lobe, or island of Reil, at first perfectly smooth and uncovered, and only at an advanced period of intra-uterine life concealed by the lips of the Sylvian fissure. The temporal lobe is developed at an early age; but the occipital lobe is a subsequent out-

growth from the hinder part of the hemisphere. At first, the surface is perfectly smooth; at about the sixth month, sulci appear. The earliest of them that can be distinctly recognised are the antero-parietal on the outer surface, and the callosomarginal, calcarine, and internal perpendicular on the inner face.

The development of the corpus callosum is a subject of considerable difficulty. According to Reichert and other trustworthy observers, at one time the hemispheres are perfectly unconnected, except by the lamina terminalis of the third ventricle. Upon the inner wall of the hemisphere is a thin depressed area, corresponding with what has been described above as the septal area; from out of the substance of the wall at the upper margin of this space transverse fibres grow out, and unite with corresponding fibres from the opposite side, thus forming the commencement of the future great commissure. Certain changes in the walls of the third ventricle only require to be noticed; by differentiation of part of its anterior boundary, a band of transverse fibres passing between the corpora striata is formed; this is the anterior commissure. Behind this, longitudinal white cords grow up from the optic thalamus and unite with the fornix, of which they form the anterior pillars; and, lastly, the upper portion of the vesicle becomes metamorphosed into the vascular "tela choroidea," which closes in the ventricle above.

PARLIAMENTARY.

ON Thursday, February 25, in the House of Commons, Mr. Leslie asked the Secretary of State for India upon what grounds the Royal warrant for Her Majesty's Indian Medical service had been so long delayed, and when the warrant would be issued.

Sir C. Wood said the hope had been entertained for a long time that a Medical service common to the Queen's army and to that of India might be established. It was only last autumn the Indian Council learnt that the War Office considered such a service incompatible with the requirements of the royal army, and separate provision had, therefore, to be made. He was naturally anxious to give to India the benefit of the improved education in sanitary matters which was now bestowed upon the officers of the Queen's army, and a warrant was prepared with that design. It was, however, uncertain whether the scheme could be carried out without infringing some of the clauses of an Act of Parliament, and the matter had consequently been referred for the opinion of the law officers. Until they reported, nothing further could be done.

The whole matter is, therefore, postponed *sine die*. Whilst men are constantly retiring from the service wearied of the chronic state of disappointment which appears to be inseparable from her Majesty's Indian commission, and every fresh effort of the authorities to obtain candidates for the vacant Assistant-Surgeoncies is only a proof of the utter unpopularity of the service, Government is content to sit with its hands folded, having quietly shelved the matter by referring it to the law officers of the Crown. "How not to do it" is a great art; but, highly as we allow Sir C. Wood and the army authorities to be skilled in it, and much as we admire their late display as an artistic effort, we shall be surprised if it reconcile the Medical officers of the Indian army to the shameful want of good faith with which they have been treated.

On Friday, February 26, in the House of Lords, in answer to a question from Lord Colville, as to the part taken by the Deputy-Judge-Advocate-General at the recent Court-martial on Colonel Crawley,

Lord De Grey explained the circumstances under which the Deputy-Judge-Advocate was selected, and stated that the appointment was quite in accordance with the usual practice. But it might be a question whether the different functions of the office should not be hereafter divided.

The Duke of Cambridge took the opportunity of correcting the misunderstanding that had arisen as to a statement he had formerly made in reference to Sir Hugh Rose. He assured the House he had never intended to make any charge against that officer. He had merely described the course of action he had himself taken, and only intended to convey that he differed in opinion from Sir H. Rose, and what he regarded as

an error of judgment had been misunderstood as a serious imputation.

Lord Chelmsford censured the appointment of the Deputy-Judge-Advocate and the course pursued by that officer during the trial before the Court-martial.

Lord Longford said the public, the press, Parliament, and the Government itself had all been carried away by a delusion as to the whole case against Colonel Crawley, and contended that in justice to that officer the Government ought to pay all the expenses he had been compelled to incur in his defence.

After some further conversation, the subject dropped.

In the House of Commons, Mr. Morritt asked the Secretary of State for the Home Department whether it would be possible for Townley, lately convicted of murder, whose sentence was commuted to penal servitude for life, to obtain, by good conduct or otherwise, at any future period of his life, a licence or ticket of leave to be at large and free from restraint in either this or any other country.

In reply, Sir G. Grey said that convicts under sentence of penal servitude for life, whether that sentence is original or remitted, are not entitled to the benefit of those regulations by which other convicts, under certain fixed conditions, may obtain the remission of portions of their sentences.

The House went into Committee on the Malt for Cattle Bill, the clauses of which were agreed to with amendments.

On Monday, February 29, in the House of Lords, Lord Granville moved the second reading of the Insane Prisoners Act Amendment Bill, having briefly explained the object and provisions of the measure.

Lord St. Leonards thought the Bill required some improvement. He detailed, at considerable length, all the facts of the crime of which Townley was convicted, contending that he was perfectly sane at the time he committed the murder, and had never been otherwise.

Lord Wodehouse objected to the visiting justices being required to put the machinery of the bill in motion. It would be better if the Secretary of State issued a special commission to ascertain the condition of an insane criminal.

The bill was then read a second time.

In the House of Commons, in reply to Sir M. S. Stewart,

Mr. A. Bruce said the second reading of the Cattle Diseases Prevention Bill would be postponed to Wednesday, the 9th of March.

On Tuesday, Sir F. Kelly said that, at the request of the Government, he would postpone the Criminal Appeal Bill until Wednesday, the 9th instant.

On the motion of the Chancellor of the Exchequer, the Malt for Cattle Bill was read a third time and passed.

W. R. WILDE ON THE VITAL STATISTICS OF IRELAND.

(Continued from page 619, vol. ii., 1863.)

THE second division of Vital Statistics for Ireland reports upon the number and condition of the blind; and, in fulfilment of our expressed intention, we now revert to it. In 1851, the first authorised special investigation of this question showed 7587 blind persons in Ireland, to a population of 6,552,385, or about 1 in 864. Such a high proportion may have depended on the epidemic ophthalmia of the three previous years, and on the exodus of the healthy. In 1861 a gross return of 8088 blind was reduced, on special inquiry, to 6879—namely, 3149 males and 3730 females—a total which, though less than that of the previous decade, stands, to the still more diminished population of the country, in the increased ratio of 1 in 843. On an extended inquiry respecting the different countries of Europe and America to the number of twenty-one, it was found that the united ratio was 1 blind in 1267 persons, a proportion, however, compounded of many, the limits being 1 in 2489 in the States of America, and 1 in 540 in Norway. This last very high relation is attributed by Dr. Richter, of Christiana, mainly to the absence of special ophthalmic Practitioners in that country.

Of the 6879 persons given above, 2947 were educated; 3690—1811 males, and 1879 females—were married. A curious table shows the previous or present occupations of this class. 358 were farmers and proprietors of land, 333 agricultural labourers, 476 knitters and netters, 180 basket-makers, 206 servants, 317 mendicants, and 3519 unspecified. The other

figures are somewhat vague, from the fact commented on in the Report, that some callings were those followed before blindness, and some acquired afterwards. The latter is perhaps almost entirely the case with the 507 musicians of the table; these were returned as performers on the violin, bag-pipes, harp, organ, flute, and piano, and are classified as ministering to amusement, although, from metropolitan experience, perhaps "torture" would have been a more correct designation.

Nine institutions for the blind are tabulated—4 for males, 3 for females, and 2 for both sexes. They accommodate 222 men and 218 women. The heads of their education are stated briefly; reading with raised letters, history, geography, and simple handicrafts forming its main elements.

In 6341 cases, the secondary question of congenital blindness was answered; 211 persons—118 males and 93 females—having been blind from birth. The causes of blindness furnish another table: ophthalmia standing for cause in 1962 cases; small-pox in 725; cataract in 416; cerebral and nervous disease in 322; accidents in above 500, among which are no less than 11 from lightning; and fever, rheumatism, amaurosis, and old age, with several other agents for a smaller number. Some valuable facts as to hereditary blindness, the want of special Hospitals and asylums, and education, conclude this section.

The statistics of the lunatics and idiots, as also of the lame and decrepit, though of the deepest importance, must, from their very fulness, be left for completer examination in their special points of view. The fifth section, on the number and condition of paupers in workhouses on the night of April 7, 1861, gives 50,010 as a general total, the excess slightly on the side of the females, and the proportion 1 in 116 to the whole population.

The sick in Hospitals, standing sixth in the contents, were divided among 35 infirmaries, 39 fever Hospitals (instead of 61, as at the previous census), and 2 special Hospitals—one syphilitic, the other ophthalmic. Nine lying-in Hospitals are, moreover, enumerated. The ratio appeared to be 1 Hospital bed to every 899 of the population not otherwise provided with in-door relief of a charitable nature. The number actually in Hospital was, however, relatively much smaller; namely, 2993 in all—a great diminution from the preceding census—fever cases alone sinking from 1117 to 356. After tables of age, sex, religion, and occupation, there is an excellent conspectus of diseases under eleven clear headings. The first class, of epidemics and endemics, contains 657. The second, of sporadic, under nine subdivisions, gives for brain, nervous system, and organs of sense, 154; for circulatory organs, 73; for respiratory organs, 344; for digestive organs, 187; for urinary organs, 60; for generative organs, 102; for locomotive organs, 624; for tegumentary organs, 316; lastly, as diseases of uncertain seat, 252. The third class, of accidents, contains 173. Unspecified cases, to the small number of 51, make up the general total given above. This table is eminently practical, and free from the mysterious nomenclature which figures in some similar documents.

Other charitable institutions furnish the seventh, and the inmates of prisons the eighth section. The ninth, and last, is devoted to the general summary of sick in Ireland, whether at home or in workhouses, prisons, and infirmaries. Fever still contributed 9322 to this category; influenza, 2330; measles, ophthalmia, and others, smaller totals. Sporadic complaints supplied 28,939 patients, 7056 being cases of insanity. Consumption returned 2650, a figure decidedly below our expectation, standing as 1 in 29 to the total sick. Among the Irish in London, probably the proportion would be much higher. On the other hand, 433 cases of cancer show the comparative rarity of this disease.

It need only be remarked in conclusion, as will have been gathered from our cursory extracts, that this document presents an excellent specimen of statistics, honestly manipulated, is very creditable to its compilers, and has a greater value from showing no trace of personal bias, or of foregone conclusions:

FROM ABROAD—THE WRITINGS OF THE INSANE—HYPODERMIC INJECTIONS SUPPLEMENTARY TO CHLOROFORMISING—TREATMENT OF HYDATID CYSTS OF THE LIVER.

M. BRIERRE, the distinguished French alienist Physician, in a recent communication, makes some interesting observations upon the writing of the insane, in relation to diagnosis and legal Medicine. First, the handwriting itself is found to be different in maniacal excitement, monomania, and melancholia. In the two first of these conditions the writings are crowded with capital letters, placed in all parts of the words, which are underlined with excessive frequency. This feature is of importance if observed in those who have already been mad, as indicating a certain return of the malady; and when existing in documents, however carefully these may be otherwise drawn up, it is a proof of the existence or return of disease. Sometimes the letters are filled with flourishes and erasures, and at others they are singularly arranged, consisting in part of fragments, difficult of comprehension, and mingled with cabalistic signs, a kind of hieroglyphics, probably having their signification to the lunatic. In melancholia the words are slowly traced, and are frequently of unequal size and unfinished. Dementia and general paralysis are recognised in the trembling writing, inequality of the lines, graphic signs, the forgetfulness of words or letters, a tiresome repetition of the same expression, incoherence of ideas, and an omission of some of the parts of speech. Remarkable exceptions, however, exist; persons in an advanced state of general paralysis having, in some instances, been able to produce well-written letters to the last. With respect to composition, the letters of lunatics written during the course of their disease, or in the intervals of paroxysms, are sometimes admirable productions, full of reason and healthy sentiments, and well calculated to deceive jurists and the public. At a recent trial for parricide, a letter was produced, in which the passion of love was painted in so simple, touching, and honest a manner, that it was at once pronounced it could not have been the production of a lunatic, until it transpired that the object to whom it was addressed had, two years before, become a wife and a mother, circumstances only to be forgotten by a madman. In another case, a lady, long the subject of maniacal excitement and nymphomania, addressed letters, models of affection and religious devotion, to her children. In the face of instances like these, great must be the surprise felt at the facility with which magistrates and men of the world pronounce upon the question of lunacy; while those who are constantly in the company of the insane are confounded by these anomalies of the intellect, which remain for them unfathomable mysteries. The general conclusion to be drawn from the above observations is, that the handwriting of the insane may supply useful material for diagnosis, and that it is an entire fallacy to suppose that reasonable letters cannot be written by lunatics.

A committee of the Versailles Medical Society has just made a report upon an interesting subject. Professor Pitha related a case in 1861 in which, after chloroformising the patient in vain, he induced twelve hours of complete and placid narcosis by injecting twenty grains of belladonna extract into the rectum; and recently (*Preuss. Med. Zeit.*, No. 47) Professor Nussbaum communicated an account of the prolongation of chloroform anæsthesia by the hypodermic injection of morphia. While the patient was under the influence of chloroform he injected one grain of the acetate, and the patient did not arouse, as is usually the case after chloroform inhalation, but remained in a most tranquil sleep during twelve hours. So sound was this sleep that even pricking with needles and knives and burning failed to arouse him. The Professor has since repeated the experiment in various other cases with the most complete success; and in one of these the result was the more remarkable inasmuch as the same dose of morphia unaccompanied by chloroform narcosis scarcely induced sleep at all. In two of the cases, half a grain of morphia induced, after chloroformising, from five

to six hours' tranquil sleep. The Versailles Committee have made some experiments upon the matter with dogs, and although these have been few in number, they feel themselves able to report (*Union Méd.*, Feb. 25) that the prolongation of chloroform anæsthesia by means of hypodermic injection of the salts of morphia may be regarded as an established fact.

The Paris Surgical Society has lately been occupied in discussing the treatment of hydatid cysts of the liver. A case was related by M. Boinet, in which he stated that he had adopted a new and certain means of treatment. As this turned out to be merely the incision of the tumour, keeping an elastic catheter permanently within its cavity, and injecting iodine, the pretension naturally met with much resistance. M. Giraldès, so familiarly versed in Medical literature, at once showed that this treatment had no claim to novelty, and stigmatised its designation sure and infallible as an unscientific procedure. The case related had been well treated by the iodine injection, and is an interesting clinical fact deserving of record; but that is a very different thing to admitting it as exemplifying any novelty of treatment. M. Dolbeau took the same view; and believes that the treatment of hydatid cysts of the liver is still a laborious and extremely difficult matter. He has met with several cases and only one cure. In fact, the disease is generally incurable, except in the case of children, who recover by all means of treatment, or even in spite of treatment. There is no need of new procedures, which are, in fact, only too numerous; for the danger does not consist, as has been supposed, in the penetration of the fluid within the cavity of the abdomen, which may be easily obviated, but in the penetration of air into the cyst, and the consequent putrid infection. In M. Dolbeau's opinion, the Surgeon's indication in these cases should be for the most part expectative. Their course is extremely varied, and they are rarely solitary, while in some cases they undergo spontaneous cure, as when a communication is opened between the cyst and the bile ducts. Our object should be to counteract inflammation, and we should only operate when the rupture of the cyst seems imminent. M. Richard considered that M. Boinet had confounded injection and *lavage* of the cyst, and yet the two should be distinguished. By the former we imply the throwing in of an irritative fluid, with the intention of causing inflammation and producing adhesion and obliteration, while by *lavage* we simply wash out matters which might prove mischievous on decomposition. He does not go so far as M. Dolbeau in recommending mere expectation, having met with success in some cases from the employment of capillary puncture followed by iodine or vinous injection. M. Boinet replied that he had characterised his mode of treatment as certain from analogy, having met with so much success from it in treating ovarian cysts. He only treats unilocular cysts by this means and cysts which are not of old date; and thus limited he deems it a certain method, although he has only employed it in two cases. He believes that the great point is to establish adhesion between the cyst and the walls of the abdomen by the agency of the elastic catheter left in; and then, having formed a counter-opening, to effect obliteration by iodine injections. Capillary puncture and injection will suffice as long as the fluid is not purulent, but when inflammation has seized the cyst and suppuration has set up this is no longer the case. The iodine does not act as an irritant, but as a powerful modifier, limiting the amount and correcting the character of the secretions. M. Velpeau reverted to the distinction which should be maintained between injection and *lavage* by iodine. The injection of closed cavities, as the joints, etc., with iodine is a very innocent procedure, while the *lavage* or injection of a cavity open to the air may give rise to the severest accidents. M. Voillemier regarded the statement that iodine is not an irritant, but a modifier, as a mere play on words; and he strongly deprecated M. Boinet's procedure as very uncertain and hazardous, and as greatly inferior to the caustic treatment introduced by Recamier, and frequently attended with success.

months in advance. The remaining sum of two shillings, to make up ten shillings and sixpence, shall be paid to the Surgeon employed out of the funds of the Dispensary.

"All patients must furnish themselves with clean bottles, and with bandages, etc., when required; and, when the nature of their illness will permit, they must attend at the residence of their respective Surgeons from eight to ten o'clock in the morning; and if they cannot attend personally, they must send their tickets without delay.

"The tickets of all classes of patients will be available for one month from the time of their date; and no patient will be at liberty to change the Surgeon under whose care he shall first place himself, during the same illness, unless such illness should continue for a longer period than one month; but he will at all times have the privilege of a consultation of the Medical officers of this institution with the consent of the committee.

"Members living within one mile and a-quarter of the Shire Hall, Stafford, may, in cases of necessity, be attended at their own dwellings. Members may choose their own Medical attendant from any of the acting Medical officers of the institution."

Through the kindness of Dr. Day and Dr. Masfen, I am able to append the report for the year 1863. This report, which has not before been printed, but is now in course of publication by the Committee, has reached me since I penned the first part of this section. It will be seen that the prospects suggested above have been fully realised.

"*Stafford Dispensary Annual Report, 1863.*

"This institution is now entering on its third year, and such has been its progress, and the favour it has found among those for whose especial benefit it was established, that, since the Committee issued their first annual report, within the last twelve months, the number of subscribers have gradually been doubled.

"The objects of the Dispensary are, to enable the working class to provide themselves with Medical and Surgical assistance when necessary, under the denomination of 'free members,' at the mere nominal cost of one penny per week; to provide similar attendance for poor persons, who, being unable to subscribe themselves, shall receive tickets of recommendation from honorary subscribers; to provide Medical attendance for poor married women during their confinement; and to consult the feelings and comforts of all, by allowing each member the choice of any of the Medical officers, and by providing them with attendance at their own homes.

"In 1862 the free members subscribed £87 7s. 6½d., and the total for that year, with honorary subscribers, amounted to £97 7s. 7½d. In 1863 the free members subscribed £164 0s. 10½d., which, with the honorary subscriptions, made up the total to £184 16s. 1d.

"*Total Number of Cases attended by the Medical Officers.*

	1862.	1863.	Increase in 1863.
Midwifery tickets	12	36	24
Honorary subscribers' tickets.	42	67	25
'Free members'' tickets	832	1851	1019
Total	886	1954	1068

PAROCHIAL MEDICAL RELIEF.

The parochial Medical relief of the Stafford Union is divided amongst four Medical officers, Messrs. Perrin, Tylecote, Weston, and Masfen. The stipend of each of these is £45 annually. Mr. Perrin's district includes an area of 17,813 acres, and a population of 6837. Mr. Tylecote's district has an area of 17,135 acres, and a population of 4033. Mr. Weston's district has an area of 16,404 acres, and a population of 2529. Dr. Masfen has the town district with an area of 1,282 acres, with a population of 11,075; in connexion with his district, Dr. Masfen also holds the Union Workhouse. I could not gain any positive information as to the average remuneration of these Medical gentlemen, per case.

THE UNION WORKHOUSE.

The Union Workhouse, situated at a distance of nearly a mile from the town, affords space for 180 inmates. It is in a deplorable sanitary state. There is an Infirmary attached, but with few necessary conveniences for the sick. Through the whole of the building drainage is deficient, and but for the porous nature of the soil it would be difficult to account for the removal of the water at all. There is a cesspool, but the privies do not communicate with it, and the whole refuse of the place

is allowed to accumulate on the premises. The water supply is from wells; the ventilation everywhere deficient; the flooring of the apartments, even of the sleeping apartments, in most instances is either of plaster or dark brick, cold, damp, and pitiless. The diet is of the regulation standard, or a little over it; Dr. Masfen thinks it is above the requirements of the inmates.

The school of the Workhouse is at the back, and is a wicked disgrace. The rooms are small low buildings of brick, like air-tight boxes. On entering upon the boys' side I could hardly believe my senses. The unhappy Dominic was at his large slate, teaching away, and looking like the spectre of a man, so pale and thoughtful; the children were equally ashy, and they said their says with a feeble drawl, interspersed every now and then with a faint caw, as though existence were too much of a burthen to be tolerated together with the culture of the art that came from Cadmus. As to the air of the place, let me not dwell on it, much less in it. It was hot, it was sharp, it was dry; it was pervaded with particles of diffused fustian and corduroy; there was a marked, though extremely delicate, odour of sulphuretted hydrogen, and an equally refined indication of the presence of dead fish that had not been hermetically sealed up. What if one could have seen as well as smelt the whole contents of that loathsome atmospheric well? The carbonic acid knee deep; the sulphuret in wavy lines gradually diffusing itself: the millions of particles of dust from garment, and desk, and floor; the myriads of organic forms flying hither and thither; settling on heads and finding quarters there; settling on skin; creeping under epidemic scale and burying there; jostling into the mouths and nostrils of those yawning children, and making explorations into their lungs and stomachs: fitting into their weak lashless eyes and drinking up their moisture: and anon enveloping the Dominic, and mocking him in his toils. Some day, perhaps, science may give us these insights, so that even the managers of the poor may be taught to see. Sufficed it for me to smell only and think, and as soon as possible leave to re-enter the great school-room of the Most High, the clear, open firmament: but it was not for many hours afterwards that I forgot that worthy schoolmaster in his premature vault, trying in vain to light up the intellectual fire without any oxygen to support the combustion.

Of course, under conditions such as have been named, there must be disease, especially amongst the children. I looked, in fact, and in vain, for one specimen of a healthy child. They are all anæmic, and amongst them skin diseases, eczema, pustular itch, and strumous ophthalmia have fine scope for development. Consumption is also common in the house, and there have been recently two outbreaks of typhoid fever. By attention to diet, Dr. Masfen has managed to reduce the prevalence of the affections of the skin, but he is placed like Sisyphus, and unaided cannot meet the overwhelming evils. Meanwhile, the Poor-Law Board hears and forbears, anxious perchance, in the interests of science, to sustain an establishment where the synthesis of disease may be seen on the most approved and comprehensive scale.

CLUB PRACTICE IN STAFFORD.

The sick clubs in Stafford are numerous. They consist principally of Odd Fellows, Foresters, and Druids. These institutions are well managed, but the pay to the Medical men is extremely small—2s. 6d. per head for the year. Lately there is a disposition shown to raise the sum to 3s., and if the representatives of the clubs were to double that, they may be assured that in the end they would be the greatest gainers. Benefit insurance companies have been tried in the town with unsatisfactory results as regards the poor.

LITERARY AND SCIENTIFIC INSTITUTIONS.

There is no Medical scientific society in Stafford, but there is a general institute and reading-room, known as the St. Mary's Church Institute. This is held at the St. Mary's Schools, and the rooms are open every evening from 5 to 10 o'clock. Games are allowed for the amusement of members, lectures are delivered, and a French class has been formed. Females are admitted to the use of the library and to the lectures. Thomas Salt, Esq., M.P., is the president of the Institution.

CHARITABLE INSTITUTIONS.

The charitable institutions of the town are numerous. I have not space to dwell at length on these, but the following abstract supplies the leading facts:--

Abstract Report of Stafford Charities.

Name of Charity.	Annual Income.			How Distributed.
	£	s.	d.	
Isaac Walton	50	0	0	To bind out two boys, sons of honest and poor parents, to be apprentices to some tradesman, £10.
Ditto	8	2	10	To some maid-servant, not under 21 years of age, having been long in one service; or to some poor man's daughter of that age, to be paid to her on the day of her marriage, £5. The remainder in coals to the poor.
Free Grammar School	316	2	10	After necessary repairs, two-thirds to the Head Master and one-third to the Usher or Second Master.
Queen Elizabeth's Charity	1260	5	8	Rector of St. Mary's, £340 per annum; Curate of St. Mary's, £170 do.; Curate of Marston, £100 do.; Head Master of King Edward's School, £4 5s.; English Master, £100 per annum; repairs of Church (St. Mary's), and cleaning the Church and chancel and bells and ropes; salaries to Organist, £45 5s.; do. to Beadle, £10.
Sir Martin Noel's Charity:— John Chetwynd, Mrs. Arnett, Philip Foley, Thomas Foley, Dr. Binns. Rev. Robert Sutton ..	40	6	0	Paid to the poor in the almshouses, 15s. 6d. per week.
Lady Barbara Crompton, of Creswell. Robert Levett .. .	7	13	4	One noble each to four scholars of Free School; 6s 8d. to Rector for sermon yearly; £2 to forty poor widows do.
Rev. Richard Startin Rev. Robert Palmer ..	2	12	0	Four poor widows yearly.
Mr. William Farmer; Rebecca Crompton. Mr. John Webb's Charity.	1	10	0	Poor of parish of St. Mary's and St. Chad's yearly.
South Sea Annuities ..	2	12	0	In bread in St. Mary's Church weekly.
Mr. Simon Fowler ..	0	6	8	To two poor widows, two houses for life; Rector of St. Mary's for sermon, 6s. 8d. yearly.
Stafford Soup Kitchen	13	10	0	Six poor widows, 5s. each yearly; remainder in coals to almshouses.
	2	0	0	Twenty poor widows.
	21	6	4	£2 a man to each of poor burgesses, in rotation, yearly.
	12	0	0	180 poor persons, 6d. each, £4 10s.; sermon, 10s.; 180 poor persons, 6d. each, £4 10s.; sermon, 10s.; two poor men for cloaks, £1 each.
	341	18	10	This institution provides lodging-rooms for infirm persons out of work; gives soup and bread; loans blankets; pays a mission woman; utilises cast-off clothes for the poor; and allows donations of money in special cases.

In addition to these there is a County Asylum at Stafford, which might be ranked amongst the charities. But of this Institution I have so many practical facts before me, that a notice of them, in abstract, would be inadequate. The description of the Asylum will be rendered next week.

COMMENTARY ON HOSPITAL MORTALITY.

The facts stated at the close of my last paper, on the subject of the mortality of the Stafford Hospital, lead me to add a column or two on the question of Hospital mortality altogether. I do this, not from any desire to enter into controversy on a question which really admits of little controversy when prejudice is removed, but because, in order to stand right with the reasonable part of my brethren, I would clear away certain misrepresentations, or assumed corrections, which have been made in reference to this history. In the Medical history of Norwich the position was taken that, *ceteris paribus*, the mortality after important Surgical operations, such as lithotomy, is less in the country Hospitals than in the large metropolitan Hospitals. In respect to the one operation named above, lithotomy, Mr. Thompson has objected to a comparison which I drew between the London Hospitals and the Hospital at Norwich. He does not dispute that during a period of ninety years the mortality after lithotomy in the country Hospital has been 1 in 7.71; he does not dispute the startling fact that, twice over, forty cases, taken as they came, were operated on for stone in two distinct series without the occurrence of a single death; but he argues from certain statistical facts of 520 cases of lithotomy which he has collected from three London Hospitals, that results equally good would have followed if the same cases operated upon in Norwich had been operated upon in London.

In reply to Mr. Thompson, I observe that in speaking of the "metropolitan" Hospitals I included not any given Hospital, but all the large Hospitals, thirteen in number. In comparing the

facts, I took for the metropolitan side the only reliable data I could obtain, viz., the tables published in the *Medical Times and Gazette*, on January 8, 1859, and on August 20, 1859. In the tables thus supplied there were offered to us the particulars of 186 operations, being the whole Hospital practice of London for lithotomy during a period of three and a-half years.

In striking the comparisons required, a difficulty immediately presented itself. In the Norwich cases, 910 in all, 36 per cent. were in children under 10 years of age, while in the London cases, 186 in all, over 58 per cent. were under 10. It was essential, therefore, in order that the start might be fair, to exclude these cases, and to take up cases over 10 years where ages were equally divisible. On this basis we find that the deaths in London ran as follows:— Between 10 and 25 years, 7 deaths in 36, or 19.4 per cent., or 1 in every 5 cases; between 25 and 45 years 4 deaths in 8, or 50 per cent., or 1 in every 2; between 45 and 60 years, 9 in 17, or 52.8 per cent., or more than half; and between 60 and 75 years, 12 in 16, or 75 per cent., or 3 deaths in every 4 cases. Let, now, the reader compare these facts with those rendered in the table of the mortality in Norwich, given in the *Medical Times* of January 9, where the deaths are stated in decennial periods of from ten to eighty years. He will find that the highest mortality occurring between the years even of 70 and 80 is only 1 in 3; between 60 and 70 years, 1 in 3.71; between 50 and 60 years, 1 in 5.5; between 40 and 50 years, 1 in 5.27; between 30 and 40 years, 1 in 15; between 20 and 30 years, 1 in 14.75; and between 10 and 20 years, 1 in 10.5. To be plain, if four men, aged 70 to 75, were operated on in London, 3 would die; if three, aged 70 to 80, were operated on in Norwich, 1 would die; or if 2 men of 45 were operated on in London, 1 would die; but if five men of 45 were operated on in Norwich, only 1 would die. Taking the mean of deaths by these calculations, I could arrive at no other conclusion than the one I did arrive at,—that if the operations for lithotomy performed in the Norwich Hospital—910 operations in 90 years—had been brought promiscuously to the metropolitan Hospitals, and operated upon in them, the deaths would have been 472 instead of what they were—118. I see no reason to retract that statement, the less so when I recall that in the years when the London statistics were taken the internal condition of the London Hospitals were very much better than they were in the first half of this and the latter part of last century. Mr. Thompson may dispute the accuracy of the statistics of the lithotomy tables from the three years and a-half of London practice; if so, we must agree to differ; for I know the Surgeon who collected the facts, and I have implicit reliance on his scrupulous accuracy. Mr. Thompson may urge that the experience of three years and a-half is insufficient; I should be very happy on my side of the argument if the records could be traced back to the practice of the thirteen London Hospitals from this day to the year 1774, when the Surgeons at Norwich first began to cut for stone. He may say that the practice of one or two Hospitals has turned the scale so determinately against London, and that point I shall not dispute with him; and, certainly, I shall not urge that it was the bad manipulative Surgery that led to the descent of the large black metropolitan pall. That Mr. Thompson should have found out three London Hospitals that have yielded results nearly as good as the one at Norwich, is necessarily a source of satisfaction to every sanitary reformer; and I shall be delighted to see him take into his tables the whole remaining ten Hospitals. Perhaps in twenty years' time he may do so, but not now.

A second point I have urged is, that it is the duty of all Practitioners to be up and inquiring why there should be so large a mortality after lithotomy and after capital operations altogether. In this inquiry, the best method is, to determine first what the varying mortality does *not* arise from, rather than speculate on any one special cause. 1. It is not luck; it is common to say so, but the saying is nonsense. When forty cases were cured by forty operations at Norwich, there was some particular agency underlying the fact which was in action throughout; and so in every case, for what has once occurred can always occur again, the conditions being the same. 2. It is not operative skill, for in a run of cases that must be, in the main, the same. 3. It is hardly the operation, because, in lithotomy, one operation is, as a general rule, performed. At the same time I must admit, in fairness, that the Norwich results would probably have been slightly better had the median operation never been introduced. 4. The result can scarcely depend on the size of the stone, although that argument has been adduced.

5. The age of the patient cannot determine sequence in every case, seeing that, in different Hospitals, the results at the same ages are widely different. 6. The result, good or bad, cannot be referred purely to the condition of the patient or the selection of case. This has been affirmed, I know, but surely the conclusion is not sound. In my experience I have never seen more ill-fed and anæmic specimens of humanity than the poor of Norwich. The London poor appear better provided for and better housed; and London patients in Hospital look healthier; while it is well known that in the Norwich Hospital the Surgeons cut as boldly as any in the world. They, at all events, never send a patient away, incurable with stone, to die, after lithotomy, in another institution.

Thus driven back, there remains only one cause for the greater success in Norwich than London—only one cause why in Norwich eighty patients have been operated upon with a result of two deaths, and why in London, with all its skill, no such result has ever been approached; and that cause is the salubrity of the country Hospital. In saying this, I would put it forcibly forward (in special correction of the entire misconstruction of my previous argument advanced by Mr. Holmes) that this difference of salubrity is not because one Hospital is in Norwich and another in London; not because Norwich air, *per se*, is better than London air; but because the Norwich Hospital is removed from the low and crowded dwellings of the poor, and because, in its construction, Benjamin Gooch arranged for 1215 cubic feet of space per bed, and for constant and perfect natural ventilation. Here is an Hospital at Norwich that is never crowded; here is an Hospital that is never pent up; here is an Hospital where the patients are never perplexed by the gaze of a crowd of students; here is an Hospital into which the Surgeons and Dressers never enter with their hands and clothes redolent of the dissecting-room; here is an Hospital that never receives air devitalised by having become charged with organic impurities; and in this Hospital we have certain results for ninety years, results nearly uniform, which carry with their mention the idea of a success that never comes to the metropolitan nor to any other Hospitals where the advantages stated above are disregarded and absent. Is there anything wonderful in this? Is it wonderful that lithotomy cases should be unusually "fortunate?" Is that fact more wonderful than another fact, that in the same Norwich Hospital, in the year 1861, the mortality of the practice altogether should have been 36·00 per cent., while the mortality of the London Hospitals was 90·00. I make these observations from no desire to decry London practice and London Surgery; if I had the full evidence in hand I might probably illustrate from Manchester or Glasgow as readily as London. But I write as seeing an evil in certain Hospitals beyond the good they do. I write as seeing brilliant Surgery condemned to ignominious burial because the light, so startlingly exhibited in the operating theatre, is carried straightway into an atmosphere, and is surrounded by conditions, in which it cannot live. Were I a Surgeon, I should like to stand up before my peers and say, I have reduced the mortality of an operation from 50 per cent. to 5; and what harm could there be in such an ambition? But suggest the thought, as it is, and the Surgeons bristle up and put out their long knives at right angles to their bodies, and brandish their forceps and their splints, and exhibit the actual cautery, as if some one was invading their province with intent to harm. Much better, I take it, for them to lay all their glittering toys quietly aside and look at the externals and study facts, and ask: Is it really true that if we amputate a thigh or cut for stone in an Hospital containing 300 inmates, the probabilities that the patient will die are as a hundred in such Hospital to forty-seven in another Hospital containing but 100 inmates, or perhaps to twenty-seven in an ordinary house? Naturally, the day will come when we shall all meet, shake hands, and agree on these points; naturally those who write warmly on extant evils are subjected to criticism; naturally these speak strongly when they hear what they hear: a judge on the bench, primed to utterance by Surgical authorities, adducing, for instance, that huge demi-charnel-house, the misnamed "Hôtel Dieu,"—where, if three men enter for operation, you may predict that one will come out of the ordeal dead as surely as if he were going to execution—as one of "the largest and healthiest of Hospitals," on a model site! Yes, opposition and criticism are very natural, but happily they cannot last. Let but one or two enterprising Surgeons build a model Hospital near to London, where each sick man will have a separate room, good air, perfect quiet, no taste by inoculation of dead man's poison, no dying comrades within sight, and no

incessant noises to disturb the sleep, and though the Surgeons have neither the hands nor the experience of a Liston, Ferguson, Syme, or Thompson, they will soon show a balance-sheet before which the present infatuated defence of a vicious system must dissolve.

I know that great buildings are very difficult to knock down; they have material foundations, very deeply laid in the earth; they are wonderful arenas, in which the ruling principles and passions of busy men can display themselves. But for all that they are doomed. They are doomed, because a much simpler organisation will replace them, and prove itself superior in the one great and sole object for which a sick Hospital should be founded—the extension of human life. (a)

B. W. R.

PROVINCIAL CORRESPONDENCE.

BIRMINGHAM.

FEBRUARY 28.

IN the long interval which has elapsed since the readers of these columns were informed, by your correspondent, of our Professional workings, a movement of the greatest importance has been set on foot—an inquiry into our local Charities. I had hoped to have been able to record the result long before this; but that must be a desideratum for a few months longer. Matters have, however, advanced so far, that it is possible to sketch the history of the movement, and to indicate its tendency, with tolerable completeness, and without risk of serious error.

The great fact which first forced itself on the attention was the heavy indebtedness of our Hospitals and minor Medical charities, the Dispensary alone excluded. The greater the efforts made to raise subsidies, the heavier seemed to grow the liabilities; and this was especially true of the General Hospital—the largest, if not the oldest, institution of its kind in Midland England. Nothing daunted, projectors of fresh charities came into the field. The Children's Hospital was started about three years ago, with the announcement that it was to be a free institution for all deserving objects, and that its management should be so conducted as to steer clear of debt. We boasted of our Ophthalmic Hospital in Temple-row, which we had good reason for regarding as equal, if not superior, to any similar provincial institution in Europe; and we had an Ear Dispensary, which was one of the earliest institutions founded for the treatment of aural diseases; but this did not prevent another Eye and Ear Hospital being started; and it is most probable that we should have had one or two more "specials on the road" had not a caveat been entered by "Scrutator," (b) in a pamphlet of rare ability; obviously the work of a full and ready writer, it was pregnant with suggestiveness: had its author selected for his model an impartial judge, analysing evidence for the truth's own sake, rather than the pleading of an advocate, who, to win his case, is often compelled to conceal or travesty truth; had his comprehensiveness of grasp been equal to his ardour; had he sacrificed less to epigrammatic style; had he been more logical and less personal, his work would have been more useful and more en-

(a) In last week's *Medical Times and Gazette*, Mr. Holmes made four statements deduced from previous papers in the "Medical History of England." The first of these I have explained above. The second statement is a misapprehension. The third statement is correct on the data supplied to me—the published annual record of the Norwich Hospital. I have referred to that record again, and repeat the statement. The whole mortality for cases admitted under the Surgeons of the said Hospital in 1862 stands as 2·50 per cent; and the whole mortality after Surgical operations (total number of cases, 309) at 3·55 per cent., or 1 in 28·09 patients. The fourth statement is a misrepresentation by Mr. Holmes, not by me. I have not said anywhere that there has only been one case of pyæmia registered in the Norwich Hospital for seven years. I said there had only been one *fatal* case, which is a very different thing. The words which Mr. Holmes has misinterpreted are—"Looking over the list of deaths for seven years, the word 'pyæmia' occurs but once." This is strictly true; and when I wrote the report on Norwich, I did not know that there had ever been a case not fatal. But Mr. Williams has kindly informed me by note that one or two such cases have occurred. The fact is really, however, of no moment in regard to the observation which Mr. Holmes would criticise, seeing that the mortality was not increased by the introduction of pyæmia. On the contrary, it shows what a good Hospital the Norwich Hospital must be to have and to hold pyæmia cases, engendered or accidentally introduced, and yet suffer from no epidemic, nor lose in seven years more than one life. Had the same accidents happened in certain London Hospitals, where would the mischief have ended? I thank Mr. Holmes for that word *pyæmia*.

(b) "The Medical Charities of Birmingham." By Scrutator. Second Edition. Price 1s. W. J. Sackett, bookseller, Birmingham.

during. But, in spite of all their faults, "Scrutator's" letters were too able, too earnest, to be dismissed without consideration. They contained many errors, it is true, but withal so large an admixture of truth that they riveted attention. They made charges too serious to be ignored, and broached some doctrines too sound and too well-timed to be totally disregarded: they wounded so many susceptibilities, and assailed so much that was time-honoured, that they could not fail to arouse opposition; but conflict of opinion on many questions notwithstanding, it was felt on all hands that the time had come for an inquiry into the Medical Charities of Birmingham.

Although "Scrutator's" attacks seemed inspired by a general desire for knowledge and for the better management of all the Institutions impeached, it very soon became manifest that a great part of the movement was purely strategic;—affairs of out-posts;—reconnoissances of wings;—feigned threats on lines of communication,—with the ripely-studied plan of concentrating all available power on what, rightly or wrongly, was considered the stronghold of defective economical and sanitary administration—the General Hospital in Sumner-lane. It had an annual deficiency of something like £1800, and yet it was proposed to spend £7000 to enlarge it. Its constitution, theoretically representative, was, in practice, said to be oligarchical; and its officers, who had gained their positions by an expenditure and practices in electioneering contests equalled in few parliamentary boroughs, were supposed to be principally zealous for retaining and extending their power, and resisting the growing desire of the public for full inquiry into the alleged excessive mortality of the Institution. To this it was replied, that a Hospital which had admittedly worked an immensity of good, could scarcely be liable to so much censure; that the would-be reformers were men who had never taken much interest in its affairs; and that professional jealousy was not the least powerful of their springs to action.

In truth, the history of the General Hospital, if fairly written, would be one of the brightest chapters in our local annals. Founded by the leader of our Profession, in his day, in the midland counties, appointments on its staff have ever been eagerly sought after by some of our most distinguished Physicians and Surgeons; its Committee of management has consisted of the purest philanthropists and most honourable citizens; and, if great Professional tact and single devotedness were sufficient to ensure the well-being of a great sanitary administration, the General Hospital would need no aid; for at no former period of its brilliant history was its staff more skilled, or its council better intentioned. But experience abundantly teaches how deep learning and large practical knowledge in Medicine and Surgery proper may co-exist, without their possessors attaching due importance to fundamental sanitary laws. Thus it is that Hospitals in which some of the greatest men have worked, and from which they have dictated wisdom to the world, might be cited as illustrations of bad architecture, deficient light, impure air, and their inseparable ills. How often have we seen a Physician learned in diagnostics, little versed in the treatment of disease! nor should we be at fault if called upon to adduce instances of distinguished men, rich in pathological and therapeutical lore, setting at defiance, or at least little heeding, the primary necessity for free ventilation. Surgeons have necessarily been taught to rely greatly on the resources of nature; but they have too frequently forgotten her laws in over-eagerness for operations. An operating theatre has been too literally a correct appellation; and the knife has not unfrequently been relied on, to the exclusion of common sense and philosophical measures for averting its necessity, and practically lessening the risks of its after-consequences. It is the old story: special knowledge is often cultivated at the expense of the general powers of the understanding; and hence the healthy rule to examine and weigh by the laws of evidence and sound reasoning the technical opinions of experts, to whatever profession they may belong.

Whilst great intellectual power and disinterested devotion are essential to good Hospital management, they are not all-sufficient; and it is not difficult to conceive how, under a government of good, and even able, men, complications, if not abuses, may, through a long series of years, have accumulated imperceptibly, and necessitate inquiry for their definition and remedy. A very able and influential committee is now investigating the affairs of the General Hospital. It was moved for with great deliberation by outside reformers, and seconded by one of the foremost men of what, for convenience, though with grateful deference, may be styled the "old party." Some

unpleasantness has been occasioned by the fact, that those represented by the mover have, in past years, seemed to take little interest in the affairs of the institution; and it is urged, with considerable force, that the lay reforming element is professionally inspired by genius more brilliant than impartial,—more impulsive than reflective. But it must not be forgotten that men long used to government rarely take the initiative in progressive changes; and it is scarcely fair to charge the members of a legislative assembly, or of a constituency, with indifference to duty, if they remain passive and wait their opportunity, while circumstances appear to render hopeless any attempt at better organisation. It would be a happy state of things if fertility of imagination and judicial impartiality were often combined,—if men of original mind were more frequently calm reasoners and practical administrators,—if mental acuteness and generosity of feeling always co-existed; but as the actual facts are otherwise, it is no use seeking the impossible, or scrutinising causes too closely. If the work to be accomplished be a good one, it must be done, difficulties and disagreeables notwithstanding.

It is heartily to be desired that the inquiry into our local charities may be so conducted that the whole truth may be arrived at, and that matters may be placed on such a footing as most surely to conduce to the good of the people and the honour and usefulness of our body.

GENERAL CORRESPONDENCE.

HOSPITAL MORTALITY.

[To the Editor of the Medical Times and Gazette.]

SIR,—The support which Dr. Farr has given to Miss Nightingale's theories has caused much surprise to those who have estimated very highly this gentleman's talents. The Profession and public cannot, indeed, be too much indebted to Miss Nightingale for the efforts which she is making for the cause of the sick poor, but the want of knowledge displayed both by herself and Dr. Farr as to the practical working of the London Hospitals is very surprising. Speaking from my own personal experience as to the Hospital to which I am attached, I can easily see how the mortality could be reduced to half, or even less, than what it is at present, and this by the most simple process. The plan would be simply to admit slight cases of disease and reject severe ones, and then our wards would be held up as models of improved sanitary arrangements. The practice, however, at every London Hospital is the very reverse of this; if, for example, on the taking-in day a patient should apply with heart disease and dropsy, or, as happened during this last winter, the patient should present himself, livid in the face and gasping for breath, he is immediately admitted. With such cases the beds are soon filled, and three or four die within a week. If, instead of admitting these cases, we were to pass them by and take in the child with chorea, the girl with chlorosis, or the old paralytic patient, our mortality would be reduced to almost nothing, and we should then exult in our excellent sanitary principles, whereby such a result was brought about.

The same rule applies to Surgical patients, whereby the worst cases are admitted; and as regards casualties, this is the rule, without any exception, a large number of persons brought in every week having fatal injuries upon them.

If the question should be whether it were better to reject cases of this kind, and admit such as simple fractures, or to refuse admission to all instances of organic disease of the viscera, and limit admission to those cases which could be cured, it would be an open one for discussion; but whilst the practice is the very reverse, the cause of the high rate of mortality is sufficiently clear. This main cause of the high death-rate appears to be overlooked, whilst the comparatively trivial one of ventilation is paramount in the eyes of Miss Nightingale. Good ventilation, although important, has not, I am sure, one-hundredth part of the influence in altering the rate of mortality as the cause I have mentioned.

As regards cases of accident, although in the most severe ones death is rightly attributable to the injuries received, yet in very many others the previous state of the health of the patient has most to do with the fatal result,—a consideration of the number of drunken persons who meet with accidents will exemplify this. I am not aware that Dr. Farr's statistics throw any light upon the unhealthy conditions of persons who die after injuries. As regards the mortality from pyæmia,

before this is attributed solely to Hospital atmospheric influence, it would be well for Surgeons to compare cases of operation with those they have in private. Unfortunately for this purpose, the latter are comparatively rare, but I believe Medical men could readily produce many instances of this fatal affection from their private note-books. I know well that some of the worst forms of pyæmia which die in Hospital are brought from the private homes of the poor.

In spite of the apparent contradiction that the value of a Hospital is in proportion to its death-rate, I believe it is a statement of the truth. This is on the assumption that all Medical and Surgical treatment, when taken in a large average, produce the same results; but it is an assumption which can be easily proved to be correct. If so, the number of deaths show the severity of the cases admitted and the wants of the neighbourhood where the Hospital is situated. If the deaths were reduced, it would show that less severe cases were admitted, but whether this would be better for the community may be an open question. It were almost worth while to adopt the plan, in spite of the suffering poor, in order for statisticians to uphold an institution (where such method was enforced) as a model of improved salubrity—an *argumentum ad absurdum*. Much more might be said, but Dr. Bristowe and Mr. Holmes will no doubt put the whole matter in a clear and correct light from their personal and practical experience of the working of Hospitals.

THE NEW HOSPITAL AT WINCHESTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—I attacked the plans of this proposed new Hospital a fortnight ago in your columns. "F.R.C.S." replies that the architect can build pretty churches, and supports his assertion by quoting a *Times*' critic. If "F.R.C.S." and the *Times* think so, I shall not go to school to them to learn architecture. But the building of pretty churches does not happen to concern the question.

"F.R.C.S." supplies me with an argument that I omitted to use. Inexperienced persons, he says, have hitherto tried to build Hospitals, and all have failed; therefore let another inexperienced person try. Rather, I should say, let some person who has gained wisdom from former failures try again.

He must excuse me from answering the remainder of his letter. Indeed, it is scarcely necessary, as he does not attempt to disprove my assertions. He says, by the way, that the Baronet in question has mastered all the details necessary for planning a Hospital, a statement which I will leave to be confuted by the plans themselves.

Allow me once more to notice the disgusting cant which places the venereal wards conspicuously apart from the rest, and disfigures their exterior, in order that the priests and Levites, as they come in to their weekly committees and boards, may have warning to hold their noses, turn up the whites of their eyes, and keep on the other side of the yard.

"F.R.C.S." says something, unintelligible to me, about disappointed persons. He has apparently got a bone, and is growling over it. I fear his views and mine on the subject of Baronets differ *toto calo*. It may be a very good rule to "take the good the gods provide thee;" but I confess to being a quadruped of an independent turn of mind, and am not inclined to turn an inch out of my course for a Baronet, not even if his little dog barks at me.

I am, &c.,

EPICURI DE GREGE PORCUS.

CASES OF SUSPECTED POISONING FROM DISEASED MEAT.

LETTER FROM W. B. KESTEVEN.

[To the Editor of the Medical Times and Gazette.]

SIR,—A few days before I read the elaborate contribution of Dr. Ballard, "On Diseased Meat," published in your Journal of January 23, I met with an occurrence which now seems to me deserving of publication, as bearing upon the remarks therein made by Dr. Ballard, and as illustrative of a very apposite observation in your leader on the same topic in the Journal, November 28, 1863, to the effect that the information that is wanted concerning the unwholesomeness of meat consists in facts, and not in *à priori* deductions.

A family of twelve persons all partook, on the same day, of a leg of pork, roasted; all within a few hours were seized

with symptoms of very severe illness, closely resembling English cholera, which continued for from twelve to forty-eight hours. The ages of the members of this family, including servants, varied from five or six to eighty years.

Great alarm was of course excited by such sudden and severe illness. The source of these effects became the subject of anxious inquiry, and they were attributed to the pork. I carefully sought out whether they could be chargeable on anything else that had been taken at the same meal, or during the same day, but I found that the pork was the one thing that all alike had partaken of. Further, it so happened that, in addition to the twelve persons who were made ill, there were, under the same roof, a coachman and his wife, who, being on "board wages," had provided beef for their own dinner on that day. These two, although they had bread, milk, butter, vegetables, etc., from the same sources as the rest of the family, were free from ailment.

I have since examined the remainder of the joint with the microscope, without being able to discover anything like disease. A dog and two cats were fed on the remainder of the joint, and were not made ill in any way. Dr. Alfred Taylor has done me the kindness to have the dripping that resulted from the roasting examined in the laboratory at Guy's Hospital, and has found no trace of poison. Moreover, I have been able to follow up the history of the animal whence the joint was taken, and have inquired of those who partook of the corresponding limb, as well as of other parts, and I can get no account of ill effects in any direction.

Guided by the canons laid down in Dr. Ballard's paper, I cannot find an explanation of this occurrence. The animal, so far as can be traced, was known to be healthy; was killed in cold weather. The meat was not unduly fat; it was cooked while quite sweet and fresh; the flesh and fat were firm; it was simply roasted, without stuffing of any kind; the central part of the leg was underdone and red, the remainder tolerably well done, but the less "done" portions had not been eaten; it was eaten hot; various vegetables were eaten at the same time, but not of the same kind by all alike. Light table-ale was drunk by some of the party, water by others; no wine or spirit were drunk at all. Light pudding and cheese were eaten by some, and not by others. The symptoms commenced within two or three hours, and passed off in some of the family within twelve hours; recovery in all cases was perfect.

The above are the bare facts of the accident. They bear out the caution implied in your remarks, but they leave the matter entirely unexplained.

I am, &c.

W. B. KESTEVEN.

Upper Holloway, February 26.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 23.

Mr. PARTRIDGE, President.

As soon as the Honorary Secretary had read the minutes of the preceding meeting of the Society,

Mr. HULKE rose and said that he wished to enter his protest against a proceeding which had taken place at the last meeting. His paper had then been read out of the order which had been announced in the journals and elsewhere, and without any notification of the intention to do so having been made to him. He had no personal feeling in the matter, but as a principle it was bad to read a paper in the absence of the author when it could be avoided. Had he been informed that his paper would be read, he might have illustrated it by diagrams; and he thought some law should be in force on the point, and that it was the duty of the Secretary to acquaint authors when their papers would be read.

Mr. BIRKETT explained that the paper was read to suit the time of the Society. He was not aware that there were any illustrations to it; and his notice to an author was not obligatory, but merely one of courtesy.

The PRESIDENT remarked that the custom of the Society was to read the papers in the order announced; but the Secretary could not, of course, determine how long the paper might take to read, or how far the discussion upon it might extend.

Under these circumstances it might occasionally be necessary to substitute a short for a long paper.

After a few more observations the subject dropped.

A paper by GEORGE NAYLER, Esq., was read on

ALOPECIA.

Alopecia circumscripta, or areata, is a disease little noticed by any author except Cazenave, who confounded it with vitiligo of the scalp. It is far more frequent in the female than in the male, the relative proportion being that of seven to four between the two sexes; and it is chiefly observed about the period of puberty. It is a non-contagious disease, and may be represented by almost any number of circular bald patches on the scalp; very protracted in its progress, and tedious to heal. Alopecia is often associated with headache, especially in the female, or with some disorder of the catamenia; and in children, with ascarides or some gastric irritation. No pain or previous symptom indicates the disease, which is generally unperceived for some time by the patient. The patch is of ivory smoothness, and ends in a circumference of sound, unbroken hair.

When recovery takes place, the new hair is finer and softer than the old, and in some instances perfectly white. (The author had recently seen a patch in a lad of 18 years where the new hair was quite white.) A microscopical examination shows the hair-bulb to be reduced to a fine point, or the bulb to be slender, and sometimes ending in brush-like filaments. In the stages of recovery, the bulb by degrees assumes its normal shape and size; but the hair itself for a long time retains its fineness and lighter colour.

Alopecia is regarded by most French writers as a parasitic disease, as by Bazen, Harding, and others; but no instance of a parasite has been found by Mr. Startin or the author. Mr. Hutchinson once detected it; but this may have been a case of *T. tonsurans* or *Pit. versicolor* of the scalp.

The prognosis is favourable, particularly when the disease is recent and the patient of early age, or below puberty.

The treatment consists in attention to the general health, and in giving steel. The local treatment is of much importance. The surface affected should be painted from time to time with some blistering fluid, and in the intervals with some form of mercury or sulphur, either as an ointment or a lotion; or a lotion of the tinctura lytta. In protracted cases, mercury and arsenic in small doses may be given internally.

In general alopecia the prognosis is less favourable, and when the disease is of long standing no good result can be expected. This form of alopecia differs from alopecia areata only in involving a greater extent of surface.

A paper by Mr. WM. SCOVELL SAVORY was read on

THE ABSORPTION OF DEAD BONE.

Can dead bone be absorbed? This question still awaits a satisfactory answer. For while careful and accurate experiments have furnished only negative results, there are unquestionable facts which compel us to admit the possibility of the occurrence. One all-important consideration seems to have been hitherto neglected in the inquiry—the influence of pressure in determining the result. Thus, in the experiments which have been performed on the subject, and which have naturally led to the conclusion that dead bone may be kept amidst living tissues for weeks or months without losing the merest fraction of its weight—in these experiments the dead bone was kept in simple contact only with living parts. It appears that no considerable pressure was maintained. Whereas when ivory pegs are driven into bone, extreme pressure is of course produced. In order to test this view, some experiments were performed, which are related in the paper. It appeared to the author that the only explanation which can be offered of the results of these several experiments is, that the absorption of dead bone, when in contact with living bone, is determined by the pressure to which it is subjected.

The PRESIDENT said the communication was interesting in connexion with the experiments of Mr. Gulliver. The state of the fragments in cases of ununited fracture had been noticed before; but it had not been attributed to the cause which was explained in Mr. Savory's paper.

Mr. HILTON said the Profession ought to feel obliged to Mr. Savory for having adduced by well-considered and well-arranged experiments such conclusive evidence of the absorption of dead bone by the surrounding living tissues—a fact not usually admitted by Surgeons. He (Mr. Hilton) had several times noticed, on looking at two ivory pegs which had been employed in the same case of ununited fracture, and appar-

ently under the same conditions, that the surface of one of them was partially absorbed, whilst the other did not manifest any loss of substance—a difference hitherto inexplicable, but now elucidated by the author's paper, as depending upon the variable pressure to which they had been subjected. An interesting point, however, presented itself for consideration to which the author had not made any reference—viz., What was the amount and duration of pressure required to induce this absorption? for dead bone was often seen buried within granulations which were undoubtedly capable of exerting much pressure without the slightest appearance of any absorption having occurred. For instance, in the case of an amputation through the femur, the same end of the bone may come away necrotic after several months' subjection to the pressure of muscles, fascia, granulations, bandaging and strapping, yet the track of the teeth of the saw used at the amputation would be seen as cleanly cut and as sharply defined as on the day of the original operation. The same kind of facts was quite as discernible in cases of compound fracture of a long bone, where the fractured end of bone, although surrounded deeply by granulations and new bone during several months, would present the sharp, well-defined edge of the fracture as evidently as on the day of the accident, uninfluenced by the pressure of any of the surrounding living tissues. Mr. Hilton had removed from the leg several portions of a comminuted compound fracture of the tibia eight years after the accident and seven years after the closure of the external wound, and upon two of them the well-defined edge of the original fracture was obvious and markedly different from the serrated edge observable where the piece of bone had been separated from the living bone by the slow process of absorption. Mr. Hilton would suggest to the author the inquiry as to how or by what combination of minute events does pressure contribute towards absorption of the dead bone, because the pressure in his (Mr. Savory's) experiments was made equally on both the living and dead bone. No doubt such an investigation could not be placed in better hands than Mr. Savory's.

Mr. PARTRIDGE inquired whether the absorption of the pegs was greater in the shaft of the bone or in the medullary canal?

Mr. SAVORY said absorption was greater in the shaft portion than in the medullary canal.

Mr. COOTE said that Mr. Savory's experiments were very interesting in confirming the view entertained by many Surgeons that, in the removal of dead bone, the action of the absorbents was possible in the material that had perished. He had himself witnessed the corrosion of the surface of ivory pegs introduced into living bone for the purpose of promoting union in a non-united fracture. The possibility of the fact, which had been doubted, was important; but, after the experiments thus detailed, could not be denied. He (Mr. Coote) thought that perhaps pressure alone was not sufficient to explain the phenomena of removal. He had witnessed the separation of large portions of bone, which he believed to be dead, on which no pressure could have been exerted. But the fact remained the same; and the value of Mr. Savory's observations must be undisputed. He (Mr. Coote) concluded with some remarks on the relative size of sequestra and the bony cavities which contained them.

Mr. BROOKE said that he doubted whether the process by which the surface of the pegs was eroded could truly be designated a process of absorption. He thought it probably analogous to the process of disintegration, by which the surface of a sequestrum is acted on by the highly-vascular granulating surface with which it is in contact. That disintegration, and not absorption, is going on in cases of necrosis, may generally be rendered evident by the appearance of the *débris* of bone-tissue in the pus discharged from the cloaca.

Mr. WOOD asked the author whether, in each of the experiments detailed, the condition of the medullary membrane in contact with the peg had been observed, as regarded the presence of granulations or other absorbing structure. In many of the cases in which the pegs had been loosely inserted, extensive suppuration, and in some instances death, had followed. Could the action set up in these cases have been that of a process destructive to the absorbing or vital powers of the bone and medullary membrane operated on, this would of course prevent the occurrence in these experiments of any absorption of the foreign or dead bone. He presumed that in all the experiments pegs made of the same dried bone had been used, and that there was in no case introduction of putrid matter. In most of the pegs shown in the box handed round which exhibited any evidence of roughening, this extended equally

through the parts embedded in the bone of the animal, although only the part traversing the compact tissue of the cylinder of bone had been subject to pressure. The intermediate portion had been in contact with the medullary substance. In the specimen from which the drawing was taken the peg seemed even more attenuated in the cavity of the bone than where in contact with its walls.

Mr. SOLLY remarked that, while agreeing with all the former speakers in the great value of Mr. Savory's paper, he did not think that it subverted all the old opinions that dead bone could not be absorbed except under pressure: for instance, in necrosis of the parietal bones—a good case of which he had in his mind's eye, where the bone died, became black, lost its sensibility, and was then separated from the living bone because it was dead. The sequestrum which was thus cast off was perforated in all directions as though worm-eaten, and absorbed in patches. Was not this an instance of dead bone being absorbed without pressure? Had not every Surgeon in the room seen such cases?

Mr. SAVORY, in reply, said he had considered it best in the paper simply to demonstrate the fact that the absorption of dead bone is determined by the pressure to which it is subjected. In working at the matter, of course he had thought of the nature of the influence thus exercised, but he did not consider any opinion which he might have formed on the subject worth expressing. The question was not in relation to the absorption of bone, whether living or dead, but to the effect of pressure on the absorption of dead bone. With respect to the case Mr. Solly mentioned, it was not enough to show that dead portions of bone bore evidence of having been partially absorbed: it must be shown that such absorption occurred after the death of the bone, and thus independently of all pressure. Mr. Savory defended the use of the word "absorption." He had not employed the term without foreseeing the objection that might be urged against it; and so he had been careful to relate how, in some of the experiments, the wounds at once closed, and completely healed without any discharge or other means by which disintegrated fragments of bone might have escaped. Moreover, if the preparations were examined it would be seen that, in some of them, the portions of dead bone which had been removed could not have escaped, for the holes were tightly plugged by the pegs which had been driven in. With reference to the destination of the bone which disappears in disease, Mr. Savory thought that the evidence advanced to prove that this is always disintegrated and cast out was unsatisfactory and inconclusive. Of course, in some forms of ulceration of bone, as in phagedenic ulcers of soft parts, disintegrating fragments might perish and escape; but in other less destructive forms of ulceration bone might disappear through absorption. Much had been made of the fact that the discharge from carious bone contains an unusual abundance of phosphate of lime, this being supposed to represent the dissolved osseous tissue. But while, on the one hand, this would prove too much, the proportion of bone which disappears not being equal to the quantity of phosphate of lime discharged, on the other hand, a better, a more philosophical explanation of the fact might be given. As in health each part assimilates to itself from the blood its own proper constituents, so in abnormal forms of nutrition it was reasonable to believe that the material furnished by different structures would present characters of composition more or less corresponding with those of the tissue whence it proceeded. Be this as it might, however, in some at least of the experiments described there was no means by which the portion of bone which had disappeared could have escaped externally.

THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 2.

Mr. PRESCOTT HEWETT, President.

Mr. WALTER COULSON exhibited

THE FRAGMENTS OF THE SHELL OF A MEDIUM-SIZED URIC ACID CALCULUS SPONTANEOUSLY DETACHED AND PASSED THROUGH THE URETHRA.

The patient, a man from Derby, aged 61, was first seen May 26, 1863. He had suffered from bladder irritation for the last five years. Seven months ago a small portion of the shell of a stone came away, and after an interval of a week another bit. He continued to void pieces with his urine for five or six weeks, by the end of which time the shell of a fair

sized calculus had been passed. During this period the urine was deeply tinged with blood, and he suffered acutely. Subsequently, lithotripsy was performed, and he was cured after five operations, and it was found that there were two calculi in the bladder.

Mr. WALTER COULSON next showed

ELEVEN STONES REMOVED BY LITHOTOMY.

In this case lithotripsy was, in the first instance, attempted, but the cutting operation was resorted to, as the patient was unable to empty his bladder except by the aid of a catheter, in consequence of the quantity of stone contained in the bladder. The patient, aged 65, made a good recovery.

Mr. WALTER COULSON also brought forward

THE SACCULATED BLADDER AND KIDNEYS OF A PATIENT ON WHOM LITHOTOMY HAD BEEN PERFORMED, ALSO TWO CALCULI REMOVED, ONE OF WHICH HAD BEEN ENCYSTED.

The patient had suffered for some years with symptoms of stone. He had been frequently sounded, but nothing had been detected. Mr. Coulson examined him with a lithotrite, and found a stone fixed on the left side of the floor of the bladder, that he was unable to seize. Lithotomy was resorted to, and the patient died three days after from uræmia. The bladder was sacculated, and contained one large sacculus on the left side of the floor of the bladder, that had evidently lodged one of the stones removed, as at the time of the post-mortem there were still portions of calcareous matter adhering to it. The ureters were both dilated. The left kidney was reduced to a mere cyst, and the kidney structure of the right was much injured. The encysted stone was removed entire, the second in fragments. Both calculi were chiefly phosphatic.

The PRESIDENT said that he had seen the patient from whom the last specimens were taken some years before, and had detected no stone. He then told the patient, however, that he had alkaline urine, and was liable to suffer from calculus. The President also mentioned that he had succeeded in detecting a stone by a catheter, which allowed the urine to escape gradually, when he could not by the ordinary sound. He considered that this was an important point, and gave several instances in which the catheter detected a stone when the sound did not.

Mr. CHRISTOPHER HEATH exhibited

A LARGE MASS OF CALCULOUS MATTER EXTRACTED BY MEDIAN LITHOTOMY IN A CASE OF RETENTION OF URINE.

A man, aged 34, was admitted into the Westminster Hospital with severe traumatic stricture, the result of injury to the perineum twelve years previously, since which time no instrument had been passed into the bladder. A few days after admission, retention of urine supervened upon an attempt to pass a catheter, and it became necessary to afford relief. The point of the catheter touching calculous matter in the prostate, and being thereby prevented from reaching the bladder, the patient was tied up in the lithotomy position, and Mr. Heath made an incision in the median line to extract the calculi. It was found, however, that, in addition to the prostatic calculi, there was a large vesical calculus, which proved to be adherent to the left side of the bladder. After one or two attempts at removal, the stone broke in the forceps, and was extracted piecemeal. A large number of prostatic calculi were removed, and there was then found to be a quantity of calculous matter adherent to the coats of the bladder in various parts. This was scraped away with the scoop as far as possible, and removed. The patient did well, and made a perfect recovery, the stricture being subsequently treated by Holt's dilator. The calculi exhibited consisted of two distinct formations, vesical and prostatic, the whole mass weighing 1084 grains (or 18 drachms, 4 grains), and the small prostatic calculi alone 46½ grains. The prostatic calculi averaged the size of barleycorns, and were of a dark brown colour. The portions of vesical stone were found to form two distinct calculi, one composed of fusible calculus around a nucleus of phosphate of lime, deeply coloured with animal matter, the pieces of which weighed 832 grains, and which had evidently been adherent to the coats of the bladder; and the other, of very remarkable shape, and weighing 104 grains, which consisted of a nucleus of phosphate of lime deeply coloured, very smooth, and of the size and shape of a sparrow's egg (39 grains), with a surrounding portion of phosphatic matter, more resembling a gigantic "os unciforme" than anything else. These latter pieces came away in the forceps in the middle of the operation, but their source was doubtful. The *débris* of phosphatic matter removed from the bladder weighed 101½ grains.

Mr. HEATH also exhibited

A SPHERICAL CALCULUS REMOVED FROM THE BLADDER AFTER DEATH.

This calculus was removed post-mortem by Mr. Bullen, of the Lambeth Workhouse, from the bladder of a man, aged 82, who had had hardly any symptoms of urinary affection during life. The calculus was remarkable for its nearly perfect spherical shape.

Dr. MURCHISON showed a specimen of

CANCER OF THE ŒSOPHAGUS COEXISTING WITH RECENT TUBERCLE IN THE LUNGS.

A man, 54 years of age, who was, until the illness of which he died, very healthy, although very intemperate, began to get thinner, to swallow with difficulty, and to vomit immediately after his meals. He died at the end of ten weeks. It was found at the autopsy that there was stricture of the œsophagus, an inch and a-half above the cardiac orifice of the stomach. The mucous membrane was free from ulceration, but was puckered, and there was a little fistula leading into the tumour from the œsophagus. The tumour, which was in the posterior wall, was dense and translucent. The glands in the neighbourhood were healthy. The lungs were found to contain, at their apices, old and recent tubercles, calcareous nodules, and cheesy matter, and scattered miliary tubercle. He had thought at first that the tumour might also have been tuberculous, but it contained abundance of characteristic cancer cells.

In reply to Mr. Sydney Jones, Dr. MURCHISON said that the tubercle in the lungs had been examined microscopically.

Mr. W. ADAMS exhibited

TWO LEGS OF A CHILD WHO HAD BEEN THE SUBJECT OF CONGENITAL TALIPES VARUS.

The child, aged eleven months, had died of acute inflammation of the lungs. Both legs, as now exhibited, were free from deformity, the achilles and the anterior and posterior tibial tendons having been divided five months before death. In each of the Achilles tendons there was half an inch of new tendinous tissue inserted between the divided extremities of the old tendon, which was thus elongated. Externally, the tendon was well defined, and its surface even throughout, so that there were no traces of the operation, but the new tissue was easily distinguished on the recent section by its grey translucency, contrasting with the opaque pearly lustre of the old tendon. Both the posterior tibial tendons had united, but in one of them the free play of the tendon was limited by adhesions, whilst in the other only very slight adhesions existed. Mr. Adams remarked that he had already published fifteen post-mortem examinations after tenotomy, and, since the publication of his work on this subject, had made at least five or six more which confirmed the opinions he already advanced. With regard to the posterior tibial tendon, Mr. Adams observed that he employed gradual extension for a week before the operation, to limit the separation of the cut extremities, and thus favour union.

Mr. BARWELL said that he had never denied that the posterior tibial tendons would unite, but had said that they contracted adhesions. He had never operated in such cases, and had never found it impossible to replace the foot.

Dr. CAMPS suggested that the deformity might be due to paralysis rather than to contraction.

Mr. W. ADAMS said that in cases of congenital varus, such as the present, there was not a shadow of evidence that paralysis ever existed. He had never seen such a case, though in some rare instances congenital deficiency of some of the muscles of the leg existed, and at first this condition might be mistaken for paralysis. Non-congenital paralytic deformities were common enough, and in some of these cases the most brilliant results in Orthopædic Surgery were obtained by tenotomy.

Mr. MAUNDER remarked that in cases of wounds, on healing, tendons would be glued to the skin in the cicatrix, but after a time they became loose again.

Mr. BARWELL said that there was a difference in the wounded limb of a strong healthy man and a weak child's leg on a splint.

Mr. POLLOCK showed a specimen of

RUPTURE OF FATTY HEART.

A lady, 60 years of age, very fat, was seized with acute pain, and died suddenly. A rent was found in the anterior part of the left ventricle, and the pericardium was distended with blood. The other viscera were healthy.

Mr. POLLOCK showed a specimen of

NECROSIS OF THE THYROID CARTILAGE.

The patient had been admitted, October 7, for extreme difficulty of respiration and husky voice and cough. A few days later laryngotomy was performed, with immediate relief. On the fifth day the patient was better, the tube was withdrawn, and finally the orifice healed. The laryngoscope showed that on one side the glottic orifice was contracted, and on the other there was swelling. The patient died suddenly one night, having had but very slight previous dyspnoea. The aryteno-epiglottidean folds were thickened, and a piece of the thyroid cartilage, necrosed, was found in an abscess.

Dr. GIBB exhibited a specimen of

STRICTURE OF THE TRACHEA AND GROWTHS OF THE LARYNX, from a lad of 19, who had been admitted into the Westminster Hospital with extreme dyspnoea, which was at first supposed to depend upon laryngeal obstruction. On the tenth day tracheotomy was performed by Mr. Holthouse, but a tube could not be worn, in consequence of the existence of constriction of the trachea, this condition being found after death to have involved the entire tube, as well as both large bronchi, thus rendering the causes of the dyspnoea threefold—namely, obstruction of the larynx, trachea, and bronchi. The patient had suffered from former attacks of laryngitis coincident with glanders.

Mr. SYDNEY JONES showed a

SKULL CONTAINING A TABLE-KNIFE.

It had been driven through the orbit into the cranial cavity, the point projecting through the bone behind.

Mr. SYDNEY JONES also showed a skeleton of a foot, in which there were two internal cuneiform bones.

Mr. HINTON presented, for Mr. Toynbee, the

LEFT PETROUS BONE, AND SOME PORTIONS OF DURA MATER, FROM A PATIENT WHO DIED WITH CEREBRAL SYMPTOMS.

This specimen had been sent him by Mr. Lacy, Surgeon to H.M.S. *Cumberland*. The patient had been under treatment a year ago for suppurating bubo, but had recovered. Fourteen days before his death he was placed on the sick-list for coryza and discharge from the ear. About a month before he had had acute pain in the ear, but none lately. The face shortly became paralysed on the left side. He sank gradually, with scarcely any complaint of pain. A day or two before his death a profuse gush of purulent matter escaped from the ear. On removing the calvaria, a number of firm growths were observed, firmly attached to the dura mater in various places, and varying in size from a pin's head to a hazel-nut. The vessels of the pia mater were full of blood, but there was no effusion or softening. The larger growths had made marked impressions on the adjoining convolutions, the largest indentation being on the left lobe of the cerebellum. Otherwise, the membranes and brain substance were healthy. The left membrana tympani was destroyed, and the roof of the tympanum had a slightly-darkened and worm-eaten appearance. The tympanic cavity was full of pus. The head only was examined, but there existed no symptom indicating disorder of any other organ than the brain.

APPEAL IN CRIMINAL CASES.—Sir F. Kelly's Bill, which waits for a second reading, proposes the establishment of a Court of Criminal Appeal. Under the Act of 1848 questions of law arising on the trial of a prisoner may already be reserved for the consideration of five or more of the judges, but this bill proposes a large extension of their jurisdiction. If any person convicted of treason or felony can obtain the certificate of a barrister that there is reasonable ground to appeal, a motion may be made upon affidavit or otherwise for a new trial, or leave to enter an acquittal. The motion may be made either before one of the superior courts or before this "Court of Criminal Appeal," but it is this last court that is to hear the rule argued if it be granted, and to dispose of the case. A new trial may be ordered, or the trial of a particular question of fact, as, for instance, of insanity. If a prisoner on being convicted declares his intention to appeal, the judge may either postpone pronouncing sentence, or pronounce sentence conditionally, and, if he think fit, release the prisoner on recognisance with or without sureties, or he may pronounce sentence to be executed as if no appeal were to be made. The Bill allows any person to apply to the Court on behalf of the convict "at any time after his conviction," upon the ground of his insanity either at the time when he was tried or at any time afterwards.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 25, 1864:—

Frederic Isaac Flower, Middlesex Hospital; Herbert Morris Spencer, London Hospital; Henry John Hunt, King's College Hospital; Arthur Long, Barham, near Canterbury; Thomas Mills, Cliff-parade, Southend.

The following gentleman, also on the same day, passed his First Examination:—

John Comyns Leach, University College.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLBUTT, THOMAS C., M.B. Cantab., has been appointed Physician to the Leeds Public Dispensary.

GILCHRIST, WILLIAM, M.D. Edin., has been appointed Hon. Acting-Physician to the Erith House Institution for Ladies with Affected Chests, Torquay.

GOLDING, JAMES P., M.D. Q.U.I., has been elected Medical Officer to the City Dispensary, Cork.

HALL, CORNELIUS S., M.R.C.S. Eng., has been appointed Medical Officer for the new Workhouse and Union Hospital for Carlisle.

WILLIAMS, WILLIAM, F.R.C.S. Eng., has been elected Medical Officer of the Dolgelly Workhouse, Merionethshire.

WOODMAN, ROBERT, M.D. Aberd., has been appointed Medical Officer for the Workhouse of the East and West Flegg District.

DEATHS.

BRISTOWE, JOHN SYER, M.R.C.S. Eng., at Clarence-place, Camberwell, S., on February 29, aged 71.

BROWN, J., M.D. 1st Assistant-Surgeon Presidency General Hospital, at Calcutta, on November 12.

BUTLER, JOHN, M.R.C.S. Eng., at 49, Rectory-place, Woolwich, on February 28, aged 65.

CRONYN, GEORGE, M.D. Glasg., at Callan, Co. Kilkenny, on December 27.

DAY, R., M.D., at Wymondham, Norfolk, on February 3, aged 49.

DEWEY, WILLIAM, Surgeon, at Grafton-road, Holloway, N., late of Taunton, on January 5, aged 64.

GRANT, JAMES, M.D. Edin., at the Dundee Royal Infirmary, on February 19, aged 28.

GREEN, JONATHAN, M.D., at Charterhouse, on February 23, aged 76, formerly of Great Marlborough-street.

HIFFERNAN, RICHARD P., L.R.C.S.I., Assistant-Surgeon, R.N., at St. John's Rectory, Newport, Tipperary, on February 25, aged 30.

HIGGINS, CHARLES C., Surgeon, at Abbot's-Bromley, Rugeley, Staffordshire, on February 12, aged 80.

JACOB, JOHN, M.D. Edin., of Maryborough, Queen's Co., at Falmouth, on February 26.

LOMAS, HENRY W. F. M., M.R.C.S. Eng., at New Shildon, Durham, on December 31, aged 34.

MACFARLANE, J., Surgeon, of Arrochar, at Glasgow, on February 16.

MARTIN, CHARLES, W. S., M.R.C.S. Eng., at 10, Dacre-park-terrace, Lee, Kent, on February 15.

MURRAY, PETER, M.D. Edin., at Scarborough, Yorkshire, on February 27, aged 82.

SPENCE, GILBERT W., M.D. Edin., at Whiteness, Shetland, on February 16.

ROYAL COLLEGE OF SURGEONS.—Some years ago the Council of the above institution, being desirous of diminishing the great amount of study required of candidates for the Fellowship of the College, passed the following resolution, much to the annoyance of some gentlemen who, at great expense of time and money, had undergone the full examination for that distinction, viz., "Graduates in Medicine of any University in the United Kingdom are admitted to the Fellowship after having passed the professional examination in Surgery only, provided the educational and other requirements of such graduates by the University in question be deemed by the Council of this College equivalent to those imposed on the candidates for the Fellowship of this College." This regulation is now suddenly rescinded, as will be seen on reference to our advertising columns, and henceforth candidates will have to undergo examinations in anatomy and physiology (with dissections in the case of junior candidates under twelve years' standing), in addition to examinations in Surgery and pathology (with operations on the dead body). The only relief afforded to the graduates in question will be exemption in the Arts' examination. It is stated that all candidates at the ensuing examination in May next will have to comply with the new terms. The above will be an answer to the correspondents who have addressed remonstrances on

the subject to the *Medical Times and Gazette*. From this matter there is no appeal. We are officially told that "all must comply with the regulation."

DEATH OF PROFESSOR CASPER.—Our readers will much regret to learn that Professor Casper, the celebrated Berlin Medical Jurist, died on the 24th February.

ACADEMIE DE MEDECINE.—The election into the Section of Hygiene, which has excited so much interest in the Parisian Medical circles, terminated in favour of M. Delpech. At the first round of the ballot-box, M. Delpech obtained 32 votes, and M. Boudin, 20; the other candidates, 30. At the second round, the numbers were:—Delpech, 47; Boudin, 20; other candidates, 16.

PRESENT TO H.R.H. THE PRINCESS OF WALES.—Amongst the valuable presents offered to Her Royal Highness on St. David's Day was a casket richly wrought in pure silver from Sir John F. Palmer, President of the Legislative Council of Victoria, which was forwarded to the Princess through His Grace the Duke of Newcastle, Secretary of State for the Colonies. Sir John Palmer, who is also a Member of the Royal College of Surgeons, having been admitted so long ago as 1826, is deservedly well known in this country as the editor of Hunter's works.

THE ROYAL LEVEE.—At the levee held by H.R.H. the Prince of Wales on Wednesday, March 2, the general circle was attended by Mr. Lawrence, Serjeant-Surgeon to the Queen. The following presentations to the Prince of Wales, on behalf of the Queen, took place:—Dr. Armstrong, R.N., Deputy-Inspector-General, on his return from foreign service and appointment as Honorary Physician to his Royal Highness the Prince of Wales, by Lieutenant-General Knollys; Alfred Atkins, M.D., Surgeon, London Rifle Brigade, by Lieutenant-Colonel Warde, London Rifle Brigade; Assistant-Surgeon Charles Browne, 1st Surrey Rifle Volunteers, by Lieutenant-General Sir George Pollock, G.C.B.; Dr. J. Balfour Cockburn, Surgeon Royal Engineers, by the Earl of Malmesbury; Assistant-Surgeon R. A. Chapple, R.A., on return from India, by Colonel H. L. Gardiner; Dr. Arthur Farre, on appointment as Physician Accoucheur to her Royal Highness the Princess of Wales, by the Lord Chancellor; John T. Griffith, M.D., Battalion Surgeon 1st Surrey Rifle Volunteers, by Lieutenant-General Sir George Pollock; Dr. George T. Gream, M.D., Physician Accoucheur to her Royal Highness the Princess of Wales, by the Lord Chamberlain; Dr. Linton, C.B., Inspector-General of Hospitals, on return from service in India, by his Royal Highness the Duke of Cambridge; Assistant-Surgeon R. Lewer, Royal Horse Artillery, on appointment, by Colonel H. L. Gardiner; Assistant-Surgeon J. T. M. Symons, M.D., R.A., on return from India, by Colonel H. L. Gardiner; Assistant-Surgeon E. Venning, 1st Life Guards, on appointment, by Lieutenant-Colonel the Hon. D. C. F. de Ros, 1st Life Guards; Mr. Thomas Spencer Wells, on appointment as Surgeon to her Majesty's Household, by the Lord Chamberlain. The following members of the Profession attended the levee:—Doctors: Dickson, Louth Rifles, William Farr, M.D., F.R.S., Sieveking, Dalton, 1st Royal East Middlesex Militia; Messrs. George Pollock, O'Leary, Surgeon-Major Judd, George Nayler, Du Pasquier.

PRESENTATION TO PROVOST ADAMS.—On Wednesday last the highly respected Provost of Lanark, Alexander Maxwell Adams, Esq., M.D., was presented, in the hall of the County Buildings, with a flattering testimonial of the very great esteem in which he is held by his fellow-townsmen and the gentlemen of the neighbourhood, both for his eminent public services, long and faithfully rendered, and the surpassing worth of his character as a private gentleman. There was a large attendance of ladies and gentlemen. The tea service and salver, forming the presentation plate, are very fine specimens of the silversmith's art. Upon the salver is the following inscription:—"Presented, along with a carriage and silver tea service, by a large number of the inhabitants of Lanark and its neighbourhood, to Alexander Maxwell Adams, Esq., M.D., Provost of Lanark, to testify their high appreciation of his public and Professional services, and private worth.—February 25, 1864." Mrs. Adams was presented with a gold brooch, an exceedingly handsome and massive jewel of great value. The carriage, an elegant little one-horse phaeton, from the factory of Mr. Sturdy, Edinburgh, stood at the door while the company were leaving. When the Provost entered it, a few of the younger members of the party unharnessed the horse, and drew Mr. Adams home amidst loud cheering.

DEATHS FROM THE INHALATION OF CARBONIC ACID GAS.—An inquest has lately been held at Bideford on the body of a young man who was found in the morning dead in his bed-room, where a coke fire had been burning all night. The room was entirely unventilated. A similar accident is reported at Gloucester. Two old persons named Gough went to bed in a completely unventilated room, in which was placed a bucketful of glowing cinders just stirred from the grate. The next morning both were found in a state of insensibility, and one died on the same day.

POISONING BY ACCIDENT.—An inquest was held at Kinniside, Ennerdale, Cumberland, on Wednesday, February 24, upon the bodies of Andrew Palmer, aged 16 years, and Anthony Fletcher, 14 years of age, who, on the previous Monday, took some sheep-dipping powder mixed with treacle in mistake for sulphur, and died on the following day. The sheep-dipping powder was found to be composed of sulphur, potash, and arsenic. The jury returned a verdict of "Accidental death."

SCOTTISH REGISTRAR-GENERAL'S REPORT.—The Registrar-General for Scotland reports that births, deaths, and marriages were all above the average in 1863. The births were at the rate of 3.53 per cent. of the estimated population, the deaths 2.30 per cent. A high death-rate is always attended with a high birth-rate, as if an additional number of children were born to compensate for the extra losses by death. In the town districts the death-rate was 2.72 per cent., and the birth-rate 3.83; in the rural districts the death-rate was 1.83 per cent., and the birth-rate 3.18. The weather of the year was remarkable for the little variation of temperature, the night temperature being higher and the day lower than usual, and the summer months less hot, and the winter less cold than usual; a certain amount of variation of temperature is beneficial to the general health. The excess of births over deaths in 1863 was 253,817 in England, and 37,904 in Scotland—an increase of 291,721 in the population of Great Britain; but only about 200,000 would remain after deducting persons of British origin emigrating to foreign countries other than in Europe. Of immigration there are no accounts. The population of England in the middle of the year 1863 is estimated by the Registrar-General at 20,554,000, and that of Scotland at 3,097,000, making together 23,651,000—an increase of more than 500,000 since the census was taken in April, 1861. 1863 is the last year in which we shall have no account of the births and deaths in Ireland.

THE SITE OF ST. THOMAS'S HOSPITAL.—As had been foreseen, the Vice-Chancellor Sir W. P. Wood has sanctioned the choice of the Stangate site. In delivering his judgment, Sir Page Wood said:—"The Legislature, though it gave the governors a wide scope within which to make their choice, restricted that choice by requiring that any site which the governors might select for the erection of a new Hospital should be subject to the approval of the Court of Chancery. But the Court was not thereby vested with an arbitrary power of rejecting any site that the governors might submit for its approval, and taking upon itself to choose a fresh site. Unless it could be shown that the governors were influenced by improper motives in making their selection, the Court ought not to withhold its sanction. No such improper motives had been shown or even suggested, nor could he come to the conclusion that the governors had not carefully, and after much deliberation, decided upon the Stangate site. With the unanimous consent of the Grand Committee and the unanimous consent of their Medical officers, they had come to the conclusion that Stangate would be a proper situation for the new Hospital. It was not, therefore, the function of the Court to interfere with a choice thus deliberately and unanimously made, when no improper motive or influence could be shown to have prevailed. His Honour then proceeded to consider the evidence and the objections raised to Stangate, and came to the conclusion that the objections raised were not sufficient to show that that site ought not to be sanctioned. The Millbank Penitentiary, immediately opposite to the bone nuisance, and on the banks of the Thames, showed by its healthy state the results that might be obtained in such a situation by good management. The death-rate proved that Stangate was rather more healthy than other parts of the metropolis. The situation was very accessible, and would have the large river area in front, which could never be built over. Some disadvantages, no doubt, there must be in any situation in the metropolis itself, but those disadvantages were by no means prominent at Stangate. The objection to the

river situation was also answered by the success of the Hôtel Dieu on the banks of the Seine, one of the largest Hospitals in Europe. It appeared upon the evidence that, although a new model Hospital had been recently established in Paris with a much larger area around it, the Hôtel Dieu had still retained its rank and success. No doubt, as to size, cheapness, proximity to the original Hospital, and more immediate occupation, there was evidence in favour of the Surrey Gardens; but, unless persuaded that the Stangate site was absolutely improper, and that there were overwhelming reasons for preferring the Surrey Gardens, he ought not to disturb the deliberate choice of the governors. He was not so persuaded, and the choice of the Stangate site would therefore be sanctioned by the Court."

POISONING BY ABSORPTION.—On Saturday, Mr. B. L. Gross, Coroner, Suffolk, concluded an inquiry into the death of a child named Boatman, the daughter of a small farmer at Wissett, near Halesworth. The case presenting remarkable features, the Coroner applied to the Home Secretary to enable Professor Taylor to make a more than ordinarily careful and costly analysis. The circumstances are briefly as follow:—The deceased was aged 9 years, and lived with her father and stepmother at a small farm-house in a lonely situation. The child was taken ill, gradually got worse, and died soon after a Medical man was called in. The Surgeon (Mr. Howard), feeling satisfied that the child died from poison, refused to certify the cause of death. An inquest was accordingly held, and when the jury viewed the body, the scalp of the head was found to be in a shocking state from ringworm, and covered with vermin. The stepmother stated that, about ten days before the death of the child, she applied some precipitate powder, and a little poison in the shape of an ointment, to the head, to kill the vermin. The Coroner ordered a post-mortem examination, and the appearance of the intestines and stomach pointing to arsenical poison in some form or other, it was felt important to ascertain whether the child died from arsenical poison, and, if so, how it was administered. The viscera were accordingly sent to Professor Taylor at Guy's Hospital, and that gentleman stated at the inquest, on Saturday, that the child died from arsenic, applied externally, and absorbed into the system. The condition of the viscera, in their appearances, in the nature of their contents, and in the minute, imponderable quantity of arsenic present in them, was not consistent with the supposition that arsenic had been given in a solid form or in a liquid form by the mouth; but it was quite consistent with the absorption of the poison through the skin of the scalp, and its subsequent diffusion by the blood. The scalp of the deceased was found to contain a large quantity of arsenic associated with a quantity of mercury (white precipitate), which had been applied, as above stated, in the form of an ointment. The jury returned a verdict to the effect that the deceased died from the results of an ointment containing arsenic applied to her head by Mrs. Boatman, she being ignorant of the consequences, and intending merely to heal disease of the scalp.

ETHNOLOGICAL SOCIETY, 4, ST. MARTIN'S-PLACE, FEBRUARY 23.—J. Lubbock, Esq., F.R.S., President, in the Chair.—A paper was read by the Rev. Frederick Farrars, M.A., "On Traditions, Real and Fictitious." The object of the paper was to prove that a most exaggerated importance had been attached to the supposed evidence of traditions in favour of the universality of the deluge, and the unity of the human race. The traditions chiefly examined were those which refer to great deluges, and it was proved that, so far from being universal, they existed only in countries which were liable to great aqueous catastrophes, and were not found at all in continents like Africa and Australia, which are wholly exempt from such contingencies. Hence it was agreed that many of these supposed echoes of the Mosaic narrative must be nothing more than the legend originated by great local disturbances, and some authorities were quoted to show that this was the view often taken by the original reporter of the tradition. It was shown that if closely examined a great number of traditions which had been prominently adduced as distorted fragments of semitic belief naturally fall into five classes, viz.: 1. Independent beliefs arising spontaneously from the observations of fact; 2. Similar allegoric representations of common catastrophes; 3. Vague legends presenting but few points of similarity with the Jewish traditions, and forced into unreal resemblance with them; 4. Mere plagiarisms from the biblical narrative; and 5. Absolute fictions and invectives. Under the first head fall the widely-spread notions respecting the

rainbow, the dove, the serpent, the origin of woman, etc. Under the second it appeared that many of the most remarkable traditions of a flood were confessedly traditions of partial calaclysms, and could not have any connection with the Noachian deluge. Under the third head various legends were quoted, and it became evident how few the points of osculation really were, and how easily they were to be accounted for. Under the fourth head the gneosis of several famous traditions was traced from a general and obscure beginning, until in the hands of later writers they had been ornamentally expanded into full-blown plagiarisms of the Mosaic narrative. Under the last head instances were adduced of admitted forgeries, and the probable and facile origin of such purely fictitious legends described. The conclusion drawn was that no tradition can be received as evidence until its antiquity, originality, and genuineness had been thoroughly proved, which was seldom the case, and that at present the supposed universal singularity of traditions could not be maintained as a fact—not in any way regarded as an adequate argument in support of the conclusion made to rest upon it.—Muti Coomara Swamy read another paper on "The Ethnology of the Island of Ceylon." He classed the different races inhabiting it into—1. The Veddahs are supposed to be the aborigines of Ceylon. They are fast dying out, and but a few remnants of them are now left in the south-west of the island. 2. The Singhalese are the inhabitants proper of the island. They are divided into the hill-country Singhalese and the low-country Singhalese. 3. The Tamils are allied to those races which inhabit the best part of southern India. Originally they came as invaders of the island from the continent, and subsequently became settlers in the northern and eastern parts of the island. 4. The Moors, as their name indicates, are the remnants of the Arab adventurers of olden days. By intermixture with the native races, they have more or less lost the distinguishing traits of their forefathers. 5. The Eurasians form now an important return of the Ceylon community, though their numbers are yet small. They are remnants of the old Portuguese and Dutch settlers, as also the children of English fathers by Asiatic mothers. 6. The European settlers of Ceylon are chiefly English, notwithstanding the trade of the island being open to all the nations of the world. The whole population of Ceylon does not, however, much exceed two millions.

A NEW THEORY OF MUSCULAR ACTION.—This is the title of a very able and ingenious thesis, read before the University of Dublin by the Rev. Dr. Haughton, of Trinity College. Dr. Wollaston, in 1809, drew attention to the "susurrus" of muscle in active contraction, and compared it to carriages at a distance passing rapidly over a pavement. He approximately estimated the frequency of the vibrations at about thirty-five or thirty-six in a second. Dr. Haughton confirms the observation by novel and more accurate experiments. These originated accidentally in an access of severe tinnitus aurium following fever, which prevented him from sleeping at night. During restlessness from this cause, he amused himself by producing the susurrus in the masseter muscles, and observed that the tinnitus was in unison with the susurrus, but separated by several octaves. Ultimately, the musical note of the susurrus was fixed at what organ builders term C.C.C. in some persons, and D.D.D. in others, notes lying two octaves below bass C. and D. respectively, and to be found on pianos of recent construction only. The sound C. represented thirty-two and D. thirty-six vibrations in the second, while the tinnitus stood on high C., five octaves above. Dr. Haughton, struck, like Dr. Wollaston, with the resemblance of the sound to distant cabs, measured the intervals of the Guernsey granite pavement, and found them about four inches apart, thus giving three impulses in the foot. Supposing the cabs to drive at eight miles an hour, we have 35.2 impulses per second, coming marvellously near the original estimate of Dr. Wollaston. An organ-pipe with a movable piston was then made, enabling it to be tuned up and down in the neighbourhood of C.C.C. Dr. Stokes, who assisted in the experiments, tuned this to the susurrus as heard in the muscles of his own fore-arm, and found, by the method of "beats," that the vibrations were 35½ per second, corresponding to a note rather flatter than D.D.D. natural. The author then proceeds to deduce from the rate of muscular contraction the "amount of work stored up in human muscles" by extending the arms horizontally, so that they are sustained entirely by the supra-spinatus and central portion of the deltoid. His own arms became tired in 7 minutes, and those of other persons in periods varying from 6.5 to 10 minutes in males,

from 10 to 15 minutes in adolescents, and from 7.5 to 12 minutes in females. From calculations based on the weight and leverage of the arm as a falling body, it is calculated that these muscles are capable of giving out work equal to raising 1083 lbs. through a foot, before they are exhausted. The muscles of the shoulder in a well-developed male subject were dissected, and the supra spinatus, as well as the central portion of the deltoid, which was easily divisible into three obvious fasciculi, were weighed, amounting to 10¼ oz. Hence it follows that 1 lb. of such muscle is capable of lifting 1.56 ton through one foot. In the third part similar modes of investigation are applied to the heart, the daily work of which is shown to be 124.6 ft. tons; more than one-third of the daily labouring force of the whole body. Lastly, this calculation is very ingeniously confirmed by a separate hydraulic process—namely, the distance to which jets of arterial blood were thrown on the floor of the operating theatre from an enlarged external epigastric artery, during the removal of a large fibro-cellular tumour by Mr. Colles, at the Meath Hospital. From this source is derived an estimate of 121.82 ft. tons, for the hydraulic work of the heart, which agrees very well with the muscular work as already given, slightly in excess of this figure. We have been much struck by this short memoir. It is an admirable specimen of the application of physical and mathematical analysis to vital forces, which is one of the most promising departments of modern physiology.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

The present arrangements of the *Medical Times and Gazette* do not permit the publication of Births and Marriages.

Many interesting communications on Hospital Mortality, etc., etc., are unavoidably postponed.

Mr. Gordon Jackson.—A Medical Practitioner is not legally bound to attend any person applying for his advice.

An Old Advocate of Beards.—The paper was published in the *Dublin Medical Press*.

Q., Blackheath, asks, with respect to a late *Court-Medical*, "by whom was the meeting summoned? was the object stated in the summons? was the defendant informed of the proceedings? had he the opportunity, if desirable, of challenging either of his judges? was a fair use made, and a fair report circulated of their proceedings? ought any report to have been made at all? will another *Court-Medical* be held on Dr. Purvis?" Such squabbles should be quietly hushed up. The publicity given them, and the contempt to which they are held up by the *South London Journal*, only damage the whole Profession. It were far better for any one of us to put up with a wrong than to let mud be cast on the whole Profession in order to resent it.

The Physique of the Danes.—The powers of endurance of this stout Northern race surpass all belief. They are out in all weather, as thoroughly at home in snow and ice as in rain and mud. They are no unworthy descendants of those Cimbrians who astonished the Romans of Marius so many centuries since by sporting half naked in the snow, and making sledges of their shields to slide down the icy slopes of the Alps,—a rehearsal of the frolics they were wont to indulge in at their Northern home. Those whom the clouds have drenched in the night, the wind, please God, will dry by day. I have often praised the length and width, the thorough fitness and comfort, of their great overcoats. They are made of coarse, spongy cloth, however; they must drink in the moisture greedily, and only let it off leisurely. I have no great faith in their thick Wellington boots either, and I would rather see foot soldiers supplied with the good light shoes and tight gaiters of the Zouave. No mere shoe leather can be proof against many hours' trudging in deep snow; and the boot, which is at all times too hot and hard for pedestrian exercise, is, besides, apt to become a reservoir in very heavy wet. Soaked or nipped, or numbed as they may be, however, these Danes always evince the same degree of manly impassibility. They stand, they lie, they march as they are bidden, never, apparently, heeding any of the scourges with which Heaven may please to visit them. Their mutual good nature, their deference to their officers, their goodwill and courtesy to all men, never belie themselves on the road or in barracks, under canvass or in citizen quarters. There is no instance, I believe, of a complaint against any of them. The fact is, they are all educated, highly-civilised men. They have a self-respect and dignity which stand them in stead of the most efficient discipline; and they are treated by their superiors with a familiar friendliness which could only be safely shown to men who know their places. Their usual demeanour is not gay—not boisterously gay, I should say. Their march is steady and silent, always in compact masses; I hardly saw any voluntary stragglers or laggards even in the disastrous retreat from the Dannewerk. They seem to have a natural instinct for order; they fall into their ranks, as it were, by mere force of gravity. They may be relied upon for stone-wall firmness, I believe—for unshaken fortitude, under the direst trials. Anything

like dash and *impetus*—what the French call *élan*—is not, I should think, to be expected of them. There is, let me be understood, nothing like gloom or sullenness—nothing of the hang-dog look about them. They indulge in a song at times, crack their joke, and have their subdued talk to while away the weariness of their long Danish miles; but, on the whole, they are a quiet, earnest, imperturbable set. To see one of their squadrons of dragoons walking their horses at a sober pace, sitting on their saddles bolt upright, demure, mute, each with a china pipe hanging from his mouth, the pipes as like each other as if they were part and parcel of their uniforms, is a remarkable sight—refreshing, edifying.—*Times' Correspondent*, February 22.

THE ASSISTANT LIBRARIAN OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I should esteem it a favour if you would give me the opportunity of rectifying an omission in the brief remarks with which I acknowledged the vote of thanks accorded to me by the Royal Medical and Chirurgical Society, in common with the other retiring officers, at the annual general meeting.

No one has such opportunities as the Secretaries possess of forming an estimate of the labour undergone by the Assistant-Librarian, Mr. Wheatley, a comparatively small portion of which only is represented by the hours during which he is seen in the library. For assiduity, intelligence, courtesy, and love of his work, he cannot be surpassed. The Secretaries have some work and some responsibility, but the assistance rendered them by Mr. Wheatley reduces their work to a minimum.

I am only doing justice to my own feelings in asking you to receive this expression as a supplement to the remarks I made yesterday. I should not have been guilty of the omission, but that I had not for a moment considered the contingency of having to return thanks, and that I had not, therefore, in any way arranged my thoughts for the emergency.

It is the thoroughness and the spirit with and in which Mr. Wheatley serves our Society which seem to me to give him a claim to a public acknowledgment at our anniversary meetings, at least, on the part of those who have the best opportunities of judging of his qualities, and who profit by them most largely.

I am, &c.

EDWARD H. SIEVEKING, M.D., late Honorary Secretary, Royal Medical and Chirurgical Society.

17, Manchester-square, W., March 2.

THE FORAGE WARRANT FOR ARMY MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Journal of the 20th ult. it is stated that by a recent warrant "all Medical officers above the rank of Assistant-Surgeon will henceforth be entitled to horse forage, or an equivalent allowance, etc.; and that an Assistant-Surgeon will be allowed forage for a horse if his duty oblige him to keep one."

Fearing this may mislead, I beg to transcribe a paragraph from page 8 of the same Warrant:—

"Each officer of the Horse Brigade of Royal Artillery shall be subject to a stoppage of 6d. a day, and each officer of Cavalry to a stoppage of 8½d. a day, out of his daily pay, for every ration of hay, straw, and oats drawn by him."

Thus, Surgeons of H.M. Artillery and Cavalry are not granted forage allowance, but in common with the Assistant-Surgeons of those corps (who of course are the only officers of the lower grade whose duty obliges them to keep horses) are mulcted in the respective sums of 6d. and 8½d. a day per horse.

I am, &c.

A MEDICAL OFFICER.

HOSPITAL MORTALITY AND HOSPITAL STAFFS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The striking differences in the rate of mortality in Metropolitan and Provincial Hospitals, and also in large and small Hospitals, as stated by Dr. W. Farr, arises, to my mind, more from the insufficiency (numerical) of the executive of large Hospitals, than from atmospheric or constitutional differences.

Could the relative severity of cases in metropolitan and provincial Hospitals be satisfactorily substantiated, the result, I believe, would be much less favourable to the former than is generally credited. It has long since appeared to me that the administration of our Medical charities is, for the most part, faulty in the extreme; that each year adds to its defects; that it heaps untold misery on the suffering poor, debars their officers from self-improvement, and deprives Medical students of that teaching which they have an indisputable claim to, and failing which, their after career must be sadly marred, and their utility to the State greatly curtailed. The fault of this state of things rests alone with that section of our Profession whose good fortune has given them official connexion with our Hospitals; for is it not notorious that whenever the governors of Hospitals have attempted to make better provision for the suffering poor, the executive have at once placed themselves in battle array, and have successfully resisted every attempt to encroach on their monopoly?

I am, &c.

Clifton, March 1.

CHARLES GREIG.

ADVERTISING DOCTORS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following advertisement appears daily in the *British Press* and *Jersey Times*, the principal paper published in St. Helier's. It generally follows a somewhat similar production from the pen of the notorious Dr. La Mert, who is at present honouring Jersey with his presence, and has more than once been preceded by an advertisement eulogising the merits of "real Dantzic spruce" in the following terms:—

"Real Dantzic spruce, real Dantzic spruce,

Deny the truth who can,

It's good for me, it's good for you,

Or—any other man."

Dr. Small is not doing himself or the Royal College of Physicians of Edinburgh any credit by the company in which he advertises, nor is it usual in the Channel Islands to tout for patients in the public prints.

I am, &c.

M.R.C.S. Eng.

"Dr. Small, L.R.C.P. Edin., M.R.C.S. Eng., L.A.C., begs to announce

that, after many years' experience in England, he has now commenced the practice of his profession in St. Helier's, both as a Physician and Surgeon. He may also be consulted respecting mental disorders, the neglect of which frequently ends in insanity. Poor people may have advice given to them, or have their children vaccinated, without charge, any Wednesday or Saturday before 11 o'clock in the morning.

"13, The Terrace."

WAS MAN MADE OUT OF THE DUST OF THE EARTH?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having been recently favoured with a copy of Dr. Herapath's able address on "Chemistry in its Relation to Medicine and its Collateral Sciences," read before the British Medical Association, August, 1863, I may, perhaps, be permitted, through the medium of your valuable journal, to express my regret that a science so noble and truthful as that of chemistry should be used to invalidate the truth of the Mosaic record. I allude to the following paragraph, page 7, in the published address which has gone forth to the world:—

"From our days of boyhood it has been most assiduously taught us that 'man was made out of the dust of the earth,' and 'as dust thou art so to dust thou shalt return.' Now, this opinion, if literally true, would necessitate the existence of alumina as one of the elements of organised structure, for no soil or earthy material capable of being employed by agriculturists can be formed without alumina existing largely in its constitution, and clay cannot be found without it; therefore chemistry loudly protests against accepting the Mosaic record, in a strictly literal sense, as geology, geography, astronomy, or any other of the physical sciences so absurdly dogmatized upon weekly from the pulpits, by those who have neglected the study of true science, but still profess to teach us that which is beyond all knowledge."

It is evident from the component parts of the human body known by analysis, that the earth supplies all the materials necessary for the formation of man. The fact of alumina or clay entering so largely into the composition of the soil, and not existing as a constituent of the animal body or man, is no proof that man was not made out of the dust of the earth. We must all acknowledge that the creation of man was, medically speaking, a physiological miracle; but chemistry proves, beyond all doubt, that man could have been made out of the "dust of the earth;" and there is no more difficulty in comprehending its literal meaning than there is in the fact of a grain of wheat (which contains no alumina) reproducing itself out of the earth, and becoming the "staff of life"—bread—which contains all the constituents of the human body.

I am, &c.

HENRY OSBORN, M.R.C.P. Lond.

Southampton, February 26.

THE PROPOSED REMOVAL OF THE MEDICAL SOCIETY OF LONDON.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—There is a good reason for believing that a proposal will shortly be made for the removal of the offices of the Medical Society of London from the present convenient *habitat* in George-street to an obscure square near Gray's-inn-lane, and that, to insure this object, a systematic plan is being pursued of placing in office men, who, from the position of their residences, are favourable to the proposed removal, or who are known to be indifferent about the matter, and ready to vote with a majority.

I would ask the fellows of the Society seriously to reflect on the consequences of such a change before the time arrives for recording their votes. When the meetings were held in Bolt-court, the Society languished, so that, in order to prolong its existence, it became necessary to amalgamate it with a thriving young Society—the Westminster. This, by entailing its removal to a more favourable locality, soon restored it to vigour, and, in spite of quarrels and consequent withdrawals, it is even now in a not unsatisfactory condition. I would ask the fellows to inquire into the cause which operated so injuriously on the Bolt-court sessions. Was it not that the locality was unfavourable? and if so, was it more unfavourable than that which is now about to be proposed? If, then, a position less central to the rapidly growing West-end than that which the Society now holds was sufficient to bring it to so low an ebb as it reached at the time of its amalgamation with the Westminster, how much more so now? Would Queen-square, Gray's-inn-lane, be likely to prove a more attractive locality than Bolt-court? Is it more easy of access? Is it more central?

One of the arguments used in advocating the removal is, that larger rooms than those now occupied could be had at less rent! On this ground a still cheaper locality would have a still stronger claim. Why not, then, select Whitechapel, or some large and cheap house in the trans-pontine regions? But, even then, it would not be cheaper than the Society's house in Bolt-court, which, if I am correctly informed, was held rent free.

I would now urge the fellows to give their serious consideration to the act which they may be called on to sanction. It seems to me to be most suicidal, for it must be evident that a society which could not continue to exist in Bolt-court is not likely to flourish in Queen-square, Gray's-inn-lane.

I am, &c.

A FELLOW.

NIGHT AIR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow a non-professional, occasional reader of your Journal to put a question in your columns regarding the ventilation of sleeping-rooms at night? I wish, if possible, to get at the cream of Medical science as to the old-fashioned bugbear, "night air."

Reduced to its simplest form, my question is as follows:—Is it an established fact that, speaking generally, and without regard to particular localities, there is something decidedly injurious (on an average) to health in "night air," irrespective of any bad effect from diminished temperature or superabundance of moisture? I speak in regard to our own climate—that of the British Isles generally.

I have lately adopted a very simple method of obtaining a constant supply of fresh external air in my sleeping-room at night without any perceptible draught. The effect is most luxurious; and I would risk the statement, although not a Medical man, that such a change of air, whether night air or not, must be vastly better, on an average, than the foul air to be met with in the hovels of the poor in our cities. But that is not my question. Almost anything would be better than the usual condition of such places. My question refers to the rooms, say, of the middle and upper classes, where ventilation is supposed to be moderately well looked after, and yet where the air of bedrooms during the night usually becomes very indifferent.

I am a victim of phthisis, and therefore, of course, interested in the subject, being desirous of making the most of what little lung power yet

remains. I need not say that I can readily detect the smallest improvement in the air I breathe as to its more important life-supporting power. But there may be invisible enemies which I unwittingly allow to enter by the same door as that which admits a welcome friend; and I have even fancied once or twice that I could almost prove that some influence of an injurious kind had been communicated by the rearing of this "gourd," which seems to promise so much satisfaction.

Your readers will perceive that I do not bring myself forward in this instance as a Howard. Nor do I wish to save a Professional fee, as I am surrounded by everything that I could desire in this respect; but I wish to ascertain the average opinion, if possible, on a question which, though suggested, in the first instance, by personal considerations, is, I need not say, of vast importance to the public generally. I will only add, that I do not wish to gain one farthing by my contrivance, the description of which would occupy very little space, and which I shall be most happy to send to you. My only reason for delaying it is the idea that I may, by writing this letter, obtain information which would be, *a priori*, so decidedly unfavourable to my method, as to make it, possibly, even worse than useless to publish it. I am, &c.

Clifton, Bristol, February 15.

WILLIAM C. BURDER, F.R.A.S.

COMMUNICATIONS have been received from—

HUNT; MR. F. BRADLEY; APOTHECARIES' HALL; AN OLD ADVOCATE OF BEARDS; A SUBSCRIBER; MR. CHARLES HUNTER; DR. EDWARD H. SIEVEKING; ROYAL MEDICAL AND CHIRURGICAL SOCIETY; MEDICAL SOCIETY OF LONDON; T. T.; M.R.C.S. ENG.; MR. F. A. BULLEY; MR. FREEMAN; EPIDEMIOLOGICAL SOCIETY; A MEDICAL OFFICER; ETHNOLOGICAL SOCIETY OF LONDON; MR. CHARLES GREIG; DR. W. FAIRLIE CLARKE; MR. JAMES TURLE; DR. HUMPHRY; MR. G. JACKSON; M.D.; ROYAL INSTITUTION; DR. CHARLES DRYSDALE.

BOOKS RECEIVED.

1. A Few Speculative and Practical Observations upon Electricity.
2. The True Way to Italian Consolidation, Prosperity, and Peace.
3. A Father's Instructions for the Education of his Daughter. All by James Billet, of Taunton.

* * * We have to thank the author of these three pamphlets for information on subjects so diverse. On electricity, though expressly stating that he is "no electrician," he tells us "there must be a vast and inexhaustible storehouse of electricity somewhere." Italy is recommended to cast off the Pope, and reform herself, morally and politically, on the model of England. His daughter is to be educated after twenty-five aphorisms; among other things, to respect old England and the English language, with help of the Eton grammar. She is to walk well, but not to dance. "Furthermore, never let her ride on horseback, because it is unsafe, if not unseemly." She is to read no novels or plays, and "to profit by Christian oratory." She is to be dissuaded from visiting foreign countries, "because so few return the better for it, and so many the worse; moreover, disappointment is the common result, as there are few sights so well worth seeing as those of Great Britain, and no history, habits, or principles so well worth studying." The strict observance of the sabbath is to be enforced. She is to "fail not to shun and faithfully avuntany Tractarian works," but to cling to the Thirty-nine Articles, as "it is apparent that a popish exerescence, contrariant to the Articles, still clings to our offices, ordinations, catechism, and canons, which cannot be otherwise than offensive to the Most High."

The Westminster Review, New Series, No. XLIX. January, 1864. London: Trübner and Co.

* * * This number is more than usually interesting to Medical and scientific readers. An excellent article on Roger Bacon, an Account of the Tunnel under Mount Cenis, an Essay on Astrology and Magic, and another on the Physiology of Sleep, all appeal to our professional sympathies. The *resumé* of contemporary literature is well compiled, and under the head of Science gives full details as to Dr. Chapman's applications of cold to medicine. Whatever may be thought of the views herein advocated, there can be no doubt of the ability by which this periodical is characterised.

Revista de Sanidad Militar Española y. Extranjera, No. 2. Madrid. 1864.

* * * This journal of military hygiene appears fortnightly under the management of a director, D. José María Santucho, five "redactores," and a secretary. The present number contains accounts of sanitary service in the Philippines, in the United States, and elsewhere, with a review of Dr. Lorado's studies in military Surgery in the Italian Hospitals in 1859, and general news. Its circulation is provided for at a moderate cost in the Peninsula, Balearic Isles, and Canaries. The price is materially advanced for obvious reasons in Cuba, Puerto Rico, St. Domingo, the Philippines, and Fernando Po. It can be obtained in Paris, London, Brussels, New York, and elsewhere.

The Sugar Question as it Affects the Consumer. By M. B. Dureau. London: Longman and Co. 1864.

* * * This translation of a French pamphlet is published by Messrs. Travers and Sons, of St. Swithin's-lane, to whose views we have before called attention. They state that the French beet-root sugar maker is represented on our side by the foreign planter, and that the interests of this class, as well as those of the sugar consumer, are antagonistic to our English refiners. The writer requests of the Emperor an extensive reform of the sugar interest.

Bulletin de l'Académie Royale de Médecine de Belgique. 1863. Bruxelles: De Mortier Fils. Nos. 6 and 7.

* * * These numbers sustain the high character of the institution from which they originate. A notice of new Surgical instruments from Dr. Soupard, and a report of the commission charged to examine the operation of Dr. Cousot for the cure of vesico-vaginal fistula, deserve notice.

Memoire sur la Périméo-plastic. Par le Dr. Verhaeghe. Bruxelles: De Mortier Fils. 1863.

* * * A reprint from the fifth number of the above Transactions. It suggests some operative improvements, and is illustrated by good lithographs, which are also inserted in that periodical.

Inaugural Address of the Manchester Statistical Society. Session 1863-4.

CHLORODYNE CHANCERY SUIT,

JANUARY 11th, 1864.

BROWNE AND DAVENPORT *versus* FREEMAN.

NOTICE.

Advertisements have appeared in the "Lancet," "Medical Times," and "Chemist and Druggist," apparently inserted by the Plaintiffs in this Suit, containing unfounded and perverted statements of the effects of the Affidavits made by various persons on their behalf, which might tend to mislead the public, were they permitted to remain unanswered.

Mr. FREEMAN deprecates most strongly any notice being taken of a Suit until its termination, but he is driven by the unfair acts of the Plaintiffs to set himself right.

It is not true that it was in any way proved that Dr. John Collis Browne was the inventor of Chlorodyne; it is still in issue; and the effects of the Affidavits filed on behalf of Plaintiffs tend to show that Freeman's Chlorodyne is becoming the preferred Medicine.

Affidavits from eminent Physicians and Surgeons, on Mr. Freeman's part, proved clearly that the Plaintiffs had no case, and so the Vice-Chancellor considered, or he would have granted the injunction.

As Mr. FREEMAN is most anxious that the world should know his Chlorodyne, and not be deceived by any other, he intends to make his Bottles, Labels, and Wrappers still more unlike any other makers as he possibly can. He also intends to continue to publish to the world the fact, that he is the Inventor of this valuable Medicine.

In Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d.

Manufactured by the Inventor, **RICHARD FREEMAN**, Pharmaceutist, Kennington-road, London, S.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT *versus* FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warrington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians: Physician to King's College Hospital.

LECTURE IV., FEBRUARY 5.

(Continued from page 249.)

The British Pharmacopœia will be found rich in Anthelmintics; and four new drugs possessing the characters of this class have been added to the Materia Medica list. These are the Male Fern, Kamela, Kouso, and Santonica.

Filix, or Fern Root, the dried Rhizome of *Aspidium Filix mas*, has been occasionally used in the form of powder, but at the present time the preparation introduced into the Pharmacopœia is almost universally substituted in its place; this is called a liquid extract, *Extractum Filicis liquidum*, and is, in fact, the oily substance of the rhizome, extracted by means of ether.

The value of this drug as a therapeutic agent is so well known that I need scarcely occupy your time in speaking of its action. As a remedy in tapeworm, it appears to cause, in successful cases, the death of the entozoon, and by itself, or by a purgative subsequently administered, effects its expulsion from the bowels. The dose of the so-called liquid or oily extract is from one fluid drachm upwards.

Kamela is much less known than Fern, and demands a few observations upon its nature and action. You will observe that it is a coarse orange-red powder, consisting of minute granules. It is the powder which adheres to the capsules of the Euphorbeaceous tree, named *Rottlera Tinctoria*, growing in India, and the substance known in that country by the name of Wurrus, and used as a dye.

Kamela, as imported, is for the most part soluble in rectified spirit, the residue consisting in a great measure of tufted hairs; the soluble portion is of a resinous character, insoluble in water, but dissolved by alkalis, from which it is precipitated by the addition of acids. Its further composition is unknown. *Kamela* has been largely employed in India in the treatment of tape-worm; and an account of the cases in which it has been administered by Dr. Gordon is to be found in the *Indian Journal of Medical Science* for 1858. It has also been used to some extent in this country, and reports of cases treated here are scattered in the journals. I have employed it in a few instances. My first trial was one of tape-worm, occurring in a gentleman, who had evidently suffered for several years, but in whom the symptoms were masked, two drachms were administered; the proper precautions of fasting for some hours, and the previous use of a purgative, having been taken: a great number of evacuations were produced; sixteen feet of the worm came away; but the head could not be discovered, although portions very close to it were observed. No symptoms of its presence have since been manifested, although two years and a-half have elapsed. In every instance in which I have ordered *Kamela* a large amount of worm has been expelled, but in some of the patients there has been a return of the affection.

I should consider *Kamela* a very valuable anthelmintic, and worthy of trial when other remedies have failed. It usually acts as a powerful purgative, and seldom requires the subsequent administration of castor-oil or any other cathartic.

It can be given in doses of one, two, or even three drachms, suspended in gruel, mucilage, or syrup.

Cusso, or Kouso, having now been long employed in this country as a remedy, needs but few words from me. It consists of the flowery tops of a rosaceous tree growing in Abyssinia, and known by the name of *Brayera Anthelmintica*, and in the specimen you will observe the pink coloured petals, as well as the calyx and stalks; you will likewise notice the

peculiar blended odour of tea and hay. One preparation only, *Infusum Cusso*, is made officinal, in which four fluid ounces contain a quarter of an ounce of the drug, and the preparation is to be administered without previous straining, so that the infused powder is exhibited as well as the fluid portion. That Kouso is a powerful remedy in cases of tapeworm there can be little doubt; but it requires numerous comparative trials with other drugs of the same class, before an opinion can be advanced as to its possessing properties superior to Male Fern, Kamela, and many others. For an adult the dose is from a quarter to half an ounce, in the form of the before-mentioned infusion. The necessity of administering the residual substance, as well as the infusion, would imply that water is unable to abstract the whole of its active principle, the composition of which, as I should have mentioned, is entirely unknown. The great bulk of the dose, due to the swelling up of the drug in making the infusion, renders Kouso a remedy somewhat difficult to be swallowed by the majority of patients.

The last anthelmintic to which I shall call your attention is *Santonica*, or, more especially, *Santonin*, its active principle. *Santonica* consists of the unexpanded flower-heads of some undetermined species of *Artemisia*, and from its resemblance to seeds the drug is commonly known by the name of *Worm Seed*. On carefully examining the specimen, the seeds will be found to consist of imbricated, involucreal scales, enclosing the tubular flowers. From this drug a crystallised body termed *Santonin* has been obtained, and you will observe that it is in white rhombic prisms, having the property of becoming yellow by exposure to light. Its composition is represented by the formula $C_{20}H_{18}O_6$, and it possesses the properties of a crystallised, resinous acid, almost insoluble in water, but dissolved by alkaline solutions. *Santonica*, or the worm seed itself, has been occasionally employed as an anthelmintic, in doses of from one to two drachms; but the objections to the use of Kouso, as far as its bulk is concerned, apply equally to *Santonica*. It is different, however, with regard to *Santonin*, as the dose would be only from two to six grains, and, beside this, it is inodorous and tasteless, and therefore peculiarly adapted for administration to children. There appears to be good clinical evidence of its value as an anthelmintic, and it has proved very successful in cases where the lumbricus or round worm is present. It has likewise been of service in cases of tape and threadworm. In addition to its worm-destroying property, *Santonica* has been stated to possess anti-periodic powers, and I should not omit to mention that in children a large dose has been followed by purging, vomiting, and symptoms of great prostration.

There is one introduction into the British Pharmacopœia which I fear will not be looked upon with any great favour in England. I allude to the *Laurocerasus*, or the Cherry-Laurel Leaves, and the preparation called *Aqua Laurocerasi*, or *Cherry-Laurel Water*. I may state that this drug would not now have been made officinal had it not been already a favourite remedy in Scotland and Ireland, and in the Pharmacopœias of both these countries.

The cherry-laurel leaf contains a principle identical with that of the bitter almond, and of many other plants of the same natural order, and termed *Amygdaline* ($C_{40}H_{27}NO_{22}$). This substance, itself not poisonous, readily breaks up under the influence of albuminous ferments, such as occur in the same plants, into *Volatile Oil of Bitter Almond* or *Hyduret of Benzole* and *Hydrocyanic Acid*. Hence, when the fresh leaves are chopped and crushed in a mortar, macerated for some hours in water, and then distilled, the distillate contains both the volatile oil and hydrocyanic acid, and forms the *Aqua Laurocerasi* of the Pharmacopœia, which possesses a fragrant odour and bitter taste, derived from these two ingredients. Probably there is also some other volatile matter present which exists naturally in the plant. *Cherry-Laurel Water* is an elegant mode of giving *Hydrocyanic Acid*, but there are, in my opinion, grave objections to its use. In the first place, it is a preparation very liable to vary in composition, from the time of year the plant is gathered, the differences of seasons, and other causes. Secondly, it is not wanted, as we have another form for prescribing *Hydrocyanic Acid*, and we have no evidence showing the superiority of this water over the dilute acid; and in the case of such powerful remedies as *Prussic Acid*, it is most desirable to keep the preparations as simple and few as possible.

For an adult the dose is from half a fluid drachm to one drachm. I may, perhaps, mention here that the *British Pharmacopœia Dilute Hydrocyanic Acid* remains of the same

strength as the London, containing 2 per cent. of real acid; but it differs considerably from the Edinburgh preparation.

Before leaving the consideration of this acid, I wish to make one remark on the desirability of Medical Practitioners *not* prescribing an acid termed *Scheele's Acid*, and which contains 4 per cent. of real hydrocyanic acid in lieu of 2. I have been told by at least one Medical man that the effects of Scheele's acid are much superior to those of the London College; but those who imagine such to be the case should be informed that the chemist first makes a strong acid, then dilutes it, so that it contains 4 per cent., and labels it "Scheele's;" dilutes it still further to 2 per cent., and calls it "Pharmacopœia Acid." I will leave it to those who make the assertion to explain the possible difference in the therapeutic action of the two preparations.

In the Pharmacopœia of this College of 1835, Bromide of Potassium was introduced, chiefly, I believe, from the statement of Dr. Robert Williams, who considered that it was a valuable remedy in the treatment of chronic enlargements of the liver and spleen; it was afterwards removed from this work in 1851, no clinical evidence having been afforded in the interim of its possessing any powers which entitled it to be placed in the *Materia Medica* as an officinal medicine. It has, however, now found admission into the British Pharmacopœia under the head of *Potassii Bromidum*, and I shall, therefore, endeavour to show you the claims upon which its title is founded. In its composition, Bromide of Potassium is analogous to chloride and iodide of the same metal, and in its physical characters it is also closely allied; if pure, it gives no blue colour when treated with starch and chlorine, but an orange precipitate is then produced. Its formula is represented by the symbol *K.Br.*, and the percentage of bromine in the salt is rather more than 67. No officinal preparations are contained in the work, but as the salt is very soluble in water, it can readily be given in a liquid form.

On the first introduction of Bromide of Potassium, it was thought to be very analogous in its action to the Iodide, although somewhat less powerful; but little, in fact, was known about its powers. About nine years since I made some extensive trials of this medicine, chiefly in Hospital practice, and found that, in certain cases of eruptions of the skin, as in syphilitic psoriasis, it acted as a curative agent, or, at least, patients when under its influence lost the affections under which they had been suffering. I was induced to give the bromide in these cases as the patients were intolerant of the action of the iodide. I discovered, likewise, that Bromide of Potassium, when pure, did not give rise to any of the symptoms to which the name of Iodism has been applied. I did, indeed, occasionally notice these symptoms, but this led me more carefully to examine the salts which had been dispensed; and it was ascertained that, with one or two exceptions, the Bromide, as sold in London, contained notable quantities of the Iodide of Potassium. After this, I took precautions to have the Bromide pure in all my observations upon its action, and the results I arrived at may be thus summed up:—

1. It produces none of the irritation of the mucous membranes of the nose and fauces—no coryza.
2. Some patients experience a peculiar sensation of dryness of the throat and neighbouring parts.
3. When given in large medicinal doses, sleepiness or drowsiness, and dull headache were occasionally noticed.
4. When administered in very large amounts, some loss of power was noticed in the lower extremities, which passed off when the medicine was discontinued.
5. The therapeutic action was decidedly what may be termed alterative—that is, it relieved certain forms of chronic disease, as syphilitic skin affections.
6. No marked action was observed upon the skin or kidneys. Soon after these observations had been made, Sir Charles Locock stated that he had found Bromide of Potassium useful in hysterical epilepsy, and in other nervous affections connected with uterine disturbance, and I was from this led to make further trials of the remedy, and have found that—
7. Bromide of Potassium exerts a most powerful influence on the generative organs, lowering their functions in a remarkable degree.
8. It is a remedy possessing most valuable powers in diseases dependent on, and accompanied by, excitement or over action of the generative organs; and hence it may be given with advantage in nymphomania, priapism, certain forms of menorrhagia, especially that occurring at the climacteric period; as likewise in nervous convulsive diseases dependent on uterine irritation; and lastly, in some ovarian tumours.

9. It appears to produce an anæsthetic condition of the larynx and pharynx, and hence has been usefully employed in examinations and operations of these parts.

Bromide of Ammonium has been lately proposed, more especially for the production of the last-named effects, but I am not aware that it possesses any powers superior to those of the salt of potassium. The bromide of potassium may be given in doses of from five grains to ten or even fifteen grains to the adult.

It is curious to observe and compare the physiological and therapeutic powers of three salts so analogous to each other in a chemical point of view—namely, the Chloride, Bromide, and Iodide of Potassium, the first producing but little action unless given in large quantities, probably from its being a normal constituent of the body; the second, the bromide, abnormal to the economy, or existing only in infinitesimal amounts, acting especially on the nervous system; the third, the iodide, also abnormal to the body, having its influence more especially directed to the mucous membranes and secreting organs. The investigation of such actions in relation to the composition of the substances administered may probably one day afford some clue to the comprehension of the effects of remedies.

In the Arsenical preparations there will be found some alterations in the British Pharmacopœia when compared with the London. In the latter work arsenious acid is placed in the list, and from it two compounds are formed—namely *Liquor Potassæ Arsenitis*, and *Liquor Arsenici Chloridi*. In the first-named solution, the arsenious acid is probably dissolved wholly or in part in the form of the Arsenite of Potash; in the second, the arsenious acid is held in solution by the hydrochloric acid, but can scarcely be supposed to exist as Chloride of Arsenic. This last preparation was that one introduced into the last edition of the London Pharmacopœia, from its being supposed to be less irritant to the digestive organs than the ordinary arsenical solution. As the preparation is omitted in the British Pharmacopœia, it may be well to endeavour to ascertain the reasons for its rejection.

In the first place it can be proved to contain arsenious acid, and not chloride of arsenic; and secondly, there is abundant evidence to show that it is an effective medicine, and valuable in the treatment of skin affections, and some forms of nervous diseases, but as yet I am unacquainted with any comparative trials with *Liquor Potassæ Arsenitis* which demonstrate its less irritant operation, although this has been asserted to be the fact. In some cases, when I have found that the patients were very intolerant of the ordinary arsenical solution, I have substituted the so-called *Liquor Arsenici Chloridi*, but have invariably seen the same intolerance, provided that the medicines were administered in equivalent doses, that is, in doses containing the same amounts of metallic arsenic. In some cases I have seen considerable irritation follow the exhibition of even one minim. It might be argued in favour of the retention of the *Liquor Arsenici Chloridi*, that it is a convenient form for giving arsenic when we wish at the same time to administer an acid, this is correct; but there can be no objection in such cases to give the ordinary arsenical solution, the small amount of free carbonate of potash not very appreciably interfering with the acidity of the draught. The *Liquor Arsenici Chloridi*, therefore, was omitted, not on account of its having any objectionable properties, but simply to avoid increasing the preparations of arsenic.

In the British Pharmacopœia we have the *Liquor Potassæ Arsenitis*, or Fowler's Solution, under the old name of *Liquor Arsenicalis*; besides which, two other salts have been added, namely, the Arseniate of Soda and the Arseniate of Iron.

Arseniate of Soda has been long employed on the Continent, and it has also been used in this country, and a solution of the salt, in the proportion of one grain to ten fluid drachms of water, is known and prescribed under the name of Pearson's Solution. Upon what claim has this salt been introduced into the Pharmacopœia, especially when the *Liquor Arsenici Chloridi* has been omitted? Let us look to the salt, its composition and properties.

The Metal Arsenic forms, with oxygen, two well-defined oxides, the first known by the name of White Arsenic, or Arsenious Acid, consisting of an equivalent of the metal and three equivalents of oxygen; the second, Arsenic Acid, in which there are five equivalents of oxygen to one of the metal. In this, as well as in very many other respects, Arsenic is closely allied to Phosphorus, and this resemblance may prove of importance in explaining the physiological action and

therapeutic properties of the compounds of the former element. When Arsenic Acid is neutralised with Carbonate of Soda, the Arseniate of Soda of the Pharmacopœia is formed—a salt, containing two equivalents of soda and one of water to each equivalent of arsenic acid, which is tribasic. When in a crystallised state, either fourteen or twenty-four equivalents more of water are present, according to the concentration and temperature of the solution from which the crystals are deposited. These salts have, of course, different forms, but in both cases are isomorphous with the corresponding phosphates of the same base, as will be seen in the specimens on the table and the formula on the board:—

Arsenious Acid = AsO_3 —Phosphorus Acid = PO_3 .

Arsenic Acid = AsO_5 —Phosphoric Acid = PO_5 .

Arseniate of Soda = $2\text{NaO}, \text{HO}, \text{AsO}_5 + 14 \text{ or } 24 \text{ HO}$.

Phosphate of Soda = $2\text{NaO}, \text{HO}, \text{PO}_5 + 14 \text{ or } 24 \text{ HO}$.

These considerations might lead us to think that, not improbably, arsenic, in its highest state of oxidation, in a state, also, which is so analogous to phosphoric acid, which exists so largely in the body, might prove much less irritating to the system than when the metal is in the form of arsenious acid, but to establish this point it was necessary to appeal to clinical experience. This I have done in several cases. The first instance was in a woman about 50 years of age, suffering from a chronic form of joint affection. Liquor Arsenicalis having produced considerable disturbance, as evidenced by the irritation of the eyelids and nausea, was omitted, and the symptoms allowed to subside; a solution of arseniate of soda accurately prepared, so as to contain exactly the same amount of metallic arsenic as the ordinary arsenical solution, was next administered, and it was found not only was she able to bear the same amount of arsenic without discomfort, but even double the quantity.

The second case selected was a young woman about 19 years old, who had a severe eczematous affection of the scalp and ears. Liq. Potassæ Arsenitis, in doses of four minims, caused much annoyance after a few days, whereas the amount of the solution of Arseniate of Soda could be increased to ten or twelve minims before disturbance of the system ensued. I next tried the effect of the Arseniate of Soda upon a gentleman who had repeatedly endeavoured, but in vain, to take a single minim of the Liquor Arsenicalis for a slight skin affection; he was, however, able to take two minims of the Arseniate of Soda solution of the before-mentioned strength for some days without annoyance.

To conclude this subject, I may state that within the last week I have been informed by letter of the effects of the Arseniate of Soda upon the wife of a Physician, who consulted me a short time since, and I will read a short extract from this Physician's letter:—

“You wished me to acquaint you with the result of the use of the Arseniate of Soda in the case of my wife, whom you were kind enough to prescribe for some weeks since. The result is highly satisfactory, and none of the bad effects following the use of Fowler's Solution have shown themselves. There has been a much greater tolerance of the drug; less irritation of the conjunctiva; no gastric irritation; and the eczema has nearly disappeared, and that in a shorter time than on former occasions, when Fowler's Solution was given.”

It appears, therefore, if these different observations are sufficiently numerous to be depended on, that the Arseniate of Soda is less irritating than the Arsenite, when the amount of Arsenic given is the same.

In the British Pharmacopœia, a solution of the Arseniate of Soda is ordered, Liquor Sodæ Arseniatis, containing four grains of the dried salt in each fluid ounce. The dried salt has been ordered, to avoid the possibility of error arising from the different quantities of water with which the salt crystallises. By calculation, it will be found that the amount of Metallic Arsenic in the solution of the Arseniate of Soda is to that in the Solution of Arsenite of Potash, nearly in the proportion of 1 to 2, or as 99 to 186.

Arseniate of Iron will also be found in the Pharmacopœia. It corresponds in composition with the blue Phosphate of Iron, Arsenic replacing Phosphorus. It occurs as a dirty green powder, and has been administered internally in carcinomatous affections, and in the form of an ointment has been applied to cancerous ulcers. The dose is about a twentieth of a grain upwards.

I have, however, had no experience of the therapeutic powers of this salt, but cannot conceive that it possesses properties which render it peculiarly desirable as a remedial agent.

ORIGINAL COMMUNICATIONS.

ON A CASE OF

TRAUMATIC TETANUS, IN THE TREATMENT OF WHICH NICOTINE WAS EXHIBITED.

By JOHN W. OGLE, M.D. Oxon., F.R.C.P.,

Assistant-Physician to St. George's Hospital.

CONSIDERING what difficulties surround the treatment of tetanus for the most part, and believing that an approximation towards any certain mode of cure equally necessitates the publicity of the untoward as of the successful cases, I have thought it right to place on record the following instance, in which tetanus was treated with nicotine, though without success:—

The use of tobacco in various modes, as well externally as internally, for the purpose of relaxing muscular action in diverse forms of disease, is, of course, no new theme, as our literature is replete with instances in which it has been resorted to, with, of course, variable results. Among other diseases, tetanus has been, in many cases, treated with tobacco, and in several with, apparently, the very happiest effects. (a) It was, therefore, but a natural and easy step to make trial of the alkaloid of tobacco in the same formidable disease; and thus it was that the Rev. Professor Haughton, of Dublin, was led to experiment upon the administration of this violent poison (b) in cases of tetanus, and as an antidote to that other poison which produces symptoms most allied to the same formidable disease, viz., strychnia. (c) The first experiments of Dr. Haughton were brought before the notice of the Royal Irish Academy in the latter part of 1856; and subsequently he published, in the number of the *Dublin Quarterly Journal of Medical Science* for August, 1862, (d) a communication detailing an account of three cases of tetanus treated by nicotine; one of poisoning by strychnia, in the treatment of which tobacco was used by Dr. P. C. Smyly, of Dublin; and also a case in which tetanus in a horse was treated by nicotine. (e)

Previously, however, to the publicity given to Dr. Haughton's experiments, it had occurred to Mr. Simon, of St. Thomas's Hospital, to try nicotine in a case of tetanus, and of this trial Mr. Simon informed me, in conversation, on hearing of the case which I am about to relate in detail, as well as by letter, since speaking with me. I have learnt also from Mr. Savory, of St. Bartholomew's Hospital, that since, and owing to, the recommendation of Professor Haughton, he has made trial of nicotine as a mode of treatment in this disease. I do not think that an apology can be needed on my part for prefacing the narrative of my case by quoting the words of these gentlemen on so important a subject (having liberty from them so to do). In the communication from Mr. Simon some remarks also exist, as appears in Dr. Haughton's pamphlet, (f) on the antagonism betwixt the effects of nicotine and those of strychnine. He proceeds, in his note to me, to observe:—“It was, I think, in 1852, or the first half of 1853, that I tried nicotine in a case of acute tetanus. . . I was sure that if tobacco was to do good (i.e., in tetanus), it must be in some less unmanageable form than the forms in which hitherto it had been used. So I determined to try nicotine; and, as I had no knowledge of previous experiments with it, I gave it at first charily—I think a quarter of a minim for a first dose, followed in an hour

(a) Regarding this mode of treatment, see Mr. Curling's work on “Tetanus,” 1836. After considering the histories of 128 cases of traumatic tetanus treated in almost every possible manner, he observes (page 177):—“I conceive that more has now been advanced in proof of the efficacy of tobacco than can be adduced in favour of any other remedy yet resorted to. I have not, indeed, succeeded in finding a single case in which, being fully and fairly tried before the powers of the constitution had given way, it has been known to fail.” “I hold it to be the best remedy that we at present possess,” etc., etc.

(b) It is stated, on good authority, that one half of a drop of nicotine placed on the tongue of a dog will cause its death in a very few minutes.

(c) Dr. O'Reilly, of St. Louis, Missouri, treated a case of strychnia poisoning by tobacco infusion with success (six grains of strychnine having been taken).—See *Med. Times and Gaz.*, 1858, Jan. 12.

(d) Page 172.

(e) A brief summary of these cases will be found in an interesting notice which appeared in the number of this Journal for October 26, 1863, p. 442.

(f) Reprint of his paper in the *Dublin Quarterly Journal*, vol. xxxiv., p. 172.

by a second; but I soon learnt that the doses might be closer together than I first gave them, and I think the frequency with which they were given (till their full effect was produced) ranged from every quarter to every half hour. For forty-eight hours it seemed as if the disease was conquered, for it made no progress; but at the end of about this time it almost suddenly began to go a-head, and I never saw more violent, or more frequent, or more painful seizures than those which the man now had, and with which he, of course, presently died. It was during this relapse, if I may so call it, of the disease, that I gave my maximum doses, and quite without effect. It is so very unusual a thing for tetanus, which has set in recently, to suspend itself for forty-eight hours, that at the time I was disposed to believe the nicotine had been the cause of this suspension. And in some experiments which I was doing about the same time on the antagonism of nicotine and strychnia, I suspected (but did not quite satisfy myself) that the former drug would postpone, where it would not otherwise appreciably antagonise the poisonous action of strychnia. Some years after my first trial of nicotine, I tried it in a second case of tetanus—one not of an acute kind. It entirely failed to do good; but when I had, after full trial, discontinued it, I treated the patient with tinct. ferri sesquichlorid., and the case terminated in recovery. About the same time I had a second case of recovery (also from not acute tetanus) under the treatment with tinct. ferri sesquichlor.

Such is the experience of Mr. Simon as regards two cases in which he made use of nicotine in tetanus. His attempts to overcome tetanus in this way took place prior to those of Dr. Haughton. But since those of Dr. Haughton, as before said, Mr. Savory treated a case of tetanus at St. Bartholomew's Hospital with the nicotine. The details of this case have, I believe, not yet been published; and I have to thank Mr. Savory for placing at my service the following notes of the case:—

“Sarah Beckett, aged 8 years, a delicate girl, was admitted into Mary Ward on October 22, 1862, by Mr. Wood, who first saw her in the surgery. At that time, she lay quietly in her mother's arms. The back was slightly arched; the lower jaw fixed; pupils dilated; no convulsive movements.

The mother stated that the child was in perfect health on the 19th; but that on the 20th she had a convulsion. She knew no cause for the child's illness; but stated that, a month ago, she was struck on the head with a “brickbat.” A small scar, about half-an-inch long, could be seen where she was struck, and she complained of much pain when it was pressed. Ordered—enema haust. sennæ comp. To be put into a warm bath.

23rd.—Remained much the same as yesterday. To have wine \bar{v} j.

24th, 1 p.m.—The child was seen by Mr. Savory, who divided the cicatrix on the scalp by a small crucial incision. No pus escaped. There was no apparent change in the child. To have morphia acetat., gr. $\frac{1}{8}$; æther. chlor., \bar{v} ij.; mist. camph., \bar{v} ij., 6tâ quaque horâ. 5 p.m.—The same. No action of the bowels had occurred. Haust. morphia, 4tâ quaque horâ; hydrarg. chlorid., gr. iij., statim.

25th.—The child appeared neither better nor worse. The corners of the mouth were visibly depressed. Bowels freely moved.

26th.—The child lay quiet. Drank large quantities of milk, and also wine and broth freely. The back remained arched, and the abdominal muscles were rigid. To take morphia acetat., gr. $\frac{1}{4}$, in the same mixture every six hours. Strong beef tea, Oij.

29th.—Up to this time, the morphia had produced no effect on the muscles, although the child had been for some time completely under its influence. The back was arched, and the corners of the mouth very much depressed. The forearms were somewhat rigidly flexed on the arms, and the fingers bent into the palms. The morphia to be discontinued. Nicotine, gr. iij.; alcohol, \bar{v} i. \bar{m} v. to be injected subcutaneously every six hours.

This plan of treatment was continued until November 2. The child complained but little of the injection, which did not excite spasm. After the first dose or two, some change for the better was apparent. The pulse (120) was not perceptibly affected; but the stiffness seemed less, and the respiration deeper. But in the course of thirty hours or so, this apparent amendment passed away, and then any attempt at examination or disturbance produced spasms, which gradually increased in severity and frequency.

The pupils were often examined, but no decided effect on them was produced by the nicotine; yet its general influence on the condition of the child was marked. She lay passive, drowsy, almost insensible, when fully under the effects of it.

Brandy was freely given during this time, and when the nicotine was stopped, the general effects of it passed off.

On the 8th, the child gradually sank and died. On post-mortem examination, the dura mater was found closely adherent to the skull-cap. There was some fluid in the posterior fossa of the skull; but, Mr. Savory thought, not more than usual. The structure of the brain was found to be firm and healthy throughout. Nothing wrong was discovered in the spinal cord or canal. The other organs were healthy.”

In the following year, Mr. Jolliffe Tuffnell, of Dublin, successfully treated a case of traumatic tetanus with nicotine, the particulars of which may be found in the *Dublin Medical Press*. (g) And, subsequently, Dr. Fleming brought before the Surgical Society of Ireland a case of acute traumatic tetanus which had occurred in the Richmond Hospital at Dublin, in which he tried the effects of nicotine (in two-drop doses, exhibited along with a little brandy and water every three or four hours until eight drops had been swallowed). The case proved fatal eventually, but Dr. Fleming considered that the severity and frequency of the symptoms were undoubtedly diminished by the nicotine. Again, in the *Dublin Medical Press* (h) will be found related a case of traumatic tetanus, in which Dr. John Barton, assisted by Professor Haughton, exhibited the nicotine with the result of diminishing the violence of the spasm to a very great extent, and for a time controlling the disease.

I will now, without further preamble, proceed to describe the particulars of a case of acute tetanus which occurred in St. George's Hospital last autumn, and which my friend and colleague, Mr. Holmes, asked me to treat in consultation with himself; at the same time taking the opportunity of thanking our Surgical Registrar, Mr. Braine, for the notes which he had taken, and has placed at my disposal, and which constitute a valuable addition to my own memoranda of the case.

The patient, Mary G., a thin, delicate-looking girl, aged 14 years, was admitted into St. George's Hospital on August 29, 1863, having a long lacerated wound of the soft parts of both sides of the left leg, which had been caught in the spokes of the wheel of a cart. The edges of the wound were much bruised, and a few days after her admission began to slough. Subsequently, the wound became cleaner, and her general health improved under the use of tonics and occasional sedatives, until the evening of September 6, when she complained of what was called “slight sore throat.” Croton oil and colocynth were given. On the following morning (September 7) there was trismus, the mouth was firmly closed, and the risus sardonicus existed. The lips were dry, the pulse small, weak, and 156 per minute. The pills had acted once. At noon I was desired by Mr. Holmes to see her with him, and found her lying flat in bed, with the head raised, the eyes half closed, the lips tightly drawn across the gums, the upper teeth and gums being freely exposed. She was utterly unable to open the mouth, and the muscles of the face were perfectly rigid, especially the masseter and buccinator on either side, and the muscles of the shoulders and back of the neck. The skin was cool; the pulse feeble, about 135 per minute. The intellect was quite clear. Both the pupils were rather large, but equal, and acting to light. Ordered, a repetition of croton oil and the compound colocynth pill, and a lotion to the wound, consisting of half an ounce of extract of belladonna to a pint of water. At 5 p.m. the bowels had acted very freely. At this stage I talked with Mr. Holmes on the advisability of amputating the limb, seeing that, owing to the nature and extent of the local injury, it would have been quite impossible to have divided separately such nervous trunks as supplied the parts implicated. Mr. Holmes consulted with two of his Surgical colleagues, Mr. Pollock and Mr. Lee, and, in consequence, the idea of amputation was rejected, as Mr. Holmes said, on the following grounds:—“1. We thought that it was too late, as the irritation, or the diseased condition, or whatever you like to call it, would be propagated by this time up the nerves, far beyond the point of section in amputation. 2. We did not think it impossible that the patient might survive without amputation. 3. She seemed so weak, that amputation would be a serious danger to her, as would (I

(g) See volume for 1863, January 7, page 1. The case was read at the Surgical Society of Dublin, and was one of compound fracture both of radius and ulna.

(h) July, 1863.

think) the necessary chloroformisation. 4. No success has, as yet, attended amputation of the thigh, I believe."

September 8, 9 a.m.—There had been very little sleep, but the patient had swallowed between one and two pints of beef-tea. There had been no spasmodic action of the muscles of the back or belly (opis- or emprostotonos). In all important points the symptoms were the same as on the evening before. Pounded ice was ordered to be applied along the spine, enclosed in a piece of intestine. 11.30 a.m.—The risus sardonicus had increased, the cheeks were flushed, but the rest of the face was pale. At her own request she was raised in bed, but the attempt to swallow a teaspoonful of porter, which she wished for, brought on spasm of the muscles of the neck and face, and she swallowed it with great difficulty; a few minutes afterwards she swallowed it with great ease. The respiration was quiet, and 36 per minute; the pulse 140. The teeth could be separated a little. As much strong beef-tea and wine as possible were ordered to be given; and it was agreed to try half-drachm doses of spirits of turpentine with the acacia mixture and water, every four hours. One dose only could be given, owing to the amount of distress which it caused. At 3 p.m. it was agreed by Mr. Holmes and myself to try nicotine; and accordingly, after procuring a genuine specimen from Messrs. Bullock and Reynolds, we proceeded, at 9.15 p.m., to give four drops of a solution containing half a grain, in ten minims of water, in a little brandy-and-water.⁽ⁱ⁾ At this time the forehead was much wrinkled; the abdominal muscles, as well as those of the neck and shoulders, were very tense. There was no hiccup, but great difficulty in swallowing. The intelligence was unimpaired; the pupils dilated as before, but acting readily to light. Pulse 140, and the skin very cold. The urine was passed along with the fæces. At 11 p.m. she stated that she felt altogether easier, and the general aspect was certainly improved. The pulse was 144, and the skin perfectly warm. The heart's action was greater than it had been. There were no spasmodic seizures, but the muscles of the abdomen were still very rigid. There was no increased perspiration. It was determined to administer an enema containing eight drops of the above-mentioned solution of nicotine, along with beef-tea and a little brandy; and it was ordered that a similar injection should be exhibited at two o'clock in the course of the night. The first injection was retained for an hour without producing any particular result, as was also an injection containing egg and brandy and beef-tea. At 5.30 a.m. on the following morning the nicotine enema was repeated, but rejected almost entire.

9th, 9 a.m.—There had been no sleep, and slight "wandering" had existed in the night. The patient complained greatly of the throat, and the tongue was very sore. The neck was very rigid, and the muscles of the lips stretched as before. Occasionally, general twitchings of the entire body existed, and especially starting of the injured leg. The patient raised the arms readily, and held on by the bed-ropes as usual. No perspiration had existed, but the skin was warm; pulse 124. I gave the patient eight drops of the nicotine solution (k) with brandy and water, and desired it to be repeated at 12 a.m. The first of these doses was retained in the stomach; the second could not be swallowed, owing to spasm of the throat, and, in its place, I ordered twelve drops of the solution to be administered with beef-tea and egg as an enema. About this time (12.30 a.m.) attacks of opis- thotonos came on (from four to eight in the hour), during which she had the sensation of falling down. These attacks were not very severe, though sufficiently marked, but became considerably intensified when attempts were made to give her the medicine. Much spasm also about the throat and "frothing" at the mouth was occasioned. Very little of the medicine was swallowed, but she could open the mouth about a quarter of an inch. A nutritive injection was retained. The pulse was regular, and 136 per minute. At 12.55 p.m., twelve drops of the nicotine solution was administered in a small enema. No spasm arose during its exhibition.

Subsequently, Mr. Holmes and myself determined to try the use of the nicotine by subcutaneous injection (l); and accord-

(i) Mr. Holmes applied a very small quantity of this solution to his tongue, and immediately became giddy and faint,—an effect which passed off in from two to three hours.

(k) Of the strength of half a grain to ten drops.

(l) In a letter from Professor Haughton, he informs me that he looks upon the mode of applying nicotine by subcutaneous injection as "a bad way." He had seen it used with a horse, as before alluded to, but "it appeared to act as a mild caustic, and not to be readily absorbed." He proceeds to say that he thinks the best way is to give it in doses of "one or two drops, in a teaspoonful of brandy, with tepid water, as an enema.

ingly, at 2.20 p.m., five minims of it, along with five of water, were injected under the skin of the left arm, which caused a slight blush of redness over the part where the injection was made. At 2.30 an attempt to swallow some porter created excessive spasm. At 3.15 the redness occasioned by the injection had nearly disappeared. At 3.30, attempts to swallow produced violent spasm of the muscles of the throat, lasting about five minutes. At 4 p.m., the arrival of the patient's mother caused much agitation and general spasm. At 4.30, Mr. Holmes injected ten minims (equal to half a grain of nicotine) into the tissues at the back of the neck. At 5.40, the same injection (ten drops) was repeated in the left arm, and was followed by some spasm. Subsequently an attempt was made to pass a flexible gum catheter through one of the nostrils, and down into the œsophagus, so as to give a nutritive injection, but most violent and long-continued spasms, with great lividity of face, and apparent suffocation, were, in consequence, produced, and the fluid was returned through the mouth. At 5.55, the abdomen was less hard and tense. At 6.30, pain was complained of at the præcordial region, and the administration of a beef-tea injection induced a most severe general spasm, the injection being at once returned. At 7.15, a quantity of the nicotine solution, equal to half a grain, was again injected under the skin. At 8.15, it was reported that since the last injection there had only been slight twitchings of the facial muscles, and the teeth could be separated a little more. Pulse 140 per minute. A few drops of water were swallowed with less spasm. At 8.40 the subcutaneous injection was repeated. At 10 p.m. the patient was reported to have been more restless. The pulse was 154 per minute. The skin somewhat perspiring. 11 p.m., the restlessness continued. The abdomen was much softer, the muscles being less tense and rigid, but she seemed weaker. Pain at the throat complained of. 11.15.—Twenty drops of the nicotine solution (equal to one grain) were injected into the subcutaneous tissues of the right arm. During the operation spasm came on, and gradually increased in intensity, and so affected the respiratory muscles that the face became livid, and breathing was altogether arrested; but after cold water had been dashed on the face, and vapour of ammonia applied to the nostrils, she gradually came round, the pulse being 164 per minute. 11.30.—The breathing was long drawn, and of a sighing character. Severe general spasm returned, lasting about four minutes. By slight pressure upon the lower jaw the mouth could be opened to the extent of half an inch. At 11.44, the breathing was sighing and irregular as to rhythm. Pulse 144, regular.

10th, 1 a.m.—Breathing the same. Pulse 150 per minute. There was a little moisture on the palms of the hands. The abdominal muscles were quite lax, but the general spasms were so continuous, though not violent, that it was thought advisable to repeat the injections of nicotine. The pupils were almost quite inactive under the influence of light. The breathing continued to have an irregular character until about 3.30 a.m., when it became very much impeded, and the spasms continued throughout, though slight as to intensity. She died at 4.40 a.m.

Post-mortem examination was not permitted.

Such are the painful records of this case, in which the use of nicotine proved unavailing. Looking to the history and details of the cases described by Dr. Haughton, I was at first sanguine as to our results in this recent one, especially as at one time some extenuation of the severity of the symptoms appeared to show itself. Possibly the local injury, considering the tender age and delicate constitution of the patient, may have been so extensive that its results would have been intractable under any mode of treatment.^(m) Possibly, again, the nicotine may have been not so potent as I had thought,⁽ⁿ⁾ or I may have been too sparing in its administration, being fearful, as I naturally was, of giving it in over-large quantities, knowing what evils have, in other hands, attended the use of tobacco when carelessly or improperly used.^(o)

(m) In the treatment of tetanus, a curious note of Aretæus exists, in which he recommends, that, if the disease is thoroughly established, the Physician ought not to compromise himself by "meddling with the case." This principle is, of course, not here alluded to with a view to its recommendation.

(n) I understand that the most reliable preparations of this alkaloid are procured from Germany, which, indeed, appears to be the great market for most of the alkaloids.

(o) The strength of the enemata (chiefly resorted to as a mode of administering tobacco in tetanus) seems to have been about that adopted in the London Pharmacopœia, which directs the "enema tabaci," to be made by adding one drachm of the weed to a pint of fluid. Pereira observes, that he was in the habit of using twenty grains at a time in the

Of course, all these supposable causes of failure in the use of nicotine may equally be assumed in the case of other remedies which are so frequently resorted to, and with a like want of success; and are sufficiently probable to allow of hope (considering the partial success which has appeared to attend its use as related by Dr. Haughton and others, and also the results of the use of tobacco in tetanus), that the nicotine may yet prove a serviceable weapon in our hands against a disease, in connexion with which more than with any other, except, perhaps, hydrophobia, is the aphorism—"Vita brevis, ars longa, occasio præceps, experientia fallax, judicium difficile"—more justly applicable.

As regards the particulars—the individual symptoms which occurred in this case I will make no further observation, as such would be foreign to the scope of these remarks. (p)

Before closing, I cannot refrain from quoting a few lines from Mr. Simon's note before mentioned, in which he further touches on the treatment of tetanus. After referring, as above stated, to the successful treatment of tetanus by the tincture of the sesquichloride of iron, he proceeds to remark,—“Once I treated a case of acute tetanus with belladonna. I think the drug was amply tried, but I am not sure that the case (which, *perhaps*, was one of centric tetanus) was quite the fairest which could have been selected, *i.e.*, on the theory which would seem likeliest to justify the trial of belladonna.” Again, Mr. Simon, alluding to the general treatment of tetanus, says:—“The other day, at Constantinople, Marko Pasha, the Sultan's doctor, told me that he had cured a large number of cases of tetanus—I believe nine out of eleven—by the use of opium, which he rubs in right and left, and gives in enemata, till profound sleep (? coma) results from it. His quantities were large; but, he said, none had died of opium, and all who slept recovered.”

These remarks, though not directly relative to the immediate subject and purpose of this communication, are so interesting, that I could not desist from quoting them in this place.

CASE OF EMPROSTHOTOSIS (?) CURED BY THE USE OF ICE TO THE SPINE.

By JAMES EDMUNDS, M.D., etc.

THE subject of this report is a married woman, 28 years of age, healthy and intelligent, altogether free from flightiness or hysteria, and of good family history. Her second child is nine months old, and at the breast.

On January 21, she retired to bed quite well, but on rising next morning at 7.30 her fingers were slightly benumbed, and between nine and ten o'clock while dressing the baby, her fingers suddenly “turned in,” so that she was obliged to huddle the child up in her arms to save it from falling. This “turning in” of the hands increased rapidly, and caused a cramp-like pain in the arms; and her lower limbs from the knees downwards also became affected in a similar way, but less severely. In about half an hour the pain was so great that she was obliged to sway herself about to try to get ease,

form of infusion as a clyster in ileus. Abercrombie used fifteen grains, remarking that in people long accustomed to tobacco a somewhat larger dose might be required. Pereira goes on to say that he had “never met with any cases in which a scruple did not produce the full effect on the system that was desired.” Cases are related in which half-drachm doses of tobacco, used as enemata, have produced death. Mr. Curling observes:—“At the commencement, a scruple of the tobacco-leaf, infused in eight ounces of water, will be enough for an injection, which must afterwards be increased in strength in proportion to its effects.” In connection with the question of the comparative strengths of the tobacco used in the form of enemata, and the nicotine derived from the tobacco-leaf, it is just possible that, as the essential oil of tobacco, the concrete volatile oil (or, as it is termed, the nicotianin), a very essential element in producing some of the poisonous symptoms arising from the use of tobacco proper, is, of course, absent when the alkaloid, nicotine, is alone used,—it is possible, I suggest, that, in using the nicotine as a substitute for tobacco, we may be losing a very important agent of treatment. Individual and opposite effects are attributed severally to the *nicotina* and the *nicotianin*; but it is a question how far their separate effects can be or have been isolated, and whether we should not have more chance of success in treating tetanus or other diseases with nicotine if we combined the volatile oil with the alkaloid in our treatment. I see that, according to Schloësing, one of the chemists who analysed nicotine, the proportion in 100 parts of American and French tobacco varied from 2.00 or less to 7.96, the tobacco which contained the smallest amount of the alkaloid being the Havana, and the highest being that from Lot.

(p) One of the most interesting symptoms which recently described cases have presented has been the elevation of temperature, observed by Wunderlich in a case of “spontaneous tetanus,” and lately described by him.

and she was so helpless that her husband first lifted her into an easy chair and then fetched a bed down stairs, and laid her upon it. The pain increased, and she could not help moaning and screaming, although her mind and her manner continued clear and rational.

Between 11 and 12 o'clock she was seen by Dr. S. C. Griffith, of London-wall. There was then extreme and rigid flexion of the hands and arms, and her head was so drawn forwards that the backs of the wrists were fixed close to her mouth; the tongue was coated; the pulse was not remarked. Some aperient medicine was ordered, of which she took one dose, and after which she was slightly sick.

At 1 p.m., Dr. Webber saw her in consultation with Dr. Griffith, and Dr. Webber noted her pulse as “slow and weak—about sixty.” Sulphuric æther and anti-spasmodics were ordered at once, and a dose of morphia after a few hours in case the pain did not abate. She had intervals of comparative ease, but, nevertheless, continued to grow worse; and at 5 p.m., seven minims of “sedative solution of opium” were administered. After this, all her symptoms were aggravated; and during the evening she suffered so much that her screams could be heard across the road. Her neck became turgid, her respiration somewhat constrained, and she was becoming rapidly exhausted.

At 10 p.m., Dr. Griffith asked me to meet him in consultation; and I did so. At this time her condition was certainly most remarkable. I had seen plenty of screaming hysteria, and a few cases of opisthotonos; but I had never seen a case precisely like this one. She lay upon the bed on the floor on her left side, with her wrists in contact with her mouth, as has been described; her spine was bent forward, and her knees bent and drawn upward, but not to the extent of coming into actual contact with the abdomen. There was an expression of great anxiety and pain upon the face, and the lips were sufficiently retracted to show the teeth; but the expression was not exactly the risus sardonicus which I have seen in opisthotonos, and she could swallow by making a great effort to ignore the tearing, cramp-like pain which occupied her, and which forced from her a continual moaning scream. Her cry was nothing like the passionate scream of hysteria. She was quite rational, and she merely swayed herself about instinctively. Her forearms were hard and rigid, and the wrists were so fully flexed that her hands were forced open, and her legs were similarly affected, but in a much less degree. It was stated that a considerable quantity of pale urine had passed from her. The pulse could not be judged on account of the spasm of the neighbouring tendons. We had the patient held up on to her feet. She could not stand, and her legs were about as much cramped as in a bad case of cholera; but they were not in a state of rigid spasm like that of the forearms.

There was no appearance of hyperlactation; no evidence of albuminuria or uremic poisoning; no history of worms; no traumatic injury, and no clue whatever to any source of eccentric irritation excepting the single fact that her bowels had not acted for three days.

I had never seen a case of emprosthotonos, but this one could be referred to no other term. Certainly it was not a case of hysteria, and, moreover, it was manifest that, unless speedily relieved, she would die either from exhaustion or spasm of the respiratory muscles. There was evidently some exaltation of the reflex irritability of the spinal cord or some acute cause of nervous irritation, and the indications for treatment were, first, to clear out the bowels; second, to lessen the irritability of the cord, so as to do away with this frightful state of spasm.

The first object was effected by at once placing upon the tongue a purge, consisting of one drop of croton oil and five grains of calomel. An enema of turpentine and castor oil was also administered to free the lower bowel from flatus or fæculent accumulation, and the purge was to be repeated in three hours. How was the second object to be accomplished? The inhalation of chloroform, on the one hand, or the application of ice to the spine, on the other, appeared to be the only remedies adequate to the emergency, and as there were some objections to using chloroform, we determined to use the ice. This was accomplished effectually by her husband, who had two ox gullets alternately filled with ice, and kept it continuously applied to the whole length of the spine for seven hours, when all her severer symptoms had disappeared.

The screaming and moans were at once mitigated by the ice, and in about half an hour ceased entirely. In two hours her feet became flexible. About 8 a.m. on the 23rd, the spasms

had so far subsided that she could open her hands, but the numbness remained. She felt very sore in her muscles when turning in bed, especially in the forearms and legs, and in the back. Her tongue was cleaner, and the pulse had increased in volume, and had risen to 76. On the morning of the 24th the numbness entirely disappeared, and afterwards she had no return of cramp or spasms, but a little subacute bronchitis and hoarseness hung about her for ten or twelve days longer. She is now in her usual health.

In this case the patient herself ascribes the relief of her dreadful pain and cramps entirely to the use of the ice; and although it is difficult to distinguish between the mere *post hoc* and the *propter hoc*, yet I cannot but believe, if ever I saw a life saved by a therapeutical application, that this patient's life was saved by the use of the ice in this way to the spine; and the case strongly supports the theory propounded by Dr. Chapman, of Somerset-street.

If it be really a fact that, by the application of cold or heat to particular portions of the back, we can directly exalt or lessen the reflex activity of the grey matter of any given segment of the cord, or of the sympathetic ganglia which govern the blood-supply of distant parts, we shall have made a rare and philosophical hit in therapeutics, and, in the discriminating application of cold or heat to the nervous system, possess a remedy which may prove useful in almost all diseases. I had seen Dr. Chapman's brochure on the subject of this discovery, and also his paper in the *Medical Times and Gazette*, but thought the idea too pretty to be anything more than a plausible theory, until my own child being in great danger from an obstinate laryngismus, connected with dentition, I tried "the ice bag" to the cervico-dorsal portion of the spine, at the suggestion of Dr. Ramskill, and it has certainly done more to keep off the strangling attacks than anything else.

Dr. Ramskill has not only adopted this treatment largely, but speaks of it to me with the greatest confidence in the treatment even of epilepsy, and in his practice it seems to be the means of doing great good, and in many cases of keeping the fits almost entirely in abeyance.

For the application of the ice to chronic cases there is a great practical difficulty in respect to obtaining perfectly waterproof bags of the proper shape. Dr. Ramskill was kind enough to give me one for my own child, and since then I have communicated with Dr. Chapman himself, who most politely forwarded me, at prime cost, some bags prepared under his direction, and these answer very well.

I am indebted to Dr. Griffith for much of this report.
35, Finsbury-circus.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

CASES OF PULMONARY DISEASE PRODUCED BY MECHANICAL IRRITATION—CLINICAL REMARKS.

(Under the care of Dr. GREENHOW.)

Case 1 is one of many examples of pulmonary disease among chaff-cutters which have come under Dr. Greenhow's care during the last ten years. Sooner or later, nearly all the men in London who devote themselves exclusively to this employment become the subjects of pulmonary disease, which, beginning with bronchial irritation, terminates either in chronic bronchitis with its usual consequences, or in chronic pneumonia, passing into phthisis, or into iron-grey induration of the lung. Chaff-cutters' pulmonary disease does not prove fatal for many years—rarely, indeed, until the age of 50; but the fact that it leads to one of the above-mentioned terminations has been verified by Dr. Greenhow in several post-mortem examinations of patients who died while under his care, as Physician to the Western General Dispensary.

R. M., aged 47, chaff-cutter; admitted an out-patient of the Middlesex Hospital, April 24, 1863. Has been a chaff-cutter for ten years, and usually works eight hours a day. His business consists in going round to the different stables belonging to his customers to cut chaff for their horses, during which process the air he inhales is charged with dust given off by the hay and straw. Has long suffered from habitual cough and tightness of chest, and recently also from dyspnoea.

Expectoration very scanty, thick, and yellow coloured; pulse quiet; skin cool; chest normally resonant in the upper and anterior regions, but slightly dull on percussion over the lower part of each lung posteriorly. Respiration sonorous in left apex; feeble in right. Three inches below the right clavicle the respiration is tubular, but free from moist sounds; four inches below the left clavicle there is coarse crepitation over a limited space; large mucous râle, almost amounting to gurgling, in base of left lung; fine crepitation in base of right. Urine free from albumen. ℞ Decoct. sennegæ, ʒjss.; tinct. scillæ, ℥xv.; vin. ipecac., ℥v.; ammon. sesquicarb., gr. v.; tinct. camph. co., ℥xx. M., 6tis horis sum.

May 1.—Improved in some respects. ℞. Hst. acid nit. mur., ʒi.; vin. ipecac., ℥x.; tinct. camph. co., ℥xx., M. ter die. sum; capt. ol. balenæ, ʒij. ter die.

22nd.—Having discontinued his work since first seen, he has improved very much. The moist sounds in the base of the left lung have given place to harsh, dry respiration; the crepitation below the left clavicle has disappeared, and the fine crepitation in the base of the right lung has become less extensive. The patient has also improved very much in appearance, and his cough and dyspnoea have decreased.

(Early in June, considering himself convalescent, he resumed his work, and was then lost sight of.)

Case 2 corresponds with the early and slighter stage of bronchial disease common among operatives who work in cotton-mills and other factories in which they are liable to inhale air charged with cotton flue, down, or similar light particles.

T. T., aged 22, machine tenter, admitted an out-patient June 12, 1863. Attends machines through which wool, cotton, and feathers are passed preparatory to their being made into mattresses and beds, and although the machines are covered, much dust and flue escapes into the air of the apartment. Has followed this employment for two years, during the whole of which time he has suffered occasionally from bronchial irritation, but more constantly during the last few months from dyspnoea and cough, attended by a yellow-coloured expectoration. The expectoration has recently been streaked with blood, and he now also complains of slight sore throat and huskiness of voice. Chest well formed, and normally resonant on percussion over its anterior aspect. Resonance clear on percussion over nipple, and for an inch below it. Slight dulness on percussion over bases of both lungs posteriorly. Respiration dry, and a little sibilant; free from moist sounds. Posteriorly, the respiratory murmur is louder on the left than on the right side. Rhonchus heard over a limited space between the middle of right scapula and the vertebral column, where also there is slight pain on percussion. Hst. acid nit. mur., ʒj.; vin. ipecac., ℥x.; tinct. hyoseyan, ℥xx. ter die. sum.

June 26.—Less cough and expectoration. Complains of pain between shoulders, where there is also considerable tenderness both on pressure and percussion. Rhonchus still heard between the scapulæ, but more on left than right side. Respiration over front of chest dry, prolonged, and wheezing. Pt. hst. capt. ol. balenæ, ʒj. ter die.

July 3.—Improving. Rhonchus much diminished, but respiration continues dry and harsh in the anterior part of lungs.

(He now went to the Convalescent Institution at Walton-on-Thames, and on his return reported himself quite well, but presented himself again after having resumed his work for several weeks.)

September 11.—Has much cough, dyspnoea, and wheezing, especially at night. Expectoration more copious than formerly, but now white and frothy. No hæmoptysis or pain of chest. Says that his present attack has come on gradually ever since he resumed work, the first symptoms being pain and oppression in the sternal region. Chest normally resonant on percussion. Respiration sibilant, but otherwise normal. ℞. Hst. acid. nit. mur., ʒj.; vin. ipecac., ℥x.; tinct. hyoseyan, ℥xx., ter die sum. ℞. Pil. conii. co., gr. v., om. noct. sum.

25th.—Has been less exposed to inhale dust since last report, his work having been changed, and is much better, the cough, dyspnoea, and expectoration having greatly diminished. Pt.

(He continued to mend, and was discharged quite well in November.)

Case 3 is an example of what has been called "grinders' asthma" or "grinders' rot." The disease commences with bronchial irritation, very soon, however, especially in dry grinders, passing into chronic pneumonia. Very frequently

as in the present case, the accession of pneumonic disease is accelerated by attacks of pulmonary catarrh, to which all persons who suffer from bronchial irritation are peculiarly prone.

T. R., aged 38, tool-grinder, from Wolverhampton, admitted an out-patient May 29, 1863. Has been grinder on a wet-stone from boyhood, but is liable to inhale dust while hacking and razing, that is, preparing the stone. Had suffered during many years from slight dyspnœa; cough and expectoration supervened three years ago, since which time the dyspnœa has been greatly aggravated. Is of temperate habits. Skin cool; pulse quiet; chest somewhat flattened in front, but equally on both sides, no obvious dulness on percussion; respiration tubular throughout right lung; bronchial râles heard throughout both lungs; expectoration white, semi-transparent, and tenacious. \mathcal{R} hst. acid nit. mur. ζj , vin. ipecac. $\mathfrak{m}x$ tinct. laricis tinct. hyoseyam. $\bar{a}\bar{a}$ $\mathfrak{m}xx.$, M. ter die sum.

Early in June he had an attack of pleuro-pneumonia on the left side, for which he was admitted into the Hospital. His pulse rose to 100, and the expectoration became frothy, and contained on examination under the microscope small portions of pulmonary tissue.

July 4.—Patient is thinner, but not emaciated; skin cool; pulse 80. Frequent hacking cough with expectoration. Dulness on percussion in both infra-clavicular regions, but most observable on the right side. Respiration on right side tubular with slight crepitation in the infra-clavicular region, but air penetrates to the extreme apex of the lung; respiration on left side a little harsh. Pt. hst. acid nit. mur. etc., Capt. ol. balenæ ζij . ter die.

11th.—Slight dulness on percussion, with diminished expansion in the upper part of both lungs, but right duller than left. Expiration prolonged in the upper lobe of both lungs. Loud snoring rhonchus in left infra-clavicular region; crepitation in right, but only now discernible during cough or forcible inspiration. Expectoration greatly diminished. Pt.

30th.—Dulness and flattening of chest as before. No moist sounds are now discernible, the crepitation in right infra-clavicular region having entirely disappeared. Still has dyspnœa and hacking cough, with scanty thick expectoration.

(Considering himself now convalescent, he returned to Wolverhampton to resume his work).

Cases 4, 5, and 6 illustrate the deleterious influence of a branch of industry which has not yet been noted as a cause of pulmonary disease. T. J., aged 21, pressman, admitted an out-patient September 11, 1863. Has worked for three years as pressman in a printing-office where bronze-printing is done. The process consists in dusting bronze-powder on the wet printed sheet as it leaves the press, by which means the air becomes charged with fine bronze-dust. Had never suffered from any affection of the chest until he went to work in this office, but soon after doing so he experienced dryness and soreness of throat. Next, his voice became hoarse, and this was soon followed by dyspnœa, cough, and expectoration, the latter sometimes streaked with blood. No emaciation; skin cool; pulse quiet. Chest well-formed, and resonant on both sides. Sound of expiration much prolonged in the apices of both lungs, but especially in the right. Slight rhonchus in the base of both lungs. \mathcal{R} . Hst. acid. nit. mur., ζij ; vin ipecac., $\mathfrak{m}x$; tinct. hyoseyam., $\mathfrak{m}xx$. M. Ter die sum. Capt. ol. balenæ, ζij . ter die.

October 30.—Cough and dyspnœa much diminished; voice still raucous; respiration dry and harsh; expiration prolonged; no moist sounds. Pt.

December 8.—Much improved in all respects. Cough and expectoration nearly gone. Has for several weeks discontinued his bronze-printing work, and is now employed at an ordinary printing press. Discontinued his attendance.

J. L., aged 31, paper stainer, admitted an out-patient August 7, 1863. His work consists chiefly in applying bronze powder to wall papers prepared to receive it, during which process much fine bronze dust is given off into the air he breathes. Says that all the men employed in this branch of manufacture are liable to suffer from cough. Has himself had almost constant cough for four or five years, attended by thick white expectoration, but until lately has had little dyspnœa. Voice hoarse, skin cool, pulse quiet. Chest well formed, expands properly in respiration, and is normally resonant on percussion. Respiration dry and sibilant in the upper part of both lungs. \mathcal{R} Hst. acid. nit. mur., ζj ; vin. ipecac., $\mathfrak{m}x$; tinct. hyoseyan., $\mathfrak{m}xx$. M. ter die sum.

August 21.—Improved, but expectoration still copious. Add to draught tinct. laricis, $\mathfrak{m}xx$.

October 2.—Presented himself again after an absence of five weeks. Dyspnœa, cough, and expectoration have increased again during the discontinuance of treatment. Skin cool; pulse 72. Respiration sibilant, expiration prolonged, no moist sounds. Pt. Capt. ol. balenæ, ζij . ter die.

23rd.—In all respects better. Has scarcely any dyspnœa, and much less cough and expectoration. Pt.

December 15.—Has steadily improved, and is now quite free from dyspnœa, cough, and expectoration. (Has been removed into another department of work.)

C. L., aged 42, paper stainer, and brother of the above patient, admitted an out-patient October 2, 1863. Has worked more or less for thirty years at bronzing wall-papers, but owing to the increased demand for this description of paper, has for the last three years been employed exclusively at this branch of the trade. Has long been subject to cough, which, indeed, has been constant the last two years, arising, he considers, from inhaling the bronze dust evolved into the air. Is now suffering from dyspnœa, cough, and expectoration. The expectoration is thick, and yellow-coloured, but sometimes mixed or streaked with blood. Voice raucous, no emaciation, skin cool, pulse 84. Always has pain in the chest, generally on the left side, before the occurrence of hemoptysis. Left side of chest expands less freely in respiration than right, and is also slightly dull on percussion. Respiration in the apices of both lungs a little sibilant, but in other respects nearly normal. From three inches below the clavicle downwards on the left side, inspiration is loud and snoring, expiration almost noiseless. Inspiration also prolonged in the right lung. \mathcal{R} . hist. acid. nit. mur., ζi ; vin. ipecac., $\mathfrak{m}x$; tinct. hyoseyam., $\mathfrak{m}xx$; M. ter die sum.

October 30.—Dyspnœa, cough, and expectoration rather increased by the accession of catarrh. Pulse 90. Slight dulness on percussion over left infra-clavicular region, but air freely penetrates the apex of the left lung. Loud snoring, respiration heard both in front and behind throughout the left lung, but most intense in the scapular region. Inspiration prolonged throughout both lungs. Pt. hist. capt. ol.; balenæ, ζij . ter die.

November 10.—Somewhat better. Pt.

December 10.—Much better in all respects. Pt.

January 4.—Improvement has continued steadily. Dyspnœa entirely gone. Cough and expectoration much diminished. Says that he can work twice as well as he could, and that he has for some time been using a coarser kind of bronze powder, less liable to become diffused through the air. Chest now expands equally on both sides. Slight dulness on percussion over the left infra-clavicular region remains. Respiration sibilant. Inspiration prolonged, expiration nearly inaudible.

Is still under observation.

GUY'S HOSPITAL.

FRACTURED RIBS—LACERATED WOUND OF THIGH—RUPTURED LIVER—PYÆMIA—DEATH.

(Under the care of Mr. POLAND.)

THIS case is interesting, as showing partial repair of injury to an organ so important as the liver. The patient died of pyæmia, probably set up by the external injuries. For the report of the case, we have to thank Mr. Whitfield Thurston, House-Surgeon.

W. B., aged 31, was admitted, under Mr. Poland's care, January 20. He had been knocked down by the handle of a windlass, which, whilst revolving, had struck him on different parts of the body, chest, abdomen, and thigh.

On admission, the eighth and ninth ribs were found to be fractured just beyond their angles on the right side, and there was a severe lacerated wound over the right tensor vaginæ femoris, laying bare the muscle, and lacerating its tendinous prolongation. He complained of pain in his abdomen; but there were no external marks of injury, and he was not much collapsed. The chest was strapped and bandaged, and the wound treated with warm-water dressing. He had spasmodic stricture of the urethra for twelve hours, which, however, yielded to treatment.

He went on favourably for some days; but then became much troubled with bronchitis, with profuse expectoration. He gradually got worse and worse, going through all the phases of an attack of pyæmia; and, notwithstanding all treatment, died on February 8, just nineteen days after admission.

Autopsy, by Dr. Wilks, Twenty-eight Hours after Death.—Fractured ends of ribs just penetrating costal pleura; right

lung irregularly consolidated, and adherent by recent lymph to the diaphragm. The left lung was in an equally diseased condition; and Dr. Wilks thought that the pneumonia was due to pyæmia. Both lungs contained consolidated masses, which, on section, showed hepatised tissue and purulent infiltration. Heart, kidneys, and spleen healthy. The descending aorta was greatly diseased, being much dilated, from about three inches above to three inches below the diaphragm. The walls were thickened and atheromatous. The peritoneum was of a black colour, from effused blood; either a small quantity only had been poured out, or else some had been absorbed again. There was a little blood in the omentum and pelvis; but, for the most part, the black colour was due to actual staining. Some coils of the intestine were quite black, and, when washed, showed the colour most on the mesenteric side. The diaphragm was adherent, by recent lymph, to the liver; but, when removed, the latter was seen to be extensively lacerated. At the upper part of its right lobe, there was a deep wound, now closed by lymph, but in the midst of the latter, some yellow biliary matter, showing escape of bile. Proceeding from this point, there were six or seven lacerations, extending in all directions around. They were all becoming closed by lymph. With the exception of the exudation over the principal rent, and which fixed the liver to the diaphragm, there was no general peritonitis.

SATURDAY, MARCH 12.

THE ARMY AND THE MEDICAL PROFESSION.

GREAT BRITAIN is certainly a warlike nation, however much she may fail to be considered a military one when contrasted with her neighbour on the other side of the Channel. Our history is in great part a succession of battles, and our present position has been won—as it has to be maintained—at the point of the sword. The extent of our colonial possessions necessitates the maintenance of a large military force, which rapidly absorbs the best blood and toughest muscle of the land to fill up the gaps caused by disease and death. Seeing that we are numerically such a weak power, and looking to the amount of work imposed upon us, the preservation of the health of our troops abroad becomes one of the clearest and gravest charges devolving on our Government. This object mightily concerns us all, as members of the British nation.

There is, however, another aspect of the same question, which comes before us as Medical men. Is there any other country in the world that has more reason to be proud of its military Surgeons than England? We can count—in common with other nations—a long list of devoted men who have served the nation well, and perished in the discharge of their duties as army Surgeons; and, what is not so common, we can point to the large amount of scientific truth which has been gained amid the din of arms, under the light and guidance of which life has been preserved, and the misery of the sick and wounded assuaged, through that series of struggles which seems to be the never-ending curse of nations.

The great Surgeon and Physiologist of our land—Hunter—carried away some sheaves of truth from the battle-field.

Jackson laid the foundation on which the whole superstructure of army hygiene and sanitation rests; and he was followed by Pringle, Marshall, and others. The principles on which we treat gunshot wounds and injuries of vessels sprung out of Guthrie's experience in the Peninsular wars. These are things which remain for the benefit of the suffering humanity of to-day, and will remain for subsequent ages, and they present a finer spectacle, and mark a truer progress to the thoughtful and humane mind, than the world bending beneath the sway of the first Napoleon. Turn to the great campaigns which have for three years desolated America with blood. It is a melancholy spectacle in every way, and not the least so in this, that scarcely a new fact, and certainly not any great discovery, has arisen in Medical or Surgical science. Our Houses of Parliament will devote any number of nights, and the *Times* any amount of space, to the discussion of the claims of rival artillerymen, or to the contending factions about the iron-clads; but how little, after all, will remain for the future historian who looks to the health and strength of a nation as the main elements for its material progress. But, it may be said, there never was a time when sanitary science occupied so much attention, or the laws affecting health and longevity were so anxiously and prominently discussed. Be it so! We have had books, speeches, reports, and commissions in abundance, and their conclusions have been trumpeted in our ears as if they were such new and powerful truths that men would immediately fall down and worship them, or that, once asserted, they would directly work the desired ends. "In all labour there is profit; but the talk of the lips tendeth only to penury." What earnest has the nation given of seeking something else than mere generalisations concerning health? What anxiety has been shown in the choice and supply of the instruments by which these conclusions are to be applied? It would almost seem as if the Government were desirous of testing the truth of Miss Nightingale's suggestion that great Hospitals are great evils, by working out in India the wider problem of whether Medical science and Medical men were not alike unnecessary.

No heed was given to the clamorous discontent in our Army Medical Department until its extreme state of unpopularity rendered a post in it the ambition of none. We regard it as a matter calling for inquiry, when an important branch of the public service is recruited, almost exclusively, from one part of the kingdom; but we regard it as a positive scandal that the authorities should sacrifice quality to quantity in the way they are doing, and endeavour to silence the claims and complaints of Army Surgeons by introducing amongst them an inferior class of men, to the manifest injury of our troops.

For how much of all this the Director-General is to be held responsible, no one can venture upon expressing an opinion, although it is impossible to prevent one being formed. There have been many changes introduced of late which would certainly seem to lie within the province and control of the Medical head, if he be possessed of any power at all. Although the journals have teemed with complaints, although the department was becoming more and more impaired by the loss arising from resignations, although it has been dying for want of fresh blood, no attempt has been made to remove the minor sources of discontent.

We have referred to the great dislike which every Medical officer, having any tinge of respect for his cloth or himself, has to the present mode of effecting the branding of soldiers. We have pointed out how, step by step, every particle of independence has been removed from the position of the Surgeon. We have alluded to the illogical and unjust way in which men are liable to be mulcted of their pay in the cases of recruiting, the allowance of extras, and the administration of drinks almost as simple and inexpensive in their nature as pure water; and we have heard that Medical officers have been threatened with the liability for any expenses incurred in sending a sick soldier before an Invaliding

Board, should that soldier recover some months afterwards of his disease. We can quite understand, that the Director-General has an extremely difficult task before him, and we can conceive of his finding evidence of carelessness, inattention to orders, etc., on the part of his subordinates, for the simple reason that the loss of independence and the want of confidence engender these very evils. It is quite possible that, in course of time, by a process of legislation adapted to the worst officers, you may so disgust the conscientious and diligent men that they will lose every particle of interest in their Profession and their work. Officers of different grades talk over these things. They come to regard Whitehall-yard as the camp of an enemy instead of the channel through which their views and feelings may be received and transmitted, at any rate with Professional sympathy, however much the exigencies of the public service may be the bar to their fulfilment. Some men there are who think that their interests would fare better if entrusted to the hands of a civilian and non-Professional man. It is a sufficient indication of the loss of confidence that such a view should have been mooted.

It is reported that the Government have at length instituted some inquiries. If the Committee, said to be sitting at the War Office, are really desirous of getting at the facts and feelings of the Profession, there would appear to be no lack of materials. We have not scrupled to express in these pages our own views. Two or three Medical officers, of different ranks, might be selected by members of the department serving in England for examination upon these subjects, and if they could not afford data to the Boards upon which to work, then their cause must be a bad one.

If the members of the Medical Department be fairly paid, treated as gentlemen of education, assigned such functions as rightly belong to them, and supported in the execution of their duties, we can assure the Government that there will be no lack of candidates; the Department, under happier auspices, will receive some of the best-educated men in Great Britain; and in a few years' time Government, officer, and soldier, will reap such advantages as will indubitably prove to them that the best material is the cheapest. How soon the whole Continent may be embroiled in war no man can tell. Never was the political horizon so lowering. The arrival of each day's telegrams is anticipated with anxiety, and it concerns us all that we should have every branch of our services in a condition of the highest efficiency. The Medical Profession, as a body, are every bit as patriotic and solicitous for the nation's welfare as any other class of men in the kingdom.

THE GOVERNMENT ANNUITIES BILL.

OUR Parliamentary Report will explain the object and provisions of this bill. It seems to be admitted by all parties whose interest does not impel them to a denial, that the scheme proposed by the Government will be a great benefit to the classes for which it is designed, if it can be carried out as a financial success. This branch of the question does not fall within our province to discuss, but the measure, seen from a Professional point of view, is certain to affect some, if not all, of our readers. One of the objections which have been urged against the bill is, that in doing so large an amount of business for so small a sum in each case, it would be impossible to have an effective Medical inspection for each person. Mr. Gladstone replies that "the Government have the means of ascertaining the value of lives, either through the Medical Profession generally, as far as their certificates are concerned, or through those special Medical officers attached to the guardians of the poor who are themselves officers of the State." Now, the bill, a document of sixteen lines only, exclusive of the preamble, contains no reference to the practical working of the plan, and accordingly makes no provision for the remuneration of Medical inspectors. How, then, is this important desideratum to be supplied? By an order of the Commissioners of the National Debt, or by a supplementary statute?

Again, are the certificates spoken of to be compulsory or optional? The suggestion that Poor-law Medical Officers are officers of the State has an ominous sound, and looks very much as if it were intended on the strength of this fact to foist upon these already overworked and insufficiently remunerated officials an additional, responsible, and onerous duty, without asking their consent, and without an adequate compensation. It may be, of course, intended that proper fees for Medical examination should be paid; the Profession, however, have no guarantee that such will be the case, and it is our duty to call their attention in time to the absence of any express provision. We have had occasion more than once in this Journal to remark on the want of common honesty shown by some inferior insurance offices to Medical referees, and it must not be permitted that the proposed measure, which is to have the effect of superseding the resort to such offices, while benefitting the artisan, should prove an iniquitous tax on the Medical Profession.

THE WEEK.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE VI.—FEBRUARY 13.

THE form, arrangement, and mode of succession of the teeth constitutes an important subject of study in connexion with the structure and classification of the mammalia. The teeth of man are composed of the ordinary constituents, cementum, dentine, and enamel, are fixed in alveolar sockets, and consist of a temporary and permanent set, the latter replacing the former vertically. In both jaws the range of teeth form an arch, with the horizontal surface very nearly level, but the planes of the grinding surfaces of the upper molars look slightly outwards, the reverse being the case with the lower ones, so that the inner edge of the upper series and the outer edge of the lower series become worn first. The upper incisors bite in front of the lower ones, and the direction of the axis of the lower canine is slightly in advance of that of the upper. The line of the teeth is unbroken by any such intervals as usually occur in the lower animals.

The teeth are divided, for convenience of description, into incisors, canines, premolars, and molars. The incisors are defined—at least, as regards those of the upper series—as those teeth which are lodged in the premaxillary bone. The suture which limits this bone is soon obliterated in man, but traces of it can often be seen on the palatal surface. The tooth situated immediately behind the premaxillary suture is called the canine, but there is no absolute mode of distinction between it and the succeeding teeth, or premolars. The peculiar form and size is the general test adopted, but this fails in the examination of the dentition of some animals. The molars are distinguished from the canines and premolars by their mode of development; they do not succeed any other teeth vertically as these do.

The special characters of the human teeth are the following:—In the upper jaw the incisors are two on each side, single-fanged, adze-shaped, narrow from before backwards, and with broad, cutting edges; the outer are smaller than the middle pair. The canines are obtusely pointed, wedge-shaped in section, not larger than the inner incisors, with a stout, long fang, which causes a marked projection on the outer surface of the maxilla. The premolars, two on each side, are much like each other, have an elliptical transverse section, fang single or more or less divided, crown with two cusps, outer and inner, of about equal size, though the outer projects somewhat beyond the level of the other. The true molars are three in number; the two anterior of nearly equal size, and the posterior smaller. Their crowns are of quadrate form, with a peculiar pattern on the surface, composed of four projections or cusps at the corners, with a depression between them crossed diagonally by a ridge which connects the anterior internal with the posterior external cusp. This pattern is

less definitely developed on the posterior molar. In the lower jaw the number of each class of tooth are the same as in the upper. The discrepancy of size in the incisors is not so great, and the inner one is the smaller of the two. The canine is not so large as in the upper jaw. The crowns of the premolars are more nearly circular, the inner cusp is considerably smaller than the outer, and generally connected with it by a transverse ridge. The three lower molars have somewhat larger crowns than the upper ones, and have a different pattern on their grinding surface, being divided by a conical groove into four cusps, with an additional small tubercle behind the posterior external cusp.

A representation of the number of the different kinds of teeth in both jaws by means of symbols constitutes what is called a "dental formula." The number and nature of the permanent teeth of man are thus shown by the convenient signs put forward by Professor Owen:—

$$i \frac{2-2}{2-2}, c \frac{1-1}{1-1}, p \frac{2-2}{2-2}, m \frac{3-3}{3-3} = 32.$$

The formula for the deciduous teeth is—

$$di \frac{2-2}{2-2}, dc \frac{1-1}{1-1}, dm \frac{2-2}{2-2} = 20.$$

It will thus be seen that this set, or the "milk" teeth as they are sometimes called, differ considerably in number from those that replace them. They differ also in their characters. In the upper jaw the crown of the first deciduous molar is considerably smaller than that of the second, and is bicuspid. The posterior one has the pattern of a true molar, and is, therefore, more complex than the tooth which succeeds it. The same rule holds with the lower deciduous molars, the first more resembling a bicuspid, and the second a true quinquecuspid molar. As to the order of succession of the teeth in man, the principal point to be noted, in reference to zoology, is that the canine comes into place in each of the jaws before the second molar.

Professor Huxley next proceeded to give an account of the organs and processes of reproduction in man. In the male the penis is external, pendulous, and not fastened by a preputial sheath to the abdomen; the testes are suspended in a well-developed scrotum, and the canal of communication between the abdominal cavity and the tunica vaginalis is completely closed in the adult. The urethra is divisible into—1. An anterior portion contained in the corpus spongiosum, and into which the ducts of Cowper's glands open; 2. A middle or membranous portion; 3. A prostatic portion, which receives the ducts of the prostate gland, the vasa deferentia from the testes, the sacculus prostaticus, a small and apparently insignificant sac, varying much in dimensions, and, lastly, the cystic portion of the urethra, or proper urinary canal, extending from the neck of the bladder to the anterior part of the verumontanum.

It is not difficult to identify certain portions of the male reproductive apparatus as corresponding with some of the female organs: thus the testis and ovary represent each other in the different sexes; the scrotum answers to the labia majora; the glans, prepuce, and cavernous bodies of the penis to the similar parts of the clitoris; Cowper's glands to Bartholin's glands; and the prostatic sac to the vagina and uterus. The prostate is not at all represented in the female, as far as we know at present.

When this problem is prosecuted further by the aid of the study of development, it presents one of the most remarkable instances of unity of plan, with diversity of modification, in the whole animal kingdom. At one period of its existence, the vertebrate embryo appears, at all events structurally, absolutely sexless. The rectum and bladder and reproductive ducts terminate in a common chamber which opens externally. There are two ducts on each side; the inner one connected above with the Wolffian body, the primordial functional kidney. The outer, or Müllerian, duct is a blind canal, connected above with no gland or other organ. Behind the Wolffian body, the true kidney with its duct develops; in

front of it arises another body, which ultimately becomes testis or ovary, as the case may be. In the male, the last-named body gradually acquires the tubular structure of the testis; and the Wolffian body, losing its function as a kidney, becomes converted into the epididymis and coni vasculosi, and its duct becomes the vas deferens. The Müllerian duct remains without function, and is in great part obliterated; its upper part becoming the inconstant vas aberrans, and the coalescence of the inferior extremities of the two forming the prostatic sacculus. In the female, on the other hand, it is in the Müllerian ducts that the greatest amount of development takes place: their upper extremities become the Fallopian tubes; their lower parts fused together form the uterus and vagina. The Wolffian body becomes the quite insignificant parovarium, the lower part being completely obliterated. These transitory conditions of the reproductive organs of the human fœtus are of great interest, as some of them remain more or less permanent among the lower Mammalia.

PARLIAMENTARY.

IN the House of Commons, on Friday, March 4, Mr. Lowe, the Vice-President of the Committee of Council on Education, replied in the negative to a question by Mr. Baines "whether it was intended to introduce any measure to make the law relative to vaccination more effectual."

On the order for the second reading of the Penal Servitude Acts Amendment Bill, Mr. Adderly moved to defer the second reading for six months. The discussion which followed principally turned on the propriety of holding out a hope of the remission of punishment, which, it was urged, made sentences uncertain; and on the clauses contained in the Bill providing for the supervision of criminals liberated upon licence. Sir W. Miles thought that the provisions of the Bill could not be satisfactorily discussed, apart from the subjects of prison discipline, diet, hard labour, and prison rules. From various examples which he quoted, he argued that penal servitude as at present carried out had no terrors.

Sir George Grey urged that most of the objections to the bill might be considered in committee. With regard to the diet of prisoners, he said that a committee had been appointed who were carefully investigating the dietaries in prisons. The amendment was finally withdrawn, and the bill read a second time.

In the House of Lords, on Monday, March 7, the Marquis of Westmeath introduced a bill to increase the penalty in certain cases for the crime of rape. He proposed that where more than one person was engaged in the commission of the offence, the punishment of whipping should be imposed. The bill was read a first time.

In the House of Commons, the most important event of the evening was Mr. Gladstone's speech on the Government Annuities Bill. The object of this bill is to offer Government security to those of the poorer classes of the community who may wish to invest their annual savings in the purchase of a Deferred Annuity for the support of their old age, or in a Life Assurance up to the sum of £100.

The Chancellor of the Exchequer explained the motives which had induced the Government to propose the plan contained in this bill. They had felt it to be their duty, he said, to endeavour to make the provision of law for the protection of small life insurers operative and real. He admitted that a proposal of the Government to undertake any species of business called for the jealous scrutiny of the House, and that cause for it must be shown. The questions were—first, whether there was an evil to be redressed; and, secondly, whether the means proposed for redressing the evil were practicable, and not open to objection. The manner and principle of the remedy proposed were precisely analogous to those of the Post-office Savings banks. He took it for granted, he said, that a great and serious evil existed; and with regard to the remedy, he considered, first, whether the plan was safe; and, secondly, whether it involved injustice to trade. Having demonstrated the safety of the plan, and that it was not difficult in operation, he examined the next question, whether it was unjust to those engaged in the same business,—namely, the principal insurance societies, the minor insurance societies, and friendly societies,—and he proceeded to show from detailed statements that the plan of the Government was a just pro-

posal as respected trenching on the domain of either of those societies. In competition with those minor societies, that dealt in what was termed industrial business, the Government, he said, would possess no other advantage than that of offering a perfect security and certain facilities, as for dropping policies. Mr. Gladstone gave a description, from public documents, of the accounts, operations, and condition of some of the minor insurance societies, existing and extinct; of the vast number of friendly societies, and the number of these that were continually failing, and of the losses of policyholders, presenting an aggregation of evils that called loudly for a remedy. The pressure of these evils fell, he observed, chiefly upon the labouring classes, and Parliament, by its legislation for friendly societies, he considered to be responsible for this state of things.

The point in Mr. Gladstone's very able statement which most nearly concerns the Medical Profession was his answer to the objection founded on the danger of loss from insuring bad lives. He argued:—

“If the assurances are not to exceed £100, they will—with exceptions so few that they may be put out of sight—be those exclusively of the working classes. We exclude children and young persons under sixteen altogether—(hear, hear)—because such lives are of a character admitting of a good deal of uncertainty and fraud, and form a department of business which we do not think it would be wise or safe to undertake. Practically, then, those who insure their lives will be fathers of families, labouring men. Is it very difficult to ascertain the value of such lives? I allege, without fear of contradiction, that it is not. In the first place, we have the means of doing it either through the Medical Profession generally, as far as their certificates are concerned, or through those special Medical officers attached to the guardians of the poor, who are themselves officers of the State. As far, therefore, as Medical means go, we have all that can be desired; but what I venture to say, and say boldly, is this, that although the ascertainment of the value of life in the higher classes of the community is a matter of great subtlety and difficulty, requiring, first of all, the application of the highest Medical skill, and afterwards a jealous scrutiny besides, yet the value of life in the case of a labouring man is a matter of comparatively simple calculation. You have to know three things, each of them easily ascertainable. The first is his age—a matter of fact, and beyond opinion; the second is his employment, also a matter of fact, not of opinion; and the third, is he a sober man, not a drunkard? Of course, I don't say that in every individual case you will know the value of the life, but that you will generally know it quite accurately enough to work your tables. Some time ago I had an opportunity of discussing this point with an eminent member of the Medical Profession in London, himself the consulting Medical officer of two assurance offices. I asked him whether that was the case. He said it was, and he used these words:—‘In the case of industrial assurances we scarcely look at our patients,’ thus distinctly affirming the proposition that in regard to the labouring classes the employment and the general character, as palpably known to all the world, are in the long run a sufficient and satisfactory test of the value of the lives. Then, as to personation, we have some experience already, because we have been working our system of savings-banks for some time, where there is plenty of temptation to personate, and yet not a single instance of it has occurred. My belief is that, comparing the case of a Government department with that of the assurance offices of a large description,—I do not speak of the friendly societies, which are strictly local in their character,—the means we have for ascertaining identity are very superior to those possessed by the assurance offices, because a man who insures with the Government has, in fact, every means of getting his identity tested. The Government knows, with regard to all its business, that it has natural allies in all those persons best acquainted with the condition of the people throughout the country. Take the clergy, the dissenting ministry, the magistrates, the Poor-law guardians, the registrars—I don't speak of the postmasters, on whom it would not be well to depend, for we want them generally for the performance of routine duty only; but with the aid of the different classes of men whom I have mentioned, and last, but not least, with that of the employers of labour, I say it is perfectly easy for the Government to defend themselves against the risks of fraud through personation. Well, it has been carefully considered in what way the system could be worked. I admit that here

we stand in a different position from that in which we are placed under the existing law, where the deferred annuity that is required to be purchased is itself a security. But, undoubtedly, all the inquiry we can make convinces me, in the first place, that the ascertainment of the value of the lives of labouring men is, as a general rule, and with very rare exceptions, a matter easy and simple; and that, with respect to frauds through personation, those frauds are not found to present any vital difficulty in the way of the societies which now exist, whereas, in my opinion, a Government department would cope with them much more easily. As to taking bad lives, consider the case of the existing societies, which have agencies all over the country, and which induce their agents to draw lives into their net by promising them, independently of their other fees, 25 per cent. upon the value of the premiums to be received. It is a matter of fact that there are now societies with their hundreds of thousands of members existing under your auspices, countenanced by you, authorised by you, subsidised by you, as I have shown, who are drawing lives into assurance in connexion with themselves, by giving to their agents, irrespective of certain other emoluments, no less than 25 per cent. of the whole premiums to be paid, which is a larger sum than ought to cover almost twice the expenditure of a sound and well-constituted society. And what is the effect of that upon fraud and personation? I say to an agent—‘Go you round a certain district, town, or village, and you shall have 25 per cent. of all the premiums of the men you can bring into assuring;’ and then I am to expect, forsooth, from that man that he is to be very scrupulous and particular in the selection of good lives. So much for the mere safety of these operations.”

In the debate which followed, Lord Stanley said that he thought Mr. Gladstone had disposed of the question of the value of the lives in a summary manner. He seemed to admit that it would not be possible to have a proper Medical inspection for each person. The line of argument which Mr. Gladstone adopted was that, after all, this inspection was not very material; because, in the case of industrial assurance, given a man's age and employment, and his habits as to temperance or intemperance, we had everything that was material to know.

The Chancellor of the Exchequer disclaimed the intention of neglecting Medical examinations. On the contrary, he said that he had referred to the advantages which might be derived from the Government connexion with certain members of the Medical Profession.

Lord Stanley: The Medical men of the Poor-law Unions. That is a question which may be better dealt with in committee; but when you consider the amount of labour which is thrown on the Medical officers already, and the vast extent of some unions, I am afraid you will find it practically impossible to have any very effective Medical examination by them, putting aside the expense which, in dealing with these small amounts, would be considerable. But as to the principle that the age, the employment, and the habits of a man's life are almost the only material points to be attended to, I hear that stated for the first time. I am not prepared to contradict it. It is not a point on which the members of this House have much knowledge. All I say is, that it is a very broad assertion, a very sweeping assertion, a very novel assertion. We have it at present only on the evidence of the single witness quoted by the right hon. gentleman. I think we ought to go a great deal more deeply and carefully into the matter before taking that which is no doubt believed by the right hon. gentleman for granted, because the question of the healthiness or unhealthiness of lives is of the most vital importance.

After a long discussion on the propriety of Government interference, and the practicability of Mr. Gladstone's scheme, the debate was adjourned.

We cordially agree in the objects of Mr. Gladstone's measure, and hope that the industrious poor may have so great a benefit conferred on them. With regard to the question of Medical examinations, the idea of dispensing with them is utterly paradoxical. We are glad to see that Mr. Gladstone disclaims it. His statement that the principal data necessary in deciding on the fitness of a life for insurance are age, employment, and sobriety, would probably prove true, if the major part of the population were assurers in the Government office. But in the case of a limited number of assurers, such a statement is refuted by the common experience and practice of all insurance offices who think it necessary to employ a

Medical referee. The amount for which lives are to be insured can make no difference in the principle on which they are selected. We only demand, if the duty of examination is to devolve on the Union Medical officers, that they shall receive a fair remuneration for their labour. This point in the measure we have already discussed; but we would especially call our readers' attention to a letter in another part of our Journal, asking for the opinion of Poor-law Medical officers on the whole subject, which should be thoroughly canvassed before the bill goes into committee.

On Wednesday, March 9, Mr. Ewart's Bill, rendering permissive the Metrical System of Weights and Measures, was read a second time. The second reading was opposed by Mr. Walters, who divided the House on the subject, when 90 voted in favour of the second reading and 52 against it. The objections urged against the Bill were that, being permissive and not compulsory, the introduction of two systems of weights and measures would throw the whole trade and commerce of the kingdom into confusion; that it would introduce a foreign system of nomenclature; and that, if decimalisation were applied to weights and measures, it ought also to be applied to coinage, and there was no probability of Parliament assenting to that. The Bill introduces a third unit, the metre—the ten-millionth part of the arc from the Equator to the Pole—into our system of weights and measures, in addition to the two already existing—the yard for lineal measurement, the avoirdupois pound for weight.

Mr. H. A. Bruce moved the second reading of the Cattle Diseases Prevention Bill. After showing, from the returns of cattle insurance offices, the large amount of mortality which had prevailed in the United Kingdom within the last few years—a mortality of cattle, sheep, and pigs representing an annual value of £6,120,000—he proceeded to show that whether the most fatal disease—pleuro-pneumonia—were contagious or only epidemic, it appeared to be transmitted from foreign countries, and propagated through the medium of infected ships, trucks, &c. He also mentioned the mortality arising from other diseases,—the "foot and mouth disease," the "scab" in sheep, and "measles" in pigs. He then notices the effect of diseased meat on the health of the population, and quoted the testimony of Professor Gamgee, Mr. Simon, Professor Maclagan, Dr. Alfred Taylor, and Dr. Letheby, as to injurious consequences occasionally produced by eating diseased meat. Professors Maclagan and Taylor referred to having frequently met with cases in which symptoms of irritant poisoning had followed the eating of meat in which no poison could be chemically detected. Dr. Taylor mentioned two cases of death, one from eating diseased mutton—the sheep having had the staggers—and one from German sausage. Dr. Letheby's testimony referred to the Kingsland epidemic, in which, of sixty-six persons who had eaten certain sausages, sixty-four were taken ill, and one died. Mr. Bruce observed that if diseased meat were not poisonous, there could hardly be a doubt that it was in-nutritious, and the evil arising from its sale fell principally on the poor. He then proceeded to give an account of the previous legislation on the subject, and stated that the object of the present bill was to consolidate and extend the existing law:—

"The bill was divided into six parts. Part I made it an offence—first, to turn out in a common field any diseased cattle; second, to expose for sale any diseased cattle; thirdly, or to place them in a field insufficiently fenced, or take them along a highway without due precaution; penalty for such offences not to exceed £20. It was also provided that if the owner of a diseased animal knowingly sell it to a purchaser, without notice of disease, he shall, in addition to the penalty imposed by the Act, be deemed guilty of fraud in making the sale, and be liable for damages to the extent of the injury inflicted upon the purchaser. The second part repeated and somewhat enlarged the 11th and 12th Victoria, cap. 107, enabling her Majesty to declare certain districts infected, and to make regulations with respect to the removal and mode of disposing of cattle in such districts. The third part was new, requiring every railway or canal company to cleanse the trucks and boats in which they carried cattle—(hear, hear)—and to water the cattle once in twelve hours. (Hear, hear.) He believed there would be no insuperable difficulty in this, and there could be no doubt of the great cruelty and mischief of the existing

practice in that respect. (Hear.) The fourth part was partly new. The 11th and 12th Victoria authorised the appointment of inspectors with powers to seize any sheep or lambs exposed for sale at any market or fair, and to destroy the pens, litter, &c. This Act extended the authority of the inspector to all cattle at fairs or markets which he might examine and exclude. This portion of the bill also defined the local authorities, and provided for their payment. The fifth part made all penalties recoverable in a summary manner. The sixth repealed existing Acts, and declared all Orders in Council now in force not to be affected."—After a short discussion, the bill was read a second time, and ordered to be referred to a Select Committee.

HOW SCOTTISH DOCTORS LIVE.

THE case of *Skene v. Stewart* gives a touching picture of the hardships endured by Scottish Medical men, whilst it arouses our indignation at the meanness of the petty *Lairds* who seek their services and deny them due remuneration. The case was referred from the Stewards' Court at Kirkcudbright to Dr. Macculloch, of Dumfries, from whose able and pungent report, published in the *Galloway Advertiser and Wigtownshire Free Press* of February 18, we extract the following particulars:—

"A country Surgeon, about twenty miles from Dumfries, attended for six months the family of a country gentleman (?—ED.) residing about a mile from the Surgeon's house, and had attended the same family for some time. After the Surgeon tendered his account, which particularises each visit and each medicine supplied from the Surgeon's own laboratory, payment was refused on the grounds that the 'account is exorbitant,' and that 'the medicine as charged is a most ridiculous amount.' The attendance began on December 19, 1862, and ended on June 22, 1863, both inclusive. During that time the Surgeon made sixty-eight visits to members of the family who were ill. For seventeen days during that time he made one visit per day. During twenty-six days he made two visits per day, and during eight days he made three visits per day; seven of the visits were in consultation with a senior Practitioner. During one of the visits he vaccinated several members of the family, during another he was detained all night, and six of the remaining visits were made after 10 p.m. and before 6 a.m. Every visit is charged 5s., with the exception of one visit, during which he was detained all night—that one is charged 7s. 6d. That is to say, the visit when the family was vaccinated and those betwixt 10 p.m. and 6 a.m. are charged neither more nor less than those during the day—viz., 5s. for each visit. During the said attendance the Surgeon dispensed to the gentleman's family forty-six powders, for which he charges 2d. each, twelve pills, for which he charges 4d., three plaisters for which he charges 6d. each, and five bottles, called mixtures, for which he charges respectively 4½d., 5d., and 8d. per ounce. One of these bottles is put down as a four ounce mixture, three of them two ounces, and one of them one ounce mixture. The four ounce one is charged 4½d. per ounce, the two ounce ones 5d. per ounce, and the one ounce one 8d. per ounce. The particular drugs contained in the powder, pills, and mixtures are not specified. The whole account amounts to £25 1s. 6d."

We cannot see how a Professional man can justify himself for charging so little. To remain all night for less than a guinea; to vaccinate several members of a family for nothing; to attend consultations and pay visits at night without extra fee, is simply to rob himself and establish a precedent for robbing his brethren. And it is of no use to commit such a mean act of self-sacrifice. It is like the old attempt to bargain with the devil. You may give him all your earthly goods and leave yourself stark naked, and then he will insist on having your skin. So the Laird, when he received poor Dr. Skene's miserable charges, emboldened to attack a man who, as no doubt he felt, had made charges scarcely consistent with self-respect, replies thus:—

"Your account is most exorbitant. I am advised to make you an offer of 2s. 6d. each visit, allowing a double fee for all calls made after 10 p.m. Upon these terms I will settle your account at once, and also pay the medicine as charged, although I consider it a most ridiculous amount. I may remark that I can prove that you have charged a day's visit that you did not make; this being the case, it is quite likely that you may have made other similar charges. I may also remark that I

do not think there is another Medical man in Scotland would make seven visits in two days and charge for them all."

Dr. Skene applied to the Stewards' Court; and the case was referred to Dr. Macculloch, whose "report" gives a most masterly solution of several questions which are often raised, such as—"Ought Medical men to have one scale of charges, or many?" "Ought a Practitioner to charge for every visit; and ought he to be paid for medicines?"

"It is well known (says Dr. Macculloch) that Medical men, especially in rural districts, must, of necessity, attend upon all classes of the people, high and low, rich and poor. It must be obvious, therefore, that they must adopt their charges for professional services to the status and means of their patients, and often to the different means of persons of the same status. This necessarily implies a maximum and minimum charge for the same service, according to the means and status of their employers, providing such charges are, in the words of his Lordship, the learned Steward-Substitute, 'fair and reasonable.' That there are fixed fees in several branches of the law I do not consider decisive of the point. As life and health are infinitely more important than property, as disease is much more rife than legal disputes, and as these fixed scales of legal fees, *de facto*, prevent persons of small means from going to law, even in many cases of great hardship, the analogy does not hold good. No doubt if a man is a pauper he can prosecute a law plea in a Peter Peebles *v.* Plainstones sort of way, but if he cannot constitute himself a pauper the man of small means cannot go to law. Not so in medicine; the doctor is morally and socially constrained to give his services to all, and in far more cases than the public conceive gets no fee at all. What then? The doctor must live, must keep up a certain status, and, like other men, endeavour to save a competency for old age and for his family, and for this the rich and upper classes must pay, otherwise they would soon have either no Medical advisers or those who would be worse than none."

"As to the defender's objection and reproach in regard to seven visits being charged in two days (continues Dr. Macculloch), it could only have been relevant if one or more of these visits were unnecessary or unexpected, which, for the above reasons, is improbable. Medical visits, *qua* employment and remuneration, are a mere matter of business, and have no claim to be considered as matters of feeling and generosity, excepting in regard to the actual or comparative poverty of the employer when such is the case. So far from numerous visits in one day being charged less, or not at all, they ought, in justice, to be charged more and more after the first and second—*i.e.*, assuming that they are absolutely necessary in a dangerous case, or that they are made under the instructions, direct or implied, of the employers, because such frequent calls upon his time in any one case are not only irksome, but interfere with and disarrange the Practitioner's duties to his other patients, often deprive him of other cases and families, and but too often cause him to travel and visit at untimely hours. The same also with regard to consultations; Medical men are constantly liable to sudden calls to cases of emergency: the time for consultations must be fixed some time beforehand, and it often, therefore, becomes either a loss or a great inconvenience. Consultations also, in general, consume more time than an ordinary visit.

"As to charges for medicines, a druggist either receives ready money over the counter, or trusts only those whom he can safely credit for the medicines he dispenses. The Medical Practitioner, however, who dispenses medicines to his patients (and those in rural districts are almost necessitated so to do), must give these medicines to a great many of those patients who he knows do not or cannot pay him for either medicine or attendance. The druggist can, therefore, afford to dispose of his drugs at a cheaper rate than the dispensing Medical Practitioner, who, were he not to charge higher than the druggist, must of necessity lose money by dispensing drugs. The prices charged by the pursuer, therefore, for drugs, are, in my opinion, fair and reasonable; and how the defender can declare that about 14s. is 'a ridiculous amount' for the drugs prescribed and supplied during an attendance of about six months on a family, one of whom is admitted to have been long 'dangerously ill,' is to me incomprehensible, excepting upon the supposition that the defender has some secret grounds for refusing payment. I have assumed that the defender is a country gentleman, living as such, and possessing sufficient means for so doing; and yet, although I am not informed by the record, or otherwise, it is possible that he may

be in straitened circumstances. If so, had he said or hinted to the pursuer that the sum total was more than he could afford, as a matter of Professional honour and custom, it would have been morally incumbent upon the pursuer to have modified his account accordingly."

"On Dr. Macculloch's report and production being lodged (says the *Galway Advertiser*), decree was pronounced in the pursuer's favour for the balance of his account, interest, and expenses of process, the Steward-Substitute remarking with reference to the duty performed by Dr. Macculloch, that it was performed with much anxiety and care."

We venture to add that we thank Dr. Macculloch for having shown the true position of our Profession so fully and so ably. We wish that his observations were collected into a little pamphlet, and that every Medical man in the kingdom would enclose one to each patient to whom he sends his next account for charges and fees.

CHARGE OF MANSLAUGHTER AGAINST A HERB DOCTOR.

THE following are the particulars of a case tried at Durham before Mr. Justice Willes on March 2. It illustrates the repugnance shown by juries to convict illegal Practitioners even on what seems to be the plainest evidence. If a charge of malpraxis be brought against a regular Practitioner, we seldom find that he receives any undue consideration at the hands of the Court; but it would seem that juries hold the ignorance of the quack to be what the French call an "extenuating circumstance," and make it a ground of acquittal. In this case, judging from the published reports, the verdict seems to have been clearly contrary to the evidence and to the judge's direction:—

The prisoner, a man named Joseph Levy Markuss, kept a shop in Sunderland, where he passed as a herb doctor, or "herbalist." Being acquainted with the deceased, Jane Sumbly, who also kept a shop in Sunderland, he chanced to call on her on Sunday, the 6th of September last, and found her labouring under the effects of a cold from standing in the market. She complained to him of pains in her back, and appeared to have been ailing for some days. The prisoner volunteered to prescribe for her, and sent her daughter for 6d. worth of pale brandy in a 6oz. bottle. Into this he put about an ounce of meadow saffron seeds, known medically as colchicum seeds, first bruising them, and directing the deceased's daughter to place the bottle before the fire for two hours, and then shake it up and give her mother a tablespoonful. The daughter did as directed, giving her mother a tablespoonful about 2 o'clock on Monday, the 7th. The deceased became ill and sick shortly after, and, after taking some tea at 4 o'clock, vomited violently, and continued at short intervals vomiting and retching till she died exhausted at 10 o'clock on Wednesday morning. Dr. Natrass was called in on Monday night, and prescribed for her two opium pills of a grain each, and next day gave her small doses of prussic acid and soda to allay irritation, and directed her to have soda water and milk, weak brandy and water, and lemon juice and water to allay her thirst, and arrowroot and weak brandy and milk as sustenance, but her stomach was so irritable it would retain nothing, and on Tuesday he ordered her an injection to sustain vitality. While attended by her daughter and neighbours, it appeared that she had several times taken small quantities of brandy neat to try and stop her sickness, and had also taken some "nerve powder," which a neighbour recommended. This powder, when analysed, was found to consist of valerian, skunk-cabbage, gentian, ginger, and some other ingredients, harmless in themselves, and which would act as a stomachic in ordinary cases. A post-mortem examination was directed by the coroner, and the deceased's internal organs were found to be healthy, with the exception of the heart, which showed slight symptoms of fatty degeneration, and the stomach, the internal coat of which was of a violet colour from intense inflammation. She had died from gastritis, or inflammation of the stomach, which the Medical men who attended her attributed to the overdose of colchicum seeds she had taken by direction of the prisoner. The bottle in which was this mixture was delivered up for analysis to Mr. Pattenson, the analytical chemist, of Newcastle, who found it to be brandy and colchicum seeds. Two grains of colchicum seeds, in the form of tincture, was a dose. A teaspoonful of the mixture would contain 18 grains, and was a fatal dose,

and a tablespoonful contained 80 grains. This was a highly poisonous and fatal dose, the drug being a narcotic irritant poison. In the judgment of the Medical men this was the cause of death. The counsel for the prosecution, in his opening, drew attention to the law, which made no distinction between regular Practitioners and quacks, both being responsible for culpable and gross negligence, and liable to be indicted for manslaughter if by culpable and gross ignorance or negligence they were the cause of the death of a patient, and submitted that it was some evidence of culpable negligence if a man, being an irregular Practitioner, and ignorant of the qualities of a dangerous drug, yet undertook to prescribe it in quantities dangerous to life, and if such an act led to fatal results he was amenable to the charge of manslaughter.

The defence urged was that when analysed the infusion, or tincture of colchicum, had become much stronger than when administered to the deceased, and that it was the continued doses of brandy, and the nerve powder, acting on a stomach attacked by gastritis from cold, which had increased the disease by increasing the inflammation, and had thus caused death.

His Lordship, having summed up the evidence, directed the jury as to the law. Every person who dealt with the health of others was dealing with their lives, and every person who so dealt was bound to use reasonable care, and not to be grossly negligent. Gross negligence might be of two kinds, and in one sense,—where a man, for instance, went hunting and neglected his patient, who died in consequence. Another sort of gross negligence consisted in rashness, where a person was not sufficiently skilled in dealing with dangerous medicines, which should be carefully used, of the properties of which he was ignorant, or how to administer a proper dose. A person who with ignorant rashness, and without skill in his profession, used such a dangerous medicine acted with gross negligence. It was not, however, every slip that a man might make that rendered him liable to a criminal investigation. It must be a substantial thing. If a man knew that he was using medicines beyond his knowledge, and was meddling with things above his reach, that was culpable rashness. Negligence might consist in using medicines in the use of which care was required, and of the properties of which the person using it was ignorant. A person who so took a leap in the dark in the administration of medicines was guilty of gross negligence. If a man were wounded and another applied to his wound sulphuric acid or something which was of a dangerous nature and ought not to be applied, and which led to fatal results, then the person who applied this remedy would be answerable, and not the person who inflicted the wound, because a new cause had supervened. But if the person who dressed the wound applied a proper remedy, then, if a fatal result ensued, he who inflicted the wound remained liable.

The jury retired to consider their verdict, and, after being absent for some time, returned with a verdict of "Not Guilty."

FROM ABROAD.—HOW TO PREPARE A NEW EDITION—THE PARIS ASSURANCE CASE—REPREHENSIBLE HUMANITY—VIVISECTION IN PARIS—NERVOUS SYSTEM OF PULMONATED GASTEROPODS.

The following seems a somewhat ingenious mode adopted by Dr. Gaetano Strambio, of Milan, for securing the materials for a new edition without too much trouble on his own part:—"A Circular to the Cultivators of Anatomical Studies. Being about shortly to prepare a second edition of my '*Treatato Elementare di Anatomia Descrittiva e di Preparazioni Anatomiche*,' in order that I may render it less unworthy of the favour which it has met with, I venture to request that all the cultivators of anatomical studies, whether in Italy or abroad, will carefully bring under my notice a *succinct* account of the results of their more recent labours and discoveries. I shall also feel singularly grateful to those who will point out to me faults in my first edition, and favour me with their advice concerning the second, as also to those journals which reproduce these requests.—GAETANO STRAMBIO."

The Paris assurance case has advanced another stage, and Dr. C. de L., the homœopathist, charged with the poisoning of his mother-in-law, and of a young woman whose life he had insured for 500,000 francs, will be put on his trial in April. M. de Gouet, "*juge d'instruction*," has caused various experiments to be made in relation to this case.

Digitaline, it seems, has been detected in the dejections and stomach; and one of the experiments consisted in poisoning a pigeon by the scrapings of the floor upon which some of these dejections had fallen. Other experiments have been performed upon frogs. The heart of one of these reptiles was carefully laid bare, the frog living a considerable time without any sensible disturbance being produced in its vital functions. Upon the heart of another frog similarly exposed a drop of digitaline was allowed to fall, with the effect of diminishing the movements of the organ, its pulsation becoming slower, and the animal rapidly dying. To the heart of a third frog a minute portion of the dejections was applied, and the same results were observed as in the second frog. The pulsations became almost imperceptible, and death speedily followed. The two latter frogs had already died while the first continued alive, no notable disturbance having been produced in the movements and pulsations of the heart.

We read this in the Paris Medical journals:—

"A young woman was brought into the Beaujon Hospital in the last stage of croup, asphyxia being far advanced, and death imminent. M. Morel-Lavallée immediately practised tracheotomy, and the canula had been inserted, when, after several paroxysms of coughing, respiration became completely suspended. All other means of re-establishing it having been tried in vain, M. Morel-Lavallée suggested the employment of insufflation by means of the canula, and M. Magnié, a pupil, though well aware of the danger to which he exposed himself, at once applied his mouth to the canula, and having made insufflation, quitted the canula, his mouth covered with blood, and mucosities issuing from the air-passages. M. Moutard-Martin at once employed himself in washing the face of his courageous pupil, and made him gargle himself; but while he was so engaged, three other of his pupils, MM. Bessey, Delfau, and Blumenthal, also devoted themselves to this task, together with M. Magnié, who, in turn, renewed the attempt. Finally, Dr. Raynaud, distinguished by his success at the concours, persevered with the same courage, which, however, proved fruitless. Strange, indeed, although consoling, was it to witness these young men, with blood-bespattered mouth and face, thus confronting, with an eagerness that does not wait to calculate, the formidable danger which may arise from insufflation performed under such conditions. Informed of this incident, the *Directeur de l'Administration de l'Assistance Publique* repaired to the Beaujon in order to thank the students for their devotion. We are informed that he felicitated them with having comprehended that a Hospital is at the same time a school of science and of humanity, declaring that the Hospital administration and the Profession would indeed feel proud of such auxiliaries. He recommended them to carry with them into their daily practice, if not the impulse of such great days, at least those dispositions of exactitude and kindness which contribute so powerfully to the well-doing of patients."

One cannot but admire the devotion to humanity displayed by these young men; but surely we must regard it as misplaced, and not calling for imitation. In fact, we consider the conduct of M. Morel-Lavallée in encouraging, or even permitting, the proceeding as reprehensible. Here we have a patient in as nearly a hopeless state as can be imagined, and with the bare hope—for this is all that could be reasonably expected—of prolonging life a short time, four or five young persons risk their lives in the performance of a disgusting operation. We say risk their lives, because, whether definitively proved or not, the belief is firmly held in France, founded on cases of no distant occurrence, that the excreta from diphtheretic or croupal air passages may impart fatal disease by coming in contact with the healthy buccal membrane. These students were sent by their friends to the Hospital in order to study the practice of their Profession, and to learn how to succour suffering humanity by all legitimate means; but surely a grave responsibility rests with those who encourage them to these "sensation" procedures, which might end in the loss of lives far more valuable to society than those sought to be saved by means which have not even the probability of success in their favour.

Some friends of humanity in Paris, not content with the in-

conclusive decision of the Academy of Medicine respecting vivisections, have petitioned the French Senate in the matter, but with very indifferent success. Nay, worse success than at the Academy, for while in this learned body there were members who admitted and denounced the cruelties that are, or were, practised, in the Senate, composed exclusively of laymen, and comprising several members of the French Society for the Protection of Animals, not a word to this effect was uttered. The reporter on the petition denied the existence of abuses, and declared (as is true enough) that the whole subject had better be left to the sense of humanity entertained by the Profession than that any attempt should be made to institute a supervision which might prove mischievous to the interests of science and progress. From expressions in the report and in the discussion which followed, it was evidently very repugnant to follow the suggestions made in so offensive a manner by the London Society, which by the injudicious mode of its intermeddling has done more harm than good. More than one speaker also exposed the inconsistency of lessons in humanity being so liberally furnished by a nation which delights in dog-fighting and boxing. The Senate, however, thinks that there is indeed room for amendment with respect to the practising of operations upon living horses in the veterinary schools.

At the Académie des Sciences, M. Blanchard has read a favourable report upon M. Salvator Trichese's minute preparations of the nervous system of the pulmonated gasteropods. M. Jacobowitch, some time since, demonstrated that the cerebro-spinal nervous system of the vertebrata really consists of three different descriptions of cells. From one of these the fibres are principally produced which constitute the anterior or motor roots; and from another the fibres which especially form the posterior or sensitive roots; while from others, termed ganglionic, prolongations occur, which, together with variable proportions of the two first, constitute the nerves. Since then, fibres of various descriptions have been met with in invertebrata; and now M. Trichese exhibits certain delicate preparations, exhibiting the very complex structure of the principal ganglions in several pulmonated gasteropods. He demonstrates in these medullary centres three kinds of cells perfectly distinguishable—large rounded cells, smaller and pyriform cells, and minute cells, without any distinct wall.

SECOND IMPRESSIONS OF THE BRITISH PHARMACOPŒIA.

By A CHEMIST.

(Continued from page 237.)

"THE people of these countries," says an old writer, "God be thanked, will not drive; they who wish to rule them must try to lead them." The preface to the British Pharmacopœia concludes with the following words:—"The Council warn all Apothecaries and Pharmaceutic Chemists that, on the publication of the British Pharmacopœia, it will be necessary, in order to discharge safely their duties to the public, that they should duly alter or destroy all Pharmaceutic preparations made according to previous and now altered formulæ. The Council must further caution all Medical Practitioners, whether at home or in the colonies, or in the public services, that, in order to exercise their Profession safely, it is incumbent on them to make themselves familiar with the changes effected by the present work." This language has naturally given very general offence. To justify it, the most stringent legislative enactments, enforced by pains and penalties, ought to have been secured. The British Pharmacopœia possesses no legal authority whatever, and the only privilege the Council have obtained by the expenditure of many hundred pounds on an Act of Parliament, is to throw the odium of a great overcharge in the price of the book on the Lords of her Majesty's Treasury. The Act merely gives to the *new* the authority possessed by the *old* pharmacopœias—that is, just *none at all*.

If, however, we interpret the above passage most charitably, and as intending only to convey *advice*, not to dictate, it affords a curious, though far from singular, illustration of the utter ignorance of business and the common affairs of life of men

like the members of the Council. Are there not thousands, perhaps tens of thousands, of prescriptions embracing the old formulæ in the hands of the public in constant and daily use? In what way is the dispensing druggist to deal with them when all his preparations are altered or destroyed? Moreover, is the Medical Council really unaware of the change effected in the Profession since the year 1815? Do they not know that the Practitioners, called Apothecaries, treat patients, prescribe, as well as prepare their own medicines, and, therefore, have no more to do in the way of obeying the injunctions of the Pharmacopœia than of the Nautical Almanac?

At the most, all that can be done by Pharmaceutics whose trade consists of preparing the medicines prescribed by Physicians and pure Surgeons, is to add to their already crowded and groaning shelves the few new forms of the British Pharmacopœia to be ready for a stray prescription or two written by the Council and their friends. But we find on inquiry that even this will entail on him a loss, as the Profession show no signs of recognising the work. They do well, as the more closely it is examined, the more faulty it appears, and we are much mistaken if it is not found necessary, as we have already suggested, at once to suppress it.

Were the Medical Council a representative body, elected by the Profession, every man whose name is on the authorised register would in a measure participate in the discredit of their egregious failure in the attempt to frame a Pharmacopœia. Happily it is not so. The Medical Council refused or neglected to take the advice of the Profession, or to secure the information they might readily have obtained had they invited it, and they must themselves bear as best they can the blame and censures pouring in upon them from all quarters. We should think that every member of the Medical Council must blush and his ears tingle when he hears the ironical praises and ludicrous exposure of their many mistakes by Mr. Theophilus Redwood, before an audience of druggists' apprentices, at the Pharmaceutical Society's rooms, amid loud and reiterated plaudits. We are truly sorry for all this, but we trust the lesson will not be lost on those most concerned. The character and dignity of the whole Profession is at stake, and steps must be at once taken to repair the blunder.

Never was the wisdom of the proverb *ne sutor ultra crepidam* more forcibly illustrated than in this case. A body of men, every one of whom we must acknowledge to be most estimable in their private character, and in professional and social status without reproach, undertake in their corporate capacity to deal with a subject of which they know little or nothing; thus exposing the Profession to which they belong to obloquy and ridicule.

Is this deserved or not? Let us see. We are almost ashamed to remark—so trite and well-known is the fact to everybody, except, as it would appear, to the Medical Council—that very many substances used in medicine are also employed in the arts, and are consequently manufactured in very large quantities. The manufacturers engaged in their production employ processes which they do not make known to the public. Many make only one or two such substances, and their success depends upon the economy of the process and the perfection of the result. The chemist in his experimental laboratory can produce any chemical substance, but only at a cost far exceeding the manufacturer's. Thus we have all the following as articles of commerce:—

Acids.—Acetic, glacial acetic, arsenious, citric, gallic, hydrochloric, nitric, sulphuric, sulphurous, tannic, tartaric. Ammonia; white bismuth; sulphate of copper; potash solution; permanganate of potash; carbonate of potash; nitrate of potash; chlorinated soda; magnesia—acetate, carbonate, oxide, sulphate, and chloride of zinc, etc.

The pharmaceutical chemist never dreams of making these—if he did, he could not do it successfully. The Medical Council occupy the Pharmacopœia with processes which are equally useless to him and to the manufacturer. Hence we ought to feel no surprise that in by far the greater proportion of these cases the methods and directions given will either not produce the desired substance at all, or do it in a most imperfect and expensive way.

Again, a great number of other chemicals have been long and in very general use. The same principle is applicable to them. They are not made by the *pharmacien*, but by manufacturers, and the articles they bring into the market are in all respects better than could be made with any amount of skill on a small scale. Thus, in the whole British Empire we doubt if there are more than two or three manufacturers of quinine. A few more may be occupied in producing all the

vegetable alkaloids. Operative chemists and smaller manufacturers also, in a great measure, make a speciality of producing and furnishing the market with the following:—Benzoic and phosphoric acids, ether, spirits of nitrous ether, nitrate and oxide of silver, calomel and corrosive sublimate; chloroform; collodion; the iodides of mercury; iodine—chlorate, bicarbonate, sulphuret, acetate, sulphate, iodide, and bromide of potash; soda, and its salts.

Now surely it was not the business of the Medical Council to write a book on manufactures. If they thought themselves called upon to instruct either the manufacturer or the chemist, they have sadly mistaken their vocation. There are, indeed, a few preparations having a certain semblance to definite chemical compounds, but which are in reality not so, and they can be made of such various composition, yet having the same physical appearance, that no testing short of quantitative analysis will enable us to determine whether they are properly made or not. Such are the pseudo-crystalline citrates of iron, citrate of iron and quinine; various granulated preparations, etc.

It seems, therefore, as fitting to give formulæ for these as for mere empirical mixtures; but, as might be anticipated, those in the Pharmacopœia are far from satisfactory. It is far different with definite chemicals,—the method by which these are made must be entirely a matter of indifference provided they prove, on the application of the proper tests, to be what they profess, and of the closest attainable degree of purity. This is partly recognised in the list of *Materia Medica*, which ought entirely to supersede the formulæ by accurate definitions, and an enumeration and description of tests. So far as it goes, the *Materia Medica* is tolerably satisfactory in this respect. Errors may be pointed out—*ex gr.*, no notice is taken of the well-known fact that most of the ammoniacal compounds of commerce are contaminated with minute quantities of offensive matter, owing to their being derived from the residues of gas works. These impurities adhere tenaciously to every preparation made from commercial ammonia, and render them unfit for internal exhibition. But there are well-known makers of ammonia and its salts who evidently go to another source for their materials; and they, as a matter of course, command the market with the better class of pharmacists. Surely some notice ought to have been taken of this.

It is by attempting to give directions for making chemicals mainly that the British Pharmacopœia is open to fatal objections. Thus, the form for *Acidum Aceticum Glaciale*, a perfectly useless article as a therapeutic agent, cannot be followed at all, or if followed will not produce it.

Acidum Nitricum is ordered to be made from nitrate of potash, and to be of such a strength that the product is a fusing, yellow, changeable, and useless article. Commercial nitric acid is colourless, stable, gives off no vapours, is strong enough for every purpose, in pharmacy or therapeutics, and being made from nitrate of soda, is far cheaper, *vide infra*.

In the directions for preparing *Hydrochloric Acid* it is forgotten to be added that heat must be applied to the materials in the retort. Another proof of what we have already alleged, that the work has been most loosely and carelessly edited.

Among the many chemicals which either cannot be produced at all, or very imperfectly, by the processes given we may enumerate sulphuric acid; nitrite of potash; carbonate of potash; tartarised iron; spirit of nitrous ether; and even pure distilled water.

The consequences of all these mistakes and errors it may be said are of no importance, because no *pharmacien* will follow the directions or attempt to make what he can buy so much cheaper and better from manufacturers.

This excuse will not do. We have to point out one instance of a mistake of a most serious nature. Among the processes we have one at page 168 for making nitric acid. If we turn to the *Materia Medica*, page 8, we find that the nitric acid made officinal by the British Pharmacopœia is to have the specific gravity 1.5. Such an acid can readily be made. The manufacturer can supply it of that strength. Two results follow. First, such an acid will, with sulphuric acid, make a gun cotton indeed, as is ordered at page 403; but there are many kinds of gun cotton, some soluble, others insoluble, in ether and spirits. The only purpose of the gun cotton ordered by the Pharmacopœia is for making collodion, as at p. 198. But that made by the process given will not dissolve in the ether and spirits, and is consequently useless. This, however, is a trifle. It is absurd enough, but of no further moment. A far more serious consequence flows from the

ordering of nitric acid to be of the specific gravity 1.5. Such an acid contained in a bottle and packed in dry straw, hay, flax, tow, etc., will, if the bottle is broken, *set it on fire*.

In hundreds of cases will nitric acid of the British Pharmacopœia strength—*i.e.*, sp. gr. 1.5—be ordered for the country to go by railway, and for exportation to be conveyed by ship, and in every such case if by accident the bottle containing it is broken a conflagration will be the inevitable result. It is far more dangerous than gunpowder, which requires at least a spark, whilst this will produce spontaneous combustion.

Let insurance companies, railway managers, and shippers look to this. We give them due warning. This is no imaginary alarm, intended to frighten the timid. Two cases have occurred. In one instance some bottles of nitric acid of the Pharmacopœia strength were sent in a package to be shipped abroad. One of the bottles was broken while the package was in a barge on the Thames; it took fire, and was luckily extinguished. The shippers paid upwards of £100 for the damage done. In another case a package was ordered to be forwarded to the country. The acid was spilt, and set fire to a railway truck.

Will the Government permit the Medical Council to adhere to their new Pharmacopœia? If so, we shall hear of abundant cases of spontaneous combustion. But as this touches property, and not merely the lives of men, women, and children, it will soon be authoritatively corrected. Suppose it is not, not a ship can go to sea in safety, not a goods train on a railway but may catch fire from this cause.

We propose in another paper to offer a few remarks on the pharmaceutical and empirical formulæ of the British Pharmacopœia, together with some suggestions for the composition of a national work. We protest against the insidious advice given to the Medical Council to issue another edition of the present. Is not its title a misnomer? We are accustomed to call our country Great Britain and Ireland. The epithet "British" seems to exclude its application to the sister country; and Colonel Dunne may with some reason make it out an Irish grievance. Nothing short of the entire suppression of the British Pharmacopœia will meet the exigency, and the production of a new work under another title. Any attempt to patch up the present, with the aid of the same persons employed on this work, will of necessity fail.

The Medical Council, we are sure, will not be thus misled. If ever a set of men could afford to admit having erred, and frankly to take measures to correct their errors, the members of that body are the men to do it. They will see at once, on reading the comments and criticisms to which that book has been subjected, that it is to the Profession at large they are to look for the information to embody in a new Pharmacopœia worthy of their vocation and station. The botanist may help them to a correct description of the plants yielding medicines. The chemist may guide the processes required in dealing with substances belonging to his science. The pharmacist may tell them the best method of compounding and preparing materials not amenable to chemistry; but the practical Physician alone can select, arrange, and characterise the agents useful in the treatment of diseases. Happily the country abounds with such, under various names, indeed, but all animated by one spirit and one aim, to advance and dignify the noble profession which they practise. We believe it has been a radical mistake of the Council to consult and defer to the opinions of persons either not belonging to the Profession or members who are committed to crotchets, which would not stand a moment were the testimony and opinions of the majority sought and listened to. Hence they were misled into attempts to describe the processes not belonging to them or to pharmacists, but to manufacturers or chemists. It would have been a perfectly logical and consistent sequence to have given directions for cultivating the plants adopted in their lists, and to have filled the book with agriculture, gardening, descriptions of manuring, ploughing, etc., or instructions in metallurgy and the fictile arts for making the vessels in which the processes of pharmacy are carried on.

(To be continued.)

TYPHUS FEVER AT CARLISLE.—Dr. Wheatley has made out a comparative return of the fever cases taken to the Fever House in the past quarter and in the corresponding quarter of last year. In last year's quarter there were nine cases of fever and one death; while in the past quarter there had been twenty-six cases, five of which had resulted in death, and three were not expected to recover.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF STAFFORD.

(Continued from page 263.)

ASYLUMS FOR THE INSANE.

THE COUNTY LUNATIC ASYLUM.

WHATEVER other disadvantages Stafford may labour under, there are very few towns that have so admirably conducted an asylum. The County Lunatic Asylum, situated about a quarter of a mile from the town itself, affords accommodation for 500 inmates. It is a noble building, and is as perfect in its internal arrangements as in its external appearance. Through the kindness of Dr. Bower, the Superintendent-in-Chief, I was enabled to make a careful inspection of every part of the Asylum, and was supplied with numerous particulars of great interest to the Profession at large.

Ventilation—Aden's System.

Not to dwell on the arrangements of the various wards, I may begin by referring to the system of ventilation. This is artificial, and is framed on the plan known as "Aden's." The air is forced in from the lower part of the building by means of steam, and steam is allowed to mix with the air on its entrance. Thus charged with moisture, the air is conveyed through iron shafts to all parts of the building, and enters into the wards and rooms at the *upper part* near to the ceiling. It escapes by a series of openings into shafts of similar size and construction at the *lower part* of the wards or rooms, and is drawn into a common shaft, situated at the upper portion of the building, by means of a fire shaft, so as to ensure for it a constant current and exit. The system works well, and I note the fact specially because it is almost the only plan of artificial ventilation which can be seen in *effective* action. In principle this ventilation is analogous to that known in Paris as "Duvour's method." The differences are two in number. In Duvour's plan, instead of the fire shaft in the upper part of the building, there is an immense cistern of hot water, which causes sufficient radiation of heat to produce draught, and at the same time affords a current of hot water, which, passing downwards through pipes, gives warmth to the various apartments. Warming is in this way combined with ventilation, a combination that is not attempted in Aden's system, the warmth of the establishment being provided for by the open fire grate. Again, by Duvour's plan the air is not admitted with steam, while in Aden's plan steam enters with the air. I was anxious to learn whether any of those evils common to the German method of driving heated air through iron pipes, and to the method of heating with iron stoves, were presented; I allude to the mischiefs arising from extreme dryness of the air and from the diffusion of minute particles of iron. On inquiry, I found that these evils were not present, and certainly it would be impossible to imagine in any room a purer and less objectionable atmosphere than that in the wards of the Stafford County Asylum. I think we may safely conclude that the English system is the best, and perhaps we may attribute its success to the admission of water vapour with the air, and to the fact that warming is effected by the open fire grate. The object of letting in the air at the upper part of the rooms and of letting it escape at the lower, is to allow the current of air, in passing, to sweep away with it all offensive matters, and to keep pure that portion of air in which the patient is placed.

Baths.

There is an improvement in the Stafford County Asylum in the construction of baths. These are made of cast-iron instead of wood, tin, or earthenware. They are painted on their inner surfaces, and are not only very clean, but exceedingly durable. They are extremely economical in the long run, and for large establishments are preferable to the other kinds of bath. The Profession is indebted to Dr. Bower for this improvement.

Beds and Bedsteads.

The *beds* are of horse-hair, and there is a method for changing the webbing which is gaining favour in other asylums, and which might advantageously be introduced into Hospitals generally. The webbing, of strong cloth, is not permanently attached to the bedstead, but can be removed altogether, whenever it is dirty or saturated with fluids, and replaced in a few minutes. The webbing is tightened up to any convenient tension by means of screws, which are worked from the outer edge of the bedstead on each side.

Decorative Art.

The Asylum is like a palace in respect to its decorations. Real palaces may be immensely more costly, but could hardly be more artistic. Every available space is occupied by some artistic production that is at once pleasing or instructive. Pictures line every wall, flowers are in abundance, and, in some of the larger corridors, doves and other birds and animals are allowed to live in large handsome cages. The mouldings, also, of the walls, the colouring, and the cornices are simple and yet very pretty. In a word, for cleanliness, purity of air, and embellishment, nothing is left to be wished for; and if the inmates who are thus nourished through the senses are not, as Wordsworth puts it—

"healed and harmonised

By the benignant touch of love and beauty,"

their malady is confirmed indeed. The governors of the Stafford County Hospital should step across to the Stafford County Asylum; they might gain a whole forehead of wrinkles for their trouble.

The Asylum Farm—Value of Sewage.

Those of our brethren—and there are not a few of them—who blend the pursuit of agriculture with the art of Physic should see the small farm that is connected with the Asylum, and which is farmed on model and economical principles by Dr. Bower. The farm, worked to a great extent by the inmates, yields valuable contributions to the house, and they have been greatly increased of late by the utilisation of the sewage. The sewage of the Gaol is now also collected in the Asylum tank, and is applied, with that from the Asylum itself, to the farm. The excretes from 1400 persons are thus utilised. The whole is first received into an immense tank, and is diluted in 1800 parts of water. Thus diluted, it is applied in limited dressings over the land, which, by the way, is all pasture land. Two tons of grass per acre is the produce—an increase double what the land would be worth, for grass, if the sewage were not utilised as it is. Dr. Bower is of opinion—and his practical and careful experience is of much value in this matter—that the dilution of the sewage, and the employment of it in moderate quantities, are all-important as means of success. In this point of view his observations tend strongly in favour of the correctness of Mr. Ellis's method for the employment of the sewage of London.

PRACTICE OF THE ASYLUM.

In the practice of the Asylum non-restraint is now carried out so fully that even seclusion and the use of the padded room are ignored. No patient has been shut up for two years past. The cases admitted are numerous in type; but unusually large numbers of sufferers from insanity and general paralysis are present. Acute mania affords the greatest number of cases; ordinary mania the next largest, and dementia the next still. Instances of puerperal mania are much more frequent than would at first be supposed; no less than fifteen females having been admitted for this complaint in the year 1862 alone. The connection of disease of the body previous to the development of mental disorder is broadly marked. Thus in the year 1862 not more than twenty-eight patients, out of two hundred and twenty-six admitted into the house, were pronounced, on entry, as in "good health and condition." Thirty-one were sufferers from epilepsy, twenty-seven from paralysis, thirty-one from disease of brain, ten from puerperal disease, seven from pulmonary consumption, and fifty-four from general exhaustion. It would be important in all cases to note, as a further addition to Dr. Bower's able examinations of cases on entry, the precise condition of the urine, with special reference to the questions of the elimination of phosphates and of sugar.

The numbers of recoveries that take place are considerable; in the year 1862 they amounted to 62.75 per cent. on the admissions for that year. The mortality is comparatively small. In the year named above, although the infirmaries were filled during the summer months with cases of paralysis and other affections of the brain, the mortality was but 8.19 per cent. on the total number under treatment. Paralysis was the cause of death in more than a fourth of the cases that terminated fatally, while about a fifteenth died from old age—senile decay. The reason for this low mortality is found in the freedom of the establishment from endemic and epidemic disorders. In point of fact, there are no such indices of what can be achieved by perfect sanitary regulations as the great lunatic asylums of England, and I was much amused once at hearing this fact referred to by an inmate of an asylum. Visiting the asylum at Lincoln a few years ago, I met there a

patient who had once been a member of the Medical Profession, and who, full of talk and nonsense, said now and then a very good thing. Amongst other arguments—for, like one of the heroes of "Midshipman Easy," he delighted in the opportunity of undertaking to argue out every point—he insisted on the immense advantages of being insane. "George the Third was a fool, Sir, till he was mad; never had a moment's happiness or peace, Sir, till he was mad. Neither had I. Now I'm a gentleman, and these folks who work here all run after me, and wait on me, while I look on and think how jolly it is to see what fools they are. I always say they are mad, and I am sane; and I'm right—ain't I, now, eh?" Then, turning to the Asylum, for this conversation took place in the grounds, he assumed a profound Medical air, cocked up his chin, pursed his mouth, and added, "Then, your cholera, and your small-pox, and fever; we've none of them in our house—they are for the fools outside. Why don't you go mad, and get away from them, and make other people work for you, and be jolly and come here—eh?"

The causes of insanity are carefully investigated at the Stafford Asylum. As each case is entered on the books a rigid inquiry is made as to cause. Alas! for Stafford county, it is not better than its neighbours. Intemperance, poverty and privation, and hereditary predisposition springing from these, are the great producers of its insane population. Year by year the same tale is told. Below we have the return of causes for 1860—an average return:—

Cause of Disorder.

	Males.	Females.	Total.
Anxiety and grief	3	16	19
Intemperance	42	10	52
Congenital defect	3	3	6
Hereditary predisposition	23	33	56
Poverty and privation	8	12	20
Disease of brain	11	1	12
Blindness, with diseased brain	1	1	2
Scrofula	—	3	3
Other bodily disease	6	16	22
Puerperal disease	—	15	15
Old age	3	3	6
Profligacy and intemperance	—	3	3
Epilepsy	10	7	17
Fright	—	1	1
Injury to spine	1	—	1
Injury to head	1	—	1
Cause not ascertained	8	6	14
	120	130	250

Cases of Singular Interest.

Asylum practice not uncommonly yields cases of peculiar interest, even in Surgery. Dr. Bower was good enough to

place before me several remarkable illustrations, of which I may note two or three. In one of these cases the patient, a female, aged 43 years, retired one morning to a water-closet, after having secreted about her dress a pair of scissors, and before she could be prevented had time deliberately to make an opening into her own abdomen, draw out some inches of the small intestine, cut the portion drawn out clean off, and throw it away. When Dr. Bower arrived he found two open ends of bowel protruding, and he endeavoured to bring them together by sewing their ends while in apposition. This direct object did not succeed; the open ends of the bowel became adherent to the wound in the walls of the abdomen, and an artificial anus was formed in the median line, midway between the umbilicus and pubes, through which the evacuations of the bowels were discharged. To the surprise of all, this woman recovered without a bad symptom, and some time afterwards she was discharged from the Asylum cured of her insanity. Later in her life she was actually one day sent from her native place to the Asylum either in charge of, or to fetch home, another patient. At that time she remained in bodily and mental health, suffering no further inconvenience than that from wearing a support, and of having to discharge the contents of the bowels through the artificial opening.

A patient was shown to me on the male side who had lost two fingers—the first and second of his hand—down to the second phalanges. The loss was occasioned, not by an accident, but positively from his having himself bitten the fingers off and eaten them. The operation appears to have been done almost unconsciously, and to have given rise to no pain. The wounds closed well, and the stumps are as perfect as if the amputations had been conducted on the most improved Surgical method.

A third case was that of a man who suffered from sloughing of the scrotum to such an extent that both testicles were exposed, and were for some weeks clearly dissected out, as it were, and pendant. The patient having improved in general health, the sloughing was arrested, reparation set in, and gradually the testes became invested in new tissue, until, at last, they were surrounded by what seemed like a new scrotum. It would have been difficult to discover, when the cure was completed, that new structure had been formed—the scrotum was so natural.

Principles of Treatment.

There is, as I have said, no seclusion or no coercion in the Stafford Asylum. Gentle work, and amusements of various kinds, such as music, dancing, exhibitions, cricket, football, etc., are the means adopted for passing the time. At this moment there is in course of construction a spacious recreation hall, in which the patients will all dine together.

The diet is liberal, as will be obvious from the scale supplied below. I think, however, it is a mistake to weigh it out—a mistake in economy and in feeling.

Diet Table.

	BREAKFAST.					DINNER.										SUPPER.

EXTRAS.—Full diet, consisting of 6 oz. of meat, with alc, wine, or brandy, in cases of illness or debility. Soup, arrowroot, eggs, bacon, etc., if necessary. To working patients: Bread, cheese, beer, and tobacco, as indulgences. Total amount of meat consumed by each patient weekly: Males, 30 oz., cooked and free from bone; females, 24 oz., cooked and free from bone.

To Make Soup for 100 Patients.—The liquor in which the meat of the previous day has been boiled, 12 1/2 lbs. of meat, consisting of legs and shins of beef, 1 1/2 lbs. of rice, 3 lbs. of onions, 3 lbs. of leeks, 6 ozs. of salt, 2 ozs. of pepper, 3 1/2 quarts of peas, with herbs, etc., consisting of carrots, turnips, cabbage, celery, parsley, and parsnips, according to the season, and sufficient water to make 100 pints.

To Make Cocoa for 200 Patients.—9 lbs. 6 ozs. of cocoa, 6 lbs. 4 ozs. of sugar, 9 quarts of milk, and sufficient water to make 200 pints.

In the medicinal treatment of the insane, particularly during periods of maniacal excitement, Dr. Bower uses full doses of digitalis with great advantage. This remedy is of special value when there is disease and excitability of the heart. In

these cases the digitalis acts like a charm; it produces calm without leading to sopor; it exerts no bad effects on the digestive functions, and it leaves no serious depression behind. Thus, it is far preferable to narcotics in cases for which it is suitable. The cannabis indica has been employed extensively as an anodyne, and occasionally its action is good, but it sometimes fails. On the whole, when opium is not administrable, the cannabis is less certain than hyoscyamus, which, when given boldly, is invaluable in the treatment of mental disease. As an opiate, a watery solution of opium is used in preference to the other forms of the drug.

In conclusion, I have only to add that the number of patients received into the Stafford County Asylum since its foundation has been 5850; that the recoveries have been 8.19 per cent.; and that the cost of each patient in the Asylum is now 8s. 6 $\frac{3}{4}$ d. per week.

Dr. Mark Noble Bower is the Resident Medical Officer and Superintendent, and Dr. Robert A. Davis is the Assistant Medical Officer.

THE COTON-HILL INSTITUTION FOR THE INSANE.

Near to Stafford is another institution for the insane, called the Cotton-hill Institution. This Asylum is for the reception of two classes of insane patients, viz.—1st. Patients in more or less affluent circumstances who shall contribute, according to the accommodation required, such weekly sum as may be agreed upon; and 2nd. Patients in limited circumstances, though not paupers, who shall be received at such reduced rates of payment as the Committee, upon a consideration of their circumstances, may in each case determine; the deficiency being made up out of the surplus moneys received from the patients of the first class beyond their actual cost, assisted by annual subscriptions, donations, and legacies. For every two guineas subscribed annually, subscribers are entitled, during payment, to recommend, subject to the powers reserved to the House Committee, one patient within the year for admission into the second class; donors have the same privilege during life for every twenty guineas.

The Medical officers attached to this Institution are—a Visiting Physician, who receives a stipend of 100 guineas a year, and a Resident Superintendent. The former office, now, I believe, vacant, has been held until recently by Dr. Wollaston, a relative of the great Physicist of that name; the latter is held by Dr. Hewson.

I cannot close the account of the charities of Stafford without referring to the labours of Thomas Salt, jun., Esq., M.P. In every philanthropic undertaking connected with the town of Stafford, he is the foremost and the untiring advocate. It was through him that the Soup Kitchen and the Church Institute were established; and to every charity and good cause, where contribution from the pocket as well as from the hand is wanted, he stands the ready minister and friend. In paying this just, but trifling tribute, I know I am expressing the general opinion of those who know Mr. Salt best; and were the spirit by which he is animated of broader representation, many of the defects to which I have drawn attention would, I doubt not, be speedily rectified.

THE COUNTY GAOL.

The County Gaol, constructed for holding 630 prisoners, is a dull, heavy building of brick, which, for style, sets the science of architecture altogether at defiance. As a gaol, however, according to modern notions, it answers its purpose, which is as much, perhaps, as can be said of any such place. The general mortality per annum is rather less than 1 per cent. Attached to the gaol is an Infirmary, which, on the male side, contains sixteen beds; and on the female, nine. The infirmary is ventilated by means of a cupola, the sections of which are opened or closed as may be required. The space for each patient in the infirmary is 500 cubic feet. The gaol is comparatively healthy. Fever cases for many years past have been unknown. Consumption at one time was prevalent, probably from greater confinement of the prisoners than is now adopted.

Mr. Hughes, the Surgeon to the gaol, and the esteemed senior representative of Surgery in Stafford, informs me of a singular phenomenon in disease that has been observed in the gaol during the past few months. For some considerable time diarrhoea was a constant symptom of disease amongst those prisoners who had been long resident within the prison walls. At last the disorder amongst them became actually endemic. Ordinary medicinal measures proving ineffective, Mr. Hughes began to try modifications of diet, and at last discovered that

the disorder could be arrested wholesale and immediately by simply stopping the animal diet, boiled beef, on which the prisoners affected were fed, and substituting for it good cheese, as a nitrogenous article. Since the adoption of this plan, modified according to circumstances, diarrhoea has ceased in the gaol.

SANITARY CONDITION OF STAFFORD.

Population.—The population of Stafford at the census of 1861 was 12,532. In this statement the borough only is given. In 1851, the population was 11,829. In the 10 years, 1851-61, the increase, therefore, of population was 703, an increase exceedingly small, and not favourable to the idea of social progress in the town. With such a slow natural increase, a severe epidemic visitation, or social causes leading to emigration, would rapidly turn the scale in the opposite direction, and lead to a decrease of population altogether. It is matter of wonder to observe how little importance is attached, even by thinking men, to this question of population. In commenting on the Medical History of Lynn, one of my Medical friends asked me why I dwelt with so much stress on the circumstance that the population of that town was suffering decrease. "There were," he said, "plenty of people born, and a town could afford to spare its lower population." No argument could be more seriously fallacious. The upper stratum of society rests as much on the lower as the walls of a house rest on the foundations. Wealth may mean the enjoyment of privileges without labour; but if there are no hands to be bought by wealth for the performance of the labour, then even the wealthy must labour, or their luxuries must be abandoned. Hence, in any town, when the people begin to decay, even though wealth has accumulated, the condition is bad.

It is bad for the Professional man, for such a town becomes uncomfortable for the rich, who therefore leave it, and go elsewhere where their money may be applied. For my part, I do not think that the importance of the question of population can be exaggerated; and if the young Medical Practitioner especially ignores it, he may depend upon it he is committing a grave fault. To look at the populations of towns and cities is to look at social maps; and to learn by them is a certain course to success. Were I again to have to decide the great question—Where, as a Doctor, shall I hoist up my colours?—I should turn to these maps, and if there is one place more than another that I should avoid, it is that place where the population is undergoing certain decrement, or where the increment is insufficient to ensure a constant balance against death.

(To be continued.)

GENERAL CORRESPONDENCE.

THE DEATH-RATE AFTER LITHOTOMY IN THE NORWICH AND LONDON HOSPITALS.

LETTER FROM MR. THOMPSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—On January 9 last Dr. Richardson, affirming the well-known fact that the mortality rate at Norwich from lithotomy at all ages is one death in 7 $\frac{3}{4}$ cases, characterised it as "a success which, by the side of many other Hospitals, stands as four to one." He further volunteers the statement, "If the same number of operations had, for instance, been performed at Metropolitan Hospitals, the deaths would, on the modern average, have been 472, instead of 118;" and, continuing the subject, he says, the death-rate of "1 in 1.88" is "common in London."

On the 16th I produced, in reply, the most trustworthy figures that exist on this subject, and showed that of 520 cases which had been performed at the only three London Hospitals where accurate records exist, the average death-rate was almost as low as that of Norwich.

After seven weeks' silence, Dr. Richardson indicated the data on which he made that astounding statement. They are at this moment before me; and they consist of 186 cases at all ages, collected by circular from Hospitals in London during three and a-half years. It seems scarcely credible, but such is the fact, that Dr. Richardson has rejected from that series all the children's cases; that he calculated the mortality from the adult cases alone (20 years and upwards), 49 only in number; and from the 26 deaths in that slender list he deduced

the rate of 1 death in 1.88 case, and actually adopts it as the London rate in comparison with the Norwich rate for all ages, for the purpose of depreciating the results of London practice.

In other words, he takes the 910 cases of Norwich,—of which exactly one-half (445) are below 20 years of age, including, therefore, all the children, whose cases are proverbially successful,—and compares the total death-rate with that derived from the London list, having first excluded from the latter all the cases below 20 years, and consequently all the cases aforesaid to be proverbially successful. The death-rate for the 186 cases of the London series, at all ages, being, in fact, 1 death in 4.65 (*Med. Times and Gaz.*, August 20, 1859).

I beg my readers now to read the quotation from Dr. Richardson placed in italics at the commencement, and ask them to characterise for themselves the process by which that result is arrived at.

I could adduce numerous other examples of Dr. Richardson's extreme inaccuracy, and shall readily do so if called upon; but they would occupy too much time and space now. Let one suffice as an example.

In the 910 Norwich cases, all stated by him to be lithotomy, are included no less than 41 cases of stone in the female, mostly adult and removed by dilatation, in which the mortality, therefore, was only one in twenty. From his London series, all the female cases were carefully excluded. Will it be believed that there were no less than sixteen female cases, and with one death only, during that term of three and a-half years? Dr. Richardson will explain why he made this difference, and his familiarity with figures will show him how much the London rate would have been improved had he treated the two series with equal fairness.

Next, Dr. Richardson compares the results of my three London Hospitals (520 cases) with those of thirteen Hospitals (186 cases); and suggests that I "have found out three Hospitals that have yielded results nearly as good as the one at Norwich;" adding "that the practice of one or two" (other) "Hospitals has turned the scale against London." I reply that I made application to all the larger Hospitals; all were most anxious to afford me results; but I accepted those only in which written records existed, carefully kept for a number of years. I leave others to judge which series, therefore, is most likely to be correct, that of the three Hospitals or that of the thirteen.

My own metropolitan tables show, and I have never said otherwise, a greater mortality than that of Norwich as regards the adult, but nothing approaching to that affirmed by Dr. Richardson. Whatever may be the influence of overcrowded wards, there are two other and most influential causes for this. First, the adults in London having calculi are not to be compared for health and strength to those of the country. I have seen enough of both, and know both classes well. Secondly, many of our patients are selected bad cases sent up from the country. Such are well described in the very article from which Dr. Richardson has culled his data; and let it be remarked that the writer is referring to the identical instances which have been adduced to prove metropolitan failure. He writes:—"Of this we are sure, that some of the very worst in the whole series were patients who had been so sent up (from the country) for operation. Not unfrequently there is a history that lithotrity has been repeatedly tried; but that the bladder becoming more and more irritable, and the patient's health failing, the case has been sent up to town for further measures." I quote Dr. Richardson's own authority, *Medical Times*, August 20, 1859.

Again, I must protest against the fallacy of drawing inferences from such small numbers as those with which Dr. Richardson has been so ready to traduce the London practice. I cannot give a better illustration of it than by quoting his purely gratuitous remark that "Mr. Thompson does not dispute" (why should I?) "the startling fact that, twice over, forty cases, taken as they came, were operated on for stone in two distinct series without the occurrence of a single death." I have to inform Dr. Richardson that it is well known that the esteemed and honoured Surgeon who met with those series of cases was little, if at all, more successful than his brethren—comparing the result of his entire practice. He had his share of fatal cases, and every accurate record will show them if only it deals with numbers sufficiently large.

One word in reference to the relative results of metropolitan and provincial Hospitals as influenced by sanitary considerations. I do not enter upon that subject, but remark only on one point arising out of the question before us.

I examine the 186 London cases produced by Dr. Richard-

son, and I find, as he says, a large number of children. The death-rate of these children's cases is 1 in 13½. The rate at Norwich is precisely the same. Now, if sanitary advantages are so great in the provinces, how is this fact to be accounted for? I commend to Dr. Richardson the striking reflections on this topic appended by the writer of the very article above quoted, which presents my view of the subject most completely.

In conclusion, I hope and believe we shall yet see much improvement to the sanitary condition of our London Hospitals; that we may have smaller wards and larger space for each inmate. All this is within our reach, and is simply a question of expense. I thank Dr. Richardson for his unflinching advocacy of sanitary reform, but I remind him that this good cause will never be furthered by propagating exaggerated statements respecting the mortality which follows the operations performed by London Surgeons. I am, &c.

35, Wimpole-street, March 7. HENRY THOMPSON.

THE MORTALITY IN THE NORWICH AND LONDON HOSPITALS.

LETTER FROM MR. T. HOLMES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am very glad that Dr. Richardson has at length recognised the necessity of producing some justification for the strange assertions made in his paper on the Norwich Hospital. The figures which he gives as proving the mortality of the London Hospitals have no application whatever to the conclusion which he drew from them, and it would, I think, have been better if Dr. Richardson had given up that conclusion altogether as erroneous, and admitted that the mortality after the operation of lithotomy in London Hospitals has never been proved to be 1 in 1.8 (as I am certain it never has been). But this part of Dr. Richardson's paper is in answer to Dr. Thompson, and will, I suppose, be dealt with by that gentleman.

I have a few words to say about each of the three other points touched on in my last letter, and answered in the note to Dr. Richardson's paper. Dr. Richardson complains that I have misunderstood him in saying that he attributed the greater success of Norwich practice to the difference in the air of Norwich and London. He now says that he attributes it to the fact that Benjamin Gooch provided each patient with 1215 cubic feet of air and natural ventilation, ignoring, as it seems, the fact that the constructors of our London Hospitals have provided their patients with more cubic feet of air and freer ventilation. If Dr. Richardson seriously intends to assert that the Norwich Hospital is more spacious and better ventilated than our large London Hospitals, say St. Bartholomew's, I would appeal to any unprejudiced person, who knows the two Hospitals, to say whether this is so or not. I think the case is demonstrably the reverse. At St. Bartholomew's Hospital there is an allowance of cubic space varying from 1350 to 1800 feet per patient; at St. George's of about 1200 to 1400; at the London Hospital about 1600; at Guy's about 2000. All these Hospitals have more complete ventilation than the Norwich Hospital, although the latter is by no means ill-ventilated. If Dr. Richardson should say that what he meant was that the Norwich Hospital was less in the town than those which I have mentioned, and, therefore, not so close to the dwellings of the poor, this may be true with respect to the other Hospitals, but certainly not for St. George's. Yet we at St. George's do not claim any superiority in the results of our operations over the other Hospitals I have named; and it is singular that our ratio of deaths after amputation of the thigh for chronic disease, in a series of years, is exactly the same as that at Guy's. I think, therefore, I was justified in assigning the above meaning to Dr. Richardson's words, which, in fact, is the only meaning that they can properly bear.

With respect to the third point—viz., the death-rate of Surgical patients in the year 1862. This is a matter which I regard as one of very minor importance, but since Dr. Richardson appears to lay great stress upon it, since he thinks that Hospital death-rates are useful in comparing their relative sanitary condition, and still more, since a writer who uses figures at all is bound to use them accurately, I think it well to correct him in this particular. I brought away from Norwich a note that the death-rate of the Surgical patients for 1862 was 5.14 per cent. On referring again to Mr. Williams, the resident Medical officer at the Hospital, he assures me that this is correct. Had not Dr. Richardson the same data?

As to the prevalence of pyæmia, I referred also to the same gentleman. Mr. Williams informs me that "in looking over the 'cause of death' book, he found two cases occurred during 1863, three in 1862, and not one in 1861 or 1860." He also informed me, on January 19, that he had written to Dr. Richardson to correct the error which he had noticed in Dr. Richardson's paper. I am much surprised, therefore, to find that Dr. Richardson should still persist in saying that only one fatal case has occurred in seven years, when he had the data before him to show that five fatal cases, at least, had occurred in four years. I say "at least," because others may well have occurred, which escaped registration in a "cause of death book." Dr. Richardson now affects to treat the matter as one of entire indifference, though before he brought it forward triumphantly as a proof and index of the healthy condition of the Hospital. The fact is, that comparing the number of cases of pyæmia given by Mr. Williams with the number of deaths (taken at 45 to 50 per annum, which is about the usual rate), they give a proportion of deaths from pyæmia about equal to that of the Metropolitan Hospitals.

I think these few particulars will give your readers a sufficient specimen of the accuracy and care of Dr. Richardson's statistics.

I am, &c.

22, Queen-street, Mayfair, March 7.

T. HOLMES.

HOSPITAL MORTALITY.

LETTER FROM MR. J. BURNEY YEO.

[To the Editor of the Medical Times and Gazette.]

SIR,—Some very interesting communications have appeared in your last few numbers on "Hospital Mortality;" may I be allowed to say a few words on this important subject?

My remarks will be confined to the Hospital with which I am connected, taking it as a fair example of a country Hospital. I must premise that it is the oldest provincial Hospital in England (it was founded in 1736), that the present building was not originally erected for a Hospital, and that its age is not unattended with infirmities. It has no efficient drainage, the ventilation of many parts of the building is bad, and the cubic space allowed to each patient in some of the wards much below what it should be (only 860 cubic feet). Indeed, as you must be aware, its days are numbered, and soon the "New County Hospital at Winchester" will supersede the present building.

Turning, then, to the death-rate in this old and condemned country Hospital—supposing the death-rate to be a test of the sanitary condition of a Hospital—one would expect to find it rather above the average of similar institutions. The reverse is really the case. The death-rate at this Hospital is below the average of other country Hospitals, as the following figures will show:—

The average death-rate in twenty-five country Hospitals, according to Dr. Farr, was 39 per cent. Following Dr. Farr's plan of calculating the per centage of deaths to the number of beds occupied, I find that in the Winchester Hospital the average death-rate for the last ten years has been only 35 per cent. In the years ending respectively June, 1862, and June, 1863, the death-rate reached only 25 per cent.; and, in the eight months that have elapsed of our current year, although our wards have been fuller than for many preceding years, the actual number of deaths has been smaller, and, therefore, the death-rate lower, than the lowest rate I have quoted above. Yet, in this country Hospital, with its low rate of mortality, I find that in 1861 there were, out of a total of 32 deaths, 9, or nearly a third, from erysipelas contracted in the Hospital. In 1858, 6 deaths out of 26, nearly a fourth, from disease contracted in the Hospital; and in 1856, 7 out of 30 deaths from like causes. These figures are taken from a printed official report.

Here, then, is a Hospital with a low average death-rate, yielding a large number of victims to so-called Hospital diseases—diseases which are generally considered to arise from defective sanitary conditions, and that this consideration is true, the experience of this Hospital appears to show clearly. For instance, the highest death-rate registered for many years was in 1861, reaching 44 per cent., nearly one-third of the deaths being from erysipelas.

This increased mortality drew the attention of the Governors of this Hospital to the sanitary condition of the present building. It was then determined that a new Hospital should be erected upon a new site. But, at Mr. Rawlinson's suggestion, the sewers, drains, and cesspools connected with the present

building were cleansed and disinfected, and the larger cess-pool ventilated, and the gases proceeding from it passed through layers of charcoal. What was the effect of this simple expedient? Why, that the next year the death-rate fell from 44 to 24 per cent. The following year it was 25 per cent.; and this year, so far as it has gone, commencing the 1st of last July, the death-rate is still lower, although the Hospital has been more crowded than for eight years previously.

After these preliminary considerations, one is in a better position to deal with the problem which Miss Nightingale says "demands solution"—viz., the low death-rate in country Hospitals compared with Hospitals in large towns. Sanitary conditions, doubtless, exert a considerable influence. But in the case of the Winchester Hospital we have a remarkable instance of defective sanitary conditions, and yet a low average death-rate.

What, then, is the true solution of this problem? Any one, I think, who has lived both in a metropolitan and in a country Hospital must be prepared to agree with Mr. Holmes, that it is in the widely-different class of cases admitted that the solution of the problem rests. Admission to country Hospitals is usually so easy, and their wards are so rarely full, that cases of a most trivial nature often find admittance. There is no selection of cases according to their severity, or with reference to clinical instruction, as in those Hospitals with Medical Schools attached to them. Chronic rheumatism amongst the men, the various forms of hysteria and anæmia amongst the women, and dyspepsia amongst both, constitute the majority of cases in our Medical wards. To show strikingly the difference between the severity of the cases in a London Hospital and those in a country Hospital such as ours, I would mention that I have just visited our Medical wards, and, out of forty patients, I find only four in bed, the rest were either sitting or walking in the ward, or in their day-rooms, or in the garden; and this is in the most sickly season of the year. In the summer, it commonly happens that one finds the Medical wards deserted—all the patients are in the garden, the men smoking, the women chattering.

If this is the case in other country Hospitals—and I believe it is so—we must admit that the metropolitan Hospitals and Hospitals in large towns are filled with a very different class of cases, especially so far as Medical cases are concerned, and that any conclusions drawn from a comparison of their respective death-rates (without taking other circumstances into consideration) must be valueless.

I am, &c.

J. BURNEY YEO,

House-Surgeon and Secretary,
Hants County Hospital.

February 27.

THE MORTALITY IN GENERAL HOSPITALS.

LETTER FROM DR. BRISTOWE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I regret that personal circumstances, over which I had no control, prevented me from writing to you until now.

Dr. Farr, in your Journal of February 13, spoke of "defects which make Hospitals ways of death to their inmates," and spoke of it as matter for hope that "general Hospitals may yet benefit mankind directly, and not merely as pathological observatories and Medical schools."

In your Journal of February 20, I adverted to the above-mentioned letter, and invited Dr. Farr to explain the grounds of the very heavy accusation which he had therein expressed or insinuated.

In answer to my appeal, Dr. Farr, in your Journal of February 27, refers to a certain letter of his, published in the twenty-fourth report of the Registrar-General, as containing some of the information which has been collected at the General Register Office respecting Hospitals."

The only information therein contained which can be supposed to bear upon the subject is in two tables. The first of these tables shows that, in proportion to the number of beds occupied, deaths occur more abundantly in Hospitals than in workhouses or lunatic asylums. The second shows that, in proportion to the number of beds occupied, more deaths occur in large than in small Hospitals.

Will Dr. Farr have the goodness to state in your journal how he connects these statistical facts with the conclusions which he first advanced?

It is the more important that this question should be explicitly answered, because Miss Nightingale (resting on Dr. Farr's statistics, and apparently with Dr. Farr's logic) would

lead the public to believe that the "death-rate" of a Hospital corresponds to the greater or less exposure of the Hospital inmates to certain removable causes of Hospital "unhealthiness," and that by such causes our great metropolitan Hospitals are rendered, as Dr. Farr expresses it, "ways of death to their inmates." Will Dr. Farr explain himself on this point?

I am, &c.

J. S. BRISTOWE.

2, Queen-square, Westminster, March 9.

ARMY MEDICAL SERVICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Allow me, through your columns, to call the attention of those young men about to become candidates for the above Service to the present state of the department.

If they will take the Army List for this month of March, and calculate the number of Assistant-Surgeons to be provided for from February, 1854, to January 1, 1860, inclusive, they will find the number to be about 513. Let them divide that number by 30 (the average number disposed of by promotion, death, and resignation each year) and the product will be 17; so that those young men who joined the service on January 19, 1860, have to serve seventeen years, in addition to the four years served since 1860 to 1864, making a period of twenty-one years before they can be promoted to the rank of Surgeon—more than double the time heretofore required to attain to that position. Will this state of things cause them to pause, and consider well before they take the step?

By the warrant of 1858 a Surgeon having twenty years' full pay service in army rank shall be styled "Surgeon-Major," with increase of pay; but I am at a loss to understand what is to become of the wretched Assistant-Surgeon of twenty-one years' service, and still an Assistant-Surgeon. Will a new grade be created for them, called "Assistant-Surgeon-Majors," with additional pay?

The extension of the age of admission now proposed, from 26 years to 30, is a strong proof of the ridiculous lengths the Director-General is willing to go in the wrong direction to fill up vacancies. Can you imagine a Medical man, having attained the age of 30, seeking to become a student at Netley on 5s. a-day, unless he be some failure in civil life—a bankrupt, perhaps, in morality? I challenge the authorities to say they consider this alteration of age is for the benefit of the service or the advantage of the sick soldier; no other motives should influence them.

I am, &c.

March 8.

AN EX ASSISTANT-SURGEON.

THE GOVERNMENT ANNUITIES BILL.

[To the Editor of the Medical Times and Gazette.]

SIR,—No one can have read the speech on the Government Annuities Bill delivered by the Chancellor of the Exchequer in the House of Commons last evening without profound admiration for the eloquence, sympathy, and good qualities of heart displayed therein. The members of our Profession will, I think, take especial interest in the object Mr. Gladstone has in view in this matter, seeing that they are ever eager to be thought, as indeed they are, among the foremost of philanthropists; and I think we as a body may be doing well in taking every opportunity of showing our concurrence with the measures contemplated in the aforesaid bill for the good of the poor. Moreover, we may in this manner be able to give a moral support of no inconsiderable extent to the intentions and endeavours of Mr. Gladstone. It will be seen that it is in prospect that the various Union Medical officers should be called upon to certify to the condition of such as shall claim the benefit of Government assurance.

We shall surely consider this a very desirable step, and for the sake of our brethren hail an operation which will tend materially to augment the remuneration and exalt the position of a class of men than whom none are more hard-worked or less paid.

But even if the bill is passed, so much will at first have to be learnt entirely from experience that I cannot help thinking that good service would accrue if, through your pages, the ideas and opinions of some of our ablest Union Medical officers on the advantages and disadvantages of the scheme in itself, and also on the difficulties likely to arise in its working, and the modes of obviating them, could be gained. No one in a parish (at any rate, a country one), is more conversant with

the feelings, habits, and tempers of the poor than the parish Doctor, and by him I think it cannot be doubted that suggestions may be thrown out which may prove serviceable to those who, in their attempts to establish for the poor so useful and provident, so secure and facile a scheme as the one alluded to, will of course be only too glad to receive hints from every likely quarter. The system adopted by the industrial assurance offices, their dealings with the poor man who from incaution or poverty, or migration, or casualties of various kinds, has been unable to pay his premium for a short time are so obvious (being in plain words downright robbery, or, as Mr. Gladstone says, "confiscation united with concealment") to any right-minded person, that I cannot refrain from asking you, as a Medical journalist, to raise your voice against it on this opportunity, to urge the reading of Mr. Gladstone's oration, or to invite discussion in your periodical by those of your readers (so many as they doubtless are) whose opinion must be invaluable on such a subject.

I am, &c.

London, March 8.

PRO-PAUPERIBUS.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 1.

Mr. PARTRIDGE, President.

ANNUAL MEETING.

At the commencement of the meeting, the President declared the ballot open for the election of the officers and council for the ensuing year, and nominated Dr. Kirkes and Mr. C. H. Moore as scrutineers.

The Reports of the Treasurers and of the President and Council were then read in succession. From the former, it appeared that the Society was in an increasingly prosperous condition. The total ordinary income of the year had been £1352 12s. 9d., which, with the amount of composition fees, £43 1s., and a balance from the previous year's account of £357 19s. 9d., gave a total of £1753 13s. 6d.; and against this sum the ordinary expenditure, inclusive of £181 14s. 6d. on the library, and £202 16s. 3d. on the *Transactions*, etc., was £985 5s.; the extraordinary expenditure (for alteration in the meeting-room, etc.), £34 7s. 7d., and the sum of £500 13s. 9d. purchased into the funds; leaving a balance of £233 7s. 2d. in the treasurers' hands. It will thus be seen that the total receipts of the Society for the last two years had exceeded its expenditure by about £700.

Mr. ARNOTT moved, and Dr. WEBSTER seconded the adoption of the report.

Dr. WEBSTER said that, from the statement just exhibited, it appeared that the Society's rent amounted to £1 2s. 10d. only.

The Report of the President and Council stated that the total number of Fellows was 634—a slightly smaller number than in the previous report; but this was accounted for principally by the large number of deaths (16) which had occurred amongst the Fellows. The report referred in detail to the steps which had been taken by the Council since the last general meeting relative to the ventilation of the meeting-room, its appointment of a committee on the subject, and their recommendations. A portion of these only, owing to insufficiency of time during the ordinary closure of the library in the autumn, had been carried out, consisting of a window over the entrance door of the room, and an apparatus for opening a portion of the skylight, by which it was believed a great improvement in the ventilation of the room had been effected at a small cost. The report also stated that 323 new works, exclusive of periodical publications, had been added to the library; and also referred to the munificent donation of Mr. Soden, of Bath, of the collection of Medical portraits formed by his late father, Mr. John Smith Soden. Other portraits had since been presented by Fellows of the Society; and in consequence of a letter from Mr. Propert, as executor of the late Mr. Squibb, and on the recommendation of the Library Committee, the Council had resolved to offer £70 for Mr. Squibb's well-known collection—subject to the confirmation of the annual meeting. If purchased, the Society would possess a collection of considerably above 2900 engraved Medical portraits, some of which were of great rarity and

value. The report also referred to the photographic collection of portraits of Fellows of the Society in continuation of the above, and the collection of pathological photographs, further contributions to which were much desired by the Council. The committee appointed by the Council "On the Uses and Effects of Chloroform," were unable to conclude their labours last year; but their report would now shortly be presented to the Society, and would be published in the next volume of the *Transactions*.

Mr. CÆSAR HAWKINS moved, and Dr. BARKER seconded, the adoption of the report.

Dr. GREENHOW remarked on the great improvement in the ventilation of the room. It had been the worst-ventilated room he had known, but now it was perfectly comfortable and healthful.

Mr. CHARLES HAWKINS thought it would not be advisable to alter the lantern; it would be throwing money away. He hoped the balance would be taken care of, and not be frittered away.

Dr. WEBSTER said that, having taken much interest in the subject of ventilation of the room, he would remark that he quite agreed that it would not be necessary to spend more money on it, as the result already obtained was very good. He thought that, as the Society was a royal Society, there ought to be either a portrait or a bust of her Majesty in the room. It would almost seem that the architect had made the recess behind the President's chair for such a purpose. In all foreign societies it was usual to have a bust of the sovereign, and he suggested that the Royal Medical and Chirurgical Society ought to have one of the Queen.

Mr. SPENCER WELLS asked if the Council intended to continue the high charges for the use of the room to the Pathological Society. Strong remarks had been made at the meetings of the latter Society on this point, and, as a member of the Royal Medical and Chirurgical Society, he felt ashamed of the extortionate charge. It did not seem fair that this Society should stand rent free by making a high charge to a sister Society. He hoped the Council would act in a more liberal spirit in this matter.

The PRESIDENT said that to double the rent of the two sister Societies (the Pathological and Obstetrical) was not so inconsistent as might appear at a first glance. It ought to be remembered that the Pathological Society was received at first at a mere peppercorn rent, as the funds of that Society were low, and it was well known that the rent was not commensurate with the advantages. Then, again, the question had been unfairly stated. It was not fair to assert that the rent was at the rate of four guineas an hour, as if the hours were consecutive. It was just the difference in engaging the Freemasons' Tavern on thirty occasions for an hour or for thirty hours in succession. Then, the proof that the rent was not too high was this, that the Pathological Society could not obtain rooms at so low a rate in any other part of London. However, he would rather the rent were less than that difficulties should arise betwixt the Societies.

Dr. C. J. B. WILLIAMS was glad to hear the President's last remark. It seemed to him (Dr. Williams) that the very fact that the Medico-Chirurgical Society was living rent free was evidence that it mullets its tenants to a good rate. It was unfair to put pressure on the Pathological Society. The rent at first was moderate, but to double it at once was preposterous. It was now a question whether the Pathological Society could meet the charge consistently with publishing their *Transactions*. Sixty guineas a year was more than the Pathological Society cost the Medical and Chirurgical Society.

Mr. CHARLES HAWKINS thought that the discussion ought to have taken place before the money vote. The words used, "extortionate" and "extraordinary," were, he thought, misapplied. If the Pathological Society were so important and so flourishing as Mr. Spencer Wells had said, it was strange that it could not pay sixty guineas a year. If that Society could get rooms at such a rate elsewhere, they might do so. They had not only the rooms, but gas, and the services of the librarian and other officers. It spoke poorly for the Society to apply *in forma pauperis*. If it were worth supporting it would be supported, but not at the expense of the Medical and Chirurgical Society. They had the *prestige* of being associated with this Society, and he did not see why they should receive anything in the way of pecuniary assistance. If Mr. Wells wished for an expression of the opinion of the Society, he ought to bring forward a distinct resolution.

Mr. ARNOTT said that, besides the use of the room, the Pathological Society received, in the way of warming, lighting,

etc., considerable advantages. He did not think the rent at all extortionate.

Dr. BARCLAY said that the item (£196) for wages to the Society's servants had been overlooked, although the Pathological Society had the services of their paid officers. It was felt at the time when the first arrangement was made that it was a peppercorn rent, and that they were scarcely acting fairly to themselves. When all the advantages were considered, he thought it would be admitted that sixty guineas was a low rent.

Dr. BARKER said it was a mistake to suppose that they lived rent free, as the Society had spent at least £1000 in the lease and in alterations.

ADDRESS.

The PRESIDENT commenced his address by advocating the expediency, for communities as well as for individuals, of an occasional retrospect of the past, with a view to the guidance of the future; to ascertain whether progress had been commensurate with opportunities, or whether there had not been seasons of indolence and inaction, the causes of which might be avoided in future. He reminded the meeting that the Medical and Chirurgical Society, like the "Royal," had its origin in a private meeting of a few scientific persons anxious for the promotion of knowledge, who held a preliminary meeting at the Freemasons' Tavern in May, 1805, and (after the organisation of the Society) a first ordinary meeting in the December of the same year. The Society's first place of meeting was in Verulam-buildings, Gray's-inn, then successively at two houses in Lincoln's-inn-fields, where it continued until its removal to Berners-street in 1855, in consequence (amongst other reasons) of its resident fellows lived west of the former locality. The first President, in 1805, was Dr. Wm. Sanders, and the first volume of the *Transactions* was published in 1809, under the presidency of Dr. Matthew Baillie. In 1812 an ineffectual application was made for a charter of incorporation. Its importance, however, was felt to be so essential to the status and stability of the Society that the application was renewed, and a royal charter obtained in 1834. On this occasion the bye-laws and other regulations of the Society were revised and adjusted. During the period of removal, the Society, through the kind liberality of the then President (Dr. Elliotson), held its meetings at his house. The first meeting in Berners-street was on February 10, 1835. Since that time the Society had steadily advanced in reputation and usefulness, revising its laws from time to time, so as to adapt them to circumstances as occasion made it expedient, becoming more just and liberal in some of its regulations, adding largely to its magnificent library, and of late increasing its utility by the frequent publication of abstracts of its *Proceedings*; and finally, by instituting, from amongst its Fellows, committees for the investigation of certain subjects of great general importance to the Profession, such as the "Committee on Suspended Animation," and that on "The Uses and Effects of Chloroform," the report of which is nearly completed. The success of the labours of the Society is attested by the publication of forty-six volumes of its *Transactions*, forming a standard work of reference on the most important topics which have engaged the attention of the Profession during the last half century, and by the formation of one of the largest and best-managed circulating libraries of Medical books in the kingdom. Still (added the President) there remain great objects to accomplish, and foremost amongst them, the acquisition of a permanent residence, either in the shape of a freehold house, with some architectural pretensions as a public building, or of apartments in Burlington House, in association with other scientific bodies. This Society might fairly look for the favourable consideration of the Government in this matter from the advanced position which it holds amongst the other Medical societies of this country, from its royal charter, and from the peculiar means which it possesses of conducting investigations of public utility upon Medical and sanitary subjects. The President then called the attention of the meeting to the very fine collection of Medical portraits and autographs now in possession of the Society, comprised—1st, in the Soden collection, recently presented by Mr. J. Soden, of Bath; and 2ndly, by the purchase of Mr. Squibb's collection, just sanctioned by the present general meeting; both together forming a collection unrivalled by any in the kingdom. Notice was also taken of the rapidly-forming series of photographs, commenced by Dr. H. G. Wright, of pathological specimens, and the Fellows were urged to contribute to these collections as opportunities offered. He then approached the painful subject of the losses sustained by the Society during the past year

in the deaths of sixteen of its Fellows. This number, though double the average of the last ten years, was yet nearly equalled in two former years, and exceeded in two others of the same period (ten years). The President gave a short memorial of each of these sixteen Fellows; but it would be impossible in this abstract to do more than allude very briefly to some of them. Amongst provincial Fellows, Mr. J. S. Soden, of Bath, Mr. Wm. J. Wickham, of Winchester, as Hospital Surgeons; Dr. Edward Stephens, of Manchester, as an anatomist and teacher; and Dr. Carter, of Deal, as a Physician in extensive practice, were the most conspicuous. Amongst resident Fellows, Mr. Henry Ansell, as a gentleman largely engaged in general practice, a man of much ability as well as of laborious research and learning, as is shown by his works on "Tuberculosis," on the "Physiology and Pathology of the Blood," and by his unpublished treatise on "Poisons of the Blood." On Mr. J. H. Green he passed a high eulogium, commenting on the great position which he held in the Profession and in the governing bodies and Professional societies of the country; upon his high, chivalric, and truly Christian character, his eloquence, and his extensive and varied learning. He thought Mr. Green's reputation would increase with time, and he alluded to the long and laborious years of study which he had given to the completion of a "System of Spiritual Philosophy," originated by Coleridge. It will interest every educated mind to know that there is a prospect of the speedy publication of this posthumous work, the result of Mr. Green's life labour. Amongst the younger Fellows, the President especially noticed Dr. Edw. R. Harvey, Registrar of St. George's Hospital, as one who, already distinguished by his researches in physiological chemistry, promised, had he lived, to have left a mark on his generation. Mr. Thos. Davis and Mr. H. C. Johnson were noticed as gentlemen who, each in his time, had enjoyed large practices, and who, without having contributed to the literature of their profession, were, nevertheless, remarkable as skilful surgeons, possessing in a wonderful degree the confidence of their patients. Finally, he deplored, as a loss to the scientific world, a foreign honorary Fellow, in the person of Professor Vrolik, of Amsterdam, whose works on the Chimpanzee, on Embryology, Teratology, etc., etc., are so universally known and esteemed, and whose reputation seemed hereditary. His noble museum, collected by his father and himself, was always open to the scientific foreigner, and his genial manner and knowledge of our language were particularly agreeable to our own travelling countrymen.

At the conclusion of the address, the best thanks of the meeting to the President were moved by Mr. FERGUSON, seconded by Dr. WEGG, and carried by acclamation.

It was also moved by Dr. C. J. B. WILLIAMS, seconded by Mr. DIXON, and carried unanimously,—“That the cordial thanks of the Society be given to the retiring Secretary, Dr. Sieveking, for his valuable and zealous services during the time he had been in office; and also to the retiring Members of Council—Dr. Hodgkin (Vice-President), Dr. West (Vice-President), Dr. Cotton, Dr. Gream, Dr. Geo. Johnson, Mr. Holt, and Mr. Holthouse.”

Dr. SIEVEKING returned thanks for the honour done him.

The result of the ballot for Officers and Council for 1864-65 was then announced by the President as follows:—President: Mr. Partridge. Vice-Presidents: Dr. A. Farre, Dr. Basham, Mr. Hilton, and Mr. Ferguson. Treasurers: Dr. Pitman and Mr. J. Dixon. Secretaries: Dr. H. W. Fuller and Mr. John Birkett. Librarians: Dr. A. P. Stewart and Mr. Henry Lee. Other Members of Council: Dr. Goodfellow, Dr. Gull, Dr. W. Jenner, Dr. Meryon, Dr. Sibson, Mr. Holmes Coote, Mr. G. V. Ellis, Mr. C. H. Moore, Mr. E. Newton, and Mr. Toynbee.

NEW CASE OF OVIOTOMY IN FRANCE.—M. Lacroix, Surgeon of the Beziers' Hospital, South of France, announces another successful case of ovariectomy. The subject was a labouring woman, aged 32, who consulted Dr. Lacroix in April, 1863, on account of a tumour of the abdomen, her health having been hitherto good. Repeated tapplings were followed by only short ameliorations, and the woman's powers failing, it was resolved to have recourse to the operation October 24. A large quantity of fluid was discharged during the operation (the details of which are given in the *Bullet. de Therapeutique*, February 29), and the tumour when removed weighed 3780 grammes. At the period of reporting the case, more than three months had passed, and the woman was able to work in the fields without inconvenience.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 3, 1864:—

John Powdrell, Farndon, near Chester; Edward Sidney Lloyd, Pill, near Bristol.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANDREW, JAMES, M.D., has been elected Assistant-Physician to St. Bartholomew's Hospital.

BROWN, D. DYCE, M.D. Aberd., has been appointed Resident Surgeon-Accoucheur to the Birmingham General Dispensary.

COOPER, THOMAS J., M.R.C.S. Eng., has been appointed Visiting Medical Officer for the Northern district of the Brighton and Hove Dispensary.

RICHARDS, DAVID, M.R.C.S. Eng., has been elected Medical Officer to the Industrial Schools and Workhouse at Brighton.

SMITH, THOMAS, F.R.C.S. Eng., has been elected Assistant-Surgeon to St. Bartholomew's Hospital.

SQUIRE, BALMANNO, M.B., F.L.S., has been appointed one of the Lecturers at St. Mary's Hospital Medical School.

WALLACE, ALEXANDER, M.D. Oxon., has been elected Physician to the Essex and Colchester Hospital.

WILLIAMS, WYNN, M.D. St. And., has been elected Physician-Accoucheur and Physician for diseases of women and children to the Western General Dispensary, Marylebone-road.

DEATHS.

BLACK, THOMAS, L.R.C.S. Edin., at Anstruther, Easter, Fifeshire, on February 29.

BUSH, G. F., M.R.C.S., suddenly, of disease of the heart, at his residence, Hardy-street, Nelson, New Zealand, aged 60.

CARLYON, CLEMENT, M.D. Cantab., at Truro, Cornwall, on March 5, aged 87.

COTTON, THOMAS ARTHUR, M.D., on February 29, aged 71.

COWAN, WILLIAM D., L.R.C.P. Edin., at High-street, Musselburgh. N.B., on February 25, aged 25.

HEAZLE, THOMAS, L.R.C.S. Edin., late Staff Assistant-Surgeon Army, Burgersdorf, Cape of Good Hope, on November 22.

JOHNSTON, FRANCIS G., M.R.C.S. Eng., at Belfast, on February 18, late of Charlton, Kent.

LANDOUZY, Professor, Director of the Medical School at Rheims, and well known to the Profession by his numerous investigations concerning Pellagra, died on March 1, while still in the prime of life.

MASON, GEORGE, M.R.C.S. Eng., at 8, Broad-street, Deal, on March 2, aged 50.

MORRISON, JAMES G., M.R.C.S. Eng., of 121, Edgware-road, W., on February 19, aged 59.

TRANT, LEONARD, F.R.C.S.I., at 18, Upper Pembroke-street, Dublin, on March 1, aged 66.

ROYAL COLLEGE OF SURGEONS.—At a special meeting of the Court of Examiners on the 3rd inst., Mr. James Alexander Grant, of Ottawa, Canada West, having undergone the necessary examination, was admitted a Member of the College; this gentleman had previously been admitted a Doctor of Medicine of McGill College, Montreal, his diploma bearing date May 4, 1854. The next primary or anatomical examination for the diploma of membership will take place on the 9th, 16th, and 30th proximo respectively; and the Surgical, or pass examination on April 23 and May 7. The preliminary examination for the Fellowship will commence on April 26, and the Professional examination on May 31.

"THE MEDICAL REGISTER."—This annual production of the General Council of Medical Education and Registration has just appeared, and our readers will no doubt be surprised to learn how liberally her Majesty's Government subscribe to the work, taking nearly 2000 copies for gratuitous distribution in the United Kingdom. To public officers and functionaries in England, 1027 are presented; to Ireland, 662; and to Scotland, 289: making a total of 1978. From an analysis of the returns to Parliament of the receipts and expenditure of the General Council during the past year, it appears that the sale of "Registers" produced for the United Kingdom £317 14s. The total receipts for fees, dividends, &c., amounted to £7243 5s., and the expenditure to £4800 14s. 7d.; leaving a balance at the bankers on account of the Branch Council for England of £2071 3s. 2d., and an account of the Branch Council for Scotland of £455 17s. 5d.;

and deducting £84 10s. 2d. on account of the Branch Council for Ireland, there appears a balance in hand of £2442 10s. 5d. The fees paid to members for attendance at General Council and Committees, with the travelling expenses, amounted to £1693 13s. For hotel expenses £176 8s. is put down.

THE BRITISH PHARMACOPŒIA.—We understand that at their meeting on Monday last the Branch Medical Council (Ireland), in accordance with the recommendations contained in a Report of the General Pharmacopœia Committee, confirmed by the General Medical Council, unanimously appointed Dr. W. D. Moore, M.R.I.A., to observe the progress of pharmacy, and to report thereon from month to month to the Branch Council.

THE ACTIVE PRINCIPLE OF THE CALABAR BEAN.—Two German chemists, Jobst and Hesse, of Stuttgart, have by their researches determined that this is exclusively contained in the cotyledons. They have obtained it by dissolving in ether the residue left by evaporation of an alcoholic solution. The ether solution, in its turn evaporated, leaves the active principle of the bean, which these chemists propose to call *physostygmine*, from the botanical name of the plant, *physostygma venenosa*. It has, however, been suggested that *calabesine* would be as appropriate, and a far more convenient name. Two drops of an aqueous solution of the alkaloid in ten minutes caused contraction of the pupil to about a twentieth of its diameter, it remaining in this state during an hour, and recovering its normal condition in from four to six hours. Taken internally, the *physostygmine* is as poisonous a substance as the most dangerous cyanides.

PRIZE QUESTIONS OF THE BELGIAN ACADEMY OF MEDICINE.—1. A medal of 1500 francs for the best essay on "A demonstration of the formation of the globules of the blood by new researches and a critical examination of existing works."—(June 15, 1864.) 2. A medal of 800 francs. "The history of glycosuria, with especial relation to the causes, nature, and treatment of the disease."—(April 1, 1865.) 3. A medal of 300 francs. "Exhibit by observations and experiment the effects of the use and abuse of tobacco in healthy man."—(July 1, 1865.) 4. A medal of 500 francs. "State the characters of the disease known as carbuncular (*typhus charbonneux*) which attacks the domestic animals, indicating its causes, the therapeutical procedures, and those calculated to prevent its development."—(April 1, 1866.) 5. A medal of 500 francs. "The chemical history of digitaline, with new researches as to its distinctive characters and composition. A simple and easy procedure for its extraction which shall furnish a constant and definite product."—(April 1, 1866.) The memoirs, written in French, Flemish, or Latin, to be forwarded to the Secretary, Place du Musée, Bruxelles, by the above dates.

MUNIFICENCE.—Mr. J. Moritz Oppenheim, of New Cannon-street, City, lately deceased, and whose will has just been proved in London under £250,000 personalty in Great Britain only, has bequeathed £100 to each of the following Medical charities in this metropolis, viz.:—The London Ophthalmic Institution, the Royal Free Hospital, St. Thomas's Hospital, and any Hospital in Hamburg which his executors may select. Another act of munificence has to be recorded on the part of Mr. Howard, of Stanley, near Perth, who has vested in the hands of trustees no less than sixteen acres of land, whereon to erect an Infirmary, to be called the Howard Institution. This gift is valued at £1000 per acre, representing a total of £16,000, and the land not necessarily required for the institution is to be let for building sites, and the proceeds to go towards the endowment of the Howard Infirmary.

ALLEGED VIOLENT DEATHS IN A WORKHOUSE.—The *Liverpool Mercury* of February 25th contains an account of two inquests held on pauper lunatics who have lately died in Toxteth-park Workhouse. One of them, who was paralysed and imbecile, died from mortification of the feet following the application of a pan of hot water. The pan was applied by an assistant, who was himself one of the sick inmates of the ward. The other case was that of a pauper lunatic, aged 71, who died from injuries inflicted by another lunatic. From the evidence adduced it appears that the attendance and nursing in the sick and lunatic wards in the Toxteth Workhouse might be greatly improved. There are no regular nurses, but their place is supplied by the convalescent paupers. The jury, in their verdict, animadverted strongly on what they considered the gross mismanagement at the workhouse.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Dr. Buchanan.—We do not know.

An Associate of Beards.—The papers appeared in the *Dublin Medical Press*.

Mr. C. Stevenson.—The greater part of the article was original. We do not recollect, after this lapse of time, from what report the paragraphs printed with inverted commas were taken.

The letter of Mr. Robert Ellis on the "New Instrument for Dilating the Cervix Uteri" is in type, and shall appear next week.

Medical Society of London.—The secretaries of this Society are authorised by the Council to state that the report contained in a letter from a fellow of the Society, published in the *Medical Times and Gazette* of March 5, that the Medical Society is about to remove from its present quarters, is without foundation.

E. C. B.—Write to Dr. John Edward Morgan, 3, Gore-street, Manchester, Hon. Sec. to the Manchester and Salford Sanitary Association. There is now no weekly publication of the health of London, save the Registrar-General's invaluable *Weekly Return* of the deaths. This may be had through any bookseller for 1½d. per week. The London Medical Officers of Health used to issue a return of sickness, but it was given up because of the expense. Returns cannot be depended on, as a rule, if they are to be collected from voluntary contributors; they must be got from paid officials, who give them as a matter of duty, not of favour.

Curious Advertisement.—In the *Gazette des Hopitaux* of March 3, appears the following singular notice. As neither the address of the Messrs. Pratt nor the direction given (probably a mis-print), appear in the "Post-office Directory," perhaps some of our readers may be able to explain the matter:—

"Students in Medicine of the second and third year, and Students in Pharmacy, provided with certificates of two years' study, are now wanted in England. They will be paid by their respective Hospitals. Address, post free, to Messrs. Pratt and Sons, 1, Russell-street, Camberwell New-road, London."

Poor-law Medical Reform Association.—Mr. Griffin begs us to announce that, within the last few days, he has received the following subscriptions in aid of the funds of the Association:—

Horton, H., West Bromwich, 5s.; Reid, R. B., West Derby, £1; Jardine, J. L., Dorking, 10s.; Gage, W. T., Williton, 10s.; Brettet, T., Watford, 10s.; Hubert, W. A., Hemel Hempstead, 10s.; Perry, C. H., Aylsham, 10s.; Black, W. S., Freckbridge, Lynn, 10s.; Brewer, J., Newport, £1; Phillips, G. M., Hitchin, 7s. 6d.; Hair, J., Sudbury, 2s. 6d.; Brine, J. E., Shaftesbury, £1 1s.; Bennett, W. H. R., Shaftesbury, £1 1s.; Miles, E. J., Shaftesbury, £1 1s.; Griffin, R., Weymouth, £1 1s.; Blenkinsop, W. H., Easthampstead, 10s.; Smith, H. B., Titchhurst, 7s. 6d.; Clouting, J., Mitford and Launditch, 10s.

A CORRECTION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your report of a petrous bone presented to the Pathological Society on the 2nd February by Mr. Hinton, for Mr. Toynbee, the name of the Surgeon of the *Cumberland* is incorrectly given. Instead of Mr. Lacy, it should be the name of your humble servant.

I am, &c.

WM. LONEY, Staff-Surgeon, R.N.,
H.M.S. *Cumberland*, Sheerness.

RETIREMENT IN THE ARMY MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your last able article on the Army Medical Department, you advocate an earlier retirement as necessitating a more rapid promotion from the rank of Assistant-Surgeon. Will you allow me to suggest that what is required is not an earlier, but a better, retirement for Surgeons-Major, who must always constitute the very large majority of retired Medical officers.

Surgeons-Major of twenty-five years' service are of course unwilling to retire upon a bare pittance of 18s. 6d. a-day, thus sacrificing in difference of pay and allowances upwards of £200 a-year, and giving up all hope, however remote, of attaining a higher rank; but give them the retiring allowance, as well as the empty title of "Deputy Inspector-General," and they may probably be induced to make room for the rising generation.

I am, &c.

MEDICUS.

NIGHT AIR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to thank you for publishing my letter on night air. The following is a brief description of my mode of obtaining pure air in a bedroom at night:—

A tin tube, one inch in diameter, and open at both ends, has one end inserted in a hole in the window-frame at the top, communicating directly with the external air, and the other end bent at right angles, so that the internal opening is at a distance of about two feet from the head of a person lying in bed. The tube is suspended near the ceiling, and carried right across the room, the bed being against a wall at the side of the room opposite to the window. The tube is nearly horizontal, but slightly inclined towards the bed. A paper wheel-anemometer is attached to the internal opening of the tube, which turns with a very delicate current of air. The length of tube allows the air, however cold outside, to attain the same temperature as the general air of the room before it is breathed by the person lying in bed. In this way a gentle current of pure air is kept up all night where it is wanted—namely, close to the mouth. By this method, as far as the experiment yet goes, the sleeper derives the full benefit of fresh air in perhaps the simplest possible manner. The colder the air outside the stronger the current, as a matter of course. My little wheel usually performs about 100 turns per minute. I have a piece of cardboard turning on a pin, by which I can stop the current at any moment without rising in bed, and which answers the purpose of a

stop-cock. I have never felt the slightest draught, the only palpable effect being a delightful freshness in the air.

I am, &c.

Clifton, March 6.

WILLIAM C. BURDER.

THE NEW ANÆSTHETIC, NITROUS OXIDE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A great deal has been written and spoken this year in favour of a new anæsthetic—nitrous oxide—especially among the dentists, where the admirers of balloons and bags for chloroform vapour have been persuaded that this gas is infinitely more safe than chloroform, not one recorded instance of death from the oxide having ever appeared, etc.

It is rather clear, I think, that the danger of anæsthetics is pretty much equal for ether, or chloroform, or anylene, or nitrous oxide, or hydrogen, the danger being in the insensibility it produces rather than the agent producing it, the danger being rather in the want of skill in perceiving signs of danger when they come on, and not stopping, than in any fanciful inferiority of this or that anæsthetic to any other. One death has just occurred in a dentist's chair from the administration of nitrous oxide; it was that of a fine young woman, in perfect health, who was induced to have this anæsthetic rather than chloroform.

I am, &c.

Sackville-street, March 5.

CHARLES KIDD, M.D.

THE DECLINE OF THE MAORIES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was much gratified on noticing a letter in your last number from Mr. Stratford, of Auckland, New Zealand, confirming my observations on the decline of the Maori race. If Mr. Stratford had had an opportunity of reading the whole of my paper, he would have seen that the points he alludes to as having been omitted by me were, on the contrary, particularly noticed, and much stress laid on them.

You will also perceive that Mr. Stratford agrees with me that the settlers, far from wishing the extermination of the natives, only desire their amelioration, and that such a result is considered of the highest importance to the colony. It is merely Exeter Hall cant to characterise the present war as one having its origin in a desire for selfish aggrandisement.

I am, &c.

JOHN B. TUKE, M.D.

Royal Edinburgh Asylum for the Insane, March 4.

THE LONDON AND PROVINCIAL MEDICAL PROTECTION SOCIETY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your issue of January 9 I perceived an advertisement of the London and Provincial Medical Protection Society, and I beg to ask a little information on a few points connected with it, if in your power to furnish it.

1st. Does the term "Medical," in speaking of the qualified Medical Practitioners, comprise Physicians only, or are both branches of the Medical Profession included—Physicians and Surgeons?

2nd. Are the means of attaining the end proposed of such a character as to save the Medical man the necessity of appearing in a Court of Justice to secure his fees?

3rd. What are the objects, more precisely, to which the Benevolent Fund is applied?

4th. What is the scale of charges adopted by the Society?

I am, &c.

T. T.

PRESCRIBING DRUGGISTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have read with much pleasure your leading article on the subject of a proposed "Charter for Chemists and Druggists," and beg to add my testimony to the pernicious effects of "counter practice," as carried on in the town in which I reside. This kind of practice, already very great, as I will presently show, would, I am convinced, increase tenfold were any kind of certificate or license possessed by the offenders, and the result would be a still greater injustice to Medical men, and a manifest injury to the public, who, for the sake of economy (?), would go to the cheapest place for advice,—advice that would be followed up by a large supply of medicine (on which the profit would be made). In 99 cases out of 100 the advice would be bad and the medicine injurious.

In this town there are three so-called chemists and druggists; one is also a grocer and stationer, another is a wine merchant, and the third a seedsman and stationer; neither has the certificate of the Pharmaceutical Society, but they all give (bad) advice—in fact, prescribe, when asked to do so. I know of at least one life sacrificed in consequence: A poor woman applied to one of the above for advice. She was suffering from symptoms of incipient typhus; he gave her eight pills, without any directions or caution as to their strength, &c. She took them all that night, and died three days afterwards from the excessive purging they produced. These pills contained twenty grains of extract of Socotrine aloes, forty grains of jalap, and six grains of calomel! In another case a chemist's assistant applied a large blister to the throat of a young woman suffering from malignant scarlet fever. This patient died from effusion on the brain. If she had not done so, the frightful ulceration which follows the application of blisters in eruptive fevers would have disfigured her for the rest of her life.

It is a very common thing for a poor woman to bring a half-dead child to me suffering from bronchitis or pneumonia, or some other acute disease, and, on inquiry, I find that she has been to Mr. So-and-So, the druggist, who "will not go any farther, as he thinks the case is beyond his skill." It is then, in many cases, too late for any skill to be of service. No doubt the experience of nearly every country Practitioner will coincide with my own in this respect.

In the face of such facts as these, it seems to me to be the duty of every Member of Parliament, and every member of the Medical Profession, to oppose to the utmost any attempt to give a legal or official sanction to such practices, for such, in effect, would be the result of granting a charter to these tradesmen.

Legislation is wanted to put a stop altogether to what is called "counter practice." There is a sad want of comprehensiveness about the Medical Act if it permits an unqualified and ignorant person to evade it daily and hourly by the miserable deception of charging only for medicine, when, at the same time, that medicine is concocted in the undiagnostic brain of the compounder. The Medical men of the present day are too well educated to require the "supervising care" so kindly offered by the druggists. Let druggists know how to read prescriptions accurately, prepare them carefully, write the directions legibly, and take care to put in all the ingredients prescribed (including the expensive ones), and no "charter" will elevate them in the eyes of the Medical Profession, or the enlightened portion of the public.

I am, &c.

A COUNTRY DOCTOR.

APPOINTMENTS FOR THE WEEK.

March 12. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Professor Frankland, "On the Metallic Elements."

14. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.
MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion.

15. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.
PATHOLOGICAL SOCIETY, 8 p.m. Meeting.
ST. MARY'S HOSPITAL MEDICAL SCHOOL, 8 p.m. Dr. Graily Hewitt, "Clinical Conference in Midwifery."

16. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

17. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.
HARVEIAN SOCIETY OF LONDON, 8 p.m. Mr. Camps, "On Some Points in the Pathology of Convulsive Diseases."

18. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

BARTH'S OXYGEN WATER holds free Oxygen in solution. It gently stimulates the functional action of the stomach and secretory organs, and is a very useful beverage. WENTWORTH SCOTT'S Analysis gives as contents of a bottle—"Nearly half an imperial pint of pure distilled water, and about 13.5 cubic inches, or 4.6 grains of gaseous oxygen; equivalent to that contained in 21.4 grains of chlorate of potash." 4s. per dozen.
OXYGENATED WATER COMPANY (LIMITED), 36, LONG-ACRE.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

TOWLE'S CHLORODYNE.

OF KNOWN COMPOSITION.

For Formula, &c., see back Numbers.

Extract of Letter from Dr. C. KIDD (Author of Standard Works on Chloroform).—"SIR,— . . . Of the value of Chloroform given internally I have no doubt; it appears to me in that form an anodyne, *sui generis*, that no other anodyne can approach. I have resolutely opposed the use of *secret* compounds of chloroform, and in every way I can encourage the use of the 'Chlorodyne' (if we must have it at all) that is made by you, as you state that its composition is known. Many Medical men think with me, and recommend your compound, but will never prescribe a secret remedy.—CHAS. KIDD, M.D.—Sackville-street, Piccadilly, London, April, 1862.—To Mr. A. P. Towle."

Extract of Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J. P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession.—To Mr. A. P. Towle."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; 4 oz., 4s.; and 8 oz., 8s.

SOLE MANUFACTURER—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

LIQ. CHLOROFORMI CO. (TOWLE'S).

This preparation is identical with "Towle's Chlorodyne," *sine* Ol. Menth. Pip. (dose 5 to 20 minims, as in Chlorodyne).

The Proprietor having for some time past, at the request of several members of the Medical Profession, made a preparation of Chlorodyne without peppermint, has lately, on account of the frequency of these demands, prepared the same for more general use, under the designation of LIQUOR CHLOROFORMI CO., which, possessing the Medical properties of Chlorodyne, may be prescribed in all cases where the Ol. Menth. Pip. is disapproved, and overcome the objection so generally felt to the use of the term "Chlorodyne."

May be obtained, as an introduction, from the following Wholesale Houses, in 2 and 4 oz. bottles, at 2s. 6d. and 4s. each:—London: Barclay and Sons, 95, Farringdon-street. Birmingham: Southall, Son, and Dymond. Liverpool: Clay, Dod, and Casc. Edinburgh: Duncan, Flockhart, and Co. Glasgow: The Apothecaries' Company. Dublin: Bewley, Hamilton, and Co. Manchester: Jas. Woolley; and the

Proprietor—A. P. TOWLE, 99, STOCKPORT-ROAD, MANCHESTER.

ORIGINAL LECTURES.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE V., (a) FEBRUARY 9.

(Continued from page 277.)

MR. PRESIDENT,—The early commencement this year of the season of Lent compels me to complete my subject during this Lecture, and the obligation thus imposed upon me to condense matter originally designed to occupy the time of six Lectures into five, obliges me to curtail my observations upon some subjects which I had intended to treat at greater length. I will therefore, select more especially matter upon which I have to offer something that, I trust, will be of interest, and subjects which I have more particularly investigated myself, and upon which, therefore, I feel some little confidence in speaking; leaving it to yourselves, if you desire a practical knowledge of the work, to fill up the many details which I shall be obliged to leave untouched.

In resuming the subject of the new introductions into the British Pharmacopœia, I shall first speak of the Salts of Lithia.

In the list of the *Materia Medica* will be found two salts of this metal which have only recently been employed as internal medicines. I allude to the Carbonate and Citrate of Lithia. In speaking of these salts, I feel some little hesitation, having been instrumental in introducing them to the Profession as remedies in certain forms of disease, and it might, perhaps, be thought that it was from my own advocacy of their merits that they have been now made officinal. With regard to their introduction into the British Pharmacopœia, I may be permitted to say thus much—namely, that they were proposed neither by myself nor any member of the London Committee, and if they are found valuable additions to the *Materia Medica* the merit of their introduction will be due to others.

As they are now placed in the Pharmacopœia, it may, perhaps, be well that I should give you a short summary of their properties and therapeutic value.

The metal lithium (so named from *λίθος*, a stone, as it was supposed to exist only in the mineral kingdom) has somewhat remarkable properties. In the first place, it is the lightest known solid—lighter even than any liquid, as you will perceive in this specimen, in which the wire is seen floating on Persian naphtha. Secondly, it possesses a very small atomic or equivalent weight, being only 7 on the hydrogen scale, whereas the equivalent weights of the other alkaline metals, Sodium and Potassium, are respectively 23 and 39 on the same scale; the saturating power, therefore, of Lithia itself is much greater than that of either Soda or Potash.

Thirdly, Another peculiarity of Lithia consists in its forming a salt with uric or lithic acid, much more soluble than those of any other bases; hence in this respect differing from potash, and far more from soda and ammonia.

It follows, therefore, from these facts that not only is a much smaller amount of Lithia sufficient to form a salt with uric acid, but likewise that the salt so formed requires much less fluid to hold it in solution; and hence it would appear that unless other circumstances interfere with their administration, the Lithia salts must be desirable remedies when our object is either to keep uric acid in solution during its transit through the urinary organs, or to prevent its deposition within the structures of the body. The characters of the Carbonate and Citrate of Lithia are seen in the specimens on the table; some of these are very beautiful. The composition is represented in the diagram:—

Carbonate of Lithia— LiO, CO_2 .Citrate of Lithia— LiO, Ci .

Both salts can be obtained in a crystalline form; the citrate in large crystals. The carbonate is peculiar in being very sparingly soluble in water; the citrate is freely soluble.

From a somewhat extended experience in the use of these salts during a period of five years, I have gathered the following information, which I will condense into a few sentences:—

1stly. Lithia salts are readily absorbed by the stomach, and pass through the kidneys, the carbonate remaining unchanged in its passage; the Citrate of Lithia and the other salts with a vegetable acid, undergo decomposition, and appear in the urine in the form of carbonate of the base.

2ndly. Lithia combined with carbonic acid or a vegetable acid, and given in the form of dilute solution, acts as a powerful diuretic, probably more so than the corresponding salts of potash or soda.

3rd. Lithia salts exert a much more powerful influence upon the condition of the urine, in rendering it neutral or alkaline, than the salts of the other alkaline metals; that is, when given in the same doses.

4th. In certain states of the system, in which urate of soda is liable to be deposited in the tissues, leading to the production of gouty inflammation, the administration of Lithia salts is attended with advantage; probably both by aiding elimination and likewise by assisting the solution of the urate in the animal fluids.

5th. Lithia is not foreign to the system; it has been found by means of spectral analysis in the ash of the blood and flesh, although its amount is extremely minute. When its administration is continued for a lengthened time, no injurious consequences ensue, although we should be guided by the same rules in suspending the use of Lithia as in the case of other alkaline remedies.

6th. The dose of the carbonate may range from three to six grains, of the citrate from five to ten grains; the carbonate may be given in aerated water; free dilution aids its diuretic action.

A drug named *Hemidesmus* is now introduced into the Pharmacopœia. It is the dried root of *Hemidesmus Indicus*, and is imported from India, and often called Indian *Sarsaparilla*.

Only one preparation of this drug has been made officinal, and this is a syrup, *Syrupus Hemidesmi*. With regard to the therapeutic effects of this plant I fear I can give you but very scanty information. It is believed to possess the same remedial powers as *Sarsaparilla*, but as even these last are somewhat difficult to define, those of *Hemidesmus* must be equally so. The syrup has a pleasant flavour and odour, and so much at least can be said for it.

Matica, or *Matico*, also finds a place in the new Pharmacopœia. It is the leaf of a species of pepper, called *Artanthe Elongata*, sometimes *Piper Angustifolium*. It is imported from Peru. The leaf has a somewhat peculiar construction, being tessellated on the upper, and downy on the under surface, with a slightly astringent taste and aromatic odour.

With regard to its composition, little is known that throws light upon its action. Its astringency is but feeble, and the amount of contained Tannin or Gallic Acid small. Possibly it may have an active principle, similar to that contained in other Piperaceous plants. There is only one officinal preparation, an infusion.

With respect to its medicinal powers, I may state that it is said to have proved efficacious, when applied externally, in arresting hæmorrhage, and its value has sometimes been attributed to the peculiar structure of the leaf. This explanation can hardly be looked upon as probable, and is rendered still less so by the fact that its infusion is equally efficacious in arresting hæmorrhage when given as an internal remedy.

In some few instances I have had an opportunity of testing its therapeutic powers, and in some chronic affections of the bladder as well as in hæmorrhage have thought that it proved efficacious. I should not, however, wish to speak positively upon the action of *Matico*.

Lastly, among the novel introductions, I must say a few words upon certain salts which have now for the first time found a place in an English Pharmacopœia.

Citrate of Potash.—Practitioners have often felt at a loss when desirous of administering this salt in a non-effervescent form from the want of a formula for its preparation, and from its not being kept by many druggists.

Citrate of potash possesses, in some respects, advantages over the other salts of the base. It is more pleasant to the taste, usually sits easily upon the stomach, is more readily

(a) Portions, especially of the latter part, of this Lecture were not delivered from want of time.

absorbed into the system, and hence less liable to purge than many other vegetable salts of potash.

It is a valuable saline febrifuge, increasing the secretions from the kidneys; it is readily decomposed after absorption into the blood, reduced to the condition of a carbonate of the base, and is in this state eliminated in the urine, rendering this fluid less acid or even alkaline in reaction. It is thus an indirect alkaline remedy, although in the stomach it possesses no antacid properties.

The dose is from twenty to 60 grains, and I have frequently given it with much advantage, made as a lemonade, in cases of uric acid gravel and allied diseases. I have also seen its antiscorbutic effects well marked both in the treatment of developed scurvy and likewise when employed as a substitute for vegetables in preventing the occurrence or recurrence of that disease.

Another preparation introduced into the Pharmacopœia is the *Permanganate of Potash*, a crystallised salt, represented by the formula, $\text{KO}, \text{Mn}_2\text{O}_7$. This substance possesses some remarkable and interesting properties. It dissolves in water, and the solution has a most beautiful pink or purple colour, according to the amount of the contained salt. The permanganate is readily decomposed when in contact with organic substances or others susceptible of oxidation; it is hence a powerful antiseptic agent, and as such can be employed with much advantage in the form of a gargle or lotion to remove decomposing matter and clean diseased surfaces.

The liquor potassæ permanganatis of the Pharmacopœia contains four grains of the salt to each fluid ounce, and as an external application may with advantage be very much diluted, a fluid drachm to five to ten ounces of water being usually sufficiently strong. Permanganate of potash has also been proposed as an internal remedy, from an idea that it possesses the power of oxidating the blood. I know, as yet, of no clinical facts which establish the existence of such a power or of any advantages derived from its exhibition; it has been given in diabetes, with the erroneous idea that the existence of sugar in this disease depends on a want of oxidising power. From my own experience of its effects in diabetes I cannot speak at all favourably of its action; the only change I have witnessed has been the augmentation of the saccharine matter in the urine when the salt has been administered in doses sufficient to produce any appreciable effects.

The last salts to which I shall call your attention are certain preparations of Zinc—namely, the *Carbonate*, *Acetate*, and *Valerianate*.

The pure Carbonate is introduced, and may be used in place of *Calamine*, which is omitted, and which is either an impure carbonate or oxide, according to the heat employed in its preparation. It is seldom used as an internal remedy, but might be employed in the same cases and doses as the oxide.

The *Acetate of Zinc*, $\text{ZnO}, \text{C}_4\text{H}_3\text{O}_3 + 2\text{HO}$, is used as an external astringent in place of the sulphate, and is preferred by some. It could also be employed, if desired, as an internal remedy, as a substitute for the sulphate, in doses of one grain and upwards.

The *Valerianate of Zinc*, $\text{ZnO}, \text{C}_{10}\text{H}_9\text{O}_3$, although long employed, and in the last edition of the Dublin Pharmacopœia, is now for the first time made officinal in England. Of course it possesses the virtues of a zinc salt, but the interesting point is to ascertain whether it also combines with such virtues those of the Valerian plant likewise. Its mode of formation is somewhat peculiar, and not devoid of interest. Instead of being made from valerian, it is procured from fousel oil, a latter product of the distillation of grain. This so-called oil is, in fact, an alcohol, and called Amylic alcohol, $\text{HO}, \text{C}_{10}\text{H}_{11}\text{O}$, which, when oxidated, is converted into valerianic acid, $\text{HO}, \text{C}_{10}\text{H}_9\text{O}_3$; hence valerianic acid bears exactly the same relation to amylic alcohol as acetic acid does to ordinary or ethylic alcohol. Valerianic acid is, however, contained in valerian, and is produced from the oxidation of the oil obtained from the root. Some Physicians are of opinion that valerianic acid does not possess the virtues of valerian; others, on the contrary, strongly believe in its powers. I have endeavoured to determine the point, but as yet without having arrived at any satisfactory result. Of course, when administered as valerianate of zinc, it is difficult, if not impossible, in diseases of the nervous system, to separate the effects due to the valerianate acid from those of the zinc; I have therefore avoided this source of fallacy, and given it as valerianate of soda. I must, however, wait for further clinical experience before venturing to decide on the value of valerianic acid as a medicinal agent. The odour and taste of the acid would

certainly *à priori* lead us to believe that it possesses the same powers as the plant which contains it.

Valerianate of zinc may be given in doses of one to five grains in hysterical affections, and other more serious diseases of the nervous system, as chorea, epilepsy, headaches, etc.

The salt has been frequently found much adulterated.

(To be continued.)

A CLINICAL LECTURE

DELIVERED AT

ST. THOMAS'S HOSPITAL.

By FREDERICK LE GROS CLARK, F.R.C.S.,
Surgeon to the Hospital.

AMPUTATION BETWEEN THE ASTRAGALUS AND NAVICULAR BONES (CHOPART'S)—RESECTION OF KNEE-JOINT.

F. H., aged 23, a labourer, was admitted on February 25, 1863. About two and a-half years since he began to suffer from pain and swelling in the foot without apparent cause. After a time pus collected, and an abscess was opened; some bone was subsequently removed. When he got better he attempted to work and had a relapse, attended with pain in the loins. During the two months previous to admittance this was accompanied by pain in micturition. When admitted the foot was much swollen, and there were two openings on the dorsum of the foot, through which a probe reached carious and exposed bone, involving, apparently, the navicular and cuneiform bones, and probably the cuboid. His urinary symptoms still continued, and his health was much deteriorated. There was albumen, and occasionally pus, in his urine, and he suffered considerable pain in the loins. Treatment was adopted, with varying success, for the relief of these symptoms, and he was frequently sounded. In June an operation was performed for the relief of the foot. A free incision was made across the tarsus, for the purpose of ascertaining the extent of the disease; but all the tarsus being found more or less extensively involved in front of the astragalus, the disarticulation between that bone and the calx behind, and the navicular and cuboid in front, was completed, and a flap from the sole was obtained to cover the stump; the edges of the wound were connected by metallic sutures. The wound healed kindly without sloughing, and the operation was attended, at first, by much relief to the urinary symptoms. The stump was in every respect satisfactory, being firm and well rounded.

Where the foot is the seat of incurable disease, the question often arises as to which operation is to be preferred. Of course there is one general principle to guide the Surgeon, which is that of sacrificing as little as possible, consistently with the utility of the member. But here are two elements of importance, which it is not always easy to reconcile. The principal operations at and near to the ankle-joint are, amputation through the joint itself, and the modification of this operation introduced by Pirogoff, in which the tuberosity of the os calcis is left, and its sawn surface adapted to the sawn surface of the base of the tibia. Then there is amputation between the astragalus and navicular bone, in which the former bone and the calx are left *in situ*, as in the case I have just narrated. Lastly, the whole foot may be removed, with the exception of the astragalus. Of the last of these operations I may at once remark that I have no experience, having never tried it. As regards the amputation between the astragalus and navicular bone, there can, I apprehend, be no doubt that it is to be preferred where the condition of the bones permits of it; and where any doubt exists on this point, I recommend you to make an exploratory dissection or examination, after you have made your anterior incision, which would permit you to finish your operation in whichever way you may find expedient. Of amputation at the ankle-joint I entertain a high opinion, and think it preferable to that in which the tuberosity of the os calcis is left. In the former the stump is broader and firmer, and therefore better fitted for support; and an artificial foot is more conveniently adapted to it than where the limb retains nearly its full length. Pirogoff's operation is easy of performance, and there is no difficulty in the adaptation of the tuberosity of the heel-bone to the sawn surface of the base of the tibia.

Excision of Knee-Joint.

Case 1.—E. C., aged 25, a widow, was admitted on April 7,

1863. About fifteen months since she began to suffer pain in the right knee, without any apparent exciting cause. The pain, which gradually increased, was unattended for more than two months with any swelling or redness about the joint, and it did not interfere with her following her occupations, and her general health was unaffected. Increasing stiffness of the joint, especially after sitting for some time, was the chief inconvenience she then complained of, in addition to the pain. At the expiration of two months, when rising from her chair, she was suddenly seized with violent pain, which was rapidly succeeded by swelling and increased heat, and general constitutional disturbance, evinced by loss of appetite, headache, and feverishness. She was almost immediately admitted into an Infirmary, where she remained until she came to the Hospital, the treatment having been painting with iodine and poulticing, with rest. In this interval the disease had gradually gained ground; an abscess was opened about six months before admission on the outside of the knee. The articular extremities of the bones and the entire joint are now much swollen and hot, and extremely tender. There is a sinus on the outside of the knee, which discharges freely. The bones are in good relation, and the limb is nearly straight. The slightest movement causes great suffering. General health feeble; pulse 96; weak; face has a hectic flush.

The patient's general condition being somewhat improved by attention to diet, etc., the operation of excision was performed on April 25, under chloroform. A semilunar flap was raised, by carrying an incision from the back of one condyle to that of the other, across and through the ligamentum patellæ. A considerable quantity of curdy purulent matter escaped as soon as the joint was laid open; this had been harboured chiefly in an abscess extending for some distance up beneath the extensor tendons. On raising the flap, the entire joint was found denuded of cartilage, and there was scarcely any vestige of inter-articular cartilage or ligament; but abundance of infiltrated granulations and disorganised tissue. Disarticulation being readily effected by forcibly flexing the knee, the surface of each bone was sawn off, Butcher's bow-saw being used for the purpose, and worked from behind forwards; the section of the tibia was made horizontally, that of the femur nearly in imitation of the normal form of its articular extremity, as no difficulty was apprehended in replacing the surfaces when the limb was extended; the articular face of the patella was also sawn off. The sawn surfaces were healthy, and bled freely; but very little blood was lost from the soft parts, and not a single vessel required a ligature. Considerable time was expended in carefully dissecting out every particle of diseased texture, and then the surfaces of bone were placed in relation, and the flap was accurately adapted, and fixed with several wire sutures. The limb was placed in a padded splint, and in a straight position, no dressing being used, but the surface of the joint being left exposed. A dose of morphia was ordered at bedtime.

On the following day, there was healthy constitutional reaction. She slept pretty well, and was freer from pain than before the operation. On the third day, the tension of the skin being considerable from the accumulation of inflammatory and serous exudation, a director was introduced into the interior from the inner side, and a considerable quantity of fluid escaped. About two-thirds of the wound were adherent. Spirit lotion, one part in three, was then applied over the surface of the joint. The greater part of the sutures were removed at the end of the first week, the flap being adherent and healed, except at the extremities.

The subsequent course of this case was slow, but satisfactory. Suppuration, to a moderate extent, continued from the outer and inner sides of the joint; but there was no abscess nor accumulation of matter. In October there were still two or three sinuses of some depth, which continued to discharge; but the patient's health was restored, and entire recovery seemed to be simply a question of time. She was subsequently sent to the Sea-bathing Infirmary at Margate.

Case 2.—E. S., aged 18, of strumous appearance, was admitted on March 25, 1863. Her statement was that she had suffered from a severe attack of rheumatism, after which the knee became much swollen, and this enlargement was accompanied by considerable pain. She derived no benefit from the treatment adopted, and, after the lapse of three months, she was brought to the Hospital. She looked delicate and suffering; the knee was swollen, hot, and painful, and the pain was increased by pressure of the articular surfaces together and by

motion; the catamenia were suspended, and her appetite was bad. The limb was fixed in a long splint, and she was ordered steel and a nutritious diet. In the middle of May an issue was made on either side of the joint, and some little time after this there seemed to be some amendment. It was, however, only temporary, and the returning suffering in an aggravated form, accompanied by loss of rest, together with the formation of abscess on the outer and upper part of the joint, which was opened without benefit, decided the necessity of undertaking some operation for her relief; and, accordingly, excision was performed on July 18, under chloroform. The operation was commenced by the semilunar incision, and the patella was raised. Disease involved both tibial and femoral surfaces of the joint, which, together with the surface of the patella, were removed. The cartilage was partially destroyed, and subarticular caries had separated a considerable portion of that which was superficially sound from the cancellous texture beneath. Carc was taken to remove, by dissection, all the disorganised tissues within reach; and in this search abundant granulations, with purulent infiltration, were discovered far back in the popliteal space. No artery required a ligature. The flap was accurately adapted with metallic sutures, but sufficient space was left at the extremities of the wound to allow of drainage. The limb was placed in a straight position, supported and lightly confined with bandages. The wound was left exposed without any dressing, in accordance with the plan recommended by Dr. Humphry, of Cambridge.

She suffered a good deal from the combined effects of shock, loss of venous blood, and chloroform, being sick and faint, with a quick, feeble pulse, and abdominal pain. Brandy and opium were administered, but she rallied slowly, and reaction did not fairly take place until the third day. On the fifth day she was rallying considerably, and a healthy discharge escaped from the wound. The sutures were then removed. On the seventh day a small abscess on the side and front of the tibia was opened, and pus could be pressed out of this opening from the popliteal space. The edges of the wound had retracted about a quarter of an inch, but it was looking healthy. After this she improved slowly; the discharge continued from the two openings on the outer side and front of the knee, and the wound gradually contracted. Being thin, she suffered from a small bed-sore over the sacrum; this probably increased a natural restlessness, and there was consequently some trouble occasioned by tendency to displacement or arching of the knee outwards. In October she was much improved in health, and the line of incision had nearly healed. She was sent to Margate about this time, but has recently returned to the Hospital in a condition which makes it doubtful whether she will ultimately recover without some further operation, as there are several deep sinuses discharging freely around the knee.

(To be continued.)

ORIGINAL COMMUNICATIONS.

SOME OBSERVATIONS ON THE LINGUAL GLANDS,

OTHERWISE KNOWN AS THE GLANDS OF BLANDIN OR NUHN;—
AS ALSO GLANDS OF THE TIP OF THE TONGUE (HENLE),
GLANDS OF THE FRÆNUM (GOODSIR).

By Dr. T. DEVILLE,

Formerly of the Ecole Pratique de la Faculté de Médecine de Paris, etc., etc.

As I have not met in any of the ordinary text-books of British anatomists with any description of these glands, I am induced to give a few particulars about them. Cruveilhier ("Traité d'Anatomie Descriptive," 3me edition, tome 3me, pp. 249—250) thus describes them:—

"Beneath the transverse fibres of the tongue, above the conjoined fasciculi of the lingualis and stylo-glossus, are found, in the thickness of the tongue, immediately behind the frænum, two glands, one on the right, the other on the left side, first described by Blandin. Nuhn, who was, without doubt, unaware of the discovery of the French anatomist, gave an account of them at a later period in an essay on "Glands not yet described." They have the form of an almond, are further apart at their posterior extremities than at their anterior, receive many vessels and ramifications of the lingual nerve. Nuhn has only found them in man and the orang-outang. The excretory ducts, variable in number, open on the fringes

of the inferior surface of the tongue. The lingual glands are composed of acini, which are nothing more than the extremities, in form of *culs-de-sac*, of the ramifications of the excretory ducts. As they are not found in the rest of the animal kingdom, Nuhn supposed that their secretion served to facilitate the movements of the tongue, and their existence was in unison with the faculty which man possesses of interpreting his thought by speech."

I have given preference to M. le Professeur Cruveilhier's description, inasmuch as M. Sappey does not, in his recent work, enter so fully into details.

My own observations differ, in some respects, from the descriptions heretofore given. I have usually found them as two oval bodies, about the size of a small haricot bean, placed obliquely near the sides of the tip, their anterior extremities directed forwards and inwards, converging towards one another, but separated by an interval of about four lines, covered on their outer borders by a few of the conjoined fibres of the lingualis and stylo-glossus. When well developed they slightly elevate the mucous membrane of the under surface of the tongue, anterior and external to the frænum linguæ. Their ducts, opening on the mucous membrane, vary in number from four to six. The glands are very vascular, being placed on the ranine arteries, and richly furnished by their branches with blood; the nervous distribution is particularly abundant, forming a complete plexus in the gland by the divisions of the lingual branch of the inferior maxillary division of the fifth pair. Indeed, I know of no glands in the human body so largely supplied with nervous filaments from the cerebro-spinal system.

The lobules which compose these glands are finer than those of the sublingual, but in other respects they have the same anatomical elements and arrangements as the salivary glands, hence their functions are undoubtedly identical. They are altogether isolated, and do not form a continuation of the sublingual glands, as described by some anatomists. The rich

nervous and vascular supply, out of all proportion to the size of the glands, would seem to indicate important physiological functions.

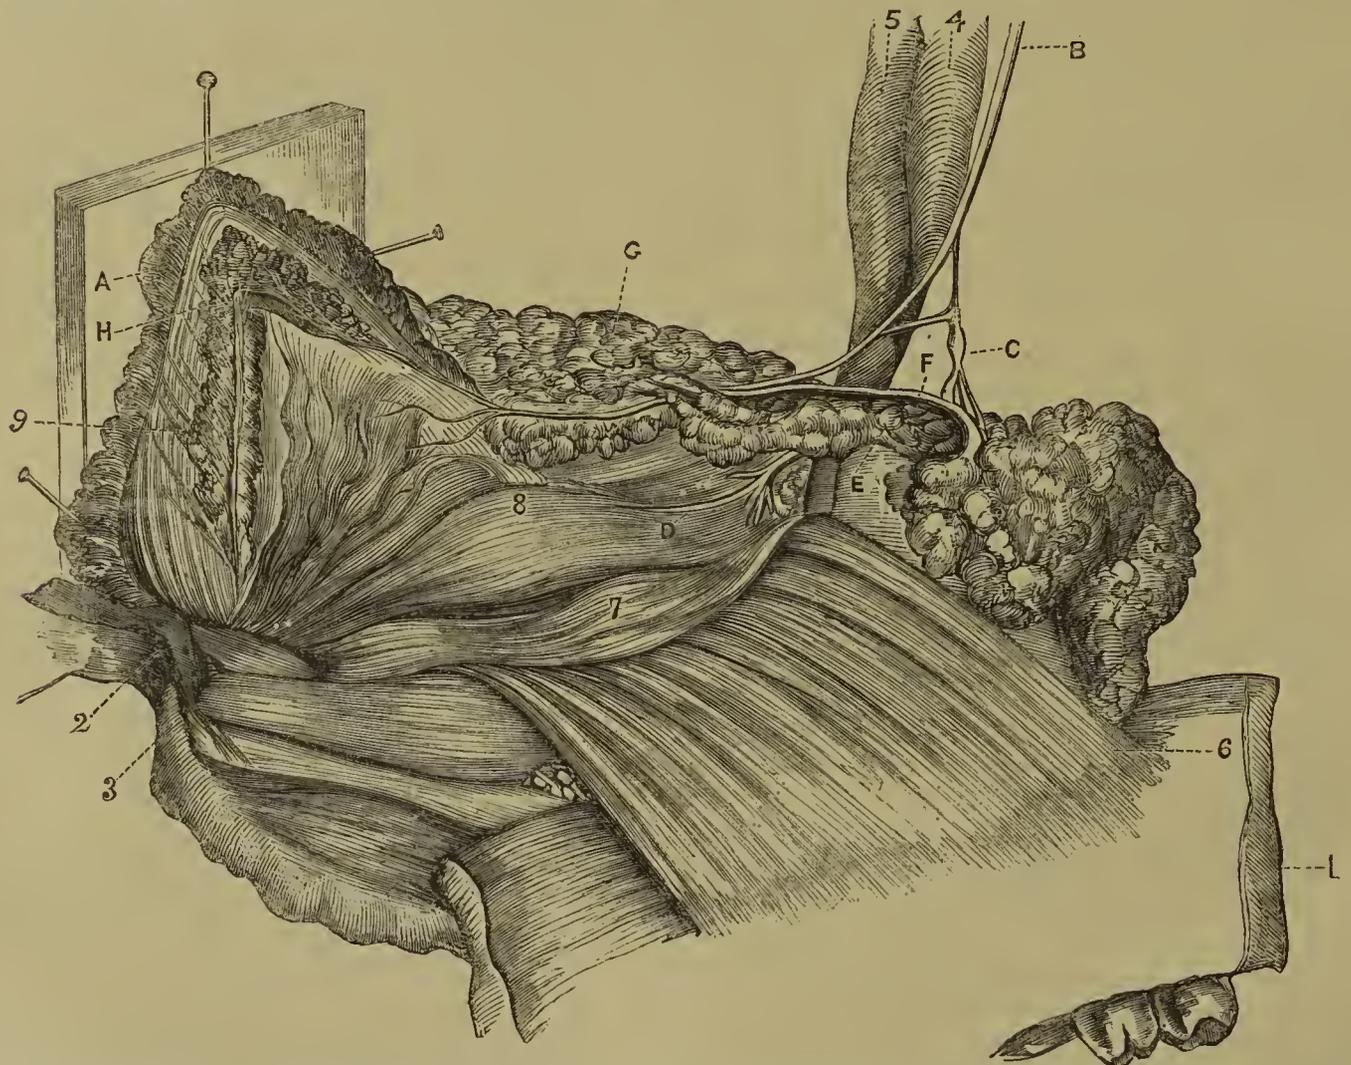

Quite recently, whilst engaged in making a preparation of the salivary glands, by desire of Professor Goodsir, of the University of Edinburgh, I have met with a remarkably fine specimen of these glands. The accompanying drawing will explain the dissection, and leaves little for me to add. The two glands are united in front, forming one mass, after the shape of a gothic arch, and at the point of union are there most developed: they are unequal in size and length, the right being by far the larger. They are placed on the outside of the genio-hyo-glossi muscles, and lie on the linguales and stylo-glossi. The lingual nerves are seen distributing numerous branches whilst coursing along them.

We often meet with unusual development of the secreting glands, and in this case the whole of the salivary and labial glands were of remarkably large size. A good example, analogous to the one now brought under observation, may be cited in the "horse-shoe kidney," where the two kidneys are united together by one of their extremities, generally the upper, across the vertebral column, and of which most museums possess a specimen. Still, I have been much interested with the preparation, inasmuch as it is to me perfectly unique, and I have no doubt it will prove equally so to most other anatomists.

The preparation is deposited in the anatomical museum of the University, and it only remains for me to give the exact measurement of this glandular mass, as made by Professor Goodsir:—Right portion, to the extreme summit of union, one inch and one-fifth; left portion, to the extreme summit of union, six and a-half lines; antero-posterior measurement of central portion of union of the two glands, four lines.

N.B.—The line is here regarded as one-tenth of an inch.

The University, Edinburgh.

1. Part of the body of the inferior maxilla cut and turned down.
2. Cut surface of inferior maxilla, near symphysis.
3. Anterior belly of digastric.
4. Posterior belly of digastric.

CASE OF

PYÆMIA SIMULATING ENTERIC FEVER,

WITH ACUTE NECROSIS OF THE ILIUM, STERNUM,
AND ACROMION, AND A PULSATING ABSCESS IN FRONT OF
THE STERNUM.

By CHARLES MURCHISON, M.D., F.R.C.P.,

Physician to the London Fever Hospital; Assistant-Physician, Middlesex
Hospital.

HENRY A., aged 18, was sent to the London Fever Hospital, as a case of "fever," on November 22, 1863. His history and symptoms on admission bore a close resemblance to those of enteric fever. He had been ill about nine days; he had suffered much from diarrhœa before admission, and a few hours after coming to the Hospital he passed a light, watery motion. The abdomen was tense and tympanitic, and there was considerable tenderness on pressure over the cœcum. The tongue was red and fissured, with the papillæ rather enlarged, and there was occasionally a circumscribed pink flush on both cheeks. Pulse 120; no headache or delirium; pupils dilated. Still, neither on admission nor at any time subsequently was an eruption discovered on the skin resembling that either of typhus or of enteric fever. On the other hand, from the first day that the patient came under observation the respirations were quickened—36 in the minute; there was a dry cough, and there was slight dulness, deficient breathing, and diminished vocal resonance at the base of the left lung, extending as high as the lower angle of the scapula behind, and as high as the nipple in front.

The diarrhœa ceased on the day of admission into Hospital, and after a few days the motions were found to be solid, but the tympanitis and abdominal tenderness continued, and the patient had sleepless nights with some delirium, necessitating a recourse to opiates.

On the 25th, he began to complain of great pain in all the joints, increased by the slightest movement, but no swelling could be discovered, and there had been no rigors. The pain was particularly marked in both hip-joints when the patient was made to sit up in bed.

On the 26th, there was an erythematous blush on the knuckles of the right hand.

On the 29th, a similar redness, with great tenderness, was noticed on the dorsum of both big toes, and on the following day half an ounce of pus was let out by incision from beneath the skin over the dorsum of the left big toe. A dirty discharge continued to escape from the wound, which had an unhealthy appearance.

On December 3, a soft fluctuating swelling made its appearance, somewhat suddenly, over the middle of the sternum. It was circular and nearly two inches in diameter, and the skin over it was moderately red. The remarkable circumstance, however, was that this swelling indicated most distinctly each impulse of the heart, and was rendered tense by coughing. Very little air could be heard entering the base of the left lung below the left nipple in front and the lower angle of the scapula posteriorly, and pleural friction was heard over the dull space in the axillary region. At first sight, the pulsating swelling, in connection with the dulness at the base of the left lung, suggested the idea of a pulsating empyema; but there was no bulging of the left ribs, the intercostal depressions were equally marked on both sides, and there was no displacement of the heart's apex. Pulse, 104; respirations, 36. On the following day, the swelling had increased in size, and was very tender; its pulsating character was even more strongly marked than before. A small trocar was now introduced into the swelling, and about six drachms of laudable pus, not at all fœtid, let out. No more could be obtained, although the patient was turned on his right side. The pain, redness, and pulsation subsided at once with the disappearance of the swelling. Poultices were applied; but the opening closed up, and by the end of twenty-four hours the swelling had returned with its former characters, and with such an amount of pain and dyspnœa, that a free incision was made into it, and about an ounce of bloody pus let out.

On December 16, there was still much distress in breathing. Pulse, 108; respirations, 40. A thin sero-purulent discharge escaped from the wound, which was not increased by turning the patient on either side. During respiration the air passed inwards and outwards through the wound. On introducing a probe, it passed completely through the sternum by a channel surrounded on all sides by bare bone. When the probe was left in, it moved upwards and downwards synchronously

with the action of the heart. At the situation of the opening, the lower third of the sternum was separated from the upper two-thirds, and the two pieces of bone could be made to move upon one another with a grating noise.

Considerable relief was obtained from the free exhibition of opiates and stimulants, but on December 11 the patient appeared much worse. He had become very emaciated. There was a deep red circumscribed flush on both cheeks. Tongue dry in the centre. Pulse 112, very feeble. Breathing at times was very hurried, at others tolerably full and easy. Nearly two ounces of pus were let out by an incision made at the top of the right shoulder. This abscess did not seem to have any connexion with the shoulder-joint. The physical signs of the chest did not indicate any extension of the pulmonary mischief.

The dyspnœa increased. Great pain and distress were occasioned by the two portions of sternum riding over, and grating on, each other during respiration. On December 12 the lad's face was very dusky, and he was evidently sinking, and at 6 p.m. he died, his entire illness having lasted about thirty days. The skin did not present the slightest tinge of yellow, and at no stage of his illness had there been any rigors.

Autopsy Forty-four Hours after Death.—Body much emaciated. Right thigh and leg swollen and œdematous; left lower limb not so. The right femoral vein was compressed by an abscess beneath the fascia at the upper and anterior part of the thigh, which contained about an ounce of pus. On laying open the abscess above the right shoulder, the extremity of the acromium was found exposed and dead, and a portion of necrosed bone the size of a pea was loose and detached. The shoulder joint was intact. Chest.—The artificial opening in the skin led into an empty circumscribed cavity behind the sternum nearly two inches in diameter, bounded in front by the sternum itself, which was bare and black, and posteriorly by the ligaments and apneurosis. At the level of the third rib, the sternum was completely separated into two pieces at what appeared to be a natural articulation. An inch and a-half of the lower portion and half an inch of the upper were quite bare, and of a dark hue on their posterior aspect. The opposed ends of the two pieces could be made to overlap to the extent of a quarter of an inch. The left pleural cavity contained half a pint of puriform fluid. The outer surface of the lower lobe of the left lung and the corresponding costal pleura were of a deep red colour, and were glued together by a quantity of soft yellow lymph. The lower lobe of the left lung was condensed (at many places sinking in water) and tough, as if from pressure of pleuritic fluid. Its section was nowhere granular. The lower lobe of the right lung was œdematous, and in its substance, near the anterior margin, was a circumscribed cavity the size of a hazel nut filled with thick yellow pus. The pleural surface of the lower lobe was coated with a few flakes of recent lymph, which were most abundant along the free margin of the base. There was no communication between either pleura and the post-sternal abscess. The pericardium contained four ounces of clear straw-coloured serum; the lining membrane of the right cavities of the heart was stained of a deep red hue; the right cavities contained a small coagulum partially decolourised. The valves and muscular tissue of the heart were normal. Abdomen and Pelvis.—There was no fluid or lymph in the peritoneum. Liver and spleen healthy. Both kidneys much injected, and both, especially the left, contained several circumscribed deposits of pus, up to the size of a pea. The stomach and intestines were healthy: there was no abnormal injection or elevation of Peyer's patches, or of the solitary glands. There was a large abscess containing fully a pint of pus in the concavity of the right ilium. The bone over a space measuring two and a-half inches in diameter was quite bare and bathed by the pus; this exposed portion of bone was of a dark hue, and surrounded by a distinct line of demarcation in the form of a superficial groove; the absence extended some inches downwards, behind the pelvic fascia, towards the perinæum; the right psoas muscle passed through it, and was surrounded by the pus. The right sacro-iliac joint was laid open, and the ligaments and cartilage destroyed, so that the finger could be inserted between the bones; and when the limb was rotated, there was considerable movement of the one bone upon the other. The lumbar vertebræ were not reached by the pus, and appeared healthy; there was also an abscess containing several ounces of pus outside the pelvis over the convexity of the right ilium. This abscess communicated with that within the pelvis through the sacro-iliac joint. The right ilium, on its convex aspect, was also bare and bathed by

pus over a space measuring about two inches in diameter. The bone here resembled the bare bone on the inner surface, and corresponded to it in situation. Two other abscesses were discovered, one beneath the fascia at the upper and anterior part of the right thigh already described, and another containing about an ounce of pus in the substance of the left iliacus muscle, but in no way implicating the bone.

Remarks.—This case presented some remarkable features in reference to diagnosis. The early symptoms were closely assimilated to those of enteric fever, and the resemblance was increased by the existence of tympanitis and tenderness over the cæcum. The absence of rose spots, which were carefully looked for every day, was the sole point of distinction; but even in enteric fever these spots are not of universal occurrence. The pulsating tumour over the sternum might, at first sight, have been readily mistaken for an aneurism or a pulsating empyema; (a) but the rapidity of its development, and the absence of the ordinary physical signs of empyema, negated both of these suppositions. As regards the pyæmic nature of the case, the complete absence of rigors or of any peculiar discoloration of the skin is worthy of notice. The origin of the whole mischief is somewhat obscure. The boy had sustained no wound or injury, that could be discovered, to account for the pyæmia; he had no sign of scrofula, nor was there any absolute proof that the pyæmia resulted from the circulation of any specific poison in the blood. The condition of the intestines showed that there had been no enteric fever; but it may be mentioned that the boy came from a locality where typhus was very prevalent, and although no eruption could be discovered on his skin, it is not impossible that he had passed through an attack of typhus before he came under observation. A formidable form of pyæmia, with purulent deposits in the joints, is well known to supervene occasionally upon attacks of typhus in certain epidemics, although this sequela has certainly been rare of late years in London. Surgical writers also speak of acute necrosis as not uncommon in "those debilitated states of the constitution that so frequently follow upon typhus fever." (b) At the same time, it is right to add that the boy's symptoms before he was brought to the Hospital were not those of typhus fever, and therefore I am inclined to conclude that the acute necrosis and pyæmia were the common result of some other unknown morbid condition of the blood.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

ABSTRACT OF A CLINICAL LECTURE ON A CASE OF EMPYEMA IN A CHILD.

By Dr. JENNER, Physician to the Hospital.

The following is the substance of a clinical lecture by Dr. Jenner. The report of the case is by Mr. Edward H. Fox, Physician's-Assistant:—

Dr. Jenner used the word "empyema" to signify inflammation of the pleura, with effusion of pus. In pleurisy, there is effusion of lymph, serosity, and pus. Inflammation of the pleura, like that of other serous membranes, never lasts many hours, or possibly minutes, without the formation of one or all of those; only one usually predominates.

On the child's admission, the diagnosis was that of fluid in the pleura. This was certain. Next, that that fluid was pus. This was highly probable, as the child was the subject of tuberculosis, and probably even of the deposit or formation of tubercle. Dr. Jenner then gave the means by which the diagnosis of fluid was arrived at. This will be found in detail in Mr. Fox's history of the case. In the adult and in the child, dulness would indicate, either fluid in the pleura or consolidation. In the adult, the further diagnosis was easy, as, in effusion into the pleura, there was an absence of vocal fremitus. But, in the child, this test was not to be obtained. We could, however, arrive at an accurate diagnosis by observing whether or not the organs were displaced. In this child, the heart, as will be seen in the report of the case, was pushed over to the right side, and the line of dulness extended half an

inch to the right of the sternum. It was certain, then, that the child's left pleura was full of fluid. The next point was to ascertain the nature of that fluid. That it was pus was thought to be highly probable, on consideration of the mode of attack. It was insidious, or, at least, very sub-acute. Then there was an absence of exciting causes. There was evidence of tuberculosis from her family history and from her build. She was, the report of the case states, "fair, delicate, tubercular-looking, and thin." The hygienic conditions under which she had lived were unfavourable. Then her having had whooping-cough just before favoured the diagnosis of pus, as did also her age. In children, effusion into the pleura was often purulent, probably because tuberculosis was very common at that age.

As to the spitting of blood, Dr. Jenner did not think that of much value as evidence of presence of tubercle when it occurred in whooping-cough. Still, it ought to be taken into account; but, as a matter of experience, he remarked, children who spit blood in whooping-cough generally recover.

The local and constitutional diagnosis having been thus made, the next point was, what was to be done to get rid of the fluid. If the effusion was very large, sudden death was not very uncommon, even when there was no dyspnoea to point to danger. This was due, probably, to the mechanical displacement of the heart and great vessels; clots in the pulmonary artery, which might extend to the right auricle; compression of the opposite lung. Then, for the sake of the lung of the same side, it was necessary to get rid of the fluid. Extreme compression would induce collapse, and possibly inflammation; and, again, the compressed lung might become the seat of tubercularisation. The longer the lung was compressed, the less likely it would be to re-expand. So far, the remarks are general; but, in reference to this particular case, there was (Dr. Jenner pointed out) hectic, either from irritative fever, or, perhaps, from absorption of fluid, showing that the child was suffering constitutionally as well as locally.

Having decided that the fluid should be got rid of, the next point was, how to do it. In order to promote absorption, as there were no immediate urgent symptoms, the child was well supported by food and fresh air. The compound iodine ointment was rubbed over the left side of the chest. Dr. Jenner said that the iodine was better than blistering, as the latter tended to increase the irritative fever. He remarked, also, that the iodine ointment was preferable to the tincture. Iodide of potassium was also given internally. It was soon found that these remedies were of no use, or rather that there was no time to be wasted. Dr. Jenner then decided to tap the chest. This was done to relieve the lung from the mechanical pressure, in the hope that it would re-expand, and that the formation of pus would gradually cease. Before passing in the trocar in the adult, we should (Dr. Jenner said) always ascertain the absence of vocal fremitus at the point of insertion; and in the child we ought to ascertain that that exact part was free by percussion and also by auscultation, as there might be a partial gluing of the lung to the chest wall. The result of the operation, and of its repetition, will be gathered from the report of the case. Dr. Jenner drew especial attention to the fact that the lung after empyema was, when contracted, diminished in every direction, and thus the lower ribs were non-oblique as well as closer, as they covered no lung. The practical point about this was, that on tapping such a chest a second time, if the trocar were too long, and not pointed up, it would pass through the diaphragm, and enter the abdomen, and thus cause death by peritonitis.

History.—Jane L., aged 5; admitted February 4, 1863; born in London. Father alive, aged 31; healthy; never yet spat blood; his father died of phthisis, and mother in childbirth. Patient's mother healthy; never spat blood, nor have any of her relations. Patient has two brothers older, healthy, not subject to cough. Patient last winter had a very bad cough, which continued to the summer, and then disappeared; did not spit blood with it. Last September, patient had whooping-cough, which has continued till now (February). Just before Christmas, the mother noticed that she spat up blood when she coughed. Appetite continued good till last Christmas, when it failed. About a month ago, complained of pain in left side; increased by being touched. Had not been exposed to any cold. Patient sweats at night about head and neck. Patient had measles when nine months old; never had scarlet fever. Mother never had any miscarriages.

Present State (February 6).—Fair, delicate, tubercular-looking child; very thin; breathing oppressed; nares act a little during inspiration; child draws in her breath, and then

(a) See Dr. McDonnell's cases of pulsating empyema, in *Dublin Journal of Med. Science*, March, 1844.

(b) See Erichsen, "The Science and Art of Surgery," Third Edition, p. 653.

holds it some time before expiring, which she does with a jerk. Left side of thorax looks much larger than right; sternum deviates to right. Intercostal spaces obliterated, even to first, presenting a striking contrast to opposite side; during inspiration the lower ones recede; a line of depression is seen around the thorax, mostly marked at ensiform cartilage. Heart can be felt beating to a little outside right nipple; apex impinges just to right of apex of ensiform cartilage; no murmur. Liver: upper margin a finger's breadth above umbilicus. Whole of left chest, from base to apex, dull; dulness extends to half an inch to right of sternum. Posteriorly: above, respiratory sounds distant and feeble; bronchial, at middle of scapula; below this, coarse, feeble, but superficial. Anteriorly: respiratory sounds distant, feeble. Right chest, anteriorly: under clavicle, expiration loud, rough; respiration divided. Reported by nurse to perspire freely night and day; skin cool; pulse, 120; respiration, 40; sitting in nurse's arms; very anæmic. Measurements of chest: right side, one inch below nipple, 10 inches; left, $10\frac{3}{4}$ inches; at nipple, right, 10 inches; left, $10\frac{3}{4}$ inches; higher up, same on both sides. Ordered, *R.* Potassæ bicarbonatis, gr. iij.; potassii iodidi, gr. jss.; syrapi, ζ ss.; aquæ ad., ζ ss. *M. ft. haustus, 3 tis hōris sumendus.* *R.* Ung. iodinii co., to be rubbed into left side. Diet: milk, beef-tea, wine ζ ij.

8th.—Face flushed; perspiring freely; coughs more during night than in day; pulse, 104; respiration, 48; measurements as at last report.

9th.—Breathing very troublesome during night; coughs a good deal; pulse, 80; respiration, 36; bowels open; urine slightly acid; specific gravity, 1020; no albumen.

11th.—Lying on left side—always does; a little more dusky; face decidedly fuller; dulness extends to $1\frac{3}{4}$ inch to right of sternum; looks oppressed; evidently suffering from mechanical impediment to breathing. Paracentesis thoracis was performed; ζ vij. of pus withdrawn. The pus is acid.

12th.—Very restless during night; slept scarcely half an hour at a time; perspired freely in night; feverish and more languid; perspiration in drops on the forehead; skin very hot; pulse, 68; seems to breathe more freely; measurements not perceptibly altered.

13th.—Slept better; more recession of soft parts on right than on left side; bowels confined; pulse, 112; tongue covered with a white fur; more resonance at apex (lung resonance) of left chest; absolutely dull up to middle of left scapula; in front, dulness up to third rib; only distant breath sounds in front; behind, distinct breath sounds in upper half, coarse; dulness, right chest from clavicle to nipple. Heart can now be felt about three-quarters of an inch inside left nipple.

16th.—Restless; skin very hot; perspired freely last night; heart beats in centre of sternum.

17th.—Very restless during night; skin hot and perspiring; perspiration in drops on forehead; considerable recession of soft parts, and action of sterno-mastoids; breathing worse; coughs a good deal more; does not seem so well, but looks anxious; tongue moist, covered with white fur; bowels acted twice during night; pulse, 140; respiration, 32. To omit medicine. *R.* Vini ferri, ζ j.; quinae sulph., gr. $\frac{1}{4}$; acid. sulph. dil., m.j.; aquæ ad., ζ ss; t.d.s. *R.* Ol. morrhuae, ζ j.; t.d.s.

18th.—Child seems more cheerful, sits up in bed, was lying on "right" side; breathing better; less recession of soft parts; tongue cleaner; perspires freely; wound in thoracic walls perfectly healed. Measurements just below nipple: right side, $10\frac{1}{4}$ inches; left side, $10\frac{3}{4}$ inches. Heart's apex impinges three-quarters of an inch inside left nipple. Dulness of right side in front continues, and enters more freely into apex of left lung; below, the dulness is unchanged.

23rd.—Slept well; perspired freely; breathing more impeded; recession of soft parts, right side, more marked; dulness, left side, increased; heart's apex impinges one inch outside right nipple; pulse 152, soft, compressible; no alteration in measurements; sitting up in bed; hands hot, palms moist; sweat on forehead; suffering evidently from dyspnoea; gets attacks of hectic, flushed cheeks, and sweats in the evening; bowels act daily. Child in nurse's arms: difference in thorax on both sides marked. Intercostal spaces cannot be seen on left side, but can on right. Even during inspiration one or two come into view, whilst on right side they can be seen and counted up to scapula. Emaciation progresses. Back: percussion clear and empty to a little above middle of scapula. It is dull below, excepting an inch and a quarter next spine, where there is still, except at extreme base, clear and empty sound. Respiration audible

over all parts where resonant, and below, everywhere, there is absolute dulness, but coarse, feeble, inspiratory sound, and rough, coarse, expiratory, somewhat bronchial. Front bulged more than on admission. Intercostal spaces visible more in front than behind; clear and empty sound or tubular. Well heard as low as second cartilage and rib; below, absolute dulness, more so than posteriorly. Heart's apex: extreme right most perceptible full half an inch to right of right nipple; perceptible at epigastrium; no murmur. Liver: upper border rounded; extreme dulness on right side even to clavicle, but less under this bone than a little below. Under clavicle on left side respiratory sound is rough, feeble, and distant. Dulness under right clavicle is probably due to heart and partly to fluid on left side, and may be some tubercular bronchial glands. Respiration very loud under right clavicle—rough, somewhat bronchial. Respiration loud and rough in right lung posteriorly. Coughs a good deal more.

25th.—Paracentesis performed again to-day. ζ vj. of pus withdrawn, acid; no air admitted; very restless all night; perspiration very free.

March 2.—No albumen in urine; size of chest not diminished. Apex-beat outside right nipple.

6th.—Heart: same position as at last report; some puffiness about opening in thorax. Posteriorly: left side, absolute dulness; posteriorly as high as angle of scapula. Right side, resonance good to middle of scapula; above that, clear and empty. Anteriorly: absolute dulness over heart; right infraclavicular region clear and empty; left ditto, but from second rib downwards, absolute dulness. On right side, infraclavicular region: breathings loud, coarse, with prolonged expiration. Left side: breathing feeble, distant. Below, in front, absence of breath-sound. Behind, coarse, diffused, bronchial, almost to base; reported to sweat profusely.

11th.—Tapped again yesterday; fifteen ounces of pus removed, acid; very restless during night; very hot, but did not perspire. Sitting up in bed this morning; better and more cheerful; pulse 104, weak. Heart as much to right as at last report. Resonance under left clavicle greater—extends behind to middle of scapula.

16th.—Looks more dusky and swollen in face; superficial veins in thorax and abdomen more distinct; abdomen large and fuller; heart felt beating at centre of right lateral region; dulness increased above, on right side; hectic continues; profuse sweats. To have meat twice daily.

20th.—Tapped again; five ounces removed.

27th.—Diarrhoea since yesterday.

28th.—Diarrhoea has ceased. To have vini ferri, ζ j., three times daily.

May 11.—Continues to emaciate; not quite so thin as she was. Inclines towards left; spine curved; right shoulder raised; sternum deviates to right. Sweats very little. Absolute dulness below angle of left scapula; above that, clear and empty. A little air enters lower half of lung; a good deal posteriorly, above angle of scapula. Under left clavicle about as much air enters as posteriorly; below, scarcely any. Apex of heart impinges a little outside right nipple.

July 10.—Left Hospital.

November 18.—Patient has just returned from a stay in the country. Is better nourished than when she left the Hospital. Inclined to left side; left side of thorax is manifestly smaller than right; flattened anteriorly. Sternum deviates to right; left shoulder lower than right. Angle of scapula tilted backwards; base is oblique, angle outwards. Spine is curved; convexity to right. Aperture in thorax closed; scar remains. Face a little puffy; has more colour. Slight, very slight œdema of lower extremities. Ribs on left side, where perceptible below, are very oblique. Difference of costal angles marked. Heart's beat not perceptible at epigastrium or below thoracic parietes; can be felt at mid sternum. By the stethoscope, it can be heard pulsating inside the right nipple, and to within a little of the left nipple. Percussion: heart's dulness extends to within a little more than a finger's breadth of the right nipple; three fingers' breadth between nipple and sternum. No cardiac murmur base or apex. Whole of left chest is dull anteriorly; a little trace of resonance under clavicle; dulness extends across sternum to right, and just to the right of the sternum, where the clear sound begins on superficial percussion; on deep percussion, there is a cracked-pot sound. Posteriorly: absolute dulness from base to spine of scapula; at extreme apex there is very empty tympanic sound; there is a little breath-sound over whole chest posteriorly; much more above spine of scapula than anywhere

else. Breathing rough; some sonorous rhonchi. Strong bronchial respiration under left clavicle, all but cavernous; no trace scarcely of breath-sound below nipple. Depression at epigastrium extends upwards to left nipple; upper margin of liver strongly marked.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

REMOVAL OF A FOREIGN BODY FROM THE ORBIT, WHERE IT HAD REMAINED UNDETECTED FOR SIX MONTHS.

(Under the care of Mr. NORMAN.)

For the report of this and the following case we are indebted to Mr. D. O'Brien, House-Surgeon.

A. C., aged 17; admitted December 10, 1863. The patient was a drummer in the — Regiment of Infantry. When stationed with his regiment at the Curragh Camp, he met with an accident which was attended with some peculiar circumstances. It appears that he had filled a stone ink-bottle with gunpowder, which accidentally exploded close to his face, forcing a piece of the bottle into his left eye, and, of course, destroying that organ. There was at the time profuse hæmorrhage, and a considerable amount of inflammation followed. The latter subsided after the usual remedies. He was discharged the service on the 22nd September last, and came to Southsea to reside with his friends. When admitted as an in-patient he was suffering from eversion of the upper lid, which was attended with a great deal of irritation. After the lapse of a few weeks, the presence of some foreign body being suspected, he was brought to the operating theatre, and, being put under the influence of chloroform, Mr. Norman removed with a forceps, using considerable force, a portion of a stone bottle, which had been embedded in the roof of the orbit, occupying, as nearly as possible, the situation of the lachrymal gland. The operation took place on the 5th of January, exactly six months from the date of injury. The fragment was an inch and a-half in length, three-quarters of an inch in breadth, and a quarter of an inch in thickness.

STRICTURE OF THE URETHRA, COMPLICATED WITH FALSE PASSAGE AND FISTULA IN PERINEO—SUCCESSFUL OPERATION.

(Under the care of Dr. SIMPSON.)

G. J., aged 54 years, was admitted November 10, 1863. He had stricture of the urethra of two years' standing, and a fistula in the perineum, through which most of his urine flowed, very little coming through the natural passage. The urethra was obliterated from the bulb to the fistulous opening, an inch and a-half in length, and there was a tortuous false passage, through which it was impossible to pass an instrument.

The following operation was performed:—A director was passed through the fistula into the bladder, that portion of the urethra being, fortunately, free; a catheter was passed down to the stricture, and an incision was made from the point of that instrument to the director. The catheter passed readily into the bladder, and was tied in for forty-eight hours. The result was perfectly satisfactory; the fistulous opening healed rapidly, and the urine now comes through the canal in a full stream. This operation is interesting in this point, that though the continuity of the urethra was lost from the bulb to the fistula, and the incision was made, as it were, at hazard, the parts are now, to all appearance, in a normal condition. A No. 10 catheter can be passed without the least difficulty.

HARRIS *v.* TWISS.—This case, tried at the Limerick Spring Assizes, was an action for slander brought by Dr. Harris, Surgeon to the Newport Dispensary, against Mr. Twiss, a member of the Board of Guardians of the Newport Union. A servant of Mr. Twiss' had met with an accident, which produced a severe contusion of the arm, but neither fracture nor dislocation. Dr. Harris saw the boy, and recommended rest and a cold lotion. A bone-setter was afterwards called in, who said the bone was fractured, and professed to set it. The slander alleged was that at a meeting of the Board of Guardians, Mr. Twiss brought a charge against Dr. Harris that he (Dr. Harris) had said that the boy's bones were not broken, when, in reality, they were; and in proof of it had stated that when the arm was set the boy was relieved of pain. Dr. Harris brought the action to vindicate his Professional character. The jury returned a verdict for the defendant, with 6d. costs.

SATURDAY, MARCH 19.

"BRITISH MEDICAL" TRADESMEN.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri: potestas modo veniendi in publicum sit, dicendi periculum non recuso."
—CICERO.(a)

Most of us would so indignantly spurn the notion of being called "tradesmen," instead of Professional gentlemen, that it is well worth while to keep in mind what the distinction really is. We may state it formally thus:—The Professional man is, of necessity, the cultivator of some branch of science; he freely communicates his knowledge and its fruits to his brethren; he must, when consulted, act or advise for the benefit of his client, and not for his own; and, lastly, he must consider himself bound, not only to cultivate science, but to hold it as a trust for the benefit of his fellow-creatures. If the cause of science or of humanity require it, and if there be no reason to the contrary, he will give all the benefits of his skill to those who are utterly unable to offer him any return; and whatever he does receive will be in the nature of a gratuity, which may be greater or less according to the means of the person benefited.

It is superfluous to say that a tradesman deals in goods; that he keeps all his processes secret if he can; that if a customer come to him he usually tempts him to buy as much as possible at the highest price, without considering whether the customer wants the goods; that he is not obliged to communicate one bit of knowledge, or part with one bit of material without return; and that he is entitled to sue any one who gets into his debt.

We are most glad to acknowledge that there are tradesmen—mere men of business by occupation—who throw into their callings a feeling of honour of which any profession might be proud. The wine merchants speak of a *chivalrous* way of doing business, when they speak of those who would submit to any loss rather than sell bad wine. There are printers, publishers, philosophical and musical instrument makers, and scores of others who are truly scientific men, and love their vocation on higher grounds than mere £ s. d. There are Professional men, too, who resort to advertising, puffing, and some of the mercenary tricks of trade, and who keep out of sight the higher duties of a profession. But no mere abuse can alter the essential nature of the two callings.

There is no doubt but that the Professional man, from his higher position, is exposed to many vexations which don't annoy the tradesman. More especially, he is always liable to be misunderstood by that vulgar herd who can conceive neither science, humanity, nor honour as motives, except in so far as they may lead directly or indirectly to money; he may at any time be confronted with persons ready enough to remind him of the obligations of his Profession, yet not equally ready

(a) We restore to its old place for once the old motto of the *Medical Gazette*. This was before true British Medical commercial principles had been publicly avowed.

to remember their own; and will, of course, meet with many fruitless, vexatious, unnecessary, and unremunerative calls on his time, and with a great deal of ingratitude.

But there is absolutely no help for it. We must submit to all this if we would be Professional gentlemen, and not tradesmen.

A lamentable case, which may serve to point our moral, has just happened at Birkenhead.

A poor pregnant woman came with her husband to Birkenhead a month ago. They were strangers, and had engaged no Medical attendant. On Tuesday night, the 8th, at about nine o'clock, she complained of pain. At half-past twelve she became worse; it was clear that premature labour had set in; and the husband went out to get a Medical man. He swore that he called at the houses of six, but that not one would attend. He deposed that one of them said to him—"Well, if you are a stranger, I will not turn out till you put a guinea in my hand." At last, one of them who had gone to bed ill, and who had refused to go on that account when applied to at one o'clock, was again applied to at four, and being adjured "for Heaven's sake, to come and save a woman's life," went as an act of humanity. But he found her pulseless; there was no brandy at hand, and the woman died.

We may be excused if we express our wonder that such a simple contrivance as an *accoucheur's bag* is not in use in Birkenhead. Every man in midwifery practice would find it convenient to have a common small leather or leather-cloth bag into which he might put ergot, chloroform, catheter, stethoscope, and all the odds and ends required at ordinary labours, including a little pocket-pistol of brandy and some concentrated beef-tea. Such a bag, standing ready to be snatched up at a moment's notice, saves always time and thought, and may save even life.

Of course there was a coroner's inquest, during which some hard observations were made by jurymen against the Doctors. One juror thought it was a pity there was no law to compel Medical men to attend in such cases. The coroner summed up fairly enough. We take the report from the *Liverpool Mercury* :—

"The Coroner: But there is no such law. The deceased and her husband had been in Birkenhead a considerable time, and yet they had not engaged a Medical man; hence all this confusion. Half a dozen Medical men were requested to attend at a moment's notice, but the members of the Profession were not in the habit of attending such cases without being previously engaged. He regretted very much that the occurrence had taken place, because he had heard of many complaints of different persons in Birkenhead who had been suddenly taken ill in the night, and no Medical man would attend. Only a fortnight ago a poor woman living near the Hospital was taken ill with violent inflammation in the dead of the night, and although her husband was a respectable man, who would be able to pay, none of the Medical men who were applied to would attend, and the woman was lost from absolute neglect. He perhaps was not right in calling this neglect, for there was no law to compel a Medical man to attend a case; but it seemed an extraordinary thing that a respectable woman, when taken ill at midnight, should die because no Medical man felt disposed to attend her. It was, he repeated, a matter much to be regretted. This was not the practice of Medical men in other parts of the country, but in Birkenhead constant complaints were being made. In the part of the country where he came from, Medical men attended such cases without first asking for a guinea, and often went several miles. They went as a matter of duty, risking whether they got paid or not. He considered that the deceased and her husband were culpable for not seeking the advice of a Medical man as soon as they arrived in Birkenhead, for unless Medical men were engaged there would always be an amount of difficulty, particularly at midnight."

It would be easy enough to retort on the butchers and bakers who sit on a coroner's jury by asking them how they would like a law that should compel them at any minute to give beef-steaks and quartern loaves to any hungry wretch who might knock them up in the middle of the night? But we cannot. To use such an argument would be to degrade our-

selves to their level. No; we cling to the idea of the *Profession*, with all its responsibilities, and we affirm that the man who had no excuse of ill-health, or old age, or previous occupation, and who refused to go without "a guinea in his hand," acted like a tradesman, and not like a Professional man. As was so well said by Dr. Macculloch, in our number of last week, "The Doctor is morally and socially constrained to give his services to all." It is his duty first to save life, and to get paid afterwards, if he can. To ask for "a guinea in hand," first, is abhorrent to the Professional character.

We are reminded from time to time that there exists a numerous and influential body called the British Medical Association, which has, if we mistake not, an Ethical Committee, and which can be severe enough on any infringement of Medical etiquette—*Quere*, what has it to say on an infringement of the law of humanity? Shall we hear of a special meeting of some *Branck* to consider this scandal, and provide against a repetition of it? Unluckily, we have an answer beforehand. The *British Medical Journal*, the "organ" of the Association, repudiates that duty of gratuitous service, which is one not only of the signs, but of the necessary conditions, of our Profession. In an article headed "Gratuitous Medical Services," it says (the italics are our own) :—

"There is involved in all this another great fallacy—indeed, a really humbugging pretence, viz., that *Medical men do these services from a high moral motive*. Any Medical man who indulges in gratuitous services-giving will, if he answer honestly, tell us that he *gives these services solely and simply because he considers it answers his purpose to do so*,—because, in fact, he *finds it a good money speculation*. To pretend that there is at the bottom of the gift any great or noble sentiment, is downright *Tartuffism*. We give our services to Hospitals because we expect thereby, indirectly, to benefit ourselves. No better proof of the fact could be shown than this, viz., that very few Hospital men, when they have attained the position in private practice which they desire, continue, all for the love of high moral motive, to give the Hospital poor the advantages of their great and accumulated knowledge. Unless their private interests pull in an opposite direction, men cease (and very properly) to give gratuitous services when their private practice enables them to be better employed—as soon, in fact, as they can secure the latter without dispensing the other."

Really, then, the hundreds of Hospital Physicians and Surgeons are not only tradesmen, but worse! Their stock-in-trade is a sham! Under pretence of doing good to the sick poor, they conceal a sordid money speculation! If they pretend to any higher moral motive, they are so many Tartufes! We congratulate the Hospital Physicians and Surgeons of England on their "organ," and hope they are proud of it.

We will not stop to ask whether Brodie, Bright, Guthrie, Graves, J. H. Green (we will not mention living men, nor yet great men of the past, but only some of those noble souls who have been removed within our own memory) whether they thought nothing of the promotion of science for its own sake,—nothing of the instruction of the rising generation,—nothing of the welfare of the needy. We will not ask whether such of us as cultivate the auxiliary sciences—the chemists, anatomists, and physiologists—really are as bad as Surgeons and Physicians, and conscious of the mere inspiration of pounds, shillings, and pence. If we want to see the fruits of the teaching of the British Medical Association's "organ," we need only look at that dead young mother at Birkenhead; but we venture to add one argument which the "British Medical" tradesman won't be deaf to, which is, that it *won't pay* to have many more such inquests as this.

OXFORD AS A PLACE OF MEDICAL EDUCATION.

DURING the last ten or fifteen years the University of Oxford has done a great deal to increase its efficiency as a place of Medical education. This is partly due to the suggestions of the recent Royal Commission, but chiefly to the attention which has been paid by the authorities to the claims of physical

science, and to the recommendations of the present Regius Professor of Medicine.

In 1850 a School of Natural Science was instituted, and the number of those who have offered themselves for examination has gone on steadily increasing. In 1855 the foundation was laid of the splendid museum in whose spacious galleries are now gathered together the various collections of natural history, comparative anatomy, pathology, etc., which were formerly scattered throughout the University.

The Radcliffe Travelling Fellowships have been put upon a new footing, which if not the best possible, at any rate bids fair to make them more useful than before. The Professorships of Chemistry and Physiology, which formerly were either in abeyance or associated with other Chairs, have entered on a new existence under the most favourable auspices. The examination for the Degree of M.B. has been divided into two parts—a theoretical and a practical, separated from each other by an interval of two years—and otherwise assimilated to that which obtains at the sister University and at the University of London. At several Colleges Scholarships and Fellowships have been awarded for proficiency in the Physical Sciences—a thing almost unheard of twenty years ago. And though the number of such encouragements is at present but small; still it is an increasing number, and we have no doubt that by-and-by it will bear a fair proportion to the place which natural science holds in Oxford education. But the greatest improvement of all yet remains to be mentioned. We allude to the statute which has recently been passed, after much discussion, and despite an active opposition. It is now ruled that if a man attains a certain standard at “Moderations”—a classical examination which he meets about the middle of his career—he may thenceforth lay aside classics altogether, and confine his attention to physical science. This will be a great boon to those who are looking forward to the study of Medicine. Hitherto the time and money consumed on a University education have prevented many of those who aspired to the ranks of our Profession from availing themselves of its advantages. Now, however, these conditions are considerably modified. The *time* which a young man will have to spend from the date of matriculation till he is able to graduate in Medicine, has been reduced by some eighteen months or two years; and the *expense* will, of course, be diminished in a proportionate degree. We sincerely hope that those who have been instrumental in bringing about this alteration may have the satisfaction of finding that they have met one of the requirements of the Profession, and that the number of those who enter the schools of natural science and of Medicine will be materially increased.

Oxford can never expect to furnish an *entire* Medical education. The city is too small to supply the Infirmary with such a succession of acute cases as is necessary for clinical teaching and study. But now, under the new statute, she does as much for our Profession as she does for the clergy or for lawyers. In each case she offers a sound classical and general education, together with the elements of a special training; but in each case that special training must be perfected elsewhere. After she has done her utmost for those who are studying Medicine, attendance at a metropolitan Hospital during a short time—say two years—will still be found necessary.

THE WEEK.

THE ARMY MEDICAL SERVICE.

A CORRESPONDENT has sent us the following extract from Horse Guards Circular, March 9, 1864:—

“Earl de Grey and Ripon is of opinion that the system of imposing fines on Medical officers who have passed recruits should be discontinued.”

The italics are our own, and we feel that, for once, at any rate, the right terms have been employed in characterising the course hitherto pursued.

THE PREVENTION OF SYPHILIS.

IN another part of our columns will be found an extract from a letter, which was published in the *Times* of the 7th inst., by Dr. Armstrong, of the Royal Navy, on the prevention of syphilis at Malta. The facts asserted in that letter have been confirmed by a Medical officer of the sister service, whose letter appeared in the same paper on Friday, the 11th. It is stated in these communications that the present amount of venereal disease on that station is far less than that met with in sea-ports and garrison towns at home; that recently, at Malta, the number of sick from diseases of this character were only 60 per 1000, whilst at home the ratio mounts up to the enormous sum of 400 per 1000. These letters, moreover, show that Malta has not always enjoyed the same immunity; that there have been times when the proportion of disease has been much higher, and that these periods have been exactly those when sanitary police regulations have been neglected or considered not compulsory. Gibraltar furnishes evidence of the same character. In 1856-57, disease was rare at Malta, but rife in Gibraltar. In 1858, police regulations were enforced at the latter station, but relaxed at the former. The result was that the hygienic condition of the two places was reversed. In Malta disease rapidly increased; in Gibraltar as rapidly diminished. In 1859 the principal Medical officer in the military service was removed from Gibraltar to Malta; his experience and knowledge of the history of the two commands induced him to press on the authorities the necessity of a new law, the enactment of which produced the same favourable results as those which followed Dr. Armstrong's efforts in the naval service. These facts cannot be too widely known at a time when Parliament will probably be called on to legislate for the preservation of the health of our armies and fleets. The practical good arising from authoritative interference must outweigh any theoretical objections, however excellent be the motives of those who urge them. To Dr. Armstrong and the other Medical officers who have aided in obtaining the enforcement of sanitary regulations at the two great Mediterranean stations, and who have thereby preserved the health of thousands of British sailors and soldiers for the nation's service, public thanks are due. We hope that the lesson they have taught will not be forgotten.

PROFESSOR HUXLEY'S LECTURES ON “THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA,” DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE VII.—FEBRUARY 16.

THIS lecture was devoted to a survey of the development of man, from the ovum up to the adult condition. The formation of the Graafian follicles, and the process of “ovulation,” or emission of an ovum, was first described. This process occurring at regular intervals gives rise to a remarkable disturbance in the economy, one of the principal effects of which is a determination of blood to the uterine parietes, proceeding to the extent of causing actual rupture of the vessels of the mucous membrane, with escape of a portion of blood into the cavity of the uterus, which being mixed with the uterine secretions and epithelium, constitutes the menstrual fluid. Should no impregnation occur, the ovum passes away, and the uterus and ovary return to their previous condition; but if the ovum should become impregnated by contact with the spermatic element of the male, a remarkable series of changes take place in the ovary, uterus, and in the ovum itself.

The changes in the ovum, and the early stages of the formation of the embryo, with its amnion, chorion, and allantois, are well known. In the ovary the corpus luteum is formed by a large quantity of exudative matter thrown out around the outer surface of the Graafian follicle. The walls of the uterus become extremely vascular; the capillaries acquire a great size, adapting their calibre to the increased pressure upon them by a process of growth, so that there is no rupture as in the temporary congestion of the menstrual period; the muscular fibres increase in number and length; the

nerves increase, and more than any other part, the mucous membrane with its numerous caecal follicular glands. Around the spot at which the ovum is lodged a fold of mucous membrane grows up, and still containing glands and vessels surrounds the whole ovum. The rapid growth of the latter, however, distends it greatly, and causes it to lose part of its original structure. This constitutes the so-called "decidua reflexa," the part of the mucous membrane between the ovum and the uterine wall forms the "decidua serotina," and the remaining part upon the inner surface of the cavity the "decidua vera." By the middle of pregnancy the latter loses its vascular connection with the tissues below, can readily be stripped off, and a new growth of lining membrane takes place beneath it.

The villi of the chorion, at first scattered all over the surface, afterwards become limited to a particular region, opposite to the decidua serotina; and the interaction of these two structures leads to the formation of the placenta. The glandular parts of the mucous membrane become obliterated by the enormous development of the intervening blood-vessels, which assume the form of large sinuses; into these sinuses the greatly-developed villi of the foetal membrane project, so as to allow of an interchange of materials between the blood circulating in the mother and the embryo.

The human ovum is thus, at first, implantal, then villi are formed on the chorion, but not attached to the maternal mucous membrane; it is placentate, but not deciduate. Lastly, the villi and the mucous membrane become so closely attached that they cannot be separated without injury. After the separation of the placenta in the process of parturition, it is found to contain, not only parts belonging to the foetus, but also maternal structures, the walls of the venous sinuses developed in the original mucous membrane of the uterus forming its outer portion. The changes in the uterus subsequent to birth consist in regeneration of the mucous membrane over the space from which the placenta was removed, and assumption of the usual condition of all the tissues of the organ by a process of retrogressive metamorphosis.

Among the changes which the foetus undergoes in its development, some of the most interesting (especially in relation to zoology) are those affecting the form and proportions of the body. In a foetus an inch and a-half long from the vertex to the heel, the head is from one-third to one-fourth of the entire length; the arms are not so long as the spine, and are about the same length as the legs. The forearm is about the same length as the upper arm, and the leg is about equal to the thigh. The hands and feet are very much alike, and the thumb and great toe are not so different from the remaining digits as at a later period. In a foetus four inches long, the head is one-fourth of the entire length; the arms are longer than the spine by one-sixth of their length, and are a little longer than the legs; the hands and feet are still about the same size, as are the forearm and upper arm, but the thigh is a little longer than the leg. In a foetus eight inches long, the head is less than one-fourth of the whole length; the arms are longer than the spine by one-fourth of their whole length, and longer than the legs, so that the extremity of the fingers reach down to the knee; the forearm is longer than the upper arm, and the thigh than the leg. At term the head is less than one-fourth of the whole length, the legs longer than the arms, the upper arm longer than the forearm, and the thigh than the leg. The hands and feet are about equal. It is thus seen that the proportions of the body change during intra-uterine life by a law of growth which does not act uniformly throughout the whole period,—the head regularly diminishes in proportion to the rest of the body, but the arms grow proportionally quicker at the middle, and the legs at later portion of the period. After the middle of gestation, also, the proximal segments of the limbs take on a more rapid development than the middle segments.

After birth changes of proportion continue to take place in the same direction as those which have occurred in the

later portion of intra-uterine life. These changes were illustrated in the lecture by a series of diagrams, copied from the work of Liharzik, and may be summed up as follows:—The entire length of the adult has increased, on an average, to three and a-half times the length of the new-born infant. The head increases at a comparatively small rate, being in the adult only twice the size in the infant. The proportion of the arms to that of the other parts remains constant, the rule that the distance from tip to tip of the outstretched fingers equals the height being good for all ages. The legs gradually increase in length, as compared with the body; at birth the central point between the vertex and sole is situated at the umbilicus, in the adult a little below the symphysis pubis. While the arms of the adult are but three and a half times the length of those of the infant, the legs have increased to five times the length.

Although, even at birth, some differences independent of proper sexual characteristics are perceptible between the sexes—the female infant being, as a rule, slightly smaller than the male—it is only as maturity approaches that the special distinctions of form and proportion are developed. The chief of these are the following:—The female is smaller than the male, the disproportion between them being greater in the tall than in the short races of men; the female head is proportionately somewhat larger than the male; the thorax, and especially the sternum, is shorter in the female, and the abdomen is longer; the legs are a little shorter, and the female pelvis, as is well known, is absolutely broader and of different form from the male. In all these differences, except the last-named (which is directly connected with the reproductive function), the female retains more of the infantile characteristics than the male. A parallel observation has been made upon the intellectual capacity of the sexes.

PARLIAMENTARY.

ON Thursday, March 10, in the House of Commons,

Mr. Buxton asked the Secretary for the Home Department whether his attention had been drawn to a statement recently made by Mr. E. Chadwick before the Society of Arts, that, "taking 104 prison returns, which enabled a comparison of the 20 gaols where the expense and the quantity of the diet were the lowest, the 20 where the expense and the quantity of the diet were the highest, and the 20 where they were intermediate, the results came out as follows:—

	Oz. of solid food per week.	Cost per head per week.	Sick per cent.	Deaths per 1000.
20 lowest prison diets .	188	1s. 10½d.	3	1½
20 intermediate diets .	213	2s. 4½d.	18	3
20 highest	228	3s. 2d.	23½	4½

and whether he would cause any inquiry to be made on the subject.

Sir G. Grey said he had not seen the statement to which the hon. gentleman referred, and he was wholly in ignorance of the sources from which the figures referred to had been taken, nor could he vouch at all for the accuracy of the results; but an inquiry was now going on into the whole question of the dietary in the convict prisons.

The House having gone into Committee upon the Mutiny Bill, Mr. Cox moved the omission of clause 22, relating to flogging. He denounced this punishment, inflicted for trivial offences, as disgusting and demoralising.

The motion was seconded by Mr. W. Williams.

The Marquis of Hartington said it was the opinion of the most experienced officers that there were in the British army men of a certain class who were insensible to any other punishment than the lash, which was inflicted only in aggravated cases of mutinous conduct, until a man was degraded for offences to the second class. The punishments in other military services were more severe, and cases of flogging were diminishing in our own.

After much discussion, the Committee divided, when the amendment was negatived by a narrow majority, there being 45 for the clause and 42 against it.

Mr. Cox then moved the omission of clause 26, relating to branding.

Mr. Headlam said it was essential that the practice of branding, the process of which inflicted no pain, should be kept up.

Men of bad character, who deserted, or were dismissed from the army, enlisted in other regiments, receiving the bounty, and there was no other effectual mode of identifying them. This was the simple object of the practice.

After another animated debate the Committee again divided, when the amendment was negatived by 80 to 50, and the clause was agreed to.

It is to us a matter of surprise and regret that no mention was made in the debate of the strong objection universally entertained by Medical officers to the present regulations as to branding. We do not think that the House of Commons can be aware that the regulations state that it is the duty of the Medical officer to "direct," "superintend," and "instruct" a subordinate in the branding of military offenders, or some small amount of the sympathy lavished on the soldier who is held to be degraded by corporal punishment, would have been bestowed on the Professional man whose feelings and self-respect are outraged by being thus made the responsible executioner of the law.

In the House of Commons on Monday, the 14th, in answer to a question by Sir M. Peto on the subject of vaccination registration,

Mr. Lowe said it was quite true that the system of registration under the Vaccination Act was very bad, but it would cost a great deal of money to improve it. Moreover, even when improved, it would not make these compulsory measures effectual to any extent. The great difficulty in working them was due not so much to defective legislation as to the reluctance of persons to prosecute poor people for disobedience to a law, the neglect of which was countenanced by too many who ought to know better. He was sorry, therefore, that he could not hold out any hopes of an improvement in the system.

On Tuesday, March 15, in the House of Lords, the Lord Chancellor said that as the Insane Prisoners Act Amendment Bill had been the subject of a good deal of discussion, the Government thought the best mode of dealing with it in that House was to refer it to a Select Committee.

The bill was then ordered to be referred to a Select Committee.

After a short discussion, the Malt for Cattle Bill was read a second time.

In the House of Commons, Mr. D. Fortescue called attention to the court-martial on Colonel Crawley, and moved for copies of a letter from Colonel Crawley, announcing, for the information of Sir W. Mansfield, the arrest of Sergeant-Majors Lilley, Duval, and Wakefield, on a charge of conspiracy, together with any documents in support of such charge; of the last half-yearly confidential inspection report on the 6th Dragoons, prior to Colonel Shute's resigning the command; and of the first half-yearly confidential inspection report subsequent to Colonel Crawley's assuming the command of that regiment. In explaining his reasons for bringing the subject again before the House—being, he observed, in consequence of what had occurred in respect to it, and of his statement last year, placed in some measure upon his own defence—he did not, he said, call in question the verdict of the court-martial which had acquitted Colonel Crawley, whatever his individual opinion might be. Having stated the facts as they had come to his knowledge, in the first instance, expressing his regret if, through any defective information, he had been led to overstate the case and make it darker than it really was, he reviewed the circumstances of the Mhow Court-martial, and the arrest and confinement of the sergeant-majors, adverting to the feelings engendered by the incidents connected therewith in the non-commissioned officers of the army, and deploring the scandal and mischievous effects resulting from what he termed this unhappy business.

The motion was seconded by Mr. H. Grenfell, who urged the importance of taking into consideration the unsatisfactory framework of courts-martial, and remedying the defects of these tribunals.

General Peel moved as an amendment a resolution that the production of any further papers is inexpedient. He did not want, he said, to debar the House from the proper control of the Army, but he deprecated its interference with the administration and government of the Army, and the constituting itself a court of appeal. With regard to the case of Colonel Crawley, which had done much, he said, to weaken the discipline of the Army, he condemned the manner in which the Government at home had acted in the matter, and especially what he considered the unfair trial to which Colonel Crawley

had been subjected, and the attempts made and defeated to obtain a verdict against him.

The amendment was supported by the Marquis of Hartington on the part of Government, and after a long debate the original motion was negatived, and the amendment agreed to.

FROM ABROAD. — UNJUST COURT-MARTIAL IN AMERICA — NEW MODE OF ADMINISTERING IODINE — TREATMENT OF INFLAMMATION BY COLLODION.

A COURT-MARTIAL now being held on Assistant-Surgeon Webster, of the United States Army, exhibits an unseemly clashing of the functions exercised by Medical and combatant officers. Dr. Webster, who is allowed on all hands to have achieved a high reputation for Hospital management, placed in charge of the McDougal General Hospital, was under the natural impression, confirmed by the tenour of the general orders under which he acted and the custom of the army, that patients placed under his charge there could only be transferred thence or disposed of pursuant to the direction of the Surgeon-General or his representative in the Department, the Medical Director. Such, however, seems not to be the opinion of the military authorities; for a combatant officer of even subordinate rank issued an order for the arrest and transfer of a patient who was under Dr. Webster's charge. With this demand the latter refused compliance, not only on the technical ground above stated, but because the patient having recently undergone a severe Surgical operation, the wound from which requiring dressing twice a-day still confined him to the ward, his life might be endangered by removal. However, arrested the man was, and without any examination of his state having been made by those removing him, he was compelled to walk a long distance on a cold, wet night, and when he reached Fort Columbus was declared unfit to be sent to his regiment—apparently the object for which he was arrested. For protesting against the competency of this arrest, and maintaining that his Medical superiors have alone a right to convey orders to him respecting the disposal of the patients under his charge, Dr. Webster is now put on his trial. He has our warmest sympathies while contending for a principle under which alone can Hospital management be satisfactorily conducted.

The vacancy in the section of therapeutics and Medical natural history at the Academie de Médecine having to be filled up this time by a member representing the therapeutical division, two of the candidates have just read papers before the Academy in support of their claims. That of M. Boinet bore for title:—"The means of administering Iodine in a completely soluble state, and entirely deprived of its irritating properties." As perhaps no Practitioner has employed iodine in its various forms more abundantly than M. Boinet, what he has to say on the subject must have great weight. The accidents which were met with when iodine was first introduced, he observes, were due to portions of this substance remaining undissolved and acting as foreign bodies. Some of these at once disappeared when the iodine had been rendered soluble by the agency of potassium. But others arose which were wrongfully attributed to the iodine, such as tumefaction of the mucous membrane, salivation, lachrymation, gastralgia, etc. These, M. Boinet is convinced, really arise from the potassium with which the iodine is combined, for results of an analogous character are observed during the use of other salts having potassium as a base, as chlorate and nitrate of potass. Now, the solubility of the iodine may be still preserved, while the inconvenient effects alluded to may be obviated by substituting *tannic acid* for the potassium. The tincture of iodine of the French codex is not a completely soluble preparation, but may be rendered so by the addition of some tannic acid. But M. Boinet thinks, further, that advantage might be derived from recurring in some sort to the practice of our forefathers of employing iodine in a state of more natural combination, as in the form of burnt sponge, marine plants, natural mineral waters, etc.,—the greater molecular division facilitating the absorption of the con-

stituent principles. It is only since chemistry has shown us that these various substances contained iodine that we have become aware to what agent they owed their curative properties—properties no less real than those belonging to our modern pharmaceutical preparations. The investigations of Chatin and others have shown that iodine is abundantly distributed throughout organic and inorganic matter, and that there are less goitre and scrofula in those countries where it is most prevalent. For all these reasons, M. Boinet thinks it desirable to resort to these more natural preparations, they being as efficacious and less injurious than those now in use. To this end he has devised a *natural iodine wine* which, while it produces no ill effects upon the digestive organs, is of easy absorption and assimilation. It is prepared by placing in a wooden vessel alternate layers of raisins and of marine plants reduced to powder, until the vessel is filled, and then allowing the whole to ferment during a fortnight, and treating it as ordinary wine. A useful combination of iodine is thus produced by which the affections to which this substance is applicable may be advantageously treated.

M. Robert Latour, another candidate, furnished the Academy with an additional illustration of a practice which he has been inculcating for several years past, though with little effect, as far as imitation is concerned. His leading idea is that inflammation is only a local exaggeration of animal heat, and that among the conditions upon which the production of animal heat is dependent there is one which is under our control, and can be suppressed—viz., the contact of the air with the surface of the body. This is done by covering that region of the body with an impermeable application, which, suspending the calorifying action of the air in that region, relieves the inflammatory action dependent upon this. The case given in exemplification is that of a lady, 19 years of age, who, having long suffered from chronic ovaritis, was suddenly seized with violent peritonitis. M. Latour immediately covered the whole abdomen with a compound of collodion and castor oil. The pulse at once sank to 60, and all went on well. At the end of six days a relapse occurred, but another and more extensive application of collodion was attended with the same excellent result. On the twenty-seventh day the various limbs became successively the subjects of phlebitis, and in all the collodion achieved its usual triumph. Some slighter relapses were met in the same way, the young lady not only recovering, but “during the course, and at the end of these terrible trials retaining all the fresh appearance of youth, and all the brilliancy of her beauty.” Surely after this M. Latour must be declared the successful candidate!

THE LEVEE.—At the levée held by the Prince of Wales, by command of her Majesty, at St. James’s Palace, on Saturday, the 12th, the following members of the Profession attended the general circle:—Sir Henry Holland, M.D., Physician in Ordinary to the Queen; Sir Charles Locock, M.D., Physician Accoucheur to the Queen; Mr. Cæsar Hawkins, Sergeant-Surgeon to the Queen; and Mr. Ferguson, Surgeon Extraordinary to the Queen. The following presentations took place:—Dr. Archer, Surgeon-Major, Her Majesty’s Indian Army, by the Right Hon. Sir Charles Wood, Secretary of State for India; Surgeon C. Finch, Bengal Retired List, by the Secretary of State for India; Mr. Peter Gowland, F.R.C.S., Surgeon Hon. Artillery Company, by Lieutenant-Colonel Lord Colville of Culross; Charles S. Halse, M.D., Surgeon 46th Middlesex Volunteer Rifle Corps, by Lieutenant-Colonel Sir John Villiers Shelley, M.P.; Assistant-Surgeon A. J. L. Hepworth, M.D., R.H.A., on appointment, by Colonel H. L. Gardiner; Staff-Assistant Surgeon John Michael, by the Adjutant-General; Dr. George Owen Rees, F.R.S., by Sir William Dunbar, M.P.; Dr. Charles John Steward, Assistant-Surgeon North Middlesex Volunteer Rifles, by Lieutenant-Colonel Whitehead. The following attended the Levée:—Doctors.—Griffith F. D. Evans, Clarke Rutherford, Watson, Thomas King Chambers, and Scott Alison. Messrs.—S. S. Scriven, G. Borlase Childs, T. Graham Balfour (Deputy-Inspector-General), J. Reeves Traer, White Cooper, J. Moncrieff Arnott, James Paget, Erasmus Wilson, and Haynes Walton. * * * In our notice of the former levée, the name of Mr. Henry Stanhope Illingworth was accidentally omitted.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF STAFFORD.

(Concluded from page 294.)

SANITARY CONDITION OF STAFFORD.

At the close of my last paper I stated the population of the borough of Stafford to be 12,532, and indicated that the increase of population from the census of 1851 to that of 1861 was 703. Let us now pass to consider the remaining facts in the sanitary history of this town.

VALUE OF LIFE IN STAFFORD.

I am enabled to lay before the reader the mean value of life in Stafford during ten years, gathered from the records of the Registrar-General referred to in a previous chapter of this history.

Average Annual Rate of Mortality in Stafford, from all Causes, at different Ages, to 100 Living, during the Ten Years 1851-66.

	Males.	Females.
All ages	2·278	2·175
Under five	5·970	5·303
Five	·806	·693
Ten	·484	·462
Fifteen	·678	1·094
Twenty	·829	·988
Twenty-five	1·365	1·348
Thirty-five	1·792	1·508
Forty-five	2·004	1·517
Fifty-five	3·135	3·310
Sixty-five	6·935	5·947
Seventy-five	15·563	12·970
Eighty-five or more	26·842	32·069

Compared with England altogether the value of life in Stafford is in favour of the town. The value of life in England at all ages is for males 2·305, for females 2·132, while in Stafford the value is for males 2·278, and for females 2·175. A close analysis of the facts shows that Stafford gains its life advantages in its youthful and most aged populations. Thus, up to the age of 15 years the value of life in Stafford stands remarkably superior; after 15 it declines; at the age of 35 the declination is very considerable, and at 65 years it reaches its extreme, the deaths in Stafford being in the proportion of 6·935 in males, and 5·947 in females, to the proportion for all England of 5·533 in males, and 5·866 in females. After the age of 65 the balance again turns in favour of Stafford.

We may infer from the facts thus supplied that children are less worked and better cared for in this town than in England generally; we may infer that the aged and infirm are also better cared for—a fact which the history of the charities of the place has already suggested; but we may also gather that from puberty to 60—65 the inhabitants are subjected to influences, arising either from occupation, want, intemperance, or disease, which lead to a reduction in the value of their physical life.

MORTALITY FROM DIFFERENT CAUSES.

The average annual rate of mortality in Stafford, from all causes, to 1000 persons living is, in round numbers, 22. This average is based on the mortality tables of the ten years 1851-60.

Average Annual Mortality in Stafford, from Different Causes, to 100 Living, from 1851 to 1860.

	Males.	Females.
Typhus	·072	·100
Cholera, Diarrhœa, and Dysentery	·081	·087
Other Zymotic Diseases	·297	·213
Cancer	·033	·075
Phthisis	·269	·320
Scrofula, Tabes Mesenterica, and Hydrocephalus	·067	·052
Disease of Brain	·413	·275
Disease of Heart and Dropsy	·124	·147
Disease of Lungs	·256	·252
Diseases of Stomach and Liver	·116	·107
Diseases of Kidneys	·038	·016
Violent Deaths	·83	·039
Other causes	·419	·492

Deaths at Different Ages.—Year 1861.

Males, total deaths of, 263. Under 1 year, 44; under 5

years, 65; from 10 to 15 years, 9; from 20 to 25 years, 13; from 25 to 35 years, 18; from 35 to 45 years, 26; from 45 to 55 years, 28; from 55 to 65 years, 28; from 65 to 75 years, 31; from 75 to 85 years, 28; and from 85 to 95 years, 7.

Females, total deaths of, 243. Under 1 year, 47; under 5 years, 69; from 10 to 15 years, 4; from 20 to 25 years, 12; from 25 to 35 years, 20; from 35 to 45 years, 23; from 45 to 55 years, 16; from 55 to 65 years, 18; from 65 to 75 years, 29; from 75 to 85 years, 23; from 85 to 95 years, 6; and over 95 years, 1.

Births Compared with Deaths of Males and Females—1861.

Males, births of, 368; deaths, 263; births over deaths, 105.

Females—births, 359; deaths, 243; (a) births over deaths, 116.

WATER SUPPLY.

The water supply of Stafford is entirely from wells. No attempt has ever been made to obtain a common supply either from the river Sow or other sources. The supply, consequently, in every case, is raised by hand labour, either by the pump or the old-fashioned chain and roller. I had hoped to give an analysis of the Stafford water, but, owing to the fact that the supplies are almost as numerous as the principal

(a) It is worthy of remark, that in the year 1772 the committee of the Stafford County Infirmary made an inquiry relative to the mortality of their institution as compared with that of the Hôtel Dieu and of St. Bartholomew's, St. Thomas's, and the other London Hospitals. The result of their inquiry is thus noted:—

	Deaths.
In the Hospital at Stafford	1 in 18
In the London Hospitals	1 in 13
In the Hôtel Dieu	1 in 5

At that time, aged people, who were not necessarily sick, were received into the Hôtel Dieu, a circumstance which would be rather favourable than otherwise to the Hospital. At this *date* about the same relative mortality is, nevertheless, maintained.

houses, this is impossible. Some years since Dr. Wrightson made an analysis of a few specimens, and it was found that in the specimens examined there was a large amount of lime and also a considerable amount of organic matter. The water in most cases, probably, passes through lime, and in all parts of the town I believe it has the character of being hard, but it is fresh and pleasant to the taste.

DRAINAGE.

No attempt—I had almost said—has been made to drain Stafford. Surface drains are seen in every street, but where they empty their contents is a mystery to the stranger. I asked one of my Medical friends in reference to a rapid and full current of drain water running along the leading street, where the current would stop, and his reply was, "It never will stop—there is nowhere for it to stop;" and this is really true, for the water, in fact, is either absorbed by the soil or lies until it has evaporated. Fortunately for Stafford, the soil is porous, and, like a good sponge, sucks up all the moisture. To the better class houses there are cesspools, and these are sufficient to allow of the introduction of the water closet into the house; but in the lower class houses there is nothing but the common privy, with a very imperfect receptacle, in most cases, for the soil. In short, Stafford is an undrained town, happily placed in respect to its natural resources, but untouched by art, and sharing, as yet, in none of those benefits of civilisation which the engineer has invented and carried out so successfully in other and less favoured localities. (b)

The sewage of the town may be considered in great part as lost, no systematic plan of utilisation having ever been adopted or practised. The town is well placed for the adaptation of the system of receiving the sewage into receptacles provided with a filtering sewer, after the method suggested by

Dr. Hawkesley, and of which the accompanying diagram will give a better description than any I could supply in words.

By this method the whole of the effete matters might be retained and utilised, and the purity of the town greatly increased, with little trouble, and at a cost that would soon be regained by the value of the product for the purposes of agriculture.

Climate—Meteorology—Site.

No correct meteorological observations have been taken at Stafford, so that it is impossible to draw any conclusions that can be considered trustworthy respecting the climatic conditions. It might be inferred that the town is generally damp, but, in fact, owing to the porous nature of the soil, dampness is not a serious evil. The site of the town is flat, and, according to Garner, may be considered as having been originally a fertile but rather marshy plain.

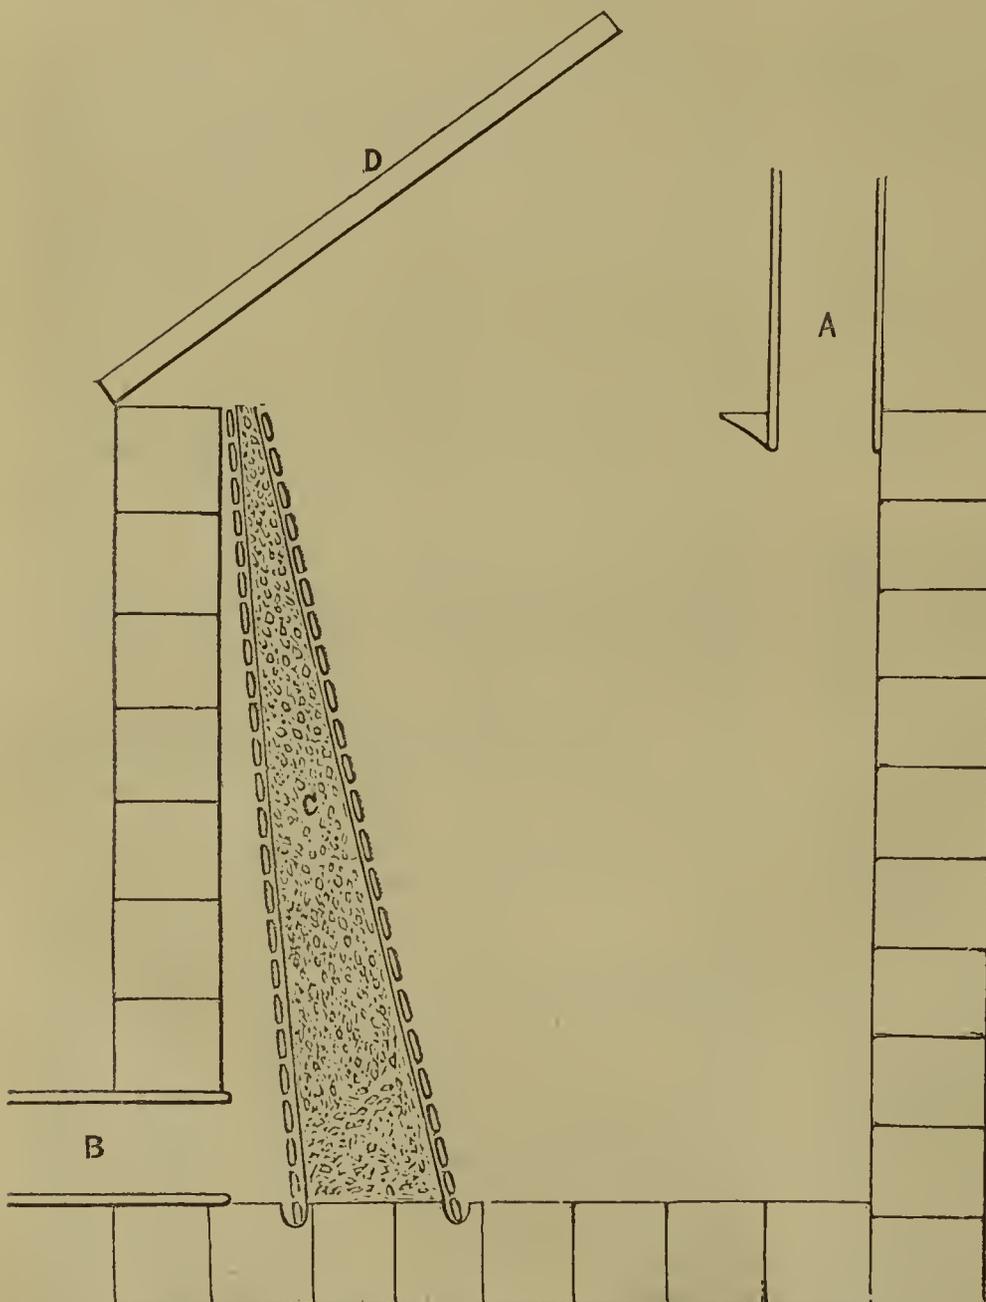

Streets and Dwellings of the Poor.

I have already referred briefly to the streets of Stafford. They are not unusually dirty, nor are they wanting in regularity. The sideways are paved with pebbles, and the streets are kept, ordinarily, in a sound and moderately dry condition. This, of course, does not obtain on cattle fair days. The dwellings of the poor are, according to my judgment, very much superior to those in Norwich, and although there is overcrowding, that is much less than in the towns which I have previously described.

Diet of the People.

The ordinary diet of the poor of Stafford, taking for example one of the manufacturing artizans, a shoemaker, is as follows:—For breakfast, tea, sugar, and bread, with a little lard, treacle, or butter. For dinner, the same; perhaps with a herring, or a portion of cheese, in addition. For tea, bread and

(b) I would like to correct a partial error in a previous paper relative to the floods to which the town of Stafford is sometimes subjected (*vide Medical Times and Gazette* of February 27). From evidence I have obtained in a subsequent visit, I learn that when the floods are out the main streets escape. I have also learned, as a further correction, that the hat trade, to which I referred in a previous paper, forms no part of the present industry of the town.

Diagrammatic section of a "receptacle" showing: A, the entrance-pipe, or house-drain; B, the exit-pipe to sewer; C, the filtering-screen, consisting of two large slabs or tiles of fine clay, freely perforated, and packed in their interspaces with gravel; D, the lid or cover of receptacle.

lard, with weak tea. For supper, if any, bread and lard. This diet undergoes but little change. Sometimes, however, especially on the male side of the population, beer is largely indulged in, not usually in a systematic way, but in what may be called "drinking bouts," during which drunkenness prevails to a large extent, followed necessarily by a decrease in the scanty allowance of food already referred to.

Prostitution.

Prostitution, carried out as a profession, is not prevalent in Stafford. There are, in the whole of the town, but one or two acknowledged houses of bad repute, and the number of common prostitutes is exceedingly limited. For this reason, venereal affections are comparatively uncommon, and the extreme effects of syphilis are rarely seen. It is possible also that the small mortality of infants and young children in Stafford is owing in part to the limitation of the specific disorder. At the same time, what is ordinarily considered chastity is by no means a pervading virtue amongst the lower classes. In these it is so common for the females to become pregnant previous to marriage that the fact is hardly thought peculiar.

Public-houses and Beershops.

The number of licensed victuallers having spirit licences in Stafford and in the borough, are no less than sixty, in addition to which there are ten such out of the borough, but so near as to be considered in the town. Of beerhouses, in the borough there are thirty, and out of the borough eleven. There are thus 111 places in all for the sale of intoxicating drinks.

Epidemics and Endemics.

At one time ague was the prevailing disease, and was, in fact, endemical in Stafford. Of late years it has almost entirely disappeared, but neuralgia is still extremely common. Scarlet fever is frequently a prevalent epidemic, giving rise to considerable mortality amongst the young. The ally of scarlet fever, diphtheria, is also now met with in its more serious forms. At the time of my visit, ten deaths had resulted from this disease in the neighbourhood within a few days, five having occurred in one family alone. Measles is less frequently met with than the other epidemic disorders; and the same may be said of croup.

Cholera visited Stafford in 1832, but caused only one or two deaths. In 1849 it again visited Stafford, causing 2 deaths. The first death occurred in the Infirmary, on January 10, when a labourer, aged 27 years, died in sixty-two hours after the attack; the other case was recorded on October 27, at St. Chad's-place. From diarrhoea, the deaths were 4. In 1854, 2 deaths again occurred, and 3 or 4 from diarrhoea. The disease on none of these occasions assumed the epidemic form.

Typhoid and typhus fevers are both met with, and this rather frequently. Thus, in the year 1862, 52 patients, recorded as suffering from fever, were admitted into the Infirmary, 13 of whom died. The fevers are confined to the lower portions of the town, and rarely assume the epidemic character.

Small-pox is a disease of rare occurrence; there has been no serious outbreak of it for many years past until this month, when it is presenting itself in the epidemic form.

Vaccination.

Vaccination is conducted to the best of their power by the Medical officers of the Poor-law districts. Two shillings and sixpence per case is paid for the operation. The operation is performed in each place in the district every week, so that the process should be well kept up. Unhappily the prejudices of the people are a persistent and formidable obstacle to the Medical men.

Etiology of Stafford.

The subsidence of the disease ague, and its replacement or continuation by neuralgia, is a very singular etiological fact, and is probably due rather to an improvement in the drainage of the lands around Stafford than to the improvements in the town itself. The neuralgia, which is so common, indicates the still remaining deficiency of drainage. Considering the hardness of the water, the marked absence of cases of stone in the bladder is singular, leading, as it does, to the inference that the presence of lime in quantity is not a common cause of calculus, as some have hastily surmised. At the same time, though calculus is rare, it does occasionally present itself in special cases in an extreme form. In St. Mary's churchyard at Stafford the friends of a sufferer from stone have

recorded the fact in a manner rather unique. The following is a copy:—

"SACRED
TO THE MEMORY OF
WILLIAM HANSON,
LATE OF HANBURY, IN THE COUNTY OF STAFFORDSHIRE,
WHO DIED IN THE GENERAL INFIRMARY OF STAFFORD,
MARCH 6, 1812,
AGED 63 YEARS,
AFTER AN OPERATION, BY WHICH A STONE WAS EXTRACTED
FROM THE BLADDER OF THE SIZE AS UNDER."

Then follows a drawing of the calculus itself, cut in the stone. Dr. Day, who was kind enough to take the dimensions for me, finds it measures seven inches in length by four in breadth. It is thus half an inch broader than the calculus retained in the Norwich Hospital, and two inches and a-half longer. On referring to the Infirmary records, it appears that the stone was extracted by Mr. F. Hughes, father of Mr. Robert Hughes, the present Senior Surgeon to the Infirmary, and that the patient died. Unfortunately, no note has been kept respecting the nature of the stone or the operation.

The presence of cases of bronchocele connects itself with a theory—which is strongly supported by various evidence, but especially by the effects of the water of the Durham Gaol in the year 1843—that the excess of lime in the water has an intimate relationship to the disease in question. I could not, however, glean any very satisfactory proofs on this question; the evidence is rather suggestive than affirmative.

The absence of cholera in the epidemic form after the occurrence of sporadic cases on three occasions is an interesting circumstance, and admits, I think, of being simply explained. The drainage of the town, although, as we have seen, defective, is safe in this respect—that it does not flow through sewers in the neighbourhood of wells, but is distributed through the porous surface on which the town is built; while the water comes through the limestone at greater depth. Hence there is no large admixture at any time of the excreta of the sick with the water supplied to the healthy. Stafford is not the only town that has escaped cholera for this apparent reason, and it contrasts strongly with those towns where an imperfect system of sewers has intersected equally imperfectly built wells, and where the contents of the sewer and well have had no alternative but to come together.

Regarding the other diseases: rheumatism—and its sequel heart disease—may be traced to imperfect diet, and, perhaps, to the still indifferent drainage of the houses of the poor, through which they are exposed to damp and cold. Consumption has its chief origin here, as elsewhere, from bad air; and the prevailing epidemics of scarlet fever and diphtheria are to be sought for, as regards their origin, in the transmission of specific organic poisons.

MEDICAL BIOGRAPHY OF STAFFORD.

Dr. Erasmus Darwin, M.D.—Dr. Darwin has been claimed as a resident of Stafford, and he was, unquestionably, one of the Physicians to the Infirmary, his name appearing on the books as having been elected in the year 1776. The great author of the "Botanic Garden," "The Loves of Plants," and the "Zoonamia," was, however, a Lichfield man, and his name and history are so identified with that place, that I must, when I write his life, place him amongst the worthies of Lichfield, not of Stafford.

Dr. William Withering, M.D.—Dr. Withering, the famous botanist, was elected Physician to the Stafford Infirmary in 1768, and held the office for six years—viz., till 1774. It would appear that Withering, who was born, in 1741, at Wellington, in Shropshire, and whose father was a Medical man in practice there, came to Stafford immediately after his graduation in Edinburgh. His attempt at practice in Stafford was unsuccessful, and he moved to Birmingham, where he became widely known as a Practitioner and a man of science, and where he remained until the close of his career in 1799. We shall take up the particulars of his active life in the history of Birmingham.

Dr. Thomas Fowler, M.D.—Dr. Fowler, better known as the presumed inventor of Fowler's solution of arsenic, and who was born in York in 1736, and graduated in Edinburgh in 1778, was elected Physician to the Stafford Infirmary in 1783. The name of Fowler has been so intimately connected with the solution known as the *Liquor potassæ arsenitis*, that a brief note of his connection with that preparation cannot but be interesting. In plain, then, at the time when Fowler went to Stafford, there was being introduced into England a

solution called "Dutch Drop," or "Tasteless Ague Drop." This solution was tried in Stafford in several cases of the prevailing disease, and was found successful. At that time, Mr. Hughes, the grandfather of the present Mr. Robert Hughes, was House-Surgeon to the Stafford Infirmary, and he, having examined the "drop," determined that it contained arsenic. Upon this he set to work to find a means of dissolving arsenic, and succeeded by the use of potash. He showed his solution to Dr. Fowler, who tried it, adopted it, and reported upon it favourably, upon which the medicine came into general repute under the name of Fowler's solution. With the other applications of this solution Fowler had little to do. It was in ague only that he saw its value. Dr. Girdlestone, of Yarmouth, was the first Physician who used the solution in lepra. Dr. Beddoes was the first who used it as a tonic in phthisis. Mr. John Jenkinson, of Oxford, was the first who employed it in chronic rheumatism, and he was soon after followed by Samuel Fothergill, a London Physician, who resided in Leicester-square. Dr. Kinglake and Mr. White, of Bath, finally established the value of the arsenical solution in lepra, psoriasis, and other diseases of the skin. It is but just to the name of Mr. Hughes that this exposition of the discovery of Fowler's solution should be given, and it is but equally just to the other members of the Profession, named above, that the credit of their applications of the remedy should be awarded to them respectively. We are accustomed to speak of Fowler's solution as though it belonged entirely to him, whereas, when all the facts are told, he had perhaps less to do with its invention and with the discovery of its virtues than any other Physician whose attention was turned to arsenic as a remedy. Thus, often does mere accidental position give name and history, and it would be but just, in rectification of a long-prevailing and great error, to call the well-known arsenical compound from this time forth "Hughes's solution."

Independently, Fowler was unquestionably an able man. His contemporaries speak of him as exceedingly cautious in observation and record. He was one of the first to study the effects of digitalis in the treatment of consumption; and he published a paper on "Galvanism," in which he endeavoured to show that dead organic structures, when subjected to galvanism, do not undergo putrefaction so readily as when they are left untouched. As I have already stated, Fowler commenced as a Physician in Stafford in 1783. He continued there, doing a large and lucrative practice, until 1791, when he returned to his native place, York, and lived in partial retirement, contributing only now and then brief communications to Medicine. One of these, on the "Effects of Tobacco," attracted considerable notice. He died at York in the year 1801.

Dr. Edward Knight, M.B. Cantab.—The only remaining name on my list of celebrities is that of Dr. Knight, who was elected Physician to the Infirmary in the year 1808; who practised in Stafford upwards of sixty years; who is remembered by a good many of us still, and who died on June 9, 1862. Dr. Knight was one of those who bridged over the old and new schools of Physic. In his early life he was one of the heroes of the famous and terrible Walcheren expedition. He was ultimately Deputy-Lieutenant of the county of Stafford, and a county magistrate. He added nothing whatever to the literature of his Profession, but he was an accomplished man, and, among other of his attainments, he knew how to play on the fiddle. He was, I am told, one of the best amateur fiddlers the county has produced, understanding music deeply, and combining with natural art those studied graces which mark the true musician.

The Medical History of Stafford is concluded.

NOTE ON HOSPITAL MORTALITY.

Mr. Henry Thompson, in last week's *Medical Times and Gazette*, blames me for allowing seven weeks to pass before replying to his previous letter. I might blame Mr. Thompson, in my turn, that he allowed only seven days, and that in his haste he could not have read what I had written. If he will refer to p. 262 of the *Medical Times and Gazette*, he will find that his statement of my having calculated the mortality from lithotomy—"from adult cases alone [20 years and upwards]"—is not correct, inasmuch as I only excluded children under 10 years of age, and this for the obvious reason that the children under that age operated upon in London were nearly three to two as compared with those operated upon in Norwich.

To his second suggestion, that female cases are excluded from London practice, I may state that, granting all the cases in the London Hospitals were males, and all the 41

cases marked females in the Norwich list were over 10 years of age, the difference in the results against Norwich is only 0.22 per cent. The reader will see that this really does not materially affect the question either way. But then we have 16 cases of females in London which I unintentionally, and not for the motive which Mr. Thompson assigns (a motive, by the way, which I should have been the last man to have attributed to him), omitted to name, and what is the story they tell? That of the 16 cases, only 1 died. The result is good by comparison with the operations on males in London; but when we turn to Norwich, we find that the good is *better*, for there 41 females were operated upon, and only 2 died.

Respecting the statement of Mr. Thompson, that adults in London are not to be compared for health and strength with those in the country, I am simply at issue with him. I, too, "know both classes well." I have seen nearly ten years of active country practice, and the same of London, and my experience is opposed to Mr. Thompson's generally, and particularly with regard to the poor of London and of Norwich. Presuming, indeed, that I am wrong as to the cause of difference of mortality, I am sure Mr. Thompson is not right in placing it on the character of the patients operated upon. That hypothesis is convenient, I know, and in Medicine as well as Surgery is too popular. "The disease would have been cured, only the patient had such a bad constitution." Who does not recognise the phrase? Who does not understand how meaningless it is,—despite that it often answers?

Mr. Thompson commits an error in stating that the eighty cases of lithotomy, with two deaths, performed at Norwich, were performed by one Surgeon; forty truly were so performed, but in the other forty three Surgeons were concerned. This is an important point to remember correctly, because it excludes the idea of simple manipulative Surgery, and of one particular method of operation, and of selection of case, and of individual experience, as causes of success.

Only one other point in reference to Mr. Thompson. He throws it at me that I have not explained why, under almost all circumstances, the mortality in children is so nearly the same after lithotomy. This is, indeed, more than I expected. It never occurred to me that a man, so intelligent as Mr. Thompson, should ask me to explain to him, and to the intelligent members of our Profession, so simple a problem. Is it not a fact of daily, hourly experience that during those years of life when the body is being built up, what is vulgarly called the vitality, or, in other words, the regenerative force through which life is manifested, is most active and most resistant to accidents from without? Do we not know that children take chloroform with a degree of safety that may be considered absolute, when compared with adults,—that they live through epidemic disorders before which the full-grown man would inevitably succumb,—and that to whatever depressing influence they are subjected, they return it with a reaction which is never observed in after life? I state candidly to Mr. Thompson that I think the mortality of children, under 10 years age, from lithotomy, or any similar operation, would be influenced by little short of anything less than subjection to an atmosphere that was directly poisonous. But when we come to men the case is very different. In the child the waste is ahead of the supply; in the matured man, the supply is ahead of the waste. Hence when the child receives a deleterious agent into its organism, it throws it off: the man retains the agent. And it may be that such retention, modified by years, follows a fixed law, determining the mortality.

Herein, then, I believe, lies the cause of that acknowledged superiority of the country over the town practice, in the cases of adults. Mr. Thompson may attribute the difference to manipulative Surgery—selection of case—or condition of patient. I defy him to run any one of these home. I assert that they all demand exclusion from the argument; and that the only cause of the difference that cannot, at this moment, be excluded is the difference in the Hospitals.

In reply to Mr. Holmes: I met his first objection very fully in my last note. The basis of the success of the Norwich Hospital rests, I believe, unquestionably on the large amount of space, and on the perfect ventilation which, from the first, was given to that Hospital. With reference to ventilation, I think, with all respect to Mr. Holmes, that the Norwich Hospital is better ventilated than any of the Hospitals he has quoted; first, because the ventilation is natural; and, secondly, because the construction of the Hospital allows of a more thorough admission of fresh air and of escape of impure air. But there are other favourable agencies also at work at

Norwich, which, though secondary, are of great importance in recovery—I mean the lesser contamination of the air, and the greater quiet and freedom from intrusion that prevails. In these regards Norwich Hospital approaches almost a private house; and by so much its ventilation is comparatively superior; added to that, the air is not impaired in its quality by passing over, for a majority of days in the year, a seething population like that which surrounds the greater number of London Hospitals.

As regards the data from which my deductions were drawn, I will state them definitely; and this is the more requisite, because Mr. Holmes insinuates, in the absence of a better and more courteous argument, that I have misrepresented facts. When I was at Norwich I was supplied with the official records of seven years, viz., from 1856 to 1862. These were prepared, printed, and published as the *bonâ fide* annual reports of the Hospital. They had passed the board of management; they had passed the Medical staff; they bear on their second page the signature of the chairman of the Hospital board, and have never, as far as I know, been challenged. They are most circumstantial, and I could not, in any way, rely on more positive data. In the Report of 1862, the cause of death in every case is supplied; the details of operations are tabled; and the percentage is drawn out. *From that record my facts are copied absolutely.* Forty-four cases are reported as having died that year. Of these, twenty-three are Surgical; the rest Medical. The percentage of deaths on the whole of the Surgical cases I find to be precisely 2.50; the percentage after Surgical operations, 3.55; the percentage altogether, including Medical and Surgical cases, 5.09. I have no other data than these official data from which to draw my conclusions, and I would accept no other, because if these are wrong in one particular they may be wrong in all.

The same fact holds good with regard to the disease pyæmia. Thinking I might have missed this word, I have not only examined the official records again myself, for the seven years to which my statement referred, viz., from 1856 to 1862, but I have submitted them to another gentleman [I should be happy to submit them to Mr. Holmes himself], and I reassert that the word pyæmia occurs but once. It marks *one death* in the year 1862. If Mr. Holmes refers to my paper of January 16, p. 67, he will see that I did not refer to the year 1863, for the record of that year was not in my hands. I may further add, as matter of fact, that Mr. Williams in his note to me did not refer to the year 1863, nor did he tell me that there had been any *fatal* cases from pyæmia previous to that year, other than were given in the official documents, neither did he intimate that the official documents were wrong. He simply stated that there had been one or two cases of pyæmia, and also of erysipelas, and my impression from his note was that these cases had not terminated fatally. Had the official documents told me that there had been fifty cases of pyæmia, I assure Mr. Holmes I should have stated that fact as readily as any other, and I assure the Profession that on the official evidence before me—which evidence I am bound to prefer to any other—my statements in this Journal for January 16 are literally and absolutely correct. So soon as the printed account of the Norwich Hospital for 1863 is in my hands I shall deal with it according to the facts it presents.

Out of respect to Mr. Thompson—whom I have long known—I have replied to his strictures; and out of respect to myself on statements of fact, I have replied to Mr. Holmes; but in the future, with all desire to be courteous and considerate, I must decline entering into controversy on points connected with these papers on the Medical History of England. The necessity for this course will be obvious when I state that nearly every day brings in some communication, which I am requested, now or in the future, to notice either specially or generally, and that already I have received upwards of seventy such communications. To answer every one were physically impossible; to answer a few only, were unfair; to say nothing of the encroachments that would be made on the space of the *Medical Times and Gazette*.

UNIVERSITY OF LONDON.—MASTER IN SURGERY.—The following gentlemen have just passed the examination for the degree of Master in Surgery:—Hewlett Richard Whitfield, M.D., King's College; Rivington Walter, M.B., B.A., F.R.C.S. Eng. Exam., London Hospital; Taaffe Rickard P. Burke, M.B., F.S.C.S. Eng. Exam., St. Bartholomew's Hospital. This was the first examination for the above degree in the University of London.

FOREIGN CORRESPONDENCE.

AMERICA.

NEAR THE RAPIDAN, February 14.

SINCE my last communication (of date December 17) was despatched to you, until a few days ago, the opposing armies have been peaceably encamped, with the Rapidan river as a boundary line to separate them. December was spent by the troops in fixing up their winter quarters,—January in enjoying and, at the same time, improving them. Comfortable quarters they are too. Our men were experienced campaigners when they settled here, for this, to many of them, is the third winter they have spent in the field. They know from personal experience what are the essentials of health and comfort in winter quarters. They know not only what had best be done, but also the best manner of doing it; hence no time was lost in useless experiment—there was no construction, destruction, and reconstruction, but everything steadily progressed towards perfection, from the time the first tree was felled until now that a vast and substantial wooden city has grown into being, with its Hospitals and churches—even its ball-rooms and concert halls. Every one takes a pride in the comfort and appearance of his quarters—in fact, a rivalry seems to exist among the men on this subject, and, in consequence, improvements are constantly being made. Passing from men to officers, we find Surgeons planning, erecting, embellishing with an energy, born, no doubt, primarily of a desire to render their sick as comfortable as they possibly can, but I have as little doubt that this same rivalry contributes in no slight degree to the perfection of camp police and the—even elegance of their Hospital arrangements.

The men's quarters are arranged in streets, which run at right angles to those of the officers. The streets are broad and clean, with, on either side, a pavement five or six feet broad, composed of split logs overlying the deep trench which drains the site on which the huts are built. Young pine trees are planted at regular distances along the side of the pavement, and these give quite a picturesque appearance to the quarters. Planked pathways, hedged in many instances at the sides by pine branches after the manner of boxwood in a garden, run everywhere through camp, so that the men, even in the most rainy weather, are preserved from contact with the Virginian mud. The huts are each built of a size to afford ample accommodation to four men. They are wind and weather proof, with a commodious fireplace and plank flooring. Behind these company streets are the quarters of the officers, and still further to the rear the regimental Hospital. It and the out-houses connected with it are surrounded by an evergreen fence, rendered irregular in front by the arched gateway which gives one entrance to the grounds. The Hospital is the ordinary army Hospital tent, capable of containing comfortably six or eight patients. It has a fireplace built of stone and wood attached to one end, in which some huge logs are cheerily burning, and diffusing around an agreeable warmth. The flooring, raised from the ground ten or twelve inches by means of logs, is formed of lumber, cut perhaps from the trees which but a short time ago hibernated on the very site now occupied by the Hospital. A dilapidated saw-mill in the neighbourhood was put into working condition by the Quartermaster's Department, who now "run the concern," and from it the Medical officers, after the usual amount of delay and red tapeism, obtained sufficient to floor and build bedsteads in their Hospitals. From the tent narrow plank pathways lead to the various outhouses in the enclosure, one of which is the kitchen; another forms the dispensary and private quarters of the Hospital steward, a third is the sink or privy, furnished with easy seats, that the exertion of going to stool may be rendered as little fatiguing as possible. These regimental Hospitals have all a well-furnished larder; poultry, farina, Boston crackers, potatoes, onions, carrots, turnips, beets, etc. Fresh oysters are furnished daily by a purveyor at the nearest railway station. Wines, lemonades, preserved fruits, etc., can be obtained from the United States Sanitary Commission. In fact, never before have field Hospitals been brought to such a state of perfection as they have now attained.

In addition to these regimental Hospitals, division Hospitals have been organised in the vicinity of camp. When the former become crowded, a few of the patients are withdrawn for treatment to the latter. Many complaints have of late appeared in the daily papers concerning the accommodation

presented by field Hospitals, and the negligence of nurses and attendants connected with them. Those who made these complaints could certainly have known but little of the matters on which they wrote. I know from personal observation what these division Hospitals are—what the food, and what the attention and treatment received by their inmates; and I can readily assert that it would be difficult to find more comfortable, and at the same time better—hygienically considered—quarters for sick men than are to be seen in the division Hospitals now existing north of the Rapidan. Men vastly prefer—at least, many of them—being nurses to carrying and using a musket, and since their position in Hospital depends solely on the care and attention they pay to the sick—the sick are cared for.

The division Hospitals of the Second Army Corps, situated in the neighbourhood of Brandy Station, from the elegance of the style in which they are got up, resemble far more pavilions built for some rural *fête* than the cheerless notions one might preconceive of a field Hospital raised upon debatable ground. All the tents are floored, and furnished with fireplaces. Requisitions were sent in for stoves, but they were disapproved. In front of the tents are promenades, garden plots, evergreen bowers, tasteful fancies executed in moss. One can scarcely realise that this ground in December was a thick-set forest, yet so it was. This Hospital can accommodate from 250 to 300 patients. To each of its three divisions are attached a well-furnished sanitary store-room, a commodious kitchen, dispensary, and sinks, and to the whole is added a post-mortem room, where the bodies of fatal cases are embalmed by the Medical officers, in order to preserve them, if required, for transmission to friends in the north. At some little distance from the main structure is a pest-house for the small-pox cases that may occur in the corps. The establishment is altogether a complete affair, and certainly sufficient praise can hardly be bestowed upon those connected with it for the energy and taste they have evinced in its construction. They were rather chagrined, however, when, on January 29, an order was received from the Secretary of War, through the Surgeon-General's office, requiring the sick of the army to be sent to Washington for treatment in the Hospitals there. They would have much rather retained their sick now that they had secured, by their own industry, accommodations of a character so complete; but there was no help for it—the order had to be obeyed. The sick left their country quarters one rainy morning, two hours before daybreak, and after a tedious and exhausting journey reached Washington in the evening. It was at first considered that an advance was in contemplation; then it was supposed that the sick had been disposed of as a precautionary measure, lest, tempted by the favourable weather and state of the roads, the enemy should be induced to beat up our quarters. Some Surgeons looked to the state of the Washington Hospitals for an explanation. At that time there were, in and around that city, twelve thousand beds, of which seven thousand were untenanted.

The rate of sickness during the last two months has been, as it usually has been in this army, remarkably small, varying from two and a-half to five per cent. These have consisted of fever, bronchitis, and scurvy manifested through the medium of camp diarrhoea, chronic rheumatism, and debility. A few cases of small-pox have occurred, but none of them have originated in the army. All the men so affected have lately come from Hospital in Alexandria or Washington, where, I believe, the disease is rife. The measures adopted in the army with reference to the isolation of these cases—their aggregation at one point, the pest-house mentioned above—have, as yet, been successful in preventing any diffusion of the variolous poison.

The following figures may give you an idea of the rate of sickness and mortality prevailing in this army during the last two months. The camps from which these ratios have been deducted contained an average strength present during the month of December of 12,000 men; during January, 11,900.

	December, 1863.	January, 1864.
Daily rate of sickness per 1000 men present	36.77	48.02
Death rate per 1000 men present during the month	2.48	2.44
During the month of January, 1864,—		
The percentage of fever cases among sick was	10.74	
The percentage of deaths among the fever cases	2.28	
The percentage of diarrhoea among sick	27.95	
The percentage of deaths in diarrhoea cases	2.55	

On February 6, we made a demonstration on the Rapidan; we crossed a small portion of our force at Morton's Ford, and had a smart skirmish with the enemy. 200 were wounded, and, what is remarkable, only ten men out of the whole number struck were killed upon the field. No bridge was laid across the stream, and as the water was deep and the banks precipitous, it was found impossible for the ambulances to reach the field in order to bear off the wounded. This being the case, the labour devolved entirely upon the stretcher carriers, who, although they had the darkness of a moonless and cloudy night to impede them in their search, did not leave a single wounded man on the south bank of the river. No operations were performed on the field on account of the depressed state in which the wounded were found. Chilled, and still in their wet clothes, it was considered the most advisable course to hurry them off to the rear, to the Hospitals of the Second Army Corps, where they now are, comfortable as they could wish to be. Dr. McParlen, the lately-appointed Medical Director of the Army, inspected their condition shortly after their arrival there, and so highly satisfied was he that he considered it would be unjust to the wounded to order—as has hitherto usually been the case after a fight—their removal to Washington Hospitals. Dr. Howard also paid the wounded a visit, on the look out for chest wounds suitable for his hermetically sealing mode of treatment, but I believe his search was unsuccessful.

The operations rendered necessary and performed after this affair at Morton's Ford were five amputations of the thigh in the middle third, one of the leg immediately above the ankle, two of the arm, and one of the shoulder-joint. Two cases of excision occurred; one of the elbow, the other of the shoulder-joint, both of which are as yet promising well (six days after operation).

Seven deaths from wounds have occurred; but of the operative cases, one only has succumbed—a thigh amputation.

Recruits are joining us daily from all parts of the North,—but such recruits! The necessity for a thorough scrutiny into all the branches of the recruiting service is severely felt by the Medical officers with the army. We in the field are aware that, according to the army regulations, every man before being accepted as a soldier has to undergo an examination, to settle whether or not he is physically qualified to bear arms and to use them; but, when we look at the men forwarded to us to fill up our ranks, we hope sincerely for the credit of the Profession that in many instances no such examination has taken place. Here are a few samples from a batch sent to one regiment lately:—

Cataract affecting right eye.

Strumous corneitis, with so much opacity that the man sees daylight only.

Syphilis—deep ulceration of fauces—arms densely crowded with rupia.

An imbecile—an epileptic—a well-marked case of phthisis—rupture.

A boy, certainly not over fourteen years of age, seduced from school by the recruiting pimps.

An old veteran, who saved his leg after the battle of Antietam at the hazard of his life.

Ask these men if they were examined by a Surgeon before enlistment, and they will tell you that they do not know anything about the matter. Most of them, like the veteran instanced above, were intoxicated at the time. He came from his country village to New York city, in order to make some endeavours towards obtaining a pension—met with some sympathising friends who, no doubt, would aid him, who, however, in the first place, persuaded him to take something. This he did, and on recovering the use of his senses, found himself once more a soldier. Proceedings such as these deserve to be investigated. In the British service Medical officers grumble because they are called upon to pay the expenses of a rejected recruit. Well would it be for America were such a law in force at present.

The regiment from which the above examples are taken obtained 500 recruits; from these (I must, at the same time, state that this is the worst case of the kind I have met), ninety, on reaching Virginia, were pronounced unfit for service. Eighteen per cent. useless; indeed, much worse than useless! Eighteen per cent. of the bounties paid by the U.S. Government thrown away in the purchase of incurables! Eighteen per cent. of the money paid by a State, that volunteering may be promoted to an extent that shall preserve its people from the draft, swallowed up by recruiting agents without tending in the slightest degree to effect the

object in view! This should not be. The regulations should be to the very letter adhered to, and deviations from them punished with marked severity. The hanging of a few of the first delinquents exposed would render the game too dangerous to be so extensively played as it now is.

These recruits, on reaching the field, are immediately pruned of all their useless members. Very few men are discharged for disability now; they are turned over to the invalid corps, to serve out their term of service. This invalid corps, organised in 1863, consists of two battalions. The first is composed of men unfit for field service, but capable of performing garrison duty; the second, of those unfit even for the light duties required of the first, but capable of acting as nurses, orderlies, etc. This corps is recruited, first, by men from the field disabled from active service by wounds received in action, or disease contracted in the line of duty; second, by men from the general Hospitals and convalescent camp; third, from those honourably discharged on account of disability, but who wish to re-enter the service.

Some time ago it was decreed that those Medical officers of the United States army, and of the Volunteer Corps of Surgeons, who had been on active service in the field for two years, might, if they wished it, be withdrawn from the army to be placed in charge of the military Hospitals now so common in all the great cities of the States, their place in the field being filled up by those whom they relieved from Hospital duty. This is but fair to those Surgeons who have been so long campaigning. They are but few who, after two years of the excitement of active military life, do not long in secret for a short period of repose in the unruffled quiet of civil life. Dr. Letterman, who filled so ably the position of Medical Director of the Army of the Potomac during all its many vicissitudes of fortune, was among the first to take advantage of the relief proffered. His position in the service has been well supplied by one to whom war is not new. His successor, Dr. McParlen, was formerly Medical Director of Pope's Army of Virginia. There are many Surgeons who will embrace this opportunity of leaving the field, not because they are tired of it, but because the pay—strange as it may appear—is greater when on Hospital duty. They have, perhaps, a family to support, and, were they to neglect this opportunity of improving their income, they would consider themselves inattentive to the duties they owe to those dependent upon them. To officers on active service Government furnishes fuel and quarters—fuel: the wild woods of Virginia; quarters: a share (one-half or one-third, as the ease may be) of a small tent, which, peradventure, may leak deucedly. On the other hand, to officers located in cities, commutation is paid for fuel and quarters, and this commutation amounts to as much as forty to sixty dollars a month. This, by officers with the army, is jocularly styled the premium paid by Government to induce men to stifle warlike ardour, and remain at home in peace. Mr. Grimes, of Iowa, in Congress, some days ago, made an attempt to reduce the pay of officers not on duty with the army, but he failed in his object. His bill did not refer to Medical officers in particular, but they, of course, were included in it.

Of grievances in the Army Medical Department here the junior members have but little to complain; but there is one in particular that is keenly felt by the seniors—those occupying high positions in the army. It is this,—rank and pay do not increase with increased responsibilities. For instance—the Surgeon who has under his charge 150 men, the remains of what was once his regiment, has the rank and pay of a major of cavalry; the Surgeon-in-Chief of a division consisting of twelve or fourteen regiments is major also; the Medical Director of a corps, having under his supervision thirty or forty regiments, has the same rank and pay; lastly, the Medical Director of the Army of the Potomac is—only a major. This, surely, on the part of the Government is but a piece of forgetfulness, requiring only to be brought into notice to be remedied. Matters do not exist thus in the other departments of the service. A corps quartermaster ranks as lieutenant-colonel; the quartermaster at head-quarters of the army, holding a position corresponding to that of Medical Director in the Medical department, has the rank and pay of Brigadier-General. Although the nation is, and has been since the commencement of the war, so occupied with subjects of much more vital interest than the proper recognition of the position held by many of its Medical officers, still it is to be hoped that ere long Congress will take the matter in hand and place the Medical on a footing similar to that held by the other departments.

Concerning the Hammond court-martial, nothing has, I believe, as yet transpired. Some time ago the matter was much talked over by the Medical men in the army, the opinion having the majority of advocates appearing to be that the Surgeon-General was the victim of a clique inimical to him, and that the inquiry would result in nothing to his disadvantage.

Being in winter quarters and having no great press of official business on hand, the Medical Department is occupying a few of its members in examining those officers who, during the preceding campaigns, have shown any Professional incapacity. These, however, it gives one pleasure to remark, form but a very small percentage of the Medical force in the field.

In conclusion, I may remark that a new form of stretcher has been invented and brought under the notice of army Surgeons by Dr. Watson, 6th Michigan Volunteers. Favourable reports concerning it have been given its inventor by all who have seen it; and in consequence he intends to endeavour to obtain its adoption by the Government in place of the uncomfortable poles and canvas now in use. His is a very complete affair, being not only a stretcher, but a bed or a double inclined plane, as occasion may require. It is durable, and constructed in pieces, which are all of a size; so that should one piece give way, it may be replaced, and the machine, as a whole, be preserved indefinitely.

GENERAL CORRESPONDENCE.

ARMY MEDICAL DEPARTMENT.

[To the Editor of the Medical Times and Gazette.]

SIR,—The deplorable condition to which the Army Medical Department is now reduced is well exemplified by the inability of the Director-General to obtain candidates legally qualified to fill existing vacancies in this branch of the public service.

This difficulty has been experienced with increasing urgency during the last four years, partly in consequence of the provisions of the Royal Warrant of 1858 having been frequently set aside, and partly because even the warrant in its integrity, although a great boon to Army Medical officers, did not contain sufficient advantages to induce men of high professional attainments, whose prospects of success in private practice have been annually increasing, to enter a service where promotion to the higher grades was slow, and where the senior members were very inadequately remunerated.

I do not propose in this letter to enter on and discuss the many causes which, collectively, now deter Medical men from entering the Department. I will confine myself on the present occasion to two of the most important, which, if speedily removed, would tend to give popularity to the service, induce young Medical men of high professional acquirements to compete for existing vacancies, and remove much of the discontent now so unfortunately prevalent among Army Surgeons; of whom nineteen out of every twenty cannot possibly obtain Departmental promotion. I allude to increase of pay for Surgeons, and earlier retirement, with increased full and half-pay, for Surgeons-Major.

I may here state that I have recently visited many of the Medical Schools in London, discussed the subject with many of the senior Medical students and Medical men now unemployed, and undecided on their future professional career, and have almost invariably found their chief objections to entering the Army Medical Department to be slow promotion, long service before retirement, and inadequate full and half-pay for the higher grades.

1. Increase of pay for Surgeons and Surgeons-Major. The rates of pay for Assistant-Surgeons are generally admitted to be equitable, but on promotion to the rank of Surgeon he receives but 15s. per diem until he completes fifteen years' service, when he receives 18s. This is continued until he attains the rank of Surgeon-Major on completing twenty years' service, when he receives 22s. per diem, and no further increase until he completes twenty-five years' full pay service, when he obtains 25s., or can claim retirement on half pay at the rate of 18s. 6d. per diem, of which almost every Medical officer avails himself.

It will be evident that these rates of full and half pay are disproportionate to the periods of service, especially when taken in combination with the broken-down health which long tropical and semi-tropical service almost invariably produces, and which generally renders the Army Medical officer

unable to add to his income on retirement by the practice of his Profession.

2. Earlier retirement with increased half pay. Constituted as the Army Medical Department is at present, and taking the average number of Assistant-Surgeons annually promoted as twenty, Assistant-Surgeons now entering the service cannot obtain promotion under from twenty to twenty-five years' service, as the great majority of Inspectors and Deputy Inspectors-General and Surgeons are comparatively young men, consequently for the future fewer vacancies than heretofore, in a given period, will occur in the senior ranks.

With such prospects before them—neither overdrawn nor coloured in the slightest degree—is it surprising that junior Medical men prefer the chances of success in private practice either at home, in the colonies, or in the mercantile navy, and almost contemptuously decline the overtures made to them to enter the Army Medical Department at present?

The interests of the public service imperatively demand that a remedy for this unsatisfactory state of our Department should be promptly applied, and I believe the most effectual means of doing so would be to enable Medical officers of twenty or twenty-one years' service who have no prospect of promotion, nor any adequate inducement to remain on full pay, to retire from the Department.

This can readily be effected by allowing Surgeons of twenty years' service and upwards the option of retiring on 20s. per diem, and a shilling per diem additional for each year's subsequent service.

This would be a great boon to many Medical officers of weak health, and there are many such at present in the service, who would at once retire on half-pay; it would give promotion to Assistant-Surgeons to such an extent as to keep the average service of this grade to about ten years, and so remove the most serious objection which at present exists against the department.

The subjoined rates of half and full-pay are submitted with confidence that, if adopted, they will effect the objects in view:—

Full Pay.

* And 1s. per diem for every additional year's service.

If you will favour me with space for this letter, I propose, in subsequent communications, to bring forward, fairly and temperately, the minor grievances under which Army Medical officers labour, as I feel assured that His Royal Highness the Commander-in-Chief, and the Director-General of our department, would, if they were brought before them in a proper spirit, take immediate steps for their removal or mitigation.

I am, &c. AN ARMY SURGEON.

“INSTRUMENT FOR DILATING THE CERVIX UTERI.”

LETTER FROM MR. ROBERT ELLIS.

[To the Editor of the Medical Times and Gazette.]

SIR,—My attention has been drawn to the communication of Dr. Priestley in your number for last week. It was with no little surprise that I recognised in the engraving my own instrument, made for me two years ago by Mr. Coxeter. I enclose you a tracing of my dilator, by which you will perceive that the instrument is identical in every respect, in form and in mechanical construction, with that described and

delineated by Dr. Priestley. It is inexplicable to me how Mr. Coxeter could have suffered Dr. Priestley to fall into such a mistake, as he must have been well aware that I originated the instrument, together with many other modifications of obstetric instruments which Mr. Coxeter has very skilfully constructed for me.

At the close of his communication Dr. Priestley makes an indistinct acknowledgment of some priority of design, but alleges that the instrument then made was devoid of his modifications. This is altogether incorrect; the only respect in which Dr. Priestley's instrument differs from my original model consists in the trifling circumstance that mine is open to its point, and his is not—a matter of very insignificant importance.

I was led to the invention of this dilator from a consideration of the facility with which I found I could pass the uterine sound even in cases of great contraction of the cervical canal. It then occurred to me that if I could design a sound which could be made to dilate, I might contrive an instrument far better adapted to effect this purpose for the canal of the cervix than any yet introduced.

After some little trouble, and with the assistance of Mr. Coxeter's mechanical skill, I contrived the excellent dilator in question, and I have had it in constant employ since that time. I have made large use of my instrument, and had purposed publishing some account of it, with cases in which it was successful, but a great pressure of other duties has hitherto delayed me. It may confirm Dr. Priestley in his opinion of the value of what he concluded to be a new instrument, to be assured that it has already done good service in practice before the idea of its design occurred to him. I am, &c.

Sloane-street, March 8.

ROBERT ELLIS.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 8.

Mr. PARTRIDGE, President.

MR. E. R. BICKERSTETH read a paper on

A NEW OPERATION FOR OBTAINING UNION OF AN UNUNITED FRACTURE, WITH REMARKS ON ITS APPLICATION IN CERTAIN CASES OF RECENT FRACTURE.

In bringing this subject before the attention of the Society, the author proposed to mention some cases that had occurred in his practice to show the successive steps by which he arrived at the process in question. He had frequently tried, in vain, friction, acupuncture, and subcutaneous division; and though resection of the ends of the bone had been successful in some instances, it was a proceeding involving a considerable risk to life. Dieffenbach's method had proved to be more successful; but this operation, though conducive to the formation of new bone, in no way provided for what was of paramount importance, viz., absolute immobility of the opposing fragments. The large external wound and injury done to the soft parts in introducing the ivory pegs were also objections to this operation. Recognising the happy influence of Dieffenbach's plan of exciting ossific deposit, and at the same time feeling the importance of keeping the ends of the bone in a condition of absolute immobility, the author was induced to try a modification of the operation; and in the case of a man admitted under his care, at the Liverpool Royal Infirmary, with an ununited fracture of the radius, he drilled a hole through the ends of both fragments, and passing a stout wire through it, secured the bone in perfect apposition. Union took place in seven or eight weeks, but on endeavouring to remove the wire so much traction was necessary that it caused the fracture again to be ununited. The difficulty of removing the wire induced the author to think of some other plan not open to this objection; and in the case of a man with an ununited fracture of the thigh, by means of a common Archimedean drill, he bored two holes in such directions that each passed obliquely through both ends of the fractured bone, and into each introduced a steel rod with a screw at the end. To do this it was necessary to make an incision three inches in length. Much constitutional disturbance followed, the wound suppurating freely. In ten weeks the splints were removed, but no union had taken place. The limb was then confined in gum and chalk

bandages. Symptoms of pleuro-pneumonia came on, and he gradually sank. A post-mortem examination showed tubercular deposit in the ends of the bone and other parts of the body. There was no attempt at repair at the seat of fracture, except where the drills had pierced the bone, and here there was a deposit of new bone. This proceeding showed that it was quite feasible to fix the bone in the manner described without exciting too much inflammatory action; and also that the steel rods caused the formation of new bone. The next case was a fracture of the lower maxilla, where the bones had united in such a position as to render the patient a most unsightly object. As the incision that would be necessary in this instance for the purpose both of putting the bone into proper position and removing the deformity of the soft parts, would not allow the use of external splints or supports, and as it was found impracticable to effect this object by fixing the teeth by an appliance within the mouth, it was absolutely necessary that some means should be devised by which the divided portions of the jaw could be securely fixed; and it occurred to the author that pegs or nails would answer the purpose, especially as he had already observed their presence caused so little inconvenience. Accordingly, at the operation, the plan just mentioned was carried out, and the apposition of the fractured portions was secured by means of two round-headed nails. They most effectually answered their purpose, and no external splint or bandage was required. The case did well, no undue action being set up. On the twenty-second day after the operation, one of the nails came away. The patient left the infirmary perfectly well, the jaw being firmly united in its proper position, and the deformity of the soft parts removed. One of the nails still remained in; and the last account states that its presence caused no inconvenience. The third case recorded was one that presented many points in common with the one just narrated. No external incision was made, and ordinary drill-heads were substituted for nails. The result was everything that the author could have wished. These cases show how readily and with what good effect fractured bones may be fastened together. Surgeons have ever recognised the use of sutures with regard to the soft parts. Why should we not, in cases of difficulty arising from an inability to keep the surfaces in proper apposition, adopt the same plan with the bones? Might not this process be applicable in some cases where division of the tendo-Achillis is required, or where such an operation as sawing off the ends of the bone is indicated? From a consideration of the cases narrated, Mr. Bickersteth proposed to treat an ununited fracture by passing one or more drills through the broken ends of the bone in such a manner as to secure their perfect immobility, and without making any external wound beyond that caused by the entrance of the drill. The limb should then be secured by properly-adjusted splints, and kept at perfect rest. After two or three weeks the drills may be removed, and water-dressing applied to the punctures. For several weeks after, it would, of course, be desirable to continue the use of the splints. In conclusion, the author begged to place upon record three cases of ununited fracture recently treated by his friend, Mr. Fletcher, on the plan that he (Mr. Bickersteth) had suggested, and in each the result had been most satisfactory.

Mr. FERGUSON said that he scarcely remembered to have heard a paper of greater Surgical interest than the one just read. It had the merit of bringing out much that was going on in the modern practice of Surgery, and he thought the paper would lead to greater improvements in practice. Here was further proof, he continued, of the advantage of wire and metal in instances in which in former times we were loth to use such materials. He had had the impression that ivory pegs, being softer, would be less likely to do harm, but now the author had shown that metal might be safely used. And it had been shown, too, that the commoner metals were as useful as the rarer; that iron wire was as useful as silver wire. In the same way, cauterisation by an iron instrument was just as useful as by a gold or silver one. Dieffenbach had used the pegs of ivory to create irritation only, but the author had gone further, and fastened the bones together by pegs of iron. The author had shown that much might be done in desperate cases of ununited fracture. From hearing the cases related by the author, he should consider that the plan was safe, and that it ought to command attention. Mr. Fergusson said that he once saw Mr. Abernethy attempt to pass a seton between the ends of an ununited fracture. Failing to do so, he left a probe sticking in the wound between the ends of the bones. The result was good.

Mr. HOLTHOUSE thought the interest of the author's plan

was not only in fastening the bones together, but in doing it subcutaneously. This was a great merit, and no doubt would lead to the adoption of the plan and to beneficial results in practice. Mr. Holthouse then gave the particulars of a case of ununited fracture of the humerus under his care at the Westminster Hospital, in which he had adopted the novel proceeding of inserting the sharpened end of the lower fragment into the cancellous structure of the upper, thus imitating an impacted fracture. This plan did not succeed. The case was, however, a complicated one, there being anehylosis of the elbow.

Mr. HOLMES COOTE rose to correct what he believed was a very general and erroneous impression as to the views of Dieffenbach. This Surgeon used to cut down to the ends of the bones and pass in ivory pegs with the hope of creating irritation; but, if he could do it easily, he used also to fasten the ends of the bones together. Mr. Coote thought that three classes of cases ought to be distinguished—first, those in which there was union in good time; second, those in which union was simply retarded; and third, those in which union could not be obtained, as the ends of the bones were in a state of fatty degeneration. In the third no good results could be hoped for.

Mr. CURLING regarded the author's plan as ingenious as a happy application of the modern treatment with metallic substances, and as calculated to be of great service not only in ununited fractures, but also in compound and in complicated simple fractures, when it was difficult to keep the parts in position. He was struck with the remark in the paper that the author had met with numerous cases of ununited fracture. Though Mr. Curling had been long attached to a large Hospital, where a great many fractures were admitted, he had seen only a few cases of ununited fracture, and all of them had been brought to the Hospital in that condition, most of them being the result of accidents which had occurred at sea. The author being Surgeon to the principal Hospital in the chief seaport city in this country probably met with an unusual number of such cases. Mr. Curling had seen, however, many cases of delayed union, and mentioned two remarkable instances of the kind, one a double fracture of the thigh which happened at sea seven months before, and might have been considered an ununited fracture, but which got firm in a plaster of Paris case. He called attention to a constitutional indisposition to ossific union, independent of the general health, which was manifested in young people as well as in adults, and gave an instance in point of long-delayed union in a fracture of the tibia in a young girl.

Mr. BARWELL, while agreeing with what had fallen from Mr. Holmes Coote concerning the degenerated condition of bones, considered that such condition was the result, more frequently than the cause, of non-union. It was a law of animal nature that any organ losing its function should degenerate. Thus, when a bone lost its power of support, the surrounding muscular pressure and other conditions of its healthy life, it would surely degenerate; but until that degeneration had reached a high point it might still be restored. A remarkable case had occurred to him lately, which would also show that in certain instances the admirable plan proposed by Mr. Bickersteth would be unavailing—as in cases where the non-union was produced by a large quantity of soft parts intruding between the fractured ends. The case alluded to was as follows:—About eighteen months ago a man broke his arm about two inches and a-half above the elbow. He was admitted into the Charing-cross Hospital. The fracture united well, and the man was discharged cured. The same night, however, he got very drunk, and broke his arm again, but took no notice of the circumstance, continuing drunk for about a fortnight. Two months ago he again entered the Hospital with a broken arm. As Mr. Barwell had been for some time taking the duty of his colleague, Mr. Canton, this case came, about a fortnight ago, under his observation, and he determined to operate. The upper and longer fragment was on the outer side, its lower end overlapping the head of the radius. The inner end of the lower fragment was half-way up the inner side of the arm. The movement to and fro of this portion was very considerable; but there was always a wide interval between the two bones, which was occupied constantly by the anterior brachial muscle, sometimes also by part of the biceps, and in certain positions it seemed as though the artery and nerve also got between the fragments. The man having been placed under the influence of chloroform, Mr. Barwell made an incision two inches long over the outer fragment, and turning out its end, sawed out a

wedge-shaped piece, so as to leave an angular gap or notch in the end of the bone. The inner fragment lay so far away from the wound, and in such close proximity to the artery and nerve, that the greatest care was required in getting its end to protrude at the wound. This, however, was accomplished without any untoward accident, and the end was cut into a wedge shape, so as to fit with some degree of accuracy the interval in the upper fragment; traction was made upon the arm, and the two portions fitted together, and with the aid of a splint they retained perfect apposition. A singular condition of bone revealed itself during the operation—namely, that the periosteum on the upper fragment was loose, and could be slipped up off the bone as a man might turn up his shirt-sleeves. This tissue was carefully replaced, yet, on account of this condition of bone, he (Mr. Barwell) could not but look to the issue of the case with some anxiety. The man had had as yet (ten days afterwards) no bad symptom.

Mr. C. H. MOORE thought the plan suggested would be valuable in some cases, but that there would be some risk to life by tetanus and pyæmia.

Mr. HILTON said that, as a Surgeon to a large Hospital, he must add to the commendations of the other speaker, his opinion that the paper was one of great interest, and that the plan was likely to be very useful, when ordinary treatment had failed. He (Mr. Hilton) understood Mr. Holmes Coote to say that when there was fatty degeneration of the bone the ends never would or could unite; yet the author had related a case of cure by his plan, although at the operation the bone was so soft that a knife was passed through it.

The AUTHOR having returned thanks, the Society adjourned.

OBSTETRICAL SOCIETY OF LONDON.

THURSDAY, FEBRUARY 4.

Dr. GREENHALGH, V.P., in the Chair.

A paper by Mr. BAKER BROWN was read on

FIBROUS TUMOURS OF THE UTERUS TREATED BY SURGICAL MEANS. The author commenced by reminding the Society that on December 7, 1859, he had read a short paper on this subject, containing a case of fibrous tumour of the uterus treated successfully by surgical means. Also on March 6, 1861, he had read a second paper on the same subject, giving six cases, four of which were cured, one was relieved, and one died. The object of the present paper was to confirm the practice previously advocated, by fourteen more cases, and at the same time to show that in most cases a very modified surgical treatment was sufficient; for whereas Mr. Brown had hitherto divided his operation into two parts—viz., first, preliminary incision of the os and cervix; and, secondly, gouging or breaking up the tumour,—he now finds that the first step will always arrest the hæmorrhage and the development of the tumour. In some cases the tumour decreases, and when small it will entirely disappear, more especially if of recent origin; and even when gouging is required a much slighter operation is sufficient. Mr. Brown, therefore, now never uses "Harper's instrument," but only a pair of long-handled, blunt-pointed, curved scissors. The author entered minutely into the mode of operating, and laid great stress on carefully and thoroughly plugging the incisions and whole vagina with oiled lint after the operation, as on this point depended the chances of hæmorrhage, and exposure to air, and consequent hysteritis, and even peritonitis. Mr. Brown then read fourteen cases, occurring in the London Surgical Home, illustrative of his remarks. Of these fourteen, ten were cured of the hæmorrhage by the incision of the os and cervix uteri alone, and one was relieved; in two only was it necessary to perform the second operation, both resulting in cure of the tumour; in six cases the tumour had either entirely disappeared or materially decreased after incision alone. Of the three deaths, one had occurred from peritonitis, resulting from exposure to cold and the restlessness of the patient; one from organic disease, independent of the operation; and one from pyæmia. Out of between twenty and thirty cases occurring in his private practice, the author stated that he had had one death, in a patient whose case was complicated with hæmatocœle, and that in his public practice he had had as many more as were now given, with no more deaths. The following practical conclusions were drawn:—1. That the fact of the curability of these tumours is materially confirmed by these cases. 2.

That it is not necessary in many cases to do more than incise the os and cervix, thereby lessening the danger of the operation. 3. That the hæmorrhage is almost invariably arrested by the incision of the os and cervix. 4. That the cure of these fibrous or fibroid tumours by Surgical means, without the danger of enucleation, is now firmly established, as proved by Dr. M'Clintock, Dr. Routh, Dr. Dawson, of Newcastle-upon-Tyne, as well as by himself (Mr. Brown).

Dr. GERVIS wished to know from Mr. Brown whether the incisions he made in the sides of the cervix uteri were ever apt to reunite; whether, if they did, the hæmorrhage recurred; and whether, if they did not, the incised condition of the cervix, in a patient who subsequently became pregnant, in any way interfered with normal parturition.

Dr. ROUTH considered the paper as evidence of the advance of Medical science with respect to a disease many cases of which had been deemed incurable. He alluded to the process of enucleation recommended by Dr. Atlee, which he (Dr. Routh) regarded as too hazardous. It was known that many cases had ended fatally under the treatment, and he regretted they had not been published. Mr. Brown, however, had acted more nobly in publishing both his successful and unsuccessful cases. Dr. Routh considered that fibroid tumours required different treatment according to whether they were in or out of the cavity of the pelvis, whether the heart and lungs were pressed upon, or micturition impeded, or whether in either case excessive floodings occurred. In any case the tumour should not be meddled with unless vital functions were interfered with. Mr. Brown's operation could not be used in supra-pelvic cases, because of the uncertainty of position, and risk of wounding the peritoneum. In such cases he considered gastrotomy the best treatment, removing both ovaries also. In the pelvic fibroids, he agreed with the author that the tumours after bisection diminished, and he considered this an established point in practice. The opening of the cervix he believed not only checked the hæmorrhage, but enabled the tumour to be more easily got at; it was, under the restrictions laid down by Mr. Brown, quite safe.

Dr. GREENHALGH considered the question of fibroid or fibrous tumours one of great importance, especially where the hæmorrhage endangered the life of the patient. In the great majority of cases he had found the best results from the use of bichloride of mercury or bromide of potassium. Still there was a certain limited class of cases in which medicines were of little avail, and it was in such that the division of the cervix uteri was attended with benefit. He had seen a few cases, and in these, although the hæmorrhage was considerably lessened, yet the size of the uterus was not much reduced. In those cases where pressure on surrounding structures had produced injurious effects, he had seen good results from pushing up the tumour above the brim.

Mr. BROWN, in reply to Dr. Gervis, stated that care was taken to prevent the incisions in the os and cervix from uniting. The oiled lint, in the first instance, and the injections afterwards, generally prevented union; but if any bands of lymph were thrown out, he always broke them down with the finger. He had never seen a case in which the patient had been confined after the operation, but it was only reasonable to infer that parturition would be accelerated after these incisions; for in the case of a primiparous woman, where the os is torn, the subsequent labours are always exceedingly quick. As to the *rationale* of the operation, Mr. Brown had avoided the question, for fear of giving too wide a field for discussion. He thought the action was twofold. The tumours were of very low vitality, and the slightest interference with them stopped their growth. Thus, in the first place, the initiatory bloodvessels were cut through by incising the os and cervix; and, secondly, the tumour was grasped more firmly by the contraction of the uterus, which always takes place after the os is incised; and thus the tumour was confined, could not grow, and often died. He was obliged to Dr. Routh for alluding to the authenticity of his (Mr. Brown's) cases, as some doubt had on more than one occasion been thrown on the subject. He could only repeat that his practice at the London Surgical Home was open to every member of the Profession. He had only given cases where severe hæmorrhage was present as the most urgent symptom, and in almost all the cases which came to him the patients had been previously treated without success.

Mr. T. BRYANT related some

CASES OF OVARIOTOMY, WITH REMARKS.

After a few preliminary remarks, the author gave the details

of ten cases of ovariectomy, six of which were successful. The following are their brief notes:—

Case 1.—Multilocular Ovarian Tumour—Ovariectomy—Death on Fourth Day.—M. C., aged 30, married. Tumour discovered two years; never been tapped. Ovariectomy on December 5, 1860; small incision; pedicle, which was broad, fastened by double ligature; wound brought together with pins. Opium freely given. Third day, vomiting with tympanitis; and death seventy-eight hours after the operation. Post-mortem: Peritonitis.

Case 2.—Unilocular Ovarian Tumour—Ovariectomy—Recovery.—E. D., aged 32, married. Disease existed two years and a-half; had been tapped once. Ovariectomy on October 15, 1862; small incision; adhesions in front; pedicle secured with clamp; wound brought together with silver sutures. Uninterrupted recovery in one month. This patient has since been confined of a living female child.

Case 3.—Unilocular Ovarian Tumour—Ovariectomy—Recovery.—A. S., aged 25, single. Disease four years; tapped twice. Ovariectomy on March 20, 1863; no adhesions; small incision; pedicle secured with clamp. Acute bronchitis. Perfect convalescence from the operation in one month. The patient subsequently died from pneumonia two months after the operation.

Case 4.—Double Ovarian Disease—Ovariectomy—Death.—E. C., aged 32, married. Disease two years; tapped once. Ovariectomy on April 15, 1863; extensive adhesions; broad pedicle secured with three whipcord ligatures on left side, on right side with two. Collapse and death in twenty-two hours. Post-mortem: Peritonitis.

Case 5.—Semi-Solid Ovarian Tumour—Ovariectomy—Death.—J. P., aged 44, married. Disease many years; tapped once. Ovariectomy on July 25, 1863; small incision; broad pedicle secured with three whipcord ligatures. Death in thirty-seven hours from peritonitis.

Case 6.—Multilocular Ovarian Tumour—Ovariectomy—Recovery.—L. W., aged 17, single. Disease existed one year; never been tapped. Ovariectomy on September 8, 1863; small incision; no adhesions; broad pedicle secured by three whipcord ligatures; silver sutures to wound. Rapid convalescence.

Case 7.—Multilocular Ovarian Tumour—Ovariectomy—Death.—H. D., aged 24, married. Disease three years; tapped three times. Ovariectomy on October 8, 1863; small incision; extensive adhesions; broad pedicle requiring seven whipcord ligatures. Collapse and death in twenty-three hours. Post-mortem: Slight hæmorrhage into abdominal cavity.

Case 8.—Multilocular Ovarian Tumour—Ovariectomy—Recovery.—H. B., aged 34, married. Disease one year; tapped once. Ovariectomy on October 8, 1863; large incision; no adhesions; pedicle secured with three ligatures; silver sutures to wound. Uninterrupted convalescence.

Case 9.—Multilocular Ovarian—Tumour—Ovariectomy—Recovery.—A. J., aged 37, single. Disease one year; never been tapped. Ovariectomy on October 16, 1863; large incision; no adhesions; clamp to pedicle; silver sutures. Rapid recovery.

Case 10.—Multilocular Ovarian Disease—Ovariectomy—Recovery.—S. C., aged 50, married. Disease eighteen months; tapped twice. Ovariectomy on December 2, 1863; large incision; no adhesions; clamp to pedicle; silver sutures to wound. Rapid convalescence.

The author then passed on to make some general remarks on the operation. He confessed that in three of the cases which had been noticed the chances of securing a successful result from the operation were looked upon as being very slight, and that he should now in similar cases refuse to operate. He dwelt upon the propriety of being very careful in selecting cases, and expressed his belief that the Surgeon had better err on the side of caution than on that of rashness. He considered that the best patient for the operation was the one who was in the best health, and that there was no special general preliminary treatment demanded which was not applicable to other operations. He enforced the necessity of isolating the patient, and of guarding her well from the contact of all who were not specially required for the treatment of her case. It was to the careful observance of this rule that he attributed his success. During the operation he preferred to place his patient in the half-sitting posture, as such was the most convenient for many reasons. He was indifferent to the length of the incision which he made, but had commenced always with the small incision, and increased it when any difficulty in the extraction of the tumour was experienced. He condemned the practice of exploring the abdominal cavity

with the hand, in the search for adhesions, and advocated the practice of breaking them down as they manifested their presence during the operation, stating that by following this rule there would be but little necessity in the majority of cases of fingering the peritoneum. As to the treatment of the pedicle, he used the clamp or ligature, according to circumstance. When it was long and narrow, he had employed the clamp, as convalescence appeared more rapid after its application than when the ligature was used; when it was broad and short, he had used the ligature, as he regarded traction upon the pelvic viscera as most injurious. He spoke in favourable terms of the practice which Dr. Tyler Smith had introduced of dropping the pedicle with its shortened ligature into the pelvis; and expressed his belief that such a practice might be more general. The practice of sponging out the pelvis he regarded as dangerous, and recommended its adoption only when an excess of blood or of semi-solid ovarian material had taken place. In the treatment of the wound he had always employed silver sutures, as such were more convenient in their application. He had also included the peritoneum and abdominal muscles in his sutures. In his after-treatment he had been guided by the ordinary Surgical principles. He had kept his patient's room warm but airy. He had given but little opium, and strongly advocated its employment as a suppository. For the first two or three days he had given only liquid nourishment, such as good beef-tea and arrowroot; but after that he had given meat and wine with average caution. He had no special treatment to recommend.

Mr. SPENCER WELLS said that the proposition with which the author commenced his very valuable paper—to the effect that ovariectomy could be performed in large Hospitals with as good results as in the small institutions which more closely resembled private houses—was refuted by the details of his own cases. In every one of these ten cases the patients had been placed in a separate room; a special nurse had been provided for them; there was no carrying to and from the operating room, nor indiscriminate admission of visitors and students;—but all those precautions had been taken which placed the women nearly in the same circumstances as if they had been in a small Hospital or a private house. Ovariectomy had been almost uniformly fatal in the large Hospitals until it had been shown, by the results of his (Mr. Wells') own cases, and those obtained by others in small institutions or in private practice, that success could only be obtained by that repose, isolation, careful nursing, and those sanitary conditions which had not been obtained in the large Hospitals. Nobody ever had asserted that the operation could not succeed in large Hospitals; but he did claim some credit for himself and for others who had shown why ovariectomy succeeded so much better in small than in large Hospitals, because he felt sure that the generous rivalry which had sprung up would not only lead to the general adoption in large Hospitals of those precautions which protected patients about to undergo ovariectomy from injurious influences, but that the same precautions would be taken before all other serious operations, and would remove many preventable causes of mortality. No one could seriously maintain that, if all the patients who had undergone amputation in Guy's Hospital had been as well cared for as the ten women upon whom Mr. Bryant had performed ovariectomy, the mortality would have been nearly as large as he himself had shown it to be in the valuable reports which he had brought before the Medico-Chirurgical Society. He (Mr. Wells) felt assured that, sooner or later, the lessons which had been taught by the ovariectomists would lead to the general adoption in the large Hospitals of such precautions as would greatly diminish the mortality after lithotomy, amputations, herniotomy, and all other important operations. Mr. Bryant's cases also resembled those of the Surgeons of small Hospitals, in the fact that he was the only operator. Did any one believe that if the ten cases had been divided among five of the Surgeons of Guy's, as ten amputations or ten lithotomy cases would have been, the result would have been as good? Ovariectomy was an operation which, above all others, demanded an experienced operator. Mr. Bryant's later cases were more successful than his earlier cases; and he had also learned by experience when to operate and when to reject cases as unfit for operation. If large Hospitals wished to have as good results as small ones, they must also adopt a system which secures a large experience to one operator. Mr. Bryant's remarks upon the rejection of all unfavourable cases must be received with some limitation. Every Surgeon would be anxious, for the sake of Surgery in general, for the credit of a particular operation, and for his own reputation, only to

operate in favourable cases; but common humanity often obliged him to make the attempt to save life, when a patient must soon die if left alone, even although the prospect of success was very small. When a poor woman whose best prospect is a few weeks or months of a life of hopeless suffering calls upon a Surgeon for aid, it might be his duty, in a case not absolutely desperate, even although her prospect of recovery was but as one in ten, to risk his reputation in the hope of saving her life. Many matters of detail, suggested by the author's cases, called for remark; but he (Mr. Wells) would only allude to one—namely, the practice of sponging blood or ovarian fluid from the peritoneal cavity. In many cases no sponging was necessary, because a cyst was removed without any of its contents, or any blood, getting into the abdomen or pelvis. But when there was either blood or fluid in the cavity—and especially when the curious products resulting from a mixture of blood with serum or mucoid fluid were present—his experience had taught him that they should be carefully removed at the operation, or afterwards if there was good reason to believe that they were doing harm. He had done this with excellent results in three cases, making a puncture by the vagina. Dr. Peaslee had even gone so far as to practise daily washing out of the peritoneum. He (Mr. Wells) would not express any opinion as to this extreme measure; but he thought the comparison of the author between these cases and those in which blood was effused into an unopened joint, or into any closed serous sac, was not a fair one; inasmuch as the opening of the cavity, the admission of air, and the mixture of ovarian or ascitic fluid with blood, almost destroyed all analogy between cases so essentially different. The rule should be so to operate as to keep the peritoneal cavity, if possible, free from any blood or fluid whatever; but, when this could not be effected, any extraneous fluid should be removed with scrupulous care.

Mr. BAKER BROWN agreed with the last speaker that the arrangements had been precisely the same as those practised in a small special Hospital, but he would strongly urge Mr. Bryant not to exclude the pupils. In the London Surgical Home, visitors, sometimes to the number of fifty or sixty, witnessed his operations, and he had seen no ill effect follow, his statistics of ovariectomy in that institution being thirty-six operations and thirteen deaths. But after the operation the patient must be separated from the others, to give her a fair chance of recovery. With reference to sponging out the peritoneum, Mr. Brown laid down this rule: if there were blood or fluid of a colloid nature in the cavity, it must be removed either by sponges or flannels, or sometimes by placing the patient on one side; if, however, the fluid was ascitic or simple mucoid fluid, as often found in ovarian cysts, and not in large quantities, he left it alone. Of course, one would not interfere with the peritoneum if there were no occasion.

Mr. BRYANT, in his reply, thanked the Society for the way in which they had received his communication. He was quite ready to give all credit to the Surgeons of the smaller Hospitals for having, by their energy and success in ovariectomy, stimulated others to practise the operation. He was ready to admit that great precautions were needed in the larger institutions to isolate the patients, and thus rescue them from all risks of contagious influences. The success which his cases had demonstrated was undoubtedly to be attributed to this caution; but it also proved that such was to be obtained in a large Hospital by attention to these points. He acknowledged that a Surgeon was placed in a difficult position when asked to operate in a case in which the prospect of success was very small; but he believed that almost desperate cases should be avoided. He would advise the sponging out of the pelvis when much blood or colloid fluid had escaped into it; in other cases it was not required. He agreed with Mr. Brown that it was a desirable thing that the pupils should witness the operation; but as this advantage was only to be obtained by incurring some unnecessary risk to the patient, he had thought it better that, to a certain extent, they should be excluded. The few who had been admitted were senior men who had been placed under a kind of quarantine for some days previously.

NEW CHAIR ON THE HISTORY OF MEDICINE.—M. Duroy, the new Minister of Public Instruction, has just appointed M. Daremberg, the celebrated Medical classical *savant*, to give a course of lectures on the History of Medicine, at the College of France. M. Rayer, when Dean of the Faculty of Medicine, tried in vain to get the sanction of the authorities to the establishment of a similar chair there.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following Members of the College, having been elected Fellows at previous meetings, were admitted as such at a meeting of the Council on the 11th inst., viz. :—

William Bell, Rochester, Diploma of Membership dated April 26, 1826; Frederick Disting Tothill, Charles-street, St. James's-square, June 7, 1833; Charles Vines, Reading, July 25, 1836; and Charles Manners Smith, of H.M. Indian Army, April 28, 1843.

The following Members of the College, having undergone the necessary Examinations, were admitted Licentiate in Midwifery, at a meeting of the Board, on the 16th inst. :—

George Frederic Thomas, L.R.C.P., Canterbury, New Zealand, diploma of membership dated February 11, 1859; Alfred Monekton, L.S.A., Brenchley, Kent, July 31, 1860; William Godfrey Watermeyer, Cape of Good Hope, November 20, 1863; Richard Thomas Freeman, Hatcham, January 27, 1864; Chas. Edward Covey, Basingstoke, May 6, 1863; James Smith Harris, St. John's-wood, July 31, 1863; William Samuel Wilson, Bayswater, April 22, 1862; Joseph Langhorn, Saville-row, January 28, 1864; and Jean Baptiste Blanshet, M.D., Quebec, January 26, 1864.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 10, 1864 :—

William Henry Brotherton, Bethnal Green-road; George Charles Walker, Bootle, Liverpool; Walter Harris, Waterford; William Chapman Grigg, Bristol.

The following gentlemen, also on the same day, passed their First Examination :—

Edward Brewster, Sheffield School of Medicine; Walter Haxworth, Leeds School of Medicine.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of Candidates who passed the Major Examination, March 16th, as Pharmaceutical Chemists :—

Antonio A. Ferreira, Rio de Janeiro; George R. Warren, Ware; Albert Cooper, Yeovil; Abraham J. Dyer, Gosport; William S. Greaves, Ironville; John Hamp, Wolverhampton; Martin Magor, Truro; John Reece, Rotherham; David P. Saer, Pembroke Dock; James Swenden, Darlington.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- BRIGSTOCKE, H., Ext. L.R.C.P. Lond., has been elected Physician to the South Staffordshire General Hospital, Wolverhampton.
- BUCKLE, FLEETWOOD, M.D., L.R.C.P. Lond., has been appointed House-Surgeon and Secretary to the West Norfolk and Lynn Hospital.
- FIDDES, DAVID, M.D. Aberd., has been appointed one of the Medical Officers of the Hospital for Incurables, Aberdeen.
- FRESHFIELD, ALLEN, M.R.C.S. Eng., has been appointed Admiralty Surgeon and Agent at Harwich.
- HAMMOND, E. C., L.S.A., has been elected House-Surgeon to the York County Hospital.
- HICKS, J. A., M.R.C.S. Eng., has been appointed Dispenser to St. Bartholomew's Hospital, Chatham.
- HILLIER, THOMAS, M.D. Lond., has been appointed Physician to the Skin Department of University College Hospital.
- JACKSON, THOMAS V., M.R.C.S. Eng., has been elected Surgeon to the South Staffordshire General Hospital, Wolverhampton.
- KEAL, WILLIAM, M.R.C.S. Eng., has been appointed one of the Surgeons to the Rutland Dispensary, Oakham.
- KEITH, ARCHIBALD, M.D. Aberd., has been appointed Physician to the Royal Infirmary of Aberdeen.
- MACKESY, THOMAS L., M.D. St. And., has been elected a Member of the Council of the Royal College of Surgeons, Ireland.
- MENZIES, DUNCAN, M.R.C.P. Lond., has been elected Physician to the Western General Dispensary, Marylebone-road.
- MILES, REES, L.R.C.P. Edin., has been appointed Surgeon to the Penydarren Iron Works, Merthyr Tydvil.
- PERRY, ROBERT, M.D. Glasg., has been appointed Dispensary Physician to the Royal Infirmary, Glasgow.
- ROBERTS, JOHN, M.D. Edin., has been appointed Surgeon to the General Hospital and Dispensary for Children, Manchester.
- SARVIS, THOMAS, M.D. Aberd., has been elected Medical Officer of Health for Bethnal-green, N.E.
- SEATON, D., M.R.C.S. Eng., has been appointed one of the Surgeons to the Rutland Dispensary, Oakham.
- SPANTON, W. DUNNETT, M.R.C.S. Eng., has been appointed House-Surgeon to the North Staffordshire Infirmary.

DEATHS.

- BAKER, THOMAS H., M.D. St. And., at John's-place, Parsonstown, Ireland, on January 13.
- BEVAN, T., Surgeon, of Newport, Pembrokeshire, on March 4, aged 63.

BURNARD, CHARLES F., M.R.C.S. Eng., Assistant-Resident Medical Officer, London Fever Hospital, on March 10, aged 21.
 DICKINSON, JOHN, M.D. Aberd., at Edwinstowe, Ollerton, Nottinghamshire, on February 23.
 FROGLEY, RALPH ALLEN, F.R.C.S. Eng., of Hounslow, Middlesex, at Brighton, March 15, aged 71.
 GLENDINING, WILLIAM, L.R.C.S. Edin., at Lastingham, Pickering, Yorkshire, aged 63.
 HAMPSON, ROGER, Surgeon, at Bolton-le-Moors, Lancashire, on January 14, aged 71.
 HARDING, ROBERT C., Surgeon, at Uley, Gloucestershire, on February 26, aged 64.
 HEATHCOTE, ROBERT H., M.R.C.S. Eng., at Chorlton-upon-Medlock, Manchester, on March 2.
 LAMOTTE, ALEXANDER G., M.R.C.S. Eng., at Tiverton, Devonshire, on January 13.
 MACPHERSON, ROBERT, Surgeon, of Birmingham, at Southport, Lancashire, on February 26, aged 53.
 MILLER, DR. WILLIAM, at Pitt-street, Edinburgh, on March 1, formerly of Demerara.
 PECK, FLOYD MINTER, M.R.C.S. Eng., at Sale, Gipp's Land, Victoria, Australia, on January 7, aged 43, formerly of Newmarket, Cambs.
 POWELL, ROBERT HUTCHINSON, M.D. Lond., at Abbey-square, Chester, on March 10, aged 46.
 SHEFFIELD, WILLIAM, Surgeon, at Farmanby, Thornton, Yorkshire, on February 16, aged 76.
 SUMMERS, JAMES, L.R.C.S. Edin., at Biggar, Lanarkshire, on February 29.

THE Royal Infirmary for Diseases of the Chest, City-road, has just been rebuilt. It is a handsome Elizabethan building, having large and well-ventilated wards for in-patients, and good accommodation for out-patients. The parent institution of its kind, it receives a fair share of public support. At a public meeting in aid of its funds in July last £1500 were subscribed, and at another dinner at the London Tavern some days back, under the presidentship of Sir M. Peto, £1000 were collected.

CLERICAL MUNIFICENCE.—The will of the Right Reverend Thomas Turton, D.D., Lord Bishop of Ely, has just been proved under £40,000, the bulk of which he has directed to be distributed to charitable institutions in equal proportions, and has not forgotten those belonging to the Medical Profession, among which are noticed the Westminster Hospital, the Western Dispensary, King's College Hospital, the Bedford Infirmary, the Huntingdon County Hospital, and the Suffolk General Hospital.

EXTRAORDINARY LONGEVITY.—The obituary of the *Times* has lately contained some marvellous instances of prolonged life, especially on the 10th and 12th inst., when on the former day the deaths of three gentlemen and two ladies were recorded, whose united ages amounted to 436 years, giving an average of 87 years and rather more than two months to each person. Advanced as were these ages, they were surpassed on the 12th inst., when the deaths of four ladies and two gentlemen were published, whose united ages amounted to 536 years, giving an average of 89 years and four months to each; the youngest in the list was a lady of 80, and the eldest of the same sex had reached 106 years; the youngest man being 82, and the eldest 86 years of age.

TESTIMONIAL TO DR. LIVEING, DEMONSTRATOR OF ANATOMY TO THE MIDDLESEX HOSPITAL SCHOOL OF MEDICINE.—On Thursday, the 10th inst., a large meeting of the Students of the Middlesex Hospital was held in the anatomical theatre for the purpose of presenting Dr. Liveing with a very handsome silver cup, in testimony of their appreciation of his zeal and ability in teaching them practical anatomy. On the cup was engraved—"Presented to R. Liveing, Esq., M.A., M.B. Cantab., by the students of the Middlesex Hospital Medical College, as a slight mark of their appreciation of his uniform kindness and attention to them while pursuing their anatomical studies." The representative of the students, on presenting the cup, made a short, but highly complimentary speech, to which Dr. Liveing briefly replied. The proceedings terminated with hearty cheering.

THE PICTURES AT BARBER-SURGEONS' HALL.—Many of our readers may be unaware that there exist some valuable portraits and other pictures at Barber-Surgeons' Hall, Monkwell-street, London-wall. The hall is about to undergo reconstruction, and, during this procedure, the pictures are to be removed to the South Kensington Museum, where they can be viewed under the advantage of an amount of illumination they do not possess in their present locality. Among these pictures is the celebrated Holbein of Henry VIII. granting the charter to the Barber-Surgeons, which is in beautiful preservation, and only feebly represented by the cartoon

in the possession of the Royal College of Surgeons. There is also another celebrated picture of Sir Charles Scarborough, successively Physician to Charles II., James II., and William III., reading his lectures on anatomy in the Barber-Surgeons' Hall. Every one, on viewing these works and the various portraits of early Surgical celebrities in the possession of this company, must regret that they did not fall to the lot of the Surgeons on their separation from the Barbers; and the question will naturally arise whether they may not be yet acquired by the College. They are lost and out of place in the keeping of the Worshipful Barbers.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The usual monthly meeting of this Society was held on Monday, the 7th inst., at the Dental Hospital, Soho-square. The chair was taken by the President, Edward Saunders, Esq. Models of irregularities in the teeth and the plan of treatment adopted were exhibited and explained by Mr. Saunders, Mr. Harrison, and Mr. Parkes. A long and spirited discussion took place on Mr. Spence Bate's paper on the "Pathology of Dental Caries," read at previous meetings. Mr. Bate maintained that all enamel had a tendency to be less perfectly developed in its external surface; that in cases where there was a deterioration in the development of teeth, that external surface would be less perfectly developed than in other teeth; that it was common to find, in teeth predisposed to decay, that the external surface had a more than usually large amount of animal tissue existing in it. Passing to the dentine, he maintained that in every tooth where there was a predisposition to decay, certain marks called areolar spaces were found, and came to the conclusion that those parts were of a less perfectly developed structure, containing a larger amount of animal tissue than the other parts. The green marks deposited on the teeth were nothing more than the decay of the external membrane, and that decay was really an absorption of oxygen by the animal matter in and about the teeth, which formed carbonic acid, that decomposed the phosphate of lime and left the animal constituents of the teeth exposed, which formed a further quantity of carbonic acid, and so on. A great many members took part in the discussion, and at the close a vote of thanks was accorded to Mr. Spence Bate.

MELANCHOLY DEATH OF DR. THOMAS BLACK, ANSTRUTHER.—The *East of Fife Record* gives a number of particulars regarding the melancholy death of this gentleman, whose lifeless body was found about seven o'clock on Monday morning last week floating in the harbour of Anstruther. Our contemporary says:—"The event caused intense sensation in the town on Monday morning as soon as the discovery of the body was made, and indeed still continues, owing to the mystery in which his death and its attendant circumstances is shrouded. About ten o'clock on Sunday evening, the Doctor had occasion to visit a patient in Pittenweem, and for this purpose hired a vehicle from Mr. Donaldson, of the Royal Hotel. He was accompanied to and from Pittenweem by the driver, Thomas Donaldson, and John Lees, arriving in Anstruther about half-past ten, when he went into the hotel, remained there about five minutes, spoke to Mr. Donaldson and John Lees, and then left, proceeding, it is said, along the High-street, in the direction of his own house, but it does not appear that he had reached it. He was not, so far as can yet be learned, seen alive after this hour, a little before eleven o'clock. Many are of opinion that the Doctor must have visited some other house or patient after that hour, and that he could not have met with his death then, from the fact that about one or two o'clock in the morning cries of distress, proceeding from the direction of the west beach or harbour, were heard by no less than nine individuals, principally residing near the shore of West Anstruther. The night was most intensely dark and wet, and the gas lights being all extinguished between ten and eleven, the most probable conjecture that can be formed is, that the Doctor in going home had lost his way in the darkness, had somehow or other gone down either to the east or west beach, and had been unable to extricate himself. Hence the cries, which are ascertained to have continued at least two hours, for help. The tide was then coming in, and the Doctor, from the effects of exertion, cold, and wet, would no doubt have to succumb at last to the watery element, and had thus been drowned. His watch, a valuable gold ring, and case of lancets, were found on his person, while his hat and stethoscope were subsequently found at different places. The watch had stopped at 9.50, which was about an hour before he was last seen; but it was not run out, and the glass of it when found, was broken. Dr.

Black had just completed the forty-fifth year of his age; was married in 1845, and now leaves a widow and four children to mourn his untimely fate. He has practised in Anstruther for a period of twenty-five years; and we think there can be but one opinion as to the loss which Anstruther and neighbourhood has sustained in the death of one who had not only attained to great eminence and skill as a Surgeon, but who was endowed with a more than ordinary degree of personal gifts and graces, which he was ever ready to place at the disposal of his neighbours."—[Stinginess in the use of gas cost poor Dr. Black his life.—Ed.]

GEMS OF MILITARY SURGERY.—[*Mem.* These could be matched by some of the old Peninsular anecdotes. Great countries cannot afford good Surgery.—Ed.] A sick officer from the 21st Regiment arrives at a hotel in Washington, and promptly sends for the Surgeon in charge of the district, who visits the patient, gives him a severe reprimand for leaving his regiment, attributes it to cowardice, thus adding insult to injury, and leaves to repeat his visit in two or three days, each time asserting that his illness was of slight importance. After a few days his friends became alarmed, and one more anxious and officious than the rest, warned his mother, who was then with him, that unless better attended, her son would die; and so he did. A captain engaged in that murderous assault upon the Heights of Fredericksburg, had the misfortune to be struck in the thigh by a "minié." He fell instantly, and rose as quickly to his feet, was assisted to the Hospital, and the ball taken out by incision posteriorly. An amputation was decided upon. To this he demurred, saying that as he could stand and walk he knew the bone was not broken, and amputation unnecessary. Several Surgeons examined and declared the bone shattered, for could they not feel with their fingers the sharp points? It was finally conceded to wait until a certain Surgeon, named by the captain, could examine it, and if he coincided with them, he would yield and submit to an immediate amputation. He came, and in his examination had the satisfaction, after some exertion, to remove one of the splinters, and taking it to the light exclaimed, "By G—d, gentlemen, that man's thigh-bone is made of gutta-percha." Then examining his pants, it was found that the ball had struck the contents of his pocket, and carried the fragments of his gutta-percha comb into the wound, and it was these fragments that were mistaken for spiculae of bone. I have seen the ball that did this mischief. The captain's theory was better than that of the Surgeon. He said, "If the bone is broken, how could I walk?" They answered, "If the bone is not broken, whence these fragments?" The limb was saved by accident, and is now as good as ever. The captain has his own self-will, and not the half dozen Surgeons in attendance to thank that he has now two legs to walk with. It was perhaps a natural mistake, but if the Surgeons possessed as much good common sense as the captain, it never should have occurred. An Assistant-Surgeon had his arm amputated in a Hospital in Washington, and died in the night from hæmorrhage. Was this not from ignorance or carelessness? Another soldier had his arm amputated just above the elbow. The Surgeon dressed it, applying fifteen yards of bandage covered with oiled silk, and tied below and at the shoulder so tight as to ligate it. He also died.

LIVERPOOL NURSES' TRAINING SCHOOL AND HOME.—The annual meeting took place at the Home, in Dover-street, adjoining the Royal Infirmary. Mr. Robert Hutchison gave a very gratifying account of the progress of the institution. Mr. W. Rathbone, jun. (hon. secretary), read the report, from which the following is an extract:—We obtained the assistance, as training nurses, of several of the nurses educated in the school established in St. Thomas's Hospital by the trustees of the Nightingale Fund; of these we have to regret the loss of one by fever—four remain in the infirmary. We cannot speak too highly of the efficiency of the system, whether as to discipline or Medical instruction, under which these nurses have been trained, or too gratefully of the advantages we have derived from it. Besides the four Nightingale nurses, there are two who have long been in the infirmary, and two of last year's probationers, who, having completed their probation, are in charge of wards. Nineteen probationers act under the instructions and inspection of the training nurses. Six of the probationers received were factory operatives from Manchester. Six women have been trained in the infirmary as district nurses; four of them are now at work in districts, and are giving satisfaction. We have still vacancies for probationers, and it is difficult to find women up to the standard required

to make good nurses. The Home is found to be particularly comfortable, cheerful, and healthy. It has thirty-one separate dormitories with a single bed in each, and these, with fourteen beds which will shortly be at our disposal in the infirmary, will allow of a staff of forty-five nurses and probationers. At present much less is being done for the mental improvement of the young women than your superintendent wished or intended, owing to the constant need for their services in the infirmary. This will be different when there is a larger staff. A library in the nurses' day-room is commenced, which will, we trust, conduce to their culture and recreation. We regret that we have as yet only been able to spare four or five for duty as private nurses; even with a much larger number we should have been unable to meet the demand that exists for them. District nursing has been much impeded both in extent and usefulness by the delay necessary to find and train good nurses."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

To Correspondents.—A Clinical Lecture by Mr. Paget, Surgeon to St. Bartholomew's, on "Some Cases of Local Paralysis," will appear next week.

J. B.—Write to Mr. Randall, the Secretary to the Court of Examiners.

Professor Gamgee's letter is in type, and shall appear next week.

If "T. T." will favour Mr. Capes, London and Provincial Medical Protection Society, 43, Lincoln's-inn-fields, with his name and address, he will forward him a prospectus, and put him in possession of the information required.

Singular Advertisement.—In reference to the singular advertisement in the *Gazette des Hôpitaux*, announcing that there were openings for French Medical students in the English Hospitals, who would receive pay for their services, we find the *Union Médicale* cautioning its readers against the deception being practised, and stating that several students have had to regret the loss of money and time in consequence of heeding the notice in question. What can it all mean?

Cattle Poisoned.—A singular accident occurred on Sunday night last, at Coneythorpe, by which ten of Lord Carlisle's cattle were poisoned. The beasts, it seems, were grazing in the "Grips," adjoining a nursery ground, and being covered with snow, the cattle seemed to have been attracted by some evergreens. They had broken through the fence, and fourteen of them had eaten of the common dwarf yew (*taxus baccata*), one of the British evergreen shrubs, the foliage of which is well known to be poisonous. The beasts strayed upon the green in the village of Coneythorpe, and aroused some of the inhabitants by their moaning. Three died in a few minutes, and although every care was taken to procure antidotes, seven more died before 9 o'clock on Monday morning. The other four are recovering.—*Malton Messenger*, February 27.

Syphilis at Malta compared with the Home Ports.—The reference made by Lord Clarence Paget in a late debate in the House of Commons on moving the navy estimates, to the amount of venereal disease in the navy, led to some remarks on the subject from Sir Morton Peto, who instanced the good results which have attended the enforcement of sanitary laws at Malta. Our readers may not be aware that the late freedom of Malta from venereal disease is mainly due to the efforts of Dr. A. Armstrong, of the Royal Navy. In a letter published in the *Times* of Monday, March 7, Dr. Armstrong gives an account of the circumstances under which the reform was introduced, and the results which followed—results, we assert, which should lead to the introduction of similar sanitary laws in all the seaport towns in the kingdom. The following is an extract from Dr. Armstrong's letter:—

"It will be remembered that the naval force in the Mediterranean underwent a great augmentation in 1859-60, when we had, I think, the largest fleet ever known before on that station, amounting at one period to upwards of 40 sail of pendants, 16 of which were line-of-battle ships, and the aggregate number of officers and men employed was little short of 17,000.

"On assuming the duties of my appointment in 1859, I was surprised at the number of cases of the disease that were then in the Naval Hospital, which had been contracted in the island, and were daily on the increase. On inquiry I learnt that a police regulation (non-compulsory) formerly in force for the prevention of evil, had been in abeyance for a very considerable time, for reasons into which it is unnecessary here to enter, and hence the spread of this gigantic evil to a frightful and almost universal extent among the unfortunates of the island.

"I at once saw what a fearful amount of aggravation would result from the presence of the fleet in harbour, and immediately represented the same in the proper quarter. Fortunately the political state of the Mediterranean at the time kept the bulk of the fleet absent from Malta until the spring of 1861, otherwise direful results must have ensued, and the Hospital accommodation would have proved inadequate for its wants. Previous to this period the force at Malta from time to time was comparatively small; it proved sufficient, however, to occupy from forty to fifty beds daily in the Naval Hospital (where none but the worst cases were sent) from disease contracted in the island, to say nothing of a great increase to the sick lists of the respective ships.

"It is at present unimportant to allude to the failure of my early efforts on this question, but on the return of the Commander-in-Chief, Vice-

Admiral Sir W. Martin, to Malta in 1861 I made a very strong representation, both personally and by letter, officially, on the subject, which met with the attentive consideration that its great importance demanded; and I now gladly acknowledge the support that I received from Sir W. Martin and Vice-Admiral Codrington in connexion with this matter.

"The question was then brought before the Governor and Council, who, with as much promptitude as official forms would permit, passed a law, based on my recommendation, in June, 1861, which was at once put in force with the happiest results—results which greatly exceeded the sanguine expectations I had formed, as may be judged from the fact when I state that the evil was at once arrested; and from that time up to the period when circumstances of a private nature compelled me to resign my appointment, about two months ago, there had not been a single case of the disease received into the Naval Hospital that had been contracted at Malta, embracing a period of upwards of two years and a-half; and, as far as I could learn, the disease had then no existence in the island.

"I willingly embrace this opportunity to bear testimony to the admirable and efficient manner in which the police authorities, under the control of the Civil Government, enforced the law, with such excellent and, indeed, unprecedented results."

ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reply to a letter signed "Medicus," relative to the retirement of Army Surgeons, I beg to state that he says what is a decided mistake. I will assert that it is the earlier retirement at twenty or twenty-one years which is wanted, as many men will leave when they are forty-two or forty-three years of age, and in the prime of life.

The few old Surgeons-Major who might resign if the retirement were better do not bother the Department much, and would make very little difference in the promotion of the Assistant-Surgeons. Every one is crying out for the early retirement, and it is the grand topic everywhere.

I am, &c.

TRUTH.

THE ALLEGED PROPOSAL TO REMOVE THE MEDICAL SOCIETY OF LONDON.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—By the publication, in your number of the 12th inst., of a letter from the Council of the Medical Society of London, denying the existence of any foundation for the assertion which I made in your impression of the 5th inst., in reference to the removal of the Society's chambers, I am compelled to state the following facts:—

A few weeks since, while the house-list of office-bearers was under discussion, an honorary officer of the Society, holding a post of much responsibility, asked two of the Fellows whether, in the event of their nomination to the Council, they would support a proposal for the removal of the Society to Queen-square. On being asked what object there could be for such removal, he assigned the reasons stated in my former letter. One of the Fellows having expressed his disapproval, the honorary officer asked him whether he would not vote for it if the majority of his colleagues in Council were in its favour.

Now, I would ask, it is probable that an influential official of the Society would, *motu proprio*, proceed to canvass the opinions of the Fellows unsupported by any of his colleagues?

I think I have now stated sufficient to show that "there is good reason for believing," etc., and that "a systematic plan is being pursued," etc.; also that there is a party holding office, and possessing influence in the Society, anxious and energetically endeavouring to accomplish the object in question.

I am, &c.

March 12.

A FELLOW.

THE HYGROMETER IN BEDROOMS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am rather diffident in offering the following remarks, not being a Medical man. My love of meteorology, however, makes me bolder than I should otherwise be in sending them to you, as the experience of many years in matters relating to the science will probably prevent my making any assertion which I cannot prove. I offer the results of my experience for more than twelve years in regard to constant bronchitis *versus* the hygrometrical state of the air in a bedroom:—

At an early stage in the history of my phthisical condition of lungs, I found that the air of a room heated by an ordinary fire up to the mark which suits me best (65° to 70°), became far too dry for my bronchial tubes. Accordingly I took measures for damping my room, and as I always was in the habit of reading the dry and wet-bulb thermometers in my room, as also of observing sundry hygrosopes (as distinguished from hygrometers) of my own construction, I was never working in the dark as to how damp or how dry the air in the room was. I had long before found that the ordinary means of damping a room were insufficient to produce any decided effect on the wet-bulb. At one time, I even adopted the (to ignorant persons) almost mad trick of watering the floor of the room with a watering-pot. But even this I found insufficient. I think my worthy brother (George F. Burder, M.D.) first suggested my using a boiler, with a tube extending into the room. I took the hint, and had one made, holding about two gallons. This kind of thing I have used ever since when the air has required damping, and frequently with the most striking beneficial results. For instance, I have sometimes felt a decidedly strong attack of bronchitis coming on when away from the house. On returning to my room, and getting up the steam, I have frequently found it completely quelled in an hour or two. Instead of a constant barking, irritating cough, the cough has so far subsided as only to burst forth once in three hours or so.

But the chief point of my letter, to which I desire to draw the attention of your readers is, that in cold weather it is quite difficult, even with the steam fully on (about a gallon of water turned into the air of the room in two or three hours) to get the room damp enough. I wish to note this fact specially, because many persons, and some doctors, have wrong ideas on this subject. I am careful not to speak out of book. To prove what I say, I will refer to the fact that, during the past winter, for instance, I have had the greatest difficulty in bringing the readings of the dry and wet-bulb as near as 10 degrees to each other, even with the steam fully on. Now, I prefer a damper air than 10° difference (at 70 dry-bulb and 60 wet), but have not been able with my present plan to get it. Without the steam, the difference would have been at least 20°, which would on several occasions, without doubt, have prevented your humble servant from writing this or any letter. I am convinced that the steam has saved my life more than once. My brother, the doctor, I am almost sure, would confirm all I have stated. To sum up. The two "great facts" which I desire to refer to are—1. The immense importance of steam-damping to patients like myself; and 2. The common error of

supposing that a room with a large fire in it can be too damp. I beg to observe that I do not offer any opinion on Medical matters in general, but merely speak of my own case. The benefit which I have derived is quite unmistakable. Apologising for the length of this letter,

Clifton, March 7.

I am, &c.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·252 in.
Mean temperature	41·5
Highest point of thermometer	53·6
Lowest point of thermometer	27·0
Mean dew-point temperature	36·8
General direction of wind	Variable.
Whole amount of rain in the week	1·54 in.

APPOINTMENTS FOR THE WEEK.

March 19. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

21. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m. MEDICAL SOCIETY OF LONDON, 8½ p.m. Mr. Jabez Hogg, "On Eye Diseases as Determined by the Ophthalmoscope, more especially in Relation to the Diagnosis and Surgical Treatment of Glaucoma."

22. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. Thos. J. Hutchinson, Esq., "On Certain Native Tribes of Brazil and Bolivia." Professor Busk, "An Account of a Human Skeleton discovered under a Bed of Peat on the Coast of Cheshire." "A Description of some Crania of the Manganjo Race of Negroes on the River Shire in South Africa, with an Account of the Tribes."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Moore, "On a Method of Consolidating Fibrin in Incurable Aneurisms, with a Case by Dr. Murehison." Mr. Bryant, "On Removal of Stone in the Female Bladder by Urethral Dilatation." Dr. Morell Mackenzie, "On the Invention of the Laryngoscope by Dr. Benjamin Babington." ST. MARY'S HOSPITAL MEDICAL SCHOOL, 8 p.m. Dr. Graily Hewitt, "Clinical Conference in Midwifery."

23. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

24. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

25. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

DINNEFORD AND CO., PHARMACEUTICAL CHEMISTS,

Beg respectfully to inform the Medical Profession that they are now Dispensing Physicians' Prescriptions
with the

PREPARATIONS OF THE NEW BRITISH PHARMACOPŒIA,

except when otherwise indicated by the Prescriber.

172, NEW BOND-STREET, LONDON.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury,
London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "*Pharmaceutical Journal*," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "*Times*," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

THE ORIGINAL CHLORODYNE.

INVENTED AND MANUFACTURED, IN 1844, BY RICHARD FREEMAN.

By the decision of Vice-Chancellor Sir W. Page Wood, R. Freeman is entitled to the SOLE right to use the word ORIGINAL as a prefix to the word CHLORODYNE.

The large and still-increasing demand which the Inventor has for this therapeutic is evidence of the high estimation in which its properties are held by the Profession generally; and on a recent occasion a number of eminent London Physicians and Surgeons of long standing in the Profession, and who hold public appointments, made affidavits to the fact that Freeman's Original Chlorodyne is a more certain and reliable, a more valuable and a preferable, preparation to that of any other maker's. It is offered to the Profession as the best preparation of the kind, and at a price which places it within the reach of the poorest sufferer.

MANUFACTURED BY THE INVENTOR,

RICHARD FREEMAN, PHARMACEUTIST, KENNINGTON-ROAD, LONDON, S.;

And Sold by all Wholesale Druggists in green Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d.

Any member of the Profession who has been deterred buying or prescribing Freeman's Original Chlorodyne through the statements of Brown and Davenport in advertisements or otherwise, will greatly oblige R. Freeman by communicating with him.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON

SOME CASES OF LOCAL PARALYSIS.

DELIVERED AT

ST. BARTHOLOMEW'S HOSPITAL,

ON FEBRUARY 6, 1864,

By Mr. PAGET.

THE subject of the lecture was a man, aged 23, who was in the Hospital, with total paralysis of the left upper extremity. From the House-Surgeon's note, it appears that five weeks ago he was driving a cart, while in good health, and was pitched out of it upon his head. He was stunned, and remained insensible in the London Hospital for fifteen or sixteen hours. At the same time he cut his face and bruised his left elbow. On recovering himself he found he could not use his left arm. He does not know what parts of his body were injured, but he knows that he never had any bruising over his neck or upper arm; but there are still bruise-marks along the forearm. With the exception of transient headache, he suffered no inconvenience from cerebral disturbance.

He left the Hospital at the end of nine days with his limb useless to him. He has attended there as an out-patient without any improvement from rest of the limb or friction with liniments. Soon the arm began to waste, and occasionally he has had very intense pain from the shoulder to the fingers. He looks well, and feels in perfect health. His left arm hangs heavily in his other hand; he has absolutely no power over it, and can only lift his shoulder. On his thumb and fore-finger are two sluggish ulcers, the result of his holding his hands closely to a fire without feeling it too hot. The upper arm is very flabby and wasted; the forearm the same, though in a less marked degree; it feels slightly warmer than its fellow. He has no sense of temperature, and does not know whether his finger is dipped into hot or cold water. The limb is rather dusky than the opposite arm, but there is no sensible difference in the pulse on either side. Sensation is better in the upper and inner part of the upper arm than in any other portion of the limb, perhaps from the intercosto-humeral nerves being unaffected; but there is also some sensibility in the outer part of the upper arm. The left pupil is smaller than the right, but both act equally well, and there is no defect of sight in either eye.

The condition of this man's arm must be ascribed, I believe, (Mr. Paget said) to some injury of the brachial nerves—probably, though it is not evident how it happened, to an injury of the brachial plexus at the base of the neck or in the axilla. Such concussion as he suffered is not at all likely to have caused complete paralysis of one arm without any other symptoms of injury to the brain or spinal marrow; and the characters of the paralysis, its completeness, the coldness of the limb, its wasting, and the occasional severe pain, and the sloughing of the skin after moderate heating, are just like the consequences of division or great damage of the nerve trunks. Nearly all these things have been observed in two other cases that I have seen. In one of them (a little girl about 7 years old) a ladder fell on the back of the left shoulder, and then broke her leg. The exact manner of its fall was not known, but the integuments over the scapula and by the side of the neck were severely bruised. She was stunned and unconscious for less than ten minutes, and then perfectly recovered her senses. As soon as she had recovered from the shock she called out "Where's my arm," and from that moment to the time at which I first saw her (about four months after the accident) there had been perfect insensibility of the arm. It had been for a time painful subjectively, and there were some kinds of contact which distressed her, but she could feel no common touch, no heat or cold, and had only morbid sensations either spontaneously or from some irritation. There had been also total loss of motion in the arm till within a month before I saw her, when the pectoral and posterior scapular muscles had regained slight power. Every part of the arm had greatly wasted, and it was habitually cold, with slight swelling and congestion of the hand.

Cases of so complete paralysis and of wasting and neuralgia of a whole limb from an apparently insufficient injury of its nerve-trunks, and with no signs of injury of the brain or spinal

cord, are very rare. But cases in some degree resembling them are those of an arm or leg, from violent pulling. Violent dragging at a dislocated humerus has been followed, I believe, by paralysis of the muscles not only of the shoulder but of the whole arm; and more simply, a child lifted by the arm has had permanent paralysis of that limb. And the force required to do this is not great—one child may thus paralyse the limb of another.

Some years ago I was consulted about a little boy, 9 or 10 years old, whose left arm, when he was an infant, was violently pulled by a little brother, and from that period, for a long period, appeared powerless. But he had gradually gained some use of it, and, when I saw him, could move it in any way, and was fond of climbing with it. It was, however, comparatively very weak, and was small, like one extremely emaciated. It was not short, but altogether not more than two-thirds of the size of the other.

Such injuries are rarer in the lower extremity, but here is an instance of one:—

A gentleman, nearly three years before I saw him, was thrown over his horse, and dragged along for a quarter of a mile with his right foot in the stirrup, and with his face downwards, and his left hip-joint exceedingly on the stretch. Since that time he had had partial paralysis of the right limb, lately rather increasing. He dragged the limb after him, but it was little, if at all, wasted, and the muscles on the thigh acted moderately well.

Another group of cases, which are probably of the same kind, are those in which pressure upon nerve-trunks, either severe or long-continued, may have similar consequences.

It has happened that a man going to sleep with his arms hanging over the back of a chair has, on awaking, found both arms paralysed, and so they have long remained—a result that we can ascribe only to pressure on the brachial nerves producing a more abiding consequence of the same kind as that numbness and so-called deadness of the limb caused by sitting on the ischiatic nerve.

I have known a similar result follow tight ligature.

A gentleman, subject to epilepsy, consulted me a few years ago, and gave this history of the case:—He was a strong, muscular man, and in the two years before had had several slight, and some severe epileptic seizures, and the slighter ones were generally preceded by half-a-minute's mania. In one of these, a month before I saw him, he was seized by six labourers, who, in their fright, and against his violent resistance, tied him down, and tied his feet and hands and arms with strong, thin cords. The cords on his feet and body gave him only temporary trouble; but those on his arms and wrists did greater damage. They were twisted and tied as tightly as possible, and kept on for a long time, I think for some hours. The marks of some of their coils, in bands of bruised and brownish skin, were still distinct when I saw him. When he was set free, his hands and wrists were powerless and insensible; he described them as "dropping," like those of one with lead palsy. Soon after the arms began to swell, and in the next four or five days they were in such a state of inflammatory œdema, that it was expected that portions of them would slough, or that there would be extensive suppurations, as with phlegminous erysipelas. For three weeks after the injury he scarcely slept, on account of the severe pain in the injured parts. After the swelling subsided (which it did without suppuration) he began to regain slight power over the muscles, and slight and increasing sensibility of the hands; but at the same time, as well as, perhaps, during the swelling, a considerable wasting of the muscles of the forearms and hands ensued, so that, though they had been very robust, they now quickly became slender and puny. His general health suffered, but not severely. When I saw him, his condition was greatly improved, and he seemed evidently recovering all that he had lost. His arm bore still the marks of the cords both above and below the elbows. All the muscles below the elbows were wasted; but the wasting was chiefly evident at the wrist, and, most of all, in the muscles of the ball of the thumb and of the little finger. Both his hands were ready to "drop" when he raised his forearms; but he could just hold up his left hand, and in this he could just bring out finger to the thumb, etc. In this hand, too, he had regained sensibility, enough to feel when and where any part of it was touched, but not enough to discern objects minutely. The hand had fairly regained its shape and size, but the skin of the finger was smooth and glossy, and the cuticle of all the palmar surface had peeled. The right hand had recovered very little power; he could

scarcely raise it, could hardly bring any finger to the thumb, and could hold nothing. Except in a few parts here and there, also, the skin of this hand was nearly, or, in some places, completely insensible. Both hands were occasionally the seat of pain; they were both also very apt to become cold; movement and pressure did not increase the pain. There was no displacement or injury of bone or joints, and no deep-seated disease could be felt. The general health was good, and the pulses were natural.

Another case of a somewhat similar kind came under my notice some time ago. It was that of a lady who, ten weeks before I saw her, when she was playing with some children, had fallen on her face, while she had her wrists tied very tightly together behind her with a silk handkerchief. In her fall she pulled her right hand out from the handkerchief tied round the wrist; and, in the instinctive effort to release her hand and save herself in falling, she pulled with great force, at the same time that the pull was resisted by the silk handkerchief tied round the wrists just above the joints. No sign of displacement or fracture was found by the Surgeon who saw her directly after the accident. The pain was not severe nor was the hand quite disabled, there was but slight ecchymosis, and no indication of her having fallen on the hand or struck it. But the hand remained after the injury very weak and very stiff, so that she could hardly move her fingers, and in all the distribution of the median nerve it was so numb that she doubted whether she could feel at all with it. Complete rest for the hand and arm were observed; warm applications, etc., were used. But when at the end of five weeks attempts were made to move it, and use friction and liniments, swelling took place about the back of the hand and the fingers, and they became hot, and red, and glistening. The numbness no longer existed, but she had more pain, and no more ability of movement. The same state of things continued to the time at which I saw her.

In both these cases the loss of power and the defect and disorder of sensation were so much greater than any other consequences of the injury, that one cannot doubt a predominant injury of the nerves in the forearm. But its effects were complicated by the damage of the muscles and fibrous textures, and the consequent hardening and adhesion of their structures.

From all the cases together, it is evident that long-continued paralysis of both motion and sensation, attended with rapid wasting, and more or less of neuralgia, may ensue as a consequence of such injury of nerve-fibres as, probably, falls far short of rupture or destruction of their substance, and that these things, in an extreme degree (as in the young man now in the Hospital), be due to an injury which, neither in its manner of occurrence nor in any other attendant character, would seem to have fallen with special severity on the nerve-trunks. It would seem as if the nerve-trunks might be rendered long incapable of their functions by such injury as, when occurring to the brain or spinal cord, we call concussion.

I am not acquainted with any case of the kind in which actual examination showed the state of the nerves. The exact pathology of the case is therefore unknown to me.

But of their treatment. It must be somewhat different in the cases of simple paralysis and in those that are complicated with inflammatory hardening of textures, neuralgia, and other various symptoms.

For the former—for that of the man in the Hospital, for example,—the main design must be to maintain the nutrition of the limb, notwithstanding its inaction. And for this purpose there must be provided, in addition to whatever may be required for the maintenance of vigorous general health,—

1. Constant warmth of the limb; the whole body must be warmly clothed; the paralysed limb and its fellow especially so. No good or quick repair will take place in a cold limb.

2. Regular friction and shampooing, especially circular shampooing.

3. Localised galvanism, that every several paralysed muscle may be made to contract.

4. Constant voluntary efforts; constant endeavours to attain every lost movement; and when any such endeavour is effectual, frequent exercise of the recovered power.

5. Swedish gymnastics, *i.e.*, set exercises for each muscle in which power is not wholly lost.

6. Guards against distortion from unbalanced actions of muscles, especially contracted fingers or elbows.

With these things patiently, that is, year after year continued, much good may be achieved. In the case already mentioned as exactly like that of the young man in the Hospital, great good has been gained by a year's treatment;

she can now move the elbow in flexion and extension, and draw the upper arm inwards, and slightly bend and extend the fingers. There are very distinct sensation in the whole arm and hand, and freedom from all pain; the natural temperature has been restored, and she has ordinary sensations of heat and cold. Galvanism seems to have done special good; the arm was observed to become weaker when it was omitted for a week.

But for the more complicated state, though the treatment must be essentially the same, it must be gentle, with less of galvanism, and less force of movement, and less of voluntary exercise, for these can rarely be borne as they can be in the cases of simple paralysis.

In both the cases which have been referred to of complicated injury to the structures above the wrist, much improvement has taken place. Two years after the accident, the first of these cases was reported to me as being much better; and of the second, the last note that I have (more than two years after the injury) is, that the hand was much better; the thumb and fore-finger could be easily brought together, and all the fingers had become much more moveable.

Two symptoms referred to in some of the preceding cases deserve particular notice; namely, what I have called the glossy state of the fingers, and the inequality of the pupils.

Glossy fingers appear to be a sign of peculiarly impaired nutrition and circulation due to injury of nerves. They are not observed in all cases of injured nerves, and I cannot tell what are the peculiar conditions of the cases in which they are found; but they are a very notable sign, and are always associated, I think, with distressing and hardly manageable pain and disability. In well-marked cases, the fingers which are affected (for this appearance may be confined to one or two of them) are usually tapering, smooth, hairless, almost void of wrinkles, glossy, pink or ruddy, or blotched as if with permanent chilblains. They are commonly also very painful, especially on motion, and pain often extends from them up the arm. In most of the cases this condition of the fingers is attended with very distinct neuralgia both in them and in the whole arm, and its relation to disturbance of the nervous condition of the part is, moreover, indicated by its occasional occurrence in cases where neuralgia continues after an attack of shingles affecting the arm. In two such cases I have seen this same condition of the fingers well marked, and only very slowly subsiding, and seeming unaffected by the ordinary treatment of neuralgia.

The inequality of the pupils is well marked in the man now in Darker Ward. The pupil on the injured side is always smaller than the other, but they both act equally well, and there is no defective sight. The same condition has existed ever since the injury in the young lady whose case I related next after his. Her right pupil, corresponding with the paralysed right arm, is always smaller than the left, and there is a very slight appearance, which is said to be increased when she is not in perfect health, as if the right eye were a very little smaller or less open than the left.

My attention was called to the existence of this inequality of the pupils by Dr. Hughlings Jackson, who suggested also what seems not improbable, that it may be due to the relations of the brachial plexus to the cilio-spinal portion of the spinal cord.

EPIDEMIC OF VARIOLA AT PADUA IN 1863.—During 1863 there were 365 persons attacked—193 males and 172 females. Of these, 110 suffered from variola, 210 from varioloid, and 45 from varicella. There were 32 deaths, and 32 still remained under treatment. Of the 365 individuals, 344 had been vaccinated and 21 were unvaccinated; and of the 32 deaths, 5 took place among the latter.

PRIZE QUESTIONS OF THE MADRID ACADEMY OF MEDICINE.—1. The Progress of Anatomy during the first half of the 19th century, and the influence which this has exerted upon that of Medicine; 2. A critical account of the means employed for the Treatment of Rheumatism, and their differential indications; 3. The Actual Condition of Surgery, and the causes which retard its progress; 4. The Regimen suitable for Soldiers and Sailors, the Sick and Prisoners; 5. The limits of usefulness of Medical Statistics on the Progress of Practiseal Medicine; 6. Fatty Matters, and their action on Salts and Chemical Agents in Pharmacology. Essays, written in Spanish, Latin, or French, to be sent to the Academy before September 1, 1864, in competition for the four first subjects, and September, 1865, for the two last.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians: Physician to King's College Hospital.

LECTURE V., (a) FEBRUARY 9.

(Continued from page 304.)

There are many substances contained in the London which have been omitted in the British Pharmacopœia. Had time permitted, I would have noticed several of these, but I must confine my remarks to two only—namely, the Acetate of Morphia and Lettuce; and in speaking of these omissions I shall take a slight survey of the preparations of opium and the salts of its alkaloids, which I hope will prove of some interest and practical value.

In the first place, I may state that all the preparations containing Opium are now named so as to indicate the presence of that drug, even those which in former Pharmacopœias concealed the fact; thus,—*Pilula Saponis Composita* becomes *Pilula Opii*; *Pulvis Ipecacuanha Compositus*, *Pulvis Ipecacuanha cum Opio*; *Pulvis Kino Compositus*, *Pulvis Kino cum Opio*; *Tinct. Camphoræ Composita*, *Tinctura Camphoræ cum Opio*; and *Unguentum Gallæ Compositum*, *Unguentum Gallæ cum Opio*. Doubtless there will be many strong opinions expressed as to the propriety of these alterations in name, some probably of a not very favourable kind; but I may state that the subject engaged much attention from the Pharmacopœia Committee, and, after mature consideration, it was thought that any inconvenience which might occasionally arise from certain patients being aware that Opium was being administered to them, would be more than counterbalanced, in the present age, by the absence of any attempts at concealment, and by all the more important medicinal preparations bearing the name of their most active ingredients.

Before going more into detail, I will first take a rapid glance at the components of the drug, upon which its value depends. Morphia is, *par excellence*, the important principle of Opium; almost all the good effect of the remedy may be obtained from its employment. It certainly possesses its anodyne and soporific powers; still, a very slight examination of the composition of Opium will show that it cannot be the sole active ingredient. Good Turkey Opium contains about 12 per cent. of Morphia, estimated as the hydrochlorate of the alkaloid; it follows, therefore, that if the whole power were dependent on this principle, we should find it much more potent than it really is; the hydrochlorate should, in fact, be about eight or nine times the strength of the crude Opium, whereas it is scarcely four times as strong. This is a point to which I have paid some attention, and, in order to determine the relative powers of the two remedies, have selected patients suffering from pain of a chronic character or habitual restlessness,—patients who were intelligent, and whose veracity could be depended upon. To these I have administered, at one time Opium itself, at another Hydrochlorate of Morphia, without the patient being at any time aware of the alteration from one to the other. From numerous trials made in this way I have become satisfied that Hydrochlorate of Morphia is about four times stronger than Opium, both as an anodyne and as a soporific.

We must hence conclude that Opium contains active principles or ingredients other than Morphia.

Let us examine the action of some of the other constituents.

A second alkaloid—*Codeia*—exists in Opium in very notable quantities, and is prescribed, both in this country and more especially in France, as a substitute for Opium and Morphia. It is asserted by some to possess the soothing properties of the latter drugs, without giving rise to the uncomfortable symptoms so often arising from their administration. I will give the results of my experience of the action of this alkaloid.

(a) Portions, especially of the latter part, of this Lecture were not delivered from want of time

Perhaps many of my hearers may remember that not long after the first employment of the Hydrochlorate of Morphia as a remedy, and when it was known to be accompanied with the Hydrochlorate of Codeia, that the irritation of the skin occasionally witnessed after the use of Opium preparations was ascribed to the presence of Codeia; that such an opinion is erroneous can be easily demonstrated, for when Hydrochlorate of Morphia is completely freed from Codeia, as it is in commerce at present, it still produces irritation of the skin in certain individuals; and again, when a salt of Codeia is given alone to the same patients, no such symptom is manifested: this I have proved by clinical observations. We have next to inquire whether Codeia produces the good effects of Opium or Morphia. I have endeavoured to test this in several cases. In one instance, that of a patient having a tumour in the orbit, giving rise to neuralgia in the branches of the fifth nerve, of daily recurrence, I had a good opportunity of putting this question to the test. I may state that half a grain of Hydrochlorate of Morphia always allayed the pain, and, in fact, relieved it completely for a time. This having been proved by repeated trials, I proceeded to give the same amount of the Hydrochlorate of Codeia; but its administration was not followed by any appreciable effect upon the pain. In other trials it was increased until five grains were administered, but still there was an absence of relief. Similar trials upon other patients have led to the same result; so that I feel quite satisfied that Codeia does not possess the anodyne powers of opium or morphia. To test the soporific properties of Codeia, I have given it in doses varying from one to three grains in cases of restlessness or wakefulness in which morphia has previously been shown to prove efficient, but in every case have failed to observe that any powers of inducing sleep were manifested. From my own clinical experience, therefore, I am forced to conclude that, although Codeia does not give rise to any of the disagreeable symptoms of morphia or the ordinary preparations of opium, yet, at the same time, it is devoid of their valuable properties; and, in fact, that it is a drug possessing slight, if any, known curative powers; whether it has any marked influence upon the spinal system, is a point perhaps worthy of consideration.

Another substance, Narcotine, a nitrogenised principle, contained somewhat largely in opium, deserves a few words. When first discovered, it was supposed to be the active ingredient of opium; to it was afterwards ascribed the stimulating properties of the remedy, but it has since been shown that both these assertions are altogether erroneous, and that, if it possesses any remedial powers, it acts rather as a tonic and antiperiodic. The late Dr. Roots, at St. Thomas's Hospital, demonstrated its inertness as an anodyne and soporific, and I may add that I have repeatedly given from ten to thirty grains of the Tartrate of Narcotine without the production of any symptoms.

The peculiar acid of opium, Meconic Acid, is likewise devoid of any detectable remedial or poisonous properties.

To what, then, can be ascribed the excess of power which opium possesses over its contained morphia, seeing that neither the eodeia, the narcotine, nor the meconic acid exert any appreciable influence? We must remember that opium is very complex in its composition, that it possesses many other alkaloids and neutral principles, whose action on the system is not understood; and besides these, there always exists in opium a considerable quantity of resinoid matter, and to this latter substance much of the difference between opium and morphia is doubtless to be ascribed.

These Resins, for they are numerous, are more or less soluble in water, especially if the solution be acid, as is the case with that of crude opium; they are also soluble to a much greater extent in spirit, and hence the various pharmaceutical preparations of opium are more or less impregnated with them. I have had several opportunities of giving these resins, and the symptoms exhibited have been giddiness, nausea, and strongly-contracted pupils,—without any very marked sleepiness; in fact, many of the effects which at times render the administration of opium very objectionable. I should feel very inclined to attribute much of the difference in the effects of opium and morphia to the presence of the resinous matter in the former. I speak, however, with some diffidence on this point, knowing that all therapeutic observations require to be frequently repeated before the results can be confidently relied upon.

Having premised these few remarks on the constitution of opium, and on what is really known of the action of its several constituents, we are now better prepared to discuss

the preparation contained in the British Pharmacopœia. You will observe, and, perhaps, be surprised to find, that the only preparation of morphia introduced is the hydrochlorate, and that the acetate, a salt so long employed and so prized by some Physicians, has been omitted. Why has this been done? We should certainly have some good reason for omitting this old-established remedy. Can we prove that it is unnecessary to retain it in the Pharmacopœia? I believe we can. As I do not know of any other clinical observations on the relative powers of the different salts of morphia except those which I have had opportunities of making, I must trespass on your time for the purpose of giving you the results which I have arrived at. There are many Medical Practitioners who certainly consider that each salt of morphia has peculiar powers; from what I have gathered in conversation and otherwise, I find that some look upon the acetate of morphia as possessing the property of determining powerfully to the surface; upon the sulphate as being much more of an irritant than the acetate or hydrochlorate; upon the meconiate (the salt existing in opium itself) as being milder in operation than the rest; and so on for the various other combinations of this alkaloid. On more closely questioning, however, the grounds upon which such assertions have been made, I failed in every instance to discover their validity; those who advocated the advantages of the acetate, had made no real or sufficient trials of the hydrochlorate, and the same remarks equally applied to the advocates of the other salts of morphia. I have carefully and clinically examined this subject, and will state my evidences and my conclusions.

I have been particular in selecting the subjects of these observations, and, among others, have chosen the man before referred to, suffering from neuralgia of the fifth nerve due to the pressure of an orbital tumour, and without exception I have failed to discover the slightest difference in the action of the acetate, hydrochlorate, sulphate, meconate, tartrate, or phosphate of the alkaloid; but in all these observations I have taken the precaution of giving exactly the same amount of the real alkaloid, not of the salt, for in the various saline combinations a different percentage of morphia is contained. In no one instance could the patient tell which salt was administered, or find any difference in the operation of the medicines. If we reflect for a moment, should we not naturally expect such a result? Suppose, for instance, we give half a grain of the acetate, can we reasonably look for any appreciable effect from the trace of acetic acid therein contained; and the same remark applies to the minute fraction of a grain of hydrochloric, sulphuric, meconic, tartaric, and phosphoric acids, contained in the ordinary doses of their morphia salts; given alone, these small doses of the acids would be absolutely inappreciable, even, I should imagine, to the eye of the homœopathist; how, therefore, can we expect that when in a state of combination their peculiar actions can be detected by the Physician?

If these statements be correct, why should we have in the Pharmacopœia more than one salt of morphia, and, granted that one is sufficient, our object should be to select a salt which possesses properties which peculiarly recommend it.

The Hydrochlorate has these qualifications. It is a well-known salt; has been long employed; is readily manufactured; forms very beautiful crystals, of a definite composition; and is not liable to change on exposure to the air; whereas the acetate is very difficult to crystallise, and is a salt liable to decompose, to lose some of its acetic acid, and to become much less soluble. These are the facts of the case, and probably the consideration of such led to the rejection of the acetate of morphia from the British Pharmacopœia.

In reference to the Tincture of Opium I should observe that its strength is somewhat less than before, but only in the ratio of 437.5 to 480, or of the avoirdupois to the troy ounce. At present one grain of dried opium is contained in about fourteen and a-half minims of the tincture, formerly in thirteen and a-half minims.

An error is very prevalent even now, concerning the strength of the tincture of opium, arising from the circumstance that it has been measured by the amount of solid residue left upon evaporation. But it must be remembered that this residue is not opium, but a weak spirit extract; and if we can prove that all the virtues of opium are extracted by the spirit employed, the strength of the tincture must depend on the amount of the drug used in preparing it. I have repeatedly shown that the residue is inert as an anodyne and soporific, and hence the tincture must necessarily be of such strength.

Of these extracts of opium I shall have occasion to speak shortly, as likewise of the wine.

I must now for a few minutes call your attention to a plant which is contained in the London and Edinburgh Pharmacopœias, but which has not been included in the list of the Materia Medica of the British Pharmacopœia. I allude to Lettuce and its dried juice, Lactucarium.

The Lettuce, more especially the wild plant *Lactuca Virosa*, contains, as you are doubtless aware, a milky juice, which is exuded when the stem is punctured, and this exudation, when it becomes dry, forms a brownish substance, having a peculiar narcotic odour, not very unlike opium, and a very bitter taste; these tears or masses pass by the name of Lactucarium, a preparation in the Edinburgh and Dublin Pharmacopœias; an extract obtained from fresh juice of the plant, under the name of *Extractum Lactucæ*, is in the London Pharmacopœia.

There is a very general idea that the eating of the lettuce by wakeful patients predisposes to sleep; also that the preparations of lettuce have powers of allaying irritation, such as troublesome cough and so forth; and the Lactucarium was thought to possess all these properties in an exalted degree, and has been frequently substituted for opium for patients in whom this latter medicine produced disagreeable symptoms.

Have these preparations any remedial powers which entitle them to a place in the Materia Medica? This is a question which I will endeavour to answer, or at least I propose to lay before you certain facts or results which I have recently obtained in the clinical investigation of the action of these medicines. In arriving at these results, I have selected patients either suffering from want of sleep or labouring under spasm, more especially spasmodic cough, or individuals afflicted with painful disorders. The usual dose of Lactucarium, or of the Extract of Lettuce, is, I believe, from five to ten grains. I have carefully observed the action of such doses, but failed to find any influence either in producing sleep, allaying spasm, or alleviating pain. I afterwards gradually increased the amount of the preparations until at last as much as sixty grains of Lactucarium or of the Extract of Lettuce were administered at a time; and these doses have been repeated three and four times during the day. In no one instance did the Lactucarium or Extract of Lettuce produce any direct tendency to sleep, nor in cases where pain was present was relief obtained. These observations were repeated frequently at different times, and on several patients, male and female. At first, on mentioning these results, I was told that the preparations I made use of must be faulty. To assure myself on this point, I made further trials with drugs which I felt sure were the best that could be obtained; but the results of these further observations were exactly the same as those obtained at first; and hence I cannot help doubting the value of Lettuce in the treatment of disease. It is supposed by some that Lactucarium may be usefully employed in cases where the stimulant effect of opium is objectionable. That it is devoid of the injurious effects of opium I am quite willing to concede, but that it possesses the valuable properties of that medicine my own clinical observations lead me to question.

I have occupied these few minutes in discussing the value of a non-official drug, feeling assured that the publication of carefully-conducted clinical observations which have led to negative results is as valuable to the Profession as those which have proved the presence of valuable properties in any remedial agent.

(To be continued.)

TREATMENT OF HERPES CIRCINNATUS BY TAR.—M. Bouchut, Physician to the Paris Children's Hospital, has employed tar with great advantage both in its vegetable and mineral (coal-tar) forms. One of his formulæ is as follows:—Starch, 1 part; glycerine, 15 parts; mix, and add tar, 16 parts. The patches are to be painted with this morning and evening. Another formula is composed of equal parts of glycerine and coal-tar. The tar may also be used without other admixture. The extension of the disease is at once arrested, and the herpetic patches undergo modification by, upon the average, the tenth to the fifteenth day, the skin, however, not resuming its normal appearance until the twenty-fifth or thirtieth day. The trials made of tar in *herpes tonsurans* were not attended with success.—*Bull. de Thérap.*, vol. lxiv., p. 540.

A CLINICAL LECTURE

DELIVERED AT

ST. THOMAS'S HOSPITAL.

By FREDERICK LE GROS CLARK, F.R.C.S.,
Surgeon to the Hospital.

(Continued from page 305.)

I have excised the knee-joint in only seven cases, with the following result:—The first case was that of a young woman, who had been the subject of disease for a considerable time, and had been subjected to treatment by rest, moxa, etc.; the knee was not much flexed; her health was failing. The entire surface of the joint, including the patella, was found diseased, and excised. This patient made a speedy and good recovery. She has since married, and has children, and is able to walk with scarcely any perceptible lameness, the joint being firm and immovable.

The second case was that of a boy, aged 13, from the country. The disease was of long standing, and the knee flexed at an obtuse angle. The whole articular surface was removed, and the boy recovered, with a good, useful limb. After an interval of two years this lad came back to me with the knee bent almost to a right angle, in which position it was almost fixed. This deformity had been gradually produced, though, for obvious reasons, more rapidly latterly. The limb was placed on an extending splint, and after six weeks or two months' treatment it was nearly straight. A leather splint was adapted to the knee as a support, which he was directed to wear for some time. There was no pain nor swelling, nor any indication of renewal of diseased action; the ankylosis was not osseous, and had given way under use.

Having failed to take the exact measurement of the limb, as compared with the sound one, when the lad was in the Hospital, I have been favoured with the following memorandum on the subject by Mr. Harland, of Mayfield:—

“The sound leg, from the anterior superior spinous process to the internal malleolus, measures $35\frac{1}{4}$ inches. The limb on which excision has been performed, from the same point, measures $30\frac{1}{2}$ inches. Both of these measurements are straight from point to point; but on measuring the same leg accurately down the bones, from the anterior superior spinous process to a line drawn between the two malleoli on the instep, it measures exactly $31\frac{1}{2}$ inches; thus allowing exactly an inch for flexion. The muscles of the sound leg are well developed from use; and the thigh, at the thickest part, measures 11 inches. The lame leg measures, at the same point, $8\frac{3}{4}$ inches. The boy's health is good, and the joint is firm and but slightly flexed.”

The third case was that of a little girl, about 7 years old, in whom the knee was flexed at an acute angle, and she was in a very feeble condition, and of decidedly strumous diathesis. There was much trouble in straightening this joint; there being constant tendency to displacement of the tibia backwards when the attempt was made. The reparative effort was feeble and ineffectual; for the child died before it could be completed. Probably, in this case, life might have been saved if amputation had been performed, though I think it very doubtful. She did not die from the effects of the operation, for she survived two or three months; but fresh disease was set up, and she was exhausted.

The fourth patient(a) was a young woman, who had been suffering for about four months. The limb had been neither confined nor supported, and was flexed at an acute angle. Any attempt to extend it produced extreme suffering. There was no external wound; but her health was giving way under constant and severe pain, which nothing relieved. The disease, in this instance, was not so extensive, but involved the cartilage of both femur and tibia, the articular surfaces of which were excised. She recovered more rapidly than the other cases, from the fact that the tissues on the interior of the joint were less extensively involved. She now walks about, with a stiff and strong limb, but with scarcely any perceptible lameness.

The fifth was a long and tedious case; but ultimately terminated satisfactorily. The patient, a young man, was much exhausted by long-standing disease, and long-continued suppuration at and near the knee-joint. I hesitated whether to amputate or excise; but finally decided to give him the chance of the latter operation. Not only was the entire

surface of the joint disorganised, but large abscesses extended up the thigh, burrowing between and under the muscles. Many months elapsed, and many abscesses were opened, before this patient could be got up. He then wore a stiff leather protection around the limb, including the knee, for some time, until it could support the superincumbent weight. There were still some spots of ulceration about the knee when I last saw him; but the limb was otherwise sound.

The sixth and seventh cases are those to which I have just directed your attention, and which may be taken as a type of that condition which is met with, in a more or less advanced stage, in most cases which are suitable for operation.

A remark was once made to me by a Surgeon, whose opinions are entitled to the highest respect, that although he regarded the operation of resection of joints as an important acquisition to conservative Surgery, as thereby amputation was often superseded, yet he feared that not a few joints were subjected to excision which would otherwise have got well by patient waiting and rest. Whether we may be disposed or not to admit the accuracy of this remark, there is no doubt that it was prompted by a just estimate of the difficulties which involve the cases as a class; for it cannot on the one hand be considered a triumph of conservative Surgery to sacrifice a joint which might have been saved, albeit the operation is successful *per se*; nor, on the other hand, is it justifiable to risk life by attempting to save a limb, without any reasonable prospect of permanent relief from a minor operation. There is no doubt that the earlier excision is performed where there is disorganisation in a joint, the better chance there is of the operation proving successful; at the same time it is important that the possible restoration of the joint, or suspension of disease, should not be anticipated by too early an operation; for spontaneous recovery with a stiff joint is preferable to recovery with the superadded risk of a serious operation.

With such difficulties surrounding the subject, conjoined with the obscurity which involves these diseases as regards the actual condition of the textures implicated, it is evident that each case must stand more or less on its own merits, and that familiar acquaintance with joint disease can alone justify a Surgeon in determining the time and character of the operation. Yet there are some general rules which may be observed in determining these questions.

The antecedent history and duration of the disease will be taken into consideration. It may be that the interior of a joint—and I refer more especially to the knee-joint—may have been the original seat of morbid action, or the joint may have been invaded by the extension of disease from without, such as caries or necrosis of the cancellous texture consequent on injury or osteitis from cold. I do not, however, attach much importance to these distinctions; if there is disorganisation of a joint, it does not import much whether the morbid changes are primary or secondary, but I think we may fairly look for a more favourable issue where the primary disease was accidental and occurring in a constitution uncontaminated by scrofula or other disease, the presence of which would impair the reparative effort. I think this point is illustrated in the cases on which I have operated. The duration of the disease is important, as it bears on the extension of mischief, in the form of abscess or otherwise, to neighbouring textures, and in the depressing effect it has had on the vital power of the patient. For, no doubt, some patients would rally after amputation, in whom we could not reasonably anticipate a favourable result after excision. As regards age, all the cases which have come under my care have been in comparatively young persons, which, I suppose, is not peculiar. I am, therefore, not prepared to say how far this element in the consideration of a case should influence the Surgeon in his election between amputation and resection. The actual extent of the disease has an important bearing on the decision. It is not so much a question of how far the joint itself is disorganised, as whether the disease is limited to the articular extremities of the bones involved. The course and termination of superficial abscesses, if such exist, should, therefore, be ascertained; and if, thereby, the presence of advanced disease in the bones, at some distance from the joint, is discovered, it would probably be a justification for amputation rather than excision. In doubtful cases an exploration of the parts would lead to a decision as to the proper method of completing the operation. Under all circumstances, after excision, the sawn extremities of the bones should be carefully examined, to ascertain that they are healthy, free from caries, and holding no sequestrum.

(a) Case related in Clinical Lecture in this Journal. See May 4, 1861.

I have never had any serious hæmorrhage in resection of the knee, and generally the bleeding is trifling compared with what might have been anticipated. The shock, too, is not usually severe; indeed, sometimes very moderate, and followed by moderate and healthy reaction. Pyæmia is said to be destructive in many fatal cases: of this I have no experience.

The operation itself is simple. I prefer a semilunar incision, extending from condyle to condyle, and across the ligament of the patella. The horns of this incision should extend far enough back to secure a free opening of the joint. The bow-saw of Mr. Butcher is by far the best instrument for removing the diseased surface of the bones; it is admirably adapted for this, as for many other purposes. I prefer making the section of the tibia from behind forwards, and generally, if practicable, remove a slice of the femur corresponding to the convexity of its surface. I have found no inconvenience result from this practice, and the limb is thereby curtailed of less of its length. The patella I have always left, after removing its surface with the saw. To the careful removal, by dissection, of all diseased tissue within reach, I attach great importance.

The limb should, if possible, be placed in its permanent position at once, a suitable splint, with cleanliness and perfect rest, being essential. The flap, being accurately adapted with metallic sutures, needs no other support; and any dressing, beyond a spirit-lotion on a thin rag, if grateful to the patient, is superfluous. Osseous union is probably, in many cases, deferred for a considerable period. In the second case to which I have referred, the union was evidently only fibrous, though the limb seemed sound, and well able to support the superincumbent weight before it became flexed. Where there is any doubt, artificial support should be afforded for some time after the patient is permitted the use of the limb. This case also illustrates the arrested development of the limb in a growing boy; but we still want more extended and accurate statistics on this point before a decided opinion can be expressed as to how far this risk should influence our practice in the case of the knee-joint; for arrested growth, resulting from excision in a very young child, might leave the subject of it even a more helpless cripple in after life than amputation. There is no doubt that the opinion expressed by Dr. Humphry is correct, viz., that, in most instances, if the line of union between the epiphysis and shaft is not interfered with, the growth of the limb will not be seriously impeded. But this rule is not without exception, as proved in the second case referred to by me.

ORIGINAL COMMUNICATIONS.

ON RUPTURE.

By JOHN WOOD, F.R.C.S.,

Demonstrator of Anatomy, King's College, London, and Assistant-Surgeon to the Hospital.

No. V.

THE CURE BY OPERATION.

THE consideration of the causes and progress of inguinal hernia treated of in the preceding papers will render it evident that, to produce such a closure of the hernial opening as shall prevent either sac, bowel, or omentum from escaping, it will be necessary so to close the tendinous sides of the inguinal canal to such an extent as to restore, if possible, the valve-like action which it exerts in restraining the egress of the viscera. It is evident that this cannot be done by dilating the openings by a hard plug of wood, as attempted in Wurtzer's and Rothmund's methods, nor by invaginating a portion of the skin of the scrotum, as in Gerdy's, nor by merely procuring adhesion of the pillars of the superficial ring, nor obliterating the cavity of the sac by seton, or injection, or by the various other methods which have been tried and failed ever since Surgery became an art. To make the parts strong, resisting, and permanently secure, the aponeurotic passage must be closed entirely up to the deep ring. To do this with safety, so as to guarantee the patient against the severe consequences which often ensue from a direct opening into the peritoneal cavity, such as followed the operations of Schmucker, Langenbeck, Abernethy, and Sharp, it is necessary to give the operation a subcutaneous character.

From the experience of the Surgeons just mentioned, resulting in the failure of almost all the cases where the operations were slight, and in a great fatality where the operations were

severe, many Surgeons have been led to doubt whether it be possible, consistent with the safety of the patient, to deal with the hernial structures so effectively as to produce a complete and permanent cure.

Direct and positive personal experience of nearly 100 cases, with the result of more than two-thirds of cures, and only one death (from pyæmia), and treated mainly in a public Hospital where the greater part of the cases have been from time to time publicly exhibited during the last six years, enables me to speak positively as to both the facility and utility of the operations which I propose to describe in the present and next papers.

In the first twenty cases, I used for the purpose of drawing together the sides of the canal, ligatures of stout waxed thread tied over a compress of wood. This, though presenting certain advantages in its flexibility and ready management, I afterwards discarded for stout copper wire silvered over. This substance I have undoubtedly found to give rise to less suppuration and more indurative action, to be less likely to strangulate the parts over much, and particularly to give the power of applying a proper and beneficial amount of pressure upon the deeper parts of the canal during the time that the wires remain in situ.

I now practise two operations for the radical cure of hernia. In both, metallic substances only are used. One operation is for large cases occurring in the adult in which the hernial openings are so large that its sides cannot be approximated without so much strain as to cut out the ligatures before they have effected all the purpose required. In such cases it is advisable to invaginate so much of the fundus of the hernial sac and its coverings as to fill up the openings completely, and to tie upon it the sides of the hernial canal, so as to procure a complete adhesion and blending together of all these structures. The skin itself is not invaginated, because, its surfaces not being capable of adhering together, the hollow glove forming the invagination serves no other purpose than to keep separate the pillars of the superficial ring and to act as a dead weight or drag upon the parts which may have become adherent above, so as gradually to draw them down and reproduce the rupture. This is what generally occurs after Gerdy's and Wurtzer's operations have been performed.

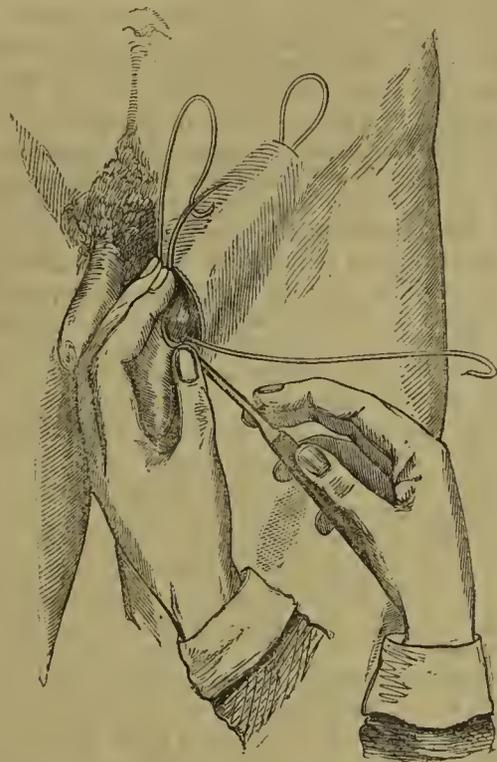

The other operation I employ for smaller cases, and those which are congenital or occur in children and young adults. It consists simply in skewering or trussing together the sides of the canal, along its whole length, by rectangular pins, which are then connected together at each end by loops, and thus are made to compress the canal and sac subcutaneously until the sides have become adherent. This operation is in itself so simple, the after-pain and inconvenience to the patient so slight, and any symptoms so rare, that, after upwards of forty trials of it, with only two failures, I am inclined to place the greatest confidence in it, when properly and carefully done, in those cases which are suitable for its performance.

THE OPERATION BY WIRE.

The scrotum and pubis being shaved, the hernia carefully reduced, and the patient placed under chloroform to such an extent as to overcome voluntary motion in some degree, as well as sensation, an inch-long incision with a small tenotomy knife is made through the skin of the scrotum, about two inches below the pubic spine, and directed obliquely downwards and outwards. The skin is then separated at the sides of the incision from the deeper fascial tissues to the extent of an inch on each side. This is done by using the point of the knife flatwise. The fascia thus detached is then invaginated into the abdominal ring and canal as far up as possible, upon the forefinger of the operator, the cord being pushed to the outer side. The lower border of the internal oblique muscle is then felt for, and hooked forwards upon the finger. This brings into prominence at the inner part of the deep wall of the canal the edge of the conjoined tendon. A stout, equally-curved needle, mounted on a strong handle and with a blunt point, is then oiled and carried along the inner side of the finger and made to transfix the conjoined tendon and internal pillar of the superficial ring from the deeper surface. When the point of the needle is seen to raise the skin of the groin, the latter is drawn over by an assistant towards the linea alba before the needle is pushed through it. One end of a well-oiled piece of silvered wire, about two feet long, is then hooked on to the eye of the needle and drawn back with it into the scrotum with a slight jerk. The needle being detached from the wire, the finger is again passed into the

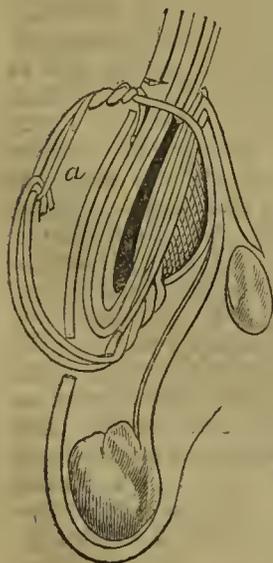

canal and placed behind Poupart's ligament near its middle, this structure being well raised up from the deeper parts, and the cord pushed over to the inner side of the canal. The needle is then passed along the outer side of the finger, and made to transfix the middle of Poupart's ligament from behind. When seen to raise the skin, this latter is drawn outwards by the assistant until the point of the needle can be passed through the hole in the groin before made. The opposite end of the wire is then hooked on to the needle and drawn through into the scrotum, leaving a loop of wire protruding at the upper puncture, the needle being then again disengaged. Next, the sac of the rupture within the scrotal incision is pinched up between the finger and thumb (see Fig. 1),

FIG. 1.

which are made to separate it from the vas deferens and spermatic cord in the same manner as in taking up varicose veins of the scrotum. The needle is then passed across the sac close in front of the spermatic cord. The inner end of the wire is then hooked on to the needle and drawn through across the sac after the needle. The ends of the wire are then twisted down into the scrotal puncture and cut off to about four inches in length. Traction is next made upon the upper loop, by which the lower twisted ends of the wire are drawn into the canal, invaginating the twisted sac up to the deep ring. Three or four firm twists of the wire loop are sufficient to retain the sac in this position, and to draw tight upon it the sides of the inguinal canal. The loop and ends of the wire are, lastly, connected together over a pad of rolled lint, placed at (a) Fig. 2, between the wire and skin, and held steady by a spica bandage and compress.

FIG. 2.

distended by a solid effusion of lymph, forming a hard tumour

up to the deep ring. In large cases that part of the sac which remains below the wire in the scrotum may suppurate and prolong the cure. In general, however, the wire may be removed about the tenth day. As a rule, the larger the rupture the longer the wire should be kept in. If suppuration be at all free, the unyielding wire forms a very good conductor for its free escape. In some very large cases I have kept in the wire for a fortnight or three weeks.

Very large cases of direct hernia require a somewhat more complicated arrangement of the wire. Thus, I have made the wires cross each other inside the canal, and by applying the needle a fourth time at the scrotal incision have obtained another hold upon the inner and outer pillars of the ring close to their insertion upon the pubis. By this means a large hernial opening is closed by a couple instead of a single stitch, and guarded more effectively against a reprotrusion of the rupture close above the pubis and behind the upper suture. This is especially required in direct cases, whether originally so or converted from oblique hernia. These cases do very well generally, though the treatment is sometimes more prolonged than usual. In every case either a complete cure or a more effective support by a truss has been the result.

MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

CASE OF PHANTOM TUMOUR—APHONIA—
CLINICAL REMARKS.

(Under the care of Dr. JENNER.)

MARY ANNE G., aged 23, a servant, unmarried, was admitted into University College Hospital October 13, 1861, under the care of Dr. Jenner. She had had measles and rheumatic fever, for which latter she was in this Hospital seven years ago. Before she was in the family-way the catamenia were very irregular. In the beginning of July last she was confined of her first child at the fifth month, the miscarriage being brought on by a fall. Soon after delivery she had shiverings, and, as leeches were applied to the abdomen, probably an inflammatory attack. From that time her abdomen had increased in size. The swelling was at first more on the left side, now more on the right side. She had had pain there ever since. A week after her confinement she had "a fit," and since she had had four more. She said that each lasted two hours. She was probably convulsed, as she said that she required "persons to hold her" during the attack. She has occasionally vomited her food, and also blood at the same time. The fits occurred after the vomiting. She lost her voice at the first fit, and was now as bad with it as at first. She had flooding three weeks after labour, and since thrice at irregular intervals. Catamenia had been absent since her confinement. Her bowels were generally confined.

After some fits she went to sleep, but not after others. She said she knew what went on around, but could not move. She made noise in fits, and bit her tongue and the sides of her cheeks during them. She tried to bite other people, and to get out of bed.

[Dr. Jenner here remarked that the great point of diagnosis between hysteria and epileptic fits was, that in the latter there was loss of consciousness; but it is very difficult to prove loss of consciousness, however, here. She admits that, at all events, in the majority of fits there was no unconsciousness. The biting of the tongue is in favour of epilepsy; but the trying to get out of bed is against the idea that there was unconsciousness in the attack. The not going to sleep after some of the fits is also against the diagnosis of epilepsy. It is always difficult to get out a history, but much more so is it in the case of hysterical people; they follow our questions so in any direction that we may lead them.]

Present Condition.—She vomits food almost every day, and soon after it is taken, and it is, therefore, but very little changed. She is much thinner than she used to be, and she has brought up her food since a fortnight after her confinement. She has also brought up blood for two years, not in any great quantity. It always comes up with vomiting and great effort; but she says that when she has fits of coughing this brings on vomiting.

[At first Dr. Jenner thought the blood was due to simple ulcer of the stomach, but on inquiry believed that it must have come from some other part.]

[She was of the age for simple ulcer of the stomach, and was just such a person as might have it; therefore there was reason for the inquiry.]

The abdominal swelling, she says, never goes down entirely, though it has been both smaller and larger than at the present time.

She lost her voice for the first time half an hour after her confinement, and never recovered it completely, but could be heard about the room. A fortnight ago she lost it again as at present.

Her loss of voice is considerable, but there is no hoarseness, no laryngeal breathing, no impediment to the entrance of air into the chest. There is (Dr. Jenner says) no disease of the larynx itself; that will cause loss of voice without any of these.

General Condition and Physical Signs.—Rather thin. Clear complexion. Little colour. Mucous membranes rather anæmic. Pupils very large. Aspect generally is that of by no means strongly-marked tuberculosis. Lungs and heart perfectly healthy; thorax well formed. Her abdomen is very much distended, and for this and loss of voice she came into Hospital. The abdomen is resistant, and varies in degree of resonance at different parts. It is smooth, but not shiny, and the umbilicus is not obliterated. The enlargement is greater on the right than on the left, and there the resistance is greater. The abdominal parietes move freely during respiration. There are silvery lines at the lower part of abdomen, the evidence of previous distension. She says that manipulation of the abdomen gives her pain. There is no fluctuation. Voice a mere whisper; it is not hoarse or harsh. There is no tracheal or laryngeal breathing; no recession of any part of the chest walls during inspiration.

November 17.—Under the influence of chloroform the whole of the tumour disappears, and walls of abdomen get flaccid.

The aphonia and tumour were, Dr. Jenner said, both hysterical.

HOSPITAL FOR SICK CHILDREN.

EMPHYSEMA, WITH DOUBLE PNEUMOTHORAX AND PECULIAR TEXTURAL CHANGE OF DIAPHRAGM—TRICUSPID REGURGITATION—SOLITARY KIDNEY.

(Under the care of Dr. HILLIER.)

C. W. R., a boy aged 7 years, was brought to the Hospital for Sick Children on February 2, with the following history:—He had always been delicate; he cut his teeth and walked late. He was much deformed from a lateral curvature of the spine, which had been first observed when he was two years old, and had gradually increased since. He had whooping-cough when four years old, not at all severely; measles followed almost immediately, but was not attended with a bad cough. He had not been subject to chronic cough or shortness of breath. He had from early infancy been subject to two peculiar symptoms: one was that he frequently woke suddenly from sleep in a state of great alarm, which lasted several minutes, and appeared to deprive him for the time of his reason. The other symptom was a difficulty in taking his food; when he had taken a few spoonfuls he would often say that the food would not go down; after waiting a few minutes he would say that it had passed, and he then went on, but was several times stopped in the same way before finishing the meal. This symptom was sometimes absent for several days together. His breath had been short for less than two months, and he had suffered for two or three weeks from palpitations of the heart. He was able to go to school till six days before his death. He had some sickness which lasted a day or two; no loss of appetite.

On Admission he was pale, thin, and suffering from dyspnœa. There is extensive lateral curvature extending from the second dorsal to the first lumbar vertebra, the convexity being to the left. In front there is great flattening under both clavicles; the upper part of sternum is also flat, whilst the lower two-thirds of that bone is tilted forward. During inspiration little expansion under the clavicles, but the muscles of the neck act vigorously in elevating the clavicles. There is a moderate amount of abnormal movement in respiration. The jugulars pulsate freely, and fill readily from below. The right infra-clavicular region is extra resonant; left infra-

clavicular also clearer than usual. Respiratory sounds almost inaudible over the right front of chest; on the left side respiratory murmur weak, and expiratory sound prolonged; the percussion note posteriorly also extrarésonant on the right side, and respiratory murmur very weak; on the left side the percussion note is clear, and the expiratory murmur is prolonged. Heart's apex beats in its normal situation; over the fourth left cartilage is heard a loud musical murmur, synchronous with the systole of the heart.

The next day he seemed better. He has had several paroxysms of dyspnœa. Takes food pretty well.

February 4.—This morning dyspnœa suddenly increased to a very aggravated degree. He cannot lie down; is very restless; his lips and finger nails are livid; air enters both lungs very imperfectly. He died at four o'clock.

Post-mortem Examination.—Whilst cutting the cartilages on the right side to remove the sternum, air escapes with an audible puff from the pleural cavity. The lung on this side is found lying far away from the anterior chest wall, occupying less than half the cavity close to the spine. On cutting the cartilages of ribs on the left side no air is noted to escape; but a small round opening is seen on the anterior surface of upper lobe of the left lung, about the size of a hempseed, surrounded by a collection of pigment. The lungs being removed carefully, and inflated under water, air escapes from the opening seen in the left lung; no air escaped from the right lung until, by forcible inflation, one or two subpleural air vesicles gave way. In both lungs there are several circumscribed patches of emphysema, each of which is surrounded by an accumulation of pigment; the separate air-vesicles of these portions could be seen with the naked eye, but were none of them larger than a hempseed. The lungs were not generally emphysematous nor otherwise diseased. Right lung weighs $5\frac{1}{2}$ oz.; left lung, $6\frac{1}{2}$ oz. There is no excess of fluid in either pleura. The parietal pleura of the left lung is a little injected. Heart weighed five ounces ten drachms. The tricuspid orifice was notably dilated, measuring $3\frac{1}{2}$ inches; the mitral measured nearly 3 inches. In other respects the heart is healthy. The diaphragm is excessively thick, in some parts measuring more than 3 lines; and on section it is very tough, almost like cartilage; in colour it is paler than usual, and much paler than the other muscles of the body. Under the microscope some of the fibres are found to be normal, most of them unusually large, measuring on the average $\frac{1}{400}$ th of an inch in diameter, whilst some are $\frac{1}{300}$ th of an inch. In many fibres the transverse striæ are indistinct, and in many others are seen a number of oval nuclei, with a very distinct nucleolus or two nucleoli. Some fibres contained many such nuclei, others two or three only. The œsophagus, stomach, liver, and spleen normal. In the concavity of the spine in the right renal region was found a solitary kidney, not quite of the normal shape; three arteries were supplied to it from the aorta, and there were two ureters proceeding from it. The supra-renal bodies were in their usual positions. The abdominal aorta was atheromatous near the origin of the cœliac axis.

Remarks by Dr. Hillier.—This case presents a number of unusual conditions; besides the solitary kidney, there was emphysema of the lungs, with rupture of a dilated air-vesicle, pneumothorax without fluid in the pleuræ, and a remarkable textural change in the diaphragm. The pleura on that side of the chest in which air was found was not obviously ruptured, whilst the pleura of the other lung was distinctly ruptured, so that air must have existed in the left as well as in the right pleura, and this was, no doubt, the immediate cause of death. The question naturally presents itself, What was the order of sequence and the connection between these morbid changes? I am inclined to regard the disease of the diaphragm as the primary lesion. The microscopic appearances would lead to the opinion that there was hypertrophy with some degeneration of that muscle. The peculiar symptoms noted during the act of swallowing and the night terrors may have been due to an irregular spasmodic contraction of the diaphragm. Is it possible that emphysema could be produced in the same way? Although such a mode of production has not before been observed, it is difficult otherwise to account for its existence and for the ruptured air cells, seeing that there had been no severe cough at any time, and no dyspnœa had existed until within a few weeks of death. We cannot suppose the change in the diaphragm to be due to the emphysema, because much more extensive emphysema is constantly found without any effect on the diaphragm. The change of texture in the diaphragm was too general and extensive to

admit of the supposition that it had been produced within a few weeks of death. The deposit of pigment around the dilated air cells was notable, and seemed to indicate some abnormal state of nutrition in these parts of the lung. An abnormal condition of the walls of the air cells is known generally to precede the dilatation of air cells in emphysema. I am not aware that such accumulation of pigment has been observed in other cases. Whatever theory is propounded to explain the symptoms and morbid appearances, the case is, in many respects, a most puzzling one, and, so far as I can ascertain, quite unique.

BIRMINGHAM GENERAL HOSPITAL.

CASES OF PROPTOSIS, WITH GOITRE AND PALPITATION.

(Communicated by Dr. RUSSELL, Physician to the Hospital.)

THE following case of proptosis affords a useful comment on the very interesting paper on this subject, by Dr. Jones, in a late number of the *Medical Times and Gazette*. Although the causes of exhaustion which had operated so powerfully upon the nervous system of Dr. Jones's patient were not discovered in the present case, and although the disorder of innervation was more local, yet, so far as regarded the function of circulation and of respiration, it existed to as great an extent, and was entirely of the character so well described by him. The remarkably excited condition of the heart and the rapidity of respiration were precisely of the kind most likely to be induced by causes exercising a depressing influence upon the nervous system, though in my patient these symptoms were carried to an extent which far transcended that which is attained in ordinary cases, and indicated that the depressing influence operated with peculiar force upon the cardiac nerves. The lessened diameter of the pupil is also worthy of note in connection with the same subject.

I have added a report of two cases of simple palpitation of the heart as affording a parallel to the case first detailed, by showing that causes of a similar character to those which produce the aggravated form of disease which is the subject of Dr. Jones's remarks, and also in operation in a more common class of cases, resembling, in many respects, the disorder in question, though differing in the comparative mildness of the symptoms and the more localised character of the affection. In each case causes tending directly to exhaust the energy of the nervous centres were manifestly in operation: in one, excessive smoking at an early age, with intemperance and extreme sexual indulgence; in the other, great mental anxiety, which had already produced very baneful effects in the nervous system of the patient. Although in these latter cases the disorder was confined to the heart, they nevertheless afford support to Dr. Jones's hypothesis by exhibiting a cause of like nature producing a similar, though more limited, result.

Case 1.—Proptosis, Goitre, extreme Palpitation.

R. P., aged 24, single, servant, was admitted into the Birmingham General Hospital. She stated that enlargement of her thyroid body had been proceeding gradually for a period of fifteen years, but with much greater rapidity during the past seven or eight months. Her health, she stated, was very good; she was equal to her ordinary duties in service, but she admitted that she never took much meat, preferring puddings, and further that she never went much into the fresh air.

Her present condition of extreme nervous sensibility has been coming on for two years, but she is given to understand that she was always "very nervous" when a girl. Since her nervous symptoms have set in, her breath has become short when she walked about, and of late she has been little able to carry a weight, or especially to shake a bed, on this account.

During the same period, too, she has suffered from much beating at the heart, producing throbbing in her neck and ears, but this symptom has not occurred after walking so much as when she is quiet in bed.

Increasing prominence of the eyeballs is also referred to the same period, the preceding two years, but she can say little respecting this symptom, as she herself was unaware of its presence, until her attention was called to it by her friends. Her appetite has not failed, but she has become thinner and weaker; she has noticed slight œdema about the ankles, and she has also slight bleeding at her nose. She has also suffered from headache, but without vertigo.

Her catamenia appeared first at fourteen or fifteen years of

age; they recurred regularly until the commencement of her present symptoms, when they were suspended for some time; they subsequently re-appeared, and resumed a normal regularity.

The condition of the patient at her admission was that of extreme nervous excitability. She lay on the bed with her eyes closed, and the lids quivering, or with her hands placed over her eyes. Her neck, and the front of the chest were shaken with each stroke of the heart; the pulsation of the carotids was very visible. Pulse was 136, answering in character to the abrupt impulse of the heart. Respiration was 40, short and hurried, and interrupted by a cough. She spoke in short sentences, each comprised in a single expiration. The veins of the neck were full and prominent. The eyeballs were covered by the lids when the eye was closed, but when it was open considerably more than the entire iris was exposed. The pupils were small. The thyroid body was considerably enlarged, and appeared to be most richly supplied with arteries.

The heart struck the chest with a sharp and violent blow, and over the cardiac region a slight diastolic impulse was sensible, as if from a rebound of the heart; its rhythm was regular. At first examination the sounds of the heart were clear and pure, but on the same occasion, a few minutes afterwards, a sharp systolic bellows-sound became audible over the base of the heart, which was not heard at subsequent examinations. A loud systolic blowing sound was distinct over the neck, and especially over the thyroid body; it was also heard over the entire length of the cervical vertebræ. The sound, though undoubtedly arterial, was more continuous than is usually the case with bellows-sounds, and in this respect approximated to the character of a venous murmur. It was not heard in the subclavian artery.

Over the carotids, and wherever in the tumour an artery was superficial, a strong thrill was felt by the hand, but only in the arteries connected with the tumour and in the carotids, which, be it observed, were deflected by the tumour from their direct course, and compelled to curve backwards. The thrill was not to be distinguished in the subclavians, nor in the superficial arteries of the neck at a distance from the thyroid.

It was afterwards observed that the thrill had left the right carotid, to which it did not return, and that in the left carotid its intensity was much influenced by the position assumed by the patient's head. Moreover, on occasion of one examination, it could not be felt until the action of the heart became tranquil, when it immediately reappeared.

The patient was rather spare, though well nourished, and had the aspect of health. She had light brown hair and eyes. She speedily passed from under observation; I had, therefore, no opportunity of placing her under treatment.

Case 2.—Palpitation of the Heart—Rhythm not Disturbed—Excessive Smoking from Early Life—Intemperance—Venereal Excess.

T. F., aged 20, bell turner, was admitted complaining of palpitation. His work was laborious, and his hours of work have sometimes been long. He has lived well, but his habits have been very dissipated. He began to smoke at 13 years of age; at the age of 16 he took to drinking, and seems to have made it a practice to be intoxicated two or three nights in each week, producing intoxication, however, quite as much by the quantity of tobacco which he smoked as by the amount of ale which he drank. He has also been in the constant practice of indulging in sexual intercourse twice or thrice in the week, on each occasion repeating the act two or three times in the course of the night; to this he has added the habit of masturbation, a vice which he still continues. For the last two years he has also had emissions during sleep. He never had any venereal affection, nor any symptom of rheumatism.

He has suffered at times from fluttering at the heart for two years, when he was excited or was overworked, and he has also had some symptoms of indigestion. His present more severe attack of the complaint has been of thirteen weeks' duration; he ascribes its commencement to an effort in raising a heavy weight; he was soon obliged to leave work on account of the palpitation, and of a sense of weakness. He has at times been faint and dizzy, and has suffered from headache, and from muscular pains in his trunk and limbs. His breathing has not been at all affected.

The action of his heart was exceedingly irritable, and very readily excited, especially when he was first addressed; the rhythm was perfectly normal; the pulsations varied rapidly

between 102 and 120; on another occasion between 108 and 112, rising to 120 after a walk along the ward; the impulse of the heart was abrupt, and very diffused; the sounds varied in quality at different examinations; on one occasion they were unusually dull, especially in the region of the apex; on another, the first sound was preternaturally sharp. The respiratory movements were perfect; in frequency 22 per minute. The pupils were below the medium size, and were indisposed to dilate when shielded from the influence of light. The patient presented few symptoms of indigestion; but his attacks of palpitation were especially liable to occur about half an hour after he had taken food, and also when he first lay down at night; they were accompanied with vertigo. He slept well. His spirits were good. He was nervous and much disposed to attend to his complaints; he had a dull, melancholy expression of face. He was well nourished, and did not present evidence of debility. His testes were normal.

The patient has improved under the administration of strychnine. He is now in the Convalescent Institution connected with the Hospital. His urine was nearly healthy. It was free from sugar, but contained oxalate of lime crystals.

Case 3.—Palpitation—Great Disturbance of the Rhythm of the Heart—Prolonged Anxiety—Secluded Life.

Mary —, aged about 50, of a strumous constitution, and of a very moveable, excitable temperament, has been for several years exposed to frequent great anxiety, the effects of which upon her health have been much augmented by her leading a very solitary life. Some years ago I attended her through an attack of extreme nervous disturbance, attended with acute mania, consequent upon sudden increase of anxiety. She had also suffered from other nervous derangements besides, due to a similar cause. Menstruation had ceased for some years before the illness to be now described. Her malady consisted of troublesome palpitation, at first coming on only after meals, then being present also in the evening, and afterwards at various periods of the day, though still increased by the presence of food in the stomach. The disordered action of the heart was now excited by the most trifling excitement, by any domestic business, even by the arrival of the postman with letters. The patient also found that matters dwelt unusually in her mind; that at night she could not free herself from the thoughts of the day. She had become hysterical, was apt to shed tears causelessly, and often to talk with unwonted excitement.

Her general health was good. Her functions were all performed naturally. She had neither pain nor vertigo. Her breathing was but slightly affected; indeed, she preferred to take her daily walk.

The heart rhythm was greatly disturbed. Not once during the two months of my attendance did I find the beats succeed each other with a normal progression for above a few seconds at a time. The pulse at the wrist was very feeble. The sounds of the heart and its impulse were perfectly healthy.

Various remedies entirely failed in affording relief. It was doubtless characteristic of the condition of the nervous system with which her disorder was associated, that both sedatives and tonics affected her very rapidly. Thus, fifteen minims of the common tincture of hyoscyamus produced very unmistakable symptoms of narcotism, and a few two-grain doses of quinine caused distinct cinchonism. The patient improved rapidly after the first sign of amendment manifested itself, which was not till the end of the second month.

The cause of the disorder in the following case is not apparent; but the case is inserted as illustrating the uncertainty which may sometimes attend the diagnosis of these disorders of the heart's action, for in the instance now to be mentioned strong reason was afforded by the physical examination of the chest to suspect the presence of some change in the walls of the heart, possibly in the aortic valves also.

Case 4.—Palpitation with Disturbed Rhythm—Cause unknown—Impulse of Hypertrophy—Questionable Bellows Sound.

E. T., aged 24, brickmaker, was admitted, suffering from severe palpitation. He had been in attendance as an out-patient for three or four months; during that period the rhythm of his heart was observed to be greatly disturbed; in other respects the results of physical examination corresponded with those subsequently obtained. The patient's health had been perfect. He had never had rheumatism, nor any œdema. He passed a round worm a year ago. His habits have been perfectly satisfactory. Careful inquiry into the subject of sexual indulgence does not elicit any circumstance of note.

He admits occasional intercourse, and has now slight gonorrhœa; but strongly denies any excess, and positively affirms that he has never masturbated. He has been temperate, and has not had any cause for anxiety. He is, however, of a very nervous temperament, and disposed to watch his ailments. His mother, too, is very nervous, and he has an epileptic sister.

His present complaint has been present about six months. He had at first slight palpitation, with some pain on exertion; but soon afterwards the symptoms underwent sudden aggravation, in consequence of his having been startled; on that occasion the beating was so violent that he had difficulty in walking home. He has left work for thirteen weeks, as he was quite unable to perform bodily labour. His breath has not suffered. He has had occasional dizziness, but all his other functions have been performed naturally. Very careful examination failed entirely in connecting the disorder with derangement of any particular organ; the sole circumstance which evidently increased the palpitation was muscular effort. His urine was quite healthy. Much care was taken to ascertain the presence of worms, if any existed, but with negative results. He was well nourished, and seemed in good health.

During the patient's residence in the Hospital the rhythm of the heart's action was regular; but the action was excited, and the frequency of pulsation was very variable—from 60 to 72, from 60 to 110, from 116 to 134, at different visits. The changes sometimes followed slight exercise, sometimes occurred spontaneously. The impulse of the heart was very diffused; it was decidedly increased in power, and had the heaving character of hypertrophy. The sound of the heart was nearly normal, but on three or four occasions a faint systolic bellows-sound was heard over the base of the heart and along the course of the aorta. When heard, the bruit was very faint; but in by far the larger number of examinations it was impossible to detect any trace of it. Respiration was normal. The pupils were rather disposed to dilatation.

Remedies failed to effect any great improvement. They included strychnine and iron, with Indian hemp at night; and he spent some time at the Convalescent Institution.

Medical Times and Gazette.

SATURDAY, MARCH 26.

IS MEDICINE A HUMANE PROFESSION?

OUR readers will recollect that last week we gave an account of the death of a poor woman at Birkenhead from hæmorrhage. We showed that her unfortunate husband had trudged about during the night, imploring Medical aid, but in vain. Charity requires us to assume that the Medical men applied to had some valid excuse—illness, fatigue, age, previous occupation;—all but one, who replied to the poor wretch that vainly implored help on the ground of his being a stranger, that, “if he were a stranger, he would not come without a guinea in his hand.” We affirm that such conduct is tradesmanlike, unprofessional, and barbarous. Wrong as it was, however, it admits of some palliation. It can hardly be called *deliberate*. It was wrung, perhaps, from some poor fellow who had gone to bed sick and soured in body and soul at the hardships of life, and the ingratitude of patients. But the blackest part of the business is, that conduct which makes us blush for human nature is deliberately and officially approved by the British Medical Association.

The journal which is the Association's mouthpiece actually spoke of this shocking scandal as a sign that the Profession at Birkenhead is in a healthy state! It ridicules the idea that Doctors would not attend if paid; and by direct inference applauds them for staying in their warm beds and letting a woman die rather than run a risk of not being paid! It claims this abominable scandal as a kind of moral reformation, and lauds itself as the apostle of inhumanity. "The principles," it says, "so often laid down in this JOURNAL touching gratuitous Medical services are at last beginning to be actually brought into play in the Profession"! It further lays down this kind of doctrine: that, because a tradesman who deals in brandy would refuse to rise in the middle of the night, and part with a bottle without payment—a thing certainly not true of all brandy merchants—therefore we are justified in refusing to save a life, unless we have a "guinea in hand" (!)

There is just one loophole with regard to this cold-blooded and degrading teaching of the British Medical Association. We may be wrong in taking it literally. It may be irony, only so clumsily worded as to look like earnest. We would gladly confess ourselves as stupid as Queen Anne's ministry who pilloried Defoe for an irony they could not comprehend, could we hope thereby to save the credit of the British Medical Association. But since the thing appears to be meant in earnest, and since there may lurk somewhere some practitioners who, exasperated by the ingratitude of patients, may think themselves justified in acting upon this teaching, or since there may possibly be some few so destitute of all education and gentlemanly feeling as to accept it without loathing, let us argue the matter gravely, and see what kind of conduct is demanded of us as Professional men. We would really hope that the time may not come in our day that a man, because a "stranger" in a town, shall be treated as if he had fallen amongst cannibals; or that we shall grow, under the teaching of the British Medical Association, into a kind of British Medical brigand, ready to shout "Your money down, or your wife's life," to any poor wretch who may implore us, for God's sake, to come and help a poor, innocent woman in her hour of greatest need.

We will not insult our readers by quoting any precept of Christianity, or any of those rules and motives which generally go under the name "religious." Let us wait and see whether the other side can attempt to sanctify the selfishness which they preach.

But there may be a hazy notion afloat that the *idea* of a profession is Christian in its origin; that it involves something superhumanly virtuous and self-denying; and that, good as it may be in theory, it presupposes that kind of excellence which nobody can reach, and which passes under the name of Christian perfection.

Quite the contrary. The notion of the *profession*, as distinguished from *trade*, grew out of the civilisation and refinement of the ancient heathens. It is not a quasi-religious dogma, such as "Love your enemies," etc., but one of the necessary consequences of the existence of an educated and refined class, which, on the one hand, shrinks instinctively from the mean and mercenary, and, on the other, sees and defines acutely the limits of every kind of duty. We claim only what was laid down by Pagans. "What are the callings that become a gentleman?" says Cicero. "Certainly not those which incur public odium, as do those of tax-farmers and usurers, nor yet the occupation of workmen who are paid for labour and not for skill, nor yet retail trade, with the fawning and insincerity it too often produces. But those professions that are founded upon scientific principles, and conducive to public utility, such as MEDICINE, architecture, and the teaching of philosophy, these are honourable. Amongst the duties of mankind, generosity is one; but it is infinitely more worthy a virtuous man to assist the needy by his talents than by his purse. Mere money giving is inglorious by comparison. As for those who employ their skill, industry, and

labour in acts of beneficence and generosity, every man they serve is a new accession of assistance to enable them to serve others. The practice of doing good renders them more ready and dextrous in diffusing the acts of their beneficence. The benefits that we confer, not by our purse, but by our talents, redound to the profit of the whole state, as well as to that of the particular persons obliged. Further, no man ought to be too rigorous in demanding, and in all his business ought to consult the convenience of his neighbour, giving up many things he might in strictness insist upon.'

These were the "Professional" notions, these the ideas of "gratuitous service," on the part of a heathen, and anything less is abhorrent—not to Christianity, but even to Pagan civilisation and morality.

But it will be asked, Do you assert that every Medical man ought to give his services to all comers indiscriminately? No more than we say a Medical man is bound to be a fool. A little knowledge of the world and a little humanity would keep most men from throwing away their services on those who do not need them on the one hand, and from allowing a woman to perish for want of help on the other.

Again, we may be asked, do you mean to assert that Medical men are legally bound to get up in the night and go to any poor wretch that may be bleeding to death? Certainly not. There can be no legal obligation whatever in any such case. We might as well ask if men are legally bound to wash their teeth, or put on clean linen, or speak good grammar. The constraint, as Dr. Macculloch well expressed it, is moral and social. When we refuse unpaid services which may save life on an emergency, we violate the first rule of morality; and when we excuse ourselves, by averring that the butcher would not give an unpaid-for joint of meat, we degrade ourselves socially, by implying that life, the subject of our Profession, is of no higher mark than goods which are the object of barter, and that we have no higher or nobler way of dealing with it than the butcher has with his meat.

But we must warn those who talk of legal obligations that they venture on dangerous ground. Two can play at that game. Where is the "obligation" which hinders Poor-law guardians from making the hardest bargain?—from advertising the Poor-law Office year after year, and putting it up at a Dutch auction to the lowest bidder? What is the aim of all the self-denying and laborious efforts of Mr. Griffin? If we are tradesmen, who let women die because we won't sell our skill without ready money, why should we not be treated as such? With what face can we besiege Parliament for increased Poor-law stipends, more generous allowances, protection from unworthy competition, and retiring pensions? Is it not that we appeal to their moral sense, and show them that we are a *Profession*, and a *humane* one, and that we do our work ungrudgingly, whether we receive much for it or little? Besides, is it likely that society will tolerate us as a privileged body if we band ourselves into a kind of trades' union, and *strike* for wages? Depend on it that on the day we are reckoned as mercenary churls, we shall find "the educated, humane, and conscientious" pharmacist ready to take our place.

If we could condescend to argue from the ground of advantage, we could show that few things pay like a reputation for humanity. Of all the titles which are given us in society, there is one in common use which speaks volumes for us. It shows that most people think us humane, unselfish, and not prone to put our own interest in the foreground. You often hear a man say, "I must consult my *Medical friend*." But, gracious heavens! would any man in his senses make a *friend* of one who would refuse to save a fellow-creature's life unless paid beforehand? Besides, we may tell our younger readers, if they do not know it already, that half the business and more than half the emolument they may look for will be gained by their humanity rather than their skill. There may be a few men, of colossal genius, who must be consulted in emergencies, and who can afford to be brutes. But for most

of us it is not the heroic operation, nor the brilliant diagnosis, that will make our fortunes. It is the common infirmities, the wretchednesses which arise out of everyday life, and quite as often from mental trouble as from bodily. It is the incurable, lingering, hopeless illnesses, where the wan sufferer looks into his *Medical friend's* face—not for a cure, for that cannot be had; but for sympathy, for a cheering word, for signs of that humanity which prompts a man to try to assuage pain that he knows he cannot remove.

We can but hope that the *British Medical Journal* will have the manliness to retract sentiments so abominable, into which it was, perhaps, led by zeal in the not unnecessary task of rebuking that indiscriminate advice-giving which only robs ourselves, and injures the recipients. As for the Association, the members must recollect that they stand self-convicted before the whole civilised world, until they shall have disavowed the voice of their accredited organ. There is one rhetorical trick which is common in that journal, which is doubtless effective enough with a certain class of readers. Being the first accomplishment of spiteful children, and the favourite weapon of vixenish women, it is remarkably easy in itself, and it is impossible of refutation. It is the trick of giving nicknames. The word *Tartufe* is applied freely enough to those who presume to differ from its policy. But we suspect that no writer of old comedy, nor of modern sensation novels, could possibly feign an organised hypocrisy so monstrous, so abhorrent to humanity—a set of conspirators so fit to be put out of the pale of society, and so odious to God and man, as the Medical Profession would be, if, with science and humanity on its lips, and with such addresses ringing in its ears as those of Walshe and Symonds, and their fellow-orators, at the annual meetings of the British Medical Association, it could tolerate the doctrine that humanity is a money speculation, and that we would let women lose their lives rather than that we should lose our fees.

THE WEEK.

MILLETT v. EDMONDS.

THE case of Millett v. Edmonds, of which an abstract appears in our Legal Intelligence, affords an instance of the dangerous tendency of certain doctrines with regard to the prevalence of secret poisoning, on which we have several times had occasion to remark. We do not hold that secret poisoning is a crime of common occurrence amongst the population of this country, and because we regard with horror the possibility of an opposite belief taking hold of the public mind, we deprecate the unfounded assertions of Medical alarmists as to its frequency. We might urge another point, that such statements tend to increase the class of crimes in question by leading ill-disposed persons to the belief that they may be committed with impunity. We congratulate the defendant, Dr. Richard Oke Millett, on the complete refutation of the accusations brought against him which this trial has established. This gentleman had the misfortune to lose several relatives suddenly, and being on bad terms with his brother-in-law, the defendant, the latter himself a Surgeon, assumed that Dr. Millett was a wholesale poisoner. Dr. Millett's brother, who was the subject of chronic hydrocephalus, happening to die of apoplexy, a charge was brought against Dr. Millett by Mr. Edmonds of having taken his life. Dr. Millett was subjected to all the obloquy of a public inquiry; and even after Dr. Taylor's report had completely exposed the baseless character of the charge, Mr. Edmonds wrote an anonymous letter to the *Western Daily Mercury*, which was intended to throw doubt upon Dr. Taylor's report and to support the original accusation. Under these circumstances, we thoroughly acquiesce in the justice of the verdict. At the trial, the chemical evidence of Dr. Taylor was supported by Dr. Albert Bernays, of St. Thomas's, and the Medical portion of his evidence by Drs. Barlow and Wilks, of Guy's Hospital. The Judge, Mr. Baron Bramwell, in his summing up, said that "Dr. Millett

might leave this court satisfied that everybody who could pronounce an acquittal upon him had done so." We are certain that outside the court public and Professional opinion will fully acquit him also.

PARLIAMENTARY.

ON Thursday, March 17, in the House of Commons,

Mr. Bazley asked the Secretary for India why Medical officers of Her Majesty's British and Indian armies were deprived of the substantive pay of their rank in India; why Medical officers of the Indian army, of ten and fifteen years' service, ranking with captains, received when on sick furlough merely the pay of a subaltern; and when the 900 Medical officers of the late Company's army, whose services were transferred to the Crown in 1857, would be informed of what their future prospects are to be as regards rank, pay, and pension.

Sir C. Wood replied that Medical officers in India were paid upon a totally different scale from Medical officers in this country. The whole subject had been under the consideration of himself and Council, and not long ago he stated that they were prepared with a general plan which would put things on a more satisfactory footing. Some further steps, however, required to be taken before that plan could be carried out.

Colonel Greville asked the Chief Secretary for Ireland if he had received the resolutions passed by the grand juries of the different counties affected by the changes proposed in the district lunatic asylums; and, if so, whether it was the intention of the Government to persevere in the contemplated changes.

Sir R. Peel replied that no resolutions passed by the grand juries had yet been received by him. When he had received them he would communicate with the hon. and gallant gentleman.

The debate on the Government Annuities Bill was resumed.

Sir M. Farquhar moved that the Bill be committed to a select committee. He complained of this measure coming by surprise upon the societies whose interests were affected by it, and of the slur cast upon insurance offices and other societies in the speech of the Chancellor of the Exchequer on the second reading of the Bill, and contended that they were entitled to be heard in their defence. He discussed a variety of statements contained in the speech, and, suggesting that the scheme might possibly not succeed, observed that it would be unjust to throw the loss upon the taxation of the country. It would be better, in his opinion, to amend the existing law so as to remedy abuses. At all events, the subject should be further investigated.

The amendment was seconded by Mr. Horsfall.

After a long debate, the Chancellor of the Exchequer said, if it were meant that the select committee was merely to consider the clauses of the Bill, he was prepared, on the part of the Government, to consent to the amendment.

Ultimately, however, the debate was adjourned.

On Friday, March 19, in the House of Lords, the House went into Committee on the Malt for Cattle Bill.

An amendment to clause 1, proposed by Lord Berners, was negatived after a short discussion, and, the various clauses having been agreed to, a new clause was added, and the bill ordered to be reported to the House.

Their Lordships adjourned until April 5.

In the House of Commons the adjourned debate on the Government Annuities Bill was fixed for April 11.

Mr. Bruce moved that the Select Committee to which the Cattle Importation Bill and Cattle Diseases Prevention Bill are referred should consist of seventeen members:—Lord Naas, Mr. Caird, Mr. Leader, Mr. Miller, Mr. Leslie, Mr. Hodgkinson, Mr. Hunt, Mr. Thompson, Colonel Bartelot, Mr. Holland, Mr. Bentinck, Mr. Cox, Sir W. Miles, Mr. Alderman Salomons, Mr. A. Egerton, Sir T. Burke, and Mr. Bruce.

Mr. Ferrand complained that no members representing manufacturing districts were nominated upon the committee, and, with a view to supply the omission, moved that the committee consist of nineteen members.

Mr. Bruce assented to the motion, and undertook to confer with the hon. member as to the additional names to be placed upon the committee.

The motion was then agreed to.

The House adjourned until April 4.

THE LOCK HOSPITAL FESTIVAL.

THE account which has lately appeared in the daily papers of the 118th anniversary festival of the Lock Hospital has a far higher claim on public and Professional attention than most reports of charity dinners. It may be safely asserted that no topic of European or home policy discussed by the Prime Minister at a civic feast has in reality a closer or more important relation to the progress and stability of the English nation than that on which H.R.H. the Duke of Cambridge, the Duke of Somerset, Earl de Grey and Ripon, Adjutant-General Scarlett, and Sir John Pakington spoke in Willis's Rooms, on Wednesday, the 16th of March. The meeting elicited an open avowal from the heads of the public services of the magnitude of an evil which has until lately been ignored by Government and Parliament, and a pledge from them to institute and support some comprehensive measure for its check. We abstract the speech of the First Lord of the Admiralty, the Duke of Somerset. In returning thanks for the navy, he said:—

“Great improvements had taken place during the last fifteen years in drainage, in ventilation, and in the regulation of temperature; but there still remained one great source of disease which had not been successfully attacked. He held it to be a great error that Christianity was opposed to the alleviation of suffering; and speaking with the information which, in his official capacity, he was obliged to possess, he knew that there was nothing officers dreaded so much as having their crews paid off in great towns like Plymouth or Portsmouth. We boasted of an advancing civilisation, but a system under which 300 or 400 men out of every thousand were laid up with sickness in our home ports, while abroad the proportion would be only 70 or 80, must be based upon a false, a prudish, and prejudiced view of the circumstances. Practical men had to deal with practical evils, and with a little energy these might be greatly alleviated. One of our own Medical officers had been shocked to see the state to which the Sandwich Islanders were reduced by disease carried there in British vessels; while at Tahiti, where the French had enforced sanitary regulations, the island was in a far healthier state. Surely we were not to go about spreading Christianity, and at the same time disease, among unfortunate and half-civilised nations. Looking at the matter in a financial point of view, a young lad who went into the navy at 16 cost £65 to train. At 18 or 19, in all the vigour of youth, he contracted disease, his services were lost to the country for weeks, and frequently he was discharged unfit for service, entailing a proportionate loss upon the country. Marines in the same way, who came back from abroad drilled into excellent soldiers, often fell into a like unfortunate condition; and the country really had no notion of the extent to which its interests were thus damaged. The noble Duke, whose speech was throughout warmly applauded, said the whole subject was hidden, perhaps necessarily, from public view; but those who knew the facts were aware how imperative it was to discover a remedy and to apply it.”

Sir J. Scarlett and H.R.H. the Commander-in-Chief made similar statements in reference to the army; and the Secretary of State for War pledged the Government to a serious consideration of the matter. Sir John Pakington also expressed himself strongly in favour of legislative interference. Thus supported, we believe that the measure which it is the intention of Government to introduce will meet with the general assent of the nation. Prevention of disease and suffering, in whatever forms they present, is a paramount duty, and cannot be in opposition either to the dictates of religion or morality.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE VIII.—FEBRUARY 18.

THE variations in the form and proportions of the human body, under the different circumstances which have given rise to the various races of man upon the earth, is an interesting and fertile subject for study, but one which has hitherto been cultivated to a very small extent with anything like the precision which its importance demands. All human beings naturally assume the erect posture, and all agree in certain great

and fundamental characters in respect to the proportions of the body; thus, the legs are always longer than the arms, the tips of the fingers do not reach the knees in the upright position, the proximal segments of the limbs are the largest, the foot is longer than the hand, the hallux never greatly shorter than the second toe, and can never be greatly abducted or opposed. There are, however, both in individuals and races, considerable minor variations of proportion, the chief of which will now come under consideration.

From a series of measurements of skeletons of Europeans and negroes, published by Dr. Humphry, it appears that the average height of the negro is less than that of the European, the arms are proportionally longer, particularly the forearm and hand; and in the lower extremity, while the femur retains nearly the same relative length as in the European, the tibia and foot are considerably increased. In these deviations from the European standard, the Australian and other low races agree with the negro; and it will be observed they recall some of the peculiarities of the proportions of the fœtus, and will be met with, only in an infinitely more marked degree, in some of the anthropoid mammalia. There is no real evidence to show that the hallux is differently constructed, or more moveable, among the lower than in the higher races of men, though in the latter the practice of wearing hard shoes rarely allows it to become developed. The same may be said of the alleged flatness of foot and increased length of heel of the negro races. The last, though constantly insisted on, is not borne out by anatomical examination, and the idea has probably originated in the altered contour of the back of the leg, dependent on a defective development of the muscles and tendons of the calf.

The modifications of the colour of the skin in different races are well known. We speak of white or black people, but in reality they are all shades of brown, darker or lighter, —a true black skin, according to Professor Huxley's observations, scarcely exists. In the character, as well as the colour, of the hair mankind vary much. The transverse section of the hairs of certain races is flattened, in others it is oval, and, again, in others nearly circular. It is asserted that the first form is characteristic of the Negro, the second of the Aryan, the third of the Mongolian races. In some hair of the first form, the long axis of the diameter gradually changes its position in the length of the hair, causing a crisp curl or spiral twist; this and other peculiarities of the hair are found in widely-separated groups. In connection with the cutaneous system may be mentioned the great accumulations of fat in particular parts of some races, as on the buttocks of the Bosjesmen, more especially the females; and also the great development of the nymphæ in some negro tribes.

The number of the cervical vertebræ in the human skeleton appears to be constant. A variation in the number of the dorsal vertebræ is not unfrequent, but it is usually more apparent than real, being caused by the development of a moveable rib on the first lumbar, thus increasing the former series at the expense of the latter. A truly additional lumbar vertebræ has occasionally been met with. An increase of the number of the sacral vertebræ from five to six is not very uncommon. This may be occasioned by either one of three ways: the interposition of an additional bone into the series, or the annexation by alteration of its characters, and ankylosis of the last lumbar or first coccygeal vertebra. The modification of the last lumbar vertebra so as to bear more or less resemblance to part of the sacrum appears to be of rather frequent occurrence among the lower races, as it may be observed in the skeleton of the Bosjes woman and female Australian in the College Museum, and in a male Australian in the Middlesex Hospital Museum.

The pelvis undergoes modifications of a very interesting nature in different races of men—modifications, however, which chiefly affect the male sex. It may be stated generally that the pelvis of the negro is in all its dimensions proportionally less than is that of the European, and in the Aus-

tralian this diminution is carried further. While the form and dimensions of the lower outlet of the pelvis is pretty nearly the same in the females of all races, this outlet is greatly diminished in breadth in the male Australian, so that among these people the pelvis of the two sexes present a most remarkable contrast. In the African negro the difference is not so marked. There appears also in the lower races to be a certain tendency towards the narrowing of the transverse as compared with the antero-posterior diameter of the brim of the pelvis. The female Bosjesman's skeleton in the College Museum presents the great peculiarity of an antero-posterior actually greater than the transverse diameter.

The form of the skull undergoes great modifications in different races. When the cranium is elongated and narrow, so that the transverse diameter is less than seven-tenths of the antero-posterior diameter, it is called "oblong," and the race or individual to which it belonged is "dolicho-cephalic." When the transverse diameter is from seven-tenths to eight-tenths of the length, the cranium is "oval." When the transverse diameter is more than eight-tenths, it is "round," or "brachy-cephalic." As a general rule, though, as is well known, the exceptions are numerous; the oblong skull is met with best developed partly among the Scandinavian races and partly among the West African negroes. The oval skull is characteristic of the so-called Aryan races, including the inhabitants of Central Europe, Persia, and the higher races of Hindoostan. The round skull is found among the typical Mongolians, occupying the central parts of Asia, and the aborigines of America. In the long-headed races the cranium is frequently raised in the middle in a ridge, constituting the so-called boat-shaped, or "scaphoidal" skull. Among the Greenlanders it is pyramidal; and there is yet another form which may be described as the "depressed" skull, characterised by its considerable length and breadth, great vertical depression, and large development of the infra-orbital ridges. Of this form there are some very good examples in the Museum from natives of Port Adelaide, South Australia. The internal capacity of the human skull varies greatly, ranging in normal healthy adults from 50 to 110 cubic inches. The variation between the proportion of the greatest internal cerebral length to the length of the basi-cranial axis (from the hinder part of the basi-occipital bone to the junction of the presphenoid with the ethmoid) is also great, the proportion in the higher races of the former to the latter measurement being as 270 to 100, while among the lower races it is but as 230 to 100, indicating a smaller development of the cerebral chamber as compared to the base of the skull and face.

FROM ABROAD—PARACENTESIS THORACIS IN PLEURISY—PROSECUTION FOR BETRAYAL OF PROFESSIONAL CONFIDENCE—THE WATER-MATRESS—THERAPEUTICAL ACTION OF OXYGEN.

AN interesting discussion has taken place at the "Société Médicale des Hôpitaux" in relation to the practice of paracentesis thoracis in acute pleurisy. M. Archambault related the case of a man, aged 34, of habitual good health, and who, while under treatment for an acute pleurisy with effusion, which remained somewhat stationary, but seemed of no great urgency, suddenly died. At the autopsy, from a quart to three pints of fluid were found in the right pleura, compressing the lung against the spinal column, but the left lung was found normal, and all the other organs of the body were quite healthy. M. Archambault is inclined to think that paracentesis might have saved this man, and ought to have been performed. He had been guided in the matter by the report of a very important committee which, in 1854, had declared that the operation was only indicated when asphyxia seemed imminent, or great displacement of viscera, especially of the heart, took place, neither of which circumstances existed in the present case. He thinks that the rule for operating should be somewhat enlarged; but how it could be applied in this case is not evident, as there was no urgency in

the symptoms, and the amount of fluid was not very excessive or on the increase. M. Chauffard could not agree that because no lesion capable of explaining death was discovered, that paracentesis would have saved this patient. Other instances are on record in which sudden death has occurred in pleurisy in which effusion, dyspnoea, etc., have been very moderate. If we compare the number of deaths, relapses, and purulent transformations becoming, sooner or later, fatal which supervene on paracentesis with the few cases of death arising from its non-performance, we should probably resort to it less often even than we do now. It is not to be denied that a large effusion may give rise to sudden death; but should we operate in the moderate cases in which the supra-spinal fossa still continues sonorous? Without denying its occasional advantages, M. Chauffard feels convinced that the operation is too frequently performed. During ten years' practice in a Hospital where pleurisy was frequent, and in a climate favourable to the affection, he had met with many cases in which the effusion was enormous, and yet there were no sudden deaths, but rapid recoveries, although paracentesis was never resorted to. M. Guérard pointed out that, while on the one hand sudden death occasionally occurred without any assignable cause, on the other, large effusions, with even visceral displacements, may be cured without puncture. M. Herard admitted himself an advocate of paracentesis, as sudden death is far more common in pleurisy with than without effusion. In some cases the effusion increases so rapidly that danger can only be avoided by an operation. This is far from being surrounded with the perils attributed to it; and in the numerous cases in which he had practised it, M. Herard had met with no accident, but frequent and prompt success. M. Bourdon stated that M. Vigla, formerly a partisan of the operation, had given it up of late, except in very urgent cases, as he had several times observed a purulent transformation ensue. M. Moutard-Martin believed that this transformation would have ensued even if the operation had not been performed. Paracentesis may not, perhaps, abridge the course of pleurisy with strong plastic excretion, but when the serous effusion is predominant and fever is intense it causes the symptoms to yield in a few days. M. Behier also spoke in favour of the operation, and thinks that for the explanation of these sudden deaths the heart should be more carefully examined than is usual. M. Woillez dwelt upon the uncertainty of the indications for the operation usually employed, as shown by the fact that frequently percussion exhibits a stationary condition of the effusion, although this has really gradually increased or diminished, while the ill effects of the displacement of the heart have been much exaggerated. The only exact means of ascertaining the amount of effusion is exact measurement of the chest, the mode of making which, under the title *cyrtometrie*, M. Woillez describes at some length. Whenever from the fifteenth to the twentieth day thoracic amplification becomes marked, the operation is indicated, secondary pleurisies being left to the twenty-fifth or thirtieth day; while whenever there is any diminution of the capacity of the thorax observed, whatever the other indications may be, the operation should be abstained from. In more than 100 cases of pleurisy, M. Woillez has seen occasion to operate in but seven; and three of these were cases of urgency. By mensuration, all danger of that excessive expansion of the chest, which itself becomes a cause of rapid asphyxia and death, may be anticipated. M. Laillier declared that M. Woillez' instrument was one of difficult and tedious application, and liable, when badly applied, to furnish no better indications than percussion and auscultation.

A case has recently occurred in Paris which shows that the betrayal of professional confidence, which with us can only be met with the reprobation which its perpetration would call down upon the head of the offender, constitutes in France a very serious breach of law. A doctor of medicine was brought on the 11th March before the *Tribunal Correctionnel*, charged with having revealed a secret disease of one of his

patients, and by the judgment of the Court he was condemned to a year's imprisonment and a fine of 500 francs, with the expenses. Moreover, at the expiration of his sentence, he is to remain for five years under the *surveillance* of the police; and as by the divulgence of the disease of the patient he has caused prejudice to the interests of the plaintiff, he is further condemned to pay the sum of 1000 francs damages, or undergo an additional year's imprisonment.

M. Demarquay has been for some time since engaged in investigating the merits of different beds in the prevention of eschars and bed-sores, and came to the conclusion that of all hitherto devised that of Arnott (or Asmolt and Arnolt, as the name is spelt in the article we quote from) bears the palm of superiority. But this is an expensive article, and has several inconveniences, and, after much time employed upon it, M. Demarquay has invented a *water mattress*, which he regards as an effectual and cheap substitute. This simple apparatus, carefully constructed by Galante, the celebrated Paris caoutchouc instrument manufacturer, resembles a small ordinary mattress, which is filled with tepid water, and placed in a bed. At the end of three months the water is found to have retained its temperature, and to have undergone no alteration. M. Trousseau speaks highly of the advantages attendant upon this contrivance.

Having given an account of their experiments with oxygen on man and animals, MM. Demarquay and Leconte next proceed to consider its therapeutical applications. The sanguine expectations raised with respect to what was termed pneumatic medicine at the end of the last century have not been realised, in part in consequence of the contraindications to the use of oxygen and other gases not having been borne sufficiently in mind. These contraindications are,—the febrile condition, except under certain diathetic conditions, as croup; deep-seated inflammatory action and visceral lesions; diseases of the heart and large vessels; neuralgia unconnected with anæmia; and a disposition to hæmorrhage. On the other hand, oxygen is especially indicated for anæmia or chloro-anæmia connected with Surgical affections, for raising the strength, and for combating certain diatheses, the depressing action of which is well known, as diphtheritis, syphilis, diabetes, etc. In these conditions, under the influence of oxygen, in the course of a few days, if the age and general condition still allow of it, the strength is recruited, and the appetite returns with such intensity that the patient demands food even in the night. The lips regain their colour, and a greater vitality manifests itself, and during these appearances of reparation, much of the nervous disturbance ceases. At this period, however, the condition of the internal organs requires to be well ascertained, for wounds now assume a greater functional activity. In a child the subject of croup, a large blister covered with diphtheritic deposit cleaned under the influence of oxygen, but at the end of a week this had to be left off, as the blister began to assume the signs of ordinary active inflammation. The action of the oxygen is prompt, especially in young subjects. It has never been administered for more than from thirty to forty days in succession, and ordinarily not more than from fifteen to twenty, when it has at all events been suspended for a time. Of course, it is not always curative, as when administered in cancer or incurable chronic disease, but at least it never does any harm.

THE PROPOSED LEGISLATION FOR CHEMISTS AND DRUGGISTS.—Although it has not been officially reported, it is pretty generally known that the Branch Medical Council for England, having deliberated on the Proposed Amended Medical Act, have come to the conclusion "that it is not expedient at the present time to engage in fresh legislation." As far as the proposed clauses in relation to chemists and druggists extend, we think that the Branch Council have taken the right view of the case. We are by no means, however, prepared to state that the clauses of the Medical Act in reference to registration and titles require no revision.

REVIEWS.

Atlas d'Ophthalmoscopie, représentant l'Etat Normal et les Modifications Pathologiques du Fond de l'Œil Visibles à l'Ophthalmoscope. Par le Docteur RICHARD LIEBREICH. Baillièrè, Paris and London.

THE discovery of the ophthalmoscope has indeed been of incalculable value in the advancement of Ophthalmic Surgery, as all must admit who have watched the great progress made by this department of the Profession within the last twelve years. It has revealed to us diseases of the inner tunics of the eye, which were before shrouded in impenetrable obscurity, and has rendered them as clear and apparent as if they were situated in the cornea or conjunctiva. The use of this instrument is, in fact, as essential and important in the treatment of eye diseases, as auscultation in affections of the chest. It is, therefore, of great consequence that the Profession at large should be acquainted with it, and should be conversant with the ophthalmoscopic appearances of, at least, the more common affections of the internal eye. But the ophthalmoscope is also of great value and assistance to the physiologist and pathologist. The eye is a microcosm in which many of the most interesting physiological and pathological phenomena may be watched with greater accuracy and certainty than in any other organ of the body. Step by step we may trace the origin, the progress, the termination of a disease. For instance, in cases of effusion into the retina or choroid, we may watch every change, however slight, in the different stages of the affection: the hyperæmia, the effusion, the various metamorphoses which the pathological products undergo, until they are, perhaps, finally, completely absorbed, leaving behind them no trace of their existence, except some slight changes in the epithelium, or some minute cicatrix. Again, the ophthalmoscope not seldom affords us the first hint of the existence of an affection of some other organ. The first suspicion of Bright's disease is frequently excited by certain appearances in the retina: atrophy, or inflammation of the optic nerve, often first calls our attention to the presence of some cerebral affection; embolism of the central artery of the retina may lead us to examine the heart, and detect some, hitherto unsuspected, lesion of this organ. This being so, it is to be greatly regretted that this valuable instrument is still so little used in England, except by men who make diseases of the eye almost a special study. But whilst regretting this, we must also remember that many difficulties lie in the way of its general employment; for ophthalmoscopy is a subject of which it is impossible to acquire even an elementary knowledge without devoting much time and patience to its study, and without the careful and repeated examination of a great number of cases. But few men in active practice can devote much time to the study of one branch of the Profession. It has, therefore, often been a matter of surprise to us that lectures on the use of the ophthalmoscope (with practical demonstrations) have not been more generally organised in our English Medical schools. A student would thus learn more, under a competent teacher, in the course of a few months, than he could acquire in years, if dependent upon his own unaided resources.

Much may, however, be also learnt from the careful study of really good ophthalmoscopic plates, and for this reason Dr. Liebreich's Atlas will prove of great value and assistance, not only to the Profession at large, but also to the ophthalmic Surgeon, for his plates are, without exception, the best which have been published. They not only furnish us with a truthful and life-like representation of the ophthalmoscopic appearances presented by the various affections of the internal eye, but they are executed throughout in the most finished and artistic manner. They are not mere sketches, hurriedly drawn and badly coloured, but are in reality a series of admirable portraits, the minutest details of which are rendered with wonderful accuracy and care. By employing a very considerable magnifying power, he has been enabled to perceive and depict minutiae which would almost have escaped observation with the ophthalmoscopes generally in use.

He has made an excellent and judicious selection of cases for illustration, for they either represent well-marked types of the different diseases, or some rare and interesting peculiarity. Some may, indeed, wish that more of these exceptional cases had been illustrated, but it must be remembered that this would have greatly increased the expense of the work, without affording any corresponding advantage.

The Atlas consists of twelve large plates, containing in all

fifty-seven illustrations. The explanatory letter-press is in German and French. Although short and concise, it will be found to contain much interesting and valuable information, and to be pregnant with important ideas, which open up a vast field of thought and inquiry—a field promising a rich and abundant harvest to the earnest and zealous labourer. This is particularly the case in those affections of the eye which depend upon diseases of other organs—*e.g.*, the brain, the heart, the kidney.

Our space will not, unfortunately, permit us to describe the illustrations in detail—indeed, no mere description could do justice to them; we must, therefore, confine ourselves to calling the attention of our readers to some of the most important plates.

It will be well for the student to make himself thoroughly conversant with the varieties in the shape, colour, and size of the optic nerve entrance, and in the colour and pigmentation of the fundus which are met with in the healthy eye. These are well illustrated in Plate II. Nothing so frequently misleads the beginner as these physiological peculiarities, which he is but too apt to consider due to same pathological cause.

Plates III. and IV. furnish numerous examples of the more important appearances occurring in the various forms and stages of staphyloma posticum (sclerotico-choroiditis posterior) and the different kinds of inflammation of the choroid.

Plate V. gives two interesting and instructive illustrations of a case of choroido-retinitis. The first was taken within a few weeks of the outbreak of the disease, and shows clearly the effusion into the deeper layers of the retina, with all its concomitant symptoms, the choroid being at that time apparently but little affected. The second figure represents the condition of the eye about a year later, when the appearance of the fundus is entirely altered. The retinal effusion has completely disappeared, but the changes in the choroid are now most marked and apparent. This case also illustrates well the different influences exerted upon the sight by retinal and choroidal affections. We often find that great and very marked changes in the choroid—as, for instance, in cases of disseminated choroiditis—are accompanied by but little impairment of vision; whereas apparently slight changes in the retina, particularly in the region of the macula lutea, produce often very considerable amblyopia.

In Plate VI. two cases of retinitis pigmentosa are depicted. The characteristic spider-like, black masses which are strewn about the fundus in various directions, but chiefly following the course of the retinal vessels, are admirably portrayed. In both, the optic nerve is atrophied, this being a frequent complication in elderly persons. Dr. Liebreich has made some valuable and interesting researches into this affection. It generally commences in infancy, but often remains undiscovered—unsuspected for many years. The external appearance of the eye is perfectly healthy. There is no pain or redness, and the patient at first only complains that his sight deteriorates towards evening. In the daytime, and in a bright artificial light, he may still, however, be able to see well. The field of vision is, at the same time, found to be more or less contracted. These symptoms of night-blindness and contraction of the visual field gradually increase, until the latter may be so excessive that the patient can see nothing but what lies in the optic axis, being quite unable to guide himself, as all around him is shrouded in obscurity. In the optic axis, however, his sight may be still so perfect that he can read the very finest print. After the age of 30-40 the disease generally ends in total blindness. Dr. Liebreich has found that nearly one-half of the persons suffering from retinitis pigmentosa were the offspring of marriages of consanguinity, and also that it not unfrequently coexists with idiocy and deaf-mutism.

But perhaps the most interesting group of cases in the whole work is that of the diseases of the retina, which are admirably illustrated in Plates VIII., IX., and X. We would call special attention to these affections, as an acquaintance with them is of importance, not only to the ophthalmologist, but also to the Physician. Here the domains of the two merge into each other: here it is as necessary that the oculist should likewise be a thoroughly educated Physician, as that the latter should be conversant with diseases of the eye and the use of the ophthalmoscope. Many of these affections depend upon diseases of other organs, being not unfrequently harbingers of the graver lesion, and first exciting our suspicion of its existence. In Plate VIII. we find, for instance, various cases of hæmorrhage into the retina occurring together with suppression of the catamenia, and together with arterio-sclerosis and hypertrophy of the left ventricle. Also a case of embolism

of the central artery of the retina in a patient affected with insufficiency of the aortic valves and consecutive hypertrophy and dilatation of the left ventricle.

Plate IX. gives two illustrations (Figs. 1 and 2) of the degeneration of the retina in Bright's disease. We consider these as the gems of the work, not only on account of their truthfulness and accuracy, but also on account of their admirable colouring and finish. We particularly advise the student carefully to compare these illustrations with those of syphilitic retinitis (Plate X., Figs. 1, 2), and inflammation of the optic nerve (Plate VIII., Fig. 6, and Plate XI., Figs. 6—9), and to note the characteristic symptoms of each affection, for the peculiarities are so marked and typical, that the differential diagnosis is not difficult. Plate X. also contains an illustration (Fig. 3) of a most peculiar form of retinitis occurring in leucocythemia. Dr. Liebreich was the first, as far as we are aware, who discovered it, and has seen six cases, in all of which the ophthalmoscopic symptoms were closely allied, and perfectly characteristic. The papilla of the optic nerve is very pale, and the retina in its vicinity somewhat opaque and clouded, this opacity having a striped appearance. In the region of the yellow spot are seen a number of pale, irregular, minute particles. The retinal and choroidal vessels are pale, and the retinal veins, though dilated and tortuous, appear of a faint rose colour. The hæmorrhagic extravasations into the retina assume the same tint. There are also peculiar white, glistening spots, which correspond closely in form and colour to those met with in Bright's disease, but they lie more to the periphery of the fundus. They depend, as do those in Bright's disease, upon sclerosis of the nerve fibres of the retina.

Plate XI., Figs. 1—5. Deep glaucomatous excavations of the optic nerve entrance. These examples of glaucomatous cupped optic nerves are most marked and typical, and should be compared with the two illustrations (Figs. 10, 11) of slight excavation met with in atrophy of the optic nerve.

Plate XII. contains illustrations of numerous congenital anomalies—*e.g.*, colobama of the choroid, the optic nerve, etc.

In conclusion, we must congratulate Dr. Liebreich upon the production of so admirable a work, which not only adds greatly to his reputation as an ophthalmologist, but proves him also to be a most excellent and skilled artist.

The Principles and Methods of Medical Observation and Research, for the Use of Advanced Students and Junior Practitioners. By THOMAS LAYCOCK, M.D., F.R.S.E., F.R.C.P., etc., Professor of the Practice of Medicine and of Clinical Medicine, and Lecturer on Medical Psychology and Mental Diseases in the University of Edinburgh. Second Edition. 8vo. Pp. 403. Edinburgh.

THE great and rapid advance which the science and practice of Medicine has made in the last twenty-five or thirty years has been mainly owing to the ardent and accurate study of pathology in its truest and widest significance. The pure morbid anatomist was too apt to stop short at the lesions discovered when disease had done its worst, to regard the foot-prints of disease as the disease itself; the true pathologist goes further back, and endeavours to trace out and interpret the nature, course, and causes of the lesions found, and combines morbid anatomy and histology with clinical observation, “so as to establish the relations of the changes which lead to the lesions, and so as to connect the general progress of disease with its symptoms and signs. Calling in the aid of inductive reasoning, he seeks to connect causes and morbid effects, and teaches the practical Physician to direct his weapons for prevention or cure against the former, instead of, or as well as, the latter; as consequences, among others, hygiene has arisen and become a “productive” study, constitutional diatheses and cachexiæ are more and more recognised, and studied as causing and influencing disease, and rational Medicine is daily strengthening its claim to be ranked among the sciences.

Dr. Laycock has been one of the earliest and most able and zealous teachers, by precept and practice, of these improvements. He is one of the first apostles of Public Health, ere “sanitary science” had become fashionable. He has studied and reported on some of the gravest epidemics of our day—cholera, purpura, typhus, and influenza. He has, therefore, special authority and information; and this work, which exhibits both, is one of the most valuable of his productions. In our review of the first edition (*Medical Times and Gazette*, vol. xiii., 1856), we expressed our high opinion of its scientific character and philosophical views, and spoke of it “as calculated to advance the science of Medicine in these

kingdoms, and to elevate its professors in public estimation." It naturally follows that we gladly hail the appearance of this second and much enlarged edition. The author's object is to educate and train the student in the use of the inductive logic, "which is [to him] the greatest essential to success, and which can only be attained, like all other arts, by self-culture, under proper training and guidance." He "has taken up some of the more important principles of observation and induction, and in the familiar language of a lecture, and devoid of the technical phrases and methods of systematic writers (which may be learnt best in Mill's system of logic, and other works), so laid them before the student, that, if zealous in self-culture, he may discipline his own mind to a successful encounter with the exigencies of his Profession." In the space that can be devoted in this Journal to a notice of the book we can best give an idea of its scope and value by enumerating the subjects treated of in the several lectures.

Lecture I. is on the "General Principles of Observation and Inquiry;" the "Nature and Acquisition of Experience in Medicine;" the "Combination of Theory with Experience and Observation;" and gives "Illustrations of the Fallacious Use of Theories."

Lecture II. on the "General Method and Objects of Clinical Study."

Lecture III. on the "Methods of Clinical Examination;" and on "Clinical Observation of General or Constitutional Morbid States."

Lecture IV. on "Prognosis and on the Order of Succession of Morbid Phenomena."

Lecture V. on the "Due Estimate of Treatment, and on the Management of the Case."

Lecture VI. on the "Numerical Method of Research in Medicine," with illustrations of its uses.

Lecture VII. on the "Analogical, Philosophical, or Purely Inductive Method of Research," with practical examples.

All these subjects are handled in a manner worthy of Dr. Laycock's reputation as a deep and accurate thinker, of large and extensive knowledge and learning, with broad and liberal views. The importance of sound and careful training and guidance in these matters cannot be too highly exaggerated; such teaching will preserve men from the dangers of the Scylla and Charybdis of too hasty and credulous a belief in the powers of treatment on the one hand, and of disappointment at and scepticism of its efficacy on the other. We consider the teachings on the "Clinical observation of constitutional morbid states," and "the natural order of diseased condition," as of special value, for, to use expressions applied by the author to the laws of vital periodicity, "they are stated or fully treated of in few, if any, of our Physiological and practical works," and "a knowledge of them is at the foundation of all inductions as to the influence of drugs and treatment."

Lecture VIII. is on "The Naming and Classification of Diseases." "Since," as Dr. Laycock remarks, "it is certain that medicine will advance very rapidly, and new forms of disease be discovered," or diseases hitherto confounded together will be separated and differentiated, it is of the utmost importance that men should be instructed in the principles to be followed, and the errors to be avoided in naming new or newly-distinguished diseases, and the principles and rules here laid down appear to be sound and accurate.

Part II. of the work is entirely new, and consists of "Nosologies and Indexes of Fevers, Constitutional Diseases, Diseases of the Skin, Diseases of the Nervous System, and of Mental Diseases and Defects," "the result of long-continued observation and inquiry." Into a critical examination of these we have neither space nor inclination to enter here. It is impossible, in the present state of our knowledge, to produce anything like a perfect nosology, and we are inclined to regard with a jealous eye anything that looks like offering a new nosology for general use at this time, when efforts have been, and are still being made, and not without considerable success, to gain for Dr. Farr's "Nosology and Nomenclature" an European acceptance. But if we understand Dr. Laycock rightly, he allows that the Registrar-General's nosology is one of the most complete in existence, and that, whatever are its acknowledged defects, it must be used for all public purposes. It is true, however, that nosologies may be formed for and "serve very different purposes;" and new ones, we think, should serve at present as private exertations of intellect and tests of the increase in extent and accuracy of our knowledge of diseases. Dr. Laycock has found his "Nosologies

and Indexes" highly useful to himself, and is justified, therefore, in hoping others may find them so also. We will only remark on them that perhaps they betray a tendency to over-refinement of distinction between different forms of disease; and this has brought upon their author an attack in his own University, where a celebrated Surgeon has publicly charged him with having placed in the hands of his pupils a list of 800, or according to a second and amended statement, of 600 fevers! The exaggeration is so gross that its absurdity deprives the charge of all force. It can only be looked upon as a joke played upon the too-credulous Surgeon by some mischief-loving student; or perhaps it owes its birth to an exaltation of intellect pathognomic of some intermittent febrile condition, which Dr. Laycock may add to his list as the febris arithmetica or numeria. Or is it possible that the Surgeon believed the Physician had invented and let loose upon a suffering world this mass of fevers? There is in his speech a pathetic allusion to "the three fevers" of former days which suggests this idea, but we can hardly suspect any Surgeon of the present day of entertaining such a notion, much less the learned and distinguished gentleman in question. Again, perhaps he thought a speech from a Surgeon at the College of Surgeons would be more *Syme-trical* if containing an attack, no matter what, against a Physician? We, with great diffidence, offer these various explanations, for to us it seems that some explanation is needed—for the speaker's sake. We have only space to add that, while Dr. Laycock modestly offers his book "for the use of advanced students and junior practitioners," we think there are not very many of any age or standing in the Profession who might not derive both pleasure and profit from its perusal.

Brevi Cermi sulla Classificazione e Cura delle Pazzie, con Alcuni Dati Clinico-Statistici, nel R. Manicomio di Torino.
Per B. F. AMEDEO, Dottore in Medicina e Chirurgia;
Assistente al R. Manicomio. Torino. 1863.

THIS pamphlet contains a report of the operations of the Lunatic Asylum of Turin, for the year 1862. The establishment is capable of accommodating about 500 insane persons; but it has attached to it an adjunct Hospital, at Colligno, a short distance from Turin, on the line to Susa, which receives about 320 others.

These asylums are both under the care of inspecting Physicians, with acting Physicians and assistant Physicians, a consulting Surgeon, etc. The attendants on the females are Sisters of Charity. Altogether the proportion of attendants upon the tranquil patients is about one to eleven or twelve; among the excited, one to seven or eight.

The report contains elaborate tables of the admissions during the year, from different districts of the country, with the proportion calculated upon the population of each district, and the same arranged as to age, sex, occupation, etc. The forms of insanity are classed under the heads of mania, lipo-mania, monomania, dementia, idiotcy, epilepsy, etc.

The total admissions in the year amounted to 394; the discharges to 208; and the deaths to 203. As, however, we have no statement of the number remaining under treatment at the commencement of the year, it is impossible to calculate the rates of recovery and death. We are, however, told that the cases cured were in the proportion of one-eighth of the men, and one-twenty-fourth of the women. The causes of death are classed under apoplexy, gastro-enteritis, pleuro-pneumony, cerebro-spinitis, etc.

The report concludes with a statement of the treatment pursued; and we observe that, in addition to the Medical treatment, stress is laid upon the necessity of providing recreation for the patients, and especially of occupation; indeed, we are informed that it was mainly in order to afford the means of occupation in the open air, in the fields and gardens, that the adjunct Hospital at Colligno was established.

FRENCH INQUIRY RESPECTING HOSPITALS.—M. Le Fort, so well known here in consequence of the favourable report he made concerning the English Hospitals, and which gave rise to a famous discussion at the Academy of Medicine, has just been despatched by M. Husson, Director of Public Assistance, to investigate the condition of the Hospitals in other parts of Europe, especially in Germany and Russia. Seeing that M. Le Fort's former report conveyed some imputations against French Hospital management, his present appointment is highly creditable to the authorities.

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON A TRICHINA EPIDEMIC AT LEIPZIG.

By Dr. E. WAGNER.

DR. WAGNER observes that this might naturally be expected from the amount of food derived from the pig consumed in the raw state at Leipzig, and from the great number of times in which encapsulated trichinæ have been found in the muscles of persons dying of various diseases. Having met with an instance of this in 1859, he has since then made a point of looking for trichinæ, and has found them in greater or less numbers in between thirty and forty bodies. They were encapsulated and generally calcified, but in every instance but two the trichinæ exhibited signs of life on the application of gentle heat.

Between November 7, 1863, and January Dr. Wagner has had eleven cases of trichiniasis in the living person under his own notice, and he thinks that the symptomatology of the affection is sufficiently distinct now to be able to dispense with exploratory punctures or "harpooning." In almost all these cases the affection remained latent for six or seven days after eating the poisonous food, the earliest symptom being in the mild cases œdema of the face, and in the more severe cases a general febrile condition, accompanied with catarrh of the stomach and slight diarrhœa. Œdema in other parts of the body was only observed in three cases. The muscular pains appeared first in the lower extremities, being increased on pressure or movement. Motion of the limbs after long rest was attended by especially severe pain; but in no cases were these pains so great as to prevent all movement. On palpation the muscles seemed in parts quite normal, and elsewhere somewhat swollen and tense. In three cases only was there pain in eating and speaking and hoarseness of voice. In four of the cases which assumed a very grave character there was considerable fever, the pulse rising from 120 to 140, but in the other slighter cases fever was not present. In two cases in which careful search was made no trichinæ could be detected in the stools. Convalescence was tedious, occupying two or three weeks in slight cases, and six or eight in severe cases, the pains of the extremities long continuing, and the emaciation being great.

Two deaths occurred in the persons of a mother and her daughter. The first of these suffered from severe muscular pains until the twenty-sixth day after the poisoning, when she suddenly died while sitting up in bed; and the daughter died on the twenty-third day, with all the symptoms of severe typhus. At the post-mortem examination, the blood of the various organs was found to be free of trichinæ, nor did hours spent in the search discover any among the contents of the intestine. The muscles contained numerous trichinæ in the encapsulated and partly calcified condition, all being alike. Not only the muscular fibres in immediate contact with the trichinæ, but also others at more or less distant exhibited signs of degeneration.—*Archiv. der Heilkunde*, 1864, No. 2.

[In the last number of Virchow's *Archiv.* (vol. xxix. No. 1) several cases of trichinæ are referred to by Dr. Samter, of Posen, and two are related by Dr. Tüngel, of Hamburg, in addition to others recorded by him. The latter Practitioner believes that the most certain diagnostic signs are those exhibited as the groups of muscles become successively attacked. When these are situated under a fascia, the œdema is felt deep-seated before exhibiting itself under the skin, while when the muscles of the face are affected it at once appears there. This affection of the muscle is especially characteristic when it can be observed from the beginning attacking a spot hitherto unaffected.]

EXCERPTA MINORA.

The Soporific Powers of Lactuca.—Dr. Frommüller, as the result of a trial of various preparations of *lactuca* in 149 cases in which anodynes were indicated, comes to the following conclusions:—1. Of all the preparations of *lactuca*, the *lactucarium* possesses the greatest soporific power—the English and German *lactucarium* being more powerful than the French preparation. The *syrupus lactucarii*, which in France has a great reputation as an anodyne, is a less powerful preparation, while Merk and Ludwig's preparation *lactucin* occupies a still lower rank. 2. *Lactuca* is the least powerful of all the hypnotic drugs. 3. *Lactucarium* to be of use must be given in doses of from ten to thirty grains.—*Deutsche Klinik*, 1862, No. 44.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

CAN any of your readers interpret this somewhat enigmatical advertisement, which I extract from the *Liverpool Mercury* of the 4th inst. :—

"To Ladies.—Dr. _____, London, W.C., corresponds and attends in midwifery. Pregnancy obstructions and all other peculiar cases successfully treated. Apartments if required. Consultations eleven to eight daily."

One can comprehend the assertion that this Dr. _____ "attends in midwifery," but how does he "correspond" in the same, and what does he correspond about, and when does he correspond? It would be rather a protracted midwifery case that would permit a correspondence by letter between Liverpool and London during its progress, and I fear that a series of even the most elaborate telegrams would be, in the estimation of most parturient women, a poor substitute for the services of a Medical attendant. But, perhaps, the "context" may throw some light on this otherwise obscure expression. It appears that *pregnancy* is "successfully treated" by the advertiser. An ordinary Practitioner thinks his treatment of a disease successful when he brings it to a speedy termination. Does the successful treatment of pregnancy bear the same significance here? It would be deeply interesting to know what plan of treatment is followed in these and "other peculiar cases," and which those are for which there are "apartments if required."

It may be that Dr. _____ advertises this in the innocence of his heart, and in blissful ignorance that any woman can be so circumstanced as to desire that a pregnancy should terminate otherwise than naturally or before the full term of gestation has arrived; but, to a woman at her wit's end for an expedient to ward off an exposure which shall take away her good name and blight her prospects, such an advertisement would infallibly suggest one way out of her difficulty—a way which has occasionally brought the patient under the notice of a coroner's jury, and the Practitioner to the bar of a criminal court.

Two cases of death in the Toxteth-park Workhouse came before the coroner on February 27, both illustrating the evils of the system of pauper nursing. The first was that of a poor fellow, a broken-down drunkard, partially paralysed, and nearly imbecile, whose feet were blistered by the injudicious application of a hot water-bottle to them. The blistering ended in gangrene, and the man died. This accident might have happened in any Hospital; but the evidence elicited that the attendance on the sick and lunatics, seventy-one in number, was confided to one man and two assistants, who were themselves sick paupers, and that there were no night nurses at all. The master shoemaker, to whom the supervision of the nursing had been confided at the time of the accident, considered that the assistance he had was ample, and that he could have had twenty more if he had wanted them; a statement curiously at variance with the fact that the governor will not allow the number of nurses represented by the Surgeon himself to be necessary in the fever wards of the same workhouse. The jury, in their verdict, expressed their opinion that there was "gross mismanagement" at the workhouse, and that "the nursing for sick persons was not at all creditable," an opinion in which most who hear of the Toxteth-park Workhouse will coincide.

The second was that of a pauper lunatic, 71 years of age. He was taken one Sunday into the washhouse, and while there nearly strangled a lad who had got the soap and would not give it up. He had retaliated by jumping on the old man's back as he left the washhouse, bringing him to the ground, face foremost, and bruising him severely. He seems to have had every attention paid him after the mischief was done; but the day fortnight following his injury he was found dead.

On making a post-mortem examination, the pericardium was found to contain a quantity of blood, firmly coagulated, and covered by a film of fibrin, on the surface of the coagulum which lay next the heart. Part of the muscular structure was deeply ecchymosed, and in the centre of this bruise was a small hole, not bigger than a pin's head, from which the blood appeared to have exuded. It seems most probable that the ecchymosis was occasioned at the time that the old man was knocked down, and that the hæmorrhage took place but a short

time before death, which was most probably due to the effusion of this blood. There was some effusion of serum on the surface of the brain, and chronic thickening of the membrane. I wonder how long it will be before the improvement in the system of nursing penetrates to the level of pauper Hospitals, or how many victims more it will require before this monstrous evil is redressed?

At the meeting of the Medical Society, on February 18, a remarkable specimen of fracture of the scapula was shown by Mr. Lowndes. The patient from whose body it had been removed was a woman aged 78, admitted into the Northern Hospital, under Mr. Lowndes' care, on December 4, 1863. She had fallen into a cellar, striking upon her shoulder. All over the surface of the scapula crepitus was distinctly perceptible. She did very well up to December 19, when, unfortunately, in lighting something at the fire, she set fire to her clothes, and was so severely burnt that she died next day. The bone was found to have been broken into several distinct fragments, the edges of which were united by firm fibrinous adhesions, visible on both surfaces of the bone. At the same meeting a bladder was shown by Mr. Nash, presenting two very remarkable tumours attached to its mucous surface. The patient from whom it was removed was an ironfounder, aged 40, admitted into the Royal Infirmary, February 4. Three weeks before he had noticed that his water at times dribbled from him, and he suffered slight pain in the back. These symptoms continued, though in varying degrees of severity, until three days before his admission, when he felt "bodily ill," and lost his appetite; but continued at work up to the day of his admission. He stated then that the day before he had passed a few clots of blood with his water. His urine passed from him involuntarily, drop by drop. He complained of pain in his loins. He had a dry tongue, quick pulse, and staggering gait. Very little dulness over the region of the bladder. A No. 9 catheter passed into the bladder failed to draw off any fluid; but on using a large prostatic catheter, two or three ounces of foetid, bloody urine were withdrawn.

The next morning the use of the same instrument brought away nothing but a little blood and some shreds. The patient then passed into a state very like that of continued fever. There was no urinous odour in the breath, no convulsion, and no coma; but a parched tongue, fluttering pulse, muttering delirium, and at the end of a week he died.

Post-mortem.—The body was well developed and very muscular. Both ureters dilated, hypertrophied, and tortuous. The walls of the bladder were thickened, and it contained five or six ounces of urine. At the orifice of the right ureter was a soft tumour, villous on its surface; a probe passed into the ureter traversed the centre of this mass. The left kidney was much enlarged, and its capsule thickened. On removing the capsule, the surface was seen to be dark in colour, but spotted with numerous elevations about the size of peas, some of these coalescing with others. The cortical substance was softened, yellow in colour, and dotted throughout with masses of substance like softened tubercle or thick pus. The medullary substance was intersected by layers of the same material. The cavity of the pelvis of the kidney was dilated. The right presented very much the same appearances. The peritoneum and the viscera were all healthy. No trace of tubercle in any organ.

The real nature of the growths and deposits was doubtless that of soft cancer.

At the following meeting a case of hydrophobia, presenting some remarkable points, was related by Dr. Ewing Whittle. He was sent for early in the morning one day in August last to see a man, aged 35, who was said to be suffering from retention of urine. While on the way, the messenger asked Dr. Whittle if he had ever seen a case of hydrophobia; and on giving his reason for so apparently far-fetched a question, replied that the patient had some difficulty in swallowing. Dr. Whittle found him with a quiet pulse, clean tongue, and no fever; but noticed that about every five minutes a convulsive shudder took place, some of these seizures being more severe than others. He seemed perfectly sound as to his intellect, and said that he felt at each paroxysm as if electrified. Putting a looking-glass before the patient brought on a convulsion, and an attempt to drink a much more severe one. At first he could not remember that he had ever been bitten; but during the day it came to his remembrance that about two months previously he was working at a gentleman's house, and had occasion to go to the water-closet, and that before he had readjusted his clothes a little lap-dog, which had been lying on a heap of shavings in the corner, flew at him: The

animal did not actually bite him, but with one of his fangs inflicted a slight scratch on the end of the penis. The injury was so trifling that he took no notice of it. The scratch healed at once, and the whole matter had passed from his memory. One of his fellow-workmen took upon himself to drown the dog, so that no information could be procured as to its condition.

The remembrance of this circumstance appeared to have a most injurious effect upon the patient. He felt himself doomed, went to bed, took leave of his children, and attempted to read a psalm to them, but was checked by the difficulty of speech which came on him. The paroxysms became more violent; he lay in bed rolling his head from side to side, bespattering the bed with a glairy mucus which constantly flowed from his mouth. His pulse rose, his face became flushed, and he was tormented with the fear that he might bite some one; but he never made the slightest attempt to do so. In consequence of his extreme restlessness, his hands were secured. He continued to suffer till about 36 hours after he was first seen by Dr. Whittle, when he died. It seems that the irritation of the bladder had been felt for two days before Dr. Whittle was sent for, the dread of drinking only on the previous evening.

There have been thus four fatal cases of hydrophobia in this town during little more than six months.

GENERAL CORRESPONDENCE.

THE LITHOTOMY DEATH-RATE OF LONDON AND NORWICH.

LETTER FROM MR. HENRY THOMPSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—Very few words suffice to meet Dr. Richardson's remarks of last week, and these only to correct an absolute misstatement of figures. My refutation of his assertion in the *Medical Times and Gazette* of January 9, 1864, that the death-rate after lithotomy in London is "one case in 1.88," remains, as it must be, unanswered.

I read most carefully what Dr. Richardson wrote; but I went further, and carefully analysed, also, the processes employed. I repeat deliberately that he arrived at the death-rate given above *only by excluding all the patients in the London series below 20 years of age* (instead of below 10 years, as he states). This is a question of figures; here is the proof:

The data upon which Dr. Richardson took his stand were 186 cases of males. Among them there are 49 cases only over 20 years of age, with 26 deaths. Let any reader make the simple calculation necessary, and he will obtain as result a mortality of "one case in 1.88"! It is not possible to arrive at this figure by any other process. Dr. Richardson could not have named that precise decimal unless he dealt with exactly those cases, and with none others. All the circumlocution in the world cannot alter that fact. I say, then, that he represented the rate from these few adults as if it were the average result of London Hospital practice, and contrasted it with the rate obtained from the entire Norwich series, of which one-half were below 20 years of age. This, and nothing else, is the point at issue between him and me, or, rather, between him and the Surgeons of London.

I am, &c.,

HENRY THOMPSON.

March 21.

HOSPITAL MORTALITY.

LETTER FROM DR. T. HOLMES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I should not have written more on this subject, were it not that Dr. Richardson appears to think that I have charged him with something implying want of courtesy on my part, or want of honesty on his. I therefore beg to be allowed to disclaim any such intention. I have said that Dr. Richardson's statistics misrepresent the facts, and I believe that I have proved as much; but I made no charge of wilful misrepresentation. On this matter further argument would be useless. Dr. Richardson's and Mr. Thompson's statistics of death after lithotomy in London can now be compared, and I am confident that only one opinion can be formed from such comparison, by any competent and impartial inquirer. I can with equal con-

fidence trust to the judgment of any such inquirer to say, after personal examination, whether the Norwich Hospital has any advantage in space or ventilation over any London Hospital; and I can trust to any Surgeon (or indeed any person of common sense, and acquainted with lithotomy), to say whether any such advantage, allowing it to exist, could possibly account for a difference of three to one in the deaths after lithotomy?

The other matters which were in dispute between Dr. Richardson and me (*viz.*, the death-rate of Surgical patients, and the number of cases of pyæmia) can easily be settled by a reference to the authorities of the Norwich Hospital. Dr. Richardson put them forward as being matters of considerable importance. If they really are so, it is the more incumbent on him to see that they are accurately stated, and if he finds the contrary, to rectify the error.

I feel that this discussion (which I hope is now closed) has not been barren of results. If it had had no other result than that of eliciting the admirable letter from Mr. Yeo, of the Winchester Hospital, contained in your last number but one, that alone could not fail to fix the minds of your readers on the true cause of the apparently greater healthiness of our county Hospitals.

I am, &c. T. HOLMES.

22, Queen-street, Mayfair, London, W., March 21.

UTERINE DILATOR.

DR. PRIESTLEY'S REPLY TO MR. ELLIS.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—I have read Mr. Ellis's letter in your impression of the 19th inst., and, in reference to it, I have only to remark that I have not seen Mr. Ellis's instrument; nor, indeed, had I previously heard Mr. Ellis's name mentioned in connexion with any form of uterine dilator. Had I been informed that Mr. Ellis had employed an instrument in any degree resembling the one delineated in your pages, I should have deemed it right to notice it in my communication.

I am, &c., WM. O. PRIESTLEY, M.D.

17, Hertford-street, Mayfair, W.

CASES OF SUSPECTED POISONING FROM DISEASED MEAT.

LETTER FROM PROFESSOR GAMGEE.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—If Medical men would favour us with the history of the very numerous cases of sickness which occur, of the class reported by Mr. Kesteven, we should in the course of time accumulate some evidence of value. I have been often told by Physicians and others that inexplicable cases of poisoning by animal food have occurred in their practice, which for want of a satisfactory explanation they had not recorded, and must for ever remain enshrouded in mystery. Dr. Ballard's suggestions may encourage Practitioners to enrich Medical literature with statements of fact, such as Mr. Kesteven's, and good must certainly accrue from this; but I am convinced that the only method of investigation suited to throw light on the effects of diseased meat is the synthetical. We cannot indulge in observations on the human subject, and experiments on the lower animals on the largest scale are imperatively called for. I am aware that very contradictory results will be arrived at, however careful experimenters may be, but in the course of time sources of fallacy would be recognised and avoided.

Referring to Mr. Kesteven's case, I wish to notice some important points. He says, "the meat was not unduly fat." It is not right to infer from meat being fat that it is calculated to induce vomiting and purging. In my frequent visits over the country, especially in Yorkshire, Lincolnshire, Essex, etc. I have frequently noticed how wholesome the enormously fat bacon is, which is often the only animal food to be had in the small farm houses at a distance from large towns. I have suffered with other members of my family from eating pork in Edinburgh not half so fat as that which I have lived on in England, and I attribute this to the disgusting manner in which pigs are fed near this city. Thousands of pigs consumed in our large towns are simply carnivorous animals, and swallow, with the entrails of the diseased animals they are fed on, the germs of parasites, which we contract from them. I have adduced evidence of the decidedly morbid condition of certain pigs, which to all appearance are in the most per-

fect health. Thus, sows fed principally on animal food do not bring forth viable young; and if the piglings ever survive, or very young pigs be bought to be fed, they soon die on the flesh-feeding system. The most robust pigs are often destroyed by eating the carcasses of diseased animals. A few days ago eight or nine died near Edinburgh from this cause; and similar instances—kept quiet, of course, by the pig-feeders—are by no means rare.

What I contend for is, the careful examination of animals in life, and the abolition of all establishments where meat is manufactured so as to render it, in all probability, unwholesome and certainly not very desirable food for man. The plan of inspecting cattle after death, and of examining meat chemically, and even microscopically, though by no means to be condemned, cannot possibly lead us to a knowledge of many conditions which render the solids and fluids of the animals we eat poisonous. Mr. Kesteven examined the joint of pork microscopically, and Professor Taylor analysed fruitlessly for poison. I was consulted with regard to outbreaks of disease in cattle, and sheep, and pigs last summer, in which the flesh of the slaughtered animals looked beautiful. The microscope and chemical analysis would be of no use in detecting the animal poison which pervaded the meat and blood of my patients, but all animals died that licked that blood or ate the flesh in a fresh state. I can say more than this—animals have, to my knowledge, been slaughtered in Edinburgh, Dublin, Newcastle, Leeds, etc., when to all appearance they were in perfect health, having been despatched from farms on which splenic apoplexy was raging, and, though many of the carcasses might have been cut up and eaten with impunity, no one can doubt who has seen pigs stagger and sink in a state of coma, with ecchymoses over their whole bodies, that many a human being has fared likewise.

I do not wish to draw any other than the most legitimate inferences from the facts as they appear before me in the course of my inquiries into the origin and nature of the disease of animals; but, with the vast amount of ignorance prevailing as to the causes of the most common human disorders, I am, I believe, entitled to hold that etiological blunders are not rarities, and scepticism is often pushed too far. Recently, a letter appeared in the *Medical Times and Gazette* commenting on the cause of death in man from inoculation with the virus of a diseased animal. That that case was one of true malignant pustule I am firmly convinced, and the pigs which eat of the bull that the poor man slaughtered died. I quoted the words of the Medical attendant, to the effect that the victim of the accident was an intemperate man, but I learn that he was not such a subject as the bloated London draymen, whom we know to suffer severely from the slightest wounds. The man got occasionally drunk when he could get drink, but he had long been too poorly paid as a labourer, having also a large family, to have it in his power to drink much or often. Concerning braxy, allow me to state that in the mountain districts of France, Switzerland, Italy, Spain, etc., human beings dare not touch, much less eat, sheep that die of the same malady as the braxy of Scotland. This fact affords us an admirable example of the difficulties attending the investigation of diseases transmissible from animals to man, and which at one time can be thus transmitted, and at another not. Anthracic diseases are unquestionably more readily communicated to human beings in many parts of the Continent than they are here, but even abroad the most singular discrepancies in the observations of Practitioners cannot fail to strike the student of Medicine.

Returning to Mr. Kesteven's case, it is important to notice that the joint of pork was "underdone and red." Animal poisons are usually, not always, destroyed by good cooking, and it is the duty of every Physician to combat the prevailing notion that underdone meat is more digestible and nourishing than well-cooked food. We must trust much to the fire in purifying our food, and we shall always have to rely on it to a great extent. Allow me, however, to suggest that Medical men should err on the safe side whenever consulted as to the wholesome or unwholesome character of the flesh of diseased animals, and if a committee of scientific men were appointed at present to determine whether the wholesale slaughter of diseased animals at present going on should be permitted, although positive proof of ill effects would be scanty, the presumptive evidence would be so strong as to lead to a very decided conclusion in favour of doing all that is possible to check the progress of diseases which are leading to the contamination of our meat markets. It is clearly the duty of every Medical Officer of Health to act as Dr. Letheby does

in the City of London; but to check the traffic in diseased meat we require measures such as those now before the House of Commons, and I do trust that the influence of the Medical Profession throughout the country will be brought actively to bear so as to ensure a good start to a new and wholesome system of cattle disease prevention. Such a system will not be amongst the most trivial of the sanitary reforms of the present century.

I am, &c.,

New Veterinary College, Edinburgh, JOHN GAMGEE.
March 7.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 23.

Mr. PRESCOTT HEWETT, President.

MR. SYDNEY JONES brought forward a boy who had
NUMEROUS EXOSTOSES.

They were very numerous, and were situated chiefly on the lower extremities; but there were some on the ribs and on the bones of the arms. They were symmetrical. Mr. Jones said that, as the boy's parents would not permit any operation to be performed, dilute nitric acid was given internally, and, he thought, with some benefit. None of the exostoses were larger, and some were certainly smaller.

Mr. W. ADAMS referred to cases of multiple exostoses under his care at the Orthopædic. They were, he said, invariably symmetrically placed and symmetrically developed. He had never given nitric acid. In ninety-nine out of one hundred the growth spontaneously ceased. He had seen cases ten years after they had ceased to grow. If an acid were to be given, he should, on theoretical grounds, prefer the phosphoric.

Mr. SYDNEY JONES said that he commenced the treatment by phosphoric acid; but he was found fault with for using it. It was said that if there were an excess of lime in the system, the acid would form with it phosphate of lime, and thus furnish more material for deposition.

Mr. HULKE said that the growth of the exostosis was due to the cartilaginous layer over it rather than to an excess of earthy matters in the system.

Mr. SYDNEY JONES thought that if there were an excess of phosphate of lime in the blood, the tendency to the increase of the exostoses would be greater.

Dr. SANDERSON suggested that it would be well to give distilled water in such cases.

Mr. BROOKE asked if lactic acid had been tried, as it was said that lactic acid removed excess of phosphate of lime.

Mr. SQUIRE exhibited

A MALE GRAB LOUSE.

This was a rare specimen, as Kuchenmeister had only examined females, and Moquin Tandon makes no mention of the male. The male differs considerably from the female. Mr. Squire also exhibited a photograph taken from the microscope, and suggested that more use should be made of photography to delineate microscopical specimens in pathology.

Mr. HY. SMITH exhibited

PARTS REMOVED IN EXCISION OF AN ANCHYLOSED KNEE.

A soldier was shot in the knee-joint at Inkermann. Violent inflammation followed, but he at length recovered with a stiff knee, and was enabled to act as a Commissionaire for six or eight years. At the end of this time inflammation again set in. When Mr. Smith again saw the patient the limb was bent nearly at a right angle, and was nearly useless. Mr. Smith removed a wedge of bone, and thus restored the limb to the straight position. He was able to remove just enough to get the leg straight by the two incisions necessary to cut the wedge. The patient, a tall, healthy man, recovered. His limb was quite ankylosed, and he was now overlooker at a mine in Wales, and could walk twelve miles a-day.

Mr. HY. LEE said that excision of the knee-joint was not so successful in adults as in children. He had recently removed a segment from the ankylosed knee of a child with an excellent result.

Mr. HY. THOMPSON thought the case should scarcely be called one of excision of the knee-joint.

The PRESIDENT remarked that the operation was rather to be thought of as one of excision of bone than as an excision

of a joint. The joint was quite gone, all the parts being fused together.

Mr. TEEVAN exhibited

AN OBTURATOR HERNIAL SAC.

It was taken from the body of an adult male which came into the dissecting-room at Westminster Hospital. The sac was about an inch long, quite empty, and had protruded before it a considerable piece of the subperitoneal fat. There was also in this subject extensive tubercular affection of both lungs, together with a scirrhus cancer of the rectum.

The PRESIDENT then related a case in which a patient with symptoms of strangulation, and who had protrusion of the femoral ring, was operated on, as for femoral hernia, but no intestine was found. The symptoms continued, and the patient died. At the autopsy, strangulated obturator hernia was found. The President remarked that Mr. Obré was the first to diagnose strangulated obturator hernia during life, and thus to save the patient's life.

Dr. MURCHISON read a report on Mr. Pitt's case of obstruction of the bowel by a concretion. The concretion contained a good deal of cholesterine, and was no doubt of biliary origin. Dr. Murchison also showed another like specimen, by which the small intestine had been obstructed; but in this case there was a fistula between the duodenum and the gall-bladder.

Dr. DICKENSON showed a piece of bowel from a patient who died of

TYPHOID FEVER.

A boy, a sweep, died of typhoid fever on the sixth day. He had had no spots, but diarrhœa and abdominal tenderness. All the solitary glands in the small intestines were in a state of great prominence, nearly as large as peas; they had large, round heads, and narrow necks. Peyer's patches were swollen, and one or two were ulcerated near the valve.

Dr. MURCHISON did not think such appearances rare in typhoid. In some cases Peyer's patches, in others the solitary glands, were chiefly affected. Such a condition of the solitary glands had led some to compare it with variola.

Dr. MURCHISON exhibited a specimen of

ABSCESSSES IN THE KIDNEY FROM A PATIENT WHO HAD HAD TYPHOID FEVER—PYÆMIA (?).

The patient, a girl, aged 19, died on the forty-second day. On the thirtieth day she was well of the special typhoid symptoms, but still did not get on, but became more and more emaciated; but she had no rigors, and none of the ordinary symptoms of pyæmia. After death, ulceration of the intestines was found, presenting good specimens of the atonic ulcer. The spleen had returned to its natural size, and the mesenteric glands were not enlarged. In the kidneys were several small abscesses. There was no other evidence of pyæmia.

TESTES FROM AN HERMAPHRODITE SHEEP.

Dr. WILKS exhibited some testes which had been given him by Mr. Turner, of Bermondsey, and which had been taken from an ewe sheep. The animal had always been regarded as a female sheep, and was cut up as such by the butcher. The testes were found in the groin. Each consisted of two rounded bodies placed one over the other; the lower was evidently an undeveloped testis, but the upper was of a more doubtful nature. It contained several large tubes, and Dr. Wilks thought it might be the remains of a Wolffian body. The vas deferens ended in a blind extremity. Dr. Wilks alluded to the fact of too much stress having hitherto been laid upon the fact of an animal possessing undeveloped testes as determining the sex. A more modern investigation, such as that of Mr. Curling, had shown that a testis retained in the body, and of the character described, was functionally powerless, and thus its possessor might have none of the attributes of the male sex. What was remarkable, however, was the fact that in such instances the animal often put on the character of the female. It was so in the present example. John Hunter had remarked the same in oxen, and in the human subject similar cases had been observed. Dr. Wilks mentioned the instance of a person who possessed every feminine quality except the essential sexual character, and yet in this person undeveloped testes existed. Although she had always been considered a woman by herself and friends, she was now (as regards the undeveloped organs) to be placed in a bottle, and ticketed as a male. There did not seem sufficient reason for so doing. Although the poet Tennyson had declared that "Woman was not undeveloped man, but diverse," this doctrine had not been physiologically proved.

Dr. WALE HICKS exhibited a specimen of

MALFORMATION OF THE GREAT VESSELS.

This specimen was taken from a child who died on the fourth day. The true aorta, arising from the left ventricle, was small, and gave off only the innominate and the left carotid and subclavian arteries, while the artery given off from the right ventricle was very large, and after giving off the pulmonary arteries, was continued over the left bronchus as the descending aorta. The septum ventriculorum was perfect. The same child was the subject of crania bifida, a circular opening in the occipital bone forming a communication between the cranial cavity and a sac formed of dura mater, lined by serous membrane, and containing fifteen fluid ounces of blood-stained serous fluid.

Dr. GIBB exhibited for Dr. Grant, of Ottawa,

A DRAWING OF THE HYPOGASTRIC REGION OF A LAD AGED 20, with eversion of the bladder, absence of the normal umbilical cicatrix, and deficiency of the corpus spongiosum. There was constant dribbling of urine, and consequent irritability of the surrounding skin. Directly above the pubes was a projecting growth, red, villous, and exceedingly vascular, three inches broad, and divided into three lobes, the whole structure arising from eversion of the bladder. The penis was rudimentary. There was a congenital inguinal hernia of the left side, and both testes were normal, and so was the body in other respects.

Mr. HINTON exhibited a specimen from a case of

LARGE AURAL POLYPUS.

The specimen was taken from a man, aged 42, who died from an injury. A fibro-cellular growth occupied the whole meatus of the left petrous bone, and protruded from its orifice. It was attached to the periosteum of the canal at its superior part, but took its origin chiefly from the cavity of the tympanum, which it seemed entirely to fill, being attached to the whole of its walls except the inner surface of the membrana tympani, the upper third only of which was destroyed. The Eustachian tube was not obstructed, but the growth was attached all around its tympanic orifice. The upper portion of the mastoid cells also were filled with a similar fleshy mass. There was no disease of the bone. The right ear was healthy.

Mr. HINTON showed also

THE PÉTROUS BONES TAKEN FROM A BOY, AGED 16, WHOSE SKULL HAD BEEN FRACTURED BY MACHINERY.

In this case the line of fracture passed from near the left orbit through the petrous bone of the opposite side (the right); it took the line of the Eustachian tube, and the membrana tympani was separated from its attachment to a small extent at its most superior part. There was profuse bleeding from the mouth and from this ear. From the other ear also, although not at all implicated in the fracture, a few drops of blood had escaped; and on examination it appeared that the membrana tympani had been detached in exactly the same spot as on the opposite side, thus indicating a line of force traversing the skull on this side corresponding to the direction taken by the fracture on the other.

HARVEIAN SOCIETY OF LONDON.

At a late meeting of this Society, Dr. WADHAM, Vice-President, in the Chair, a paper was read by Dr. CHARLES DRYSDALE ON

EVIDENCE AGAINST THE INTERNAL USE OF MERCURY IN SYPHILIS AND OTHER DISEASES.

The author first pointed out the difficulty there exists in proving any drug to be a specific. We could (he observed) understand the action of Epsom salts or chloroform, because we know how they acted upon human beings in health; but, with the exception of quinine in ague, we had perhaps no undisputed antidote for any diseased condition. He quoted from Mr. J. S. Mill to show how difficult it is to treat disease experimentally. Skey, Desruelles, Copland, etc., had shown that mercury has the power of causing caries of bones and complete degradation of the body, both in human beings and in dogs. Of all the properties assigned to mercury, the only one which it undoubtedly possessed was that of acting as a purge, and, from its bad effects upon some individuals, it was evidently a bad purge. Mercury was called a cholagogue, but recent experiments on dogs had proved that calomel actually diminished the biliary secretion. The use of calomel

and opium was now abandoned by the best Surgeons in all traumatic cases and in peritonitis. In iritis, mercury had been shown to be useless, and probably injurious, by Hugh Carmichael, Dr. Williams, of Boston (who treated sixty-four cases of iritis without it, sixty of which recovered perfectly), by Dr. Hughes Bennett, and by Mr. Zachariah Laurence. Mr. Acton, too, confessed that he thought that syphilitic iritis was frequently produced by courses of mercury. As to pericarditis, forty cases, published by Dr. Taylor, of University College, had proved the evils of salivation, and its inutility. In acute hydrocephalus, again, there was reason to believe that the great mortality of the complaint was partly to be attributed to the mercury and bleeding employed. As to mercury in bronchitis, pneumonia, and pleurisy, there had lately been 150 cases of uncomplicated pneumonia consecutively treated in Edinburgh by Professor Hughes Bennett without mercury or bleeding, all of which had recovered. Dr. Walshe held that mercury did harm, not good, in inflammatory complaints; and Dr. Hughes Bennett considered mercury always to be an evil, and that it should never be administered in any disease. Passing on to the citadel of mercurialists—syphilis—he said he agreed with Syme, Ricord, etc., that ulcers on the genitalia and eruptions had always existed, although Celsus was unaware of their sequence. He quoted Dr. Wm. Fergusson's works of 1812 and 1846, showing how many thousands in the British army had recovered from primaries and secondaries without ever having taken a particle of mercury; and how dreadfully the army had suffered in Portugal from the effects of mercurial inunction. Next, from Mr. Guthrie, late President of the College of Surgeons, to show that all ulcers of the organs of generation recover without mercury. Of 407 cases treated by Dr. Hennen, iritis occurred in 1; exostosis in 1; and no case of nasal bone affection occurred without mercury. In 1818, and subsequently, Dr. John Thompson had in Edinburgh treated a large number of cases of venereal disease among the troops, and the only symptoms observed were sore throat and eruptions, slight, though somewhat tedious, and all recovering perfectly without mercury. He had not had any deep ulcers of the skin, or bone disease, as when mercury was used. Dr. Desruelles had, in the Val de Grace Hospital, treated a large number of soldiers from the year 1819 to 1841 without mercury with the best results. He mentions that up to the year 1841 upwards of 300,000 cases so treated in England, France, Germany, and Sweden had been recorded. Dr. Fricke treated, in the Hamburg Hospital, from 1824 up to 1844, 15,000 cases of all kinds of venereal disease without mercury. In his work, published in 1828, he says of the cases therein mentioned, that iritis had not occurred, nor any case of bone disease, or deep ulcers of the skin, which affections were very common when mercury was used. His treatment consisted of cleanliness, low diet, and external application, with Epsom salts as a purge. Dr. Drysdale mentioned the large experience of the Swedish Government, where 46,687 cases were recorded, and where non-mercurial treatment had proved far the more successful. 5271 cases recorded by the French Council of Health had shown a result of one or two cases of exostosis, no caries. M. Ricord had founded a new school, which gave in indurated sores a six months' course of a daily dose of mercury, followed by three months of iodide of potassium, to act as an antidote to the poison. Dr. Drysdale quoted from Mr. Syme how "a fearful system has recently been founded on the ruins of the mercurial delusion." Mr. Syme says that the natural history of syphilis, where treated by hygiene and external applications, without mercury, is that of a very slight disease; and Professor Hughes Bennett says:—"The idea that mercury is an antidote for the syphilitic poison, and the incalculable mischief it has caused, will constitute a curious episode in the history of Medicine at some future day." Mr. Weeden Cooke and Mr. Spencer Wells both attribute the bad tertiary effects in syphilis to the use of mercury—not to the natural disease. Professor Boekh's (of Christiana) experiments, published in 1863, show that 1008 cases of primary disease and secondaries, treated with calomel and iodide of mercury, required, on an average, sixty-two days for treatment; whilst 611 similar cases, treated with Epsom salts and external applications, required only thirty-eight days. Also, when primary sores were treated with mercury, 24 per cent. had secondaries, and, when treated without mercury, 14 per cent. only. The United States Army direction had recently forbidden the administration of calomel, which was (Dr. Drysdale remarked) the result of their conviction of its inutility; and Dr. Diday was now treating most cases of

secondary syphilis without mercury, and had recorded the dreadful effects of M. Ricord's plan of treatment in causing mania, apoplexy, dyspepsia, and frequent salivation. MM. Cullerier, Fournier, and others in Paris, with whom he had conversed, have abandoned mercury in treating all primary sores, and await the eruption, which (Dr. Drysdale said) he hoped was but the prelude to giving up the drug altogether, and returning to the rational, or non-specific treatment, which was so superior in its results. The author said, of infantile syphilis—(1), he thought it very frequently the result of mercurio-syphilis in the parents; (2) it was injured, instead of benefited, by mercury, as recently proved by Mr. Allingham and himself.

Mr. ZACHARIAH LAURENCE said, in referring to his paper "On the Treatment of Inflammation of the Eye by Morphia," in the *Edinburgh Journal*, that, in his opinion, the greater part of these inflammations originated in irritation of the branches of the fifth nerve, to which the congestion of the blood-vessels was but secondary. As familiar illustrations of this, Mr. Laurence alluded to the act of blushing, and the congestive conditions of the cheek following severe neuralgia of the part. The so-called absorbent powers of the combination of mercury and opium he considered a natural consequence of the subsidence of the inflammation, altogether independent of the specific action of either of the drugs. He lastly called attention to the fact, that the advocates of mercury employed three agents in their "experimental" inquiries:—1. Mercury. 2. Opium. 3. Nature. To which of these three should we ascribe their results? Mr. Laurence agreed with the views of Dr. Drysdale in ascribing them to the latter. At any rate, the non-mercurialists had the advantage of simplicity, inasmuch as they only employed one agent—Nature—in their inquiries.

Mr. SEDGWICK was quite disposed to agree with Dr. Drysdale, especially in regard to syphilis. He had had considerable experience of the non-mercurial treatment of this disease, having been assistant to the late Mr. Morton, of University College, for upwards of a year, when that gentleman treated a large number of cases with Epsom salts and external applications with the greatest success. Subsequently, when Surgeon to the 70th Regiment, he had treated many cases of syphilis, and found the disease quite amenable to hygiene and external applications. In fact, he considered that we ought to look on the eruption as a means of getting rid of the poison, and not treat it as in any way a grave disease.

Mr. DE MERIC said the Society ought to be much obliged to Dr. Drysdale for the elaborate collection of evidence produced on his side of the question. The author had, however, shaded his picture too deeply, and the arguments reminded him of those used against alcohol, which resulted in failing to convince, for people still partook of it. It must not be supposed that, because such an array of facts can be brought against the use of mercury, therefore there is nothing to be said on the other side. He objected to the appellation of *mercurialist* as being applied to a Practitioner who was in the habit of giving mercury, when experience had taught him the case required it. Men of experience use the drug because they have found it produce good effects, and, when carefully used, no bad effects. Did they think that any man would go on giving it if he found it injurious? With regard to the experiments quoted, from the time of Fergusson and Guthrie down to that of Fricke and Desruelles, they were valueless, because these writers did not discriminate the cases treated. Practitioners would not now give mercury in the majority of the cases mentioned. And as to bone disease being caused by mercury, he had seen destruction of the nasal bone when no mercury had been taken; and, indeed, in some cases, periostitis had been the first secondary symptom, leading on, in some cases, to a fatal result. Phagedæna, too, is due to dirt, neglect, and intemperance, not to mercury. Hereditary syphilis had been said by some not to require mercury, and to be caused by mercurio-syphilitic disease of the parents; but he had recently shown that children of syphilitic parents may be born perfectly healthy. With regard to an argument in Dr. Drysdale's elaborate work on the subject of the paper, viz., on the treatment of syphilis, etc., without mercury, which he had had the advantage of reading, that there had recently appeared to him in the Paris Venereal Hospital very few bad cases of syphilis compared to what he used to see, which he ascribed partly to the fact that Cullerier and all the present school had left off mercury for primaries, he considered this a most unwarranted inference.

Mr. LANE, after complimenting the author on the mass of evidence on one side of the question, said, if authorities were

necessary on his side, he could point to Lee, Langston Parker, etc. If there was one fact better ascertained than another in modern Surgery, it was the necessity of administering small doses of mercury in syphilis. The indurated sore is much benefited by it, and there can be no doubt of its utility in secondary symptoms, which disappear rapidly when mercury is administered. In the tertiary symptoms, however, it should not be used. With respect to bone disease, he could corroborate Dr. De Meric's statements, for he had seen bone disease where no mercury had been taken by the patient. He thought mercury also most valuable in cases of infantile syphilis, especially in inunction.

Mr. WEEDEN COOKE observed that the error of Practitioners lies in considering mercury to be a specific for syphilis. Were it merely given in an occasional dose to promote the elimination of the poison, he would not find any fault with the practice. He thought we ought to consider syphilis as an animal poison, and that the eruption is the cure of the disease. In most cases the skin and liver act well, and completely eliminate the disorder if let alone; whilst, when mercury is used, the eruptions return indefinitely. As to the term "mercurialist," complained of by Dr. De Meric, being a reproach, he might remind him that he (Mr. Cooke) had suffered under the appellation of non-mercurialist, which at present was considered a reproach, although he held the contrary opinion. He complimented the author on his boldness in bringing this subject so prominently before the Society. He had scarcely been bold enough to do so.

Mr. ALLINGHAM said: In the first place, what we now want is to know the natural history of syphilis, *i.e.*, what the disease will result in when not interfered with by so powerful a drug as mercury. For his own part, he had for a long time treated all primary sores without mercury; and, although not so rooted an anti-mercurialist as the author, he must say he believed that all forms of syphilis could be successfully treated by means of hygiene and local applications, and without mercury. As to infantile syphilis, he had been so discontented with the mercurial treatment of that form of the disease, that he had made some researches upon the subject, which resulted in the discovery that 29 per cent. of deaths took place under this kind of treatment. He had therefore abandoned it, and now gave only chlorate of potash; and he had treated twenty-three cases in this way, with very excellent results; out of fifteen cases, all got well except one.

OBITUARY.

MR. RALPH ALLEN FROGLEY.

THE subject of this memoir, Ralph Allen Frogley, of Hounslow, the son of a Surgeon residing in that town, was himself educated for the Medical Profession, pursuing his studies at the Windmill-street School and at St. George's and the Westminster Hospitals. He became a member of the College of Surgeons in the year 1812, and in consequence of the failing health of his father, was obliged at once to commence the active practice of his Profession. So great was his energy and determination of character, combined with rare Professional knowledge and skill, gentlemanly manners, and an address which inspired confidence, that he speedily established himself in a lucrative and extensive practice, which he carried on alone until the year 1839. Many eminent men were his pupils, among whom we may mention Mr. Samuel Lane and Dr. Emmet, of Egham, the latter of whom he took into partnership. Subsequently, on the retirement of Dr. Emmet, he was associated for a short time with Mr. Benfield, now one of the Surgeons of the Leicester Infirmary. From 1849 to 1854, Dr. Hall, of Brighton, was his partner, who was succeeded by Mr. Douglass and Mr. Bullock, who now carry on the practice. Mr. Frogley was well known as a skilful operator and successful Accoucheur; in evidence of the former it may be mentioned that, among other operations, he tied the carotid and femoral arteries, cut for the stone, and on one occasion operated for hernia, and amputated the thigh close to the hip-joint, the patient being the subject of enchondroma. The limb removed weighed upwards of a third of the body. The case is recorded in the *Medico-Chirurgical Transactions*, and the patient is still alive. So successful and popular was he that he was often consulted in difficult cases of all kinds by neighbouring Practitioners, and the name of Frogley was well known for many miles around Hounslow. He held at various times numerous public appointments, including that of Medical

Officer to the parishes of Feltham, Bedfont, Norwood, Hanworth, Heston, Cranford, and Harlington, and the School of St. George's and St. Giles's, Bloomsbury, at Heston, and was also Surgeon to the T division of police, and to the extensive powder mills of Messrs. Curtis and Harvey.

Mr. Frogley was universally beloved by all classes of his patients; to the poor he was especially kind and attentive, never allowing social *status* to make the slightest difference in his treatment of a case. In spite of the arduous duties of a large practice, he for many years cultivated a considerable farm, and was known as a first-rate judge of stock. The town of Hounslow is mainly indebted to Mr. Frogley's energies and exertions for the erection of a town-hall.

In 1853 he was elected a Fellow of the College, and on March 15 in the present year he died at Brighton from anasarca and congestion of the lungs, the results of valvular disease of the heart.

NISI PRIUS COURT.—(Before Mr. Baron BRAMWELL and a
Special Jury.)

MILLETT v. EDMONDS.

MR. COLERIDGE, Q.C., Mr. H. T. Cole, and Mr. Bullar were counsel for the plaintiff; and Mr. Karslake, Q.C., and Mr. Kingdon for the defendant.

The declaration alleged that the defendant had maliciously and without probable cause made an information before the Recorder, Mr. Tonkin, imputing to the defendant that he had maliciously administered poison to Jacob Curnow Millett, with intent to cause his death, and that he had so caused his death; that an application was made to the Secretary of State for an order for the exhumation of the body; that the charge was pursued before the magistrates; that the case was heard for many days, and resulted in the discharge of the plaintiff.

The case, as may be recollected, created a great sensation at the early part of this year. The plaintiff was Richard Oke Millett, and was a member of the College of Surgeons. The defendant was also a Surgeon residing in London, and had married the sister of the plaintiff. The action was brought to recover damages for a malicious prosecution, which charged that the plaintiff had caused the death by poison of his own brother, Jacob Curnow Millett. The charge was made in the most deliberate manner, and was persisted in. The deceased resided with his brother, the plaintiff, at Penpoll, in this county. There had been an estrangement in the family, in consequence of the marriage of the plaintiff's sister with the defendant. Jacob Curnow Millett was of peculiar habits, had water on the brain, and was a man of very generous habits and strong religious feelings. Last year he had been failing, his eyesight had become impaired, and he complained much of his head, and could take but little exercise. In February, 1863, he altered his will, and bequeathed everything to the plaintiff. On December 30 he partook of a very hearty dinner, and afterwards complained of feeling "sinking." The plaintiff gave him brandy, and he said he thought he felt better, but complained of cold. In the course of that evening it was evident that he had a seizure, and in a few hours he died. The plaintiff then sent for the coroner and the undertaker. An inquest was held, and a verdict was returned that the deceased had died from natural causes, and he was in due time buried, but in a short time the defendant applied to the Secretary of State for an order for the exhumation of the body. This was granted, and on January 22 the plaintiff was arrested by two policemen on a charge that he had poisoned his brother; he was the next day taken before the magistrates at Hayle, where a large mob had collected. He was taken before the magistrates four times, but he was detained in custody all the time, as bail was refused; he was fourteen days in custody, but eventually he was discharged, and he then brought this action.

The plaintiff was examined at very great length, and he swore that there was not the slightest pretence for saying that he had anything to do with his brother's death or his uncle's death. His uncle was found dead in his bed. He found his father dead in his bed. His sister Jane had been found dead in her bed by his sister Caroline, who slept in the same room.

Dr. Taylor was called, and stated that he examined the viscera of the deceased, which were sent to him, and he could not detect any symptom of poison, nor the effect of any. The appearances were quite consistent with death having

arisen from natural causes. The circumstances attending the death also led to the belief that death had arisen from natural causes. A copy of his report had been sent to the Secretary of State. He believed the deceased had died from pressure on the brain, from the serum found in the ventricles of the brain. The pain in the stomach of which the deceased had complained was to be accounted for by the hearty meal he had made. It was not a symptom of narcotic poisoning.

Several Medical men (amongst whom were Drs. Barlow and Wilks, of Guy's Hospital) were examined, who agreed in the view taken of the case by Dr. Taylor.

The defence was that, in consequence of the sudden deaths of several members of the family, there were rumours in the neighbourhood which had at last reached the defendant, and that he had thought it incumbent on him to cause an investigation; that he had acted perfectly *bonâ fide* in the matter, and had not been actuated by any ill will or malicious motive towards the plaintiff. In his examination, the defendant stated that, although at the time he considered there were sufficient grounds for the course he had adopted, yet he was now fully convinced of the plaintiff's innocence of the charge.

Mr. Baron Bramwell, in summing up, observed that it was impossible not to say that the plaintiff had been entirely acquitted of the charge which had been made against him. He was acquitted on the evidence of some of the most eminent authorities in the world, and on the statement of the defendant himself.

The jury having retired, returned a verdict for the plaintiff—Damages, £400.

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON,
1864.—Examination for the Degree of Master in Surgery:—

PASS LIST.

Richard Whitfield Hewlett, M.D., King's College; Walter Rivington, B.A., M.B., London Hospital; Rickard Patrick Burke Taaffe, M.B., St. Bartholomew's Hospital.

HONOURS LIST.

First Class.—R. Whitfield Hewlett, M.D. (Scholarship and Gold Medal), King's College; Walter Rivington, M.B. (Gold Medal), London Hospital.

This was the first Examination for the M.S. Degree in this University.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a General Meeting of the Fellows, held on Monday, March 21, 1864, Thomas Watson, M.D., F.R.S., was unanimously re-elected President of the College for the ensuing year.

At the same Meeting, the following Gentlemen, having undergone the necessary Examination, were duly admitted Members of the College:—

Frederic Bagshawe, M.B. Cantab., 21, Connaught-square; William Henry Witherby, Coombe, Croydon; and James Alexander Grant, M.D., Montreal, Ottawa, Canada West.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 17, 1864:—

Joseph Morris. Studley, Warwickshire; Edward Peter Shorland, Westbury, Wiltshire; Daniel Iles, Fairford, Gloucestershire; John Hargreave Wraith, Over Darwen, Lancashire; Charles Richard Price, London Hospital; William Garlick, Park-square, Leeds; Harvey John Philpot, Wilton-terrace, Kensington; William Gandy, South-street, Park-lane; Algernon Newbegin Watts, Westminster Hospital; John Henry Edwards, Llangefin, Anglesea; Walter Whitehead, Windermere; Edward Colden, St. George's Hospital.

The following gentleman, also on the same day, passed his First Examination:—

Frederic George Denton, Hornsea, Hull.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BECKETT, A. R., L.F.P.S. Glasg., has been appointed one of the Resident Medical Officers of the Liverpool Workhouse and Fever Hospital.

BELLAMY, EDWARD, M.R.C.S. Eng., has been app. inted Surgical Registrar to King's College Hospital.

CRUCKNELL, H. H., M.B., has been appointed Physician to the Great Northern Hospital, Caledonian-road.

ELLIS, JAMES, M.R.C.S. Eng., has been appointed Resident Medical Superintendent of St. Luke's Hospital for Lunatics.

HARDESTY, JAMES JEFFREY, L.R.C.P.E., has been appointed Medical Officer and Public Vaccinator for the Parish of Garwald, Haddingtonshire.

HARGOOD, FREDERICK H., M.R.C.S. Eng., has been appointed Medical Superintendent to the Royal Lunatic Hospital, Liverpool.

HEAD, EDWARD, M.B. Lond., has been elected Physician to the Surrey Dispensary, Great Dover-street.

KILGOUR, ALEXANDER, M.D. Aberd., has been appointed Consulting-Physician to the Aberdeen Royal Infirmary.

MITCHELL, THOMAS R., M.D. St. And., has been appointed Admiralty Surgeon and Agent for Swanage.

MORRIS, JOHN G., M.R.C.S. Eng., has been appointed one of the Visiting Surgeons to the Hereford Dispensary.

MONCKTON, ALFRED, M.R.C.S. Eng., has been elected Medical Officer and Public Vaccinator for Nos. 6 and 7, or Brenchly and Horsmonden districts, of the Tonbridge Union, Kent.

NAYLER, GEORGE, F.R.C.S. Eng., has been elected Assistant-Surgeon to the Orthopædic Hospital.

REITH, ARCHIBALD, M.D. Aberd., has been appointed Physician to the Royal Infirmary of Aberdeen.

SCOTT, NATHANIEL G., M.R.C.S. Eng., has been appointed Resident Medical Officer to the City of London Hospital for Diseases of the Chest, Victoria-park.

SMITH, J., M.R.C.S. Eng., has been elected Resident Medical Officer to the Notting-hill and Shepherd's-bush Dispensary.

DEATHS.

BOND, HENRY, M.R.C.S. Eng., at Euucha, Australia, on January 2, aged 40.

KING, GILBERT, M.D., Inspector-General of Hospitals and Fleets, R.N., at 38, Gibson-square, Islington, N., on March 18, aged 73.

MACARTNEY, JOHN, L.R.C.S.I., Staff Assistant-Surgeon at Barbadoes, on January 30.

MACKENSIE, THOMAS, C.B., late Inspector-General of Hospitals, Bombay, at 2, Segrave-villa, Cheltenham, on March 17.

SYKES, JOHN, M.R.C.S. Eng., at 252, Mile End-road, E., on March 17, aged 42.

TOBIN, DR. JOHN KELLY, at Brussels, on February 17.

THE CORNWALL LUNACY CASE.—The trial of Samuel Porter, of Flushing, near Falmouth, for maltreating and wilfully neglecting his brother, Robert Porter, a lunatic under his charge, was concluded on Thursday, March 17, before Mr. Baron Martin, at Bodmin. The case, it will be recollected, created a great sensation a few months ago. It is sufficient to say that all the allegations as to the horrible condition of filth and neglect in which the lunatic existed when discovered by Dr. Byrne were entirely proved by the evidence of the Commissioners and himself. The jury found the defendant guilty of neglect, but added the following extraordinary and disgraceful clause to their verdict:—"That they recommended him to mercy, on the ground that they did not think he was aware of the law." Sentence was postponed till the opinion of the Court of Appeal shall be known on a point of law raised by the defendant's counsel. It was urged by his counsel that the statute under which the indictment was drawn referred only to persons keeping asylums or taking in lunatics for hire; and a case was cited which was allowed by the Judge to have some bearing on the question, in which it was decided that a husband could not be considered to have "care and charge of a lunatic wife within the meaning of the statute, as such a charge was only of a domestic nature." If this be valid law, the very fact of the relationship of the prisoner to the poor wretch—a circumstance which, if anything can do so, enhances tenfold his barbarity—places him out of the reach of retribution. Such a miscarriage of justice is not unlikely, for the man has been discharged on his recognisances to appear in case the Court of Appeal decide against him.

THE SANITARY CONDITION OF LIVERPOOL.—At a special meeting, on Wednesday, February 24, the Town Council of Liverpool adopted a bill enabling the Corporation to borrow £100,000, and to lay on a rate not exceeding a penny in the pound, for improving the sanitary state of the town—especially of the courts and alleys. The necessity for such a measure will be seen by the following extracts from the speech of Mr. Bowring, the Chairman of the Health Committee:—"From the Medical Officer of Health's return for the borough of Liverpool, he found that the deaths in the borough in 1863 were 15,266, a number which, the Medical officer stated, was greater than in any year since 1859, and 549 above the corrected average of the last ten years. Those deaths were not all due to violent epidemics or to any disease of a special character which visited the town, but they were caused by all diseases to a great extent prompted by existing circumstances around them. They had, then, a death-rate of 33 in the thousand in the whole borough, against 27.5 in 1859 and 25.7 in 1860. If

they sought further to analyse that death-rate they would find that in 1863 the rate for the parish was 36, and in the out townships 29, per 1000; and he was sure, from the experience of the past few weeks, from the commencement of the year to the present time, that if this year went on in the same way that it had commenced the death-rate of the year would be in considerable advance of 1863, great as it was that year. It was certainly unfair to compare Liverpool with the general average of the kingdom: it was, indeed, scarcely fair to compare it with the general average of the towns of the United Kingdom, at least not the smaller towns. But he would take the average of the larger towns, as stated by statistics in whom the Council might rest confidence, to be about 27. And when he found, on comparison of that estimate with the actual fact, that they had in Liverpool a loss of life of six in 1000, amounting to a loss of 2790 lives every year, he thought they were bound to conclude that some cause of mortality existed in Liverpool not found in other large towns." In considering the causes of this high death-rate Mr. Bowring said he would call the attention of the Council to a paragraph in the borough engineer's report, in which, after stating the number of courts and alleys in the town, and describing them, the engineer said:—"Unfortunately, however, such are the exceptions"—referring to the superior courts. "The majority of the courts in Liverpool is very different indeed. The houses are generally built back to back; one end of the court is closed as a rule either by houses or, which is worse, by the privies and ashpits; or a worse state of things still, the privies and ashpits are placed at the entrance of the court, and the only air supplied to the inhabitants must pass over their foul contents. But even this miserable state of things can be outdone. There are courts which by a perverted ingenuity have been formed in the following manner:—An ordinary street house has had its lobby converted into a common passage leading to the back yard. The passage is of course roofed over, and is in fact a tunnel, from which the back room of the original house, now converted into a separate dwelling, has its entrance. The back yard has been filled with other houses in such a manner as to have only the continuation of the tunnel for access, and from this little area of three feet wide the houses receive their supply of light and air. The passage is generally terminated by the privy and ashpit common to all the wretched dwellings, with its liquid filth oozing through their walls, and its pestiferous gases flowing into the windows of the last two houses." Mr. Bowring cited Medical evidence to prove that fever was never absent from these buildings. The first to feel the effects of the foul atmosphere were the women and children, and he believed the largest portion of the excessive mortality of the borough was amongst the children.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Mr. Sadler's valuable remarks "On Biniodide of Mercury Ointment" next week.

Winchester.—Presumption and self-sufficiency are vices, but there are worse—viz., discourteous and violent language applied to a member of the Profession, even if a junior.

Damocles.—The enclosure to which our correspondent refers has not been received.

Singular Advertisement.—It will be seen by a letter we publish in another column that the French Medical Students who wrote over here in answer to the advertisement which appeared in the *Gazette des Hôpitaux*, received a prompt reply that most advantageous and well-paid appointments awaited them, but that a necessary preliminary was the transmission of thirty francs.

Poor-law Medical Reform Association.—Mr. Griffin, Weymouth, begs us to state "that the Select Committee on Poor Relief have had three sittings, and it is understood that they have determined not to examine any further witnesses, and are now considering their report." Since March 9, the following subscriptions have been received by him in aid of the funds of the Association:—T. G. Doidge, Launceston, 5s.; Joseph Toynbee, Saville-row, £1; J. A. Ledgard, Wetherby, 5s.; G. Pound, Ash, 5s.; W. Pritchard, East Retford, 10s.; J. T. Barrett, Ashton-under-Lyne, 5s.; H. B. Harris (Watton post mark), 2s. 8d.; W. S. E., 1s.; C. Mott, Chertsey, 10s.; G. Bury, Barnet, 10s.; A. Bennie, St. Thomas's, 2s. 6d.; W. Roe, Barton-upon-Irwell, £1; D. Dorming, Barton-upon-Irwell, £1; H. Adyc, Barton-upon-Irwell, 10s.; J. L. Fletcher, Barton-upon-Irwell, 10s.; J. Rogers, Strand, 10s.; T. F. Greenwood, Southwell, 2s. 6d.; F. J. Brown, Rochester, £1 1s.

THE "CURIOUS ADVERTISEMENT."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Number of March 12, you inserted an advertisement copied from the *Gazette de Hôpitaux* as follows:—

"Students in medicine of the second and third year, and students in pharmacy, provided with certificates of two years' study, are now wanted in England; they will be paid by their respective Hospitals. Address, post free, to Messrs. Pratt and Sons, 1, Russell-street, Camberwell New-road, London."

I received the following letter from Paris yesterday. As we want no students in this Hospital, the whole thing must be the work of some swindler. I therefore think it right to send the communication to you, to caution your readers. No doubt you will hear more from other quarters; of course I have written to Paris to caution students there.

I am, &c.

D. O. BRIEN, Secretary and House-Surgeon.

Royal Portsmouth, Portsea, and Gosport Hospital, March 20, 1864.

"Monsieur le Directeur de l'Hôpital, Portsmouth, Angleterre.

"Monsieur,—D'après une demande d'étudiants en médecine pour l'Angleterre j'ai écrit à l'adresse indiquée dans cette demande à MM. Pratt and Sons, 1, Russell-street, Camberwell New-road, pour demander à ces messieurs de m'indiquer leurs conditions et la position qui me serait faite.

"On me répond ainsi (vous me permettez, Monsieur, de prêter les détails des conditions qu'on me faisait et d'arriver tout de suite à la dernière phrase de cette lettre qui est la plus importante pour ce que j'ai à vous demander):—'Si ces conditions vous conviennent, me dit-elle veuillez pour vous arriver cette place qui nous est demandé (à Portsmouth) et pour que nous puissions compter sur votre engagement, nous envoyer 30 francs en timbres-poste et dans quelque temps vous recevrez un billet de seconde classe pour votre voyage gratis.

"Signe, pour Mess. Pratt and Son, D. VAVIS."

"J'ai répondu aussitôt le 9 Mars, en envoyant les 30 francs qui m'étaient demandés et beaucoup de mes amis et collègues ont fait comme moi. Depuis je n'ai rien reçu ni billet de seconde classe ni lettre m'accusant réception des 30 francs.

"En conséquence, craignant d'être dupe d'une escroquerie sans exemple, je viens vous prier de vouloir me dire si le fait est vrai et si on a besoin d'étudiant à l'Hôpital de Portsmouth, vous me rendrez service.

"En attendant votre réponse qui me tirera de cette incertitude, deigniez agréer l'assurance de mon profond respect,

"PH. MOREAU, Etudiant in Médecine.

"Boulevard St. Germain, No. 38."

THE THERAPEUTIC VALUE OF MERCURY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—An article entitled "Hospital Notes," in your number of February 27, on the subject of Mercury in Syphilis, etc., has interested me greatly; and perhaps you will do me the favour to insert a few observations on this subject.

It appears to me that no more important topic could at this moment occupy the attention of the Profession; and I hope that as thorough a discussion upon this matter may be excited as has recently taken place on the question of alcohol.

The writer of "Hospital Notes" has afforded us much valuable information as to the present tenets of some of our most distinguished London Physicians, from which I gather that Dr. Gull never uses mercury either in pericarditis, pleurisy, or in iritis; also that Mr. Cock, Senior Surgeon of Guy's Hospital, in company with the late Dr. Addison, is of opinion that the diseases of bone generally ascribed to syphilis are due rather to the mercury used, or rather abused. Again, that Mr. Dixon says:—"If the ophthalmoscope had done nothing else than limit the wholesale administration of mercury in eye diseases, it would have conferred an enormous boon upon mankind." Also that Dr. K. Chambers says:—"There is no physical agent capable of doing so much harm in albuminuria as mercury." With your permission I beg to add some more evidence against the drug.

Mr. Prescott Hewitt (*Lancet*, February 20, 1864) says:—"Our museums abound in syphilitic, or so-called 'syphilitic' skulls. I say 'so-called syphilitic,' for, as most of these specimens are without any history, it would be difficult to say how far the ravages which we see in these skulls were dependent on syphilis, and how far upon mercurial cachexia." He proceeds to say that formerly such cases were frequently met with, but now that mercury is so sparingly used, they are comparatively rarely met with.

In a pamphlet entitled "A Synopsis of the Different Modes of Treatment employed at the University Hospital of Christiana by Professor Bøkh, 1863," the writer, Dr. Bidentap, after mentioning that mercury has been abandoned in the treatment of venereal diseases for the last ten years in that Hospital, says:—"The very rare cases of tertiary syphilis are met with in patients who have taken a mercurial treatment in other places, especially in foreign parts. Formerly, on the contrary, relapses and obstinate tertiary symptoms formed the majority of the cases treated in the Hospital." We may conclude that the exclusion of mercury from therapeutics has been the cause of it.

Dr. Hughes Bennett ("Principles of Medicine," 1860) says:—"The idea that mercury is a specific for syphilis, and the incalculable mischief it has caused, will form a curious episode in the history of medicine at some future day;" and he asserts that he has never seen even a rupia "but in individuals who have been subject to mercurial poisoning." Professor Syme tells us that, without mercury, ulcers of the organs of generation occasionally have secondary symptoms of a mild (though sometimes tedious) character; but that tertiary disease, such as deep ulceration, and bone disease never occur except when the patients have been poisoned by mercury. Mr. Weeden Cooke, in his "Nature and Art in the Cure of Syphilis," says that he has never seen bone disease where a course of mercury had been omitted. Mr. Spencer Wells endorses this expression; and I am informed that Mr. Skey has completely abandoned mercury in the treatment of venereal disease for some years.

Fricke, from 1825 to 1843, treated 15,000 cases of venereal disease in the Hamburg Hospital, and found the disease, without mercury, a mild and tractable one; whilst, when the drug was used, the most frightful mutilations were seen. Fergusson, Guthrie, Hennen, John Thompson, the French and Swedish Councils of Health, etc., have all repeatedly asserted the same thing—*i.e.*, that mercury makes the disease a formidable one, instead of being a matter easily treated by hygiene and local applications. Professor Bock tells us, in his "Recherches sur la Syphilis," published last year, that, of the cases of ulcers and secondary symptoms treated by

him, those treated without mercury recovered in nearly half the time; and, again, that there were nearly double the number (24:14) of secondary symptoms when ulcers were treated with mercury.

With regard to mercury in iritis, it appears to me that (unless something can be said to the contrary) the experiments of Hugh Carmichael, of H. Williams, of Boston (who, of sixty-four cases of every variety of iritis, had sixty perfect recoveries), of Dr. Hughes Bennett, and recently of Mr. Zachariah Laurence, have shown (1) that the theory of mercury breaking down the lymph is untenable, and (2) that it produces iritis in many cases (*vide* Acton, Travers, etc.), but never has been proved to do any good in any of its varieties. Mr. E. Hart and Mr. J. Hogg do not use it in cases of rheumatic iritis.

Dr. Gull, then, disapproves of mercury in pleurisy, pericarditis, and other chest complaints, in company with Dr. Hughes Bennett, Dr. Habershon, the late Dr. J. Taylor, of University College, and Dr. Walshe (who has never seen mercury do good in any inflammatory disease, but often do harm). Dr. Pollock, indeed, at a recent debate in the Harveian Society, said he believed it was the general opinion of the Profession that mercury was of no service in any internal inflammation, such as pleurisy, pericarditis, or peritonitis.

Symptoms of deflection from the mercurial ranks abound. Thus, M. Cullerier and Dr. Fournier lately informed me that they never treat any form of primary sore with mercury, but wait for the eruption. Dr. Diday, of Lyons, goes further than this; for he now talks of a mild syphilis and a grave poison, and gives no mercury for the former, either for the ulcer or the eruption. He also confesses to much damage being done by Ricord and the eclectic school of six months' mercury for indurated sores, and gives cases of eruptions which have been treated without the specific, and without relapses, for as many as sixteen years.

We used to be taught that "so-called" infantile syphilis imperatively demanded the specific. Cases, however, published by myself in the *Medical Times and Gazette*, November, 1862; and, again, fifteen cases published by Mr. Allingham (*Medical Times and Gazette*, October, 1863), in which fourteen recovered (whilst, by the mercurial treatment, nearly 30 per cent. die), have proved that this was but another phase of what Professor Syme calls the "mercurial delusion." The evidence, too, of Hennen, who says that of thirteen children born of parents treated without mercury, eleven were born alive, and none of them had exhibited any symptoms, although some were three years old, would tend to prove that, in most cases, the disease in the children is caused by the poisoning of the parents with the specific; and Bell says that it is believed to cause abortions.

I do hope, Sir, that those eminent members of our Profession who still have great faith in the virtues of mercury will do us the favour to try to disprove, if they can, the value of the evidence given by so many illustrious men.

I am, &c.

CHARLES DRYSDALE, M.D., F.R.C.S. Eng., M.R.C.P. Lond.

Southampton-row, March 1.

ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In continuation of my letter which, with your usual courtesy and interest in the welfare of the Medical Profession, you were good enough to publish in your issue of the 19th inst., I shall now very briefly bring forward some of the other causes of discontent and dissatisfaction now so widely prevalent among army Medical officers, and which cause the Army Medical Department to be the most unpopular branch of the public service at present.

3. *Relative Rank and consequent Military and Social Status.*—No act of the military authorities has given rise to more annoyance and produced a deeper feeling of injustice in the Army Medical Department than the infringement of the provisions of the Royal Warrant of 1858 on this subject. In clauses 16 and 17 of that Warrant, after definitively settling the relative rank of Medical officers, it is stated that "such relative rank shall carry with it all precedence and advantages attaching to the rank with which it corresponds," etc., etc.; but during the last four years these clauses have been so modified and altered as to deprive army Medical officers of several of the advantages therein conferred.

Army Medical officers have no desire to have the right and consequent responsibility of "military command." They do, however, wish for—and I hope the day is not far distant when they will obtain—that amount of military authority essential to maintaining their proper position in the army and the efficient performance of their responsible Medical duties.

What is that position at present? The army Medical officer has not the authority to place a non-commissioned officer under arrest, or to send a private soldier to the guard-room, no matter what crime these soldiers may commit, even in Hospital! Again, the officers' mess has lately been decided to be a "military parade," and consequently the junior ensign takes precedence of the Surgeon-Major, an officer, it may be, of twenty or twenty-five years' service, and supposed to have the relative rank of lieutenant-colonel; and, as if to humiliate Medical officers still more in public estimation, a Warrant was issued a few months ago, in which it is indirectly stated that the military authorities consider any Medical officer unfit to preside at courts of inquiry, boards, etc., even if the subjects of inquiry were intimately connected with their special duties, and for which they might fairly be considered particularly well qualified, such as the sanitary condition of barracks, Hospitals, etc.

Is it surprising then, under these circumstances, that the service should be avoided by every Medical man of independent mind, and fair professional acquirements, and that the vacancies now existing in the Department are double the number of candidates?

The 17th clause of the Warrant of 1858 alluded to amply provided for the relative rank and military status of army Medical officers, and the restoration of that clause in its integrity would reinstate Medical officers in their proper positions in the service. Why Medical Officers were deprived of this position, solemnly guaranteed to them by H.M. Warrant of 1858, is inexplicable, based as the provisions of that Warrant were on the unanimous recommendation of a royal commission, presided over by a Secretary of State for War, the late Lord Herbert, who will ever be remembered by the British army as the "soldier's friend."

4. *Examination of Assistant-Surgeons before Promotion.*—I cannot join in the opposition to existing regulations on this subject, as I believe they have been attended with advantage to the Medical Department and to the army. I would, however, suggest that the examinations take place on a certain day annually, and that all Assistant-Surgeons of a certain standing, say eight years, be examined, and that branch surgeoncies or other rewards be conferred on a certain number of the best men of the year. This, without injustice to others, or interfering with departmental promotion by seniority, would be sufficient inducement to Assistant-Surgeons to study their Profession for years prior to the examination, and enable

hem to keep pace with the progress daily making in medicine and the collateral sciences.

5. *Uniform.*—A large majority of army Medical officers are satisfied with the uniform of their respective ranks, whether regimental or staff, with the exception of the black shoulder belt. This is neither ornamental nor useful, but if retained it would be greatly improved in appearance by the addition of narrow gold bands, the number corresponding with the officer's rank—viz., a gold edge for Assistant-Surgeon on appointment, one band in addition after completion of six years' service, two for Surgeons, and three for Surgeons-Major.

6. *Banding Soldiers.*—A very strong feeling, and very justly, is entertained by army Medical officers against having the duty of superintending the infliction of this punishment imposed on them. That it is requisite and cannot be dispensed with every officer in the service is convinced, but it is inexpedient and unjust to Medical officers to compel them to superintend its infliction. As the operation is but very slightly painful, and neither affects the soldier's health nor prevents him performing his duty, there is no reason why Medical officers should have this duty imposed on them.

I would suggest that this punishment should for the future be inflicted in the guard-room (and not in the Hospital, as hitherto), under the supervision of the captain commanding the soldier's company, and that the Medical officer's sole duty in the matter should be to examine the soldier subsequently, and send in the necessary certificate to the commanding officer.

I have now detailed the more urgent grievances of army Medical officers, and have ventured to suggest the remedies which should be applied for their removal, and it is earnestly hoped that, as their existence cannot any longer be ignored, the authorities will frankly and liberally take the necessary steps to place army Medical officers in a position in the service commensurate with their high Professional character and value to the State, and that will induce candidates of a superior class, both Professionally and socially, to compete for existing and future vacancies.

I am, &c. AN ARMY SURGEON.

SUGGESTIONS FOR AN EFFICIENT REFORM OF THE ARMY MEDICAL DEPARTMENT.

1. The great question to be decided is, whether we are to be placed on a footing with civilians or military men? If relatively with the former, we must be better paid, and be exempt from mess and band subscriptions, and attendance at mess, being considered as honorary members only. If with the military, we must enjoy the full relative advantages, without exception, of our relative rank in all matters and on all occasions where military command is not strictly involved, as at the mess table, boards, committees, etc. To have a voice and vote accordingly, and sit as president where our rank demands it. We pay subscriptions to the mess and band funds according to relative rank; and it must, in fairness, be conceded that our voice and authority should go hand-in-hand with the obligations and the rank. At present, the voice of the junior ensign is more powerful, on many occasions, than the most senior or grey-headed Medical officer's, even in such small matters as to what tune the band shall play, or whether it shall continue or cease to play.

2. That relative rank may be duly recognised, it is essential that the names of all staff officers should be inserted in italics amongst the ranks of the military (as in the case of the adjutant and instructor of musketry) in the "Army List," and, in addition, if deemed necessary, classified separately at the bottom of the "Army List," according to their relative rank, and not as at present, where they are classified according to no rule, paymasters coming first (relative rank, captain or major), instructors of musketry second, adjutants third (the two latter appointments are always held by subalterns), quartermasters fourth (a subaltern, most frequently risen from the ranks), lastly, the Surgeon and his assistants (relative rank of Surgeon, major or lieutenant-colonel; Assistant-Surgeon, lieutenant or captain, according to length of service). At mess and other meetings you are often called upon to vote in this rotation, commencing at the Assistant-Surgeon, and so on through the ranks of ensign, lieutenant, captain, major, and lieutenant-colonel. Such confusion renders it difficult for the quartermaster to assign—say the Assistant-Surgeon—his quarters, according to his seniority in the regiment. The rotation in the "Army List" is taken as a guide in most matters and in all documents. This obnoxious arrangement is not according to the rules of the service in like cases, and conveys on the face of it, particularly to those uninitiated in military matters, the idea of social inferiority.

3. Assistant-Surgeons to be promoted to the rank of Surgeons after ten years' full service pay, in order to quicken promotion.

4. Surgeons-Major to be allowed to retire after twenty years' full service pay, for the same reasons. In March, 1863, there were somewhere about 632 Assistant-Surgeons. From the year 1857 to 1863 there were 112 promotions, or, on an average, 16 a year. The junior, at this rate, would be thirty-nine years without promotion.

5. Assistant-Surgeons, when promoted to the relative rank of captain, after six years' service, should be Gazetted, as in the case of Surgeons, who, after twenty years' service, are Gazetted Surgeons-Major. To distinguish such Assistant-Surgeon from his juniors, he should be called a Junior Surgeon, or First-class Assistant-Surgeon.

6. As the examination of recruits is a very unpleasant and very responsible duty, often performed in addition to ordinary regimental duties, it is nothing but right that the Medical officer should be paid for performing that duty, particularly as all others engaged in the recruiting service, from the adjutant or recruiting-officer to the bringer, are paid, and more particularly still, as the Medical officer is the one who is visited most severely with pecuniary punishment when a recruit is rejected after passing through his hands. Pecuniary responsibility generally involves pecuniary reward.

7. To place Medical officers of cavalry and artillery on a footing with those of infantry and the staff with regard to pay, additional pay being given them for the keep of one or more horses, upon the principle that the price of commissions in the cavalry and infantry, while being the same, the pay of the cavalry is much greater.

8. The branding of prisoners not to be performed in Hospital, but on a regimental parade, the Medical officer attending.

9. A Warrant to be issued, and the Queen's Regulations amended accordingly, embracing the above advantages, and not hereafter to be tampered with.

There may be other minor matters which might be rectified hereafter, but the great stumbling-blocks being removed, the rest would soon follow, and no lack of good candidates, that the service need not be ashamed of, would be wanting to fill its ranks. To prevent references and disputes, military command to be strictly defined. I am, &c. TRUTH.

APPOINTMENTS FOR THE WEEK.

March 26. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

28. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m. MEDICAL SOCIETY OF LONDON, 8½ p.m. Dr. E. Symes Thompson, "On Indigestion in Early Phthisis."

29. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ST. MARY'S HOSPITAL MEDICAL SCHOOL, 8 p.m. Dr. Graily Hewitt, "Clinical Conference in Midwifery."

30. Wednesday.

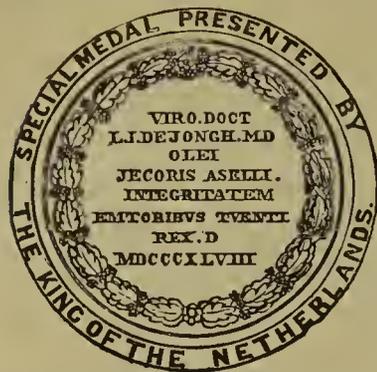

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

31. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.

April 1. Friday.

Operations, Westminster Ophthalmic, 1½ p.m. MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of the Council. WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Mr. Vasey, "On the Management of Children's Teeth."

DR. DE JONGH'S
(Knight of the Order of Leopold of Belgium)
LIGHT-BROWN COD-LIVER OIL.

SELECT MEDICAL OPINIONS.

Sir HENRY MARSH, Bart., M.D., Physician in Ordinary to the Queen in Ireland:—"I consider Dr. de Jongh's Cod-liver Oil to be a very pure Oil, not likely to create disgust, and a therapeutic agent of great value."

Dr. BARLOW, Senior Physician to Guy's Hospital:—"I have been well satisfied with the effects of Dr. de Jongh's Cod-liver Oil, and believe it to be a very pure Oil, well fitted for those cases in which the use of that substance is indicated."

Dr. LANKESTER, F.R.S., late Lecturer on the Practice of Medicine, St. George's School of Medicine:—"I consider that the purity and genuineness of

this Oil are secured in its preparation by the personal attention of so good a Chemist and intelligent a Physician as Dr. de Jongh, who has also written the best Medical Treatise on the Oil with which I am acquainted. Hence I deem the Cod-liver Oil sold under his guarantee to be preferable to any other kind as regards genuineness and medicinal efficacy."

SOLE CONSIGNEES AND AGENTS,
ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

DINNEFORD AND CO., PHARMACEUTICAL CHEMISTS

Beg respectfully to inform the Medical Profession that they are now Dispensing Physicians' Prescriptions with the

PREPARATIONS OF THE NEW BRITISH PHARMACOPŒIA,

except when otherwise indicated by the Prescriber.

TOWLE'S CHLORODYNE.

OF KNOWN COMPOSITION.

For Formula, &c., see back Numbers.

Extract of Letter from Dr. C. KIDD (Author of Standard Works on Chloroform).—"SIR,— . . . Of the value of Chloroform given internally I have no doubt; it appears to me in that form an anodyne, *sui generis*, that no other anodyne can approach. I have resolutely opposed the use of secret compounds of chloroform, and in every way I can encourage the use of the 'Chlorodyne' (if we must have it at all) that is made by you, as you state that its composition is known. Many Medical men think with me, and recommend your compound, but will never prescribe a secret remedy.—CHAS. KIDD, M.D.—Sackville-street, Piccadilly, London, April, 1862.—To Mr. A. P. Towle."

Extract of Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J. P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession.—To Mr. A. P. Towle."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; 4 oz., 4s.; and 8 oz., 8s.

SOLE MANUFACTURER—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

LIQ. CHLOROFORMI CO. (TOWLE'S).

This preparation is identical with "Towle's Chlorodyne," *sine* Ol. Menth. Pip. (dose 5 to 20 minims, as in Chlorodyne).

The Proprietor having for some time past, at the request of several members of the Medical Profession, made a preparation of Chlorodyne without peppermint, has lately, on account of the frequency of these demands, prepared the same for more general use, under the designation of LIQVOR CHLOROFORMI Co., which, possessing the Medical properties of Chlorodyne, may be prescribed in all cases where the Ol. Menth. Pip. is disapproved, and overcome the objection so generally felt to the use of the term "Chlorodyne."

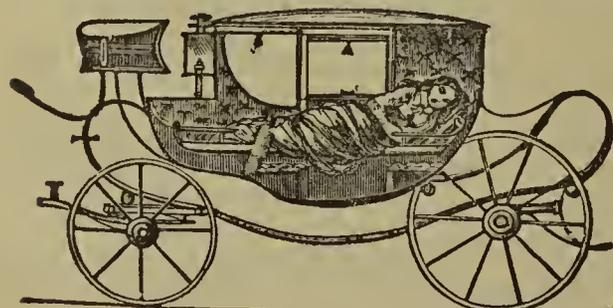

May be obtained, as an introduction, from the following Wholesale Houses, in 2 and 4 oz. bottles, at 2s. 6d. and 4s. each:—London: Barclay and Sons, 95, Farringdon-street. Birmingham: Southall, Son, and Dymond. Liverpool: Clay, Dod, and Case. Edinburgh: Duncan, Flockhart, and Co. Glasgow: The Apothecaries' Company. Dublin: Bewley, Hamilton, and Co. Manchester: Jas. Woolley; and the

Proprietor—A. P. TOWLE, 99, STOCKPORT-ROAD, MANCHESTER.

To the Surgical and Medical Professions.—W. F. Durroch, Manufacturer

of Surgical Instruments to the Royal Navy, Greenwich Hospital, Guy's Hospital, &c., &c., begs to inform the Profession that he continues to manufacture SURGICAL INSTRUMENTS of every description, and that he has attained the highest reputation by the approval and patronage of the most eminent Practitioners and Lecturers for the improvements made in various articles. Gentlemen favouring him with their orders may rely on having their Instruments finished in the best and most modern style. Surgical Instruments made to Drawings and kept in repair. Established 1798.

No. 3, St. Thomas's-street, S.E., near Guy's Hospital. Late Manufacturer to the leading Houses in the Trade.

READINGS' INVALID COT CARRIAGES,

THE GREATEST LUXURY AND COMFORT EVER INTRODUCED FOR REMOVING INVALIDS, BEING FITTED UP WITH THE PATENT NOISELESS WHEELS.

These Carriages may be engaged, on Moderate Terms, for any journey, on application to

H. & J. READING,

COACHBUILDERS, 14, RIDING-HOUSE-STREET, CAVENDISH-SQUARE.

Also a good assortment of New and Second-hand Broughams and other Carriages for Sale or Hire.

ORIGINAL LECTURES.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE V., (a) FEBRUARY 9.

(Continued from page 334.)

Having completed my remarks on the medicinal substances newly introduced into the *Materia Medica*, or first part of the *Pharmacopœia*, I will now draw your attention for a short time to the consideration of the second part, which contains their Preparations and Compounds.

Differing from all the *Pharmacopœias* hitherto published in Great Britain, it will be found that throughout the second part of the work a strictly alphabetical arrangement has been adopted. There is no attempt at grouping the preparations under the head of alkaline, ethereal, metallic, and other compounds; but still this very alphabetical arrangement necessarily implies that all the important Galenical preparations shall come together. This arrangement is extremely convenient, and gives greater uniformity to the work.

In the British *Pharmacopœia* there will be found processes for the preparation of almost every chemical substance contained in the first part, as likewise of all Galenical or pharmaceutical compounds. In this respect the present work differs much from that of the London College. The object of this College, more especially in the last edition of its *Pharmacopœia*, was to omit the processes for the preparation of such chemicals as could be readily procured, giving only methods for making substances which it was considered important should be obtained in a state of purity, and which were not always procurable, and hence the edition of 1851 contained far fewer processes than that of 1836. It is the opinion of many that all such processes should be omitted from a *Pharmacopœia*, that they should be entrusted to the chemist alone, but that tests for ascertaining their purity should be inserted. It was, however, ruled in the Committee that processes for the preparation of all chemical substances should be introduced unless in any instance a good reason could be given for the omission, and hence only very few are omitted, as, for example, that for preparing commercial oil of vitriol, carbonate of soda, and so forth, substances which can only be made on a large scale. The introduction of the processes has its advantages and disadvantages. One of the advantages consists in the propagation of a certain amount of knowledge of chemistry among a large class both of the Medical Profession and druggists, as the *Pharmacopœia* is often looked upon as a textbook, and the complete understanding of its contents a matter of necessity.

On the other hand, the introduction of these processes adds much to the bulk of the work, besides which it cannot be expected that manufacturers will always adhere to the directions therein contained; each following peculiar methods, especially in the details, which he often keeps more or less secret. The only point required to be secured in the manufacture of chemical substances is their purity or fitness for medicinal administration, and a complete set of tests for each article would ensure this. I believe it will be found that, taken altogether, the processes in the British *Pharmacopœia* are good; doubtless many improvements could be suggested, but it does not follow, as some are apt to suppose, that because they may in some respect differ from their own, they are therefore necessarily faulty.

I have already seen and heard many objections to individual processes; for example, to those given for aconitia and

the citrate of iron and quinine, but I may, perhaps, in answer to such objections, state that the process for aconitia was kindly supplied by a maker of this alkaloid on a very large scale; and that for the citrate of iron and quinine by a firm which stands among the highest for the manufacture of that salt. The object of the Committee has been to give processes by which each chemical drug can be made, not the one to be necessarily adopted in its manufacture. If the result be the same, as far the quality or purity of the drug is concerned, the mode of making it cannot be of consequence.

I shall not attempt (as it would be quite out of place in these lectures) to make any remarks on the chemical processes of the *Pharmacopœia*, but I will give a rapid sketch of the various pharmaceutical groups, and of the alterations and additions which have been made to them.

In the *Aque* or *Waters* of the London *Pharmacopœia* no great change will be found. Our old *Mistura Camphoræ* is there as *Aqua Camphoræ*, and no one, I think, who considers the nature of the preparation will object to the change. I have already had occasion to refer to *Aqua Laurocerasi* when speaking of the introduction of laurel leaves into the *Materia Medica*.

I have nothing to remark on the *Cataplasms*, and I may observe that the group of *Vinegars* is altogether abolished, as well as that of the *Cerates*. One vinegar, that of *Cantharides*, is now placed in a modified form under the *Liniments*, and some of the cerates are now found among the *Ointments*.

Several *Confections* have been discarded, as *Confectio aurantii*, *Confectio cassiæ*, *Confectio opii*, *Confectio Rutæ*; two new confections have been added—namely, of Sulphur and Turpentine. The almond as well as the aromatic confection will be found under the heads of *Pulvis Amygdalæ Compositus* and *Pulvis Cretæ Aromaticus*. The turpentine confection is, I am informed by one of the committee, who has used and taken it largely, a valuable and not unpleasant form of administering this somewhat nauseous medicine.

There are some alterations among the *Decoctions* worthy of passing notice. *Decoctum Amyli* is now termed *Mucilago Amyli*. *Chimaphila* and *Cydonium* have been omitted from the list, and, therefore, their decoctions from the group. *Decoctum Cinchonæ*, *Pallidæ*, and *Rubræ* have been discarded; that of the Yellow Bark only retained. *Decoctum Dulcamaræ* and *D. Senegæ*, *D. Uvæ Ursi*, substituted by *Infusions* of the three drugs; and, lastly, decoctions of Gall nuts, Pomegranate fruit, *Tormentilla*, and Elm root omitted, the latter evidently by error. The Compound Decoction of Barley is also left out.

Among the *Plasters* you will notice the absence of *Emplastrum Ammoniaci*, *Emplastrum Cumini*, *Emplastrum Potassii Iodidi*. And in addition to the *Plasters* of the London *Pharmacopœia* you will observe *Emplastrum Calefaciens*. *Emplastrum Plumbi* is now called *Emplastrum Lithargyri*.

In the *Enemata* the changes are the omission of *Enema Colocynthisidis* and the addition of *Enema Magnesiæ Sulphatis*.

We have next to notice the group of *Extracts*, in which extensive and important alterations have been effected. In the manufacture of what are termed the "Green Extracts," care has been taken to remove the albumen contained in the juices, and by this means their liability to decomposition is prevented; if you examine the manner in which these extracts are ordered to be made, you will see that the freshness of colour is not necessarily a proof that a low temperature has been employed; for the green colouring matter or chlorophyle is first coagulated by the application of a heat of 130° to the juice, then removed by filtration, and only again added at the end of the process. Among the omissions in this group are the *Extracts* of Pale and Red *Cinchona Bark*, *Lettuce*, *Poppy*, and *Uva Ursi*. Among the additions are *Extract of Camomile*, *Extract of Bark*, *Extract of Calumbo*, *Extract of Indian Hemp*, *Extract of Ergot*, *Extract of Male Fern*, *Extract of Rhatany*, and *Extract of Quassia*; and also some liquid extracts in lieu of, or in addition to, solid extracts of certain drugs. It may be well to speak a few words upon some of these changes.

Extract of Elaterium, the name of which has so often been complained of, is now placed in the list of the *Materia Medica*, and called simply *Elaterium*.

The name of the Compound *Extract of Colocynth* has been restored. You probably will remember that in the London *Pharmacopœia* of 1851 it was termed *Compound Colocynth Pill*, but even to the present day more commonly prescribed under its old designation of *Compound Extract*.

(a) Portions, especially of the latter part, of this Lecture were not delivered from want of time.

Extract of Jalap has been somewhat altered. Formerly the tubers were exhausted by rectified spirit, and afterwards by boiling water. In the British Pharmacopœia, maceration in cold water is employed as a substitute for boiling the tubers; and thus a large amount of starchy matters are left behind. The product is consequently much smaller, and the activity greater; for I may observe that I have made several trials of the spirit extract, the cold-water extract, and, lastly, of the extract prepared by boiling the residue in water, and have found that the first is active as a purgative, but the cold-water and boiling-water extracts are inert; the only advantage, therefore, of the Extract of Jalap over the Resin is in its consistence, which renders it more adapted for the making of pills.

It will be seen that several liquid extracts have been introduced—for example, in place of the ordinary Extract of Yellow Cinchona Bark, a liquid preparation has been substituted, which closely resembles the inspissated infusion of the same drug of the London Colleges. If we look at the quantity of bark made use of, and compare it with the product, we find that there are sixteen ounces of bark to four fluid ounces of the extract. We must not, however, imagine for one moment that one fluid part by measure represents, as far as the alkaloids are concerned, four solid parts of the bark; for it has been proved that the refuse bark left after the operation is still very rich in quinine, and to the manufacturer of that alkaloid of considerable value. This is owing to the extreme difficulty of extracting the quinine from the bark; and the maceration and percolation of the process are quite unable to effect the exhaustion.

The Liquid Extract of Ergot is a preparation worthy of notice. Formerly it was thought that the oily matter which exist in such large amounts in the ergot was the active portion. This, however, has been disproved; and in making the liquid extract the oily matter is first removed by ether, and a watery solution is then made; and afterwards evaporated; a little spirit is finally added; and the total result is a liquid extract, in which the active matter of one solid part of ergot is contained in each fluid part of the preparation.

Many eminent Physicians, especially those engaged in the treatment of affections demanding the use of this remedy, have made trial of the liquid extract of ergot, and I understand that all agree in considering it a very convenient and valuable preparation of the drug.

There is likewise a liquid extract of opium, containing one part of the solid watery extract in twenty fluid parts, and supposed to be of about the same strength as the tincture of opium, but devoid of certain matters contained in opium, which are not soluble in cold water. It will probably be a substitute for the so-called sedative solution.

A most convenient form for administering Pareira will likewise be found in the Pharmacopœia—an agreeable substitute for the decoction. In this liquid extract one part of the root is employed in the production of one fluid part of the preparation; it is termed *Extractum Pareiræ Liquidum*, and I am informed by some eminent Surgeons that it possesses all the valuable properties of the plant, and can be given with great advantage in many cases in which the bladder is in a chronic state of inflammation. The new extracts of chamomile, columbo, rhatany, and quassia may at times be found serviceable when we desire to give these medicines in a solid and concentrated form.

In the group of *Infusions* there are points to comment upon. Some of these preparations are made for the first time with cold in lieu of boiling water; for example, infusion of columbo; the advantage here consists in the infusion not containing the starchy matters so liable to speedy changes; cold water is likewise made use of in making the infusion of quassia; and water at the temperature of 120° in the infusion of chiretta and cussparia; for the remainder boiling water is employed.

There are also certain omissions and additions. Amongst the former, that of infusion of horseradish, pale cinchona bark, simple and inspissated; the concentrated infusion of yellow bark being transferred to the liquid extracts. The additions are infusions of chiretta, kouso, dulcamara, ergot, matico, and senega; with the exception of the infusion of orange peel, which is still termed compound, this affix has been omitted; but the former compound infusion of roses is called an acid infusion. Throughout the different pharmaceutical groups you will observe the frequent omission of the word compound, and the rule has been not so to designate a preparation unless it contains more than one real medicinal agent; substances

which are merely introduced to give flavour or odour, or to suspend insoluble ingredients, not being looked upon in that light.

I have alluded to the substitution of an Infusion of Dulcamara in place of the decoction. Of the reason for this change I am not aware, as even when boiled in water Dulcamara does not yield any very active ingredient. Some years since I gave the decoction in large amounts to a girl who had long suffered from severe psoriasis, and she soon became well, or all but cured. After three years she returned to the Hospital covered with the eruption. The medicine was again given in similar doses, but failed to give relief; and doubtless the disease in the first instance had worn itself out, having been long treated with powerful drugs. I have administered as much as sixty fluid ounces of the decoction during the day, reduced to a smaller bulk by evaporation, and still no physiological symptoms were induced; and to show that even the fruit of the Dulcamara, or bitter sweet, does not possess the poisonous properties often attributed to it, I may state that I have seen five pounds of the ripe berries taken in a space of ten days in the form of a preserve or confection, and still no symptoms followed.

(To be continued.)

THE OPTICAL DEFECTS OF THE EYE.

A COURSE OF LECTURES DELIVERED DURING THE SUMMER OF 1862 AT THE

Surrey Ophthalmic Hospital,

By J. ZACHARIAH LAURENCE, F.R.C.S., M.B.

Univ. Lond.,

Surgeon to the Hospital.

PART I.—OPTICAL CONSIDERATIONS.

GENTLEMEN,—In the present course of lectures I propose laying before you an account of those defects of vision which depend either upon a misformation or a perversion of function of the optical structures of the eye. Up to a comparatively recent period the pathological deviations of the refractive and accommodative powers of the eye were, from the want of any system in their discrimination, involved in such hopeless confusion, that the determination of the glasses requisite for their correction became unsatisfactory and empirical in the last degree; the error having been that most ophthalmic Surgeons rested satisfied with but a superficial knowledge of optics, whilst opticians regarded the eye rather as a production of their workshops requiring some correction, than as a structure of the human body, endowed with all the attributes of vitality. I shall, therefore, not conceive the time ill-spent, if we confine our attention, in the first instance, to optics considered as a pure science,^(a) altogether independently of the applications we shall hereafter have to make of our knowledge thus acquired. To attempt to understand the optical construction and defects of the eye without such a previous knowledge, is simply impossible; and it is to the absence of any such preliminary information that I am led to ascribe the unintelligible character which most of the communications hitherto published on this subject have possessed for the Profession at large.

The eye is, in its most important relations, essentially an optical instrument, through whose medium we take cognisance of the most obvious and necessary events of the external world. This, in its turn, becomes the subject of our visual observation by that physical force which we understand by the term "light." Light is one of those agents of nature the existence of which is inferred from its effects, just as that of heat, electricity, mechanical or vital force is inferred from their effects. The effect of light which principally concerns us is that which it exercises on the retina; but photography, magnetism, vegetation all demonstrate the existence of light as a perfectly independent physical agent. In other words, supposing all the world were blind, still, light would exist, even in its purely optical sense: it would still be reflected, refracted, polarised, although we should be unable to recognise any such effects. Some of the bodies of nature are, in themselves, sources of

(a) In the course as actually delivered by me, all the leading phenomena of optical science, as the laws of reflection and refraction, etc., were fully discussed, but as these subjects are but imperfectly intelligible without such experimental illustrations as I then produced, I have omitted them in the lecture, as now published, proceeding at once to the consideration of optical lenses, which constitute the most essential elementary knowledge for the due comprehension of the physiological and pathological optics of the eye.

light—*self-luminous*—such as the sun, the stars, bodies in a state of ignition. On the other hand, the great majority of bodies are not self-luminous, but derive their luminosity from reflected light, which itself is, in the first instance, derived from self-luminous bodies. Thus, the objects in a perfectly dark chamber only become visible by the introduction of a light; extinguish this latter, and they are no longer seen.

For the sake of precision in the investigation of the laws of the propagation of light through space, it is necessary to consider all luminous bodies as composed of an infinite number of infinitely small luminous points, each of these points to give off, in all possible directions—radiate—an infinite number of straight lines of light of extreme tenuity. These lines of light are individually called *rays* of light, whilst the combined bundle of rays which emanate from, or converge to, a luminous point is called a *pencil* of rays. (b) If the component rays of a pencil of light, in their onward progress from their initial source—the luminous point—separate further and further from

is, say, twenty feet from us, the rays of light from each luminous point which strike the area of the pupil of the eye form practically parallel pencils, and, *a fortiore*, in ascending progression, those which strike the pupil from a lighthouse, from the sun, from the fixed stars. But if the recipient surface on which the rays of light from a candle flame fall be, say, a large target, from the lighthouse a large extent of the ocean, from the sun the earth, from the fixed stars the entirety of space, we may, in the first two instances certainly, in the two latter not unreasonably, assume that the pencils of rays are of divergent character in regard to the magnitude of the surfaces on which they fall. Strictly speaking, then, no such rays as parallel rays exist in nature; but for the recipient surfaces we shall have to deal with our eyes, lenses, reflectors, etc., we may practically regard all rays of light which proceed from near objects as divergent, those from distant ones as parallel, (c) whilst convergent rays are not to be found in nature at all, but may be produced by certain optical means, of which we shall soon come to speak.

What evidence have we of all the above assumptions? Their truth is inferred from the fact that the great majority of optical phenomena are only deducible from such assumptions, and that the laws of optics hence deduced have led by a chain of inferences, not only to the explanation of more complex phenomena, but have served as the land-marks to the investigation of, up to the time, unknown fields of discovery in optical science. Two different theories have been advanced of the more intimate nature of light. The Newtonian (corpuscular) conceives each luminous point to be constantly giving off a succession of luminous corpuscles, which follow each other in uninterrupted succession on an imaginary axis, like a string of beads coursing along a rigid thread. The undulatory theory, on the other hand, considers space as pervaded by a subtle gaseous fluid or ether; that luminous bodies have the power of communicating to this ether a wave-motion, which affects the retina, just as the undulations of the atmosphere from vibrating bodies affect the auditory nerve, or, to take a ruder simile, as the waves of the ocean impart their movements to the vessel that rides on them. The undulatory theory is of far wider significance, however, than its mere physiological application. Sir John Herschel, speaking of it, says, "It is a theory which, if not founded

in nature, is certainly one of the happiest fictions that the genius of man has yet invented to group together natural phenomena, as well as the most fortunate in the support it has received from all classes of new phenomena, which at their discovery seemed in irreconcilable opposition to it. It is, in fact, in all its applications and details, one succession of *felicities*, inasmuch that we may almost be induced to say, 'If it be not true, it deserves to be.'"

(To be continued.)

PROFESSOR OWEN, F.R.S.—This distinguished physiologist had the honour of delivering before the Queen and Royal family, on the 29th ult., the first of a course of four lectures "On Natural History."

THE DENTAL PROFESSION.—The anniversary dinner of—as they now term themselves—"Licentiates in Dental Surgery" was held at Willis's Rooms a few days ago, when the chairman, Mr. Lawrence, a member of the Board of Examiners in Dental Surgery of the Royal College of Surgeons, made the following statement, which no doubt will create great surprise among the members of that College:—On proposing the toast of "The Degree of Licentiates in Dental Surgery," he said, speaking of the curriculum and examination which future candidates will have to go through:—"Well, if they undergo that examination, why are they not to be members of the College of Surgeons in the same way as those of their brethren who have undergone the usual examination for the membership? That is a question I cannot answer. I do not see any reason why they should not. *My opinion is that they will be absolutely better informed.*" Again, speaking of Dental Surgeons, he added:—"The word 'dental' is only an adjective. Therefore, I cannot see how they (the College of Surgeons) can refuse giving them all the rights, privileges, and immunities that belong to the other members. (Hear, hear.) I hope you will soon acquire those rights."

(c) Another view of the subject is, that in the latter case only the *axe* of the pencils and the rays in the immediate proximity of these *axe* (practically parallel to them) strike "our eyes, lenses, reflectors, etc."

FIG. 4.

each other, then we have before us a *divergent* pencil (Fig. 1); if, on the other hand, the rays approach each other closer and closer as they proceed onwards to a point, then we have a *convergent* pencil (Fig. 2); whilst, lastly, if the rays of a pencil neither diverge nor converge in their onward course, we have a *parallel* pencil (Fig. 3). A luminous point is termed, in the language of optics, a *foc*us of rays, or, shortly, a *foc*us.

As an illustration of divergent and convergent pencils, the case of the flame of a candle before which a convex lens is held may be taken. The rays of light diverge from the constituent luminous points of the flame, and are converged to as many points again by the lens, as we shall discuss fully at a later period of these lectures. From what has been before said, it may be inferred that all luminous bodies emit their rays of light in the form of divergent pencils. If a luminous point (*O*) (Fig. 4) be at a certain distance from a recipient surface, *AB* (the pupil of the eye, *e.g.*), any two divergent rays form some angle, as *AOB*, with each other; if the luminous point (*o*) be further off, the angle, as *AoB*, will be less; if still further off, the angle, as *A ω B*, still less; and so on. This fact is obvious to the eye from a mere inspection of Fig. 4; but it is also geometrically demonstrable (Euclid i., 21). Following up the same reasoning, if we suppose the luminous point infinitely far off, any two proximate rays will form no angle at all with one another—will be, in a word, *parallel*, it being in all cases understood that the surface on which the rays of light impinge is of limited extent in comparison with its distance from the luminous point. Thus, if a candle flame

(b) We may obtain an approximate concrete idea of a "ray" of light by allowing the light from the sun to pass into a dark chamber through the minutest possible hole drilled in a thin plate of metal; enlarge this hole, and several rays, constituting a "pencil" of light, will enter the chamber.

ORIGINAL COMMUNICATIONS.

ON TRICHINA DISEASE: ITS PREVENTION AND CURE.

By JULIUS ALTHAUS, M.D., M.R.C.P.

Physician to the Royal Infirmary for Diseases of the Chest.

THE discovery of trichina disease, or trichiniasis—no doubt the most important Medical event of the last few years—affords a happy illustration of the close connexion that exists between the several branches of Medical and natural science, since the concurrence of zoology, experimental physiology, pathological anatomy, and clinical Medicine, working for one common purpose, was indispensable to enable us to arrive at a complete knowledge of the remarkable and interesting phenomena included under the above heading. I intend in the following paper to give a concise account of the subject in its principal bearings, and shall therein follow chiefly the researches and writings of Virchow, (a) Vogel, and Leuckart, (b) and Mosler. (c)

Trichinae were first discovered in England, where, in 1832, Mr. Hilton noticed, in the human subject, the cysts in which trichinae are generally found enclosed, and which appear to the naked eye as small white corpuscles. Mr. Hilton believed

FIG. 1.

these corpuscles to be animal formations, but he did not perceive the worms contained in them. In 1835 Professor Owen discovered the nematoid worm enclosed in the cyst, and called it *trichina spiralis*, on account of its resembling a hair in its minute filiform size and its being coiled up into spiral turns. This name has been generally accepted by zoologists, and it is only quite recently that M. Davaine, the author of a well-known treatise on entozoa, has proposed a different name for it—viz., *Pseudalius Trichina*. (d) The only reason that can be given for this innovation is, that the tail of those trichinae which are found in the human intestines is divided in two horns or cones, and that the same peculiarity exists in *pseudalius Duj.*; but in every other respect the structure of trichina entirely differs from that of *pseudalius*, the former worm being in fact far more closely allied to *trichocephalus* and *trichosomum*, from which latter it is only distinguished by its size and a different structure of the genital organs. It is therefore by no means probable that M. Davaine's innovation will find favour with zoologists, as it would only lead to confusion; and no doubt the worm in question will always be called by the name first given it by Professor Owen.

FIG. 2.

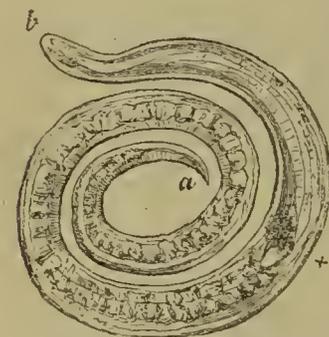

FIG. 2.—Female trichina from the muscle of a man; the cyst is removed, but the spiral turns are preserved. a is the head, b the tail. The alimentary canal begins at a; its structure is cellular, and it fills up the whole of the inner part of the body from a till b, while from b to c it is reduced in thickness.

Since its discovery in 1835, trichina has been frequently noticed, more especially by German and English anatomists. In the anatomy rooms of the Universities of Berlin and Edinburgh trichinae have been found in 2 or 3 per cent. of the subjects dissected. They were also noticed by several observers in Denmark, France, and the United States. The animals in which they have been found are the cat, the crow, the jackdaw, the hawk, the mole, and the pig; it is, however, not yet settled whether some of the worms found in the former of these animals do not rather belong to a different species—viz., *trichina affinis*. It was, however, only in 1860 that more

minute investigations concerning the nature and development of trichina were undertaken, and Professors Virchow and Leuckart, who worked independently of one another, simultaneously came to nearly the same conclusions as regards the natural history of the worm. Zenker was the first to find, in a girl who had died at Dresden, numerous trichinae in the striated muscles, and to recognise the parasite as cause of the illness and death of the patient. In the spring of 1862, about thirty cases of trichina disease occurred in Plauen, in Saxony. In some patients small pieces of muscular tissue were excised and examined by the microscope, and thus, for the first time, the diagnosis of trichina disease was made in the living subject. Since then numerous cases of it have been observed, especially in the kingdom of Saxony and the Prussian province of Saxony, as in Magdeburg, Leipzig, Eisleben, etc. From the end of October to the middle of December, 1863, there was a true epidemic of this disease in Hettstedt, near Eisleben, in which 150 persons were affected, and 24 of them died. It is, however, not probable that the disease is confined to the districts just mentioned, as no doubt many cases of it have occurred elsewhere, but have not been recognised as such by the Medical Practitioners. A striking instance of this kind may be given. In 1863 Professor Langenbeck, of Berlin, excised a tumour which had grown on the neck of a man. During the operation he noticed that the muscles which were laid bare contained a number of encysted trichinae. The patient being questioned whether he had not at one time or another been affected with a remarkable illness, related the following history:—In 1845 a committee, consisting of eight gentlemen, were occupied with the inspection of schools in Saxony. On one occasion they dined together at an inn, and partook, amongst other dishes, of ham and sausages. One of them, however, went away without having taken anything but a glass of claret. The other seven—amongst them the man who related the history—drank hock, and ate of the dishes mentioned. They all fell ill, and four of them died. Suspicion fell upon the meal and the host. The wine that had been drunk was analysed; no poison was found, but the host continued to be suspected, and was at last obliged to emigrate. (e) No doubt suspicion of poisoning may frequently have attached to innocent persons, who had unwittingly provided a meal with dishes containing trichinae. Several cases of a similar kind have been related by Dr. Husemann. (f)

All observations made on human trichinae until 1860 concerned such cases only in which the trichina disease had healed, that is, in which the worm had been seen in the encysted, not in the free state. We now know that, at least, two months are necessary for the production of a complete cyst, and that men or animals, which live so long that the trichinae existing in them may become encysted, are likely to survive the disease. Before this was known the opinion, therefore, gradually gained ground that trichina was a harmless animal, and more a curiosity than a source of danger. On this account the Practitioners and clinical observers took no further interest in the worm, which was left to the care of zoologists and anatomists. In a purely scientific point of view, however, trichina soon proved to be a problem of surpassing interest, as nobody knew whence it came, nor how it could migrate into the flesh of living men, nor how it was generated, for no organs of generation, no ova, no progeny had been found. It is, therefore, scarcely surprising that even good observers resorted to the old hypothesis of spontaneous or equivocal generation in order to explain the origin of trichina. Thus, Dr. Bristowe and Mr. Rainey believed that trichina was generated from fat formed between the muscular fibres, and that the nuclei, which became visible after the fat had gradually vanished, played an important part in those intermediate changes which occurred between the appearance of the animal and the disappearance of the fat! (g)

In many respects trichina resembles cysticercus, which is most frequently found in pigs, but is by no means rare in man. It is true that cysticercus is larger than trichina, for while the former has the size of a pea, or even of a small cherry or bean, the latter appears only as a little white speck, even if the cysts are taken together with the animal. On the other hand, however, cysticercus is, just as trichina, destitute of organs of generation and of ova; it often occurs in large numbers, and it is also found in the flesh. We know that cysticercus cellulosæ is the larval state of *tænia solium*; that, in fact, the same worm lives for some time as cysticercus, and is afterwards

(c) Virchow, *l. c.*, p. 40.

(f) *Deutsche Klinik*, No. 8-10. Berlin. 1864.

(g) *Transactions of the Pathological Society of London*, 1854, pp. 293-94.

changed into tænia; that tænia produces not only ova, but also living progeny, which first become cysticerci, and afterwards are again metamorphosed into tæniæ. These facts, which went far to render the theory of spontaneous generation untenable, soon led zoologists to inquire whether or not similar processes might take place with regard to trichina. Virchow was the first who succeeded in showing, by experiments, the existence of alternate generation in trichina. (h) He fed a dog with encysted, but still living, trichinae, taken from a man, and found, four days afterwards, numerous free trichinae in the intestines of the dog. These animals were seen to possess sexual organs, containing ova and spermatozoa. He also showed, that the cyst in which the animals are enclosed, when found in muscles is nothing but a changed muscular fibre; and it thus became evident that the animals did indeed penetrate from without into the structural elements of muscles. These and other experiments of Virchow, which were confirmed by those of Leuckart, Claus, and others, have led to the conclusions, that there exists alternate generation for trichinae as it does for cysticercus; that if animals are fed with trichinae taken from the muscles, intestinal trichinae are formed, which produce ova and living progeny; that these latter, without leaving the animal in which they have been generated, immediately penetrate the coats of the intestines and migrate into the body, more especially into the striated muscles, where, unless the animal in which they are contained should previously die, they are, after a time, encysted, and wait for the moment when they may be eaten by another man or animal, to undergo the same changes as before.

It thus appears that the danger which may accrue to man from trichina is far greater than that with which he is threatened by cysticercus and tænia. While the latter require to be eaten on two several occasions, the former only requires to be eaten once in order to produce a progeny which infects the whole system. Moreover, cysticercus and tænia scarcely ever cause a fatal result, while even within the last three years a large number of deaths is known to have been brought about by trichina. A knowledge of the nature of the worm, of the symptoms of trichina disease, of the way in which this is brought about, and of the means by which we may hope to prevent or cure it, is, therefore, of considerable importance for the Medical Practitioner.

If men or animals have eaten meat infected with trichinae, this is dissolved by the gastric juice, and the trichinae become freed from their cysts. With a magnifying power of 300 m.d., we are then able to distinguish their alimentary canal, which

FIG. 3.

FIG. 3.—Magnifying power, 200.

FIG. 4.

FIG. 4.—Magnifying power, 150.

begins at the somewhat sharp anterior extremity of the animal; it is at first a narrow tube, but soon widens and appears as a broad cellular body, which fills up more than one-half of the whole length of the animal, while at its posterior third the tube again becomes narrow, and at last opens outside at the posterior extremity. When once in the stomach and freed from their cysts, the trichinae awake from the torpor in which they were held previously. They begin to move about; they lose their spiral figure, and become stretched, so as to appear somewhat similar to ascarides. They soon grow rapidly, so that while a trichina musculorum is only from two-fifths to three-fifths of a millimeter long, the trichina intestini is no less than from one to three millimeters long. At the same time, generative organs are developed.

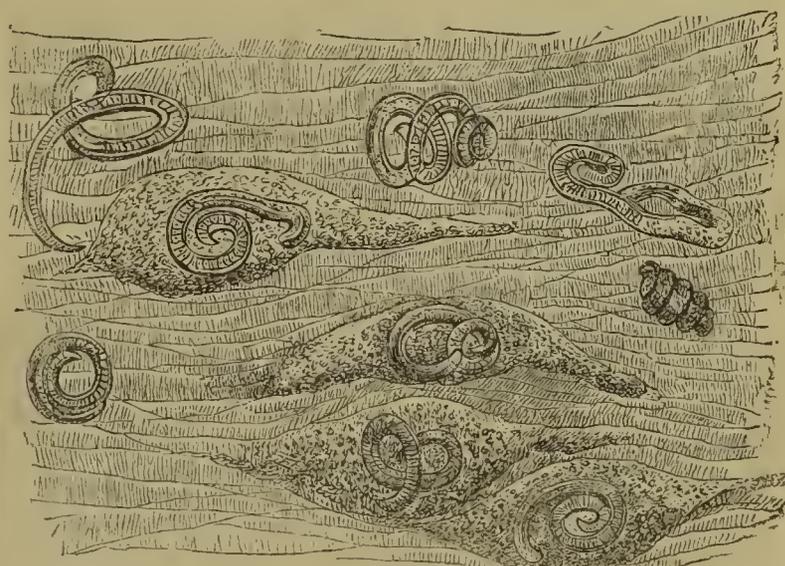

The male trichinae may be recognised by containing, in the posterior third of the body, testicles with excretory ducts (Fig. 3, 2), and by having at the posterior extremity two prominences similar to thorns or cones (Fig. 3b and Fig. 4b). These latter are the organs of copulation. A full-grown male trichina is from 1 to 1.5 millimeters long, and from 0.03 to 0.04 millimeters wide. It is probable that the males die soon after connexion has taken place; for while at first their number almost equals that of the females, it soon decreases, and from the tenth to the fourteenth day after the trichinous meat has come into the stomach only females are observed, which

live longer than the males, as they require more time for maturing ova and producing progeny. Six weeks after feeding, no trace either of males or females is to be discovered in the intestines.

The full-grown females are considerably larger than the males, viz., from two to three millimeters. This is owing to the greater development of the posterior part of the body, the ovaries and Fallopian tubes being much more extensive than the testicles. The posterior extremity is more rounded than it is in the males, and is devoid of the cones found in the latter. Copulation takes place a few days after the animals have arrived in the stomach. In each ovum after a time an embryo is formed, which becomes free by rupture of the membrane enclosing the ovum, and travels towards the anterior part of the Fallopian tube (Fig. 5, 4—5). As soon as the embryo has arrived at the opening of that tube (5) it goes out and begins its individual existence. At this period the embryo is very small and quite transparent; it is 0.05 millimeters long and 0.005 millimeters wide, and devoid of any special organs. The time required for the intra-Fallopian development of the embryo varies, according to Vogel (i) from two days to six weeks, the difference being obviously due to two causes. In the first instance it appears that the development lasts longer if the trichinae that have been eaten were very young; in the second place, the number of ova contained in one female must be taken in consideration. Most females contain from 300 to 500 ova, which only gradually advance towards the anterior opening of the Fallopian tube, and it is therefore evident that more or less time must elapse between the birth of the first and the last of the progeny.

Soon after birth the trichinae leave the intestines and migrate into the peritoneal sac. For this they have to perforate the coats of the bowel, which, on account of their minute size, they probably accomplish without tearing the membranes, but merely driving them, as it were, asunder. This process is facilitated by the shape of their head, which may under certain circumstances become sharply pointed. From the peritoneal sac they proceed to all the striated muscles, excepting only the heart, in which they are scarcely ever found. They find their way to the muscles, where they are led by instinct, through the connective tissue, without, however, leaving any visible traces of their migration. They penetrate through the sarcolemma into the interior of the muscular substance, which is, by their invasion, considerably altered. In moving through the fibres, the worms, in fact, break through the more delicate constituents of

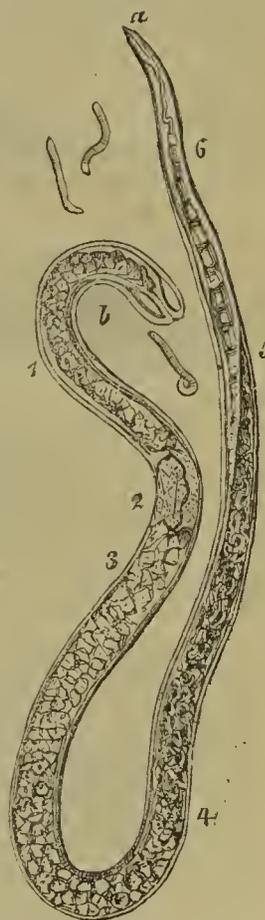

FIG. 6.

(i) l. c., p. 21

(h) Comptes Rendus de l'Acad. des Sciences, vol. xlix., p. 660.

FIG. 5.

the contents of the fibres, and at the same time take from them nourishment for their own use. At this period trichina is furnished with a mouth, an œsophagus, and intestinal canal; within a few weeks it grows so much that it attains thirty or forty times its previous size, which would be impossible if it did not assimilate nutritive material from the muscles. It not only destroys the muscular substance, but has also an irritating effect upon the adjacent parts. This latter may be chiefly perceived in the sarcolemma and the muscular corpuscles, and more especially their nuclei. On the spot where the animal has fixed itself, the sarcolemma becomes thickened, the nuclei of the muscular corpuscles increase in number and size, a firm substance is deposited between them, and in this way the worm gradually

FIG. 7.

FIG. 7.—Magnifying power, 120. Trichina from the muscle of a dog, five months after the animal had eaten trichinae. Earthy deposit at the upper extremity of the cyst, within which the worm is still visible.

becomes enclosed by a thick cyst, which generally contains only one, but sometimes two or three, trichinae. In proportion to the growth of the animal, it gradually assumes a spiral form similar to that of the spring of a watch. The time taken for these processes extends generally from the third to the fifth week. Within the next few months further changes go on in the cysts. Chalk is deposited in them, first at one extremity (Fig. 7), and afterwards in the whole of the cysts (Fig. 8). This latter is

FIG. 8.

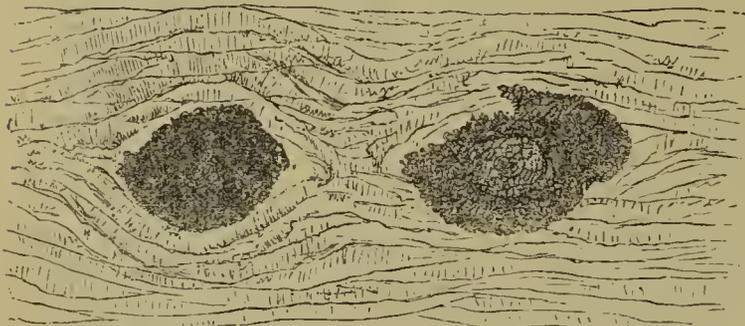

FIG. 8.—Magnifying power, 120. Piece of trichinous muscle from a human subject. Cysts completely calcified. The trichinae within them only become visible after the lime has been dissolved by the addition of acetic acid.

then no longer transparent, and its coat appears very much thickened. In this state it may be seen with the naked eye (Fig. 1). The flesh has a sandy feel, and on cutting it through with a knife it grates. The animal is now enclosed in a shell, like the egg of a bird. According to Vogel (k) the deposition of lime begins towards the fifth month. In those trichinae which have been so frequently observed in the dissecting-rooms of Edinburgh, Berlin, etc., the cysts are generally completely calcified. It is probable that years may elapse before this occurs. In most cases the trichinae contained in these cysts still preserve their vitality, and are capable of development; if the lime is dissolved, and they themselves are warmed, they begin to move about; if given to animals to eat, they undergo all those changes which have been related above. Sometimes, however, the worm itself is calcified and dies.

The number of trichinae which may be found in muscles varies exceedingly. In some cases there are not many of them; in other instances a piece of flesh not larger than a pin's head contains twenty and more. The sum total to be found in a man or an animal may amount to several millions. Six thousand millions trichinae only weigh one pound.

How should Suspected Meat be Examined for Trichinae? From which Muscles should Specimens be taken?

I have already mentioned that the cysts are visible to the naked eye as whitish, round, or ovoid spots, with which the surface of the muscle is sprinkled. If these are touched with a drop of acetic acid, or, better still, with diluted hydrochloric acid, the lime is dissolved and the white colouring disappears. This experiment is, however, not perfectly certain if larger pieces of flesh are examined, for the acid then produces a deposit from the muscular juice, whereby the whole surface becomes indistinct and turbid. It is, therefore, the best plan to cut off a very small piece of flesh with a fine pair of scissors, to tear this asunder with needles, and to free the cysts as much

as possible from the flesh. If this is done on a glass resting on a dark object the cysts may be clearly distinguished as whitish grains, and the dissolving power of acids becomes well apparent. If the spots retain their colour, it is probable that small pieces of fat, nervous fibres, or similar formations are present. But as pieces of fat may be connected with the cysts, a negative result is not so decisive as a positive one, and it is, therefore, in doubtful cases always better to use the microscope in order to decide the point.

It does not matter very much from which muscles the pieces to be examined are taken. Even if there are only a few trichinae, they generally exist in all the muscles of the body, excepting the heart. The heart of pigs may therefore be eaten with impunity. Trichinae are, however, more numerous in the tendinous extremities of the muscles, which is probably due to the circumstance that a large number of trichinae penetrate as far as possible in the muscular tissue, and only stop their progress if certain impediments (as tendons) offer. If we, therefore, wish to make the diagnosis of trichiniasis in man, it is best to excise a little piece of flesh close to the insertion of a muscle.

Trichinae which have not yet become encysted can only be recognised by means of the microscope. A thin layer of flesh should be cut out with a sharp scalpel, spread over a glass plate, and moistened with a drop of water. If it is then covered with a thin sheet of glass, we may distinguish trichinae, if there are any, with a magnifying power of 50. Their intimate structure, however, can only be recognised with a power of 300.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

JERSEY HOSPITAL.

CASE OF AMPUTATION OF THE LEFT ARM AT THE SHOULDER-JOINT—RECOVERY.

(Under the care of Mr. GODFREY.)

GEORGE P., aged 25, was admitted into Hospital June 8, 1863, as he was suffering acutely from an enlarged and much inflamed shoulder-joint, of which he gave the following history:—

He fell, early in January, from the side of a large vessel with his left shoulder across a hawser. The fall was stated to be about sixty feet in height, and was attended with great pain in and about the shoulder-joint, and the arm remained quite helpless. He was therefore admitted into an Hospital, and treated for fracture of the head of the humerus.

May 28.—He was discharged with a still helpless and painful joint, in which state he came under my notice.

July 28.—After various changes in the treatment without any marked improvement, his health began to fail, phthisis threatening to set in. Consequently I had a consultation with Messrs. Wood, Blood, and Leacroft, when it was agreed to amputate at the joint. I accordingly did so, with their kind assistance, from which time he rapidly improved, and regained his usual health. He was discharged September 10, since which he has always enjoyed perfect health.

Appearance of Bone after the Operation.—The glenoid cavity was healthy. The head of the humerus was necrosed, and a fracture extended downwards for about an inch and a-half. The structure around was much thickened and disorganised.

CASE OF AMPUTATION OF THE RIGHT LEG AT THE HIP-JOINT—RECOVERY.

(Under the care of Mr. GODFREY.)

F. J. L., aged 13, was admitted into the Hospital June 11, 1863, giving the following history:—Four months previously he had a long journey to perform in cold, wet weather, and that immediately after he was taken with severe shivering, followed by fever, and acute pain in the hip and thigh. He was then a thin strumous-looking lad, having a large abscess over the trochanter major, with a fistulous opening leading to bone, and another over the outer ankle, which also led to decayed bone. He was put on meat diet, wine ζ vj., daily, ol. morrhuae ζ ss. ter. die., under which he greatly improved.

September 6.—I had a consultation with several friends, when it was agreed that the patient should be placed under

the influence of chloroform, and then the fistulous opening enlarged so as to remove, if possible, the necrosed bone. I did so accordingly, but found that the disease ran into the joint as well as down the shaft, and that amputation was his only chance. However, as he was much weakened by the chloroform, which he apparently took with difficulty, the operation was postponed till September 8, on which day I removed the limb. He lost a remarkably small quantity of blood, the artery being well secured by Dr. Maclagan. He, nevertheless, remained in a very weak state, and for three days after the stomach was unable to retain even a grain of solid opium; consequently injections of beef-tea and brandy were given regularly, with the addition of an opiate at night, which acted very beneficially.

September 12.—He took a little champagne and ice, which the stomach retained. Bowels acted in the evening. Injections discontinued. The femoral ligature came away on the fifteenth day, and the flaps, which were kept together by stout silver wire, united very willingly.

October 14.—He was discharged in perfect health, which he still enjoys.

MIDDLESEX HOSPITAL.

CASE OF DISCOLOURATION OF THE SKIN.

(Under the care of Dr. GREENHOW.)

THIS case, Dr. Greenhow thought, would be considered interesting in reference to the possibility of similar ones being mistaken for the bronzed skin of morbus Addisonii.

The patient, who was 65 years of age, had been admitted into the Middlesex Hospital on June 3 last. She had been tramping about the country, and was in a very filthy condition and swarming with vermin, much emaciated and anæmic from hardship and long-continued scantiness of diet. Her appetite, however, had never been impaired, and she was quite ravenous at the time of her admission. Face and conjunctivæ were sallow, and feet slightly œdematous. Under good diet and Hospital management she had improved greatly in flesh and strength, and was now in very good condition.

The following notes of her case were taken by Dr. Greenhow on August 24:—

Pulse 86, of fair volume, not particularly compressible. Face scarcely sallow, but a little dark under the eyes. Conjunctivæ slightly yellow and muddy-looking. Tongue clean and normally red. Lips and buccal membrane also of normal colour. Arms, from a little below the insertion of the deltoid downwards, and legs below the knees, were also of normal colour. Body generally of a dark black-brown colour, excepting a large patch in the lower part of the left axillary region, and a smaller patch over the costal cartilages on the same side. The darkness not greater at the axillæ nor around the nipples, which are of normal colour and appearance, neither any increase of darkness round the navel. The dark surface has, on close inspection, a mottled appearance, being interspersed with minute patches of normal-coloured skin. The integuments, viewed under a lens, appear, in fact, to be of four shades of colour, viz.:—1. The normal colour. 2. A yellowish sallow hue. 3. Brown colour. 4. Specks of almost black hue. The darker patches appear to consist of small specks, or points of black and brown conglomerated together, and in some places the darkened cuticle under the lens looks raised, and in others a little rough. The appearance of elevation is especially noticeable in those darker patches which do not fade into a lighter degree of darkness, but end abruptly in pale, apparently normal coloured skin. Discolouration in front gradually fades into a yellowish sallow hue under the chin, and there disappears. Discolouration rather paler on back than on chest, and extends from the hair downwards to thighs. On anterior surface of legs numerous small isolated spots, some of which, under the lens, look red, others rough or covered with a small crust, others brown, closely resembling the darker patches on the trunk. A few similar spots on arms.

On August 26, in order to determine the seat of the discolouration, the cuticle was raised in two small patches on the chest by the use of liquor vesicans, and for some weeks after the healing of the blistered surface those parts remained pale, but gradually resumed the dark colour of the surrounding skin. Patient was ordered to have an alkaline warm bath three times a-week, and to take full doses of nitro-muriatic acid.

Under this treatment the discolouration has very considerably diminished, especially at the axilla, and on the back and

shoulders, on which considerable friction has been used after the baths, and the woman's health has become perfectly good.

From the description and the history of the case it was, Dr. Greenhow thought, evident that, although the discolouration of skin at first sight strongly resembled that found in morbus Addisonii, yet the entire absence of the characteristic constitutional symptoms, the almost entire absence of the discolouration from the face and other exposed parts, and the patchy character and defined margin of the discolouration itself conclusively distinguished it, in Dr. Greenhow's opinion, from true cases of Addison's disease.

THE ROYAL LONDON OPHTHALMIC HOSPITAL.

CASES OF ONYX AFTER SMALL-POX.

[Communicated by Mr. SPENCER WATSON.]

Case 1.—William T., aged 31, an engineer, generally in good health. He is pitted with recent small-pox, which came on about four weeks ago. He says that three weeks ago his left eye first became inflamed, and that it was then very painful, and disturbed his rest.

January 3, 1863.—There is now a yellow central opacity, of roundish form, and of the size of a millet seed; surrounding it is an irregular nebula. The pupil acts freely. He has intense intolerance of light, but is in no actual pain, and sleeps well at night. Atropine drops were administered, and he was directed to use belladonna embrocation and to take decoction of bark.

Under this treatment he improved up to January 24, when he began to complain of pain in the eyeball, and there was, at the same time, increased vascularity and intolerance of light. A blister behind the ear and a smart purgative relieved these symptoms; but it was found necessary to apply blisters three times after this, on January 31, and February 11 and February 21.

February 14.—There is still some intolerance, but no pain. The pupil is dilatible.

March 4.—The cornea is now much clearer, the yellow opaque spot having disappeared, and an ulcer formed, from giving way of the anterior layers of the cornea.

14th.—There is now no intolerance of light.

After this date the improvement continued, and vision became daily more distinct. On April 11, only a faint nebula, extending from the site of the onyx to the lower margin of the cornea, remained, and he was able to read pearl type—(No. 2 of test types).

This is a case of onyx which ran a very favourable course. The quantity of pus between the layers of the cornea was small; in the first instance, it made its way out forwards, and thus rendered the danger of iritis and prolapse less imminent; and the vital powers of the patient were sufficient to carry on the process of repair rapidly, and without any too copious effusion of plastic materials in an opaque form.

Case 2.—Emma S., aged 7 years, applied at the Hospital on January 28, 1863, with a diffuse haze of the right cornea. She had had small-pox seven weeks before admission, the pits remaining from which are plainly visible. She was then in great pain at nights, and suffered from considerable intolerance of light. There were nebulæ occupying the outer half of the corneal area, and a vascular zone surrounding it in the sclerotic. Atropine drops were administered; a blister was ordered to be put behind the ear, and decoction of bark was given in half-ounce doses three times a-day.

On February 4, so far from being improved, she was found to have an onyx occupying the whole of the central region of the cornea; the pain and intolerance of light had increased; she had been using belladonna embrocation with considerable relief. A leech was applied to the temple.

March 4.—There is now no pain; the cornea is clearer; there is less photophobia, but considerable lacrymation.

After this she came no more to the Hospital, and as she was improving at the last opportunity of seeing her, it is fair to conclude that this improvement continued.

Case 3.—Jem D., aged 40 years, a farm labourer near Barnet, applied at the Hospital on January 14, 1863. Three weeks before this two of his children had had small-pox, and he himself had had a few spots about him, but had not been laid up by it. At this time his left eye became inflamed.

On admission the whole corneal area, with the exception of a narrow circumferential rim, was occupied by an opaque yellow patch, evidently the result of pus between the layers

of the cornea, and there was probably pus in the anterior chamber at the same time. He had great pain in the brow and forehead, and intense photophobia. His general health did not seem to have suffered, and his appetite remained good. Two leeches were applied to the temples. Liq. cinchonæ, in fifteen minim doses, was administered, and atropine drops were directed to be used three times a-day.

On the 21st the pain was relieved, but in other respects he continued in the same state.

January 28.—A blister was ordered to be put behind the left ear, and decoction of cinchona was given three times a-day.

February 4.—The whole cornea is opaque. The pus, however, has disappeared, and at the outer margin of the cornea there is some puckering of the conjunctiva as if from rupture of the former and cicatrising of an ulcerated wound. There is now no pain.

March 11.—The cornea is still nebulous throughout, and at the central region threatens to become staphylomatous. He has with this eye only a quantitative perception of light. There is no pain nor photophobia.

March 27.—The central region has so far cleared that he can count fingers held between him and the window. There is a well-marked pterygium on the outer and a slight one on the inner side.

This case is a good example of one of the worst possible forms of onyx, and of the probable result in such cases. It was no doubt neglected in the early part of its course, though it may be a matter of doubt whether the result would have been different had treatment been earlier adopted.

Case 4.—Louisa W., aged 4 years, applied May 2, 1863, with recent pits of small-pox and a central opacity of the cornea. The eye affection had only existed fourteen days, the small-pox having attacked her five weeks ago.

There is a deposit of lymph near the centre of the cornea and vessels passing from the conjunctiva and sclerotic across the margin towards it—in fact, interstitial keratitis, the whole cornea being hazy and nearly covered by vessels. She had intense photophobia. Liq. cinchona was given in five minim doses three times a-day, and atropine drops were used twice a-day. Little improvement, however, resulted, and on June 10 there was evident onyx and hypopyon. On June 15 a blister was applied behind the ear, and on the 17th tincture of henbane was added to the bark. She now began to amend, and continued to do so. On August 15 the cornea had become so far clear that she could distinguish large letters (No. 20). The health also had much improved in every respect. On October 24 she continued to improve. There was a dense opacity, partly vascular, occupying the site of the interlamellar deposit of pus; but the rest of the cornea was perfectly clear. Vision had not improved.

Case 5.—Wm. T., aged 20 years. He is a spare man, and has just left the Small-pox Hospital, where he has been six or seven weeks. About one week after his admission into the Hospital the eye became inflamed, and has continued so ever since.

When first seen, June 10, 1863, at the Royal London Ophthalmic Hospital, there was a grey patch of exudation over the centre of the cornea; great photophobia and constant pain in the eye, which prevented sleep. He was directed to use the belladonna embrocation, and to take muriate of iron, ℥xv. of the tincture three times a-day.

On subsequent occasions he had quinine and henbane in addition to the above remedies.

He improved rapidly, and on July 11 an ulcer, which had formed over the patch of exudation, had begun to cicatrise, the pain and photophobia had ceased, and vision was improving.

November 14.—The condition of the eye was as follows:—Over the central region of the cornea, and partly overlapping the pupil, the cicatrix of the ulcer forms an opaque leucoma, but the cornea is clear elsewhere. He is now able to read No. 18 of the test types, and on dilating the pupil with atropine, No. 16.

It is difficult in this case to decide whether the keratitis was synchronous with the eruption of the variolous pustule or not, the probability is, however, that it commenced during the scabbing of the pustules, as in the previous cases. By the timely exhibition of tonics, the formation of pus between the layers of the cornea seems to have been prevented. At the same time, the youth and strength of the patient must be taken into account as materially influencing the favourable issue of the case.

Case 6.—Henry H., aged 24 years, applied at the Royal London Ophthalmic Hospital on September 23, 1863. Two months before he had small-pox. For the last six weeks he has suffered from inflammation of the eye. There was a patch of lymph covering the surface of the cornea, and the pupil was contracted and irregular. He was directed to use the belladonna embrocation, and decoction of bark with a small dose of bichloride of mercury (one-sixteenth of a grain) was prescribed to be taken three times a-day. At the same time the strong solution of atropine was applied.

September 19.—The inflammatory redness is subsiding.

October 7.—The central region of the cornea is of a bluish-grey colour, sodden and opaque. The sclerotic zone has returned, and he suffers from pain, especially at night. He looks pallid and much enfeebled. Ordered—Pil. saponis comp., gr. v. o.n.; hst. cinchon., ʒj. t.d. s.

The patient has not since returned to the Hospital, the history therefore remains incomplete, but it is nevertheless instructive, as showing the sequence of phenomena after small-pox, and the tendency there is to destructive inflammation in the corneal tissue, even after the variolous poison has to all appearance become extruded from the system.

Case 7.—Celia M., aged 4½ years. A strumous child, who had measles six months and small-pox four months before admission, September 30, 1863. She is marked with recent pits of small-pox, and on the right cornea there is a partial staphyloma of recent formation, with considerable vascularity and inflammatory opacity in the surrounding structures.

She was put upon a course of steel tonics, and a compress was applied over the protrusion.

On December 2 the inflammation had quite disappeared, but some intolerance of light remained. There was only very slight amount of vision, owing to the nearly complete opacity of the cornea around the staphyloma.

Case 8.—Emma H., aged 20 years, applied at the Hospital November 28, 1863. Six weeks previously she had had small-pox, which had left pits over her face. Two weeks ago, inflammation of the left eye commenced.

There is now (November 28) a deposit of pus at the outer side of the centre of the left cornea of the size of a rape seed, and an ulcer occupying the same region, but more extensive. She suffers from aching pain and much intolerance of light.

She was put upon decoction of bark and belladonna embrocation.

December 5.—Less vascularity and very little pain. The ulcer has not extended.

19th.—No photophobia; less vascularity; the ulcer healing.

The improvement continued, and on January 27, 1864, the inflammation had quite subsided, but had left a leucoma over the central region. She could, however, read No. 16 of the test-types.

On February 13 her vision had not improved: the leucoma will probably be permanent, as it has not materially changed in its characters since the last note. On testing her with glasses, it was found that she had a high degree of hypermetropia, which, to some extent, may account for her imperfect vision.

Case 9.—Emily P., aged 15. A strumous girl, with abscess in the neck. She had small-pox three months ago. The left eye was inflamed before the attack of small-pox, but became much more so during the disease.

October 28, 1863.—An ulcer occupying the outer side of the pupil; much photophobia, but no pain. She was put upon quinine, and belladonna fomentations were used, and this treatment was continued up to December 9, when only a faint nebula remained, and the photophobia had entirely disappeared.

THE TRICHINA PANIC IN GERMANY.—The extent to which this prevails may be judged of by the advertisements which appear respecting the trichina in the newspapers and Medical journals. In the latter we find "The Trichina Mirror. A popular scientific demonstration of the Nature of Trichina Disease, illustrated by twelve woodcuts, price 3d." "Preparations of Trichina for the Microscope, put up under the superintendence of Professor Vogel, of Halle. Trichinæ of Muscle, 18s. per dozen, or 1s. 6d. each. A suite of three pieces, viz., Intestinal Trichinæ, Muscle Trichinæ at the commencement of encapsulation, and Trichinæ with calcified capsules, for 6s.; or a dozen containing four suites for a guinea."

Medical Times and Gazette.

SATURDAY, APRIL 2.

TOPICS OF THE DAY.

LAST week we announced that the Branch Council of Medical Registration and Education for England had agreed to recommend the General Council to abandon for the present the proposed Amended Medical Act. We confess that we are neither surprised nor sorry at this decision of the most important section of the Council. The recent taste the Profession have had of legislation is by no means appetising. Our experience of the past begins with a poll-tax, and culminates in the British Pharmacopœia. Any other reminiscence left by the working of the Act or the exertions of the Medical Council is of the most shadowy description. The benefits which were to be conferred turn out to be wholly imaginary. The only tangible thing we have got is a Register, in which heretics and orthodox are indiscriminately mixed, and a Pharmacopœia which is so faulty that it has just been publicly stigmatised by the President of the Royal College of Physicians. We do not now stop to inquire whether this entire failure is the fault of the Medical Act or of the Medical Council. The broad fact remains that a legislative enactment, which has been only obtained after years of exertion, and which has cost the Profession an enormous sum of money, has proved utterly futile and unremunerative. It might reasonably be held that the complete failure of so costly an experiment should at least postpone its repetition for some time. But there is a class of Medical politicians who are so wedded to the principle of State interference that they can only see in all that has passed a reason for repeating the process. They fully acknowledge that legislation has been a dead failure, but they think that the remedy for the failure is more legislation. One of the most influential of our Medical contemporaries holds this opinion. Like Dr. Sangrado, when the patient dies after the fifth bleeding, and a proportionate quantity of hot water, it in effect gravely asserts that death took place from his not having drunk more water and lost more blood. As amongst the ills of the body physical there are certain diseases which are said to be cured by a reiterated inoculation of their specific poisons, we are recommended a curative course on the same principle for the body politic. We are to kiss the rod, and humbly beg for its fresh application.

These observations have been in part suggested by the eagerness which certain bodies hitherto considered outside the pale of the Profession have at once shown to take advantage of any disturbance in the present state of things and to assert a claim to be admitted into our ranks. We have lately examined the pretensions of the chemists and druggists. But another set of aspirants are the dentists, or rather, we should say, the possessors of the dental certificate of the Royal College of Surgeons. We confess that the position of these gentlemen is somewhat anomalous, and it may be fairly asserted that they have met with but scant courtesy from their adopted mother in Lincoln's-inn-fields. They have paid their fees and

have passed a nominal examination, which, however, in the case of future candidates, is, we are assured, to be of a more searching character, and they have hitherto received in return from the College nothing but a parchment conferring neither privilege nor protection. We think the College is bound to extend to them the courtesy of admission to the reading-room and museum and to the College lectures. But, at the same time, we maintain that the possession of a certificate of fitness to practise dentistry from the College of Surgeons gives them no real claim to be placed on the register of Practitioners of Medicine and Surgery. It may be true, as Mr. Lawrence asserted at the recent dinner of the Dental Licentiates, that the curriculum to be hereafter followed by candidates for the dental certificate will render them better informed than are the members of the College. If it be so, all we can say is that the fault rests with the College, which regulates the curriculum and the examination imposed on its members. But whatever may be the advantages conferred by the respective educations, there is no doubt that the examination for the dental license is essentially different in kind from that for the diploma of the member. The Profession, however, will not tamely submit to see a new body of men, the great majority of whom have passed only a nominal examination in dentistry, placed on the Government Medical Register. The public will reasonably suppose that a very slight difference exists between the Dentist and the Surgeon. The former will prescribe lawfully for all affections connected with the dental apparatus and the other organs of the mouth, neuralgia, affections of the antrum, salivary glands, and tongue, and any constitutional treatment they require will at once be competed for by the new order of Practitioners. To metropolitan Physicians and Surgeons this will probably make but little difference, but it will seriously affect practice in small towns and villages. We are actuated by no narrow spirit of jealousy in these remarks. The Medical Profession will be most happy to recognise in dental practitioners valuable allies, but they have no wish to meet them as rivals. If the new curriculum imposed on these gentlemen be in reality superior to the curriculum for the membership of the College, let the Licentiate in Dental Surgery, as a preliminary step, obtain the diploma of membership, and afterwards pass a special examination in the dental art. Then, and then only, will the Medical Profession cordially welcome the dentists into their body. At present, as is well known, the majority of the gentlemen who have obtained the dental certificate have passed through no prescribed course of study, whilst the examination to which they have been subjected has been of an entirely nominal character.

Now we are on the subject of the dinner of the Dental Licentiates, we are tempted to notice a post-prandial oration of the "Nestor of British Surgery," Mr. Cattlin, F.R.C.S., to whom the Medical and dental Professions are equally indebted for much self-denying work done for both, had hinted his hope that the examination for the dental license would, in time, be preceded by an examination in classics and mathematics. This very reasonable and laudable aspiration met with no sympathy from Mr. Lawrence. He is evidently at variance with all the ancient as well as modern theories on the beneficial effects of the humanities. He said:—"I think a person who is decently acquainted with reading, writing, and arithmetic, if he gets thoroughly acquainted with his own profession, will become a very useful member of society, though he does not know Latin or Greek, nor the elements of mathematics." Of course the same might be equally affirmed of a farrier; though how a person can be acquainted with the nomenclature of anatomy, natural history, and botany without a smattering of Greek and Latin, or can master the elements of physical science without some little knowledge of mathematics, we are at a loss to understand. No doubt there have been here and there men of enormous talent, like John Hunter, who have become great Surgeons without much preliminary training, although it is to be remembered that Hunter, as a Scotchman, certainly

got something more in the way of early education than merely "the three R's." But the generality of minds which have only been exercised up to this point would be quite incapable of "getting thoroughly acquainted with their own profession." Had such an opinion come from any authority less eminent than Mr. Lawrence we should have passed it over in silence as unworthy serious examination. We hope that we are mistaking Mr. Lawrence, and that he spoke in irony, and not in sober sadness; if otherwise, we can only attribute his extraordinary and unique opinion to a love of paradox and a natural relish for differing from the rest of the world.

Amongst other "topics of the day," the re-election of Dr. Watson to the Presidential chair of the College of Physicians may be mentioned as a proof that that learned body are as keenly alive as ever to everything that is worthy of veneration—scholarship, character, and Professional skill. We wish that we could speak in terms of equal approbation of another act of the College. It has lately been employed, at the request of Government, in the revision of rules for public general Hospitals in the colonies. Amongst the recommendations confirmed by the College at its last meeting is one which appears to us not merely extraordinary, but reprehensible. They have recommended, "That all cases of infectious diseases, excepting small-pox, should be treated in the same wards as other patients." This, in the face of the accumulated experience of the Fever and the other London Hospitals, involves the College in a heavy responsibility, which we suspect few other Medical Corporations would be willing to share.

SCHOOL DIETS.

WERE we to summon a congress of parents, schoolmasters, and other authorities on the rearing of our species, for the purpose of drawing up tables of diet for children, the result, we suspect, would be hopeless confusion. As many dietaries would be proposed, and stoutly supported, as there might be members of the "congress"—"*quot homines (feminaeque) tot sententiae*," the utmost we could hope for would be a general, and useless, resolution "that children should be dieted according to their respective constitutions;" and such a resolution as this even would be certainly opposed by some, who would contend that the diet should make the constitution—not the constitution the diet. We incline, however, to the belief that in private life, except when mamma happens to be cursed with a smattering of Medical reading, or is ruled by semi-scientific theories, the feeding of children is prone to err rather on the side of excess than of deficiency. Certainly among the lower classes the rule obtains, more or less, that children should eat when they like, what they like, and as much as they like; and among the upper classes there is more danger of a child being overfed than starved, unless a half-educated or a "highly accomplished and learned" mother is so blown up with imperfect and semi-digested theories of physiology that the voice of instinct and common sense is totally suppressed. Then, indeed, children are too often starved both as to food and warmth, and their life kept at a low ebb with an idea of making them vigorous and hardy. But as a rule, children in private life are fully well fed, and so also in schools now-a-days. In our large public schools, and in the great majority of private schools, the diet is ample and good, and in many luxurious. Young gentlemen will, indeed, while at school abuse the food provided for them, and will spend all they have, and much more, at the "tuck shop;" but as soon as they get home they turn up their noses at the domestic early dinner, and swear it is not half so good as what "Old Jones" gives them. Still, no doubt there are many mysteries in the way of feeding to be learnt in the small schools scattered over the country, and our minds have been much astonished and exercised by the revelations made on this subject during a late trial in a provincial town.

The Misses Green, who keep a boarding-school, sued a

restive parent for two quarters' board, etc., for a boy of 9, whom mamma had had home during the quarter, and had kept at home without any notice or warning; and mamma's defence to the action was that her boy had been ill in consequence of insufficient and bad diet at school. The charges at the school were certainly very moderate—if they should not be more justly called immoderately low. They were suited to the meanest capacity of purse—only £15 a-year was charged for board, lodging, and instruction! We do not learn what "extras" there were, nor what was the curriculum of instruction; but as it is in evidence that the Misses Green had paid "their Music Teacher's" bill, we may infer that it embraced even what may be called the luxuries of education; and there is nothing to show that the school did not enjoy a fair repute. No other protesting mammas appeared but this one, and no other injured children. Thinking, then, on how little of the £15 could remain to pay for food, we looked with great curiosity to see what the diet was, and found it thus fully given by a hostile witness, who was servant in the school in 1862 and 1863:—

Breakfast.—Milk thickened with flour and water, and a round of bread; or nettle or onion broth made with oatmeal and water.

Dinner.—Sunday, meat, plenty of vegetables and pudding. Monday, pudding. Tuesday, cold meat and vegetables. Wednesday, boiled rice and treacle. Thursday, meat. Friday, rice-pudding. Saturday, boiled bacon or pig's face, and boiled peas.

Tea.—A cup of tea and a round of bread and lard, or more if they wanted it.

And, "not more than three times a week"—on, we suppose, the no meat days—soup made from sheep's-head and pluck.

All this, with such an education, for £15 per annum! We are compelled to regard the Misses Green with profound admiration.

Compare their dietary with that of a great and eminent educational establishment, that of Christ's Hospital. In 1857 the following was the diet-table at the Hertford branch, in which the boys average from 7 to 11½ years of age, the girls from 7 to 15:—

Breakfast.—Bread, five ounces, and half a pint of new milk

Dinner.—Bread, two and a-half ounces; potatoes (or rice), six ounces; roast or boiled meat, four ounces—the first six days of the week. Saturday, bread, five ounces; one pint of pea-soup, one-third of an ounce of butter.

Supper.—Bread, five ounces; butter, half an ounce; milk-and-water, half a pint.

"Some of the elder girls have additional nourishment."

The Misses Green did not measure out their food by the ounce! and the soup of "sheep's-head and pluck" may have been made as nourishing as "four ounces of meat." The Surgeon who gave evidence on the mamma's side says, indeed, that "he could not consider that soup made of sheep's lights was a proper thing for the regular diet of children," and we must admire his courage in offering such an opinion; but it hardly seems to apply here, as the soup was provided "not more than three times a-week," and the sheep's-head was added to, not only the lights but, the "pluck" as an ingredient, and forms—as our Scotch friends at least will allow—a very important addition.

But our greatest admiration is given to the nettle porridge. Some of the ignorant and prejudiced witnesses spoke slightly of it as "nettle broth," but it was evidently oatmeal porridge with nettles added. Such an item of diet evinces a tenderness of regard for health, enlightened by a degree of judgment and learning that excites our highest consideration. The Misses Green are evidently deeply versed in the lamentably-neglected knowledge and use of simples. In the interest of their little charges they have studied our old herbals, and are aware how wrong it is to regard the nettle as a "weede, seeing that it is so profitable to many purposes." We need only

quote in proof of this from Thomas Cogan's "Hauen of Health," 1589:—

"Ægris dat somnum: vomitum quoque tollit et usum,
Compescit tussim veterem; colicisque medetur:
Pellit Pulmonis frigus ventrisque tumorem.
Omnibus et morbis sic subvenit articulo rem."

The very thing for scrofulous children! and how infinitely superior in many ways to brimstone and treacle! We acquire a deeper sense of the iniquities of Dotheboys' Hall; we had imagined that Mr. Squeers was screwing but a miserable living out of his boys; but if the Misses Green can get any profit out of their school at £15 a-year now, Mr. Squeers must have been rapidly making a fortune. We suspect, however, that the Misses Green are secret benefactors; hiding their good deeds under the pretence of keeping a school for profit, they were really sacrificing their ease, time, and substance for the benefit of the rising generation. If not, we could wish that British wives would take a lesson in economy from them, for we know but too well at present that we cannot board, lodge, and educate our children in their style for anything like £15 per annum.

THE WEEK.

LESSONS FROM OUR NEIGHBOURS.

MR. GREAVES, President of the Lancashire Veterinary Association, delivered a capital address to the members at their late meeting in Manchester. Are there any country Surgeons who groan at the idea of becoming Councillors of the Royal College of Surgeons? Let them learn from Mr. Greaves that—

"We see our ex-President, with his extensive practice, go up to London to the meetings of Council seven times every year, and to Scotland once or twice every year, to exercise that fine perception of judgment necessary for an examiner, travelling a distance of over 3720 miles yearly, at an expense of over £30 for railway fare alone, to say nothing of the loss of time—time which is to him of far greater value than money. We are under a deep debt of gratitude to that gentleman, and I feel I must honour that man for his zeal and the great sacrifices he has so nobly, generously, and freely for so many years laid upon the altar of veterinary science."

Are there any of us perplexed at the failure in life of some of our brethren? Let us hear Mr. Greaves, whose words might well be written in letters of gold, and hung up in every Medical school:—

"In our daily life, on a cursory view of human nature, we see many things calculated to perplex and embarrass us. We see, for instance, men rich in intellectual attainments unable to secure for themselves a sufficiency of ordinary necessities, whilst, on the other hand, we see plain uneducated men, of unquestionably a lower order of intellect, quietly and diligently plying their avocations, it being an invariable rule with such men, under all circumstances, to execute business with prompt and decisive action, and by a wise, economical application of time and means amassing money; and in a few years of wholesome thrift we find them rolling in wealth. We are apt to refer matters of this kind to some mysterious dispensation of Providence beyond our comprehension, and wholly independent of human control; but, on a closer inspection of the circumstances of any particular case, we often find all mystery vanishes, and we are able to trace men's failures to natural causes. It will frequently be found that such failures are referable to some weak point in mind or body, or to a defect in the balance of power amongst the different functions—a victim to the baneful effects of the worst of all habits, procrastination, and irresolution, a want of nerve and energy, a deficiency of animal and moral courage, which is necessary for success in the practical struggles of life. With him there is a constant miscalculation of time and means, occasioning continual hurry, difficulty, expedients, penury."

Are there any of us inclined to degrade our calling, and listen only to the inspiration of the *auri sacra fames*? Mr. Greaves says of the motives which induce the Veterinarian to come to an Association meeting—

"We may liken it to an *errand of mercy*, in which we feel impelled by a strong intellectual desire to acquire more practical knowledge, by which we may with more ease administer

relief, and with more certainty remove suffering and save life. What object on earth, I would ask, can be more laudable or more praiseworthy? Talk of a heavenly calling being compatible with an earthly calling!—why, in its very contemplation it has an infinite charm."

This is true professional enthusiasm, and we congratulate the Veterinarians most cordially upon it.

THE ROYAL COMMISSION ON PUBLIC SCHOOL EDUCATION.

FOR the last few years a Royal Commission has been sitting to inquire into the state of education at our public schools. The Commissioners have just brought their labours to a close, and issued their report. It is a ponderous volume, and embodies a great deal of evidence, collected from a variety of sources. But the suggestions it contains—at least, so far as they interest us—may be given in a few words. The Commissioners recommend that the Greek and Latin classics should still retain their place as the basis of education; and for this they assign what appears to us to be very good reasons. But they are anxious to promote other studies as well, and among these they would include *at least one branch of natural science*. And if one of the natural sciences is taught, it is probable that several will be; for it would be difficult to say which of them ought to be selected to the exclusion of all others. Further, the Commissioners recommend, with certain limitations, a system analogous to the French *bifurcation*, by which a boy, on reaching a given position in the school, would be allowed to choose his own line of study, even though such choice led him to lay aside classics altogether, and devote his whole attention to natural science. Of late years arrangements have been made at many schools for teaching natural philosophy, chemistry, geology, etc., but now a Royal Commission, speaking to the foremost schools in the country, and with the voice of authority, recommends that these subjects should form part of the regular course of study. Thus, then, the natural sciences, which Aristotle and the ancient philosophers studied and taught, but which have long been excluded from our English schools, are in the fair way of being admitted. A knowledge of chemistry or geology will no longer be considered as an "elegant accomplishment," but as an integral part of a good education. Nor is this without its interest for us. Our Profession is the natural outlet for a boy who has a taste for the physical sciences. If a lad is well taught in chemistry or botany at school, he will find his Medical studies so much the lighter when he enters upon them. Moreover, every encouragement given to the study of natural science tends to raise the standard of Medical education; and just in proportion to the measure of education which is general among us will be the usefulness, the influence, and the social position of our Profession.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE IX.—FEBRUARY 20.

IN this lecture the account of the variations of human structure was resumed. Daubenton was the first to point out that the position of the occipital foramen, in man situated near the centre of the skull, gradually recedes backwards as we descend through the animal series, and that the plane of the foramen, at first horizontal, gradually becomes more oblique, and at last vertical. The best way to measure this is to bisect the skull in the longitudinal and vertical direction (without which no examination can be made with any approach to completeness or exactitude), and then draw a line from front to back in its greatest length, and let fall another at a right angle with this, through the middle of the occipital condyles. The point at which the line drawn through the condyles meets the longitudinal diameter varies greatly in the human species, both in individuals and races. In a well-formed European skull, the space behind the condyles being represented by 100, that in front will be about 115, but it has been found to reach 140, though this is very uncommon. In the lower races, on the

other hand, 100 to 140 represent a very frequent proportion between the parts of the cranium thus divided. M. Gratiolet has pointed out a difference in the order in which the sutures become obliterated, the coronal and sagittal disappearing sooner than the inferior sutures in the lower races, and *vice versa*; but this remark requires a larger basis of observation before it can be accepted. The different planes in the interior of the skull, mentioned in the first lecture, vary considerably in different individuals, but their variations have not been shown at present to accompany any marked difference of race; it is important, however, to remember that variations may exist. The plane of the squama occipitis also varies extremely, sloping sometimes backwards and sometimes forwards from the superior curved line on the occiput, corresponding with the development of the posterior lobe of the brain.

The development of the face and jaws, in proportion to that of the cranium, is a very important point of difference in various races of men. The determination of their proportions by the facial angle of Camper is not very successful, as the points chosen for its measurement are not relatively fixed. The best method is to bisect the skull, and find the cranio-facial angle, or the angle formed by the basi-cranial axis (from the posterior end of the basi-occipital to the junction of the presphenoid and ethmoid), with a line drawn from the last-named point to the anterior extremity of the premaxilla. It will be seen, by comparing sections of different skulls, that this angle varies greatly, the face undergoing a kind of rotation on the skull; when the angle is open, the jaw projects, giving rise to what is termed "prognathism;" when it is nearer a right angle, the skull is "orthognathic." But projection of the jaw is not only caused by great angulation of the face; the actual size of this part of the skull ("macrognathism"), as compared with the cranial part, must also be taken into account. The jugal arch differs very greatly in size, strength, and lateral projection; when a skull is held at arm's length, with the vertex towards the observer, in some cases the arches are seen projecting beyond the sides of the cranium; such skulls Mr. Busk proposes to call "phanozygous." In well-formed European skulls the chin is straight, or projects beyond the level of the incisor teeth; in the lower races it retreats somewhat, though the recession appears greater than it really is, in consequence of the prominence of the teeth in these races. The arch formed by the teeth in the European, and especially in the short-headed races, is wide and evenly rounded; in some of the lower forms it becomes prolonged and narrow, the sides being nearly parallel. In the lower races the posterior molars are not so disproportionately smaller than the others, as in the higher groups.

Passing from the skeleton, it will be necessary to point out a few of the variations which have been observed in the arrangement of the muscles of the extremities,—a subject which has not been sufficiently attended to, considering the vast opportunities afforded by the dissecting-rooms of our numerous Medical schools. If teachers or students would take the trouble to note all such deviations from the normal structure as may come under their observation, they would render great service to the science of anatomy. In the hand, the flexor pollicis proprius sometimes divides into two tendons, one of which goes to the index finger; sometimes the extensor minimi digiti gives a second tendon to the fourth digit. The extensor indicis is occasionally absent, and sometimes sends a tendon to the third digit; in some rare cases, short extensors have been seen in the hand, and the interossei of the second space have been observed to assume the same arrangement, as to their origins, as those of the foot. In the foot the tibialis anticus is not uncommonly divided into two muscles at its lower end, one inserted into the entocuneiform bone, and one into the first metatarsal; there are sometimes one or two additional peronei passing behind the malleolus; the flexor brevis not unfrequently arises only partly from the calcaneum, the slip for the fifth toe coming from the deep flexor tendon. It appears from these instances that the hand may occasion-

ally assume some of the characters of the foot, but there is no evidence yet to show that the foot ever does the same to the hand.

The brain of man varies greatly in size, weight, and form; perhaps no part of it so much as the posterior lobe, as may be seen in the collection of casts of the interior of crania lately added to the College Museum. There seems no relation between the projection of this lobe and the position of the individual in the scale of human beings; on the whole, it seems as great or greater among the lower than in the higher races. The posterior cornu and hippocampus minor among the internal structures are the most variable, the former being merely a relic of the great original cavity, its greater magnitude would indicate a low, rather than a high condition. The hippocampus minor is constant; but its appearance in the ventricle, being entirely dependent upon the form and size of the cavity, varies greatly. A great range may be observed in the complexity of the convolutions in different brains. On the whole, they are simpler in women than in men, and in the lower races the convolutions have a greater simplicity and symmetry than in the higher. Gratiolet called attention to this in his description and figures of the brain of the Bosjes woman who died at Paris, called the "Hottentot Venus," and though it has lately been asserted that this person was an idiot, there is the best possible evidence to show that such was not the case. Recently Mr. Marshall has obtained from the Cape the preserved brain of another female of the same race, and his description of it, communicated to the Royal Society, fully bears out Gratiolet's conclusion.

The important question now remains, what is the value of the differences which have been shown to exist in the structure of human beings? This resolves itself into two other questions,—1. Are they sufficient to justify us in supposing them to indicate distinct species of men? 2. Can any of the deviations be considered as transitional towards the lower forms of animals? In respect to the first, it is certain that well-defined types occur in different geographical localities; those whose characters are most distinct are,—1. European or Caucasian; 2. Mongolian; 3. Negro or Ethiopian; and 4. Australian. That these types are observable and distinct there can be no doubt, and any zoologist taking a well-marked example of each, without any other evidence, would pronounce them distinct species; but extended knowledge shows that every intermediate form can be found between the most typical, and there is no proof that they are not all fertile, not only *inter se*, but the resulting race is also fertile. These two considerations conclusively show that there is no foundation whatever for the doctrine of the diversity of mankind; the well-marked varieties may be called *races*, but not *species*. As to the second question, it may be answered equally conclusively. Although, here and there, as in the lower races of men now upon the earth, and in the skeleton found in the cavern in the Neanderthal, the human type varies a little in some particulars in the direction of the Ape, the extent of this variation is very slight indeed, when compared with the whole difference which separates them, and it may be safely affirmed that there is at present no evidence of any transitional form or intermediate link between Man and the next succeeding forms in the vertebrate scale.

FROM ABROAD—LEZE-PROFESSION AT FOGGIA — TRIAL OF M. ARMAND.

THE Profession has been somewhat scandalised in Italy by the conduct of the Medical Practitioners of Foggia, near Naples. Typhoid fever having broken out in the Military Hospital, it decimated the troops to such an extent that the Military Medical officers no longer sufficed to pay them suitable attention. The civil Practitioners were therefore appealed to for their aid, but in vain, for, with the exception of one, all refused their assistance. We have not seen what reason they assigned for this extraordinary conduct; but at all events it

has proved very unsatisfactory, for the Executive Committee of the Italian Medical Association, stationed at Turin, having full opportunity of becoming acquainted with all the facts, has addressed a circular to all the presidents of the local committees of the Association, calling upon them for the immediate opinions of these various committees as to the propriety of expelling from the Association any of these Foggian Practitioners who, being members of the Association, may be proved to have thus "deserted the field of duty." The Committee has also addressed a letter to the Minister of the Interior, acquainting him that a sufficient number of Practitioners in this and other provinces of the kingdom hold themselves in instant readiness to repair either to Foggia or to any other place where a similar emergency may prevail; and expressing "its confidence that this exception, new in the history of Medical practice, will not prejudice the reputation for abnegation and courage which is a deserved possession of the Italian Medical Profession."

The hackneyed saying, "They manage these things better in France," will certainly not gain an illustration from the last *cause célèbre* which has just been concluded in that country, the trial of M. Armand, of Montpellier, for the murder of his servant. Notwithstanding the *code*, concerning the simplicity, precision, and adaptiveness of which we have heard so much, the most elementary principles of the administration of criminal justice may, it seems, be set at defiance, and procedures put into force worthy of the tribunals of the middle ages. A man of unblemished antecedents, upon the uncorroborated deposition of one of bad character, is kept during eight long months within the walls of a prison, subjected to a system of harsh discipline, reserved by ourselves, if put into force at all, for those who have been condemned. Having been duly tortured by attempts to induce self-condemnation, he finds himself, when put upon his trial, confronted with a judge whose object seems to be to procure, at whatever cost, his conviction, and who, demeaning himself as a prosecuting counsel, manifests irritation when that end is not attained. An acquittal notwithstanding ensues, but by some process, which to us is simply unintelligible, the accused is mulcted in the sum of 700*l.* or 800*l.* for blows declared to be "inadvertent," but which, if inflicted at all, were directed with murderous intention. We are not yet in possession of the Medical evidence, but before long we shall doubtless have M. Tardieu's report in full, in which he has exposed the imposture of the accuser. We may observe, however, that in reporting our English trials we are accustomed to severely criticise the discrepancies prevailing among the Medical witnesses, and to say that such exhibitions would be impossible on the Continent, where the system of official experts prevails. Well, on the present occasion, great was the variety of opinion promulgated, and acrimonious was the altercation which it gave rise to.

EXAMINATION OF THE BRAIN OF A CRETIN.—Professor Wedl gave an account to the Vienna Medical Society of the examination of the brain of a cretin girl. The skull-cap was very thick, and in many places beset with bony deposits. The dura mater was attached to the cranial bones, and the walls of the vessels had undergone thickening. The grey substance of the periphery was considerably diminished in quantity, and also changed in colour and structure. The form of the base of the skull was very remarkable, and the occipital foramen was proportionally very large. With the microscope the walls of the capillaries were found thickened (a deposit of a mass of colloid structure existing there also), while their cavities were in part abolished. There were thickening and sclerosis of the cells of the grey substance; but the most important appearances were large masses of white corpuscles, which Professor Wedl regarded as colloid corpuscles. These were only found in those portions of the section in which nervous masses were present. Professor Lenhossek has figured similar bodies observed in canceroid formation in the spinal marrow.—*Wien, Allg. Med. Zeit.*, 1862, No. 49.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

(Continued from page 319.)

THE MEDICAL HISTORY OF WOLVERHAMPTON.

Few English towns are more uninviting to the stranger than Wolverhampton. On entering the place for the first time, it promises nothing save dulness, and the thought that the sooner you are out of it the better comes into the mind with painful spontaneity. The town is hardly to be considered the capital of the black country—at least, not by its blackness, for in this respect it fails to match with Dudley—but still it is dark, irregular, and, curiously enough, considering that it is so large a manufacturing centre, it is quiet. After a short acquaintance it improves greatly, for beneath all its heaviness one discovers a vitality which is refreshing, and indications of progressive improvements which largely relieve the first monotony.

In all their future work for the good of Wolverhampton the authorities there are fortunately placed. Whoever laid the first stone for them knew what he was about: it must surely have been some more than usually wise old abbot, or some learned, peripatetic Freemason, who was conscious, without any professed scientific or sanitary knowledge, of all the requirements, in the matter of site, of a dwelling-place for mankind. Often as we ride along county districts, when we come upon a village or a town, we ask "Why, in the name of all things foolish, was that spot pitched upon for houses? The place is in a valley, or a 'hole,' as they say in 'Loamshire;' it gets no sun, and little wind; when the snow falls on the surrounding hills and melts, the houses are flooded; when rain is withheld, there is water nowhere except at some one spring on a hillside, or at one well which never runs quite out; and so in extremes of season the habitation is next to uninhabitable, and at the best of seasons is susceptible of little advancement physically." From these disadvantages Wolverhampton is free; it stands on a model site for the sanitarian. It is situated on a high ground, its basis a sandstone rock, with a small portion of green or trap rock at the north-eastern part. The water supply—I mean that which is natural to the town—is abundant, and the fall of water is so easy, and the outlets so free, that drainage is secured to a considerable extent without the employment of any artificial means.

The history of the town dates from the year 966. Plott, who is considered a great authority on Staffordshire, states that the town took its origin and its name from one of the noble ladies of the Anglo-Saxon race. Wulfrune, or Wolfrune, said to have been the wife of Athelme Duke of Northampton, is given as the foundress. When the Duke Athelme died and poor Wulfrune was left a widow, with a pious intent, characteristic of the age in which she lived, she built a church, or a monastery, or an abbey, or some other holy place—for the historians are not very clear as to the actual building—and there people congregated, first for religious and afterwards also for secular purposes. Thus there sprang up a commune or town, which took a name from the name and title of its foundress—Wulfrunes-hampton, which name gradually lapsed into the shorter expression, Wolverhampton.

The history of Wolverhampton during its early period is little known; it probably remained for many centuries a small retired place, with its people engaged mainly in agriculture. That it was not considered of very great importance in the middle ages may be inferred from the fact that the old church is a deanery attached to Windsor, the Dean of Windsor being also the Dean of Wolverhampton. When it became a seat for trade, what raised it first into a manufacturing town is not so obvious as might at first be supposed. Doubtless the chief reason for the change which it has undergone, and for its present wealth and, I may say, commercial greatness, is the wealth of the district,—the natural wealth of the earth near and around. The townfolk have followed rapidly the industry that has been called forth by the skill of the miner, and, taking up the treasure that he has dug out, have applied themselves to make it useful to the world at large. Thus, in the course of de-

velopment, certain specialties of occupation have been added to the town, and it has become a representative place in the realm. Towards this progress its position has given to it immense facilities. Few towns in England are more easy of access, few so commanding in regard to the country at large. A central locality, and elevated beyond most others, it looks over the broad lands of the kingdom towards all points of the compass, and if it were requisite to build a tower high enough to bring this half of our island under survey, the engineer would unquestionably select Wolverhampton for his foundations.

At the present time the town is divided into two boroughs, or, rather, into a municipality and a parliamentary borough. The municipality is limited to what, I think, was originally the parish of Wolverhampton; the parliamentary borough includes four large parishes, viz., Bilston, Sedgeley, Willenhall, and Wednesfield. In every one of these parishes the development of industry and of the population increases with wonderful rapidity,—with such rapidity, in fact, that now the houses of Wolverhampton represent in round numbers, and by number, the inhabitants of the place during the first year of the present century.

The present condition and occupation of the people of Wolverhampton are best understood by following facts, the results of the last census, 1861. In the town, at that date, the classes were divisible as described in the table:—

WOLVERHAMPTON IN 1861.

Classes of Persons of or above Twenty Years of Age, with Proportional Numbers per cent.

Total	66,282.
Professional class	1,229 or 1·9 per cent.
Domestic class	27,460 or 41·4 „
Commercial class	2,505 or 3·8 „
Agricultural class	3,271 or 4·9 „
Industrial class	28,764 or 43·4 „
Indefinite (unproductive class)	3,053 or 4·6 „

If we turn from this general statement to an analysis of the principal branches of industry, we find the following series of facts bearing on the numbers of the principal industrial classes of the town specially enumerated:—

Occupations of Wolverhampton, including those for which it is most noted, and Classified according to Sex.

	Number of persons aged twenty years and upwards.	
	Males.	Females.
10. Gunsmiths	105	—
6. Engine and machine makers.	452	—
5. Japanners	272	250
2. Coal miners	3,808	—
4. Iron miners	620	—
7. Brass founders	388	—
3. Locksmiths	2,293	—
1. Iron manufacturers	3,903	38
9. Nail manufacturers	181	55
11. Screw cutters and makers	—	64
8. Tool makers	206	—

Of certain of these industrial classes, Wolverhampton may be considered as containing more artisans than any other town; thus, in the iron manufactures, she stands above Bedwely, and from three to four times above Birmingham; in coal miners she stands sixth in the list; in locksmiths she is richer than Penkridge, Walsall, and Birmingham put together; in iron miners she stands seventh; and in japanners she is first on the list; she is a little above Birmingham in the number of artisans in this last department, there being in Birmingham only 270 male and 239 female workers.

Judging from the number of artisans employed we should assign to Wolverhampton the following occupations, according to their local importance as branches of industry:—Iron manufacture, coal mining, locksmithing, iron mining, japanning, engine and machine making, brass founding, tool making, nail manufacturing, gunsmithing, and screw cutting. It will be observed that amongst the artisans no less than 400 women are employed in occupations which are considered generally as removed from women's work. Thus, 64 women are engaged in cutting screws, and 55 in making nails, while 250 follow japanning,—a branch of industry for females which might, I think, be very largely extended, as it is light, in many instances very delicate, and admitting of great refinement. There are, in addition to the above, several other

important branches of industry in Wolverhampton, among which I will especially name the chemical works for the manufacture of chemicals and medicine. The firms of Mander and Weaver and of Bailey and Son will be at once recognised by Medical men. In these works various drugs are manufactured, I had almost said, for the empire, and I learned some curious facts respecting the use of certain drugs which we are generally accustomed to consider as falling out of the fashion. Thus Mr. Weaver, in taking me through his extensive manufactory, informed me that he alone manufactures not less than from ten to twelve tons of the golden sulphuret of antimony a-year, and from nine to ten hundred-weights of calomel per week. As the calomel is used exclusively in medicine, it is rather important to know whither it goes. Fortunately, it does not all enter the stomachs of her Majesty's lieges in the mother country; a portion of it is sent to the colonies and to India, and a fair share of it is prescribed for dumb animals by their private Practitioners; indeed, as the home trade for calomel has not declined, and as the home consumption of it by man has declined in a remarkable degree, we are forced to the unpleasant inference that the use of cannibals—I beg pardon—I mean of calomel, in the treatment of the inferior creation is on the increase—an inference to which it is only necessary to direct the attention of Mr. Colam to insure the immediate application of his zealous exertions.

The aspect of Wolverhampton is precisely that which would be expected of a place that has risen rapidly, and has been added to house by house, and building by building, to suit the purposes of particular trades and occupations. There are no large and commanding edifices, as in older towns, comparatively few churches, and none of the great buildings for manufactories or warehouses such as are seen in many manufacturing districts of very much smaller size. There is no trace of tall chimneys, nor is the air charged with smoke, nor can the town as a whole be considered dirty. Picturesque old houses, such as those in Stafford, are wanting; but the new ones even look old, as though, like men who give themselves up too much to business, they had arrived at premature maturity. Art there is none in the construction of the streets, and I saw but one secular building that an artist would claim; and that one was a School of Art, which has recently, and not too recently, been erected. The Reading-room is, however, a spacious building, and within is handsomely decorated; and the Agricultural Hall, although not remarkable for its style, is an agreeable modern addition, and is arranged with a keen eye to the useful. The Infirmary is commanding, and the new Orphan Asylum, although not artistic, is a noble foundation.

On the surface, poverty does not seem to be broadly marked in Wolverhampton. I saw very few instances of staring squalid poverty in the streets, and even in the ragged schools (of which I shall have to say more in another place) the children were better clothed and evidently better fed than in any other ragged schools that I have seen. I learned, however, that an immense amount of poverty does exist, and that large numbers of the Irish poor are resident here. The occasion for poverty amongst those who are of the "manor born" is not overwhelming; there is ample work usually both for men and women who choose to learn one of the local trades; and large numbers of the artisans earn sums of money sufficient to enable them to live in the highest respectability. But there are numerous small masters who undertake work at a minimum price, and who in turn are undersold by their workmen. If a master can produce a gunlock or a coffee-mill for a shilling, straightway there are workmen who can produce the same thing for tenpence; and so in this form of competition much real wealth is lost, added to which the true meaning of the word "provident" has as yet penetrated a very little way into the minds of the industrial classes.

With all this it seemed to me—I beg very humble pardon if I am wrong in my estimate—that the desire to make money was the one absorbing principle of the good people of Wolverhampton, and that the man who accomplished the most in this direction was the most respected. Hence the beautiful appeared to me to lie under the foot of the useful, and a great many days promise to pass before the sciences and arts, other than those that are applied to local industry, will receive their full recognition. I ought, however, to do justice to the Corporation of the Borough for the labour which they are bestowing at the present time for the benefit of the town. I have before me the last annual reports of the several committees of the corporation, and they are most valuable documents, full of useful information, and showing an enlightened

and active public spirit. Amongst other things recommended is the appointment of a Medical Officer of Health—a recommendation that always conveys the idea of advancement. There is added also a tabular statement giving the number of inquests held; the number of children lost and found wandering in the streets; the premises found open and insecure by night; the public-houses; the number of fires in the year; and the statistics of crime. It would be well if every corporation in England would take these reports as models, and publish similar annual records. I shall have occasion further on to point out the various improvements that have been effected with regard to sewerage, the utilisation of sewage, and water-supply. Provisions are abundant, and, for a working town, luxuries hold a prominent place; these latter are specially called for by the colliers, who are a singular race of men. They, in the early part of the week, when they "play,"—that is to say, when they have their wages in hand—live in sumptuous style. They select the choicest viands that can be obtained, and will have whatever is in season. Ducks, geese, lamb, game, asparagus, everything that money can buy they purchase, so long as there is a sou in the locker; and not unfrequently they keep up their feast for three or four days; then they fall to work again, and live on anything they can get, faring as badly as they before fared sumptuously. Amongst all classes, but especially amongst the poorer, pork is the leading article in the way of animal food, and the pig market is, consequently, an important institution. I dwell on this fact because it has a significant bearing, as we shall see when treating of the Etiology of Wolverhampton, on some of the prevailing diseases of the locality. From these general statements respecting Wolverhampton, we may now descend to particulars, beginning with the Hospital.

(To be continued.)

APPENDIX TO MEDICAL HISTORY OF NORWICH.

Since my last paper, the official report of the Norwich Hospital for the year 1863 has been sent to me. From the references that have been made to this Institution, I had naturally feared that the results of the practice of its past year had been opposed to those previous results, so excellent by comparison, to which I directed the attention of the Profession in the first parts of this work. To my relief, I discover that the reverse is the actual fact. There has been no serious Surgical epidemic of any kind. Only two cases of erysipelas are recorded, and these were not fatal. Of pyæmia it is stated, that after secondary amputation of the leg in two cases, death occurred from pyæmia and shock; and it is further stated that one death, after the removal of a loose cartilage from a joint, occurred from pyæmia alone. Thus, during the year, after 302 operations, there was only one purely fatal case of pyæmia, it being impossible to say of cases complicated with shock that pyæmia was the cause of fatality.

In the course of 1863, the total number of operations performed has been 302; the deaths 9. The deaths per cent. (excluding minor operations) were 4.56, the death-rate being 1 in 21.8.

Attached to the report, the following tables are rendered; they are of interest, because they bring the statistical history of the Norwich Hospital fairly down to the present date:—

General Statement of Patients under Treatment during the Year 1863.

Average number resident daily throughout the year	123.12	{ Males 72.33 Females 50.79
Mean residence of each patient	41.34 days	
Rate of mortality over all the cases	5.24 per cent.	{ Males 5.28 per cent. Females 5.17 "
Death rate	1 in 19.07	
Medical cases:—		
Average number in Hospital	50.64	{ Males 23.72 Females 26.92
Mean residence	42.20 days	
Rate of mortality	6.62 per cent.	{ Males 7.33 per cent. Females 5.90 "
Surgical cases:—		
Average number in Hospital	72.47	{ Males 48.61 Females 23.86
Mean residence	40.76 days	
Rate of mortality	4.31 per cent.	{ Males 4.31 per cent. Females 4.32 "
Total number of in-patients admitted during the last 91 years	56,177	
Total number of deaths during the same period	2,993	
Average number of in-patients admitted yearly during the last 91 years	617.32	
Average number of deaths yearly during the same period	32.89	
Death per-centage per year during the same period	5.32	
Death-rate per year during the same period	1 in 18.76	

Table of Cases of Stone in the Bladder operated on at the Norfolk and Norwich Hospital, from January, 1772, to December, 1863.

Age.	Operations.	Cured.	Died.	Mortality.	Operations.	Cured.	Died.	Mortality.	Operations.	Cured.	Died.	Mortality.

Females	42	40	2	1 ,, 21

In the Medical Times of January 9 of this year I made the following remarks about lithotomy:—"The median (operation) itself—the most fatal of all in Norwich—has been more successful there, in forty-one cases, than any kind of cutting operation for stone performed perhaps in this century in the London Hospitals; since the deaths after the median at Norwich are at most but 1 in 3.72, or nearly 1 in 4, instead of 1 in 2, or even 1 in 1.88, as is common in London."

I will not insult the intelligence and good nature of the readers of this journal by any more elaborate refutation of the angry letter that appeared on the above quotation last week. *Ira furor brevis est*,—still anger need not nurse sophistry. In the above quotation, as will be seen, there is not a line implying that the absolute average mortality in London after lithotomy is 1 in 1.88. It says that the common mortality is 1 in two, or even 1 in 1.88. It is a statement based on Mr. Hutchinson's tables (in which tables I for one implicitly believe), and as a statement it is rigidly and solemnly correct. If any one remains who persists in reading the quotation as though it conveyed that the absolute rate of mortality in London is 1 in 1.88, I must leave that critic to his anger, his intolerance, his blindness, his pride, or any other of such amiable qualities, until time and reflection set him right—for the moment, argument, and even appeal to simple reason and fair play, is effort thrown away. No circumstances in the world can alter that fact.

SECOND THOUGHTS ON THE BRITISH PHARMACOPEIA.

By A CHEMIST.

No. III.

THE compilers of the British Pharmacopœia have adhered to the precedent of the old ones in most points, and yet have introduced innovations which naturally excite the inquiry why they do not go further. If it were deemed advisable to describe the substances derived from vegetables by their physical properties, we may ask why not state their chemical constitution so far as analysis has revealed their proximate constituents? We may indeed infer from the preparations ordered in another part of the work, what is thought to be the best menstruum for extracting their virtues, but we consider that it would have been an improvement to state the fact in distinct terms directly following the descriptions in the Materia Medica. The same place would be most appropriate for placing the infusions distilled waters, decoctions, and tinctures when of simple substances, throwing together compounds and empirical formulæ at the end.

In both the Materia Medica list and among the prescriptions articles are inserted to which we can apply no milder term than that they are frivolous. Thus, we have *Sugar of Milk*, a substance of no earthly use in Medicine—was this intro-

duced in deference to Homœopathists?—Oil of Coriander, Gun Cotton, Fonsel Oil, etc.

Among the preparations we find directions for separating lard from pig's flare. Having given this recondite process, why is nothing said of a method of preserving lard from becoming rancid so as to be fit for ointments? Such methods are known and practised. Under the term ointments we have formulæ for certain quantities of calomel, of creosote, of galls, of turpentine, of sulphur, and of oxide of zinc, to be mixed with lard. Is it to be inferred that the same proportions are applicable to all cases? That it must not be varied by special prescription? If a Pharmaciën prepares these forms for keeping, it is most probable that nine out of ten prescriptions presented at his counter will not precisely adhere to the proportions; and besides, the presence of these constituents with the lard will, in most cases, tend to produce chemical changes which will render the ointments worse than useless. The presence of very minute quantities of foreign matter will often render external applications injurious, no part of the system being more sensitive than the skin when abraded, wounded, or affected with eruptions. At one period glycerine was a highly irritating substance when applied externally. When a method was discovered for making it perfectly pure, it became the most soothing and calmative. If we thought the British Pharmacopœia susceptible of amendment, we should urge the addition of the compound of glycerine and starch, now so extensively used instead of ointment or lard.

On what principle, we might ask, is the quantity of Epsom salts and other materials to be used as enemata fixed? or why at all insert forms for suppositories? Every case wherein such appliances are demanded must require special material, and in peculiar quantities. They must be varied infinitely, and instead of six, which is the number given in the Pharmacopœia, hundreds of formulæ would not meet the exigencies of practice. It is most unaccountable that the notion of suppositories once occurring, the expressed oil of *Cocao* should not be mentioned. This substance, known as *butter of Cocao*, has peculiar physical properties, exactly fitting it to this use. We thought every Obstetric Practitioner in this country must be acquainted with it. In Spain and the Spanish colonies it is used very extensively as the basis of suppositories and skin applications.

Again, we have the following recondite information:—

Bread.—Bread made with wheat flour.

Chalk.—Soft, white, amorphous, native carbonate of lime.

Cotton.—The hairs of the seed of various species of *Gossypium* (Linn.) earded.

Flour.—Wheat Flour.—The grain of wheat (*tritium vulgare Villars*) ground and sifted.

Hog's Fat.—The internal fat of the abdomen of the hog.

Sus Serofa, Linn.

Milk.—Cow's milk.

Ox-bile—Ox-gall.—The fresh bile of the ox. *Bos Taurus*, Linn.

White of Egg.—The liquid albumen of the egg of *Gallus Bancksia* var *domesticus*, *Temminck*.

How very learned! We suppose the discovery of the authorities on which the names of these *rare* productions of nature are adopted constitute the laborious researches in natural history spoken of in the preface!

We have already noticed the remarkable absence of commercial information in the Pharmacopœia. Two or three others may be added—namely, 1. *Oil of Lemon* is ordered to be either expressed or distilled, its use being intended as a flavouring material. Now, any one having the slightest knowledge of the drug trade could have told the compilers that these are two quite dissimilar things. The expressed oil alone is applicable for flavouring, the distilled oil being used as *scouring drops*, as it is called—that is, as a less offensive substitute for turpentine, which it resembles—for removing grease-spots from silks, etc. Why not bug-poison, furniture polish, etc.?

2. Oil of Rosemary is ordered to be *English*, the fact being that English Oil of Rosemary is very rare and costly, and if a demand to any great extent should arise for it, could not be obtained. At the same time the foreign is for every purpose quite as good.

3. A process is given for separating the resin of scammony from other matters forming commercial scammony. This process is the subject of a patent belonging to the Professor of Chemistry to University College, and its use would subject the Pharmaciën following it to legal proceedings. And after all, in the preparations of which scammony forms a part, the Pharmacopœia allows commercial scammony or the pure

resin to be used indifferently! Indifferent whether the druggist makes *Conf. Scam.* with 20 to 40 per cent. more or less of the resin!

In *Materia Medica* we have *Creta Preparata* defined as *Carbonate of Lime* nearly pure. We should be glad to be informed where it is to be got? In every sample of many obtained from the best shops we have found so much silicea as, in our opinion, to render *Creta Pp.* wholly unfit for internal exhibition; and yet we have it ordered in *Mist. Cretæ*, *Pulv. Cretæ Arom.*, *Pulv. Cretæ Arom. e. Opio*, and *Hydrarg. e. Cretæ*. We advise the reader to try the easy experiment of dissolving *Creta Prep.* from any source in dilute hydrochloric acid.

Throughout the entire work, as we trace the alterations made in the formulæ of medicines and compounds used for subordinate purposes, we are struck by their frivolity and random character. Thus, mucilages of acacia, of starch, and of tragacanth and simple oxymel are to be made with new proportions of their several ingredients, without any apparent reason or advantage for the several changes.

In compound colocynth pill—powdered colocynth in substance is substituted for the extract—this new form, indeed, is the common *pil-cochia* of the shops, familiar to the public in poor neighbourhoods, and is a most coarse griping purgative. Have the members of the Council ever tried it on their own persons? We guess not! Do they intend to order the *Pil. Coloc. Co.* made with extract to be thrown away, and the above substituted for it?

From *Pulv. Cretæ. Co.* they have excluded the only astringent ingredient, *rad. tormentilla*, and thus greatly impaired its value; and, on the other hand, they have added *pulv. kramcria* to *Pulv. Catechu Co.*, which already contained both catechu and kino, and therefore scarcely required another astringent ingredient. No notice is taken of a very elegant and convenient article in much use, namely, *Krameria Tannin*, a mixture as it exists in the root of tannic and krameric acids.

If we could believe that the simple preparations of vegetable medicines are founded on practical experiments, and not by "rule of thumb," we should pronounce them to be the most valuable part of the work. It is obviously of the greatest importance in practice to know how to exhibit in the simplest form such remedies, both for the benefit of the patient and our own satisfaction. So few can be given in substance; powdered barks, roots, and leaves being bulky, nauseous, and often fallacious from adulterations with "powder of post;" but if our infusions, decoctions, tinctures, etc., contain little or nothing of the substances intended to be exhibited, the Practitioner is deceived into false notions of the value of them as remedies, and does a great injustice to the patient who takes them. It is, perhaps, not too much to say that this matter is the cornerstone of the science of Medicine, so far as therapeutics is concerned. If we do not know with certainty the nature and amount of the remedies exhibited, experience is worthless, and it would be better to eschew drugs altogether, and allow Nature to take her course with all diseases.

We are unwilling to advance so serious a charge against the British Pharmacopœia in positive terms, but there is ground for strong suspicion that few, if any, of the formulæ for preparing vegetable remedies are based upon experiments. Brought together, they warrant the suspicion of being merely the result of verbal discussions and sheer guess-work.

How, we would ask, does it happen that only rectified spirits of sp. gr. 0.838, and proof spirit 0.920, are used as menstrua for dissolving the soluble parts of plants? Are there no instances of substances which would best dissolve in a mixture (for example) of equal quantities of Sp. Vin. R. and water, or in other proportions? In one case only is a weak spirit ordered, namely, in compound infusion of gentian; but this is an old empirical formula. And we may add another query,—can all, with propriety, be subjected indifferently to the same treatment? By mixing Sp. Vin. R. with various proportions of water, a number and variety of solvents are obtained severally suited to use with various vegetable substances. These are all ignored.

In the Continental Pharmacopœias many varieties of spirits as to strength are ordered.

The following tables embrace all the simple preparations of the several classes in the new Pharmacopœia:—

Tinctures.

A.—To be made with rectified spirit, sp. gr. 0.838. One pint to be used, and made up to a pint.

1°. The quantities irregular.

Substance.	Quantity.	Treatment.
Arnica root . . .	1 ounce	Macerate 48 hours. Percolate.
Capsicum	$\frac{3}{4}$ do.	Do. do.
Castor	1 do.	Macerate 7 days.
Kino	2 do.	Do.
Nux vomica	2 do.	Do. 48 hours. Percolate.
Indian hemp extract	1 do.	Dissolve.

2°. Quantities the same. $2\frac{1}{2}$ ounces to the pint.

Substance.	Quantity.	Treatment.
Aconite root	Macerate 48 hours.	Percolate.
Assafœtida	Do. 7 days.	
Tolu	Do. 6 hours.	
Myrrh	Do. 48 hours.	Percolate.
Ginger	Do. do.	do.

B.—Tinctures ordered to be made with proof spirit (five parts rectified, three parts water), sp. gr. 0.920. One pint of spirits to be used, and sufficient added, at the end of the operation, to make one pint of tincture.

1°. The quantities irregular.

Substance.	Quantity.	Time and manner.
Socotrine aloes (ex. liquorice, 1 ounce)	$\frac{1}{2}$ ounce.	Macerate 7 days.
Orange peel	2 ounces.	48 hours, and percolate.
Belladonna leaves	1 ounce.	Do. do.
Cantharides	$\frac{1}{4}$ do.	Do. do.
Yellow bark	4 ounces.	Do. do.
Saffron	1 ounce.	Do. do.
Opium	$1\frac{1}{2}$ ounces.	Do. do.
Ergot	5 do.	Do. do.

2. The quantities both of the menstruum and substance being the same—namely, $2\frac{1}{2}$ ounces to the pint.—All to be macerated 48 hours, then percolated, and made up to a pint:—

Buchu, Columbo, Cascarilla, Catechu (with Cinnamon, 1 ounce), Chiretta, Cinnamon, Cochineal, Colchicum seed. Hemlock fruit, Digitalis, Galls, Henbane, Jalap, Stramonium seeds, Lemon peel, Lobelia, Hop, Savin, Squills, Senega, Serpentry, Krameria, Valerian.

Infusions.

A.—To be made with boiling distilled water, 10 ounces; strain.

Substance.	Quantity.	Time to be infused.
Chamomile flowers	$\frac{1}{2}$ ounce.	15 minutes.
Orange peel	Do.	Do.
Buchu leaves	Do.	1 hour.
Columbo	Do.	Do.
Cloves	$\frac{1}{4}$ do.	$\frac{1}{2}$ hour.
Cascarilla	1 do.	1 do.
Catechu (cinnamon, 30 grains)	160 grains.	$\frac{1}{2}$ do.
Yellow cinchona bark.	$\frac{1}{2}$ ounce.	2 hours.
Digitalis leaves	30 grains.	1 hour.
Dulcamara	1 ounce.	Do.
Ergot	$\frac{1}{2}$ do.	$\frac{1}{2}$ do.
Rhatany	$\frac{1}{2}$ do.	1 do.
Linseed (liquorice, 60 grains)	160 grains.	4 hours.
Hops	$\frac{1}{2}$ ounce.	2 do.
Matico	Do.	$\frac{1}{2}$ hour.
Rhubarb	$\frac{1}{4}$ do.	1 do.
Red rose petals (sulph. acid dil. f. 5j.)	Do.	$\frac{1}{2}$ do.
Senega	$\frac{1}{2}$ do.	1 do.
Senna (ginger sliced, 30 grains)	Do.	Do.
Serpentry	$\frac{1}{4}$ do.	2 hours.
Uva ursi	$\frac{1}{2}$ do.	Do.
Valerian	120 grains.	1 hour.

B.—In 10 ounces of distilled water at 120°.

Substance.	Quantity.	Time to be infused.
Chiretta	$\frac{1}{2}$ ounce.	$\frac{1}{2}$ hour.
Cuspassia	$\frac{1}{2}$ do.	2 hours.

C.—In 10 ounces of cold distilled water.

Substance.	Quantity.	Time to be infused.
Quassia	60 grains.	$\frac{1}{2}$ hour.

Infusion of Kouso.—Kouso, in coarse powder, $\frac{1}{4}$ ounce; boiling distilled water, 10 ounces. Infuse 15 minutes; not to be strained.

Compound Infusion of Gentian (rather a weak tincture).—Gentian, $\frac{1}{4}$ ounce; bitter orange peel, 30 grains; coriander,

30 grains; proof spirit, 2 ounces. Infuse 2 hours; add 8 ounces of water. Infuse 2 more hours, and strain.

Decoctions.

	Proportion.	Boil.	To make
Iceland moss1 oz. Water	$1\frac{1}{2}$ pts.	10 min. 1 pt.
Cinchona (yellow)1 oz. „	1 pt.	10 min. 16 oz.
Pomegranate bark (fresh)	2 oz. „	2 pts.	1 pt.
Logwood (cinnamon, 60 grs.)1 oz. „	1 pt.	10 min. 16 oz.
Barley (well washed)2 oz. „	$1\frac{1}{2}$ pts.	20 min.
Poppy heads4 oz. „	3 pts.	10 min. 32 oz.
Pareira	$1\frac{1}{2}$ oz. „	$1\frac{1}{2}$ pts.	15 min. 1 pt.
Oak bark	$1\frac{1}{2}$ oz. „	$1\frac{1}{2}$ pts.	10 min.
Sarsaparilla (not split)	$2\frac{1}{2}$ oz. „	$1\frac{1}{2}$ pts.	10 min.
Broom tops	$\frac{1}{2}$ oz. „	$\frac{1}{2}$ pt.	10 min. 8 oz.
Dandelion root (dried and sliced)1 oz. „	$1\frac{1}{2}$ pts.	10 min. 1 pt.

Compound Decoction of Sarsaparilla.—The form for this important medicine, as of the simple decoction, is adopted from the Dublin Pharmacopœia, with the simple addition of half an ounce of sarzæ. The Dublin form had two ounces, the British has two and a-half ounces to the pint. This augmentation of quantity is entirely uncalled for; in fact, a pint of water will not take up much more than half the extractive matter of even two ounces of the root. Actual experiment will show that two ounces of the root treated according to the directions with a pint of water will not be exhausted. On treating the same root with another pint of water, a considerable portion of extract will be obtained, not sensibly differing from the first. The addition, therefore, of the half ounce is simply adding to the waste, and we cannot avoid the inference that it was not made on any experimental ground, but simply from mere whim. If there is any difference between the first and last extracts we are entirely destitute of any testimony to the fact.

(To be continued.)

THE NEW INFIRMARY AT LEEDS.

(From our Special Correspondent.)

ON Tuesday last the foundation-stone of a new Infirmary was laid at Leeds by the President of the Building Committee—one of the most active and liberal townsmen of Leeds—James Kitson, Esq. The ceremony naturally excited great local interest, but we refer to the matter in its wider acceptation, for, in truth, there are numerous points of professional and general importance connected with it.

We may premise by stating that the Infirmary at present at Leeds, now called the “old Infirmary,” and which remains until the new one is ready to take its place, has for some years past been considered a doomed building. In 1768 the foundation-stone of the old Infirmary was laid, and three years later, viz., on March 1, 1771, the institution was ready to receive the sick poor. From then until now its doors have been open, and more than 280,000 persons have been received into it. It has also been applied to clinical purposes, the students of the Leeds School of Medicine going to it for their practice of Medicine and Surgery. On the original plan of the old Infirmary various modifications have been made, and two new wings have been added; still it was felt to be ineffective; it was not sufficiently large for the present and pressing wants of Leeds, and it did not admit of being extended or of being improved upon by alteration. Hence, after long seasons of discussion and much conflict of opinion, it was determined to build a new Infirmary on approved principles, and on a new site.

The new Infirmary is laid in the north-western part of the town, facing Great Georges-street: it is about half a mile distant from the centre of the town, and is away from the busy manufacturing parts. Before any plan was drawn out, the Building Committee very wisely determined to institute an inquiry as to the best construction of Hospitals; and Dr. Chadwick, the senior Physician to the present Infirmary, accompanied by Mr. Gilbert Scott, R.A., the architect, went to the Continent, and visited the Hospitals of Paris, Brussels, and Bruges.

The report made by Dr. Chadwick and Mr. Scott led the Committee to fix upon the pavilion principle for their new building. The Infirmary will consist, therefore, of five pavilions—two in the front and three behind, with an open court

between. Each pavilion will contain two wards—one beneath, the other above. The wards, lighted by windows on each side and at their extreme ends, are to receive thirty beds each, nearly two thousand cubic feet of air being allowed to every patient. Each ward is distinct, and can only be entered from the corridors, which lead into the open air. At the foot of every ward there is a hydraulic lift for raising patients: thus in all accidents the patients can be carried into the grand entrance without being raised a step, and being placed on the lift full length, can be gently hoisted into the ward without inconvenience or undue pain. Any one who has seen the methods by which patients with fractured limbs are commonly taken into Hospitals—now on stretcher, now in a chair, again on the back of some strong man, or in the arms of two or three weak men—will appreciate the advantage of the lift fully.

In its general outline the new Infirmary will resemble the Hospital at Bordeaux and the Lariboisière; but the character of the ground has prevented the plans of those Hospitals from being absolutely followed out, the site being narrow and long, rising rapidly from front to back. This apparent disadvantage has, however, been seized upon by Mr. Scott with great foresight and skill, and has been used by him to introduce an actual improvement in the construction; he has arranged in the front part to get a second story below the ground story of the Hospital itself, in which all the offices for administration, and all the out-patient departments are placed. In this extra story are rooms for the House-Surgeon, for the matron, for students, for the committees and the like. Another improvement is introduced into the pavilions: at their further ends there is a large central window, and from the angles at the ends there are projections which, to use a technical phrase, are "canted," so as to make each corner of the ward take a kind of octagon form. In these octagons baths and water closets are placed.

The wards are to be warmed by central open-grate stoves, with descending flues, so that the air admitted will flow downwards in its escape by the stoves. This is a good feature, and of importance specially in the Surgical wards, where wounds have to be dressed, and where, from the level of the bed, organic matter is cast off. Another internal improvement worthy of notice is the introduction into the wards of shafts for the immediate removal of dirty bed linen and dressings. These, thrown into the shaft, fall into a part of the Hospital beneath, near to the laundry, which has no connexion whatever with any ward. The ventilation is entirely on the natural plan. The arrangement of the windows allows the air to traverse from side to side and to move freely in every direction. The building will be of pressed brick, with stone for adornment.

There is thus now laid in Leeds the foundation-stone of a model Hospital. There are certain accessories yet to be provided, such as a hot-air bath and large convalescent rooms; but taking it all in all, and speaking by comparison, the Leeds Infirmary will, when completed, be the largest and nearest approach to the model Infirmary of the kingdom, and we doubt not that it will be studied generally as a model. It would be a feature to have the roofs of the pavilions turned into airing grounds, if that could be done; and it would be another feature to arrange for the actual treatment of pyæmic cases in the open air on the pavilions, during seasons when the weather would permit of the carrying out of this only true treatment of this Surgical disorder. A lift from the ward to the airing-ground of the pavilion would carry the worst case easily into the air, and there the sufferer might have all the advantage of an unpolluted atmosphere, he himself being, in turn, no cause of pollution.

It will be an interesting subject of research, when the new Hospital comes into use, to determine the actual influence of Hospital accommodation on mortality. In the old Infirmary, which is indifferently constructed, the mortality has been rather high after operations—viz., one death in rather more than seven and a-half cases, or 13 per cent. in some years. Now, then, will come the test; the locality will be virtually the same, the Surgery the same, the class of cases the same in the new Hospital as in the old. Query, will the mortality be less in the Pavilion Hospital? The sanitarians will say yes! Let them wait and see, for the experiment will be crucial. Leeds compared with Leeds; no quibble about the class of case; no possible argument to the effect that an amputation or a lithotomy in one town, say London, is a more serious operation than it is in another town, say Leeds, but everything so clear that he who runs may read.

The ceremonial of laying the foundation-stone was admirably

conducted, and excited the warmest enthusiasm. In his speech to the crowds assembled around him, Mr. Kitson referred to the labours of the Medical Profession in terms which did equal honour to his head and to his heart.

"We cannot," he said, "look back upon the past management of the Leeds General Infirmary without great admiration and respect for the characters of the many excellent men who have been and are connected with it Professionally and otherwise. To the generous and assiduous care which has continuously been devoted to its management; to the laymen who have given their time; and to the high Professional ability with which the Medical officers have devoted themselves to its service, it is owing that the Institution has obtained its deservedly high position. I hope it may be considered a pardonable but a honest boast if I say that amongst the gentlemen who are now and have been Professionally connected with this Institution, we find those who have deservedly taken rank amongst the highest ornaments of a Profession to which society under its most trying circumstances is so deeply indebted for relief."

After the stone was laid, a luncheon was provided by the chairman in the Town Hall, at which 180 guests were present. Amongst them were ministers of every denomination in Leeds, the members for the borough, and large numbers of the Medical men. On the part of the Medical officers of the Infirmary, Dr. Chadwick replied in one of the most brilliant and effective speeches we have ever heard. Modestly, and yet fairly, he defined the true position of the Physician and Surgeon to these charities. He expressed that amongst those who work together at Leeds there is but one object and one mind, and he promised that in this generation, at all events, the Leeds Infirmary should not fail or fall in its Medical and Surgical departments.

In bringing to a close this notice, we may mention that on Monday Mr. Teale and Mr. Samuel Smith were elected Consulting-Surgeons to the Infirmary, that Mr. Nunneley, Mr. Claude Wheelhouse, and Mr. T. P. Teale, jun., were elected Surgeons, and Dr. Allbutt Physician, in place of Dr. Hardwicke. The munificent sum of £65,000 has been already collected towards the expenses of the new building.

GENERAL CORRESPONDENCE.

BRITISH MEDICAL TRADESMEN.

LETTER FROM MR. WILLIAM OGLE.

[To the Editor of the Medical Times and Gazette.]

SIR,—As a member of the British Medical Association, I thank you for your article on British Medical Tradesmen.

I am, &c.

Derby, March 26.

WILLIAM OGLE.

CANDLER *v.* PEAT DEFENCE FUND.

*** We have received the following letter from the Peat Defence Fund Committee. We need not say a word to support their appeal, which we hope will meet with a hearty response from the Profession.—Ed.

[To the Editor of the Medical Times and Gazette.]

SIR,—As Committee of the defence fund in the above iniquitous case, we beg to make, through your columns, a further appeal to the Profession.

The bill of costs sent in to Mr. Peat amounts to £152 17s. 6d., and we consider the charges fair and reasonable. Since the termination of the suit, Candler has become bankrupt, and the whole of the above charge consequently falls upon Mr. Peat. Candler, in his statement before the Colchester Medical Society, admitted that the prosecution was undertaken as a speculation.

As members of the Medical Profession, we consider that it will reflect great discredit upon us, as a body, if we permit one farthing of these costs to fall upon Mr. Peat. The question is not one confined to the members of the Profession residing in our county or neighbourhood, but it bears upon every Practitioner in the United Kingdom. At present, the subscription does not reach half the amount of the costs. Had we not, in the first instance, limited the amount of individual subscription, the sum would in all probability have been generously raised by a comparatively small number of the Profession.

We considered, however, that the more widely the area was extended, the greater would ultimately be the protection afforded to those who may be placed in a similar position to Mr. Peat; for it is quite certain that if the law is not altered so as to secure costs in case of failure of these iniquitous speculations, a very large and comprehensive union of Medical men will be necessary to protect the interests of the Profession.

We sincerely hope that this second appeal will be sufficient. Any amount of subscription, or even second sums from those who can afford it, will be most gratefully accepted. Amount already received, £73 9s. 6d.

C. R. BREE, M.D., Treasurer, Colchester.

A. WALLACE, M.D., Colchester.

R. S. NUNN, Colchester.

J. H. PARTRIDGE, Colchester.

C. P. MINGAYE, Dedham, Colchester.

D. P. MORRIS, Secretary, Colchester.

To any of whom subscriptions may be sent.
Colchester, March 23.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 22.

Mr. PARTRIDGE, President.

A PAPER, by Mr. CHAS. H. MOORE, was read on

A NEW METHOD OF PROCURING THE CONSOLIDATION OF FIBRIN IN CERTAIN INCURABLE ANEURISMS.

WITH THE

REPORT OF A CASE IN WHICH AN ANEURISM OF THE ASCENDING AORTA WAS TREATED BY THE INSERTION OF WIRE.

By Dr. CHARLES MURCHISON.

In this joint paper the theory of the operation was first described by Mr. Moore. Dr. Murchison furnished the report of the case, with Medical comments upon it. For the Surgical remarks, Mr. Moore was alone responsible.

In February, 1863, Mr. Moore had been led to review the conditions of such aneurisms as could not be Surgically treated through the artery, and had devised a method of producing consolidation of them in accordance with the mode of their natural cure.

The principles involved in this method were—1, that large aneurisms can only be benefited by the deposition of fibrin within them; 2, that the natural means of obtaining fibrin from the blood are inadequate, because it can only settle in layers on the wall; 3, that in the central part of an aneurism there is a large quantity of blood with fibrin ready to collect on any apt material; 4, that fibrin may be elicited from arterial blood by exposing a foreign body in it. Two cases were quoted in which this had occurred: one, an instance in which gangrene of the leg had resulted from plugging of the arteries by fibrin detached from a needle in the left ventricle; the other, that of a sailor, who died three days after being shot, and in the interior of whose ascending aorta was a bullet imbedded in fibrin.

The foreign body which, according to our present knowledge, would produce least irritation was wire. If a large quantity were coiled in an aneurism, it would attract fibrin, as the twigs do in whipping freshly-drawn blood, support the mass which it entangled, and lead to the cavity of the aneurism being eventually filled. The wire might be passed in through a small canula, with care not to leave the last end in the minute wound, and not to direct a coil into the orifice of the artery.

Only a sacculated aneurism could be so treated, not one which had two orifices, since fragments of fibrin would be broken off by the force of the current. Brasdor's operation might be previously required in some parts. This danger might be incurred in a sacculated aneurism also, if wire enough were not introduced, because of the large intervals which would be left between the few coils of wire. The wire would remain in the solidified aneurism, and be harmless.

Mr. Moore then described the operation by which the foregoing proposal might be carried out.

Report of a Case of Saccular Aneurism of the Ascending Aorta projecting through the Anterior Wall of the Left Side of the Chest.

Daniel D., aged 27, became a patient at the Middlesex Hospital, under Dr. Murchison, on November 10, 1863. Eight years before, he began to suffer from palpitations and dyspnoea, and after some months he had an attack of hæmoptysis. The hæmoptysis recurred at intervals, and in November, 1862, he first noticed a pulsating swelling in front of the chest, to the left of the sternum. This increased with considerable rapidity, and the patient now became subject to severe attacks of angina pectoris. At the time he first came under observation, the tumour was situated in the angle formed by the left clavicle and the left margin of the sternum; it measured ten inches in circumference at its base, and projected about two inches from the wall of the chest; its surface was rounded, and tolerably uniform, except at the upper part, where there was a tendency to point. Over the whole surface of the tumour distinct pulsation could be felt, each beat corresponding to the impulse of the heart. Nothing resembling an aneurismal bellows-murmur could be heard; but both cardiac sounds, and particularly the second, were louder over the tumour than at the base of the heart. There was dulness on percussion to the right of the tumour, over a space measuring two inches transversely, and three inches from above downwards. The apex of the heart could be felt beating between the fifth and sixth ribs. The cardiac dulness was slightly increased, but the sounds heard on auscultation were normal. There was no inequality of the arterial pulse on the two sides of the body. The voice was normal. The patient had an occasional cough, and expectorated a viscid muco-purulent matter, but there was nothing peculiar in the character of the cough. Over the whole of the left side of the chest there was comparative dulness on percussion, with coarse, at some places tubular breathing, and sub-crepitant râle. On the right side of the chest the percussion was clear and the breathing puerile. The appetite and digestion were good, and the bowels regular. There was no dysphagia, and no pain or tenderness at any part of the spine. The pupils were of normal and equal size. On Nov. 20, and again on Dec. 28, the urine was ascertained to be free from albumen.

After the patient was admitted into the Hospital, on the 20th of November, the attacks of angina almost entirely ceased. The pulse varied from 104 to 116 when the patient sat up, but would fall to below 100 when he lay down. The size of the tumour continued to increase, until, on the morning of January 7, 1864, it measured 16 $\frac{3}{4}$ inches at its base, and projected 2 $\frac{2}{3}$ inches from the wall of the chest. The tendency to point at its upper part became more decided, and the integuments at this part were much attenuated, and assumed a dusky-red discoloration, while occasionally they were the seat of pricking pains, and were slightly tender. These changes were most marked during the last week of December and the first week of January. The patient's general health notwithstanding did not suffer. He ate and drank well; he got up daily, and walked about the ward. On the evening of January 6 he played a game of draughts with another patient, and on the following morning he was up and walking about as usual.

Early in January it became obvious that the bursting of the aneurism through the integuments could not long be delayed. It was accordingly resolved to recommend to the patient Mr. Moore's proposed operation. During the month of December this operation had been carefully considered, but it was then deemed inadvisable to have recourse to it. It was now explained to the patient that the procedure in question offered some chance of prolonging his life, although in itself it was not free from danger. The patient at once assented, and the operation was performed on January 7, at 1:30 p.m.

The operation consisted in the introduction of a quantity of fine iron wire into the aneurism, with the object of inducing coagulation. A small pointed canula was inserted into the tumour, and the wire was passed in through this without difficulty. The operation occupied one hour, and the quantity of wire introduced was twenty-six yards. It gave rise to no pain or inconvenience excepting a slight and transient feeling of faintness. The quantity of blood lost did not exceed half a fluid ounce.

The immediate effects of the operation were a reduction of the pulse from 116 to 92, an almost complete cessation of the pulsation in the tumour, and a diminution in its size. Immediately before the operation the circumference of its base was 16 $\frac{3}{4}$ inches; at the close of the operation it was 16 inches.

These changes began to be noticed soon after the commencement of the operation, and became more marked as it was proceeded with. At 11.15 p.m. the patient was asleep, and his pulse was only 78. He slept comfortably during the night, and had no bad symptom until the following morning.

On January 8, at 9 a.m., the patient was seized with a fit of rigors lasting three-quarters of an hour, and followed by great pain in the back of the neck and some pain in the tumour. At 1 p.m. the pulse had risen to 144, and was full and bounding. The action of the heart was tumultuous, and all the arteries of the body could be felt throbbing with considerable force; but there was no difference in the force or volume of the beat on the two sides of the body. The patient complained of great pain in the tumour when he moved. The tumour was already somewhat larger than before the operation, and the dusky discolouration was of a deeper tint. There was intense thirst and great restlessness; the skin was dry and very hot; and the respirations were 40. At twenty minutes past 1 p.m. the patient was bled to the extent of eighteen ounces, and at half-past 3 p.m. twelve ounces more blood were abstracted. After the second bleeding twenty minims of Battley's sedative solution were administered.

From these measures the patient derived temporary relief, but he had a restless night, and at half-past 6 a.m. of the following morning (January 9) he had a second attack of rigors. At 1 p.m. he had a third attack. At half-past 1 he was in great distress, owing to pain in the tumour and at the back of the neck. The tumour was extremely tense and decidedly tender, particularly at its upper part. Its circumference at the base measured $1\frac{3}{4}$ inches more than before the operation. Distinct pulsation could be felt again at its upper part. The pulse was 136 and soft; the action of the heart was less tumultuous, and there was no abnormal cardiac sound. Large and repeated doses of opium and digitalis were now commenced. At half-past 10 p.m. the pulse had fallen to 126, but the patient complained of being afraid to cough on account of a severe jerking pain in the tumour which the effort to do so always induced.

On January 10, at 10 a.m., the patient had taken seventy-three minims of tincture of digitalis, and the equivalent of almost ten grains of opium, during the preceding twenty-one hours, and the result was that he was in less pain, the pulse had fallen to 104, and the tumour was slightly reduced in size, its circumference being half an inch less than on the preceding day. At 7.30 p.m., however, he was seized with a severe burning pain in the tumour, and a feeling of tightness as if he were going to burst. The tumour was larger and more tense than ever; the pulse rose to 132; the heart's action was again more impulsive, and there was intense thirst. To-day it was noted for the first time that the pulses in the right temporal and radial arteries were slightly fuller than in the corresponding vessels on the left side.

Opium in large and repeated doses, along with digitalis, was persisted with. In the course of two days and a half (commencing on January 9) as much as the equivalent of twenty-seven grains of opium was administered. The treatment, however, failed to give relief. The tumour increased rapidly in size, and on the 11th distinct pulsation could be felt at several parts of its surface. The radial pulse was 128, small and compressible, and still fuller on the right side. The beat of the right anterior tibial artery was also decidedly fuller and stronger than that of the left. The cardiac impulse was extremely feeble. The respirations were performed chiefly by the diaphragm and the muscles on the right side of the chest; the left side of the chest was almost motionless. The whole of the left side of the chest in front, unoccupied by the tumour, was dull on percussion, and no respiratory sound could be heard on this side, except immediately below the clavicle. Brandy and other stimulants were given, but without any decided result.

On the morning of the 12th the patient was evidently sinking. The pulse was about 136, but was so weak as to be counted with difficulty. The circumference of the tumour at its base was now $3\frac{1}{2}$ inches more than before the operation, and the urine passed during the night was found to be loaded with albumen. At 11 a.m., four days and twenty hours and a half after the operation, the man died.

An autopsy was performed a few hours after death. The walls of the external tumour were formed by the integuments and fibres of the pectoral muscle, infiltrated with serum. They were nowhere less than a quarter of an inch in thickness. The skin covering a great part of the tumour presented a deep livid hue. The interior of the tumour was filled, for the most part,

with a fibrinous coagulum, enveloping and imbedded in the coils of wire, and firmly adherent to the surrounding walls. The rest of the cavity contained fluid black blood. The interior of the outer tumour was nowhere lined with a prolongation of the arterial coats; but it communicated with the proper aneurismal sac within the chest, by two large openings in the first and second left intercostal spaces, the intervening rib being bare and eroded, and at one place broken through. The aneurismal tumour within the chest was about the size of a man's fist. It lay immediately behind the sternum; it encroached slightly upon the upper lobe of the left lung, and inferiorly it rested upon the right auricle. It was partially filled with a fibrinous coagulum, which was continuous with that in the outer tumour, and was adherent at one part over a space measuring about one-third of an inch in diameter. It communicated by a circular opening, scarcely so large as a sixpence, with the ascending aorta. Through this opening a clot projected from the aneurism into the vessel, and extended downwards into the heart, and upwards into the arch. The greater part of this clot was evidently of post-mortem date; but part of it, close to the opening, was pale, firm, and laminated. There was considerable atheroma of the coats of the thoracic aorta. The pericardium contained about eight ounces of turbid serum, and its opposed surfaces were coated with a thin layer of recent lymph. The upper part of the parietal pericardium presented a patch of livid discoloration, about the size of a florin; and at the centre of this patch the cavity of the pericardium was merely separated from that of the aneurism by a delicate membrane. It was at this part of the aneurism that the coagulum was adherent. The heart was slightly hypertrophied. Its valves and muscular tissue, and likewise the coronary arteries, were healthy. The left lung was everywhere firmly adherent, and its pleura much thickened. On section, numerous cavities were observed, evidently resulting from dilatations of the bronchial tubes. In the intervening spaces a firm fibrous tissue took the place of the normal vesicular structure. The right lung was for the most part healthy. Both kidneys contained a number of circumscribed abscesses, varying in size up to that of a small pea. A cluster of six of these small abscesses was found at the apex of the left kidney. In the cortical substance of both kidneys a number of patches of yellowish deposit, of a large size, but less defined outline, were also observed. On microscopical examination, this appearance appeared to be due to the presence of a granular exudation deposited between the uriniferous tubes. The liver was large and fatty. The other parts of the body could not be examined.

After recording the history and post-mortem appearances of the case, Dr. Murchison enumerated some of the more important features of clinical interest, independent of the operation, which it presented.

In his concluding remarks, Mr. Moore referred first to the circumstances of the operation, and to its early effects, which were highly satisfactory. So much fibrin appeared to have collected at the end of an hour that the pulsation of the tumour and its sharp second stroke were no longer perceptible; the aneurism had much diminished in size; the pulse, which, notwithstanding medicines, had beat 112 for weeks previously, and was 120 before the operation, had fallen to 92, and at night was about 80. This unlooked-for abundance of the fibrine, accumulated not by an inflammatory, but by a mechanical process, was an unprecedented circumstance. Its effects could not be foretold. It appeared to have caused local inflammation and the rigors, with great acceleration of the pulse. No aneurism could long resist such a pulse. Death had probably resulted from acute pericarditis, which was induced, not by continuity with the inflammation outside the chest, since neither the inner aneurism nor the pleurae were inflamed, but incidentally by the imminent bursting of the intrathoracic aneurism into the pericardium. No fragments of the clot of fibrin, large enough to be detected by the naked eye, had been detached, but microscopic portions were supposed to have existed in the kidneys. Neither the old nor the recent disease of the kidneys had actually caused death, which was due to the changes about the chest, and was, through the pericarditis, an indirect and not inevitable consequence of the operation. No coil of wire had passed through the opening of the aneurism.

Three facts appeared to Mr. Moore to justify a repetition of the operation, or of some modification of it:—1. The separation of fibrin upon the foreign body, and its rapid deposition. 2. The exemption of the inner aneurism from inflammation, probably to be accounted for by its possessing a lining mem-

brane, which the outer cavity had not. 3. The firm adhesion of the clot to the wall.

Not having yet thought of a more suitable foreign body than wire, he had but two modifications of the operation to suggest:—1. The introduction of a smaller quantity. The objections to this had already been pointed out. 2. The use of slender needles as temporary means of procuring the consolidation of the fibrin. The safety of this must depend on the number of needles which might be inserted, the gentleness with which they should be withdrawn, and the period at which fibrin so procured should acquire a sufficiently firm attachment to the wall of the aneurism to allow of the artificial support of the needles being dispensed with.

The PRESIDENT inquired if the reading of Mr. Moore's concluding remarks was essential, the time of the Society's meeting having nearly expired.

Mr. MOORE said he should be happy to spare the Society from the reading of his remarks in full, and very briefly recounted their principal points. In answer to another question by the President, Mr. Moore observed that the method of treatment which he had suggested differed from that by galvano-puncture in that the latter caused consolidation of the entire mass of the blood between the points of the needles, which was objectionable, as not being permanent and curative; whilst the former elicited fibrin from the blood, which was the material of natural cure.

Dr. COPLAND remarked that the case was one of very great importance, but it proved nothing in favour of the mode employed for coagulating the blood in an aneurismal tumour. It would be observed, however, that the wire had not been introduced into the inner aneurism, and this to some extent might explain the failure of the proceeding. Moreover, he thought that no such plan could supersede the treatment of aneurismal tumours by diet and medicine, which he believed in most instances would be found more effectual in coagulating the blood. The case before the Society might, however, serve as a guide to Surgeons for the future; but the proceeding should not be resorted to so long as diet and medicine could afford benefit.

Mr. HILTON wished to ask Dr. Murchison what he considered to have been the cause of the patient's death?

Dr. MURCHISON stated, in reply, that several causes had, in his opinion, contributed to the fatal termination. In the first place he was inclined to put the contamination of the blood with inflammatory products derived from the tumour giving rise to pyæmia and embolism. The purulent deposits found in the kidneys left no doubt as to the existence of pyæmia. These deposits had been carefully examined microscopically by himself and by Dr. Cayley (the pathologist to the Middlesex Hospital), and had been found to present all the characters of pyæmic abscesses. It was true that they were small, the largest being about the size of a small pea; but this circumstance was at once accounted for by the short time that the patient had survived the supervention of the symptoms of pyæmia. An important observation had been made in this case on the third and fourth days after the operation—namely, a very appreciable difference in the force and volume of the arterial pulse on the two sides of the body. This condition had not existed previously, and was not accounted for by the anatomical relations of the aneurismal tumour. No opportunity had been afforded of examining the arteries of the limbs after death, but the observation referred to, taken in connexion with another morbid appearance found in the kidneys—namely, that of extensive inter-tubular deposit of a recent nature—led him to infer that embolism was one of the results of the operation. An observation had been made in the case which seemed to clinch, as it were, the development of these lesions found in the kidneys at a date posterior to the operation. Before the operation the urine had been free from albumen, but the urine passed on the day before death had been loaded with albumen. It was worthy of remark that the anatomical characters of the aneurism were less favourable to the contamination of the blood with fibrinous flakes and inflammatory products than they would probably be in most aneurisms where the operation would be thought of. The orifice of communication with the aorta was small—not so large as a sixpence; and the whole of the proper sac of the aneurism within the chest had been interposed between the aorta and the external tumour, into which alone the wire had been introduced. Nevertheless, the blood had become contaminated. With regard to the pericarditis, it was a subject for speculation how far it was pyæmic in its origin, or whether it was due to a propagation by continuity of the inflammatory process from

the sac of the aneurism, or resulted from the threatened bursting of the aneurism into the pericardium. The last explanation might be the true one; but while it was uncertain if the bursting of an aneurism into the pericardium was usually preceded by pericarditis, there could be no doubt that the pyæmia existing in this case would predispose strongly to pericarditis excited by any cause; and the fact that the pyrexia was ushered in with repeated attacks of severe rigors indicated that the pyæmia, rather than the pericarditis, was the first link in the chain of morbid events. Moreover, it was probable that the pointing of the aneurism in the direction of pericardium was determined by the operation. Although an aneurism of the thoracic aorta often burst spontaneously into the pericardium, it was well known that this was a very rare event when there was an external tumour. The condition of the circulation on the day after the operation—a full, bounding pulse of 144—was extremely favourable to the giving way of a weak portion of the aneurismal sac. The causes of death, then, appeared to be pyæmia and pericarditis supervening on the operation.

Mr. FERGUSSON regretted that this case had been detailed with so much unnecessary minuteness, thereby occupying so much time that there was no opportunity of discussing it. It should have been condensed into one-fourth of the space which it occupied. (Hear.) The case, however, was one of great interest, and the Society must feel grateful to Mr. Moore and Dr. Murchison for the description of a case and of a mode of proceeding never before put into practice on the living body. He regretted that the experiment had not been carried out to its full extent, the wire not having been introduced into the aneurism proper, so as to produce a more direct influence of the heart's action on the blood. He considered the proceeding would be justifiable in cases similar to the one related, and in those aneurismal tumours of a more Surgical character in which the mode of treatment to be pursued did not clearly suggest itself to the Surgeon. The plan of passing wires and needles into aneurismal tumours had been suggested as much as thirty years ago; but he had never heard that it had been actually carried into practice until the present case.

Mr. MOORE, in reply to the observations of Dr. Copland and Mr. Fergusson, said that in the performance of the operation he had taken particular care not to introduce any of the wire into the inner aneurism, both because he had considered it essential to keep the distribution of it within that cavity which he had explored with the probe, while of the inner aneurism, and of what might become of the wire in it, he knew nothing; and also because, had the patient survived and required it, the treatment of the inner aneurism might have been the subject of subsequent consideration. He bowed to the opinion enunciated by Dr. Copland, that no aneurism should be submitted to this treatment so long as Medical and dietetic measures were of service; and he should not think of recommending or adopting it except when these measures had lost their beneficial effect on the aneurism. Beyond those circumstances of the case which appeared to his colleague, Dr. Murchison, to have occasioned the fatal issue, he ventured to call attention to one other which he thought to be the most important and the starting-point of them all—namely, the very large mass of fibrin which had collected through mechanical means in the aneurism. To it he attributed both the local and the constitutional excitement which had commenced on the morning after the operation, and had, he believed, caused the pericarditis and the death. The main question before the Society of course was the prospect of advantage which this case held out from a repetition of the operation, or of a modification of it. He had come to the conclusion that the fatal issue was not an essential inevitable result of the operation, and that cases might occur in which it would prolong life. The first effect of the insertion of the wire had been very surprising, the pulsation of the aneurism and the peculiar sharp second stroke having become imperceptible at the end of an hour. This fact implied that the same effect might be produced in a little longer time with a smaller quantity of wire than had been used in the present case, and that that portion of it which had been inserted with difficulty might have been dispensed with. He did not wish, however, to be supposed to be laying down a positive rule for the treatment of other and perhaps dissimilar cases. The grounds on which the operation was based were all of them facts previously known, and familiar to all the Fellows present, whom he considered equally capable with himself of forming an opinion, and of contributing to avert the causes of the failure of the proceeding in the present case.

Some discussion subsequently took place respecting the reading of very long papers *in extenso*, and some irregularities in the manner in which papers were forwarded to the Society. The matter will probably come before the Council.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, FEBRUARY 11, 1864.

Mr. PYLE in the Chair.

PREVALENT DISEASE: DEGENERATION IN INSANITY.

Dr. PHILIPSON read a first monthly report of the prevalent diseases of the district. This seems to be the germ of what may be a most practically useful proceeding—the prevalent disease of the district described, the results enumerated, and plans of treatment discussed. Scarletina and diphtheria seem to have been the leading diseases.

Dr. KENNETH McLEOD then read a paper on

FATTY DEGENERATION IN INSANITY,

from which we extract the very telling and able peroration:—

"I have sufficiently demonstrated the fact that in insanity one great truth, perhaps the great and practical truth, is the tendency to imperfect nutrition and degeneration as an invariable concomitant and necessary consequence. The importance of using every endeavour to promote by hygienic, dietetic, and medicinal means, the nutrition of the body, becomes very apparent and imperative. I assert this most emphatically, because means prejudicial thereto—blistering, depletion, purging, starving, mercurials, antimonials, etc.—are still too often employed, and with the worst possible effect. It is a fact of daily experience besides, that the free and judicious exhibition of stimulants and nutrients are the principal agents in bringing about the recovery of the insane. We sometimes admit thin, pallid wretches, with large blister marks on nape of neck, leech-bites on temple, red line on gums, whom we have to ply with wine, beef-tea, and cod-liver oil and iron, and we invariably find that as the flush of health again mantles the cheek, cerebral action becomes more healthy, and sanity returns. Of course other medicinal and moral means are employed; drugs, such as hydrocyanic acid, to restrain the excessive and deranged brain action, and moral means, to induce conduct and thought more in adaptation with circumstances; but the most efficient and powerful remedial agent is undoubtedly—*nutrition*."

This was followed by an important paper, by Dr. Murray, on the "Administration of Chloroform in Chorea and Epilepsy," and a discussion on "Placenta Prævia."

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Wednesday, March 23, 1864:—

Alfred Philipps, Lamb's Conduit-place, W.C.

On Thursday, March 24:—

Francis Fox, Ringwood, Hants; Evan Evans, Llandyssie, South Wales; John Hall, East Retford, Notts; Revett Coleridge Powles, Ipswich; James Ricketts, Liverpool; Albert Lloyd, Bristol; Edward Thomas Shaw, Packington-street, Islington.

The following gentleman, also on the same day, passed his First Examination:—

Frederick Edward Worthington, Manchester.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ADAIR, PONSONBY, M.R.C.S. Eng., has been appointed by the Bombay Government to the Medical Charge of the Expedition Proceeding to the Persian Gulf to Lay the Submarine Cable of the Government Telegraph to India.

ARMSTRONG, JAMES HUNTER, M.R.C.S. Eng., has been appointed House-Surgeon to the Ashton-under-Lyne Infirmary.

DOUGLAS, ANDREW H., M.D. Edin., has been appointed Acting Physician to Chalmers' Hospital, Edinburgh.

FRODSHAM, JOHN M., M.D. Edin., has been elected Hon. Medical Officer to the Royal Pimlico Dispensary.

JACKSON, T. VINCENT, M.R.C.S., has been elected Surgeon to the South Staffordshire General Hospital, Wolverhampton.

M'NAIR, F., M.R.C.S. Eng., has been appointed House-Surgeon to the Surrey Dispensary, Great Dover-street.

MILLER, JAMES, F.R.C.S. Edin., has been appointed Acting Surgeon to Chalmers' Hospital, Edinburgh.

PATERSON, JAMES, M.D. Glasg., has been elected Registrar to the Faculty of Physicians and Surgeons, Glasgow.

QUINLAN, FRANCIS B., M.D., T.C. Dub., has been appointed by His Excellency the Lord Lieutenant to the Office of Medical Superintendent to the Intermediate Prison, Smithfield, Dublin.

WATSON, THOMAS, M.D., F.R.S., has been re-elected President of the Royal College of Physicians, London.

WILSON, Dr. J. CLARK, has been appointed House-Surgeon to Chalmers' Hospital, Edinburgh.

WORGER, T. H., M.R.C.S. Eng., has been appointed Assistant House-Surgeon to the Kent and Canterbury Hospital.

DEATHS.

AMESBURY, JOSEPH, M.R.C.S. Eng., at 93, Lansdowne-place, Brighton, on March 27, aged 68.

BRADY, THOMAS, F.K.Q.C.P.I., at Upper Temple-street, Dublin, on March 16, aged 62.

HAMILTON, JAMES, L.R.C.S. Edin., at Dungannon, County Tyrone, on March 10.

INCE, EUGENE S., M.D. St. And., at 3, Wilton-street, Grosvenor-place, S.W., on March 25, aged 28.

McGILCHRIST, JOHN, M.D., at 63, Castle-street, Edinburgh, on February 27.

QUINTON, WILLIAM, M.R.C.S. Eng., at Cannock, Staffordshire, on March 14, aged 53.

RANKINE, Dr. J., at Beulah-lodge, Helensburgh, late of Blackwood, South Australia, on March 15, aged 61.

ROYAL COLLEGE OF SURGEONS.—The lectures at this institution are brought to a close for the present, owing to the theatre being required for the examinations of the great number of students now offering themselves for the ordeal which will take place on the 9th, 16th, and 30th inst., and the 7th proximo; and early in the ensuing month (June) Professor Fergusson will deliver a course of six lectures "On the Progress of Surgery during the Present Century." Professor Huxley brought his course of twenty-four lectures, "On the Structure and Classification of the Mammalia," to a close on Saturday last.

DR. MOORE AND THE BETHNAL-GREEN GUARDIANS.—We regret to state that the Poor-Law Commissioners have arrived at an unfavourable conclusion in Dr. Moore's case, and have consequently dismissed him.

POISONING BY SULPHURIC ACID.—On March 28, at the Assizes at Bury St. Edmunds, a young woman named Brown was tried for the murder of her illegitimate child. The post-mortem examination and chemical analysis of the stains on the child's clothes incontrovertibly proved poisoning by oil of vitriol. The post-mortem examination was conducted by Mr. H. P. Leach. The mouth was filled with frothy mucus, the œsophagus was white. There were two large jagged perforations in the stomach. The cavity of the abdomen contained a quantity of fluid, in which were floating pieces of charred tissue, food, and mucus. The peritoneum was inflamed. The analysis was made by Mr. Image, of Bury, and appears to have been quite satisfactory. The jury did not consider the evidence sufficient to prove the administration of the poison by the mother, and therefore acquitted her.

THE NEW PHARMACOPOEIA.—An address was delivered on Tuesday, March 15, in the Manchester Athenæum Library, by Mr. J. T. Slugg, "On the British Pharmacopœia; its Contents, Effects, and Defects." To judge from the report we have seen, the latter occupied the most prominent place in the lecture. Mr. Slugg said: No doubt a new Pharmacopœia might be needed every ten or fifteen years, but he contended that the greatest care should be taken not to disturb existing foundations of formulae and names of drugs. The general opinion was that in this case such caution had not been observed. It was a question with some whether they had not "jumped out of the frying-pan into the fire," and whether the remedy was not worse than the disease. Certainly his own opinion, and that of many others with whom he had come in contact, was that the inconveniences arising from the three Pharmacopœiæ under the old system were not at all to be compared with the inconveniences of the production before him. He thought, too, if there had been fewer men on the council who drew up the new Pharmacopœia, and more practical dispensers, the work would have been done better. That the work was a failure was evident; one proof was that everybody was afraid to begin with it, and they could not find any Medical man now using it. It was also a great defect

that no time had been specified when the new Pharmacopœia was to come into use. This necessitated chemists keeping two kinds of preparations, and really might tend to serious complications. Another defect, to which he had previously alluded, was the petty alterations which had been made in the names and strength of Medicines.

THE MEDICAL PROFESSION.—The greater part of the capital of the Surgeon is sunk in his sustenance and education. A considerable sum is necessarily sunk in acquiring practice. The amounts vary, but capitals ranging from £1000 to £5000 are expended in the establishment of a Surgeon or Physician in full practice. The income, after some deduction for the cost of articles, is net. It gradually rises from nothing to £1000 or £2000 a year. A few Physicians, Consulting Surgeons, Accoucheurs, Dentists, and Oculists in London earn incomes of £5000 a year, and one or two eminent Surgeons have realised, by intense labour, £10,000 a year or more for several successive years. Sir Astley Cooper is said to have gained £21,000 in a single year. The income and outgo are lowest in thinly-peopled districts. In exceedingly remote districts, Surgeons cannot live: the incomes are highest in towns. The business decreases in healthy seasons, and increases in epidemics. Chaucer's Doctor had "kept that he won in the pestilence." It has been argued that Medical Men profit by plagues, and are interested in their prevalence, although it is admitted that all sanitary improvements began with them. Against this is to be set the danger of dying by pestilence incurred by the Medical attendant—a danger from which they now never shrink. Epidemics, too, like cholera, destroy the ailing patients at one fell swoop. The Surgeon loses in two ways in an unhealthy place; the people become poor, and unable to pay, while his life is shortened, and his income, being of the nature of a life annuity, is reduced in value. It would, however, be advantageous to families of all classes to pay their Medical adviser fixed sums annually, so that he might have the opportunity of preventing as well as curing diseases.—*Appendix to Report of Census for 1861.*

A NEW "CURE" FOR PERTUSSIS.—Several children suffering from whooping-cough at Calais have been taken to the gas-works of that town, and caused to inhale the fumes which are disengaged during the purification of the gas by lime. The success is said to have been most remarkable, great relief at once following exposure to these fumes for a few minutes, and two or three visits sufficing to produce a complete cure.

MEDICAL MISSION HOSPITAL AT ANTANANARIVO, MADAGASCAR.—Dr. Andrew Davidson has issued an appeal in behalf of the above project. We commend it heartily to the charity of our readers. No better platform for the introduction of pure religion can possibly exist than an institution in which physical suffering is alleviated by persons who give their labour and, if need be, their lives for the benefit of others. The following extracts from Dr. Davidson's proposal will show what is wanted:—"The population of the vast island of Madagascar is usually reckoned at 4,000,000. The natives, although they are considerably removed from a state of barbarism, and have attained to a certain degree of advancement in many of the useful arts, are entirely ignorant of Medical science. The London Missionary Society has established a Dispensary, and maintains a Physician at the capital. The numbers who daily apply for medicine and advice evince the value put upon that institution by the Malagasy. More substantial proofs are not wanting. The nobles have contributed cheerfully towards the erection of the buildings; and while none are refused medicine because they are unable to pay for it, yet many, even of the poorest, willingly give a small sum, as they are able, to help to meet the current expenses of the establishment. During the past year—a year of revolutions—above 3000 patients have been prescribed for, out of tens of thousands who have applied. One Medical man to so great a population can do little, even were he furnished with all the means and appliances for the healing of the sick, and it is manifestly impossible to treat many of the cases of every-day occurrence unless he possesses an Hospital for the reception of those who have to undergo severe or dangerous operations, or who suffer from diseases requiring the constant and careful attention of the Physician or the nurse. Diseases of the eye requiring Surgical operations are common, as is the case in most Eastern countries. In these the success or failure of an operation often depends to a great extent upon the after treatment. For seven months of the year fever is prevalent and deadly; many die of the fever, many more from the ignorance or inattention of their attendants. Without mentioning more,

there is one class of sufferers in whom we must all feel a lively interest, and for whose welfare I most earnestly plead to be furnished with an Hospital—these are the children. In the central province of Imerina alone thousands of infants and children perish every year from diseases that cannot be successfully treated unless the patient is under the eye of the Physician. One grand object which the Medical mission here has been intended to accomplish, is to train Christian natives in Medicine, so that they may be able to act as pioneers to the regular missionary, and such an Hospital, if properly worked, and if proper assistance be obtained, will enable us to give a more complete training to young men from distant parts of the country, which, though nominally under Hovah rule, has hitherto been quite inaccessible to Europeans. If these regions and tribes are to be Christianised, I know no more likely means of accomplishing it than this. For this purpose it is proposed to raise £1000. The Malagasy Government have granted a suitable site, and may do more. The native Christians will assist in the erection of the building, but without the aid of England it can neither be completed nor efficiently maintained." Donations or subscriptions to the Hospital, Antananarivo, will be received by the directors or officers of the London Missionary Society, Mission-House, Blomfield-street, Finsbury.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

W. B.—He is certainly eligible to hold a Poor-law appointment. We do not think he could recover in a Surgical case under the new Medical Act.

Medical Inquirer.—Lay your plants between coarse blotting-paper made for the purpose. You can get the paper at Lewis's, the bookseller's, in Gower-street. Lay the sheets of blotting-paper between two mill-boards, and press in a common clothes' press, or put them under your mattress. In the latter way, one of the first botanists of the day made his first herbarium.

Gratuitous Service.—The following sensible remarks conclude a letter by Dr. Walter Garstang, M.D., of Blackburn, in reply to an application that he should certify gratuitously to the fact of sickness amongst the recipients of public relief:—

"No person, or body of persons, has assuredly the least pretext to expect, *still less to impose*, the execution of any kind of Professional labour, as such, without frankly attaching to it pecuniary remuneration. Charity wears many false airs; one of the most repulsive among them is found in the matter of gratuitous Medical service done in behalf of the public."

A Londonderry Subscriber thinks that acute maladies in Ireland arise from the upper and lower extremities of the body not being sufficiently protected from wet. Could not a change in the fashion of dress to some extent remedy this evil?

Counter Practice of Chemists.—A correspondent of the *Chemist and Druggist*, February 15, 1864, speaks out on this point, and shows what the country general Practitioner may expect, when the chemist and druggist is decorated with new privileges and authorised to assume a higher status. He replies to some remarks of Mr. Thompson, an eminent chemist, at Leeds:—

"I am aware that a dispensing chemist may do any amount of counter prescribing he thinks proper, the law holding every man ignorant of the science of medicine responsible for the evil consequences of his ignorance; and I agree that no man ought to prescribe ignorantly, but I am not prepared to admit that in ninety-nine cases out of one hundred it would be better to send the patient to a doctor. I think Mr. Thompson's illustration somewhat unhappy, and his analogy, in a great measure if not altogether, a failure. Had his audience consisted of tradesmen whose daily avocations and pursuits were utterly distinct from the practice of *physic*, then it might have been legitimate for him to institute an analogy betwixt what they ought to do for the derangements of a watch and the derangements of the human system. For instance, supposing them to be all watchmakers, it would have been perfectly consistent for Mr. Thompson to recommend them, if consulted in a case of measles, to do what they would advise a doctor or a chemist to do if consulted about the derangements of a watch; but I presume his audience consisted of gentlemen who had, to some extent, studied the practice of *physic* and given some attention to the symptoms of all ordinary diseases; and I contend that in ninety-nine cases out of one hundred presented to him, the intelligent chemist is as well able to draw a correct diagnosis and prescribe successfully as the general Practitioner, and that he does so is sufficiently attested by the fact that a respectable chemist and druggist is seldom, if ever, called upon to answer a charge of ignorant prescribing."

This is plain speaking. For our own parts, we deride *protection*. John Bull will not be driven, but may fairly choose for himself whether he will be treated by a man who sells medicines, or by one whose business it is to study diagnosis, and knows what he gives medicine for. But we should be fools indeed if we concurred in any measure for giving the chemists any additional semblance of professional character.

THE NATIONAL MEDICAL REGISTRATION ASSOCIATION.

Dr. Henry G. Wright requests us to announce the following contributions towards the liquidation of the debts still owing by the National Medical Registration Association:—J. T. Clover, Esq., £1 ls.; Dr. Tuke,

£1 ls.; — Obré, Esq., 10s. 6d.; R. Dunn, Esq., £1 ls.; Dr. Wright, £2 2s.; Dr. Savage, £1 ls.; J. F. Clarke, Esq., £2 2s.; — Slyman, Esq., £1 ls.; Dr. Webster, Nottingham, £1 ls.; Dr. Henderson, 10s.; Dr. Birkett, 10s.; Dr. Headland, £1 ls.; Dr. Ridsdale, 10s.; T. S. Wells, Esq., £1 ls.; G. Shepherd, Esq., 10s. 6d.; Dr. W. O. Markham, £1 ls.

There still remains a sum of £143 13s. 7d. to be paid off, and the creditors (many of whom have been waiting two years) are pressing their claims. It is surely but right and fitting that the members of the Profession should come forward to assist in defraying the law cost of actions undertaken in their behalf, and the expenses incurred in defending and promoting their interest. At a time when the grievances of the Profession are so many, and so greatly need redress, it will certainly deter persons of influence from actively assisting to promote the welfare of the Profession if they learn that there remains unpaid such a debt as that to which we have alluded.

Dr. Wright, 23, Somerset-street, Portman-square, W., is the Treasurer of the Indemnity Fund, and will be happy to receive contributions.

EARLY MENSTRUATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Should you consider the following worthy of a place in your journal, I shall be glad if you will insert it:—

On the 24th ult. I attended Mrs. W., aged 26, in confinement of her first child. She informed me that she began to menstruate when only two years and a-half old, and continued to be perfectly regular until she became pregnant. Her health has always been very good; she is of very small stature, but her parents, brothers, and sisters are very tall.

Are there any cases of earlier menstruation on record?

I am, &c. WILLIAM TAYLOR COLBY.

Wentworth Ville, Malton, Yorkshire, March 28.

THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having read the letters of "An Army Surgeon," in your two last papers, and that of "Truth" in your issue of the 26th, as well as the letter of "Consilio Manuque" in the *Lancet* of the 26th, I am of opinion that if the suggestions therein contained were acted up to in letter and spirit there would be no more grumbling, and the Government would get some of the best men in the Profession to enter the lists of the Army Medical Department, instead of being compelled, as at present, to raise the age of admission from 26 to 30, and thereby to ensure a supply of inferior men, who have tried their luck in civil life, and failed, either from their misfortune or fault, or both combined. The letters above referred to leave me little to add.

I am, &c. COMMON SENSE.

FREEMAN'S CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to deny most emphatically the statement made by Mr. Freeman in a previous number (November 14, 1863), in reference to the use of Freeman's chlorodyne in this Hospital by Dr. O'Connor or any other member of the Medical staff; and further, I assert that it was Mr. Freeman himself who stated (in the presence of several persons) that Dr. O'Connor was in the habit of frequently prescribing his chlorodyne.

This statement I distinctly refuted, at the same time assuring him that if he continued to advertise what he knew to be untrue, I should bring the matter before the notice of the authorities of the Hospital.

I am, &c.

JOHN D. HILL, M.D., Resident Medical Officer.

Royal Free Hospital, March 30.

PURE AND WARM AIR IN BED-ROOMS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am happy to bear testimony to the truth of the remarks made by my friend, Mr. W. Burder, in your last Journal, touching the value of moisture in the atmosphere of the apartments of the phthisical invalid, and, indeed, also, in most cases of bronchial irritation. Warm and moist air is a most valuable sedative to the cough, in all such cases so troublesome and tedious; nor, indeed, do I believe there is any drug in the Pharmacopœia equal in value to a well-regulated and duly humid atmosphere. Mr. Burder describes the mode of obtaining this moisture, which he will be glad to know is in very general use by the Profession in this locality. I take this opportunity also of expressing my admiration at the ingenious contrivance described by Mr. Burder in a former letter, by which he obtains a constant supply of pure and warm air in his bedroom day and night, and a knowledge of which mode I could wish was very generally diffused, since it would add most essentially to the comfort of all invalids (alas! a great host), who spend their days, and weeks, and months within the area of a moderately-sized room, most difficult to ventilate, but yet an operation most necessary for the comfort and improvement of the occupant, be he suffering from any form of disease whatever.

I am, &c.

EDWARD HUMPAGE.

8, Cotham-road, Bristol, March 23.

THE ALTERATION IN WEIGHTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We are beginning to feel that in depriving us of the scruple and drachm weights, the Medical Council has put us to an inconvenience similar to, and, Medically speaking, as great as, that which would result if the Mint was to withdraw the silver coinage to-morrow, and tell us to conduct our small monetary transactions with half-pence. The inconvenience, indeed, threatens to be so great, and the liability to mistakes following the use of a complex series of figures from 1 up to 218.7 (the ʒss. avoird.), is so obvious, that I need not insist upon these points. One objection to innovation I will, however, anticipate. It may be said that it is as easy and as plain to write lx. or 120, as it is to write ʒj. or ʒij. It may be so; but which is least liable to be mistaken? The dots I take to be an effectual safeguard in the latter case.

If the Roman numerals were adopted, the objection on the score of liability to mistake would be lessened, because they could not be written fluently; but if the Arabic numerals in common use be employed, the very fluency with which they may be written—resulting as it very frequently does in illegibility—is a sufficient objection to their use. Granting, then, that some weight less than the ʒss. would be advantageous in pharmacy, the question remains, what weight can be substituted in place of the now pharmaceutically obsolete ʒj. and ʒij.?

We can do very well without the former, but we want something equivalent

to the latter, which can no longer be used, since it is not a fractional part either of the avoirdupois ounce or pound. Neither can we adopt the avoirdupois drachm for two reasons, namely:—1st. It does not represent a whole number of grains; 2nd. Its adoption under the symbol ʒ would lead to a confusion of literature referring to pharmacy past and to come.

It appears, therefore, that sooner or later we must have a new weight, designated by a new symbol, and I beg leave to submit to the Profession, through the medium of your valuable journal, whether a weight possessing a distinctive and appropriate symbol, and representing the one-seventieth part of the avoirdupois pound—namely, 100 grains—would not meet the requirements of the case.

The symbol I would propose is a C, formed of a line of uniform thickness. C is appropriate, inasmuch as its signification of 100 is immemorial; but, as it is at present used to denote the gallon measure, I would represent it reversed—thus, ̄C; ̄Cj. = 100 grs.

The advantages which would attend the use of this symbol, and the signification I would give it, are the following:—

1. A symbol representing 100 grains would have the advantage of simplicity in relation to a decimal system.

2. ̄Cj. bears a simple proportion to the pound avoirdupois, ̄Cxxx. = 1lb.

3. ̄Css. = 50 grs., is so nearly equivalent to the obsolete ʒj. = 60 grs., that, generally, we may at once substitute the former for the latter.

̄C is sufficiently distinct from ̄C, although, allowing that there be some distinction in point, it would be a matter of no importance if they more closely resembled each other, since the scruple and its symbol is now obsolete in Medicine.

A friend to whose opinion I attach very much weight says:—"I should prefer the C to the ̄C, and do not think there is any fear of this being confounded with Cong.; indeed, we may rarely prescribe gallons except for baths, when the C. used for Cong. would lead to no mistake." I entirely agree with him that there could be no mistake, but it has since occurred to me that Gr., written hurriedly, with a wide loop above and a short down-stroke, might too closely resemble the unreversed C.

King's College, March 14.

I am, &c.

JOHN HARLEY.

DEATHS FROM ANÆSTHETICS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As the "numerical method" must assist much in arriving at the exact nature of the cause of death by anæsthetics, I wish you would let me insert an abstract of three other deaths from anæsthetics, the particulars of which have been sent to me this month,—two from America, one from Australia. It may appear that I am a sort of "stormy petrel," always in trouble or in at the death,—always horrifying people with such deaths; but my excuse must be, that the collection of such cases, in a scientific point of view, is all-important,—as much so, indeed, as the collection of cases of alleged bronze skin with supra-renal capsule disease of Addison, hippocampus facts in the gorilla controversy, jaw-bones alleged to be found in the drift, or any similar thing where the numerical system will help us and uncertainty prevails.

One case is that of an apparently active man, a prisoner at Pentridge, in Australia, who died in an instant, while under chloroform, a few weeks since, during the passing of a catheter. It appeared at the inquest "that not more than half an ounce had been used, and that death took place rather from syncope (fainting) than congestion." From the analogy of a few such cases, and a curious tendency to syncope, referred to by me, and mentioned, irrespective of chloroform, by Heurte-loup and Syme, which has been observed in Hospitals in urethra operations, I think this syncope as a coincidence is most likely. In obedience, however, to former errors as to the lancet, the infallibility of the Marshall Hall method, etc., we are told twenty ounces of blood were taken by a lancet from the arm of this patient as a chloroform restorative,—"something of more than questionable utility," as remarked by the *Australian Medical Journal*. We can well conceive, indeed, what a mistake it would be to take twenty ounces of blood from the arm of a hysteric girl in a faint, placed bolt upright in a chair; and these poor prisoners are in much the same state of nervous debility or anæmia.

The second case is a little out of the common class of accidents; but the fatal result was admitted to be from inhalation of the vapour of chloroform, though apparently in its external use. Mr. J. B. S—, of Syracuse, in America, who died also suddenly in February, 1864, from the effect of the external application of chloroform. "He had been bathing his limb with the fluid," says the *American Medical Times*; "his wife entered his room and found him lying upon the floor dead. A handkerchief saturated with chloroform and an open bottle were found by his side. A post-mortem examination revealed the fact that his lungs were very much congested from the effects of the inhalation of the chloroform." He was rubbing a chloroform liniment.

The third case is that of a gentleman, this year also, of New York, who, for a very trivial operation, had the nitrous oxide gas. "He continued to grow worse, and died in about two hours. (This is the second case of death from this gas of late.) The deaths here, as well as those from ether and the "ether mixtures," now so fashionable in Hospitals and mid-wifery, are always slow, by a sort of intense drunkenness. The blood globules, we know, too, are destroyed, which does not occur under chloroform; indeed, under some of the gaseous anæsthetics, the blood is so thoroughly destroyed and broken up that it is a miracle such patients ever recover. The deaths also from ether and "ether mixtures" are not dissimilar from those produced by gases; while the use of the "mixtures" is excessively tedious for the Surgeon about to operate.

Sackville-street, March 25.

BOOKS RECEIVED.

The Battle of the Standards: the Ancient of Four Thousand Years against the Modern of the last Fifty Years. By John Taylor. London: Longman and Co. 1864.

* * This is a singular, not to say eccentric work, in which Ægyptology, poetry, mensuration, politics, and theology have come into unusual combination. The "Ancient" of the title is neither more nor less than the Great Pyramid. In his honour the book opens with a poem by Patrick Scott, Esq. He remarks, that

" 'Tis not for poet to inquire
Why thou wast built? and when?"

and then, rather inconspicuously, launches into the inquiry. He is followed by a sonnet from Petrocchi, a translation of which "was originally sent by Mr. Strong to the *London Magazine*, which the editor (*qu.* author) conducted from 1821 to 1824, with the aid of the late John Hamilton Reynolds and the late Thomas Hood, his valuable coadjutors."

Then we have an account of the Pyramids, tending to show that they were intended as observatories for the then pole-star *α draconis*. This calculation is extracted from Sir John Herschel's celebrated Astronomy, and enables the writer to assert (why we cannot imagine) "That while Noah was still living the Great Pyramid was constructed. It had been revealed to the builders of that wonderful structure that the earth was a sphere, the measurement of which they then made with great exactness; that it revolved daily on its axis, which was inclined 30° above the level of the horizon, that the axis was on a line with the polar star, and that the earth's orbit was completed round the sun in the course of a year." Having established this startling conclusion to his own satisfaction, the author indignantly asks "Shall we admit as evidence of this wonderful revelation a monumental record of the most imperishable nature? or shall we ignore its existence, and be content with what is taught erroneously as the truth in our schools and universities?"

A long comparison of our measures of length with the equatorial and other diameters of the earth follows, and the product is applied to the measurements of the Pyramid. Noah then comes on the stage with his sacred cubit, in the character of an antediluvian Brunel, and forms the starting-point of some marvellous semi-theological speculations, showing that the "unwritten revelation" aforesaid is the foundation of our modern measure of length.

There follows a brief memoir of the Great Pyramid, offered to be read before the Royal Society in 1859, but which that learned body seems to have succeeded in shelving.

Then we have Sir John Herschel's two well-known letters to the *Athenæum*, on a British Modular Standard, and the leading article, letters, and other communications published in the *Times* when the decimal system was lately discussed. All these allude with respect to Mr. Taylor's views on the mathematical coincidences in ancient and modern measures, and also as to the proportions of the Pyramid. But they make no mention of his theological doctrines, which probably come now for the first time before the world. The book produces a very painful effect from its mixed power and incoherence.

The Medical Report on the Great Western, Bristol and Exeter, and South Wales Railways' Provident Society, for the Year 1863.

* * The Medical staff of the Great Western Railway is a very important body; it consists of ninety-four country Surgeons and Doctors of Medicine; two Consulting Surgeons, Mr. Lane, of London, and Mr. Hester, of Oxford; two Consulting Local Physicians, Dr. Budd, of Bristol, and Dr. Drake, of Exeter; three *Honorary Officers*, viz., Dr. Markham, Honorary Physician; Mr. Wall, Honorary Examiner; and Mr. Keddell, of Bristol, Honorary Surgeon; and Dr. Cooper, Consulting Physician and Medical Superintendent. These gentlemen have drawn up a very useful Report, calculated to show the state of health of the labouring population. For example, they examined 857 candidates for appointments, passed 512, and rejected 345. Among the rejected, "general labourers" and "porters" figure largely, being, for the most part, unskilled labourers, of indifferent health, forming part of the loose population of towns. Out of the 345 causes of rejection, small and malformed chest was reckoned in 172 cases; diseased lungs, scrofula, and consumption, 65; curved spine in 22; and near sight in 7. The Railway Provident Society numbers 3130 members, amongst whom were 907 cases of illness, lasting 2076 weeks, and 262 cases of accident, lasting 940 weeks. The following is the result of the actual illness during the past year:—

Number ill out of 100 liable to sickness	29 persons.
Number ill, including accidents, out of 100 liable	37½ "
Average (for each member liable) for sickness alone	4½ days.
" " " " including accidents	6½ "
" " " " duration of each case of sickness	16 "
" " " " accident	25½ "
" " " " from all causes	18 "
Deaths from sickness alone	22, or 7 per thousand.
" " " " all causes, including 8 for accidents	30, or 9½ "

The value of such Reports is evident from the fact that the quantity of sickness amongst the 3130 persons was 785 weeks less than might have been expected.

Quarterly Return of the Births, Deaths, and Marriages Registered in the Divisions, Counties, and Districts of Scotland. Quarter ending December 31, 1863.

Supplement to the Monthly Returns of the Births, Deaths, and Marriages Registered in the Eight Principal Towns of Scotland; with the Causes of Death at Four Periods of life. Year, 1863.

* * * Respecting births we have here some curious facts. The rate was highest in Greenock, lowest in Perth. In all the towns it bore a close relation to the death-rate, being generally highest where the mortality was highest, and lowest where the mortality was lowest. In every ten births one was illegitimate. In Aberdeen no less than 16 per cent. of the births were of this character. Deaths were due to epidemic and contagious disease in 29.8 per cent.; in Glasgow, scarlatina, typhus, and whooping-cough were prevalent; in Edinburgh, measles and typhus; in Dundee, scarlatina, typhus, and small-pox; in Paisley, typhus, measles, and croup; in Greenock, small-pox, whooping-cough, and typhus; in Leith, typhus and measles; in Perth, typhus and croup. There is added an interesting comparison of weather with mortality from certain diseases.

APPOINTMENTS FOR THE WEEK.

April 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

4. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m. EPIDEMIOLOGICAL SOCIETY, 8 p.m. Annual Meeting. Address by Dr. Babington, F.R.S., on his retirement from the Presidency. MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion. ODONTOLOGICAL SOCIETY, 8 p.m. Meeting. ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

5. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting. PATHOLOGICAL SOCIETY, 8 p.m. Meeting. ROYAL INSTITUTION, 3 p.m. Professor Helmholtz, "On the Natural Law of Conservation of Energy." ST. MARY'S HOSPITAL MEDICAL SCHOOL, 8 p.m. Dr. Graily Hewitt, "Clinical Conference in Midwifery."

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m. HUNTERIAN SOCIETY, 8 p.m. Dr. Risdon Bennett, "On a Case of Hydatid Disease of the Liver, with Remarks." OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Papers by Dr. Meadows, Dr. Day, Dr. Barnes, etc.

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; West London Hospital, 2 p.m. HARVEIAN SOCIETY OF LONDON, 8 p.m. Mr. Weedon Cooke, "On the Tumours Affecting the Female Breast." A Discussion "On Diphtheria." ROYAL INSTITUTION, 3 p.m. Professor Helmholtz, "On the Natural Law of Conservation of Energy."

8. Friday.

Operations, Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 8 p.m. Dr. J. Percy, F.R.S., "On Iron."

DINNEFORD AND CO., PHARMACEUTICAL CHEMISTS,

Beg respectfully to inform the Medical Profession that they are now Dispensing Physicians' Prescriptions
with the

PREPARATIONS OF THE NEW BRITISH PHARMACOPOEIA,

except when otherwise indicated by the Prescriber.

172, NEW BOND-STREET, LONDON.

Pulvis Jacobi ver, Newbery's,

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

BARTH'S OXYGEN WATER holds free Oxygen in solution. It gently stimulates the functional action of the stomach and secretory organs, and is a very useful beverage. WENTWORTH SCOTT'S Analysis gives as contents of a bottle—"Nearly half an imperial pint of pure distilled water, and about 13.5 cubic inches, or 4.6 grains of gaseous oxygen; equivalent to that contained in 21.4 grains of chlorate of potash." 4s. per dozen.
OXYGENATED WATER COMPANY (LIMITED), 36, LONG-ACRE.

FOREIGN NATURAL MINERAL WATERS.

VICHY, Orezza, Pullna, Seltzer, Carlsbad, Kissengen, Fachingen, Spa,

St. GALMIER, FREDERICKSHALL, HOMBOURG, SEIDLITZ, MARIENBAD, BAREGE, BONNES, PYRMONT, and all the principal Continental Waters direct from the Springs at reduced prices. Price-lists on application. The Medical Profession and the Trade supplied on liberal terms.

INGRAM & CO., IMPORTERS, 35, BUCKLERSBURY, LONDON, E.C.

Hogg's Supercarbonated Lithia Water,

LITHIA POTASH, and LITHIA AMMONIA.

"Mr. HOGG'S LITHIA WATER is always uniform, and contains the proportion of 2 and 5 grains of Pure Carbonate of Lithia; it is highly carbonated, very agreeable, and we can confidently recommend it to the Profession as an elegant and carefully-prepared Mineral Water."—Medical Times and Gazette, November 9, 1861.

CITRATE of LITHIA and POTASH WATER, containing 4 grs. Citrate Lithia, and 30 Citrate Potash; CITRATE of POTASH and IRON, 30 grs. and 5 grs.; CITRATE of POTASH, 30 grs.; BICARBONATE of POTASH, 20 grs.; SODA, 15 grs.; SELTZER and VICHY, from their respective analyses.

HOGG, Pharmaceutical Chemist to the Queen, 9, Albion-pl., Hyde-pk.-sq.

Aerated Lithia Water. — Messrs.

BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. GARROD's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain 2 grains and 5 grains in each bottle, either by itself, or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.

The following Waters as usual:—Potash, containing 18 grains of the Bicarbonate in each bottle; Citrate of Potash, 30 grains; Soda, 15 grains; Ammonia, 10 grains; Seltzer and Vichy from their respective analyses; and a very delicious, as well as useful, MINERAL ACID WATER.

BLAKE, SANDFORD, & BLAKE, Pharmaceutical Chemists, 47, Piccadilly.

Natural Mineral Waters of Vichy,

efficacious in stomach, liver, and renal diseases; gout, rheumatism, diabetes, &c.

Also, the celebrated OREZZA MINERAL WATER, containing Iron, and which is extensively prescribed as an invaluable Tonic.

VICHY PASTILLES, the best Digestive Lozenges; and VICHY SALTS for Baths. Also, other French and German Natural Mineral Waters.

VICHY WATERS COMPANY, only Depôt in Great Britain, 27, Margaret-street, Regent-street, London, W.

Gaseous Orezza Water (Corsica),

containing much iron, and of pleasant taste, employed with great success in cases of chlorosis, sluggishness of the abdominal viscera, fluor albus, in chronic affections of the alimentary canal, and as a tonic. Pamphlet free.

Sole Agents, VICHY WATERS CO., 27, Margaret-street, London, W.

Pure Aerated Waters.

ELLIS'S, RUTHIN, SODA WATER.

ELLIS'S, RUTHIN, POTASS WATER.

ELLIS'S, RUTHIN, SELTZER WATER.

ELLIS'S, RUTHIN, LEMONADE.

ELLIS'S LITHIA AND POTASS WATER,

An excellent internal Remedy for Gout.

The public are particularly requested to observe that every cork is branded "R. Ellis and Son, Ruthin," without which none is genuine.

May be obtained from all respectable Chemists, Confectioners, and Hotel-keepers; and, Wholesale only, from R. ELLIS & SON, Ruthin, North Wales.

Superphosphate of Iron and

SUPERPHOSPHATE of IRON and LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. Mr. GREENISH will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.

20, New-street, Dorset-square, N.W.

Nunn's Marsala or Bronte Wine, 25s.

per dozen, £7 4s. per six dozen, £12 15s. per quarter cask. Rail paid to any station in England. This wine will be found of superior quality, is soft and old, and, though full flavoured, entirely free from heat or the slightest approach to acidity. THOS. NUNN and SONS, Wine, Spirit, and Liqueur Merchants, 21, Lamb's Conduit-street, W.C. Priced lists on application. Established 1801.

Price's Glycerine: its Uses and Purity.

See "De la Glycerine, de ses Applications à la Chirurgie et à la Médecine," by the eminent French Surgeon, M. Demarquay. Pp. 240. Paris: P. Asselin. 1863. Or, "On Glycerine and its Uses in Medicine, Surgery, and Pharmacy," by Dr. W. Abbotts Smith. London: H. K. Lewis.

Sulphates of Quinine, Patented

28th July, 1853.—WHITE, in 1 oz. and 4 oz. bottles. UNBLEACHED, extensively used in the large London and Provincial Hospitals, Dispensaries, &c., &c., and, though naturally less refined than the White, is equally free of Cinchonine. In 1 oz. and 3 oz. bottles. To be had of all the Wholesale Druggists, and in quantities of not less than 100 ounces, from the Manufacturer, JACOB HULLE, Chemical Works, Lombard-road, Battersea, S.W.

Blancard's Pills of Unchangeable

IODIDE of IRON.

Recommended by the Academy of Medicine of Paris, And authorised by the Medical Council of St. Petersburg, Extensively tried in the Hospitals of France, Belgium, Ireland, Turkey, &c. Favourably noticed at the Universal Exhibition of New York, 1853, and Paris, 1855.

"Of all the modes hitherto proposed of administering iodide of iron in the pure state, I think Mr. Blancard's the best."—Chemistry Applied to Therapeutics, by M. Mialhe, Deputy-Professor to the Faculty of Medicine of Paris, Pharmacien to the Emperor, 1856, p. 319.

These Pills stand now very high in the therapeutics of every country, as may be seen by the above quotations, and also by the numerous scientific articles in Medical periodicals and works. (a)

Being enveloped in a very thin resino-balsamic coating, they present the great advantage of not being liable to any deterioration, of having no taste, of being small, and not distressing the stomach. As they possess the properties both of iodine and iron, they are especially beneficial in chlorotic, scrofulous, tubercular, or cancerous affections, as also in leucorrhœa, amenorrhœa, anæmia, &c., &c., and they furnish the Medical man with an excellent means of modifying lymphatic, feeble, and debilitated constitutions. Dose, 2 to 4 pills a day.

N.B.—Impure or altered Iodide of Iron is an unsafe remedy, and may even prove dangerous. Only such bottles as bear an electro-plated seal fixed to the lower part of the cork, and the signature of the inventor placed on a green label, are to be considered as prepared by Mr. Blancard. The public should beware of spurious imitations.

To be had at M. BLANCARD'S, Pharmacien, No. 40, Rue Bonaparte, Paris. General Depôt in England at M. Gabriel Jozeau's, French Chemist, 49, Haymarket, London. In the United States, at E. and S. Fougere, Chemists, 30, North William-street, New York. To be obtained retail from the principal Chemists.

ORIGINAL LECTURES.

A LECTURE
ON THE CONSERVATION OF ENERGY.

By Professor HELMHOLTZ.

DELIVERED AT
The Royal Institution
ON APRIL 5, 1864.

THE natural sciences occupy at present so prominent a place among the different branches of human knowledge, they have exerted so great and all-pervading an influence on the whole state of modern society and civilised life, that every one who considers their rapid and rich development during the course of the two or three last centuries will feel inclined to ask what may be the causes which have favoured these sciences in so peculiar and extraordinary a way; while other branches of human study, which relate either to the mental and moral qualities of man, like psychology, moral philosophy, the science of language, of literature and art, or to human instincts, actions, and energy, like history, political science, law, etc., have made progress not so incomparably surpassing that of ancient times, or even sometimes did not reach that wonderful degree of artistic perfection, which ancient Greece had succeeded in imparting to the exposition of scientific questions. Mankind, of course, have always been obliged to observe nature, because they wanted to procure for themselves food, clothing, shelter, and medicine; and we find, indeed, in the books of Aristotle a rich collection of facts, bearing evidence of a very attentive and unprejudiced observation of nature. But one cannot say that these facts were connected into anything like science; so very strange are the metaphysical speculations on natural objects brought forth by that same philosopher, for whose genius we must feel the highest degree of admiration, where he treats of the faculties or inclinations of the human mind. Now, I do not hesitate to say, that the principal cause of the great development of natural science has been the discovery of the strict order and lawfulness pervading all nature. In no other branch of human knowledge have we been able to discover laws of so exact a precision, so large a generality, and such unexceptional validity as are the physical laws. Wherever the faculties and instincts of the human mind, the energy of the human will intervene, we are not able to determine the consequences with certainty and without doubt. If you know the character, the previous life, the degree of intellect, the feelings of one of your intimate friends as well as it is possible to know them all, you may guess, perhaps, with less or more probability, what he will do under such and such circumstances; but you will find yourselves quite unable to predict it with any degree of certainty. How much greater is the difficulty of such a conclusion when you have to deal with the feelings, the intellect, and the energy of a great number of human beings, as in social science and in history! Although there may be definite laws of the human mind, and although we shall be able perhaps in future time to bring them into a more precise form than men have hitherto succeeded in doing, the number of different influences acting on that inextricable tissue of ideas and feelings and remembrances, called the human soul, is so immeasurably great, that there appears not to be much hope of solving these problems much better than they have been solved.

When you compare with the uncertainty and vagueness of our knowledge in mental and moral science, the great and admirable system of modern Astronomy (which is, as it were, the ideal of scientific perfection, and which is founded on that one simple law of gravitation discovered by Newton); when you look at the precision and certainty with which the phenomena of the heavens can be calculated, in spite of the complicated mutual attractions which influence the motions of celestial bodies—calculations which can be extended over far distant centuries of past and future time—you will see the difference, and conceive what a powerful instrument the exact knowledge of such a general law as that of gravitation is. It has been acknowledged, even by the renowned logician, Mr. Stuart Mill, that the human race has become acquainted with the whole degree of power of firmness and of refinement which the operations of their understanding may reach only by the study of natural laws and the development of their consequences. How would it be possible to embrace within our

memory, and to keep ready in our minds, all those innumerable facts and observations stored up in the study of nature, the number of which increases every year, if we could not bring them into a well-arranged order and under the dominion of a few simple laws? The other branches of natural science have not reached that same degree of scientific perfection as Astronomy; but the knowledge of those natural actions, which go on at the surface of our earth, is of even more importance to us: for, in the same degree as we master mentally the overpowering richness of the phenomena which Nature offers to every attentive observer, we become also in reality masters of her forces; by knowing their laws we become able to constrain them to act according to our will; we make them obedient servants of our wishes. Science and industry are interested to the same degree in a complete knowledge of these laws; and we have seen, and shall see, them both progressing together in close connexion. Let me add that natural laws are not only means to understand and to connect those facts which have been discovered already, but that they open also very often the way to new discoveries. Newton's law of gravitation was not only the basis for the explanation and calculation of the motions performed by those planets which had been discovered independently from the knowledge of the law: there are two celestial bodies discovered by the application of the law—at first the planet Neptune, the place of which was calculated by Messrs. Leverier and Adams from the disturbance of Uranus, before anybody had seen it; and, secondly, the invisible companion of Sirius, the existence of which was predicted by M. Peters, of Altona, and which has been really found by Mr. Clark, of Cambridge, U.S., as a feebly shining star visible only in the mightiest telescopes. It is a most astonishing result that inanimate nature, which is itself destitute of the faculties of consciousness and thinking, can be made subject to laws and rules and to the processes of ratiocination, which we used to consider as the characteristic property of mind; and that it is even more accessible to these mental operations than the actions of this our mind itself. Of course we must avoid falling into the error of the philosophers of ancient times and the middle ages, who believed they could find laws of nature by metaphysical speculations, transferring the laws of thinking to the external world. We can find these laws only by the most faithful and unprejudiced observation of nature; but, when we have found them, the development of their consequences shows the most perfect and accurate agreement with nature. Thereby a certain congeniality is revealed between the external world and the logical faculties of our mind; and I might say that the feeling of this relationship gives the real scientific interest to the researches of natural philosophy. The principal reward for the labours and pains of these researches is the satisfaction we experience in subjecting to the dominion of our understanding, as well as of our will, all these forces which appear so irrational and so strongly opposed to our nature until we have penetrated into the mystery of their laws.

For the reasons I have stated, you will perceive that the knowledge of the laws of nature is essential and most important for all scientific investigation. The principal purpose which I shall endeavour to carry out in the present course of lectures, will be to give you an idea of the bearings of such a general law of nature, of the astonishing richness of its consequences, its applicability to all kinds of natural and technical processes, its theoretical and practical importance. I choose for this end the so-called law of the Conservation of Energy, because it has the additional advantage of not having been very long known, whereby the consequences of this law become more striking than those which have already passed into the stock of common scientific knowledge. For a limited number of natural processes—namely, for the motions effected by gravitation and other mechanical forces—the law of which I am to speak was brought forward by Sir Isaac Newton and Daniel Bernouilli; but the first attempts to generalise it for all natural processes have been made only since the year 1842 by different philosophers, independent of each other. I may name here Dr. Robert Mayer, of Heilbronn (a German Physician), Mr. Grove, and myself; but the man to whom we are the most indebted for the new views which have been opened by this great generalisation, although he was not the first to publish it, is Dr. Joule, of Manchester, because he undertook the most laborious part of the work—that of comparing experimentally the principal consequences of this law. Without his exertions and his skill, the new theoretical views would have been probabilities, but not truths.

The law which I have mentioned establishes that the Sum of Energy, or of the power of natural forces capable of working, which is contained in the Universe, is a constant quantity; that it cannot be increased or diminished, in spite of all the various changes which go on continually throughout the great realm of nature. Now, before going to the subject itself, I must explain at first the meaning of these scientific terms "energy," or "quantity of work." When we speak of the work of machines, it is evident that we apply the term "work" in deriving it from a comparison of the work of machines with human work; and, indeed, there are many and principal points relating to the law which I have named—many similarities which introduce us immediately to the essential points to which we have to direct our attention. The value of human labour and human work depends very much on intellect and on skill. It is clear that if we speak of the work of machines, we have to lay aside all that is the effect of intellect and skill in the machines; for if there are traces of intellect in the work of machines, they are not parts of the machine itself—it is the intellect of the constructor or of the inventor. We have only to regard the blind force which acts in the machine.

The first point to which I wish to direct your attention is that there is the utmost variety of effects and of motions produced by the action of human hands and their work. You know how various the motions of our hands may be, and you know, also, how various are the effects we can produce with those motions. Compare the work of a blacksmith, who lifts his hammer and strikes with it on heavy masses of iron, and the motions performed by the arm of the violin player, who brings forth the most delicate alterations of sound, and the work of the lacemaker, who connects almost invisible threads into a fine web, and you see how various are the effects of human handiwork. When you look to a number of different machines, you will find the same variety of effects, the same variety of motions—motions which are sometimes rotatory, like the motions of wheels,—then, again, motions which go to and fro, like those of pistons,—motions of the utmost degree of velocity, which are so rapid that you cannot follow them with the eye, and motions so slow that you cannot perceive them. But all this variety of the final effect depends upon the same moving force, as well in the work of human hands as in the case of a machine. All the motions of our hands are performed by the contraction of our muscles; they all depend upon the property of our muscles to contract if they are irritated by our nerves. This one force of contractility brings forth all the variety of motion in our hands, and all the variety of effects which can be produced thereby. You find in all these motions one simple, primary cause, one simple force, which is always the same. You find it the same, also, if you look at the different effects of machines. You may have nearly all kinds of machines worked by steam engines. The force of the steam engine is capable of moving every kind of mechanism and producing every kind of work. You have here, therefore, the same variety of final effect by one and the same primary moving force. This is the first point to which I wish to direct your attention, that the variety of effect does not at all imply similar variety of primary causes which produce this effect. There is only a quantitative difference between different exertions of our muscles. Of course, a blacksmith who lifts up his heavy hammer must perform a greater exertion of his muscles than the violin-player or lacemaker; and, in the same way, those steam-engines which have to drive rollers, and hammers, and cylinders of great iron works, require far greater power than a small corn-mill driven by water, which moves millstones, or the little mills one sees sometimes in the houses of the peasants in the Tyrol, which are moved by water, and have no other use than that of rocking the babies in their beds. You have a difference of quantity in the power of machines, and this is the only difference which we want to find for the moving force. Therefore, we may speak of a different quantity of energy of the moving power of a machine, and we may compare this with the different exertions of our muscles in performing different kinds of handiwork. There are some other circumstances in which human handiwork and the work of machines is similar. Our muscles are fatigued when we use them. We cannot do more than a certain quantity of work during a certain time. Our muscles want repose and food for restoring their energy and their power. Now, it is not quite so evident beforehand that the same is the case with machines. We shall see hereafter that those forces also which drive and move our machines are exhausted by doing the work itself, and that if there is not a continuous, fresh supply

of energy they lose the faculty of working again—they are also exhausted in their energy.

Now this comparison of the working power of machines with the working power of our hands may give you at first an idea of the meaning of these terms; but we must have an accurate definition of what we are to understand by the name of Energy, and that can only be given if we consider in what way energy may be measured. The simplest way to measure the amount of energy is seen in those cases where we apply the simplest and best known of physical forces, the force of gravity. Take, for instance, a common Dutch clock, which is moved by a falling weight. There you have a cylinder, round which a string is wound, and on the string there is fastened a weight; the weight sinks down; it draws the string with it, the string moves the cylinder, the cylinder is connected with the wheels of the clock, and so the whole clockwork is moved. Now, I beg you to remark that the clock cannot be kept going without the descent of the weight, and when the weight has arrived at the lowest point to which it can get, the movement stops, and the clock cannot go on. You see that the force of gravity which moves the weight produces motion and alteration only so long as the weight is sinking, and that the power of moving the clock is exhausted by the sinking of the weight itself. When the weight is down, we can raise it by the force of our arm; it then sinks again, and as long as it sinks the clock moves. You see here the same circumstance I have before mentioned, that the power of moving the clock is exhausted by its own effect, and that this exhaustion of the energy or the moving power of the weight is necessarily connected with the motion itself. In this case, the work which the weight does is not very great; it has only to overcome the resistance made by friction or the resistance of the air and the loss of motion caused by the little shakes and beats which different parts of the clockwork perform; but these resisting powers must be overcome in order that the clock may go on. This example gives us the means of measuring the quantity of work which is performed. If you take two clocks constructed in the same way, with an equal weight, they will go at the same rate. You may connect the two weights into one, and the double weight will be sufficient to do the double work. The work to be done by the weight increases as the weight itself. Or you may double the length of the string, and so double the amount of work which is done. The whole quantity of work which is done in the clock is proportional to the length of the string or to the distance through which the weight can fall. Therefore we find that the amount of work done by such a weight falling under the influence of gravity, is proportional at first to the weight itself, and, secondly, to the height through which the weight can fall; so that we must measure the quantity of work which is done by a falling weight by the product of the weight with the height through which it falls. And if we measure the weight by pounds, and the height by feet, it will be the product of one pound and one foot, or a number of pounds and a number of feet; and we call the unit of this measure, for measuring energy or work to be done, a foot-pound. A pound falling through four feet, therefore, gives a quantity of energy measured by four foot-pounds. The same with two pounds falling through two feet, or four pounds through one foot. Now, in this case we must wind up the weight by the force of our arm; by that means we impart a certain quantity of working-power to the clock, and this working-power is given out and used during the next day, as long as the clock goes, by overcoming friction. We do not gain in this way new working power. If we want to gain work, we must use weights which are lifted, not by the strength of our arm, but by other natural processes. There is a sort of machine which is driven, indeed, by the falling of weights, namely, over-shot water-mills, of which we have here a sketch. You see the water flowing down from a height upon one side of the wheel, which in that way becomes heavier, and it is drawn down by the weight of the water. The little boxes into which the water falls are emptied when they go up on the other side, and, therefore, have no weight; so that the wheel is always heavier on the side where the water flows. It is the weight of the falling water which moves such a wheel; and you see that we have here the same circumstances as in the case of the clock moved by the falling weight. Here, also, the water cannot move the wheel unless it descends—comes from a height to the lower part; it can only be moved by the water sinking down, and the energy of the water is destroyed by the motion of the wheel—the force of gravity is lost.* Now, such a heavy body which comes down from a height does not lose its gravity.

The water is as heavy when it arrives at the lower part of the wheel as it was on the superior part of the wheel; and the weight moving the clock is as heavy when it touches the ground as it was when it was wound up. It does not lose its gravity; but those conditions under which alone the gravity can act, under which the force of gravity alone can produce an effect, a change, or alteration—those conditions are altered; and if the weight is upon the earth, gravity can only fix it, so that it lies quietly on the ground; it can produce no other motion or change.

There is a common objection made to these statements that I have brought before you, taken from every-day experience. You know that one uses levers, pulleys, and other machines, cranes for instance, for raising great weights. One man who is not at all capable of raising a heavy stone, can do it with the help of such pulleys as you see here; and the common belief is that by such machine it is possible to make a heavy weight light, and to gain a quantity of work. Now, if you look accurately to this matter, you will see that whenever by the construction of such an apparatus it becomes possible to raise a heavy weight by slighter exertion or by a lighter weight, the time increases as much as the exertion of the arm is lessened. We have here a single pulley and two equal weights which are in equilibrium, so that I can move them with the slightest exertion of my finger. As I draw one down, the other will ascend; and the distances through which both the weights move are equal. We have here also a more complicated form of pulley, used for raising heavy stones. By its means we can lift double the weight which can be drawn by a man; but then double the time is used for raising it. Here is another still more complicated, by which we can lift four times the weight; but the distance and the time will be four times as great. It is the same thing with levers and cranes. In all these cases the time of working is increased as much as the exertion is diminished. There is really no gain; it is only that the exertion of the man who works such a machine is brought into a more convenient form. Here is another form of work, in which a wheel is driven by rapidly flowing rivers; the wheel dips only with its inferior margin into the water, and is moved, not by a falling weight, but by the velocity of the river. We have many other cases where velocity gives a power of motion. Take the case of a rifle ball. If you put a bullet into your hand, it lies quietly there, a harmless thing. If you move it by the force of gun-powder, it has a great velocity, breaks through all hindrances, and develops a most intense power of destroying. Here we have a ball suspended by a string, forming a pendulum. It is now at its lowest level. If I lift it on one side, and then let it go, it will descend to its former place with a certain velocity; and if I do not disturb its motion, it will go up the other side and return again to my hand. So that you see the energy which I have imparted to the pendulum by raising it, is at first changed into velocity, and the velocity is again changed into this form of energy which is given by a raised weight. You have in this instance a change of the energy of a raised weight into velocity, and of velocity into a raised weight; for at the ends the pendulum has no velocity, but it is a raised weight; in the midst it has velocity, but it is down to the lowest level which it can reach. The first form of energy is lost, but it has gained a second form of energy, that of velocity; and again the velocity is lost, and the energy of a raised weight is gained. You see by this simple experiment, that the energy imparted to the pendulum by raising it can be turned into quite another form; and from the second it can return to its first form, going up just as it went down. The cause of this is the so-called inertia of such heavy masses. Every amount of matter which is moved cannot cease to move, if it is not hindered by any force. When there is no force to diminish the motion, it must go on to all eternity in a straight line. Therefore, if the pendulum comes down to this lowest point, it has its velocity, and the velocity can only be destroyed by force; this force is the gravity which is opposed to the motion, which gradually diminishes it, so that the pendulum comes to repose at its lowest point.

Other mechanical forces, like elasticity, are of the same description. In the common watches and timepieces we have as a moving power, not the gravity of a weight, but an elastic spring. When the watch has ceased its motion, we must wind it up; we then impart new power, new energy to the wheel-work, so that the watch can go on again. In this case, also, you see that the working power is exhausted by its own effect, and that it cannot work without being destroyed. When we wish to gain by the force of elasticity, we cannot do it by wind-

ing up the spring, for then we only impart energy to the spring, and we must give this energy by using our arm. To gain energy and working power by elasticity, we must choose instances where the tension of an elastic body is produced in another way, by other processes of nature. Now, we can act upon elastic bodies by chemical processes and by the action of heat. We have here a glass vessel as used for saturating water with carbonic acid. In the inferior part of the glass vessel we have pieces of chalk, to which I have put some hydrochloric acid. You see, as the gas develops, the coloured water contained in the vessel is lifted to the upper part, and we might raise the column of water much higher if the tube permitted. We can raise a column of water in the same way by the action of heat applied to air and increasing its elasticity. We have here a tin vessel with a little water at the bottom, and above there is a glass tube communicating with the air. By pouring boiling water on the upper surface of the vessel the air is warmed and its elasticity is increased; the water is thus raised, and a jet produced, as you see. In this case the air is enclosed by water, which falls at the bottom of the vessel. We have the same effect in the steam-engine, only on a larger scale and going on continuously. There it is not water which encloses air, but the solid piston which fills the cylinder, and which is moved on one side by the steam generated by the influence of heat; then the connections of the cylinder with the boiler are changed, and the steam comes in the other side and moves the piston there. We do not use heated air, because the expansion of heated air is not so great as the expansion of water which is changed into steam. We find, then, that heat can be used as a moving power. Now, the question arises, is the moving power of heat also destroyed by its action, and has a certain quantity of heat (as, for instance, the heat developed by burning a quantity of coals) a limited amount of working power which can be produced by it? or is the working power to be produced unlimited? It was difficult to answer these questions as long as the old theory of heat was held by scientific men. According to the old theory of heat, it was considered as a sort of imponderable matter spread out through all ponderable bodies. Now, the first characteristic peculiar to matter is that its quantity is constant, that its quantity cannot be diminished or augmented; therefore, natural philosophers who were of this opinion were obliged to infer that the quantity of heat could not be diminished or increased, and it was not clear from what effect the working power of heat should be derived. There were some experiments in which heat vanished and became again apparent; but they were considered to be cases in which heat only became latent heat, or latent heat became apparent. In many cases formerly observed, it was possible to give such an explanation of the phenomena; but there are other instances in which that is not so. Take the case of any heavy body falling down from a height. We have seen that in some instances such heavy body, after falling, can rise again, and go to the same height as that from which it came; but in the common cases, if a heavy body falls to the ground, it lies there, and is no longer moved. The force which produced its motion seems to be lost, but in reality it is not lost; we find that the body which fell has become heated—not much, but sensibly. There are a great number of other influences which seem to destroy mechanical work. We know that, in spite of the law of inertia, according to which every motion should go on in a straight line to all eternity, in all our experience collected from terrestrial phenomena, all motions cease if they are not kept up by new moving forces. There is always friction, and the resistance of the air, which destroys a part of the motion; and there are the impacts and shocks of the different parts of the engines; and we cannot keep up a terrestrial motion without diminishing it by those influences. You know from daily experience that in those instances where resistance exists heat is generated. If the wheel of a carriage cannot be moved easily enough—if it is stiff and has great friction, which opposes its motion, you will find, if you put it into motion with greater power, the wheel becomes heated, and it can be heated so much that it begins to burn. Rubbing a common match along a piece of wood, you see that it is inflamed; the small quantity of inflammable substance on the top becomes so heated that it is inflamed and burns. If you strike a flint with a piece of steel, you see sparks flying off. The sparks are only small glowing particles of the flint and the steel, which are heated by the force of impact. You see, then, that such small powers as these are capable of giving heat; indeed, it is a constant effect of impacts and of friction that heat is produced. Now, one

of the greatest results of our modern investigations, and principally of those of Mr. Joule, is that the quantity of heat which is produced by the loss of working power is proportional to the amount of working power. If you measure the amount of working power by foot-pounds, then you can calculate how much heat is developed. According to the results of Mr. Joule, the heat which is required to increase the temperature of a quantity of water one degree of Fahr. can be produced by a power which is equal to the amount of work done by the same quantity of water falling down 772 feet. This number 772 is called the mechanical equivalent of heat—the equivalent of one degree of Fahrenheit, and it is quite a constant quantity. In all cases where heat is produced by mechanical power, we find that so much heat is produced as is given by this equivalent. Therefore, if a stone falls to the ground, its motive force disappears as it seems, but in reality it disappears only as the motion of the great visible mass of the stone; it is altered into small vibrations which go on in the molecules of the stone and the ground which it has touched, and it can be re-changed. You have seen that we could raise a weight of water by the power of heat; and we have seen that the pendulum, after falling down, is raised again by changing its velocity into an elevation. Commonly heat is produced by chemical processes, by the burning of coal. The coal which burns is combined with oxygen; and you may consider the affinity of the coal to oxygen like the force of attraction working only at very small distances. This force of attraction, which draws together the molecules of the coal and of the oxygen, must give the same effects as the force of gravity drawing down a weight to the ground; it must give a great velocity, and this velocity cannot be lost; because in the motions of the atoms there can be no friction. All friction is only a change of motion of visible masses into motions of the molecules; and therefore in the motion of the atoms there can be no friction. This force of affinity, then, which draws together the atoms of the coal and the oxygen produces a velocity, but a velocity of molecular motion, that is heat; but if this velocity is removed, the force of chemical attraction between the molecules of coal and oxygen exists in the same degree as before, but its only effect is to keep together the atoms which form carbonic acid—they cannot then be separated. You see, then, that the working power of chemical affinity is destroyed by the working itself. We ask, can it be restored? It is only possible to restore chemical force by other natural forces. I cannot show you the restoration of the chemical force of carbon and oxygen combined into carbonic acid, as they cannot be freed again except by complicated processes. But in all our fuel we have not only carbon, but hydrogen; and we can at least show the restoration of the force of hydrogen and oxygen, by conducting an electric current through water, which is the compound of oxygen and hydrogen. By this current we can restore the elements of which water is composed. (Experiment.) You see a number of gas-bubbles going up along the platinum plates, which are in the interior part of the vessels. In this way the two gases are developed in an isolated state. In this case the chemical force of the affinity between hydrogen and oxygen is hindered, and ceases only because resisted by another chemical force, the chemical force of the galvanic battery which gives the electric current. In the battery zinc is dissolved in sulphuric acid, and nitric acid is separated into its elements, so that there is one chemical force opposed to another. But we can do the same thing in another way—we can separate the chemical elements, and restore the energy of their force of affinity, by purely mechanical means, by means of the electro-magnetic machine. (Experiment.) To show the effect of the machine in producing an electric current, I put a small piece of platinum wire between these two points, and you will see that it begins to glow when the machine is worked. The effect of the current produced by the mechanical force of my arm keeps the platinum wire glowing. Heat, then, is here generated by another method—by the energy of my arm, just as I could produce it by rubbing a match on a board. Now, if we connect the machine with a little apparatus for decomposing water you will see that the power of my arm is sufficient to resist the chemical affinity of oxygen and hydrogen. You see that the working power of chemical affinity, if it has been destroyed by the action and the combination of the elements, can be kept up and restored by another action. You see on the screen the inverted images of platinum wires dipped into a small vessel filled with diluted sulphuric acid. I work the machine, and you see the bubbles apparently descending, but, as the

image is inverted, they are in reality ascending. You see that in this way also we can restore the power of chemical affinity.

We have, therefore, very different kinds of natural forces all connected together; and the energy which is lost is capable of being restored in another form. We have seen that the energy of a raised weight can be changed into velocity; that the velocity of the weight when it strikes against the ground can be changed into heat; that by heat we can gain mechanical power to raise weights, and so on. We have seen that there exist equivalent relations between these different kinds of natural forces, that we can change one into the other; and modern researches into these relations have given the result, that if one form of energy is destroyed, another form is gained in equivalent relations, so that by another series of actions the first form of energy can be completely restored; that there is no loss, but only a change in the form of energy. From this rate of equivalents we may conclude that there is a store of Energy in the Universe which cannot be increased, or diminished, or changed by any natural action; for all changes in nature are only changes in the form of energy; the energy is brought always into a new aspect; it is neither destroyed nor increased. Therefore, also, all energy that we want for our machines and for the actions of our own body can only be taken from the great store of energy which is contained in the universe; and to understand the actions on the surface of our earth, those actions with which we are surrounded during our life, to find out their real and principal cause, we must look to the great store of energy which is contained in the universe; and this will be the task of our second lecture.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE V., (a) FEBRUARY 9.

(Concluded from page 360.)

The *Liniments* have been altered considerably, and two omitted, those of Verdigris and Subcarbonate of Ammonia; but as many as seven have been introduced—namely, Liniment of Aconite, Belladonna, Cantharides, Chloroform, Croton Oil, Iodine, and Turpentine with Acetic Acid. I have already had occasion to speak of the Aconite and Belladonna Liniments, and shall confine my remarks now to those of Cantharides and Iodine.

The first is intended as a blistering agent when employed by itself, or as a rubefacient if united with other milder preparations. It is made by digesting the cantharides in acetic acid, and afterwards percolating with ether. I have used many ounces for the purpose of raising blisters, and have found that one application is almost always effectual. The ordinary acetic acid of 28 per cent. is employed, because the glacial acid produces too severe an irritation of the skin, and is apt to cause in some patients sores somewhat difficult to heal.

The Iodine Liniment contains as much as 109 grains of iodine to the fluid ounce of the preparation, and a sufficiency of iodide of potassium to render the iodine soluble in the rectified spirit. If employed in its undiluted state, it will usually cause the production of blisters.

On looking over the group of *solutions*, one fact will be observed—namely, that in all cases in which the solution is made by directly dissolving a salt, the strength has been adjusted so that each fluid ounce of the solution contains four grains of the substance made use of. This holds good with Liquor Arsenicalis (the former Liquor Potassæ Arsenitis),

(a) Portions, especially of the latter part, of this Lecture were not delivered from want of time.

Liquor Atropiæ, Liquor Morphicæ Hydrochloratis, Liquor Potassæ Permanganatis, Liquor Sodæ Arseniatis, and Liquor Strychniæ. Such an adjustment cannot fail to prove most convenient to the prescriber, as there will be now no difficulty in remembering the strength of each solution—each fluid drachm containing half-a-grain of the medicinal agent. I must not omit to call your attention to the alteration in strength of the Solution of Hydrochlorate of Morphia; it is now only half that of the London Pharmacopœia preparation. The reasons which led to this change were very cogent. Already the Edinburgh solution contained four grains to the ounce, and in that of the Dublin College the amount was about the same; such being the case, it was considered very undesirable to increase the strength of the preparation in Scotland and Ireland, a change which might have been productive of serious consequences, whereas no such liability would arise from lowering the strength of the London solution. It was also found convenient to effect this change in order to make the morphia solution correspond with those of other substances; besides which, the preparation of the London College was liable to undergo some alteration in strength from the crystallisation of a portion of the Hydrochlorate of Morphia.

Liquor Potassæ has been somewhat reduced in strength: its specific gravity is now 1.058 in lieu of 1.063. Liquor Sodæ is also weaker: sp. gr. 1.047, in place of 1.061, as ordered in the London Pharmacopœia. The neutralising power of the two solutions for acid is nearly the same. In the London Pharmacopœia, Liquor Sodæ was introduced solely for the purpose of preparing the Oxysulphuret of Antimony: now it must be looked upon as a remedial agent, as it is placed in the list of the *Materia Medica*.

I cannot help thinking that it would be desirable to institute some clinical trials upon the comparative action of the Solutions of Potash and Soda. Both are doubtless direct antacid remedies, and likewise sedatives to the mucous membrane of the stomach. There appears to be also good evidence that potash salts affect the secretion from the kidneys, and soda that from the liver; but still the carbonates of the two alkalies are often prescribed indiscriminately. I have met with two instances in which the difference of action was marked—in one most strongly so. This latter occurred in a patient who had suffered for many years from eczema, covering a large portion of the body, always present in some degree, but occasionally becoming severe. The exhibition of twenty grains of Bicarbonate of Soda was usually followed by relief, shown by a lessening of the irritation of the skin; but the same dose of the Bicarbonate of Potash would at any time aggravate the skin affection, and likewise produce a sensation of discomfort in the stomach. The trials of the two alkalies have been frequently made, and always with the same results.

The dose of Liquor Sodæ is from ten minims to thirty minims, or more. We should increase the amount of liquid in which it is administered as we augment the quantity of the solution.

There is a preparation of lime termed Liquor Calcis Saccharatus newly introduced: it is a solution of lime, in which the alkaloid earth is rendered much more soluble by the addition of sugar. A pint of distilled water will not take up more than eleven grains of lime; but in the Saccharated Solution of the Pharmacopœia 140 grains are present in the same quantity, or about seven grains to each fluid ounce. Under certain circumstances, this may prove a useful preparation.

The only other solution to which I shall direct your attention is Liquor Chlori. It is simply a saturated solution of chlorine gas in distilled water. Being very liable to decompose, it should be used when freshly prepared. As a medicinal agent it may be administered whenever the action of free chlorine is desired; and I should think its advantage over Liquor Sodæ Chloratæ or Liquor Calcis Chloratæ very questionable. It may be employed also as an external application to foul ulcers and other purposes.

The dose is from ℥xx. to ʒj., diluted with an ounce or more of water.

Concerning the small group of *Mucilages* there is nothing of special interest to remark; and with regard to the *Pills* I shall only state that a Compound Colocynth Pill has been introduced in addition to the Compound Extract, into which the colocynth enters in the form of the powdered pulp, and with Barbadoes instead of Socotrine aloes; that there is likewise the same pill containing extract of henbane under the name of *Pilula Colocynthidis et Hyoscyami*; there is also a pill made with the Saccharated Carbonate of Iron, in the place of

the *Pilula Ferri Compositus* of the London Pharmacopœia; a pill of the Iodide of Iron; and lastly a pill termed *Pilula Plumbi cum Opio*, containing acetate of lead and opium, the latter ingredient forming one-eighth of the mass.

About the Powders there is little to remark, beyond what we have already had to notice under other heads. You will remember that *Pulvis Amygdalæ Compositus* and *Pulvis Aromaticus* are virtually the same as *Confectio Amygdalæ* and *Confectio Aromaticus* of the London Pharmacopœia, and that certain alterations have been made in the names of the preparations containing opium. One compound new to an English Pharmacopœia has been introduced, namely, *Pulvis Rhei Compositus*, long used and prescribed under the name of Gregory's Powder.

In the group of *Spirits* many alterations will be observed, the more important of which we will now shortly notice. In the London Pharmacopœia many of the Spirits made with the volatile oils contained but minute traces of these substances, and hence were but very inefficient remedies, unless given in such quantities that the Spirit administered became an item in the action of the preparation. In the British Pharmacopœia all such spirits are made of uniform strength, containing one third part of the oil in ten parts of the Spirit; such is the case with *Spiritus Cajaputi*, *Spiritus Camphoræ*, *Spiritus Juniperæ*, *Spiritus Lavandulæ*, *Spiritus Menthæ Peperitæ*, *Spiritus Myristicæ*, and *Spiritus Rosmarinæ*, and hence the strength of some of these has been augmented many hundred times. *Spiritus Chloroformi*, made by dissolving Chloroform in Rectified Spirit, differs in containing only one part in twenty; and this strength was chosen as it is known that, if much more concentrated, the Chloroform is apt to separate when the preparation is diluted with water, especially if much saline matter is dissolved in that menstruum.

We have already had occasion to notice *Spiritus Ætheris*, and the omission of the Oil of Wine from its composition, as likewise *Spiritus Ætheris Nitrosi*, and its altered preparation and composition, and lastly, *Spiritus Ammoniac Aromaticus*, from which the Oil of Cloves has been removed.

The fresh Juices from three plants have been introduced, namely, *Succus Conii*, *Succus Scoparii*, and *Succus Taraxaci*; the preparations consist simply of the expressed juice from the fresh plants, to which one-third of the volume of spirit has been added. These Juices are thought highly of by some Practitioners; they doubtless possess all the virtues of the plants from which they are derived, but we must not forget that their strength is liable to considerable variation, dependent on the season. In a wet season the juice is much more dilute than when the weather has been for a long time dry. The activity of the juice is greatly augmented by the concentration of the sap.

A suppository of Tannic Acid and one of Morphia have been placed in the Pharmacopœia; the former containing two grains of the acid, the latter a quarter of a grain of the hydrochlorate of morphia in each suppository, the basis in each consisting of lard united with wax and glycerine or sugar.

In looking over the group of syrups, some additions, alterations, and improvements will be observed. *Syrupus Floris Aurantii* is an elegant adjunct to medicines; *Syrupus Ferri Phosphatis*, a valuable and pleasant ferruginous preparation, each fluid drachm containing one grain of the phosphate of iron; and *Syrupus Sennæ*, a medicine of considerable power, and an agreeable mode of administering the drug.

We next come to the extensive group of Tinctures. 256 of these preparations are contained in the British Pharmacopœia. As in former Pharmacopœias, we find rectified spirit; proof spirit, spirit of ether, and the aromatic spirit of ammonia employed as solvents of the active portion of the drugs, according to the nature of each; it will also be seen that instead of simple maceration, this combined with the method of percolation has in many instances been made use of; of the value of this latter process I will not speak, leaving the discussion of the subject to the pharmacist, whom it most concerns.

Of the individual tinctures I have only to remark that *Tinctura Aconiti* is only one-third the strength of the London tincture, and hence a more manageable preparation for internal use; *Tinctura Belladonnæ*, half the strength; *Tinctura Conii* is now termed *Tinctura Fructus Conii*, and, from my observations, about twice the strength of that from the Leaves in the London Pharmacopœia. Of the several new tinctures I have already spoken when describing the drugs from which they are made.

Lozenges, under the Latin name of *Trochisci*, long officinal in the Edinburgh Pharmacopœia, are contained in the British work. They are six in number, and are made of tannic acid, subnitrate of bismuth, catechu, hydrochlorate of morphia, morphia and ipecacuan, and opium. If it is ever desirable to administer the above-named drugs in the form of lozenge, then it is advantageous that a formula for their preparation should be made officinal, more especially in regard to morphia and opium, in order that the amount of the active principle in them should be definite, and that they should be regarded as belonging more to the pharmacist than the confectioner. Each tannic acid lozenge contains half a grain; each bismuth lozenge, two grains, united with carbonates of magnesia and lime; the catechu lozenge, rather more than one grain, together with a little capsicum; of morphia, $\frac{1}{36}$ th of a grain in each lozenge; of morphia and ipecacuan, $\frac{1}{36}$ th of a grain of morphia salt, and $\frac{1}{12}$ th of a grain of ipecacuan; of opium, $\frac{1}{10}$ th of a grain of the extract of the drug.

The only remaining groups to be noticed are the ointments and wines. Of these little need be said. You will remember that certain preparations, formerly termed cerates, are now included amongst the ointments, and thus one class of pharmaceutical compounds is abolished; in other respects, also, the groups have been simplified. There are a few new introductions, as Unguentum Aconitiæ, Unguentum Atropiæ, Unguentum Calomelanos, Unguentum Cocculi, Unguentum Creosoti, Unguentum Hydrargyri Iodidi Rubri, Unguentum Plumbi Carbonatis, Unguentum Plumbi Subacetatis, Unguentum Terebinthinæ, and Unguentum Veratriæ. The ointments made with the vegetable alkaloids are of uniform strength, all containing eight grains to the ounce of prepared lard.

The only point worthy of notice in the wines is that Vinum Ferri is now made by dissolving the Tartarated Iron in sherry wine, instead of digesting Iron Wire in the same, and that Vinum Opii is made from opium itself, instead of the extract, and without the addition of the aromatics. Time will not allow me to dwell at any length upon the Appendices of the British Pharmacopœia, nor is it at all necessary to do so in lectures which have been more especially devoted to the therapeutic value of the medicines.

In Appendix A will be found articles employed in the preparation of medicines, and such an account of the properties and composition of them as may be necessary to their right understanding.

Appendix B (1) contains the articles employed in chemical analysis; and Appendices B (2) and (3) the test solutions both for qualitative and quantitative or volumetric analysis. Appendix C, a list of the elementary substances mentioned in the British Pharmacopœia, with their symbols and equivalent weights; and lastly, in Appendix D will be seen the relation of the measures to the weights of the British Pharmacopœia, and the relation of these to metrical weights and measures.

I have now, so far as time has permitted me, given a slight, but, I fear, very imperfect account of the remedies newly made officinal by the publication of the British Pharmacopœia, and likewise of some of the more important alterations which have been made in the various preparations of the medicines therein contained. I have occasionally expressed doubts as to the efficacy of some of these new introductions; but when I have done so it has been from the result of clinical observation alone, and from no theoretical opinions which I had previously formed or imbibed. Many, and, in fact, most, of the results which I have stated to you have been arrived at since the decision at a conference of the whole Committee as to the remedial agents and preparations which should be introduced into the work. I doubt not but that the truth of some of my statements will be called in question. All I can say with regard to them is, that, should further experience render a modification of any of my views necessary, I am freely open to conviction and correction. In pursuing my observations on the action of medicines and on their therapeutic value, I trust I have, after some years of experience, so trained my mind as to wish for no results but truth alone, and to feel equally satisfied whether my pre-conceived ideas of the efficacy of any favourite remedy proved fallacious or correct when brought to the test of rigid clinical study. I have not scrupled to make known negative results, for I feel convinced that a record of unsuccessful trials is of great value.

Whether speaking in favour of or against any remedy or preparation, I have carefully avoided alluding to individual members of the Pharmacopœia Committee, or attributing intro-

ductions or omissions to any one. For my own part, as a member of that Committee, although I may not agree with everything that has been done, I feel it to be my duty to take my share of responsibility with my colleagues. That the work should be perfect, or even approach perfection, could not be anticipated, seeing the necessity of uniting in one Committee minds in many respects differing so greatly—minds which had been long imbued with such diverse opinions.

Still, I cannot help feeling satisfaction and pleasure that throughout our work the labour has been lightened by the kindly feeling which has been felt and expressed among the different members of the committee; and that, at last, a national Pharmacopœia has been produced; it will rest with the Medical Council, in the publication of a future edition, so to construct the committee entrusted with the task of revision as to bring the different portions of the work into a harmonious whole, and to make it one which will be more fully adapted to the wants of the Profession in the different divisions of the United Kingdom.

I cannot conclude these lectures without expressing my thanks to you, Mr. President, for the kindly interest which you have expressed regarding them, and to you, gentlemen, for the patient attention with which you have listened to my somewhat tedious remarks; my only regret is, that I have so imperfectly accomplished the task with which I have been honoured by this College.

To those gentlemen who have so promptly responded to my request for specimens for the purpose of illustrating these lectures, to Messrs. Bell and Co., Mr. Squire, Messrs. Morson and Son, Messrs. Sanford and Blake, and Messrs. Hopkin and Williams, I am under a debt of thanks.

ORIGINAL COMMUNICATIONS.

ON TRICHINA DISEASE: ITS PREVENTION AND CURE.

By JULIUS ALTHAUS, M.D., M.R.C.P.

Physician to the Royal Infirmary for Diseases of the Chest.

(Concluded from page 364.)

Up to 1860 the diagnosis of trichiniasis had never been made in the living subject. In that year, however, Dr. Zencker, of Dresden, recognised an epidemic of this disease in the town and neighbourhood of Dresden, and showed the existence of trichinæ in a ham and several kinds of pork sausages of which the persons affected had eaten. The pig had been slaughtered at a country house near Dresden. The butcher and others who ate of it fell seriously ill, and one case, which was that of a servant-girl who had been quite well up to that time, ended fatally. At the autopsy, an immense number of trichinæ was discovered in the muscles of the body. Dr. Zencker sent specimens of the ham, as well as of the muscles of the dead body, to Professor Virchow, of Berlin, who made a series of important experiments with them. A rabbit was fed with the trichinous meat, and died a month after. The autopsy showed that trichinæ had become developed in the muscles of the rabbit. Another rabbit was then fed with flesh from the first, and it also died a month after. Flesh was again taken from the latter animal, and three other rabbits fed with it; two of these died three weeks, the third a month after. From the latter another rabbit was infected; it died six weeks after. In all of them the muscles were crowded with trichinæ, so that in every piece of flesh, however small, several worms were found. In order to be quite sure that there were no trichinæ in the rabbits before they ate the trichinous meat, Professor Virchow examined their muscular tissue before feeding them, and did not find a trace of trichinæ, which are, in fact, never observed in rabbits unless they are previously fed with trichinous meat. He also found trichinæ in the lymphatic glands of the intestines, the peritoneal sac, and the pericardium. Since then numerous evidences of trichina disease have been recognised in Germany.

The morbid symptoms caused by the immigration of trichinæ are interesting in a practical as well as in a scientific point of view. There are, in fact, few internal diseases where the cause of the disorder is so manifest, and where its action on the system may be so distinctly traced in all its successive stages.

Trichiniasis is a more or less severe affection, according as few or many parasites are eaten, and a small or large progeny is produced. Thus, in the epidemic of Burg, near Magdeburg

a woman who had eaten a quantity of raw pork with bread fell ill and died. Her child, who had sucked a spoon used by the mother, had symptoms of mild trichiniasis, and recovered.

Three stages of the distemper may be distinguished, the first of which comprises the time from the arrival of the trichinæ in the intestines until the birth of the first of the progeny. This stage generally lasts from four to eight days, and its symptoms are by no means remarkable. There is only loss of appetite and general malaise. The second stage is the most important one, and lasts from the time when the embryos commence their migration from the intestinal canal into the muscles until they have taken up their permanent abode in the muscular tissue. The first symptoms in this stage are generally those of a more or less violent irritation of the bowels. There is pain in the abdomen, and either profuse diarrhœa or, what is more frequent, obstinate constipation. In severe cases—that is, in such where the number of trichinæ is very large—fever of a typhoid character soon sets in. There are rigors, followed by heat; the pulse rises to 130 beats; animal temperature is increased; there is loss of appetite, general prostration, and sometimes even delirium. The urine is highly coloured, and contains sediments of uric acid. The quantity of urinary water is sometimes diminished and sometimes normal. The fever is no doubt caused by the irritation set up by the worms acting at the same time upon an innumerable multitude of primitive nerve fibres, capillary vessels, and other delicate structures.

A symptom scarcely ever wanting is early œdema of the face, where most of the muscles which become infected by the trichinæ lie close under the skin, and are not covered by fasciæ. The œdema of the lower extremities and other parts of the body, which may be observed at a later period of the disease, is due to a hydræmic condition of the blood which is gradually developed.

The symptoms caused by the parasites in the muscles themselves are not less striking. There is pain, especially if the patient attempts to extend the muscles; these are rigid and swollen, and there is a feeling of great lassitude. The muscular pains are generally first perceived in the legs, and are increased by pressure and by voluntary movements. They are more considerable at the first attempt to move which is made by the patient after they have remained for some time in the same position; the movements which are afterwards made are not quite so painful. Muscles which have special functions are affected in a special manner. Thus, dyspnœa is produced by trichinous infection of the diaphragm, the intercostals, and other muscles of respiration. If the muscles of the larynx are infected, there is hoarseness and loss of voice. By trichiniasis of the tongue and the muscles of mastication and deglutition, the processes of speaking, masticating, swallowing, are impeded or rendered impossible. In cases of extreme severity, the muscular irritation is so great that the patients are quite unable to move, just as in cases of rheumatic fever—with this difference, that the joints do not suffer. The extremities are, as it were, transfixed in a half-flexed position. The fever soon becomes of a more asthenic character; the temperature rises to 104°; profuse perspiration sets in; miliary vesicles appear on the surface; the mind wanders; meteorism, diarrhœa, decubitus, hæmoptœ, lobular pneumonia, and effusions in the pleura may be observed; and at last death ensues with all symptoms of excessive prostration and irritation of the nervous centres. A fatal issue may take place five days after the commencement of the illness, but it mostly occurs during the third or fourth week. The average duration of the second stage of trichiniasis is from three to six weeks. If pregnant women are infected, abortion takes place.

The third stage, or chronic trichiniasis, commences as soon as the parasites have taken up their permanent abode in the substance of the muscles, and have begun to coil themselves up and to be encysted. The function of the muscles still remains disturbed for some time, and they may be weak and stiff for months. In a few cases, baldness of the head, desquamation of the skin, and painful furunculæ have been observed to follow.

I have no hesitation in expressing my belief that, on reading the foregoing account of the symptoms of trichina disease, many Practitioners in this country will recollect cases of this kind having at one time or another fallen under their notice, and which, in the absence of sufficient information on the subject, have most likely been set down as forms of typhoid fever.

Trichiniasis in man is probably always caused by eating raw or underdone pork, ham, and sausages. Beef, mutton, poultry, game, etc., never contain trichinæ, and those other

animals in which the parasites have been found (viz., the cat, mole, crow, hawk, and jackdaw), are scarcely ever eaten. In Paris, however, where cat's flesh is notoriously served up in certain *cabarets*, men may become infected with trichinæ by eating of such ragouts.

The wisdom of Moses in forbidding the Jews to eat pork (a) has thus received an additional striking proof. It may be that Moses forbade pork to be eaten because pigs take unclean and putrid food; but it is just as possible that he may have done so after having observed people fall ill and die after eating pork. In the less complicated conditions of social life at that time, observations on the effects of poisonous meat could be made with far greater facility than is possible now, and if a large number of persons fell ill or died after partaking of meat from one slaughtered animal, the cause of the accident must needs have struck an accurate observer.

Some years ago, when it was shown that tapeworm in man is caused by eating pork containing cysticerci, it was believed that Moses' law regarding pork was made for the prevention of tapeworm; but tapeworm seldom causes considerable illness: it is not really dangerous to life; and if pork was forbidden from a knowledge that it produced disease, it is far more probable that the law was meant for preventing that disease which is now known to us as trichiniasis.

The diagnosis of trichiniasis may, in somewhat severe cases, be easily made during life. The course and the symptoms of the distemper are, in fact, very peculiar. In mild cases there are gastric disturbances, pain in the muscles, and œdema of the face. In severe cases there are, besides these symptoms, swellings of the muscles, fever of a typhoid character, but no tumour of the spleen. There is, moreover, dyspnœa and hoarseness. If, under such circumstances, the patient admits of having a short time ago eaten raw or underdone pork, ham, or sausages, and especially if several patients are affected at the same time in the same house, or in the same neighbourhood, there is every probability of the disease being trichiniasis. Absolute certainty, however, is only to be acquired by finding trichinæ either in the evacuations or in the muscular tissue.

To show trichinæ in the evacuations is very troublesome to the Physician, and to show them in muscular tissue not very pleasant to the patient. If the fæces are not fluid water must

FIG. 9.

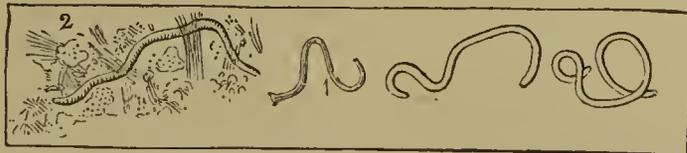

FIG. 9.—Intestinal trichinæ from a young dog, five days after having been fed with trichinous meat. 1 is a male trichina, with cones at its posterior extremity; the others are females. At 2 the parasite is surrounded with fæcal matter.

be added to them, and the matter is then brought, drop by drop, upon the object-glass. With a magnifying power of 20 m.d., we may be able to find intestinal trichinæ, but the examination takes several hours to accomplish, and often yields negative results, although the patient is infected with the parasites.

For showing the presence of trichinæ in muscles, it is necessary (unless there should be, by chance, an open wound in which a muscle is laid bare) to take out a small piece of any

muscle and examine it. The operation may be done by Middeldorpf's harpoon, or a small incision may be made at the lower portion of the deltoid, where issues are usually made, and a piece of flesh the size of a lentil may be cut out by Cooper's scissors. If there are any muscular swellings, it is best to take the specimen from the muscles thus affected, and examine it with the microscope. Such a proceeding is by no means dangerous, and quite justifiable. If the disease is severe, the first specimen taken generally contains trichinæ. If certain muscles are

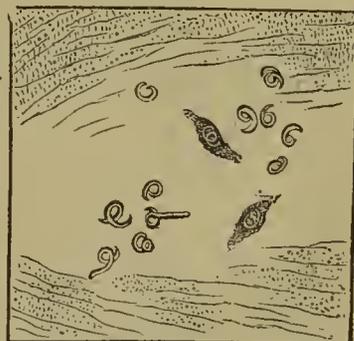

FIG. 10.—Magnifying power, 19. A piece of muscle rendered transparent by the addition of acetic acid. There are two encysted trichinæ in the middle; the others are free.

(a) Leviticus, xi. 7-8:—"And the swine, though he divide the hoof and be cloven-footed, yet he cheweth not the cud; he is unclean to you. Of their flesh shall ye not eat, and their carcase shall ye not touch." The same is repeated, Deuteronomy xiv. 8.

more swollen than others, it is best to take specimens from the former. Where the cysts are calcified, no magnifying power is necessary. If the trichinæ are encysted, but no earthy deposit has as yet taken place, an ordinary magnifying-glass shows them in a distinct manner, especially if diluted hydrochloric acid is added.

The only formations which may possibly be confounded with trichina-cysts are the so-called Rainey's corpuscles,

FIG. 11.

which are sometimes found in the muscular fibres of the pig, and have received their name from having been first described by Mr. Rainey. They consist of a dark granular mass, enclosed by a transparent ovoid cyst, and are found imbedded in the interior of primitive muscular fibres, which are thereby somewhat dilated. The nature and mode of development of these formations are at present unknown. It is only certain that they have nothing to do with trichinæ, and they never enclose a worm; so that an accurate observer will always be able to distinguish them from trichina-cysts. Rainey's corpuscles are never found in human muscles.

The prognosis of a case of trichiniasis depends upon the circumstance whether the person affected has eaten few or many trichinæ. Where few have been eaten, the patients may feel unwell, but they soon recover. Even in cases of medium severity a fatal issue is rare, and after an illness of a few weeks convalescence sets in. Cases of great severity either end fatally, or the patients very slowly recover, after having been dangerously ill for weeks, and they remain weak and out of health for months afterwards. Of special importance for prognosis are the muscular pains and the fever; if both are severe, the prognosis is mala, or at least dubia.

As regards the treatment of trichiniasis, the results have, up to the present time, not been very satisfactory. Many patients have died in spite of treatment, and those who recovered would probably have done so without special treatment. Professor Friedreich has recommended using the picronitrate of potash, which, in a case he had under his care, appeared to exercise a most beneficial action; but further experiments by Dr. Fiedler and Professor Mosler have shown that this substance, even if given in large doses, kills neither the intestinal nor the muscular trichinæ, nor does it prevent the immigration of the parasites into the substance of the muscles; so that a further use of that remedy in trichiniasis does not appear justifiable. On the other hand, Professor Mosler(b) has found, as the result of careful experiments, that benzine (or benzole) is a poison for trichina. Benzine was discovered by Faraday, in 1825, and is represented by the formula

It rapidly kills lice and other vermin, and seems to have the same effect upon cysticercus and trichina. But benzine is also a powerful poison for large animals and man, and, if used in the treatment of trichiniasis, should be employed with special caution. A rabbit can take ten grains, a pig thirty grains, and a cow half an ounce of benzine per diem without its producing alarming symptoms of poisoning. From thirty to forty drops may be given to an adult man *pro dosi*, and, as the smell and taste of this substance are peculiarly nauseous, Professor Mosler has recommended it to be given in the form of "capsules gélatineuses," each capsule to contain ten drops, and one to be taken every two hours. Up to the present time benzine has not yet been employed in trichiniasis in man, but its use in the more severe forms of this affection seems justifiable. It would, however, be most desirable to discover an efficacious drug which is less noxious to the system than benzine.

In most cases a symptomatic treatment must be resorted to. If the Practitioner should be called in soon after the taking of trichinous or merely suspicious meat, an emetic should be given at once. At a later period, neither emetics nor purgatives seem to do much good. The experiments of Fiedler, which have just been published,(c) have, indeed, shown that even large doses of purgatives have not the least influence in removing trichinæ from the intestinal canal, nor to prevent the

development of the embryo and their immigration into the muscles. For the muscular pains, tepid fomentations, or frictions with oil of hyoseyamus are useful, or the patients may be subjected to a moderate cold-water cure. If the fever is very severe, mineral acids and digitalis are the best remedies, and care must be taken to regularly empty the bowels and the bladder. In profuse perspiration and miliary vesicles, fomentations with vinegar may be employed. If œdema is troublesome, diuretics, especially ol. junip., should be given, which may be done the more unhesitatingly as the kidneys do not suffer in such cases. Albumen has never been found in the urine, even if there was considerable dropsy. At the same time the vital powers must be sustained by a free administration of milk, beef-tea, and, if necessary, alcohol. Animals infected by trichinæ seem to die chiefly in consequence of being, by the painful affection of the muscles of mastication and deglutition, prevented from taking food; and they live much longer if milk and other nutritious fluids are injected into the stomach. The same holds good for man, especially in cases where high fever exhausts the frame. To most patients, the idea "of being eaten alive by worms" is so revolting that it is better to keep them in ignorance of the nature of the complaint.

In the third stage of the affection the patient should be treated according to general rules. If anæmia or hydræmia are present, tonics, especially iron, should be freely given; if there is stiffness, weakness, and atrophy of the muscles, tepid baths and Faradisation are to be employed.

The old adage that *prevention is better than cure* was never more applicable than to trichiniasis. This disease would, in fact, never occur in the human species, were pork eschewed. This being one of the cheapest meats, it is not likely that its use will be discontinued by the poor, but they might at least be taught the necessity of taking every precaution against the ill effects which may ensue. It has been shown that if pork, ham, or sausages are thoroughly well roasted, boiled, smoked, or salted, all trichinæ which may be present are destroyed. A temperature at which albumen coagulates (144° to 164° F.) kills the parasites; but it is often only the external layers of the joint or the cutlet which undergo this or a greater heat, and the inner fibres generally remain underdone. In these latter, therefore, the blood and albumen are not coagulated; they are soft and of a pinkish hue, and may contain a large number of live trichinæ. On the other hand, it has been shown by the experiments of Küchenmeister(d) that if pork is salted for a certain length of time, or if sausages are subjected to hot smoke for twenty-four hours, the trichinæ are killed. Cold smoking does not kill them unless it is continued for a long period; but when sausages which have been subjected to cold smoking are kept for a long time, the life of the parasites generally seems to be extinct.

It now only remains to be seen what measures of precaution should be adopted by communities against trichinous infection. The following points are the most important for this consideration:—1st. Great cleanliness of the stables in which pigs are kept should be observed, and as pigs can only become infected by eating meat or fæces containing trichinæ, they should as far as possible be prevented from taking suspicious animal substances. 2nd. A microscopical examination of pork should be made before it is offered for sale, either by Medical men, Veterinary Surgeons, or naturalists, who should be paid for their services either by the pork-butchers or by the municipal government. In large towns, each district should have a special slaughter-house for pigs, to which a microscopist should be attached, and no pork should be allowed to pass out without a certificate of its being uninfected. A full examination of one animal may be made in ten minutes by a good observer. In small country places curates, schoolmasters, or others conversant with the use of the microscope, might undertake the office.

Pork-butchers should not oppose such examinations, as it is they who are in the first instance exposed to the danger. In almost all epidemics which have occurred in Germany, pork-butchers, their wives, children, and servants were the first to suffer. In several German towns pork-butchers therefore employ competent observers to examine all animals before offering them for sale; and the meat is therefore guaranteed pure to the public.

In concluding this paper, I have much pleasure in stating that the Medical Department of the Privy Council are fully alive to the importance of the subject, and are taking it into their serious consideration.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

GUY'S HOSPITAL.

ANEURISM OF THE ASCENDING AORTA, COMMUNICATING WITH THE SUPERIOR VENA CAVA—ERYSIPELAS—DEATH.

(Under the care of Dr. GULL.)

[Reported by Mr. GEORGE EASTES.]

THE following case is of great interest, especially as, about ten days before death, Dr. Gull stated, as his opinion, that the patient had an abnormal venous communication in the chest, whether aneurismal or not he could not say:—

John M., aged 34, Arsenal labourer, residing at Woolwich, was admitted into Stephen ward, under the care of Dr. Pavy, on February 5; transferred to the clinical ward, to Dr. Gull's care, on February 15.

February 15.—He is a well-nourished man, of middle height, and has a good family history. He was formerly a private in the 89th Regiment during the Crimean war; several of his toes were then frozen off, many other men being frost-bitten at the same time. Whilst in the Crimea he began to suffer from a cough and dyspnoea, with which he has ever since been afflicted, especially during the winter months. He has laboured in the Arsenal for six and a-half years, but found that hard work increased the severity of the above symptoms. About five weeks ago his face began to swell, and became of a purplish hue. His neck grew puffy, then the right arm, and subsequently the left, slightly. The dyspnoea became much worse; he obtained a cough-mixture from a chemist, and then came to the Hospital for advice. For the last ten days he has been under the care of Dr. Pavy; during that time venesection has been performed on two separate occasions, to the extent altogether of thirty-two ounces. The dyspnoea has been considerably relieved, and the congestion about the head and neck slightly so.

At present the appearance of the patient, when stripped, is very striking: the head, neck, thorax, and arms seem to belong to a full-bloated man; while the abdomen and lower extremities seem to be parts of another individual, for they are not gorged with blood, and are of the normal colour and dimensions. The lips and cheeks have a purplish tinge, and are very puffy; the colour disappears upon pressure. The veins of the skin of the thorax are gorged, giving the skin a mottled appearance, which extends from the clavicles as low as to a line drawn horizontally round the body on a level with the apex of the ensiform cartilage. Below this there is no mottled appearance; but the large veins are full, and upon putting a piece of tape round the centre of the abdomen the superficial abdominal veins fill from above. The skin of the lower extremities is normal. The saphenous veins do not show through the skin, and the legs are not swollen. On inspiration the upper ribs on the right side rise very well, while the lower ribs fall in slightly; on the left side this falling in of the lower ribs is a little more marked. A vibratile thrill synchronous with the second sound of the heart is perceptible to the eye over the right side of the chest; it is made more evident by causing a feather to adhere perpendicularly to each side of the chest; that on the right is the most moved. The percussion note is everywhere normal, except that the cardiac dulness in the recumbent position is a little too low. At the apex the first sound of the heart cannot well be made out; the second sound is clear. No murmurs with the cardiac sounds. All over the ascending portion and middle of the arch of the aorta a soft whizzing murmur is very distinct. At the commencement of the arch it is diastolic. Upon moving the stethoscope upwards, the murmur is found to be both diastolic and systolic, but more diastolic. Over the third right costal cartilage the greatest sound is heard. The character of the whiz is venous; it is, in fact, a continuous churning sound. Dr. Gull remarks that it resembles that heard over the thyroid gland when all the vessels are enlarged. There is no sound in the right side of the neck. Anteriorly there is bronchial breathing at the base of the right lung; otherwise the pulmonary sounds are normal. Posteriorly, at both apices the respiration is natural; at each base there is coarse crepitation. At the root of the lungs respiration is slightly harsh. He suffers much from a short,

sharp, reedy cough, and his face and neck become much congested at each attack. Sputa mostly frothy and colourless, but mixed with a little yellowish matter. He generally experiences great difficulty in raising the phlegm from the chest. The radial pulse is small, but regular in rhythm, the right being less than the left; 108 beats per minute; respirations, 33. No nausea, nor vomiting, nor difficulty in deglutition. He experienced a sense of tightness about the chest and arms when first admitted; that is now relieved. Has never had a fit. Urine clear, non-albuminous, sp. gr. 1020. Ordered—Acid nit. dil., ℥x.; tinct. aurantii, ℥xx.; syrupi simplicis, ℥j.; ex aqua, ter die sumend. Bleeding from the arm to twelve ounces. Middle diet and two eggs.

21st.—He has continued about the same since the last report till yesterday, when the thermometer stood below 32°F. the whole day. In the evening I found him suffering much from dyspnoea, and coughing badly. Pulse, 120; respiration, 42 per minute. Ordered, sp. æth. s. co., ℥xx.; æth. tinct. lobel. inf., ℥xv.; ex aquæ. camph., ℥iss., 6tis horis sumend. He has passed an indifferent night. Pulse, 128; respiration, 42. Under the right axilla there is a mottled redness of skin, which is hot; inflammation of the obstructed veins. Ordered, julep ammoniæ, ℥j. c.; æth. chlor., ℥v.; liq. opii. sed. (Battley), ℥ij., 4tis horis sumend.; brandy, 3 ozs., and arrowroot. 9 p.m.—Pulse, 140; respiration, 52. Great tenderness in right axilla.

22nd.—Pain in axilla worse; the inflammation spreading slowly in all directions.

23rd.—Inflammation still spreading. His neck is less swollen, and the carotid artery can now for the first time be felt beating on the right side; urine clear, decidedly albuminous, sp. gr. 1025; bowels not relieved for three days. Pulse, 118, small and thready; respiration, 42. Ordered, pulv. jalapæ eo., gr. xl., statim sumend.

29th.—Since the last report the inflammation spread down the right arm and to the trunk; next, the left axilla and shoulder assumed an erysipelatous blush; and, finally, the skin over the left side of the abdomen became inflamed. Flour was sprinkled over the diseased parts. The cough became at last quite incessant, and after severe suffering he died yesterday at 8 p.m. The same venous roaring sound continued in the chest to the last.

This afternoon an examination of the body was made by Dr. Wilks, eighteen hours after death; the following is his report:—

Head, not examined. On opening the chest, the anterior edges of the lungs were seen to overlap the heart; and on raising the right there was seen to be some recent pleurisy on its under part. The lungs filled the chest, being full of air. The tubes contained much mucus. On opening the pericardium a few flakes of lymph were seen floating in an opaque fluid, showing a recent pericarditis. The aorta was seen bulging forward on its right side, and it was here that the lung was adherent. On removal this protrusion was found to be an aneurism of about the size of the closed fist. It occupied the right side and posterior wall of the ascending aorta; commencing about an inch above the valves, it reached the innominate artery. This description applies to the opening into the sac; the latter projected both higher and lower than this, being seen, indeed, in the pericardium. The sac contained a recent clot, but no ante-mortem fibrine. The walls remarkably thin, and at one spot ready to give way into the pericardium. Passing along the front of the aneurism was the superior vena cava, with the brachio-cephalic at the upper part. On opening the vena cava a perforation was seen at its back part, just as it entered the auricle. This entered the aneurismal sac, so there was a free communication between the aorta and vein. The opening was about the size of an ordinary lead pencil; its edges were smooth, and everted towards the vein. The opening was evidently not very recent. Aorta elsewhere covered with atheroma. Heart natural size.

OBSTRUCTION TO RESPIRATION FROM THE LODGMENT OF A DATE-STONE IN THE RIGHT BRONCHUS—TRACHEOTOMY—DEATH—AUTOPSY.

(Under the care of Mr. BRYANT.)

A girl, 2½ years old, was admitted March 22, and died on the 25th. She was supposed to have swallowed a date-stone, or, rather, to have drawn it into the air passages. The symptoms at first did not appear urgent, but soon the breathing became difficult, although not in paroxysms. The child was raised and shaken, to see if the foreign body could be dislodged, but with no benefit. As the dyspnoea increased,

tracheotomy was performed by Mr. Bryant, but still with no result; the breathing became worse until death. There were no violent fits of coughing or choking from the beginning.

The post-mortem appearances, as gathered from Dr. Wilks, were as follows:—A date stone was found fixed in the commencement of the right bronchus. It had passed into about its middle, but from its size could get no further, and projected across to the opposite bronchus, or rather to the trachea just above it. Judging from the ulceration in the mucous membrane, it must have been fixed there the whole of the time. In the left bronchus and on the opposite side of the trachea was a depressed spot in the mucous membrane, exactly corresponding with the form and position of the date-stone. It was clear that, as it lay across the trachea, it had partially closed the main passage, and from its shape not corresponding to that of the bronchus that air had no doubt entered the right lung. Probably the great impediment to its exit was the upper point of the date-stone being fixed firmly against the trachea. The tubes were inflamed throughout, and covered with secretion. The lungs were more or less consolidated throughout by lobular inflammation, small grey spots of hepatisation being scattered through both organs, especially in the upper lobes.

MIDDLESEX HOSPITAL.

NECROSIS OF THE PARIETAL BONE — HEMIPLEGIA—TREPHEINING WITH RELIEF.

(Under the care of Mr. DE MORGAN.)

THIS case is an example of partial paralysis following injury to the head. The paralysis was on the same side as the most obvious disease, but we must remember that there was pain also on the other side, and from disease on that side we should, reasoning anatomically, explain the production of the hemiplegia. But in some cases in which paralysis has occurred from lesion on the same side of the brain the theory of reflex action has been called in to account for the paralysis.

A case like this, with the exception that the disease was much more extensive, and also on the side opposite to the hemiplegia, we saw, under the care of Mr. Paget, a few weeks ago. A very interesting case of hemiplegia in a monkey following injury to the head (on the opposite side) is recorded by Dr. Haughton in a recent number of the *Dublin Medical Press*.

Not unfrequently after injuries to the head, instead of paralysis, we have unilateral epileptiform convulsions, and, indeed, generally there is both, the epileptiform seizures being followed by paralysis, more or less permanent, in the arm and leg convulsed. We may, perhaps, make the statement wider, and say that epilepsy, or epileptiform seizures from organic disease, are generally unilateral. Hence, epilepsy dependent on syphilis frequently affects one side only, as syphilis often produces deposits in the pia-mater over one hemisphere, thus imitating the effects of injury to one side of the head.

For the following notes of the case we are indebted to Mr. Ferguson:—

Henry McB., aged 28, was admitted on October 6, 1863, under the care of Mr. De Morgan. He was a soldier for eight and a-half years, and received a blow on the forehead at the battle of Inkermann, but continued in action. Seven years ago he had syphilis—chancre with suppurating bubo—of which he got well without treatment. Two years after he felt considerable pain on both sides of the head, and a swelling appeared over the left parietal bone of the size of a walnut, which was very painful. He was admitted into the Hospital and was under the care of Mr. Hulke for five weeks, when he left very much improved. He got worse again, and in sixteen months the skin gave way, and he was readmitted some weeks afterwards.

October 6.—There is now a piece of dead honeycombed bone exposed, about as large as a shilling. A probe can be passed beneath the skin, the ulcerated edges of which are extremely sensitive, to the extent of about an inch and a-half, throughout which space the bone is exposed and rough. There is a large discharge of very offensive matter, which comes partly from beneath the skin, partly through irregular perforation in the bone. The matter coming up through the bone is forced out, mixed with air, by the action of the vessels within, which communicate their pulsation to it. But sometimes there is a cessation of all oozing out of matter, and no pulsation can be seen; then on any momentary excitement, as on his being suddenly spoken to, or on his stooping quickly, the matter and

air will well up again, and again gradually subside. His chief pain, however, is over the right orbit, and this he says he has felt ever since the blow at Inkermann. It has become more severe since the swelling came on the left side. The pain is always worse at night.

Towards the beginning of December his health became much impaired, and he began to complain of sickness, and sometimes vomited after food. He had severe pains down the left side of the head, and shooting across the forehead, which were worse when he was up. On standing he became dizzy. The pupils were slightly dilated and sluggish; there was an increase of discharge. These symptoms were relieved for a time by purging and blistering to the neck, but they recurred frequently with more or less severity. On January 20 he had severe shooting pain over the forehead, giddiness, and partial loss of vision, with intolerance of light; the pupils were contracted, and not very moveable, but there was no sickness. The blister again relieved him.

On February 1 it was found that for some hours there was marked loss of power in the left arm and leg. For a short time there was loss of temperature in these parts, but afterwards the temperature rose from two to three degrees above that of the opposite side, and there was considerable hyperæsthesia. For a time these symptoms passed off, but there was occasional slight return. The bone during all this time remained quite firm, and Mr. De Morgan was desirous not to interfere with it if it could be helped. There was a question whether the symptoms depended on the existence of the necrosis on the left side, as he complained continually of pain on the right side of the head, and the paralytic symptoms attacked the left side; but, as nervous symptoms were gradually creeping on, and assuming more serious forms, he determined to trephine, and so to get a perfectly free exit for the pus.

The operation was done on February 15. A medium-sized trephine was applied over the exposed part of the bone, a piece of it removed, and the internal edges pared down. A probe could be passed freely between the bone and dura mater for about two inches around the upper part of the opening. A free incision was made through the scalp over the highest part at which it was detached, and the bone under this part was found perforated and honeycombed just as the exposed portion had been.

The nervous irritation was at once relieved by the operation; the man slept better on the night following it than he had done for months previously. He has since rapidly regained strength and flesh. There is still free discharge of matter, but it is of a more healthy character, and comes principally from between the scalp and the bone. The bone remains still immovable, but the surface of the dura mater and the edges of the ulcerated skin are healthy in character.

CASE OF STRANGULATED CRURAL HERNIA—OPERATION—SLOUGHING AND EXFOLIATION OF SAC—PURULENT ŒDEMA OF THE CELLULAR TISSUE BETWEEN THE ADDUCTOR MUSCLES—DEATH.

(Under the care of Mr. HULKE.)

A charwoman, aged 62, was admitted into Bird Ward, September 14, at night, with a strangulated crural rupture. The symptoms were very urgent, and had lasted three days, during which she had taken several violent purges. She thought her rupture quite a recent thing, but its oblong figure, its extension outwards along the groin, and a certain knobiness in its outer end, such as thickened omentum might form, favoured the suspicion that it was of much older date.

The taxis under chloroform failing, the rupture was operated on by a limited straight incision at its inner side. It was necessary to open the sac and divide its neck. A small knuckle of deeply congested bowel was returned, and a piece of pelley omentum, weighing, perhaps 5j., scarcely congested, was left in consequence of its extensive adhesion to the sac. A very copious loose stool was soon passed. The wound suppurred. Her strength declined, and she died on October 9, twenty-four days after the operation.

At the post-mortem examination, the sac was found necrosed and loose at the bottom of the wound. The omentum which had been left in it was congested and infiltrated with pus. The pubic portion of the fascia lata behind the sac had disappeared, the exposed surface of the pectineus was sloughy, and this muscle with the adductors and the intermuscular cellular tissue were infiltrated with purulent serum

as low as the middle of thigh. The skin over these parts had a perfectly natural appearance. The knuckle of bowel which had been strangulated adhered to the abdominal walls near the crural ring. It was dark red, but not softened or ulcerated.

**VERY LARGE STRANGULATED SCROTAL RUPTURE
—OPERATION—RECOVERY.**

(Under the care of Mr. HULKE.)

A strong, hearty labourer, aged 40, was admitted into Clayton Ward, December 23, 1863, with a strangulated hernia in the right side of the scrotum, measuring eighteen inches round, and eight and a-half inches in its long axis. He had been ruptured seven or eight years, during which he had occasionally, but not lately, worn a truss. The rupture had hitherto been completely reducible, and he was confident that on the previous day the sac was quite empty. Strangulation had occurred at nine o'clock on the morning of his admission. Attempts to reduce the rupture during faintness in the hot bath, and under chloroform, having failed, Mr. Hulke operated at 3.30 o'clock p.m., making a small incision in the axis of the swelling, over the external ring. It was necessary to open the sac, which was as thin as tissue paper, to a limited extent before its contents—a large quantity of small intestine—could be returned. The wound granulated, and had closed soundly by January 5.

On the 7th, his bowels not having acted since the operation, and his belly feeling a little uneasy, a castor-oil enema was ordered. This produced several copious stools, the belly became soft. His food was changed from slops to ordinary food and porter, and he left the Hospital on the 15th, three weeks after the operation.

In some remarks to the students on this case, Mr. Hulke deprecated the injurious practice of giving purgatives soon after hernia operations, where the bowels do not spontaneously act. Here fifteen days had passed without a stool, and in some cases we might wait longer than this without anxiety for the bowel to resume its action.

**OBSTINATE URETHRAL STRICTURE OF FOUR
YEARS' DURATION TREATED WITH HOLT'S
DILATOR.**

(Under the care of Mr. HULKE.)

A pale, dyspeptic, hypochondriacal tailor, aged 37, came to the Hospital last spring with stricture of the urethra of four years' date, and chronic catarrh of the bladder. The stricture had been preceded by a neglected gonorrhœa. A No. 1 silver catheter was with difficulty introduced into the bladder. After three months' patient trial, No. 4 only had been reached, and the contractility of the stricture was so great that on several occasions on the third or fourth day after No. 4 had been passed, No. 1 and 2 only would go through. Under these circumstances, Mr. Hulke split the stricture with Holt's dilator, and immediately passed No. 10 catheter easily. This was followed by a rigor. The catheter was passed at intervals of two or three days. He was then taught to use it himself, and he now, February, 1864, micturates freely, and introduces his catheter once a week to secure himself against a return of the stricture.

ACADÉMIE DE MÉDECINE.—The election into the section of therapeutics to fill the vacancy left by the death of M. Moquin-Tandon has terminated in favour of M. Pidoux, who polled forty-four votes, to M. Béhier's fourteen and M. Gubler's twelve.

THE PARIS FACULTY OF MEDICINE.—The summer courses commenced on April 4, and are thus disposed, each Professor lecturing three times a week:—Medical Natural History, MM. Baillou; Physiology, Longet; Midwifery and Diseases of Women and Children, Pajot; Therapeutics and Materia Medica, Grisolle; Legal Medicine, Tardieu; Pharmacology, Regnaud; Surgical Pathology, Gosselin; Pathological Anatomy, Laboulbère for Cuveilhier; Medical Pathology, Monneret; Hygiene, Bouchardat. Clinical Lectures are also to be delivered on Medicine by MM. Bouillaud, Piorry, and Perrot, in place of Rostan and Trousseau; on Surgery, by MM. Jobert, Laugier, Velpeau, and Nélaton; and on Midwifery, by M. Depaul. Supplementary Clinical Lectures are to be delivered by M. Hardy on Diseases of the Skin, by M. Roger on Diseases of Children, and by M. Follin on Diseases of the Eye.

SATURDAY, APRIL 9.

A LIFE OF PHILANTHROPY.(a)

A NOTICE of the memoirs of the late Dr. Andrew Reed would some time since have appeared in these columns from the pen of a distinguished contributor who was associated with Dr. Reed in more than one of his philanthropic enterprises, but that his continued indisposition has prevented him from carrying out his wish. Though not a Medical man, Dr. Reed took so deep and practical an interest in the well-being and advancement of various classes of sufferers, more particularly of two,—the idiot and the incurable—for whom, when he established the institutions at Earlswood, Colchester, and Putney, no systematic relief had been attempted in this country—that we cannot but regard him as one of the most valuable of those allies who, independently of their own Professional engagements, work also with us in the promotion of the great object of our lives.

Dr. Reed was born in London in the year 1787. On the completion of his education, he was for a time engaged in his father's business of watch-making, but his great natural ability and literary tastes soon prompted him to leave this for a wider and more congenial sphere; and such a sphere the deep religious feelings which he possessed from a very early age led him to seek in the ministry of the denomination to which he belonged. After the usual collegiate course, he became the minister of a large congregation, assembling in Wycliffe Chapel, Stepney, and retained this pastorate for fifty years with remarkable success. Not long, however, had he been engaged in his ministerial work, before the spirit of philanthropy which appeared to imbue his whole nature urged him to enter upon the first of those efforts for the benefit of the orphan and the afflicted, any one of which would have sufficed to perpetuate his memory, but which in the aggregate represent an amount of untiring benevolence which places him in the foremost rank of the benefactors of mankind. In the summer of 1813 he instituted the London Orphan Asylum, and after surmounting a host of difficulties he had the satisfaction of witnessing the completion of the noble building the charity now occupies at Clapton in 1825, and its establishment upon its present secure basis. In 1827 he drew the attention of the public to the necessities of infant orphans under seven years of age, for whom no society had at that time made any provision. In this new undertaking he again had many difficulties to contend with, but his perseverance and energy triumphed; he enlisted the interest and sympathy of Royalty, the Queen became the patron, and the Prince Consort laid the foundation-stone of the Asylum at Wanstead: the friends who had helped him before rallied around him again, and the permanency and success of the

(a) Memoirs of the Life and Philanthropic Labours of Andrew Reed, D.D. Edited by his sons, Andrew Reed, B.A., and Charles Reed, F.S.A. Second edition. London: Strahan and Co.

Infant Orphan Asylum became fully assured. In the course of time, however, having felt obliged to withdraw from active participation in the management of these asylums, from a conviction that charity in its bounty should be wholly catholic, and unrestrained by sectarian limits, yet his earnest benevolence would not allow him rest until he had inaugurated a third asylum for the orphan, now known as the Asylum for Fatherless Children. This asylum he instituted in the year 1844, designing that it should receive the fatherless from their birth until fourteen years old, irrespective of religious connexion, and without the imposition of any denominational test. Its first home was at Stamford-hill, from whence, in 1854, it was removed to an admirably-arranged and handsome building erected on a rising ground near Croydon; the name of Reedham, in commemoration of its founder, being given to the estate by the Board of Management.

In 1847, Dr. Reed, having previously had his attention called to the neglected condition of the idiot in this country, placed himself in correspondence with different Continental Medical men respecting their modes of treatment of idiocy, and the success obtained. Dr. Conolly's interesting report of a visit to the Bicêtre, and a published letter from Mr. Gervis, of Tiverton, calling attention to it, came also before Dr. Reed's notice, and enlisted still more completely his interest in this unhappy class. He visited Dr. Guggenbühl's establishment in Switzerland, the Abendberg, and other similar Continental institutions, and, arriving at the conviction that the idiot is capable of improvement, and of a certain amount of education, he, in the autumn of the same year, inaugurated, by a public meeting, the formation of an Asylum for Idiots. Sir James Clark, Sir John Forbes, Dr. Sutherland, Dr. Little, and many other eminent members of our Profession took an active share with Dr. Reed in the preparation of plans for the care and treatment of the inmates of the asylum, and Dr. Conolly, on a vacancy occurring in the honorary secretaryship, in 1851, accepted (and still holds) that position. Dr. Conolly, with characteristic generosity, speaking in the presence of the Vice-Chancellor of the University of Cambridge, said, "It may truly be said that the attempt now making in this country in favour of the poor idiot is wholly to be ascribed to Dr. Andrew Reed." The Asylum, at first, was placed at Highgate; a branch was subsequently established at Essex Hall, Colchester; finally, in 1855, the inmates of both homes were removed to the noble building at Earlswood. In addition, however, to this great central Institution, Dr. Reed was most anxious that Essex Hall should still be retained as an asylum for the idiots of the Eastern counties. In this wish he was much opposed by many who thought that the two kindred institutions would each interfere with the needed support of the other; but in the end he, as usual, obtained his wish, and the Essex Hall Asylum still flourishes, while other similar local institutions are rising into being. In reference to this event, Sir John Forbes said of Dr. Reed "that the more they knew him the more they would say that he was the most extraordinary man in this city—a man of that great amount of energy capable of sustaining himself against the most difficult course possible, and of sustaining an Institution like the present against any odds." "When Dr. Reed," say his able biographers, "sent forth his appeal on behalf of the neglected idiot, he did so in the belief that this was the most forlorn of all the subjects of affliction, and the only class of sufferers not hitherto cared for by the benevolent institutions of the land. But while thus engaged in searching out the cause which he knew not, there occurred to him another which at once laid fast hold of his tenderest sympathies, and implanted in his mind a deep conviction that when the fitting time should arrive one more work of mercy remained to be accomplished by him. This last object of compassion he found in that extremity of woe which falls to the lot of one who, after long and fruitless attempts at cure, is discharged from the great Hospitals of the land as incurable, and as such disqualified for the duties of life."

In his proposal to establish a Hospital for the permanent care of the incurable whose former station in life unfitted them for the workhouse, but who, "either by disease, accident, or deformity, were hopelessly disqualified" for gaining a livelihood, Dr. Reed received very considerable encouragement from our Profession, always ranked by him "as second only to that of the Christian ministry." A document was signed by forty Hospital Physicians and Surgeons, testifying to the need of the Institution, expressing their approbation of the proposal, and stating that its establishment would in no way interfere with existing Hospitals. Thus certified, this last of Dr. Reed's works of philanthropy, thanks to his untiring zeal, and marvellous aptitude for winning and directing the benevolence of the public, speedily attained success, and on November 27, 1854, the first election of inmates for the Home at Carshalton took place, a crowd of applicants seeking the admission which could be granted only to a few.

"My birthday, (Dr. Reed writes)—usually spent alone in my family; but the time is short, and it seemed to me that I might consecrate it at least equally by devoting a portion of it to the first election of the poor, unhappy beings who seek to secure a last refuge in our new Home. The business of the election went off well. There were many people, and many generous givers; but the circumstances of the new Institution are very peculiar. I was strikingly reminded of the groups which must have often surrounded the blessed Saviour—the maimed, the halt, the helpless, and the crippled. Here was one completely doubled up with chronic rheumatism; another without feet, living on a sledge; another paralysed from birth, and crawling like a reptile. Well, we have espoused their cause: they are all helplessly incurable; and, if God helps us, we will help them.

"The urgent pleadings of these poor helpless ones afflict me. But it is the hopelessness of their condition that afflicts me most. The very breathlessness of their importunity seems to draw my life out of me. Poor things! to win an election is to them not only the struggle of life, but for life; and not a few sink down and perish in the hot and stormy conflict. No case can be so sad as theirs. Theirs is, after all, the extreme of woe.

"The greater the necessity, the greater the charity."

In the closing years of Dr. Reed's life, increasing weakness compelled him gradually to withdraw from actively sharing in the management of the earlier of the institutions he had founded; but his interest in all continued unabated, and in the welfare of the Royal Hospital for Incurables, the youngest offspring of his benevolent zeal, he showed a thoughtful concern almost to the last, examining, and advising on, the plans for the proposed new building to within a few days of his death. He died on February 25, 1862, aged 74, apparently more from natural decay than from any particular malady.

In reviewing the life of so remarkable a man as Dr. Reed, the ordinary terms of eulogy seem poor. He was one of the comparatively few men who, while manifesting an especial capacity in some one or two things, are yet excellent in everything. As a preacher he was characterised by a combined simplicity and earnestness of style, the effectiveness of which was evident from the constant and increasing success of his fifty years' ministry. As a public speaker, his clear and logical address, and impressive manner, never failed to powerfully influence his audience. As an author, his language was singularly refined, well chosen, and expressive, and in his appeals for the charities he founded alike forcible and touching. As a public man, he possessed an almost unique power of enlisting the interest and co-operation of others, and in his transaction of business the highest business authorities speak of him as "unrivalled." Finally, as a philanthropist, he is certainly entitled to a foremost place among his country's worthies. To have founded three asylums for the orphan, two for the idiot, and one for the incurable, constitutes a claim to the title of philanthropist which has been equalled by few. To these asylums he gave munificently of his time, his money, his influence, his thought, and his care; they were wholly the creation of his benevolent mind; fostered by the devotion of his best energies; guided by his judgment, and

maintained by his fervent and ever gratuitous advocacy. He was their strength during his life; he bequeathed to them very considerable sums at his death; and as his presence and visits used to be hailed with delight by those he so greatly benefited when alive, so will his memory never cease to be revered by his friends, and remembered with admiration and respect by all.

THE "BRITISH MEDICAL" TARTUFE.

"WHEN you have no defence, abuse the plaintiff's attorney!" Such is the Old Bailey maxim which we are sorry to see acted upon by the *British Medical Journal*. It has been our unpleasant duty to comment on the thoroughly low tradesmanlike tone which it inculcates, and which, if carried out, will most assuredly damage the social status of the Profession. We never advocated the insane idea that a Medical man shall give away his services indiscriminately; but we do say that this is no argument against giving help on an emergency. Neither do we say that the Medical Profession ought to be called on to do what "society" should do; but yet that is no reason why a poor woman should be allowed to die in childbirth; and it strikes us that if we are to preach to "society," and ask it to put its hands into its pockets, it can only be by pointing to what we ourselves do, and to the character which fortunately we have acquired for ready unselfish benevolence. The *British Medical Journal* has one answer to all arguments. It can call its opponent Tartufe, and there it stops. But our contemporary may be aware that there are characters even less respectable than Tartufe. The philosophical novelist of the last century depicted a Surgeon, a true British Medical tradesman, after our contemporary's own model. Turn to Fielding's marvellous sarcastic tale of "Joseph Andrews." He, poor fellow, had fallen by night amongst thieves, who left him naked and bleeding in a ditch, whence he was rescued by a passing stage-coachman, who brought him to the Dragon Inn, kept by Mrs. Towwouse, and then, before driving on the next stage, says Fielding, "took an opportunity to call up a Surgeon, who lived within a few doors." Meanwhile, the wounded man was put to bed by the chambermaid at the inn. "Imagining, as she afterwards said, by his being so bloody, that he must be a dead man, she ran with all speed to hasten the Surgeon, who was more than half dressed, apprehending that the coach had been overturned and some gentleman or lady hurt. As soon as the wench had informed him at his window that it was a poor foot-passenger who had been stripped of all he had and almost murdered, he chid her for disturbing him so early, slipped off his clothes again, and quietly returned to bed and to sleep." If our British Medical tradesman will carry on his research a little further, he may see in the pages of this great writer, as in a glass, what the effect of his teaching would be. Mrs. Towwouse, the landlady, might have been a student of the *British Medical Journal*. The novelist shows us the British Medical philosophy in action. Mrs. Towwouse objects to the charity which her husband was disposed to show to the poor wounded man. "My dear," said Mr. Towwouse, "this is a poor wretch." "Yes," says she, "I know it is a poor wretch; but what the devil have we to do with poor wretches?" "My dear," cries Towwouse, "this man hath been robbed of all that he hath." "Well, then," says she, "where's his money to pay his reckoning?" We wish our space allowed us to show what followed. How Parson Adams came to the Dragon, and claimed acquaintance with poor Joseph. How Betty came and "told her mistress she believed the man in bed was a greater man than they took him for, for besides the whiteness of his skin and softness of his hands, she observed a very great familiarity between the gentleman and him." Whereupon the severity of Mrs. Towwouse's countenance was abated. She said, "God forbid she should not discharge the duties of a Christian, since the poor gentleman was brought to her house. She had a natural

antipathy to vagabonds, but could pity the misfortunes of a Christian as well as another. God forbid he should want anything in my house!" We won't follow out this matter, except to say that if the British Medical teaching prevail, and brutality to the poor and servility to the rich be the inevitable rule, future novelists will have no lack of fun and sarcasm in our degraded Profession.

THE WEEK.

THE LADY AT THE "HALL."

AMONGST the successful candidates at the "Hall" last week was a young lady, whose pursuit of Medical knowledge has been carried on under obstacles invincible to one of less "masculine" energy. (We hope the adjective will be taken as a compliment.) She is said to have passed a first-rate examination. The Apothecaries' Society, by their "Act," were obliged to admit her to examination. We are by no means in favour of female Practitioners; but in this, as in many other matters, we need not trouble ourselves to prophecy, and may leave the event to time. If an unemployed young lady have the brains and money requisite for the study of physic, we think they would be better bestowed on other pursuits; but there is no chance that Miss Garrett can have many rivals of her own sex.

DR. LIVINGSTONE.

THE Medical Profession will read with sincere pleasure the following letter, which appeared in the *Times* of the 1st inst.:

"To the Editor of the *Times*."

"Sir,—By the mail from Cape Town received here on February 25, bringing news from the colony to the 21st of the previous month, a report reached this country that Dr. Livingstone had met with an untimely end on his expedition up the Zambesi. As this created great uneasiness among all those interested in the welfare of that great philanthropist and his expedition, it will, no doubt, be a satisfaction to the public to learn that I have this morning received by the *Murray*, one of the Orient line of packets from Adelaide, a letter from my son, now resident in Cape Town, dated January 29, in which he says that news had been received by Her Majesty's ship *Rapid* that Dr. Livingstone was 'all well.'

"I am, Sir, your obedient servant,
"150, Leadenhall-street, March 31." "G. THOMPSON."

GARIBALDI.

THE visit of the Italian patriot to this country is a compliment to British Surgery. It is understood that one of his main reasons for seeking our shores is that he may place himself again under the care of his old attendant, Professor Partridge, and of Mr. Fergusson. Garibaldi still suffers from great stiffness in the seat of his injury, and can only walk slowly and limpingly with the aid of a stick. The newspapers report that in a speech made to his fellow-passengers on the eve of his arrival at Southampton, he said "that he owed his life to England." We trust that he may still reap further benefit from British Medical science, and that he may leave this country in full possession of the health and vigour which he needs. He is accompanied by his Italian Medical attendant. His appearance is better known by portraits and photographs of all kinds than perhaps that of any man in Europe. The *Times'* correspondent, however, in describing him on his landing at Southampton, writes that the idea of his *physique* which many of his photographs give is incorrect:—

"In stature he is below the middle height, but his well-set frame and rather broad shoulders give him an appearance of great natural robustness and activity, from which even his lameness could not much detract. His features, when not in conversation with friends, have rather a sad aspect; but nothing can exceed the animation of their expression when speaking (especially in Italian), and there is a winning appearance of good-humour about his eyes which is not easy to be described, but which those who see it can never forget. For the rest, his portraits are like him in all but this expression,

and in the fact that the photographs convey the idea of his being an older and much taller man than he really is."

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE X.—FEBRUARY 23.

HAVING concluded the sketch of the anatomy of man, Professor Huxley passed in this lecture to a description of the structure of those animals which approach most nearly to him. These are by universal consent admitted to be the gorilla, the chimpanzee, the orang, and the gibbon. How far they resemble, and in what respects they differ from man, and which approaches nearest to him, will now be considered, the chimpanzee being taken first, because of its anatomy we have the fullest illustrations in the College Museum.

This animal, *Troglodites niger* of the zoologist, is an inhabitant of the West Coast of Africa, ranging from Sierra Leone to Congo. Trustworthy information as to its habits in its native state is scanty, but it appears to live in small families or troupes, and to be essentially arboreal in its nature, only occasionally descending to the ground. When it does so, it sometimes for a short time assumes the erect posture, but its usual position in walking is semi-erect, the body inclined, the soles of the feet flat on the ground (the outer edge brought down first), and the hands bent, so that the knuckles form the point of support for the fore-limbs. It builds a kind of nest of branches and leaves, lives entirely on vegetable food, and is, on the whole, of a timid and gentle disposition, especially when young, though the adult males can use their powerful canine teeth as weapons of offence and defence. The intelligence of the young specimens which have lived in confinement in this country has often been remarked upon.

When full-grown, the chimpanzee probably never exceeds four feet four inches in height. The proportions of its body differ widely from those of man. When erect, the middle point of the vertical height is three or four inches above the symphysis pubis, indicating the relative shortness of the lower limbs. The upper limbs, on the other hand, are so much longer than those of man that the extremities of the fingers reach below the knees, and the extreme span measures about seventy inches, the height being only fifty. The forearm is nearly equal in length to the humerus; the tibia is longer in proportion to the thigh than in man; the thigh bone and humerus are of nearly the same length. In all these proportions it will be remembered that there was a slight variation between the higher and lower races of man, and that in the latter they deviated from the normal standard in the same direction, though in an infinitely smaller degree, as now shown to be characteristic of the chimpanzee. The hand and foot are nearly of the same length, the former being, if anything, somewhat longer. The palm and the sole are remarkably narrow. The tarsus, metatarsus, and digits are of nearly equal length, the middle segment being rather the shortest. The heel is much shorter than in man. The distal segment of the tarsus rotates freely on the proximal part, being much less solidly united than in man.

Among the external features may be noticed the ears, very large, but preserving all the essential parts of the human ear, except that the antihelix is rather less marked. The nose is flat, the nostrils look downwards, and the septum between them is narrow. The thumb is very short, reaching only to the base of the first phalanx of the index finger. Perhaps the most striking character is that the great toe is greatly devaricated from the others, and partakes of that thumb-like appearance which gave rise to the name of *Quadrumanus* applied to the whole group of monkeys. The colour of the integument is a pale brown. The hair is black, abundant on the scalp, and, contrary to what obtains in man, more developed on the dorsal than the ventral surface of the body; on the arms and legs its disposition is similar to that of man, converging towards the elbow, and sweeping away from the knee-joint. There are distinct eyebrows, eyelashes, and whiskers; the

beard and moustache are exceedingly scanty and of a pale colour. The penis is altogether external and pendulous, the scrotum placed behind its root, and the mammae are pectoral.

The skeleton presents the following important characters:—The vertebral column is comparatively straight, for though it possesses all the curves observed in the human body, they are far less marked. The same holds good with the vertebro-sacral angle. The cervical vertebrae are seven in number. The dorsal and lumbar taken together are seventeen, as in man; but there is a thirteenth rib, so that they are reckoned as thirteen dorsal and four lumbar, instead of twelve dorsal and five lumbar. The spines of the cervical vertebrae, instead of diminishing in length in the middle of the series, are nearly equal, and except in the dentata are but slightly, or not at all, bifid. The last lumbar vertebra, as a general rule, unites with the sacrum and iliac bones in the adult animal; this character was met with as an anomaly in the human subject, more frequent in the Australian and African races than in Europeans. The sacrum differs greatly from that of man, in being narrower and more elongated from above downwards. The sacral and coccygeal vertebrae together are from ten to twelve in number, the upper five generally coalescing to form the sacrum. The coccygeal vertebrae continue the line of the curve of the sacrum as in man. Of the ribs seven are true, or articulate directly with the sternum, and six are false. The sternum much resembles that of man, being flat and broad. The thorax generally is longer from above downwards, and deeper from before backwards, than in man.

The skull presents in its external form some obvious and striking differences from the human skull, especially the small mass of the cranium compared with that of the face, the prominence of the supra-orbital ridges, and the great projection of the jaws. A longitudinal section shows, however, that these differences appear greater externally than within; and, as previously shown, there is among the lower races of men a tendency to approach them. The cranial capacity of the largest chimpanzee measured is $27\frac{1}{2}$ cubic inches, that of the smallest normal adult man being 55. The cerebral length to the floor of the skull (basi-cranial axis) is as 180 to 100. The occipital foramen is situated further back than in any human skull, the length in front to that behind the condyles being as 258 to 100. The plane of the occipital foramen has an upward inclination. The olfactory and the tentorial planes are still nearly horizontal. The squama occipitis is inclined upwards and backwards from the superior curved line, but this is placed higher on the occipital bone than in man. The great projection of the supra-ciliary ridge is connected with the large development of the frontal sinuses. The crista galli is small or absent. The ethmoid fossae are not deeply sunk. The orbits are very large, their roofs pushed up into the skull considerably diminish the size of the cranial cavity in this region. The ethmoid and presphenoid unite together without being covered over by the frontal; in this character man and the chimpanzee agree, and differ from others of the anthropoid apes. The upper edge of the squamosal is straight, and unites with the frontal, so that the alisphenoid does not join the parietal; this is sometimes the case also in the human subject. There is no deep fossa on the inner surface of the petrosal for the lodgment of a portion of the cerebellum. The mastoid prominence is of very different form from that of man, and there is no trace of an ossified styloid process. The middle root of the zygoma is greatly developed. The jugal arch is so much developed in proportion to the cranium that the skull is much more phænozygous than any human skull. The sutures of the cranium disappear at a comparatively early period. The jaws are larger in proportion to the cranial cavity, and project more forward than in man, so that the chimpanzee is both macrognathous and prognathous. The cranio-facial angle is about 120° . The chin is entirely wanting to the lower jaw. The anterior nasal spine, which rises up from the pre-maxillary in man, is entirely absent. The shape of the palate differs from that of man; its sides are

straight, being, if anything, wider behind. On the middle of its posterior border there is a spine projecting backwards. The sutures between the pre-maxillary and the maxillary bone does not become obliterated till the commencement of the second dentition. The nasal bones lose their distinctness very early, but as long as they remain separate are seen to be flat and broad, and rather contracted in the middle.

HUMAN HYBRIDITY.

IF sciences are to be divided into the exact and inexact, we think we may fairly place the new one of Anthropology at the bottom of the list of the latter as the *ne plus ultra* of incertitude. We find that of Man collectively, in a zoological sense, we really know nothing, and, as far as we see, we do not think we are likely to get much beyond the simple negation of knowledge. One authority tells us emphatically that Man forms a sub-class, of which he is the sole order and species. Another that he is a genus consisting of several species. A third, that, like the Apes, he forms a section of the order Primates. One philosopher denies that any two races can be successfully intermingled—for instance, that the Anglo-Saxon "species" can be thoroughly and beneficially amalgamated with the French, the Irish, or the Spaniards, and thereupon prophesies the ruin of all mixed States, such as the Americans. Another finds in the crossing of the races of old Europe the cause of the downfall of the Roman empire; whilst the next asserts that the former are all wrong, and that it is only some intermixtures which are comparatively infertile. Meanwhile, the great work of peopling the world goes on, unmindful of the disagreements of *savans*. Demand and supply, reward for labour, and the struggle for existence, have been for ages working out the very problems on which learned societies are now disputing with no apparent chance of agreement. Of course, the old-fashioned ideas of the community of origin of the human race, the oneness of the species, the universal brotherhood of mankind, still may keep their hold on the uninitiated, supported as they are by the better instincts of our nature, and acquiring strength from their relation to ethics and religion. But such traditional ideas meet with little respect from modern philosophy. People may wish that the philosophers would give them something certain in place of the opinions they so ruthlessly destroy. Science, however, recognises no such necessity. We are by no means convinced that modern *savans* would be satisfied with the dull level of a conclusion. It is so much more pleasurable to be in a condition where you can think anything, but be sure of nothing. It gives so much scope for the imagination to discover that whatever be the truth it is impossible to find it out.

Dr. Paul Broca, Secretary of the *Société d'Anthropologie* of Paris, has lately published an essay on the "Phenomena of Hybridity in the *Genus Homo*," which has been very well translated into English by Mr. C. Carter Blake, and is now circulated under the auspices of the Anthropological Society of London. The subject is one of some political as well as scientific importance; and although the author of the essay can scarcely be supposed to have satisfied himself—much less to have satisfied his scientific readers—that he has arrived at any certain and well-grounded conclusion, he deserves the credit of having written with some research and acumen. It is evident that the writer of the book has a strong bias to the polygenist theory of the origin of mankind, but although we do not agree with him in his principal deductions and statements, we willingly allow his work to be an able monograph on a highly-interesting and curious subject, and one that will well repay perusal.

The following are the conclusions at which he arrives. The first only is supported by original facts, drawn from the returns of the conscription in the different provinces of France. M. Broca's observations show that the two races—the Celtic and Kimric—have perfectly amalgamated in those districts where they have originally intermixed in about equal proportions,

and that the resulting population is physically quite equal to that descended from either of the parent stocks:—

"1. That certain intermixtures are perfectly engesic (perfectly fertile).

"2. That other intermixtures are in their results notably inferior to those of engesic hybridity.

"3. That mulattoes of the first degree, issued from the union of the Germanic (Anglo-Saxon) race with the African negroes appear inferior in fecundity and longevity to individuals of the pure races.

"4. That it is at least doubtful whether these mulattoes, in their alliances between themselves, are capable of indefinitely perpetuating their race, and that they are less prolific in their direct alliances than in their re-crossing with the parent stocks.

"5. That alliances between the Germanic races (Anglo-Saxon) with the Melanesian races (Australians and Tasmanians) are but little prolific.

"6. That the mulattoes sprung from such intercourse are too rare to have enabled us to obtain exact particulars as to their viability and fecundity.

"7. That several degrees of hybridity, which have been observed in the cross-breeds of animals of different species, seem also to occur in the various crossings of men of different races.

"8. That the lowest degree of human hybridity, in which the homœogenesis is so feeble as to render the fecundity of the first crossing uncertain, is exhibited in the most disparate crossings between one of the most elevated and the two lowest races of humanity."

We may dismiss the question of African and English hybridity, with the remark that M. Broca brings forward no new fact, all that he advances has been already urged *ad nauseam* by Nott and Gliddon, and other American writers. As it is long before most scientific men will believe that Spaniards and Englishmen are of different species, they will not allow much weight to the fact—if fact it be—that the negro race is but sparingly prolific with the English, but freely prolific with the Spaniard. With regard to the prolificacy of mulattoes between themselves, it is clear that unless they are completely separated from pure white and black populations the experiment cannot be made on a sufficiently large scale. The testimony quoted by M. Broca on this point is of too vague and unsatisfactory a character to carry conviction. In the case of the Australian savage and English, M. Broca appears to have entirely overlooked the fact, that from the aborigines of Australia not only are there, but few mulattoes produced, but also very few pure black children. The fact is, the vitality of the race seems exhausted. Centuries of scanty food, privation, and hardship seem to have sapped the vigour of the stock, and it only required the introduction of the vices of civilisation to complete its destruction. The native population of the new world, like its indigenous fauna and much of its native flora, seems destined to disappear before that of the old. In the case of the Australian savages, it does not seem difficult to account for this. The struggle for existence they maintained before the first Europeans brought grain and cattle had been too much for the race. Physically and morally, they were reduced to the lowest condition of which humanity is capable. The arrival of the European was but the last link in the chain of causes which completed their destruction.

We have before us the Government Statistical Register of Victoria from the foundation of the colony. From it we abstract the following statements, which are certified by Mr. Thomas, the appointed Guardian of Aborigines:—In 1836 the number of aboriginal natives of the Melbourne or Port Philip tribes, including the Yarra and Western Port tribes, was 350. In 1851 it was 76. From April 1, 1839, to December 31, 1849, the number of deaths amongst the natives of these tribes was 158, whilst the number of births was only 20. We suppose that M. Broca would not deny that there is a greater chance of fertility amongst the coloured population themselves, than from occasional and illicit admixture with Europeans. M. Broca scouts the idea of infanticide of hybrid children being one cause of their rarity, although it has been asserted by

Cunningham and other original observers. He, perhaps, will accept Mr. Thomas's evidence as to the way in which the full-blooded native children disappear. That gentleman appends the following note to the table from which the above figures are quoted:—"It will be apparent from this return, taken carefully from my journal and reports, that there has been no comparison of births in proportion to deaths. The Almighty only knows the cause. It would be as well to remark here that of these innocents (the twenty infants born) scarce any of them lived over the first or second months. My firm belief is, that they are made away with, as scarce-ever a death occurred while I was with the encampment; but parents, with a few others, would ramble, and invariably return, after a week or two, childless." From these facts, which cannot be disputed, we maintain that any deductions made from the rarity of hybrids in Australia are utterly valueless. The Australian *gins* do not conceive by Europeans for the same reason that they do not conceive by their own husbands. It is also entirely improbable that mulatto children, the result of illicit intercourse, should escape the fate which assuredly awaits the full-blooded Australian infants.

FROM ABROAD—SEPARATION OF THE ARM DURING THE REDUCTION OF A DISLOCATION.

THE hall of the Paris Society of Surgery was crowded the other evening in order to hear the narrative by M. Alphonse Guérin of a case, perhaps, unique in the annals of Surgery. A woman, aged 63, entered the St. Louis Hospital for a dislocation of the shoulder of three months' date, the arm being in a state of complete paralysis. The patient having been placed under chloroform, extension was made, through the medium of bands applied above the elbow and at the wrist, by four intelligent assistants. While traction was thus being accomplished gently, a noise was suddenly heard, the separated limb fell to the ground, and the opened artery freely spirted out its blood. This was compressed and tied; the projecting end of the bone was excised, and covered over by a lateral flap which had been left when the limb was torn away. On examination, the limb was found to have separated at the elbow-joint, and every tissue, muscle, bone, vessels, etc., was found from one to the other in a soft and friable condition. The muscles separated under the pressure of the finger just as would a soft coagulum of blood; and the bones were also excessively friable. Microscopical examination further exhibited complete disintegration of the various tissues. This condition of the parts sufficiently explained the occurrence, but it remained a matter of great surprise that such changes, comprising all the tissues of the limb, should have continued latent and unrevealed by any outward sign. Neither œdema or any trace of inflammation or suppuration was present; and prior to the accident nothing was present besides the ordinary signs of an old dislocation. The traction employed was but moderate, the assistants standing quite erect. M. Guérin attributes the production of the lesions to which alone the accident was due to the compression of the brachial plexus by the luxated head of the humerus, although M. Malgaigne does not admit that such compression takes place in sub-coracoid dislocation. M. Larrey considered that this case, at all events, was not without its analogies, for paralysis, and especially traumatic paralysis, sometimes tends to favour the occurrence of fracture through ramollissement of the osseous tissue. He had communicated to the Society three cases of spontaneous fracture of the femur occurring in subjects of paraplegia. M. Voillemier, while admitting the presence of lesions which account for the accident, could not attribute them to paralysis; for if this existed, how happened it that the head of the bone remained applied beneath the coracoid process, instead of rolling from one side to the other by its own weight when no longer maintained by the contraction of muscles? M. Verneuil did not consider that the bones of the limb had undergone a sufficient alteration to constitute

the essential element of the accident. This should rather be sought for in the condition of the muscles; and the employment of chloroform may have contributed to their relaxation and defective resistance. The paralysis, however, sufficiently explains the changes observed in these organs, similar change being sometimes both rapid and extensive. In the course of six weeks the fibre may lose its properties, this implying the occurrence of a fatty transformation; so that when in a dislocation which has persisted for that period, and still more when it has continued for two or three months, the existence of paralysis is proved, the Surgeon should only make attempts at reduction of a very moderate character, and continued during a short period. This case of M. Guérin should serve us as a lesson; but the most extraordinary feature about it, in M. Verneuil's opinion, is the rupture of the skin—an occurrence of which no other example is on record. M. Guérin could only refer again to the microscopical examination of the bone to prove to M. Verneuil that its structure had undergone the most complete alteration, there being, in fact, ramollissement, friability, rarefaction, and interstitial hæmorrhage. As to paralysis after luxation, it is a very common occurrence, and is rather an additional indication for the reduction of the luxation than a motive for non-intervention. M. Broca, while admitting this to be a very serious case, hoped that it would not be allowed to intimidate Surgeons from attempting the reduction of old dislocations, which is good and excellent Surgery. He believed, contrary to the opinion of M. Guérin, that the lesions of the osseous tissue in the separated limb were dependent on disease of this tissue anterior to the luxation, some of the microscopical appearances being only referable to an older date. Investigations which he pursued at the Salpêtrière and at the Bicêtre demonstrated to him that these changes due to ramollissement of the bones in aged persons are of only slow progress. In this case the microscopical appearances, in conjunction with the age of the patient, indicate senile ramollissement, the phenomena of senility, as is sometimes the case, being somewhat precarious in this instance. This condition is nowise inconsistent with the occurrence of dislocation rather than fracture, as the ligaments also become thin and feeble, and the muscles are relaxed. M. Guérin's patient died a few days after the accident, the autopsy furnishing no explanation of the cause of death. No statement is given as to whether the other bones of the skeleton manifested appearances of disease.

TRUE COMMERCIAL PRINCIPLES APPLIED TO HOSPITAL OFFICES.

(From a Correspondent.)

IN consequence of the remarks of one of our contemporaries upon the unpaid services of Medical officers to charitable institutions, we understand, upon good authority, that it is in contemplation to endeavour to ascertain, by the aid of a commission appointed for the purpose, the commercial value of some of the unpaid Physician- and Surgeon-ships to our leading Hospitals. It is anticipated that, contrary to the opinion of our contemporary, many of the posts would fetch very high prices, and the committee of one leading institution think it probable that Physicians and Surgeons of even greater eminence than any of those now attached will come forward and offer large sums for the advantage of conferring gratuitous services upon the poor of the highly populous surrounding district and holding office in a leading institution. Our contemporary thinks that each Physician ought to be paid by the committee. The committee, on the other hand, consider that if the posts were fairly put up for competition, they would fetch large sums. It is suggested with some reason that if it was worth while for a distinguished Surgeon to spend £500 in a contested election with only the chance of success, many Surgeons of at least equal eminence would gladly contribute an annual donation towards the support of an unendowed Hospital for the privilege of attending the patients. The committee are sanguine of success, and are now anxiously looking forward to the resignation of the present staff, who, like our contemporary, are indignant at not being remunerated for their services. The committee feel confident of receiving from £1200 to £1500 a-year increase to their permanent income, and at the same time are convinced that they will obtain the services of gentlemen who will defer to them in every particular, both as regards the medi-

cines ordered, the quantity and quality of the food and stimulants, and in the general management of the patients—matters which occasionally give rise to the greatest difference of opinion between the committee and existing unpaying and unpaid Medical officers. Should the unpaid staff shortly resign, as is confidently expected, upon the ground of not being paid for their services, it is the unanimous determination of the committee to put up the posts at once for competition, without waiting for the report of the commission of inquiry. It is said that all competitors must be Fellows of the Royal Society, Fellows of the Colleges of Physicians or Surgeons, and all Physicians must be M.D.s of the Universities of Oxford, Cambridge, London, Edinburgh, or Dublin. Each post will be put up at £200 a year, but it is confidently expected there will be a most animated competition, and that eventually the services of very highly distinguished men will be obtained, who will gladly pay £300 a year towards the funds of the charity.

Although many of our readers may be disposed to doubt if the post of Hospital Physician or Surgeon be a labour and an honour worth paying as much as £300 a year for, it is quite clear to all the world that these posts possess considerable commercial value, and that it would really answer the purpose of many to pay the committee and governors for the privilege of holding them.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF WOLVERHAMPTON.

(Continued from page 194.)

THE SOUTH STAFFORDSHIRE GENERAL HOSPITAL AND WOLVERHAMPTON DISPENSARY.

ADMINISTRATION.

The South Staffordshire Hospital was originally a Dispensary. It was transformed into an Hospital a little over fourteen years ago. The institution stands a short distance from the town, and is a fine and commanding edifice. The walls are of brick, and the frontage is well chosen; the house is surrounded by a very limited portion of ground.

NUMBER OF PATIENTS TREATED.

The number of patients admitted for treatment within the Hospital varies from 480 annually to 600, or even 649. Thus, in 1856, 572 patients were admitted; in 1857, 597; in 1858, 487; in 1859, 536; in 1860, 609; in 1861, 649; in 1862, 693; and in 1863, 559. In the out-patient department the numbers are extremely large. In 1856 they amounted to 3931; in 1857, to 4517; in 1858, to 4679; in 1859, to 5149; in 1860, to 6268; in 1861, to 7237; in 1862, to 7750; and in 1863, to 7316. The residence of each patient in Hospital averages six weeks, and the period of attendance of each out-patient is placed at the same average—six weeks.

RULES FOR ADMISSION OF PATIENTS.

At the half-yearly general meeting of the Governors, held the 10th day of September, 1861, it was resolved:—

“That for every two guineas subscribed, and for every twenty-five guineas hereafter given in donation, the subscriber or donor shall have the privilege of recommending yearly one in-patient, or six out-patients at his option. That for every one guinea subscription the subscriber shall have the privilege of recommending yearly three out-patients, and for every subscription of half-a-guinea the subscriber shall have the privilege of recommending yearly one out-patient.” A subscription of half-a-guinea gives admission to a child either as an in- or an out-patient.

“That subscribers shall be allowed the privilege of super-numerary tickets of recommendation on paying at the time to the Institution £2 2s. for an in-patient ticket, and 7s. for an out-patient ticket.”

I may add that the officials of the Hospital are extremely careful not to admit to the benefits of the charity any persons who are not by circumstances fit and proper objects of the charity. The rule on this subject is very strict. It runs thus:—“No patients shall be admitted but such as are themselves unable to pay for advice and medicine, and are destitute of friends to make such provision for them. Gentlemen's servants, in place, shall be considered under the above rule as inadmissible as in-patients. In cases where servants, in place, may labour under any complaint, or the effects of any accident which may require constant Medical or Surgical attendance,

and his or her master shall be desirous of sending such servant as in-patient to the Hospital, they be admitted on the Receiving Physician or Surgeon stating it to be a proper case, on the master's payment of 1s. 6d. per day for the board of males, and 1s. per day for females.” Amongst the subscribers are several of the working classes, whose subscriptions average not less than £100 a-year.

Originally, by rule of the Hospital, children under 6 years of age were not admitted as in-patients; but in the year 1862 a movement was made to abolish this rule, and to establish a children's ward. In the course of 1863 this project was carried out; a new and beautiful ward was built, and furnished, and the children's department is now one of the features of the Institution.

No woman advanced in pregnancy; no persons disordered in their senses; no person suspected to have the small-pox, or other infectious distemper; no person having habitual ulcers, or cancers not admitting of operation, epileptic fits of long standing, or dropsies in their last stages, in a dying condition, or judged incurable—are admitted as in-patients, or, if inadvertently admitted, are suffered to remain.

No male patients are admitted more than once, and no female patients more than twice, for venereal complaints; and in all cases of this class, the complaint is stated on the face of the recommendation, and the subscriber recommending has to certify that the person has been an inhabitant of the county for the preceding six months, or a parishioner legally settled therein.

Patients are admitted, through subscribers, by ticket, as a general rule; but a large number being urgent cases are admitted at once without attention to this routine, as the cases of accident in Wolverhampton that demand instant admission are very large. Thus, in 1863, while 183 Surgical cases were received into the house by the proper form, no fewer than 240 were admitted for accidents, as cases requiring immediate attention; while among the out-patients for 1862, 3425 came under treatment with a ticket, and 3550 were taken on at once. An immense number of the accidents received are from burns. At one of my visits I saw as many as five bodies in the dead-house, the deaths having arisen from that cause alone, and not from one fire only, but from three different fires.

A register of patients is kept; its parts are arranged under the following heads:—Date of Admission; Name and Residence; Age; Trade or Occupation; Single or Married; Nature of Disease; Duration of Illness; Under whose Treatment; Recommended by ———; Result; Date of Discharge.

INCOME OF HOSPITAL AND COST OF PATIENTS.

The Hospital building is the freehold property of the charity. It is vested in the hands of four trustees. The income varies from two thousand five hundred to three and even four thousand a-year, and is derived from investments, annual subscriptions, and donations, the subscriptions being the largest item. There is usually a deficiency amount on the current account of each year, this deficiency reaching in 1861 no less than eight hundred and thirty-four pounds. The average cost of each in-patient may be taken at £3 13s. 6d., and of each out-patient at 3s. 4d. This sum is considerably larger than in the Stafford Hospital, being full 15s. more for each in-patient and 4d. more for each out-patient. The daily average of patients in the house varies from fifty-eight to sixty-three.

MEDICAL STAFF.

The Medical staff of the Wolverhampton Hospital consists of a Consulting Physician, Dr. John Topham, M.D.; two Physicians, Dr. William Millington, M.D., and Dr. Henry Bridgestock; three Surgeons, F. A. Nesbit, Esq., W. E. Thomas, Esq., and Vincent Jackson, Esq.; one House-Surgeon, J. O. B. Kough, Esq.; and an Assistant-House-Surgeon, Dr. D. Brown.

SANITARY ARRANGEMENTS.

The Hospital may be considered to consist of two stories for the reception of patients. After passing through the entrance hall, you enter a long, wide, and open corridor, which, in fact, extends to the upper part of the building, and into which the wards of both stories open. This corridor admits of very free ventilation, and is warmed from the lower story by means of hot-water pipes which run under a handsome perforated iron grating.

The wards are twelve in number. There are now no special fever wards: formerly there were two—one for men and one for women—and these did not communicate with the house, but were entered from without. These are now joined to the other wards by doors, and one is turned into an acci-

called the scales of diet, but they are subjected to considerable modification, and, to a large extent, the system of weighing out the food to each patient is discarded.

Diet Table.

Meals.	Full.	Ordinary.	Low and Extra.
Breakfast ..	Bread and butter; pint of milk.	The same as full diet, except that on Tuesday, Thursday, and Saturday a pint of soup and rice-pudding replace the solid animal food.	Special, consisting of beef-tea, arrowroot, etc., according to the wish of the Physician or Surgeon. Extras are ordered in the same way.
Dinner	Boiled beef, or boiled or roasted mutton, 4 ozs.; vegetables in season without stint; beer, $\frac{3}{4}$ pint.		
Tea	Same as breakfast, or tea for milk.		
Supper	Broth or beef-tea, 1 pint; bread.		

The bread is baked at home, and is allowed at all meals, 14 ozs. being given out for the day to each patient.

USE OF ALCOHOLICS.

Alcohol is rather freely given in the Wolverhampton Hospital. The average amount of wine is about one oz. per patient, and of brandy $\frac{1}{4}$ oz. An allowance of ale and porter is also to be reckoned, to the extent on an average, of half-a-pint to a patient per day.

PRACTICE OF THE HOSPITAL.

The Medical cases consist chiefly of consumption, rheumatism, and all forms of chest and heart disease: chorea is very prevalent, and is almost universally connected with heart disease. Gout is a malady of constant occurrence. Grinders' phthisis is common, also lead colic and paralysis. Diabetes is rare, not presenting more than three cases a-year. Uterine diseases are frequent, and in the out-patient department tape-worm is a prevailing disorder. Syphilis, in all forms, is met with daily; but the primary variety is least common amongst adults—indeed, it is rare in them. Horrible as is the statement, it is true, nevertheless, that in young children—girls—primary syphilis is constantly brought under the eye of the Surgeon. It springs up under the influence of what may truly be called a bestial superstition, to the effect that if a man having syphilis cohabits with a young child, he is sure to be cured of the disorder. It is the fact, that one child has recently died in the Hospital from primary syphilis and ulceration of the os uteri. Infantile syphilis is necessarily prevalent, and the number of miscarriages amongst women from syphilis is alarming. Amongst the classes who yield this disease, indeed, marriage is held as of no moment. They live for the day and the hour.

Amongst the purely Surgical cases, malignant diseases present probably the largest number. Stone is also very common; it yields at least twelve cases a-year: the uric acid calculus is the usual type. The accidents constitute the important features of operative practice. Burns occur at the rate of three a-week during the months from October to May; the burns are about equally divided among children and adults, and the sexes also are equally divided. At least six cases a-week come to the Hospital for the Surgeons to extract from the eye fragments of steel. The lancet is used for extraction, and oil is afterwards applied.

Simple accidents are rare. Usually, owing to the circumstances under which the accidents occur, the mischiefs are compound, and entire smashes of the body are by no means rare. To give an idea of the Surgical practice of this Hospital, I may say that last Saturday, when I was present, there were, in addition to five terrible cases of burn, the following operative cases in the Hospital:—An excision of the elbow-joint, following a railway smash, two amputations of the thigh, one amputation of the fore-arm, two amputations of the lower third of the leg, one Syme's amputation at the ankle, and one amputation at the shoulder-joint; to say nothing of a large number of minor cases of operations.

OPERATIONS.

Statistics of the operations performed in this Hospital have not been systematically kept—a fact which is greatly to be lamented, because much valuable information is thereby lost to science. Mr. Kough has, however, collected records of every case of operation, with the results, from the beginning of the year 1862, from which it appears that seventy-four capital operations and fifty-seven minor operations have been performed. These represent a fair average for several years past.

MORTALITY.

The general rate of the mortality of the Wolverhampton Hospital in the year 1861 was 44.74 per cent. This is 8 per cent. above Stafford and Norwich, but is below most of the other Hospitals of the kingdom.

The Surgical mortality is somewhat high as compared with other provincial Hospitals, such as Norwich. I refer, however, only to mortality after operations, because I have no data bearing on the mortality from the whole class of Surgical cases. The mortality after all operations has been at the rate of 1 in 10, or 10 per cent. Excluding from these the seventy-four capital operations, and taking the mortality of these alone, we find it to be 1 in 5.69, or 17.56 per cent. In order to give a clear idea of the Surgical practice of the Wolverhampton Hospital, I subjoin a table of the seventy-four capital operations to which attention has been drawn, with the results:—

Sex.	Age.	Nature of Operation.	Results.	
			Deaths.	Recoveries.
M	66	Amputation of arm for smash	Died, 6 days after operation.	
M	27	" of shoulder-joint	Died, 7 weeks after operation.	
F	77	" of fingers after smash	..	Recovered.
M	33	" of thigh after compound fracture	..	"
M	13	" of upper arm	..	"
M	25	" of leg, middle third	..	"
M	50	" of hand	..	"
M	9	" of thigh for disease of knee	..	"
M	49	" of toes	..	"
M	43	" of thigh	Died.	"
M	21	" of hand at wrist	..	Recovered.
M	34	" of thigh	..	"
F	30	" of part of hand	..	"
M	27	" of part of penis	..	"
M	23	" of hand	..	"
M	27	" of left leg	..	"
M	40	" of penis	..	"
M	..	" of thigh for disease of knee	..	"
M	..	" of thigh for necrosis	..	"
M	53	" of thigh for malignant disease of knee	Died, 7 days after operation; cancerous deposit in lungs.	"
M	40	" of part of hand	..	Recovered.
M	..	" of lower third of thigh	..	"
M	..	" of right upper arm, middle third	..	"
M	18	" of middle third of thigh	..	"
M	23	" of leg, lower third	..	"
M	..	" of thumb	..	"
M	..	" of leg, lower third	Died, 6 days after operation.	"
F	..	" of thigh for disease of knee	Died, 10 days after operation.	"
M	..	" of middle third, humerus	..	Recovered.
M	..	" of shoulder-joint for smashed arm	..	"
F	..	" of part of hand	..	"
F	7	" of thigh, middle third, for smash	..	"
M	14	" at wrist-joint for smash	..	"
M	..	" at ankle (Syme's) for smash	..	"
M	..	" at wrist for smash	..	"
M	..	" of thigh for disease of knee	..	"
M	..	" of leg, middle third, for smashed foot	..	"
M	..	" of part of hand	..	"
M	31	" of part of hand	..	"
M	20	" of both legs for complete smash	Died.	"
M	33	" of part of hand	..	Recovered.
M	38	" of right arm after smash	Died, 40 hours after operation.	"
M	42	" of thigh after smash	Died, 20 hours after operation.	"
M	16	" of lower third of arm after smash	..	Recovered
M	40	" above elbow	..	"
F	34	Amputation of breast	..	Recovered.
F	48	" of breast (left)	..	"
F	44	" of breast (both)	..	"
F	..	" of breast (left)	..	"
M	32	Removal for necrosis of head of femur	..	Recovered.
M	38	Resection of ankle	..	"
M	16	Cystic disease of lower jaw	..	"
M	..	Removal of portion of necrosed pelvis	..	"
M	12	Excision of head of femur	Died.	"
M	..	Anchylolysis of elbow, broken up under chloroform	..	Recovering.
M	..	Resection of right elbow	..	Recovered.
M	40	Removal of tarsal bones	..	"
M	19	Tracheotomy	..	"
M	28	Trephining after fracture of parietal	Died.	"
M	29	Radical cure for hydrocele	..	Recovered.
M	5	" " "	..	"
M	..	" " "	..	"

Sex.	Age.	Nature of Operation.	Results.	
			Deaths.	Recoveries.
M	16	Lithotomy	..	Recovered.
M	10	"	..	"
M	21 $\frac{1}{4}$	"	..	"
M	4	" (calculus 26 grains)	..	"
M	13	" " 110 "	..	"
M	8	" " 46 "	..	"
M	61	" " 1 $\frac{1}{2}$ ounce	Died, from hæmorrhage.	"
M	10	" " 3 $\frac{1}{2}$ drachms	..	Recovered.
M	10	" " 3 "	..	"
M	33	Puncture of bladder through rectum for retention	Died.	
M	47	Extirpation of the right eye	..	Recovered.
M	29	Removal of hæmatocele of thyroid	..	"

CHLOROFORM.

Chloroform is usually administered by placing it on lint: the lint is held to the face with a handkerchief thrown over it. The narcotic is measured out in quantities of a drachm. The administration is entrusted exclusively to the House-Surgeon, who never leaves the patient. For a time Snow's inhaler was used, but it is now thrown aside as cumbersome. No death has occurred from chloroform in the Infirmary. From the period of the introduction of chloroform the administrations have not been fewer than 4000.

POINTS OF PRACTICE.

But few new points of practice are being carried out at the Wolverhampton Infirmary, but there are one or two subjects to which I may direct attention. *In the treatment of burns* the best practice is found to consist in placing the patient, in the first instance, in a tepid bath; this invariably soothes and affords great relief. Then oil is laid on all the burnt parts, cotton wool is applied, opium is administered freely as an internal remedy, and, at the same time, the patient is supported with good food.

Acupressure is being used, especially by Mr. Thomas, in amputations. The plan succeeds well in arresting the flow of blood, but union by the first intention has not been secured by it, and the process is found to take up considerably more time than the ligature. However, its value is still *sub judice*.

In the treatment of a case of poisoning by the inhalation of the fumes of nitric acid, Dr. Millington some time ago employed blood-letting with great advantage. The patient at the time when Dr. Millington first saw him seemed to be dying from the embarrassment of the breathing and the oppression of the heart. Twelve ounces of blood were drawn from the arm with instant relief. After a few hours the symptoms returned, and once more venesection removed the anxiety. Again, and once again, there was relapse, and again, and once again, the lancet proved immediately effectual. Without any other remedy the man made a good recovery; and Dr. Millington, in describing the case to me, said that nothing could be more remarkable than the immediate relief that followed the withdrawal of the blood. The patient, opposed to venesection, became, after the first abstraction, so easy that he would have had it carried further than was necessary. When we recall the two fatal cases from inhalation of nitric acid fumes that occurred in Edinburgh last year, we cannot but regret that the same effectual line of treatment was not there pursued.

I have only to refer to one other very simple, but useful and economical practice. The Surgeons of the Wolverhampton Infirmary use a prepared tissue paper instead of oiled silk or gutta percha. The paper is brushed over with boiled oil, to which a little gold size is added; then it is put away to dry, and after a few days is dusted over with magnesia or French chalk, when it is ready for use. A specimen of this paper lies before me, and it seems equal in every way to oiled silk. Of course, it is less durable—indeed, it requires to be renewed each day; but it can be made in Hospital, and it is always new and clean for application.

LIBRARY AND MUSEUM.

There is a *Library* at the Infirmary, but it is very small, containing only a few hundred volumes of books published during the last twelve years.

There is no *Museum*, but about a hundred calculi have been retained. These await analysis and classification.

PROVINCIAL CORRESPONDENCE.

GLASGOW.

THE CONVERSAZIONE AT THE FACULTY HALL, GLASGOW.

BY ONE WHO WAS THERE.

THERE is no phrase which goes more kindly to all hearts than "Auld Lang Syne." We delight to live over again the days of our youth, and to talk of our early companions and play-fellows. Where are they? What has become of them? Are they rich and making a figure in the world, or doomed to drag the load of poverty, and battle for a bare existence? How have our expectations of any of them been realised, and where is the lucky fellow who has made his mark? These are questions we all delight in. We cannot forget our early friends though we would, and somehow seem to feel that our school-fellows and college companions know and understand us better than any one else:—

"Ah, days! that come but once a life,
Yet with all blessed memories rife,
Ye quickly pass, yet never die,
But deep within our being lie:
A heritage through all our years,
Of calmer smiles and mellow tears."

He would be a poor fool who could affect airs beside an old fellow of the same form, and who, meeting with one "fallen on evil days and evil tongues," sans coat, or hat, or creature comforts, could coldly forget the early bond of brotherhood. I know nothing finer of this sort than the gentle Cowper's protest in favour of Warren Hastings. Cowper and Hastings had been together at Westminster School, afterwards to be widely and distinctly separated, the one becoming a great man, the governor of a mighty empire; the other to shrink into retirement, and become the recluse of Olney. But Will, never forgot Warren, and when the latter was impeached, and battered and barked at as though he were a badger, forth there came from the Solitary at Olney six lines, which are as immortal as anything in our literature, and which must have been "grateful as oil poured forth" on the galled spirit of his distinguished school-fellow—

"Hastings! I knew thee young, and of a mind,
While young, humane, conversible, and kind;
Nor can I well believe thee, gentle then,
Now grown a villain and the worst of men,—
But rather some suspect, who have oppressed
And worried thee, as not themselves the best."

This was a pure tribute to early friendship, and, I think, "beautiful exceedingly."

In a mood of this sort, dreaming of other days, I went on Friday evening, the 11th current, to the *conversazione* held in the large hall of the Faculty of Physicians and Surgeons, Glasgow, given by the President and Fellows of that ancient corporation. Invitations had been very general; men from the hills were expected—sturdy, intelligent fellows, with the tear and wear of twenty years of professional life on their faces; while there would be seen mingling with them in friendly discussion on subjects common to both the more polite and elegant *savants* of the valleys below. There was to be a Medical re-union, a social gathering of old chums and acquaintances. Old half-forgotten faces would once more become familiar, and voices *sugh* through our ears the music of lang syne. Moreover, Dr. William Weir, a man venerable with age, honourable for his acquirements, and loveable for the excellence of his heart, was going to read a paper on the early history of the Faculty and Medical Profession of Glasgow, endeavour to unroll the past, and raise, as it were, from the dead some all-but-forgotten names,—to linger over them with respect and reverence! This of itself promised no common treat, for to me clouds and darkness rested upon the predecessors of such men as Cleghorn, McCorkindale, Jaffray, Allan and John Burns, McNish, Moses Buchanan, Lawrie, and other honoured names, whose memory floats like incense over the bleak road of professional life.

The Faculty Hall, a magnificent mansion in the west end of the city, was crowded when I entered. My name was roared out by an official in a voice of thunder, and I had the honour of shaking hands with the President. Dr. Ritchie had too many hands to shake to say much to me; but he was evidently at home in receiving his guests, and his conduct throughout the evening was marked by high feeling and great suavity of manner. He is a white-haired venerable man, with

a broad, hazy, Chalmers-looking face; and his honours hung gracefully around him. In a minute more I was in the heart of the saloon, sipping tea with some hundred Doctors Medicinæ surging around. The place was brilliantly lighted, and well-spread tables groaned under the good things of the season. There they were, old fellow-students who had not met for many years, laughing and talking about the days of yore, and of distant friends, and of the "chimes" which they had heard together "at midnight." It was most agreeable to witness the hearty shake, and slap, and laugh of friendly remembrance which was passing everywhere around. That pat on the shoulder; when, on turning, one was sure to recognise, in a well-known face, your old crony and still true friend. There is a thoughtful man from the "bonny banks of Ayr," with his hair closely cropped: he has had fever, and now he is telling us "visions of the Andersonian float before me to-night." Yonder is Andrew Anderson; and, look you, there goes Easton! How fresh and young! What did you think of that expectorant he lately administered to Gardner? It was capital, and ought to have had a place in the new Pharmacopœia.

Who the deuce is this, with "good fat capon lined," looking as though he perfectly understood the science of life? He has just been lecturing on that subject; and began it, I am told, by eating pickled oysters. I was to be present at the feast; but a confounded midwifery case came in the way, and I lost my share of the Pandors—by the way, I think they were not Pandors, after all, but Strauraers; mind you, there is something in that! Allow me to introduce you to J. G. Wilson, who has succeeded our old and valued friend, Dr. Patterson, in the Chair of Obstetrics at Anderson's. Wilson is a rising man; and what is singular, no one grudges him his success. By the way, have you seen *that* French forceps he is showing upstairs, and which G. H. B. declares would require to be yoked so that a pony might pull them? But George, you know, "loves to draw it strong," and we remember Balaklava. *Comprenes?* There is Perry and George Buchanan, clever fellows both; the latter I believe to be one of the best operators in the West of Scotland. "To be, or not to be?—that is the question." Here, I declare, is Whitelaw cultivating a beard, and grim as John Knox himself. And so with laughing, joking, and eating, the time arrived for us to congregate in the large hall, and listen to Dr. Weir's history of the Profession in Glasgow. The Doctor was introduced by the President in a few words, and took occasion to say what pleasure it gave them all to see so many gentlemen present, especially from the country. Though they could not favour them with a display of beauty, nor entertain them with music, or any of the accompaniments of a *conversazione*, he felt satisfied, on the simple ground of Professional union, they would be benefited by thus meeting together.

In expressing these feelings he would not like to intrude on Dr. Weir's particular subject, but he had a man of great fame to speak about—one Dr. Peter Low—to whom, indeed, they owed their present meeting together, and whose portrait they saw at the other end of the room—a face bearing on it the stamp of wit, of humour, and of great force of character and benevolence that characterised the original. That gentleman nearly 300 years since, had been a Physician in Glasgow, of great social influence, employing it constantly for benevolent purposes, and one of his great objects being to raise the status of the general Practitioner. The President could not resume his seat without referring to another who was still in the flesh, and whom he would not hesitate to call Dr. Peter Low *secundus*; he referred to their estimable friend, Dr. James Watson, who had also done much for the Faculty, and who had sought at once to lift the general Practitioner in Professional status, and extend his usefulness. The President concluded by introducing Doctor Weir, who, in a clear silvery voice, read a paper on the origin and early history of the Faculty, which, he said, had existed for nearly 300 years, giving full-length portraits of Dr. Peter Low and Dr. Robert Hamilton, its early founders.

Dr. Weir's paper was characterised by strong good sense and pawky humour, and keenly enjoyed. We trust he will print it, and so let us live the hour over again. Dr. Allan Thomson, in moving a vote of thanks to Dr. Weir, took occasion to compliment him on the manner in which he had arranged his facts, and the interest he had thrown around the subject; and taking a key-note from the paper just read, which had detailed the early system that our forefathers had pursued of apprenticeship, he contrasted practical and theoretical teaching, observing that they must be grafted, and,

referring especially to his friend Mr. Syme's pamphlet on that subject, concluded an able and energetic speech by expressing a hope that the invidious distinctions between Surgery and Medicine would soon cease, for he who was qualified to practise either was assuredly equal to both. Dr. Thomson's speech, to our mind, was equal to the man and the occasion that called it forth, and was received with rounds of applause.

Dr. Weir having replied, Dr. Thomson, from Kilmarnock, neatly and appropriately, in a few words, proposed a vote of thanks to the Chairman, which was given with three times three, when the proceedings terminated. But many of the guests continued after this to wander through the apartments, to sip tea, and enjoy other good things. Mr. W. B. Hilliard had in one of the rooms a collection of Surgical instruments, well worthy a special inspection. Messrs. Murdoch Brothers had in another room many beautiful preparations of rare and new medicines; while a crowd was always to be found in another enjoying the wonders of the microscope. Thus closed the first great gathering of Medicals in the west of Scotland, which, we venture to say, generated much kindly feeling, will be remembered as a night of rational enjoyment, and looked back upon, years after this, with pleasure. May we soon have another such!

J. T. B.

GENERAL CORRESPONDENCE.

HEALTH OF HOSPITALS.

LETTER FROM DR. J. S. BRISTOWE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Farr has, in your journal, brought an accusation of general unhealthiness against the Medical charities of this country. I have invited him in the name of the Profession to which he belongs to lay before that profession the facts on which this very heavy accusation is based. I regret that Dr. Farr has failed to respond to my invitation; and has thus placed himself in the position of a man who has made an accusation which he cannot substantiate, yet will not retract.

I am, &c. J. S. BRISTOWE.

2, Queen-square, Westminster, April 5.

MORTALITY AFTER LITHOTOMY IN LONDON AND NORWICH.

LETTER FROM MR. HENRY THOMPSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Richardson has at last admitted that the average mortality of London Hospital lithotomy is *not* "one death in two cases, or even one in 1.88." Had he done so in reply to my first letter (January 16), this long discussion might have been spared.

But, if he did not mean that, and nothing else than that, why did he write, when speaking of the 910 cases of lithotomy at Norwich: "If the same number of operations had for instance, been performed at Metropolitan Hospitals, *the deaths would, on the modern average, have been 472 instead of 118?*"

This is as distinct statement as could have been made, that the *average rate* of London mortality is one death in less than two cases; a statement which he now, after close pressure, disowns.

Dr. Richardson thinks fit to announce that he shall leave any one who differs from him in this matter "to his anger, his blindness, his intolerance, his pride." I have never yet in any discussion felt it right or needful to condescend to personalities, and I distinctly refuse to follow Dr. Richardson in this, the larger, portion of his remarks.

I am, &c. HENRY THOMPSON.

Wimpole-street, April 4.

A NEW HOSPITAL AT WINCHESTER NOT WANTED.

LETTER FROM MR. CHARLES MAYO.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having noticed in four different numbers of the *Medical Times and Gazette*, from February 20 to March 12, four several letters, relating to our county Hospital as it now stands and a proposed new one, I am induced to offer a few explanatory observations. I will not encroach upon your space by considering whether the "Epicuri de Grege Porcus"

is right in his estimate of the architect, which he seems to have formed from inspection of the plans, or whether the "F.R.C.S.," who seems to found his reply upon general report, is to have greater credit for his representations, because I propose to show from the report of your third correspondent, our present House-Surgeon, that it is by no means clear that a new Hospital is wanted. He premises that ours is the oldest provincial Hospital in England, founded in 1736. Now, Addenbrooke's, in Cambridge, dates 1719, and Bristol 1735. This is not very important, but he reasons upon its consequent decrepitude without knowing that in its infancy a much smaller building sufficed for many (sixteen or seventeen) years. The centre of the present building was (and is) a substantial mansion, fronting east and west, to which two wings, extending north and south, were added, with three floors in each, forming six commodious wards; so that all that portion occupied by the patients was purposely built for them, with single long wards facing east and west, in accordance, as I understand, with Miss Nightingale's more recent plans. With regard to the infirmities or decrepitude of the building, I see that the walls are firm and upright, but the floors here and there somewhat loosened, and the window frames require to be renovated or painted; such repairs seeming to be purposely neglected for the last two or three years, that the expense of effecting them may make the case stronger for the necessity of a new Hospital.

Now, about twenty-five years ago a large building and a piece of ground were purchased by voluntary subscriptions at the northern extremity of the old Hospital above described, which being cleared made room for a transverse wing running east and west, and in it were constructed four additional and commodious wards, a handsome room, chapel, and a well-lighted and convenient operating-theatre, all of which are in substantial repair, and enable us to accommodate 120 beds, whereas sixty or eighty were the extent in the original building.

It is true that the drainage has been at fault from time to time, and has required correction and improvement, which Mr. Yeo has shown has been attended with the best results. To such an extent has been the amendment, that "the death-rate at this Hospital is below the average of other country Hospitals." But I do not agree with Mr. Yeo that all the cases of erysipelas and other infectious diseases should be set down as contracted in the Hospital, because such diseases have been at times epidemic, and occurring in various parts of the city and suburbs, and were so in 1861, if I remember rightly, both at the county prison and union workhouse; and within the last month we have had a case of scarlatina, evidently brought in by a little girl previously infected.

Now, as I took a great interest in the construction of this important addition to the Hospital, which now accommodates one-third of the patients, and is quite sound in its structure, I cannot endure with complacency the idea that Mr. Yeo, who is a newly-appointed officer, should stigmatise the whole Hospital as old and condemned, when, by his own report, he allows it to be more healthy than it has been for some years. In a subsequent paragraph he says:—"In the case of the Winchester Hospital we have a remarkable instance of defective sanitary conditions, and yet a low average of death-rate," apparently forgetting what he had before stated of the improvement of the drainage and ventilation, through the suggestions of Mr. Rawlinson. Now, let us inquire by whom and for what has this Hospital been condemned? Six out of eight of the Medical officers attached to it signed a memorial against the removal of it when the question was first agitated about two years ago, and to these were added other Medical and retired officers' names, together with those of nearly 150 principal inhabitants, who entrusted the Mayor of Winchester with its presentation and advocacy at a court of governors. Nothing has since happened to invalidate the sound sense of this memorial, but everything to confirm it. The subscribers thereto saw nothing in the defects of the present building but what might be remedied by erecting another transverse wing at the southern end, or by repairing or reconstructing the old wards, and so, by spreading the patients over a larger area, to allow a greater number of cubic feet to each. The distance of the proposed new Hospital from the centre of the city and the surrounding population of the county is an objection that will more than counterbalance its greater airiness, which may, in fact, be called bleak, especially as the building is to face nearly north and south, on the side of a steep hill, and nearly a mile from the city. The resistance which has been made by the Medical staff of St. Thomas's Hospital to its removal from the centre of the population for which it was intended may be

adduced in confirmation of the above objections, and to these may be added the difficulties and delays of access both for patients and Doctors, especially in cases of accidents, such as have recently occurred.

Having stated thus much, I must apologise for the length to which my zeal for the old building has extended, to counterbalance the idea that "you must be aware its days are numbered," etc. One word more as to drainage, which, in the proposed new Hospital, is to be by cesspools, as in the old; but ground and buildings have been purchased which will enable us to remove them to a greater distance; and we are in a much better situation to participate in the general drainage, which will eventually happen, than on the high ground above spoken of. I do not meddle with Mr. Yeo's death-rate statistics, which I am glad to observe have been so much commended.

I am, &c.

CHARLES MAYO, Senior Surgeon.

County Hospital, Winchester, March 29.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 15.

MR. PRESCOTT HEWETT, President.

DR. WALE HICKS read a report on his case of

CRANIA BIFIDA.

He had found that the sac protruded through the opening was formed of the tentorium cerebelli, and that under it was a communication with the left, but not with the left lateral ventricle.

In reply to the President, Dr. HICKS stated that there was no cerebral matter in the opening.

DR. WALE HICKS also read a

REPORT ON A PORTION OF THE LUNG OF A HORSE EXHIBITED AT A PREVIOUS MEETING OF THE SOCIETY.

The portion of lung examined was found to be very slightly crepitant, and on being cut into small pieces some of them sank in water and others barely floated. On naked-eye inspection, it appeared to contain a quantity of greyish-white matter, filling up the spaces of the lung tissue. On microscopic examination this whitish matter was found to occupy the air-cells, filling up most of them more or less completely. It was seen to consist of corpuscles, varying somewhat in size and shape, the predominant form being spherical. These corpuscles contained much granular matter, and many of them appeared to be nucleated.

DR. HARLEY said that Dr. Quain had reminded him that the specimen on which Dr. Hicks had reported was very like one he (Dr. Harley) had received from the Veterinary College. On section the lungs presented innumerable white spots, looking at first sight like entozoa. When he received the specimen it so happened that no less than seven pathologists were present, and none of them had seen a similar condition in the lungs. They were removed from a young horse, four years of age. The animal had had good health until six weeks before death, when it began gradually to lose flesh. The appearance of the lungs being very unusual, they were sent from the country to the Veterinary College, but the Professors there said they had never seen lungs in that condition. Dr. Harley looked for ova, but found none; but on microscopical examination found appearances similar to those Dr. Hicks described in his report, and he had no doubt the specimen was some form of cancer. Unfortunately, the other organs had been thrown away. Dr. Harley came to the conclusion that the cancer was secondary. Since examining this specimen he had received another nearly like it, but here there were masses of soft cancer in the spleen, and in the lung also were several large nodules, as well as the smaller ones found in the other specimen.

DR. WALE HICKS said that in his specimen no distinct spots were found. The matter was uniformly infiltrated.

DR. QUAIN suggested that Dr. Hicks should examine Dr. Harley's second specimen, and present a report upon it, and that it should be ascertained whether Dr. Harley's first specimen was not the one on which Dr. Hicks had just reported.

DR. MURCHISON brought forward a specimen of

NECROSIS OF THE HYOID BONE.

A woman, 35 years of age, was first seen by Dr. Murchison

October, 1862. She had had loss of voice for some months, and a few days before had coughed up the piece of bone exhibited. There was ulceration of one tonsil, which extended to the root of the tongue, tenderness on swallowing and movement, and also grating between two ends of the hyoid bone. There was no evidence of syphilis. In August a smaller piece was coughed up. For ten months she was under observation, and grating could be readily felt. In September, 1863, she was seen again. Then the voice was good; the grating was not to be felt; but the two ends of the bone were still moveable.

Dr. GIBB said one interesting point in the above case was the absence of evidence of specific disease. He (Dr. Gibb) had collected nine cases, and in two, or, perhaps, three, only did he find distinct history of syphilis. The disease, he said, began by acute periostitis; and he alluded to a case which he had successfully treated in this stage.

The PRESIDENT would not be certain that the bone was part of the hyoid, and he had doubts also as to the grating being anything abnormal. Some years ago a girl was admitted into St. George's Hospital for a diseased heel. She had a little tenderness over the larynx, and the Surgeon under whose care she was found grating. He considered this was evidence of disease of the larynx, and frequently drew the attention of others to the grating as a curious and rare symptom. The Surgeon was rather startled to hear from Mr. Gregory Smith, who saw the case, that grating on pressure of the larynx was normal. The patient died, and at the autopsy no disease of the larynx was found.

Dr. MURCHISON thought that if the President had seen the patient from whom the specimen was removed, he would have had no doubt as to its nature. He could take hold of each end and press them together; and this, too, was done by several observers. At first he fancied there might have been disease of the vertebræ, and that this might have been the source of the bone; but the symptoms were chiefly laryngeal, and the bone, on comparison with the normal hyoid, looked like a piece of that bone. Dr. Murchison said that if he could succeed in finding the patient he would send her to Dr. Gibb for laryngoscopic examination.

Dr. GIBB said that there could be no doubt that parts of the hyoid were coughed up. In one case the whole of the hyoid had been expelled.

Dr. Gibb was requested to examine and report on the specimen.

Mr. BARWELL brought forward a boy who had

A PECULIAR DISEASE OF THE TONGUE.

The tongue was fissured and in parts ulcerated. It began when the boy was four years old, but no cause could be ascertained. It followed a scratch on the upper lip. There was no evidence of syphilis, but the appearances in an adult would have suggested syphilis.

In reply to Dr. Crisp, Mr. BARWELL said he did not know whether the boy had been in the habit of eating coarse bread, and, in reply to Dr. Buchanan, that he did not know whether the boy had had any of the exanthemata.

Dr. QUAIN asked the President if he thought the appearance was disease, or merely a natural condition. He (Dr. Quain) knew a family in which several members had this peculiarity, and had often seen it in people who had no disease.

Mr. BARWELL remarked that the fissures might be natural, but that ulceration must signify disease.

The PRESIDENT said that from a cursory examination it seemed natural. He had often seen tongues looking like it, sometimes with ulcers and sometimes with clefts only.

Mr. BARWELL showed several

PHOTOGRAPHS OF CLUB-FOOT.

He brought them forward in order that he might speak on certain points in muscular pathology which had been touched on at a previous meeting. Mr. Barwell said that muscular fibre had two kinds of contractility—one directly dependent on cerebro-spinal stimulation, viz., active contraction; and the other a sort of elasticity, tonic contraction. The former was powerful and evanescent; the latter feeble, but constant. In the most severe affections of the nervous system there was no such thing known as continuous active contraction of muscles, so that it never occurs in nature that an active muscular contraction is either violent or continuous enough to produce permanent distortion. Mr. Barwell did not include deformities from assumed position or from disease of joints, but would take club-foot as an illustration of his views. This, he believed was due, not to active contraction of one set of muscles, but to paralysis, so that the tonic contractility of

the opposite set produces the distortion. It was analogous to the distortion of the face in paralysis. Mr. Barwell thought that no sound judgment would admit that active contraction, which never produces non-congenital club-foot, would be a frequent cause of the congenital. He was rather surprised to hear Mr. Adams at a recent meeting say that he "could never find the slightest trace of paralysis in these cases," as he (Mr. Barwell) had found that there was in such cases a considerable loss of contractility under the electric stimulus. Had it ever, Mr. Barwell asked, occurred to the orthopædic mind that to distort a foot by active contraction a muscle must act with such energy that, if its tendon were cut, the ends would fly asunder like arrows from a bow? Mr. Barwell was surprised to hear it stated that brilliant results in Orthopædism were obtained in paralytic cases. Apart from theoretical considerations, he must say that the amount of lameness he had found left after operation in these brilliant cases was extreme.

Dr. HENRY DICK said he could not agree with Mr. Barwell on the subject of cutting tendons. The history of subcutaneous tenotomy was very instructive. Before Delpech and Stromeyer cut tendons, club-foot was not curable. Venel, in Switzerland, made strong efforts, in the last century, to cure deformities by extension, and he rarely succeeded except in slight cases. Scarpa did know well the pathological anatomy of club-foot, and advised judicious instruments; but still club-foot was rarely cured, and it was only since the introduction of tenotomy that the treatment made any progress. The elements of the deformity are not only the muscles, but also the ligaments and fasciæ. To overcome these elements of the deformity we are obliged to cut the tendons, and daily experience shows us that without cutting the tendons we cannot cure club-foot. Slight cases of club-foot or paralytic cases might do well without cutting. Dr. Dick always found that the action of the muscles after tenotomy was not weakened, and, as a rule, the patient gets a useful limb; so far experience was entirely in favour of judicious subcutaneous tenotomy.

Mr. ERNEST HART did not know if Mr. Barwell extended his views to the ophthalmic as well as to the orthopædic mind. The action of the muscles of the eye admitted of careful study and specialisation, and if Mr. Barwell would consider their condition in squint, both before and after operation, he would find that he had overstated his case.

Mr. BARWELL said, in reply to Dr. Dick, that there was no reason why club-foot should not now be cured without cutting tendons, because before Stromeyer began to cut them club-foot had never been cured at all. He knew, too, that instruments were used, without cutting, in the cure of club-foot, but he objected to them as much as he did to tenotomy. In reply to Mr. Hart, he said that he thought squint was more likely to be due to paralysis of the external, than to contraction of the internal rectus. If he could treat strabismus without cutting the tendon, he should prefer to do it; but it was impossible to treat the eye like the foot. We could not, he said, fix springs in the eye, but now and then we could cure strabismus without operation.

Mr. HULKE thought it would be doing an injustice to Donders, who had done so much in the investigation of strabismus and paralysis of the muscles of the eye, if he did not now mention that he had demonstrated the real cause of strabismus. In 95 per cent. the eyes of squinters were hypermetropied. The squinting was not due to paralysis of the external rectus, but to undue convergence to increase the refractive power of the eyes. In slight cases of squint cure might be effected by spectacles.

Mr. BARWELL said that double squinting in such cases was analogous to the deformity which occurred from an assumed position.

Mr. HART thought that Mr. Barwell had not yet seized the point in question, that squinting was due to spasm, and not to paralysis.

(To be continued.)

REMARKABLE FECUNDITY.—Dr. Pomeroy, of Wisconsin, in the United (?) States, records the birth of eight living and two dead children in a lady patient under his care in the short space of two years. This case, which is published in the *Boston Medical and Surgical Journal*, bids fair to exceed in the number of living offspring any of the cases referred to by Dr. Warren, and it is hoped that Dr. Pomeroy will not fail to keep the Profession informed of the ratio of increase hereafter, and also of the state of health of the living children, with other particulars connected with so remarkable a case.

LAYING THE FIRST STONE OF THE NEW CARMICHAEL SCHOOL OF MEDICINE IN DUBLIN,

BY HIS EXCELLENCY THE EARL OF CARLISLE, K.G.

ON Tuesday, the 29th ult., the foundation-stone of the new Carmichael School of Medicine about to be erected in North Brunswick-street, Dublin, with funds bequeathed for the purpose by the late Richard Carmichael, F.R.C.S.I., and made available during the lifetime of Mrs. Carmichael by her generous liberality, was laid by his Excellency the Earl of Carlisle, K.G., Lord Lieutenant of Ireland, in the presence of a large assemblage, including the President of the College of Physicians, Dr. Corrigan; the President of the College of Surgeons, Dr. Colles; the Regius Professor of Physic, Dr. Stokes; the University Professor of Surgery, Dr. Adams, one of the founders of the Richmond School; the Dean of the Chapel Royal, the Very Rev. Dr. Graves; etc., etc.

Dr. MacDonnell said:—I regret to say that the duty devolves on me of presenting to your Excellency the address on this occasion, in consequence of the unexpected illness of my colleague, Dr. Mayne, the senior proprietor in the School of Medicine, the first stone of which we are now going to lay. I regret his absence for many reasons, but especially because he is a man of whom we are all in this school, very proud, and very justly proud. He has been the master of all of us, as he is now our colleague, and our very valued friend. Dr. MacDonnell then read the following address:—

“MAY IT PLEASE YOUR EXCELLENCY,—Being the senior lecturer at the old Carmichael School of Medicine, I have been deputed by Mrs. Carmichael and my colleagues to express to your Excellency our grateful acknowledgments for the high honour you have conferred upon us in graciously consenting to lay the foundation-stone of the new Carmichael School this day.

“By Mrs. Carmichael and by all of us your presence at this ceremonial is hailed as an auspicious omen of the success of an undertaking which we owe to the princely liberality of her late illustrious husband, Richard Carmichael.

“Your Excellency will permit me to add that we never for one moment doubted that your Excellency’s reply to our humble request would have been in the affirmative, for the whole history of your Viceroyalty has shown the deep interest which you have at all times taken in every enterprise calculated to develop the resources of this country,—art, science, and literature, commerce, trade, and agriculture having each in turn, as occasion offered, received your patronage and support.

“With your Excellency’s permission, I shall state in a very few words the history of the enterprise which we are about to inaugurate this day.

“In the year 1826 three distinguished Dublin Surgeons—two of them at that time connected with the Hospital of the House of Industry, but now, alas! no more!! one of them still connected with the Hospital of the House of Industry, and, I rejoice to say, present amongst us this day—conceived the design of founding a School of Medicine in the immediate vicinity of the Richmond Surgical Hospital.

“They were led to this project from observing that the splendid Hospitals of the House of Industry (in the midst of which we now stand) were not in those days as available for Medical education as they ought to have been, from the want of a sufficiently convenient Medical school, in which the elementary branches of Medicine, Surgery, and the collateral sciences might be learnt, the students who then frequented the Richmond Surgical Hospital being compelled to seek at distant parts of the city, and at a great sacrifice of time, instruction in those branches of Medicine which can be taught only within the walls of a Medical school.

“Richard Carmichael, Ephraim McDowel, and Robert Adams accordingly founded, at their own expense, in North Brunswick-street, yonder, the Richmond Hospital School of Medicine, and there (*mutato nomine*) it flourishes to the present day.

“The success of the Richmond Hospital School of Medicine is best attested by the large number of Physicians and Surgeons whom it has educated for all the different branches of the public service, civil and military.

“In the Medical Departments of the Army and Navy very many of our old pupils now hold Her Majesty’s commission; and in the Civil Service they are to be found in every county

in Ireland in charge of the county Infirmaries, or of the Work-houses, or as Dispensary Surgeons under the Poor Law.

“A remarkable circumstance in the past history of the Richmond Hospital School of Medicine has been the large number of its lecturers who have been promoted to Professorships elsewhere.

“At the present moment no less than four of the Professorships in the School of Physic in Ireland are held by gentlemen who formerly lectured here; and within a comparatively short period of time we have supplied seven Professors to the College of Surgeons.

“It is a source of honest pride to us to feel that so many of our old colleagues have been promoted to posts of honour and emolument, however deeply we may regret the loss of their valuable services to our own School.

“It is scarcely necessary for me to say that the late Mr. Carmichael, having taken an active part in founding the Richmond Hospital School of Medicine, continued ever afterwards to be its most devoted friend and patron.

“Previous to the year 1840 he had already given a large sum of money to found the Carmichael Prizes. These costly rewards of merit have been to the present day awarded annually at the close of the Medical Session to the best answerers in Medicine, Surgery, and the collateral sciences, and have largely contributed to the success of the School.

“It was the first attempt to introduce on a large scale the competitive system into the Medical Schools of Dublin, and it affords a signal proof of Mr. Carmichael’s sagacity and foresight that he should have initiated a system which was afterwards adopted so extensively, and with such excellent results, in other departments.

“Almost the last act of Mr. Carmichael’s life was to bequeath the munificent sum of £10,000 to rebuild the Richmond Hospital School of Medicine, either on the old site or elsewhere, as might be considered most advisable. This bequest was to be contingent upon the demise of Mrs. Carmichael.

“On June 8, 1849, the Medical Profession in Ireland was suddenly deprived of one of its brightest ornaments, and Medical science lost a favourite son. The circumstances attending Mr. Carmichael’s death are far too vividly impressed upon the minds of all who now hear me to need repetition. In the midst of health, and in the vigorous discharge of his Professional duties, an accident removed from amongst us the noblest, the most munificent, and the kindest-hearted of Surgeons.

“From that day the Richmond Hospital School of Medicine has borne his name as a memorial of the affection and esteem entertained by its proprietors for their lamented friend and benefactor.

“Some months since, Mrs. Carmichael, with a noble generosity, intimated to the proprietors of the Carmichael School that it was her intention to place Mr. Carmichael’s bequest at their immediate disposal. In doing so, she voluntarily deprives herself of a very considerable income, in order to carry out the most cherished wish of her heart—that of seeing with her own eyes her husband’s intentions fulfilled.

“After much consideration it was decided that the site of the old Carmichael School was not the most eligible for the new School. The Hospital Committee, with a view to the mutual advantage of the Hospitals, of the House of Industry, and of the Carmichael School, and in order to identify them, as far as possible, with each other, proposed to place this plot of ground at our disposal. The Board of Works, with your Excellency’s sanction, confirmed the proposal of the Hospital Committee; and Mrs. Carmichael at once assented.

“For the lecturers whom I have the honour to represent today, I have only further to say that the time and labour which they have hitherto devoted to the old Carmichael School shall henceforth be devoted with increased assiduity to the new Carmichael School, and that this noble educational establishment, worthy of the name and worthy of the fame of Richard Carmichael, shall never fail from any shortcoming on their part.

“On such a theme, were I to follow the bent of my own inclination, much more might be said; but the sentiment of the Roman poet forcibly occurs to me; and my classical friends will agree with me, and my fair friends will, I trust, pardon me, for addressing you in his words:—

“Cum tot sustineas . . .
in publica commoda peccem
Si longo sermone morer tua tempora.”

His Excellency replied as follows:—Gentlemen, I have accepted most gratefully, and, indeed, with a deep sense of personal obligation, the invitation to lay the first stone of the

new Carmichael School. It would be most superfluous here, in the heart of Dublin, in the immediate neighbourhood of the noble cluster of the surrounding Hospitals, and above all, in the presence of so many of his own associates, pupils, and admirers, to recur to the professional reputation, memorable achievements, or not less signal personal qualities of Richard Carmichael. I would merely remark that there is a most appropriate and admirable consistency between the engrossing and devoted labours of his illustrious life and that parting and posthumous bequest of which, by an act of this afternoon, we are about to realise the beneficent results. In drawing an omen from the past efficiency of the Richmond Hospital or old Carmichael School, it must be most gratifying to see the inaugural work on which we are now engaged graced by the presence of Mr. Adams, who was one of the original colleagues of Mr. Carmichael in founding the primary institution, and who has trod the same path of honour and usefulness. This brief address would be, indeed, most incomplete if it made no mention of her who had the most interest in the fame of her husband, and who, showing a wiser as well as a nobler love than the Carian Queen of old, has not sought to raise over his cold remains her mausoleum in the dumb marble or lifeless statuary, but has caused him, though dead, still to speak in precious services to suffering humanity, still to live in the thanks and blessings of rescued multitudes.

The Lord-Lieutenant having advanced, aproned, and with trowel in hand, spread the mortar in true masonic style; and the stone having been lowered and adjusted, his Excellency having applied the plumb-line, etc., and declared the foundation well and truly laid, called on all present, including the ladies, to join in three hearty cheers for the "New Carmichael School of Medicine." The call having been duly honoured, one of the students present cried for three cheers for his Excellency, which was also loudly responded to. The important and interesting proceedings of the day then terminated.

The building will contain on the ground floor the entrance-hall, registrar's offices, lavatories, etc., for professors and students, anatomical theatre, students' reading-room, staircase, museum, curator's-room, porters'-rooms, and stores. On the upper story will be the dissecting-room, lecture-room for the demonstrator of anatomy, chemical lecture-room, laboratory, apparatus-room, museum of *Materia Medica*, and residents' apartments. There will be a basement under a portion of the building, containing the injecting-room, coal cellar, and ash-pit. A lift will communicate between the injecting-room, the anatomical theatre, and the demonstrator's-room, which latter adjoins the dissecting-room. The staircase, which will be stone, with an open timber roof and lantern light, will be supported by arcades resting on Bath-stone columns, with carved capitals and bases. Under the arcade will be placed the bust of the late Richard Carmichael, part of his munificent bequest to the School. The dissecting-room is placed on the upper story, in order to have the advantage of top as well as side light; the roof of this room will be open timber, with ample provision for ventilation. The principal front will be faced with punched granite ashlar, the window dressings of Caen stone; all projecting strings, cornices, and hood-moulds will be of Portland stone. The windows on this front will have semicircular heads, the discharging arches of granite and limestone alternately. The flanks and rear will be faced with black stone, with red brick window dressings, the funds at the disposal of the proprietors not allowing the granite facework to be carried round the whole building.

The architect to the building is Mr. J. E. Rogers, of Dublin, and the contractors are the well-known firm of Gilbert Cockburn and Sons, of Great Brunswick-street. The total cost will be about £6000, and the School will be handed over to the proprietors before the first day of October next.

TRACHEOTOMY IN CROUP.—Dr. Widerhofer presented two children (aged twenty-two months and three years) to the Vienna Medical Society as examples of the successful performance of tracheotomy in the last stage of croup. The operation was performed in four cases out of the twelve which occurred at St. Anne's Children's Hospital between October, 1862, and June, 1863, with two recoveries and two deaths. The indications for the operation, in his opinion, are—continued cyanosis with complete aphonia, irregular respiration, together with loss of consciousness and pulse; in a word, the stage of asphyxia.—*Wochenblatt d'Gesellsch in Wein*, No. 34, 1863.

LEGAL INTELLIGENCE.

NORTHERN CIRCUIT.

FOX v. GLEDHILL—IMPORTANT TO THE MEDICAL PROFESSION.

Mr. Price, Q.C., and Mr. Maule were for the plaintiff; Mr. Seymour, Q.C., and Mr. Kemplay for the defendant.

The plaintiff, a mechanic at Halifax, brought his action against the defendant, a Surgeon, practising at the same town, to recover damages for having wilfully neglected his duty in the exercise of his Profession, whereby the plaintiff's wife died in childbirth. On September 30 last she with her mother-in-law waited upon the defendant at his residence, and he agreed to attend upon the plaintiff's wife during her confinement. Symptoms of approaching labour were manifest on December 8, and on the morning of the following day Mrs. Fox became so rapidly worse, that her mother-in-law waited on the defendant and requested his immediate attendance. He declined, alleging as an excuse that he had to go down to the County Court, he having twenty cases to attend to, and if he were not present the judge would be angry with him. The mother-in-law returned, and when the plaintiff came home to dinner he was told the condition which his wife was in, and he instantly ran off for the defendant, who reluctantly consented to return with him to the house. The defendant then ordered the poor woman to be put to bed, some gruel to be given to her, but no brandy or any other stimulant. He told the plaintiff that his wife was "soft," and said that he should not be wanted for twenty-four hours, or perhaps three days or a week. The defendant then went away. At four o'clock next morning the plaintiff went to the defendant's house, and knocked loudly at the door. The defendant, who was in his night-dress, put his head out of the window, and the plaintiff told him to come down directly, as his presence was required immediately upon his (plaintiff's) wife. The defendant said that the woman was "soft," and if she went on in that way she would tire both him and the woman. They must be wrong in their heads to send for him in that manner. The plaintiff insisted upon the defendant seeing his wife, upon which he said if the plaintiff insisted he must go. On the road he remarked to the plaintiff that he was surprised at the women, as they did not seem to study his comfort. Before they arrived at the house they were met by the plaintiff's brother, who informed him that the poor woman was dead. The defendant then expressed his regret at what had happened, and said he wished he had attended plaintiff's wife the night previous. In justice to the defendant, it ought to be stated that he has been in practice thirty years, has never been considered a negligent man, and his character for humanity and respectability has never before been called in question.

Mr. Seymour submitted, in defence, that his client had undertaken to attend the case when in his belief his services should be required. When he first saw the woman he found that she was going on slowly in the right way, and that there was nothing at the time to excite alarm. He ascertained that the confinement could not in all probability take place within twenty-four hours, and exercising careful judgment and skill he was justified in the conduct he had pursued. Had he been present previous to death he could not have saved the woman's life. The learned counsel contended that the defendant had not been guilty of any negligence or a breach of contract, that there was no proof of the actual cause of death, and that it might have arisen from some other cause than that of labour.

The defendant was called, and he stated that when he was waited upon he told the party that he had to attend the County Court, and requested that another Medical man might be engaged. He saw the plaintiff at eight o'clock at night, and then requested him to send before ten if his services should be required. No person came, and soon after twelve he went to bed, and was not aroused by the plaintiff until nearly five o'clock next morning. He entirely denied any reluctance to attend the case, and also denied making use of the unkind remarks attributed to him. It was not improbable that disease of the heart might have caused the death of the plaintiff's wife. Verdict for the defendant.—*Yorkshire Gazette*,

THE MEDICAL PROFESSION.—From the general classification of the population enumerated in England and Wales at the census of 1851 and that of 1861, it appears that the Physicians increased from 1771 to 2385, but the Surgeons and Apothecaries decreased in number.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 31, 1864 :—

John New Moore, Moreton-in-Marsh; William Samuel Wilson, Hereford-road North, Bayswater; Eugene St. Paul Hadwen, Waterloo-road, S.; George White, Thatcham; Walter Tawell Colman, London Hospital; Philip George Philips, Westbourne-park-road; Lyttleton Frederick Osbaldeston, Hatfield, Herts; William Reuben Booth, Great Queen-street, S.W.

The following gentlemen and lady, also on the same day, passed their First Examination :—

Edward Charles Evans, King's College, London; George Arthur Brown, King's College, London; John Thomas Langley, St. Bartholomew's; Elizabeth Garrett, 22, Manchester-square.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

COULTAS, Mr. H., has been appointed Professor of Botany in the Charing-cross Hospital Medical College.

FERRIS, JOHN SPENCER, M.R.C.S. Eng., has been appointed Resident Medical Officer to the Bloomsbury Dispensary.

MOIR, JOHN, F.R.C.P., Edin., has been appointed Physician to the Royal Hospital for Sick Children, Edinburgh.

FRANCE, CHARLES R., M.D. Edin., has been elected one of the Physicians to the Plymouth Public Dispensary.

TWIGG, Dr., Jun., has been appointed Medical Officer to the Dungaunan Workhouse and Fever Hospital.

WOODMAN, WILLIAM R., M.D. St. And., has been appointed Surgeon to the N division of the Metropolitan Police.

DEATHS.

ANDERSON, Dr., at Nice, formerly of Newburgh, Scotland, on March 16.

BELL, JOHN, M.D., Edin., at Jedburgh, Scotland, on March 26, aged 34.

BEVERIDGE, JAMES H., L.R.C.S. Edin., at Tarbert, Argyleshire on March 15.

CHEETHAM, JAMES K., M.D. St. And., of Lord-street, Rochdale, at Eaton-road, Chester, on March 24.

DIXON, Dr. F. B., at St. Thomas's-square, Hackney, N.E., on April 3, aged 50.

HENDERSON, JAMES, R.N., Deputy-Inspector-General of Hospitals and Fleets, at 5, Belgrave-terrace, Lee, Kent, on March 31.

HUNT, John J., L.K.Q.P.C.I., of Danesfort, Mallow, at Bournemouth, Hants, on March 19.

JOHNSTON, FRANCIS G., M.R.C.S. Eng., at Antrim-road, Belfast, on February 18.

KING, GEORGE HENRY, M.B. Lond., at Horncastle, Lincolnshire, on March 29, aged 40.

MARLAND, RICHARD, M.D., Edin., at Blackburn, Lancashire, on March 28, aged 69.

SANDERSON, JOHN THOS., M.D., Staff-Surgeon, H.M.I. Army, at Kurrachee, Scinde, on February 15.

TAYLOR, WILLIAM BAKER, late Surgeon-General, Army Medical Board, Bombay, at the Grand Hotel du Louvre, Marsilles, on March 29, aged 61.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on Monday, April 4, Colonel Yorke, F.R.S., Vice-President, in the chair, Alexander Collie, Esq., Albert Grant, Esq., Bernard Augustus Hewitt, Esq., the Rev. Sir Edward Jodrell, Bart., M.A., F.S.A., Godfrey Lushington, Esq., Vernon Lushington, Esq., Colonel Richard Cornwallis Moore, Royal Artillery, C.B., James Stern, Esq., John Tozer, Esq., LL.D., Serjeant-at-Law, were elected Members of the Royal Institution. Dr. Leckie, Dr. Stevenson, Dr. De Leon, Colonel Salkeld, and Colonel A. Palk were admitted Members of the Royal Institution. The Secretary announced the following additions to "The Donation Fund for the Promotion of Experimental Researches :"—Samuel R. Solly, Esq. (second donation), £20; Henry Lainson, Esq., £10 10s.; Colonel Philip J. Yorke, £10; John J. Bigsby, M.D., £5 5s. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

ELECTION OF A CORRESPONDING MEMBER OF THE SOCIETY OF SURGERY OF PARIS.—Mr. J. Sampson Gangee, of Birmingham, has had the distinguished honour conferred upon him of Corresponding Member of the Society of Surgery of Paris. The diploma was accompanied by the following gratifying letter :—"Society of Surgery of Paris, Paris, March 31, 1864. My dear Colleague,—I have the honour to address you the diploma of Foreign Corresponding Member, which the Society of Surgery conferred upon you during its sitting

of January 13, 1864. The Society is happy, my dear *confrère*, to have added your name to its roll of members, and it hopes that you will have the goodness to communicate to it your new works. I am happy that it pertains to my official duties to offer you the first salutations as a new colleague, and I take this opportunity to present you the particular expression of my most distinguished consideration.—The General Secretary, Legoust, Surgeon of Val de Grâce."

BRADFORD EYE AND EAR INFIRMARY.—LAYING OF THE FOUNDATION-STONE.—On Tuesday morning, March 29, the foundation-stone of the new Infirmary, intended to be erected by the committee of the Bradford Eye and Ear Institution, was laid in Hallfield-road, by Titus Salt, Esq., of Saltaire. The following is a description of the intended building :—The new building will be nearly 100 feet long and 60 feet wide, and five stories high. It is designed in the early decorated style of Gothic art, and will group well with the new chapel and schools below it, presenting a very effective appearance from Manningham-lane. In the centre of the front is a large gable with an arcade opening into the principal entrance hall, and above this an oval window. On each side of the centre are 3 three-light windows, with shafts and carved capitals, and over them two-light windows with pointed and traceried heads and Norman gablets above. The ground floor is devoted on one side of the entrance hall to the dispensing, waiting, and consultation rooms, with separate ingress and egress for the out-door patients; and on the other side a large convalescent patients' room to the front, and the kitchen department to the rear, with has also a separate entrance. On the first floor are two male and two female patients' wards, containing 18 beds, each bed with a space of 1600 cubic feet, totally distinct from each other, with nurses' rooms, bath rooms, lifts, and every convenience. The operating room is on this floor, but totally isolated, and lighted in the most approved manner. The entire building is heated with hot water; but open fireplaces are also introduced, and attention has been paid to thorough ventilation. The total cost of the building, including furniture and land, will be £5500.

EPIDEMIOLOGICAL SOCIETY.—The annual meeting of the Society was held on the 4th inst. A report was presented by the Council, which showed that the state of the Society, both generally and financially, was most favourable; and the following office-bearers were elected for Session 1864-5 :—*President*—Gavin Milroy, M.D., F.R.C.P. *Vice-Presidents*—His Excellency the Earl of Carlisle, K.G.; the Earl of Shaftesbury, K.G.; the Right Honourable W. Cowper, M.P.; Benjamin Guy Babington, M.D., F.R.S.; Henry W. Acland, M.D., F.R.S., Regius Professor of Medicine in the University of Oxford; Alex. Bryson, M.D., F.R.S., R.N., Inspector-General of Fleets and Hospitals; Edwin Chadwick, Esq., C.B.; James Copland, M.D., F.R.S.; William Farr, M.D., F.R.S.; J. Brown Gibson, M.D., C.B., Director-General, Army Medical Department; William Jenner, M.D., Physician to the Queen; Sir J. Ranald Martin, C.B., F.R.S., Physician to the Council of India; Alex. Nisbett, M.D., R.N., Inspector-General of Fleets and Hospitals; John Simon, Esq., F.R.S., Medical Officer of the Privy Council; Sir Andrew Smith, M.D., K.C.B.; Thomas Watson, M.D., F.R.S., President of the Royal College of Physicians; William D. Chowne, M.D., F.R.C.P.; Charles Murchison, M.D., F.R.C.P. *Foreign and Colonial Secretaries*—Belgium and France: Dr. Waller Lewis; Germany and Russia: Dr. Hermann Weber and Dr. Swaine; Sweden, Norway, and Denmark: Dr. Gordon Latham, F.R.S.; Portugal and the Brazils: Dr. Bryson, R.N., F.R.S.; Egypt and Syria: Dr. Camps; East Indies: Dr. James Bird; West Indies and North America: Dr. Dickson, R.N. *Treasurer*—Wm. Camps, M.D., F.S.S., F.L.S., 40, Park-street, Grosvenor-square, W. *Secretary for the Navy*—Dr. Mackay, R.N., Secretary for the Army. *General Secretary*—J. N. Radcliffe, Esq., 32, Guildford-street, Russell-square, W.C. *Other Members of Council*—Dr. Aldis, F. G. Burge, Esq., Colonel Hough, Ernest Hart, Esq., C. F. J. Lord, Esq., Dr. Crawford, J. F. Marson, Esq., Dr. Morehead, Dr. Odling, F.R.S., Dr. Richardson, Dr. Sanderson, Dr. Seaton, Dr. Haward, and Dr. Letheby. After the election of office-bearers, Dr. Babington, on retiring from the chair, which he has occupied for thirteen years, delivered an address on the "Origin, Present Position, and Prospects of the Society."

PERCHLORIDE OF IRON AND COLLODION.—This combination constitutes a good hæmostatic in the case of cuts, leech-bites, etc. One part of the crystallised perchloride of iron is to be dissolved in six parts of collodion; but this

must be done very gradually, or the heat which is produced will cause the ebullition of the collodion. The mixture is a yellowish-red, limpid fluid, which, when applied to the skin, gives rise to a small yellow pellicle possessed of great elasticity.—*Reine Med.*, Nov. 15.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

H. G.—The "Trichina Mirror" is published by Denicke, of Leipzig. Dr. Walker's paper is in type, and shall appear, if possible, next week. Mr. R. Oke Clark.—Each fluid ounce of the Extractum Ergotæ Liquidum is equal to one ounce by weight of ergot.

A disgusting book of the Manly Vigour class, entitled "Short Account of Sir Astley Cooper's Vital Restorative," bears on the title-page the name of Messrs. Harvey and Co., Consulting Surgeons, (registered under the new Medical Act), 44, Weymouth-street. Of course, there is no such name and direction on the Register. Surely this is a case in which the Medical Council are bound to interfere. The Act clearly gives them power to do so.

A Fellow—We believe the rent paid both by the Pathological and Obstetrical Societies to be extremely moderate, and that neither could get elsewhere anything like the advantages for double the money. Besides, it is a great convenience to the members of the Pathological or Obstetrical Societies who also belong to the Medico-Chirurgical. Gentlemen may differ about the value of everything on earth. What is objected to is not the amount, but the determination which was supposed or alleged to exist, to screw up the tenants and exact a hard bargain. If the Medico-Chirurgical were really to act the gripping landlord, it would be *infra dig.*, no matter whether the sum claimed be great or little. All such arrangements should be on a friendly and gentlemanly footing, not on a commercial footing. We believe the best feeling exists on both sides, and that the matter should be let drop. But we repudiate the notion that the Medico-Chirurgical can consistently attempt to treat these younger societies as mere lodgers, or to make a profit out of them, and to argue that it is to their interest to stay, and, therefore, that the screw may be put on. We look on the present arrangement as equitable on the part of the landlord and advantageous to the tenants. The *British Medical Journal* is true to its trade character in this as in most things, but the Profession will not tolerate a large infusion of the commercial element.

Errata.—"On Trichina Disease," p. 362, line 30 from the bottom, read, "the male trichinae," instead of "those trichinae." By an error of the press, a comma, instead of a full stop, was placed after the clause "Nestor of British Surgery," in the article "Topics of the Day," which appeared in our last week's number, p. 367.

CHRONIC ULCERATION OF THE TONGUE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Could any of your numerous readers assist me in the treatment of the following case? P. T. has been troubled with small ulcers appearing on and under his tongue and fances, in successive groups; and as one lot disappears, another begins to show itself. He says they commenced five years ago, and he cannot account for them; he never had any eruption of any kind on his skin, neither was he ever salivated. So far as I can make out, they have not originated from syphilis. I am, &c. H. M. S.

THE STATISTICS OF MITRAL DISEASE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Have you any precise statistics by which you can answer the following question:—

Which is the most frequent pathological condition in mitral disease?—*i.e.*, Incompetency—1st, Regurgitant disease without obstruction; 2, regurgitant with obstruction. Simple obstruction—3, Obstruction without regurgitation.

My experience is that although the regurgitant murmur is the sound most frequently heard, it is also the sound most easily heard. The presystolic sound which should be heard in obstruction is sometimes not heard, and when heard at all, there is generally a difficulty in hearing it; but from a number of cases I have had the opportunity of examining after death, I have found what is commonly called the "button-hole" contraction the most frequent of all, and certainly incompetency of the valve alone the least frequent. I am, &c.

Stafford, April 4.

HENRY DAY, M.D.

THE ARMY MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference more especially to the letter of "Truth" in your Number of the 26th inst., will you kindly permit me to refer to the N.B. of a letter from "Quarter Century," in the *Medical Times and Gazette* of March 31, 1860, page 325, a copy of which I transcribe:—

March (a), 1860, N.B.—"The late regulations, so far as the wants of regimental Medical officers are concerned, in our view were carried in a wrong direction, taking away what semblance of substantial rank they had, and making it like that of civilians, a mere mark of length of service. To pay Medical officers as really civilians is quite out of the question, nor is it desirable, if the finances of the country even admitted of it. It is only by substantial rank and military honours," etc., etc.

Nor can we agree with "Truth," that the army should, in any way, become a school and convenience, but that having made, it should also have the benefit of the ripened experience of its Medical officers,

I am, &c.,

QUARTER CENTURY.

(a) This was when the new regulations seemed to be giving so great satisfaction, and it had been well they had never been so altered, and questions raised. The "weary siller" blinded the eyes.—Q. C.

THE LIVERPOOL MEDICAL SOCIETY ON THE BIRKENHEAD CASE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am directed to ask the favour of your insertion of the enclosed resolution, passed at a meeting of the Liverpool Medical Society, held on the 31st ult. I am, &c. HENRY LOWNDES, Hon. Sec. 1, Catherine-street, Liverpool, April 1.

Resolved—"That the Medical Society of Liverpool regrets that sudden and dangerous accidents and illnesses occasionally occur among the poor of large towns, to meet which the present arrangements of the Poor-law Board and of the Medical charities are inadequate. That the public has no right to expect that the members of the Medical Profession shall, *volentes volentes*, be burthened with gratuitous attendance upon such cases, and insulted at inquests for declining to attend strangers. That it is the duty of Boards of Health or of the police to secure Medical attendance on such cases, by paying, out of the public purse, fees for all such urgent cases as the police officer on the beat may report as requiring immediate attendance."

POTASSIO-TARTRATE OF IRON IN SYPHILIS—AMYLENE AS AN ANÆSTHETIC.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In Braithwaite's "Retrospect of Medicine," vol. 35, p. 234, Dr. Behrend, of Liverpool, after detailing some interesting cases of primary syphilis, successfully treated with the potassio-tartrate of iron, stated that he was not then prepared to speak of its efficacy in secondary syphilis, but that he had several cases at the time under treatment, the results of which he would make known as soon as they were arrived at. May I ask have those results been published since, and have they been as successful in the secondary as in the primary form of the disease?

In p. 356 also of the same volume, it is stated that the vapour of amylene in midwifery was then upon trial at the various London Hospitals, but that a positive opinion could not at that time be yet pronounced on its merits. I should be glad if any of your readers would inform me of the result to which those experiments have conducted, and the opinion now entertained by the Profession in reference to the use of amylene. At the page indicated it is stated—"Dr. Tyler Smith thinks the advantages, as compared with chloroform, in midwifery, would seem to be the suddenness of its influence and its asserted safety, and the rapid disappearance of the insensibility after the amylene is withdrawn." If those advantages, with the others described by Dr. Smith in the article quoted, have been experienced also by other Practitioners, I should suppose the amylene to be at present in extensive use, and I shall feel obliged by whatever information you can afford on this subject.

April 4.

I am, &c.

B. W. C.

[* * Since the fatal case which occurred in Dr. Snow's practice, amylene has been very seldom used as an anæsthetic in this country.—ED.]

THE ARMY & CIVIL PRACTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I perceive that some of the Assistant-Surgeons of the Army are getting dissatisfied with their position—a thing which is far from new—but some are going the length of resigning their post and coming to swell the already crowded ranks of civil practice. Now these, like other Government appointments, are not easily obtained; one might say unobtainable without that social or political influence commonly called "friends at court," and this notwithstanding the competitive examinations. Yet things are not pleasant enough for the holders of them, who appear, some of them, to have taken to the idea that there are no disagreeables in civil life—no hope deferred nor trying delays, and have rushed to the ills they know not of.

In your Number of this week there is a letter from one of these resigned, but discontented, individuals. I take the liberty to inform him that if it were as easy to get into the Army on leaving private practice as it is to join the civilians, there would soon be practices thrown up and assistances vacated in numbers sufficient to supply the wants of half a dozen armies; that men without influential connexions have to seek practice when and where they can, and that it is a piece of unsavoury cant and a gross calumny to insinuate that they are deficient in morals or attainments if they are not in satisfactory practices soon after 25.

Surely the morality of civil life will bear comparison with anything to be found in the Army at any age, and it is certainly quite new to see red coats and white chokers combined. Moreover, it is common enough to meet with men still attending lectures after they have passed 25, or, in some cases, even have attained 30; besides, there are others obliged to retain the post of assistant in civil practice, and does he think any of these get 10s. a day and quarters, or does he mean to tell us that money and influence of the kind I have referred to represent just so much brains and quality? He will, perhaps, tell us how he and so many others came to shirk the difficulties and uncertainties of civil life at the age of 25. Was he not himself afraid of being a failure where the merits of every one are severely scrutinised and criticised, often with reckless disregard to justice?

Sunderland, March 17.

I am, &c.

AINE.

* * We can inform our correspondent that at present Assistant-Surgeoncies are most easily obtainable. There are, we hear, now about a hundred vacancies.

HOW TO BECOME STOUT.

By C. W. STEVENS, Esq., A.B. Cantab., B.Sc.

I am uncertain whether I have met with more obese persons who were anxious to reduce their redundant corpulence than thin individuals who wished to become stout. As I have fortunately made some encouraging experiments, I will make a few suggestions which have appeared the most useful. Mr. Banting has so successfully come to the rescue of the first class that I shall allude only to the second.

Dr. Prout says justly, "In an individual unnaturally fat or lean an error exists somewhere, and either he inherits a propensity to disease or he is producing it for himself." As extreme examples, I will mention the "Living Skeleton," and a young woman whom I saw in America, and who weighed 600 lbs. ! Since the causes of these morbid conditions (whether malignant disease, dyspeptic, or other functional organic disorder) are too numerous to be specified here, I shall omit them.

1st. *Diet.*—In regard to bread, I wish particularly to recommend Indian corn, or maize, which is richer in oil than any other cereal. It should be used in the form of superfine yellow meal, of universal use in America. Made into loaves and sweetened with treacle, or into stir-about or hasty pudding, it is delicious, and its fattening properties are very important. Cod liver-oil, which has recently been largely given in France to fatten

domestic animals, and with brilliant success, should be daily taken. If used with equal parts of Liq. Calcis, or if a drop of Ol Amygdalæ be added to two ounces, it is not disagreeable.

Breakfast.—Bacon, bread and butter, or, instead of butter, fresh olive oil, cocoa or chocolate, omelets, eggs, olives.

Dinner.—Turtle soup, liver of the cod, roast pork or sucking pig, brains of birds, fat roast mutton, peas, carrots, rice, suet pudding, figs, nuts, wine or stout, but no spirits nor spices.

Tea and Supper.—Indian meal, bread and butter, or hasty pudding, with milk, wine or stout, or cocoa, but no tea, nor spirits, nor spices.

2nd. *General Habits.*—Early retiring to rest and long sleep are necessary. I recently read in a hydropathic work a serious anecdote of a jockey who, by training, reduced himself from fourteen to ten stone. After the race he slept for sixteen hours uninterruptedly, and on waking he weighed the original fourteen stone! *Credat Judæus non ego.* It is certain that in sleep the metamorphosis of tissues is very small, and the powers of mind and body are invigorated. Excess in venery should be avoided; nay, "*Venere si fieri potest abstinendum est.*" There should be daily moderate exercise, but not to produce perspiration; for this quickly reduces weight. Smoking or chewing tobacco should be abandoned. Mr. Headland has adduced the use of tobacco as the cause of the lanky, thin appearance of many of the Americans. It would be easy to disprove this by remarking that Mexicans, Spaniards, and Germans smoke as much, if not more, than Americans; and, secondly, that it is the dietetic habits of the Americans which produce this. It is certain, however, that excessive expectoration weakens digestion and reduces weight.

POOR-LAW MEDICAL REFORM ASSOCIATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Be good enough to allow me space to inform the Poor-law Medical officers that, on March 30, I forwarded to the Select Committee on Poor Relief a pamphlet containing a summary of the principal points of the evidence relating to the Medical relief of the poor, which I had the honour of submitting to them last February. I did so in consequence of observing in *Knight's Official Advertiser* that "it is understood the Committee have determined not to examine any further witnesses, and are now considering their report." Having, therefore, great fear my evidence might not be taken into consideration, I adopted the simple course of sending a condensed report of it to each member of the Select Committee, thinking it just possible that during the Easter recess he might have leisure to read it.

Mr. Cane, in his "statement" to the Committee, took my evidence and replied to it almost *seriatim*. I have adopted a similar course with his "statement," and, in like manner, have given a rejoinder, which I hope will entirely refute his plausible, but erroneous, conclusions.

I regret the low state of the finances would not permit me to print a sufficient number of copies for all the Poor-law Medical officers; one, however, I have sent to each of the subscribers to the Association for this year, and, so far as the remaining part of the 200 copies will go, I shall be glad to forward them to those who may send their subscriptions. I understand it is probable the Committee will shortly make their report to Parliament. I sincerely trust it may be favourable to our views, but whether it is so or not, I feel convinced that we have proved our case, and judgment ought to be given in our favour.

Since March 20, I have received the following subscriptions:—Morris, N. T., Wigan, £1; La Fargue, P. A., Meriden, 5s.; Prowse, W., Amersham, 2s.; Fairthorne, G., Amersham, 2s.; Brickwell, B. A., Amersham, 2s.; Barker, Dr., Aldershot, 5s.; Odell, T., Hadfield, 10s. 6d.; Dowling, J. H., Cerne, 5s.; Kendall, T. M., Freebridge, Lynn, 10s.; Harper, T., Plymouth, 2s. 6d.; Stevens, J. N., Plymouth, 2s. 6d.; Hicks, J. H., Plymouth, 2s. 6d.; Dale, W., Plymouth, 2s. 6d.; May, J. H. S., Plymouth, 2s. 6d.; Kingdon, A. S., Bideford, 10s.; Pridham, T. L., Bideford, 5s.; Fernie, A., Barnstaple, 10s.; Berryman, J. P., Gt. Austell, 6s.; Irving, W. B., Newark, 5s.; Harday, G., Rugby, 5s.; Smith, Dr., Weymouth, £1 1s.; Smeathman, G. T., Wycombe, 5s.; Wood, H. S., Tavistock, 5s.; Young, W. B., Reading, 10s.; Walford, T. L., Reading, 5s. 8d.; Workman, F., Reading, 5s.; Dodgson, H., Cockermouth, 5s.; Bell, H., Cockermouth, 5s.; Giles, H., Witham, £1; Moore, E., Bethnal-green, 2s. 6d. I am, &c.

12, Royal-terrace, Weymouth, April 2.

RICHARD GRIFFIN.

INSTRUMENT FOR DILATING THE CERVIX UTERI.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to mention in your columns the following facts in connexion with the above instrument:—Some little time since, during my residence in the Lock Hospital as House-Surgeon, I was sitting with Mr. Walter Coulson in his study, and while conversing upon the subject of diseases of the urinary and urino-generative system in the female, Mr. Coulson said to me—at the same time that he showed me the instruments—"It has occurred to me that we might use this"—referring to Holt's urethral dilator—"for the purpose of dilating the cervix uteri." I replied that the objection which would be at once urged against it would be, it is dangerous because of the amount of bruising or even of laceration that might be, or indeed would be, inflicted upon the contracted or rigid tissues in order to effect our object; and, besides, that the uterotomy, either of Dr. Greenhalgh or Dr. Simpson, was a very efficient and safe instrument.

I added, that I thought if one adopted this method of forcible dilatation the urethral dilator of Mr. Henry Thompson, of University College Hospital, was very much to be preferred to the instrument devised by Mr. Holt, since we might be enabled to ascertain the exact seat of constriction, and so act upon it alone or chiefly. I had not seen, or even known, that Mr. Thomson had devised and used an instrument different from Mr. Holt (because I had never seen it used in Dublin, Mr. Holt's being employed, or some modification of it,) until I saw Mr. Thomson himself operate at the University Hospital upon a patient suffering from an old relapsing stricture. When Mr. Thomson, with his usual courtesy, was explaining the instrument and its working to me, it occurred to me that the same or a modification of it might be admirably adapted to cases of narrowed cervix, and might in such be used with immense advantage. I did not know that Mr. Ellis had been using an instrument of this kind for some time, and in such cases, nor that Dr. Priestly had devised one on a similar principle and with a similar object.

On my return from University College Hospital, I called upon Mr. Pratt, in Oxford-street, that I might more minutely examine the urethral dilator of Mr. Thomson, with a view to ascertain if it could be employed with safety as a uterine dilator. I was satisfied in my own mind that it might be used in such a way, and with perfect safety to the patient. The correctness of my inferences has been attested by Dr. Priestly and Mr. Ellis.

Of this I am confident, that Mr. Coulson was likewise not aware that this kind of instrument had been used or proposed when it had suggested itself to him. In conclusion, I would merely say that my conversation with Mr. Coulson upon this subject took place after I had seen Mr. Thomson's instrument for the first time, and after it had occurred to me that such an instrument might be applied for dilating the cervix uteri.

Since Mr. Ellis has been acquainted with it now for some time, and has in many cases tested its value, I must express regret that he has not brought it under the notice of the Profession before the present occasion. It is, for the sake of science and for the sake of our suffering fellow creatures, to be very much regretted, that talents are buried in napkins and lights hidden in bushels—that inventions, no matter what they may be, or in whatever department of science—that discoveries in medicines, in their therapeutic properties or otherwise—discoveries in the symptomatology of diseases dependent upon causes known or unknown, in the application of certain drugs or remedial agents for the successful combating of those symptoms as they arise—are not at once given out for the public weal or submitted by the discoverers or inventors to the test of general use and the experience of others than themselves.

I am, &c.

G. DE GORREQUER GRIFFITH, late House-Surgeon at the Hospital for Diseases of Women and at the Lock Hospital, Claverton-terrace, St. George's-square, April, 1864.

AFRICAN-AID SOCIETY.—AFRICAN SURGEONS FOR AFRICA.

The African-Aid Society addressed the following letter to the Right Honourable Earl de Grey and Ripon, President of the Educational Committee, etc., under date 1st of February, 1864:—

My Lord,—The perfect immunity from yellow fever enjoyed by the native-born African, when this destructive epidemic is sweeping off the Europeans on the West Coast of Africa, has long been viewed by this Society as worthy of particular regard in questions of British Administration in her Majesty's colonies, forts, and settlements on that Coast.

It seems particularly desirable that when an epidemic of so virulent and fatal a nature is raging, there should be no lack of Medical assistance, as there unfortunately has often been in consequence of the deaths of European Surgeons from yellow fever.

It having been fully established that native Africans are capable, if properly educated, of attaining such a degree of efficiency in Surgery and medicine as entitles them to, and secures for them, the confidence and respect, not only of educated people of colour, but of eminent Europeans on the West Coast, the Society take the liberty of expressing their opinion that there can be no doubt as to the advisability and necessity of an adequate supply of properly qualified native African Surgeons and Physicians for service on the West Coast, by which the certainty of Medical attendance for the sick at periods of violent epidemics, as well as at all other times, will be secured.

The Society having in view the many loathsome and destructive maladies which assist in depopulating Africa, and increasing the misery of its people, cannot avoid the further expression of their opinion that it is the duty of this Christian country, on the ground of common humanity alone, if on no other, to endeavour to qualify many natives of Africa in medicine and Surgery, to supply the means of mitigating and removing much of that misery.

The Society is aware that it has been suggested to Her Majesty's Government that a Medical school for the educated natives of various parts of Africa should be established by Her Majesty's Government at Sierra Leone, in a great degree, if not entirely, under the direction and superintendence of competent Medical men—natives of Africa—who have passed with success through the Medical schools in Great Britain, and have since given proofs of efficiency in Her Majesty's service in Africa.

The Society has the honour to solicit for that suggestion the full and impartial consideration which Her Majesty's Government must naturally be disposed to give to a matter connected with an economy of valuable European life in Africa—an ultimate economy of money in the Medical department of Her Majesty's service in Africa—and an effective application of the inestimable benefits of Medical and Surgical skill among the suffering multitudes of Africa, who are known to appreciate this result of our civilisation whenever it is brought within their reach.

On behalf of the Council of the African-Aid Society,—I have the honour to remain, etc.—*African Times*.

COMMUNICATIONS have been received from—

Mr. JAMES BEAVAN; Dr. E. E. DAY; Mr. RICHARD GRIFFIN; ANONYMOUS; Dr. E. BRONNER; Mr. CHRISTOPHER HEATH; Mr. A. RIANT; APOTHECARIES' HALL; Mr. HENRY LOWNDES; Professor HAUGHTON; MEDICAL SOCIETY OF LONDON; Mr. WALTER BERNARD; Mr. HENRY THOMPSON; N. G.; QUARTER CENTURY; Dr. E. GRIFFITH; B. W. C.; Dr. R. S. Sisson; Dr. THOMAS J. WALKER; Mr. ROBERT OKE CLARK; ETHNOLOGICAL SOCIETY OF LONDON; Mr. JOHN S. FERRIS; Dr. J. S. BRISTOWE; H. M. S.

BOOKS RECEIVED.

A Manual of Diet and Regimen for Physician and Patient. By Horace Dobell, M.D. London: John Churchill and Sons. 1864.

* * A very well meaning attempt to construct diet tables on a scientific principle. The quantity of nitrogen, carbon, &c., required by the average healthy man is calculated, and the equivalent quantities of meat, bread, butter, potatoes, etc., etc., are arranged in diet tables, each containing enough for a day's consumption. There are also lists of articles, copies of which, we suppose, are to be given to the patient with the word "no" written against those prohibited;—lists also of wines, etc., with the quantity of alcohol contained, and of various articles with the percentage of plastic, respiratory, etc., etc. Very pretty, and there we stop. It is well known that the average man does not exist—no more does the average dinner—a man may require half as much again on Monday as on Tuesday. Still less can an average wine be talked of. When our author speaks of Roussillon, Sherry, Cape Madeira, South African port, and Port, and of their contents in alcohol, and gives rules for prescribing those and other fermented liquors by the average quantity of "absolute alcohol" they contain, we can only shrug our shoulders, and bless ourselves that we don't often dine with a man who estimates his wine by such a standard. The diet tables have a very workhouse-look. The whole thing is unpractical.

Excision of the Scapula. By James Syme, F.R.S.E. Edinburgh: Edmonston and Douglas. 1864. Pp. 35. Plate and Woodcuts.

Mr. Syme lays it down that the entire scapula, either alone, or together with the arm, may be removed without much difficulty or loss of blood; 2. That the wound thus inflicted may heal quickly and soundly; 3. That the arm if preserved may be strong and useful; therefore, that excision of the scapula may be recognised as a legitimate and established procedure of Surgery. Case 1.—Old woman of 70; osteo-sarcoma of scapula, size of cocoonut; removal; recovery virtually *quoad* operation; death on sixtieth day from debility. Case 2.—Man aged 43; head of humerus removed for osteo-sarcoma on November 14, 1860; recovery; tumour of scapula appeared in 1861, removed November, 1862; recovered in six weeks. Case 3.—Man aged 40; head of humerus removed September 16, 1860; tumour of scapula in 1863; removed successfully.

On Paralysis, Neuralgia, and other Affections of the Nervous System, and their Successful Treatment by Galvanisation and Faradisation. By Julius Althaus, M.D., etc. Third Edition. London: Trübner. 1864. Pp. 236.

This is a gentlemanly, readable work, and not chargeable with the sin of ignoring other remedies, or of unduly exalting the virtues of galvanism. It contains much that the Practitioner ought to know before he uses or recommends this agent.

The American Journal of Medical Sciences. January, 1864. Philadelphia: Blanchard and Lea.

Contains some very good original articles, including a narration of a case of hypertrophied cervix uteri of twenty-six years' standing, with prolapse relieved by a very carefully devised and complicated operation; good histories of epidemic fevers and influenza; ease of amputation at the hip-joint; remarks on wounds of arteries, aneurism, etc., besides reviews, notices, etc., which render this journal an admirable quarterly summary of medicine, as it presents itself to our transatlantic friends.

Tertiary Syphilis (third series); the Growth, Progress, and Present State of Knowledge of Nervous Syphilitic Diseases. By Thomas Reade, M.B., etc., Belfast. Dublin: John Falconer. 1863.

This is a reprint from the *Dublin Quarterly Journal of Medical Science*, containing further details and references on this important subject.

Revista de Sanidad Militar Española y Extranjera. Num. 3 and 4. Madrid, 1864.

The former of these numbers contains a clinical review of the Hospitals of London, with details of a case of ligature of the axillary artery for subclavian aneurism by Mr. Canton.

The Cultivation of Medical Science and Art: an Oration delivered before the Members of the Hunterian Society on February 10, 1864. By John Jackson, M.R.C.S.E., etc. London. 1864.

A clear and sensible criticism of several current Medical theories printed at the request of the council of a practical and useful Society.

Montpellier Medical. Janvier—Fevrier, 1864. Montpellier: Boehm et Fils.

This excellent journal, from which we have already largely borrowed, retains its high character, and in interest exceeds some similar Metropolitan French productions. In the January Number, articles on Yellow and Typhoid Fever, on Viability, and on the Chemistry of Gouty Deposits; and in the February issue, a valuable memoir on the Health of Verdigrismakers, deserve attentive examination.

Systems of Admission at Hospitals: A Plea for Reform. Being a Selection from a Series of Articles reprinted (by permission) from the *Birmingham Daily Post*. With a Preface. Birmingham: Printed by B. Hall, 71, High-street. 1864. Price 3d.

Worth twenty times the money. This pamphlet ought to be circulated amongst all persons who have taken on themselves the responsibility of becoming members of the Committee or Governing Board of any Hospital. The writer pleads for a *free* system of admission, instead of a *privileged* system; in other words, that the benefits of the charity ought to go to the persons most deserving or requiring relief—not to those who are selected by subscribers. Common Hospitals are not charities. When a man has given a subscription to a charity, his property in it ceases; it belongs to the poor. But common Hospitals are joint-stock institutions, in which the subscriber retains his property in his subscription, and exacts the value of it, often very much more. Would that this clear logical paper were well read!

Medical Ethics and Etiquette: a Lecture delivered in Queen's College, Belfast. By John C. Ferguson, A.M., M.B. Belfast: A. Mayne. 1864.

A thoroughly high-minded and high-principled production. All the common circumstances under which Medical men can show good conduct or bad when brought into contact with the public or with each other are described and commented on as might be expected from a thorough Professional gentleman.

British Journal of Dental Science. January, 1864. London: John Churchill and Sons.

This monthly journal deals principally with matters of special interest to its professed readers. But in the Hospital case-book will be found facts of general interest. In the present Number, for instance, is a case of fractured lower jaw; one of tetanus, said to have resulted from operations on the teeth; one of hare-lip; and one of excision of the jaw for fibrous tumour of the antrum.

A Toxicological Chart; exhibiting at One View the Symptoms, Treatment, and Modes of Detecting the various Poisons, Mineral, Vegetable, and Animal. 12th Edition. Revised by W. Stowe, M.R.C.S.E. London: John Churchill and Sons. 1864.

A useful ornament for the Surgery wall. We marvel that the author did not mention ardent spirits, or ammonia in full doses, or both, in the treatment of snake bites.

A Dictionary of Chemistry and the Allied Branches of other Sciences. Founded on that of the late Dr. Ure. By Henry Watts, B.A., F.C.S. Part 13.—Glucose—Gytge. London: Longman, Green, Longman, Roberts, and Green. 1864.

Homes without Hands; being an Account of the Habitations constructed by various Animals. By the Rev. J. G. Wood, M.A., F.L.S., Author of the *Illustrated Natural History*. Part 3. London: Longman, Green, Longman, Roberts, and Green.

The Edinburgh Medical Journal. March, 1864. Edinburgh: Oliver and Boyd.

Observations on some New Remedies (made in the Edinburgh Royal Infirmary). By James Watson, M.D. Edin., L.R.C.S.E. Edinburgh: Oliver and Boyd. 1864.

A System of Surgery. By James Miller, F.R.S.E., F.R.C.S.E. Edinburgh: A. and C. Black. 1864. Pp. 884.

A fusion of the author's former works into one complete system.

An Elementary Text-book of the Microscope. By J. W. Griffith, M.D. F.L.S. London: J. Van Voorst. 1864.

The Stream of Life on our Globe: its Archives, Traditions, and Laws. By J. L. Milton, M.R.C.S. London: R. Hardwicke. 1864.

Advice to a Mother on the Management of her Offspring, and on the Treatment of some of their more urgent Diseases. By Pye Henry Chavasse, F.R.C.S. Seventh Edition. London: John Churchill and Sons. 1864.

The Edinburgh Veterinary Review. No. 47. March, 1864. Edinburgh: Macleachlan and Stewart.

The Englishwoman's Journal. No. 73. March, 1864. Published by the Englishwoman's Journal Company, 19, Langham-place, Regent-st., W.

British Journal of Dental Science. March, 1864. London: John Churchill and Sons.

Pulvis Jacobi ver, Newbery's,

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warrington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

TOWLE'S CHLORODYNE.

OF KNOWN COMPOSITION.

For Formula, &c., see back Numbers.

Extract of Letter from Dr. C. KIDD (Author of Standard Works on Chloroform).—"SIR,— . . . Of the value of Chloroform given internally I have no doubt; it appears to me in that form an anodyne, *sui generis*, that no other anodyne can approach. I have resolutely opposed the use of secret compounds of chloroform, and in every way I can encourage the use of the 'Chlorodyne' (if we must have it at all) that is made by you, as you state that its composition is known. Many Medical men think with me, and recommend your compound, but will never prescribe a secret remedy.—CHAS. KIDD, M.D.—Sackville-street, Piccadilly, London, April, 1862.—To Mr A. P. Towle."

Extract of Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J. P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession.—To Mr. A. P. Towle."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; 4 oz., 4s.; and 8 oz., 8s.

SOLE MANUFACTURER—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

LIQ. CHLOROFORMI CO. (TOWLE'S).

This preparation is identical with "Towle's Chlorodyne," *sine* Ol. Menth. Pip. (dose 5 to 20 minims, as in Chlorodyne).

The Proprietor having for some time past, at the request of several members of the Medical Profession, made a preparation of Chlorodyne without peppermint, has lately, on account of the frequency of these demands, prepared the same for more general use, under the designation of LIQUOR CHLOROFORMI Co., which, possessing the Medical properties of Chlorodyne, may be prescribed in all cases where the Ol. Menth. Pip. is disapproved, and overcome the objection so generally felt to the use of the term "Chlorodyne."

May be obtained, as an introduction, from the following Wholesale Houses, in 2 and 4 oz. bottles, at 2s. 6d. and 4s. each:—London: Barclay and Sons, 95, Farringdon-street. Birmingham: Southall, Son, and Dymond. Liverpool: Clay, Dod, and Case. Edinburgh: Duncan, Flockhart, and Co. Glasgow: The Apothecaries' Company. Dublin: Bewley, Hamilton, and Co. Manchester: Jas. Woolley; and the

Proprietor—A. P. TOWLE, 99, STOCKPORT-ROAD, MANCHESTER.

ORIGINAL LECTURES.

LECTURES
ON THE CONSERVATION OF ENERGY.

By Professor HELMHOLTZ.

DELIVERED AT
The Royal Institution
ON APRIL 7, 1864.

LECTURE II.

LADIES AND GENTLEMEN,—In my first Lecture I tried to explain the views which have been developed during the last twenty years by physical researches concerning the general characteristic nature of the physical forces. We have seen that all the natural forces are of such a kind that, when they produce any change or any alteration, when they produce motion, their faculty of acting is destroyed by their action itself, that they cannot act without diminishing or losing the faculty of new action. We have seen that in these cases, if one of the natural forces in this way loses its energy, other forces regain a certain amount of energy; that they are brought into new conditions where they are able to act, and that amount of energy, which is lost on one side, is gained on the other side; so that the whole quantity of energy, the whole sum taken altogether, remains the same; that the energy alters only in its form, and is brought into a new aspect; but that it is neither lost nor increased in any change throughout the whole of inorganic nature. We infer from this that it is impossible to gain energy for our own purposes, for our machines, without taking it from the great store of energy which is contained in the universe; and we infer from the same statements, that it is impossible that energy should be destroyed; that this store of energy which is contained in the universe must remain the same through all eternity, as long as the natural laws which we know at present are valid; and that, therefore, motion and the faculty to produce new motion cannot be lost; that motion and activity in the universe must be everlasting, but they may be lost for single parts of the universe, for single celestial bodies, but then their equivalents must be found in other parts of the universe. Now, the energy which we want to have for our own purposes, and the energy which is working on the surface of our earth, must be taken from the great store of energy contained in the universe; and if we are willing to look into the origin of all these kinds of energy, we must look to this great store, and, therefore, we must look at first to the energy which is stored up in the celestial bodies. We have already seen that our water-mills must be driven by water coming from the mountains. It is lifted to the mountains by the heat of the sun, which vaporises the water of the ocean. We have seen that our steam-engines must be kept going by the use of fuel, and this fuel is either the result of present vegetation, or it has been produced a long time ago by vegetation, the remains of which are deposited in the layers of coal. All the motion of an animal body can only be kept up by the use of food. Food is taken either from animals which eat plants, or it is taken immediately from the vegetable kingdom, and, therefore, it can be produced only by the action of solar rays, which are a necessary condition for the growing of plants.

You see, therefore, that all these kinds of motion have their last origin in the rays of the sun; and, therefore, to go back to the origin of all the energy which is working on the earth, we must go back into the spaces of the universe and look to the stores of energy contained in the sun and planets. We have, at first, the motion of the planets; that is a store of mechanical power. The planets move around the sun under the influence and attraction of the force of gravitation which acts between the sun and the planets, and under the influence of the original velocity which is given to the planets, and by which they are moving in a circular way. To explain these conditions, I have here a sphere which represents the sun, and here a smaller sphere fastened on a thread; and you see this sphere, if I draw it away for a short distance, is attracted to the centre of the sun. It is not attracted by the sphere, but it is attracted, at least, to it; and to whatever place I may bring it, it falls down to the sphere when I let it go. You see, then, there is a force attracting this little sphere to the centre of the great sphere. If I impart a tangential velocity to this little sphere, it goes round the greater sphere in the same way, under the action of similar forces, as planets go round the sun;

and it will go on a long time in a circular movement. You see, to bring it into this sort of motion, I am obliged to draw it from the greater sphere against the force which strives to move it to the centre of the greater sphere; therefore, we want at first an amount of energy capable of removing the smaller sphere against the attraction of the greater sphere. Then I will give to the smaller sphere a certain velocity, the effect of which is that the smaller sphere cannot fall down upon the greater sphere. It is now going on by tangential velocity in a circle. In this way the little sphere can keep its energy a long time. Its energy is destroyed at last by the resistance of the air, a resistance exerted as well to the sphere itself as to the motion of the thread by which the little sphere is fastened; so you will see the little sphere comes nearer and nearer to the central body in proportion as it loses its energy. Planets moving through the interplanetary space, which can be considered very nearly as vacuum, where no resistance is ever offered to their motion, go on for ever and ever without any retardation of their motion; and you see, that if the motion of the planets is of such a kind, that after every rotation they return to the same place, nothing is lost of their energy. They keep their energy as long as they are going in this way round the sun, and as long as their distance from the sun is not diminished. Astronomical observations, as far as their accuracy reaches at present, show that the motion of the planets, indeed, is not diminished in any sensible degree by the continuance of their motion; but that they go on at the same distance from the sun and with the same velocity, and go round the sun in the same time as they have gone through so many centuries during which they have been observed by men. If any amount of energy of this mechanical power, which drives the planets onwards, should be lost, the planets would approach to the sun and at last fall into it. This is the first part of the energy contained in the solar system, and we shall speak afterwards of the possibility that this energy may be lost and changed into another form. Then we have another great store of energy contained in the heat of the sun. The sun gives out continuously rays of heat and rays of light, which radiate through space to our earth and other planets; and those of them which are not retained by meeting a solid body, a planet, go on and on into the vast spaces of the universe. The quantity of heat which is given out by the sun is really enormous. We shall see hereafter how great this quantity is. Now, the opinions about the nature of the sun have been very much altered under the influence of our knowledge of the law of conservation of energy; and therefore I am obliged to give a more especial description of our notions about the nature of the sun. You know that by astronomical observations we have found out that the sun is a sphere of very great diameter and very great volume. Its diameter is nearly 900,000 English miles, and its distance from the earth nearly 95,000,000 miles. Its diameter is so great that if you suppose the earth to be put into the centre of the sun, the sun itself being like a hollow sphere, and the moon going about the earth, there would be a space of more than 200,000 miles around the orbit of the moon lying all interior to the surface of the sun. Therefore we have there an immense mass and volume; and corresponding to this great mass, also the attraction of heavy masses to the centre of the sun is very great. The force of gravity on the surface of the sun must be nearly twenty-eight times greater than the same force on the surface of our earth. But in spite of this enormous increase of the force of gravity, which strives to draw the matter of the sun to its centre, the density of the sun is very small: it is not much greater than the density of water, and it is only a quarter of the density of the earth, although, as we shall see immediately, it is very probable that the sun is composed of the same substances as the earth. There must be a cause that so enormous a body as the sun can remain in such a small degree of density in spite of the attractions to the centre of the sun; and I think we must find this cause in the enormous temperature of the sun. As for the outside of the sun, we find that it is of a brilliant luminosity, and when we look at it through blacked plates of glass, we see that it is not quite of an equal aspect, but that it has a more mottled appearance, and that there are darker spots on its surface—the so-called solar spots. I will show you a beautiful photograph of the solar spots made by Mr. Warren de la Rue, projected by the electric light on a screen. These spots commonly show a dark nucleus surrounded by a half dark area. [The photograph was exhibited.] The spots move round the surface of the sun, and it is only by this motion that we have been able

to perceive the motion of the sun. The time of his rotation has been determined by observations made on the time which the spots require to go around the sun. The spots are not quite steady on the sun; they have their own motion along the surface. This is proved principally by the fact, that when we strive to determine the time of the rotation of the sun by observations made with different spots, one finds the times lying between twenty-three and twenty-five days; and a German observer—Mr. Spöhrer—has found that those spots which are near the equator of the sun go more swiftly round the sun than those which are more distant from the equator. This shows a very great velocity along the surface of the sun. There must be spots which go on with the velocity of nearly one English mile in a second; a velocity three or four times greater than the bullet of the heaviest Armstrong guns. You see by this that very great motions and distortions must take place along the surface of the sun. The spots are continually changing. Formerly a comparison of the different shapes of these spots was only possible by means of drawings made by the hand, so that one could not get so accurate a comparison; but at present we have a great number of photographs of the solar spots, and you can see by comparing photographs of the same spot made on two successive days very great alterations in its shape. Sometimes there are spots which go round the sun five or six times before they vanish, and new spots come as old ones disappear. There is a continual alteration.

Besides these spots there are other very singular appearances along the surface of the sun, which can only be seen during a solar eclipse, because the luminosity of the sun is so very intense that it is impossible to see the less illuminated parts which are near the surface, and it is only when the direct light of the body of the sun is removed by a screen which must be exterior to our own atmosphere, like the moon in an eclipse,—it is only when our eyes are sheltered against the luminosity of the sun, that we are able to see those curious protuberances, sometimes in the shape of mountains, sometimes in the shape of clouds of very different forms, which are near to the surface of the sun. I can show you some of these protuberances by some very beautiful photographs taken by Mr. Warren De la Rue on the occasion of the last eclipse of the sun in Spain.

In the first photograph you see a large luminous margin; in the other you observe the protuberances on one side; and then, in a later stage of the eclipse, you have them appearing on the other side. You observe that the dark body of the sun is surrounded by a sort of halo, the so-called corona, which shows that there are illuminated transparent parts. There is a sort of atmosphere which projects to greater distances even than the protuberances. I can show you also a very nice imitation of this corona made artificially by Mr. Ladd. Formerly it was considered doubtful if these protuberances belonged really to the sun, and if there were not some optical phenomena produced by the margin of the moon. It is only by these beautiful photographs that these protuberances are proved to belong really to the sun, because they move quite in the same way as the sun, and they remain quiet or in repose relatively to the centre of the sun during the time when the moon is passing before the surface of the sun. You see by these phenomena that there is a very great atmosphere round the sun, subject to extremely violent disturbances. The movements of these solar spots, and the always-changing appearances of the protuberances—for they show a new aspect at every new eclipse of the sun—indicate that there are very violent motions along the surface of the sun, and that there is an atmosphere of immense height and density surrounding it. These protuberances which you have seen in the photograph extend to the height of 50,000 miles—more than six times the diameter of the earth; and the solar spots are some of them so great that their diameter is nearly ten times that of the earth. These phenomena, then, exist on a very extended scale, and their dimensions are extremely great when compared with the dimensions of our earth.

Lately we have had a series of new facts and new evidences concerning even the chemical nature of the atmosphere of the sun and the nature of solar light—evidences which are of great importance for our present purpose. They are given principally by the researches of my colleagues Professors Bunsen and Kirchhoff, who have shown that by analysing the spectrum of the solar light one can inquire into the chemical composition of the solar atmosphere. In order to explain this, I must refer to some of the statements which my colleagues have made, and the results they have obtained concerning the nature of

luminous spectra. You know that the light of glowing bodies is composed of different kinds of light. It was first shown by Newton that the white light of the sun is not simple. Now, we will use on this occasion the light of glowing carbon. You have here a projection on the screen of two charcoal points which are glowing in the electric lamp, and you observe between the two points an interval, which is occupied by gas, by air, and by vapours given out by the charcoal points themselves. You have here two solid bodies glowing with a very intense white heat; and there is a stratum of glowing gas through which the electric current passes. The further we remove the points from each other the greater becomes this stratum of gas. By removing the charcoal points, you see the light of the gas; by keeping them together you get the spectrum and the light of the glowing solid bodies. By passing the light of the charcoal points through two prisms, it is deflected from its first direction into another, and the angle through which it is deflected depends upon the refrangibility of the light in the substance of the prism. The refrangibility of the light is different in the different rays, which are distinguished by their colour, by their wave-length, and so on. Thus we get these different kinds of light separated from each other; and instead of having, as in the first image, a representation of the charcoal points themselves, we get a long surface covered with light; and you see how the different rays are separated. I beg you to remark that this is a continuously illuminated surface, presenting no dark lines. We must infer from this experiment that glowing solid bodies like these charcoal points give out all kinds of rays, which are visible from the extreme red to the extreme violet. There is no interruption of the series of rays. You have every variety of wave-length lying between the wave-length of the extreme red and that of the extreme violet. Now, if we take the spectrum, not of the solid body, but of the glowing gas, the aspect is quite changed. We will project on the screen the light of the glowing charcoal points, between which a small quantity of felspar is placed. Felspar contains several chemical elements—alumina, silica, and soda, which is the most volatile of these bodies. We have here between the coal points a stratum of glowing gas, containing principally volatile substances, as well of our own atmosphere as of the felspar, and among these sodium is the most abundant. Now, you observe the result is not a continuously illuminated surface, but that there are several bright lines, and among these is a golden yellow line, which is produced by the sodium, and which can also be produced by other chemical combinations containing sodium. There are other bright lines given by the other substances contained in the coal and the felspar. From this we conclude that the glowing gases give out only some definite kinds of coloured light, and not all kinds—not a continuous series of different wave-lengths. I will now show you another gas spectrum—that of silver and brass. Here you will see the same appearance—viz., that the spectrum is composed of several bright lines separated from each other, or only connected by a feeble intensity of light depending upon the glowing points.

Now, if we inquire what is the spectrum of the sun, we find an illuminated surface which is traversed by a great number of dark lines. I have here some sketches of the spectra given out by the sun, and by several other fixed stars. You observe that they are continuous spectra, only crossed by dark lines; and you see that these dark lines are different in the light of different fixed stars, and that there are some stars, particularly those which are distinguished by their white light, which have no dark lines at all. This is important, principally because it proves that the dark lines do not depend on our terrestrial atmosphere, but that they belong to the fixed stars themselves.

If we ask in what way can such spectra be produced, the experiments of Kirchhoff and Bunsen give a very complete explanation. Professor Kirchhoff has shown that those glowing gases, which give spectra composed of separated bright lines, have the power of absorbing the same light which they give out; the other light which they do not give out themselves goes through them without being absorbed, quite freely and without loss. The rays which the gases themselves give out are absorbed; therefore when the light of a very intensely heated glowing body goes through a stratum of vapour, we get a spectrum in which we find dark lines in the same places where the glowing gas gave bright lines. You have seen that the spectrum given by silver and brass was quite different from that which was given by the felspar—indeed, every single chemical element has its peculiar spectrum; and observing either the bright lines of the glowing gas spectrum, or the dark

lines of the spectrum of a glowing solid body the light of which is brought through a glowing stratum of gas, we are able to determine to which chemical element the dark or the bright lines belong. By means of these experiments Bunsen has been able to discover two new elements, Rubidium and Cæsium; and since then Thallium and Indium have been discovered by other observers,—elements contained in our minerals only in excessively small quantities. It is possible also in this way to determine the elements which produce the dark rays in the solar spectrum. I have shown you a rough sketch of the solar spectrum; and I have here another drawing which represents, on a larger scale, the small distance between two of the lines in the first sketch. By these drawings you can obtain an idea of the extremely large number of these dark lines contained in the solar stratum. We will try to get one such dark line by vapours of sodium. (Experiment.) We have now the spectrum of the glowing charcoals, and in this lamp before the electric lamp a small quantity of sodium will be heated. You see at present the continuous, uninterrupted spectrum of the glowing charcoal points. The light of the electric lamp passes through the flame containing the vapour of sodium, and you will see a dark line where before you saw the golden yellow, the bright light of the sodium. You now see the same golden yellow reflected from all parts of the lamp, because the sodium gives a great quantity of this yellow light—the same golden yellow which is here absorbed. Now, we see the same dark line in the solar spectrum, and we must infer from this that the light of the body of the sun has passed through a stratum of vapours containing sodium, so that the golden yellow has been absorbed. In this way it has been possible to ascertain a great number of chemical elements contained in the atmosphere of the sun. The greatest number of the dark lines of the solar spectrum agree with the lines which are given by the spectrum of iron. More than seventy lines of the solar spectrum are lines of iron, so that there must be an abundant quantity of iron in the form of vapour or gas in the atmosphere of the sun. Other dark lines of the solar spectrum belong to other elements, which we know as parts of our terrestrial minerals. Thus there are lines of calcium, magnesium, copper, zinc, soda, and others. Other elements like gold, mercury, antimony, arsenic, and so on, are wanting; their dark lines are not to be found. I can give you a projection of some of the drawings of Kirchhoff. I will pass them quickly before the lamp, and you will see the excessively great number of lines which are contained in the solar spectrum. (The drawings were exhibited.)

We conclude from these observations, first, that the light of the sun is the light of a solid or fluid body going through an atmosphere containing different gases; secondly, that this atmosphere contains iron, magnesium, calcium, and several other chemical elements, which can be vaporised only by the most intense heat that we can obtain by terrestrial means. Iron is one of the least volatile substances of our earth. It can be vaporised, indeed, by some processes which give a very intense heat. Substances containing iron are vaporised in the interior of volcanoes, and are deposited near the mouth of their abysses; and the lines of iron are seen in the light of the heated gases which have passed through the fluid iron in the Bessemer process, as observed by Professor Roscoe of Manchester. Magnesia is also a very refractory substance. It is commonly used as a sort of crucible in chemical experiments, because it cannot be volatised in the least degree by our flames. You see, then, that these substances are contained as vapours in the atmosphere of the sun.

Now, it can be proved further that the temperature of the solid body which gives the spectrum must be excessively high, when compared with the temperature of the stratum of gas which gives the dark lines, because the gas itself gives out light. You have seen the spectrum of the sodium which was a golden yellow line; and this yellow line can only be changed into a dark line, when the light of the solid body is so much more intense than the light of the vapours of sodium that these vapours appear dark when compared with the intense light of the charcoal points. This is a law which can be proved mathematically; and it has been proved by Kirchhoff. The temperature of the solid body which gives out the light must always be much higher than the temperature of the gas. Therefore, we infer from these facts that the atmosphere of the sun is at so high a temperature that iron, magnesium, and calcium are contained as vapours in it; that the temperature of the solid or fluid substance of the body of the sun is far higher, otherwise we could have no dark lines in the solar spectrum; so that the temperature of the sun must be much higher than any

temperature we can obtain by our terrestrial means. When I say that the spectrum of the sun must be that of a fluid or solid body, it is not necessary to conclude from this that it is the continuous body of the sun which gives out the light; it may also be given out by little particles swimming in the atmosphere like a sort of fog. Our fog is composed of particles of water; smoke is composed of particles of coal swimming about the air; such little glowing particles give the same spectrum as solid masses of the same substance; therefore, this spectrum of the solid or fluid substances of the sun may be a spectrum of glowing fog, and not necessarily of the body of the sun itself. You see that these conclusions are very different from the ideas which have been formerly entertained with regard to the nature of the sun. Those ideas were founded principally upon the observations of the solar spots—first, by Wilson and afterwards by Sir William Herschel. They found that the solar spots, when they came near the margin of the sun, changed their aspect in such a way that the observers were obliged to conclude that the dark central spot was in a lower level than the area of the spot, and that the spot must be of an infundibuliform shape—that it is an excavation in another luminous substance. The conclusion drawn from these facts was, that there existed an outer layer of glowing substance called the photosphere, which gives the light; that the body of the sun itself was dark, and that between the photosphere and the body existed a cloudy atmosphere, which gave a shadow to the body of the sun, so that it was not illuminated. Arago, who afterwards received the same hypothesis, gives even more especial descriptions of the probable nature of the sun. He supposes it possible that the body of the sun is not of a very high temperature, that even the photosphere may be compared with a sort of aurora borealis, giving out light, without being itself very much heated. Now, you see these new facts about the nature of the sun show that along the surface of the sun must be a temperature much surpassing all the temperatures we can obtain by terrestrial means. It is not possible that any body which is surrounded everywhere by a covering of uniform temperature, and which has no interior means of cooling, can remain a long time in a different temperature from that of its covering; and since the whole atmosphere surrounding the sun is of so intense a degree of heat, we must conclude that the body of the sun also is at least of the same temperature—it may be higher.

Professor Kirchhoff has given a new explanation of the solar spots. He supposes that a smaller dense cloud is situated immediately above the surface of the sun, and another stratum of clouds, less dense, at a greater height. This hypothesis would not quite agree with the descriptions of astronomers as to the change of form of the solar spots when they come near the margin of the sun; and I, therefore, propose another explanation, which I have roughly represented in a diagram. You see represented the body of the sun heated intensely to a white heat. I suppose that in the interior of the sun are contained different mixtures of chemical elements, some of them more volatile than others. From the heated surface, vapours will arise; and we are justified in assuming that even vapours of iron and magnesium and such substances are rising from the surface of the sun. These vapours may be condensed, may be changed into the form of a glowing fog, by the cooling along the surface. The yellow stratum represents such a fog, composed, perhaps, of glowing particles of iron, magnesium, calcium, and so on. Now, suppose there are less volatile substances, say water, coming up from the interior of the sun to the surface; they will be changed into vapours very quickly, will boil and give out a great quantity of vapours which separate the glowing fog. By the boiling and the swift evaporation, this portion of fluid will be cooled. I have represented it here as red, to show that it is only a red heat, and not a white heat. The vapours of water will remain in a state of transparent vapours in this intensely-heated atmosphere; and, therefore, we have here a transparent excavation filled with vapours of water, then a cooler part of the surface of the sun, and at the sides of the excavation the glowing fog of iron and magnesium will meet with the vapours of water which are cool, and the fog also will be cooled. You see in the diagram a relatively dark space, and such an excavation, the walls of which are also darkened by cooling; and you see the glowing fog which covers the whole surface of the sun. I propose this explanation only to show that the theory according to which the sun is an intensely-heated body can be brought into agreement with astronomical observations; and I think this is a sufficient explanation, based

on rather simple suppositions, concerning the nature of solar substances. We must now go into further investigation as to the quantity of solar heat and the quantity of energy which is diffused by the sun into the surrounding spaces; and that will be the task of my next lecture.

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

LECTURE III.

GENTLEMEN,—We have now to consider the constituents of the urine individually, and we shall begin with that substance which, in consequence of its occurring in greatest quantity, is looked upon as the most important ingredient of the human urine.

UREA.—($C_2H_4N_2O_2$). Atomic equivalent = 60.

Urea is to be found in the urine of all animals, but exists in greatest quantity in that of the mammalia. It never occurs as a urinary deposit, in consequence of its great solubility in water, being, in fact, deliquescent.

Before entering upon the physiological, and pathological relations of urea, it will be necessary for me first to say a few words regarding its appearance and properties.

The urea of commerce is a white, semi-transparent, crystalline body, (b) with a bitter taste. When heated it melts, burns, and gives off ammonia. It is soluble in alcohol, as well as in water, but nearly insoluble in ether. It is readily decomposed by strong mineral acids, and by hydrated alkalis. With chlorine it yields carbonic, and hydrochloric acids. Nitrogen gas being at the same time set free. In contact with animal ferments urea takes up two equivalents of water, and is converted into two parts of carbonate of ammonia.

Hence the peculiar ammoniacal odour of putrid urine.

Urea readily combines with nitric acid to form the most important of its salts:—

The Nitrate of Urea ($UrNO_5HO$), which forms, when rapidly crystallised, flat, shining, rhomboidal plates; when slowly crystallised, fine prisms. It is very soluble in both water and alcohol, but only sparingly soluble when they contain an excess of free nitric acid.

We have here three specimens of urine—man's, horse's, and dog's—representing the three subdivisions of the animal kingdom into omnivora, herbivora, and carnivora; the first two urines have been concentrated to about half their normal bulk, the third is left in its natural state, it being by far the richest in urea. To each I now add equal parts of strong nitric acid, when instantly you perceive they begin to crystallise, and before many minutes elapse each of the liquids will have become one compact mass of shining crystals; I shall be able to invert the glasses without danger of spilling their contents. You observe the crystals are coloured. Those from the dog's urine only slightly, those from the horse's very deeply. This is not owing to the nitrate of urea being a coloured salt, but simply because it happens to be deposited in a coloured liquid, part of the colouring matter of which has united with it; just as sugar—a white substance—when crystallised in a solution of carmine, yields red crystals. The higher coloured the urine, therefore, the deeper coloured the crystals; the paler the urine the whiter the crystals.

With oxalic acid urea forms an oxalate (UrC_2O_3,HO) which crystallises in prisms and quadrilateral tables (Fig. 7), sometimes separate, sometimes adhering together in groups. This salt is freely soluble in hot, but sparingly soluble in cold, water. Hence it is that we occasionally, though very rarely, detect crystals of oxalate of urea in concentrated human urine.

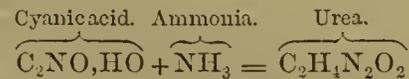

PHYSIOLOGICAL RELATIONS OF UREA.

Urea was first discovered in human urine, and it was for a long time thought to be one of the special products of the animal

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

(b) The crystals are usually four-sided prisms, more rarely needle-shaped. The urea sold in the shops is prepared artificially, but it possesses the same characters as that obtained from human urine.

world. Modern chemistry having, however, succeeded in preparing it artificially from a variety of substances, among which may be mentioned the cyanates of lead and silver; together with the fact of its being also formed by the union of cyanic acid and ammonia—

many persons are inclined to regard it as merely the cyanate of ammonia.

FIG. 7.

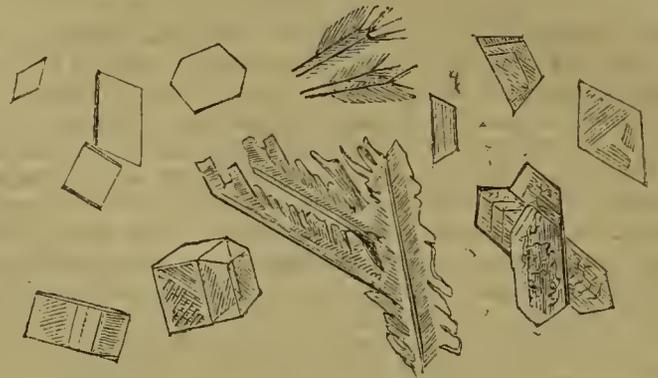

FIG. 7.—Crystals of oxalate of urea from human urine.

Urea, though found in the urine, is not formed in the kidneys, but only excreted by them from the blood, where it has been detected by Garrod, myself, and others. Picard found 0.016 per cent. in normal human blood, and on one occasion I found as much as 0.320 per cent. In the defibrinated blood of a sheep I found 0.559, and in that of the dog as much as 0.747 per cent. In a normal state the blood of the renal artery contains twice as much urea as that of the renal vein (Picard), but in cases of its retention, both vessels contain about an equal quantity. Wurtz obtained urea from the healthy chyle, and lymph of the ox, horse, and dog. It has been found in the humours of the human eye, and is one of the ordinary constituents of the amniotic fluid of all mammalia; but, as I said before, it owes its presence in the latter situation to the urine excreted by the fœtus while still in utero.

It has been asserted by some (Robin and Verdeil) that no urea is to be found in the urine of very young children; this, however, is an error, as I have detected urea in urine taken from the bladder of a still-born child, and in that of an infant aged 8 weeks I found as much as five grammes per thousand. In fact, from the subjoined table it will be seen that children actually excrete relatively more urea than adults; and males absolutely as well as relatively more than females, at all periods of life.

Sex and age.	Quantity of Urea in the 24 hours' Urine.			
	Absolute amount.		Relative proportion per lb. of bodily wght.	
	grammes.	grains.	grmes.	grains.
Boy aged 18 mths.	8 to 12 = 124.0 to 186.0	0.40	6.2	
Girl „ „	6 to 9 = 93.0 to 139.5	0.35	5.4	
Man aged 27	25 to 35 = 387.5 to 542.5	0.25	3.8	
Woman „ „	20 to 30 = 310.0 to 465.0	0.20	3.1	

In this table it will be seen that the amount of urea daily excreted is liable to considerable variations. Before attempting, therefore, to draw any conclusions from the changes observed in its amount during disease we must make ourselves thoroughly acquainted with the causes upon which the normal fluctuations depend, and in order to do this the more effectually we must first inquire into its normal source.

No urea has as yet been detected in any of the human solids, except what might readily be accounted for by the presence in them of blood. Its source seems to be two-fold; firstly, the disintegration of the tissues; and, secondly, the excess of nitrogenised food absorbed into the circulation.

The effect of food on the daily elimination of urea is well marked in the results obtained by Von Franque while experimenting on himself:—

Diet.	UREA.				
	In 24 hours.		Per hour.		Per lb. of bodily weight.
	grmes.	grains.	grmes.	grains.	
Animal ($3\frac{1}{2}$ lbs. of flesh).	92 = 1416.0	3.86 = 59.8	0.53 = 8.2		
Mixed . . .	37 = 573.5	1.58 = 24.4	0.21 = 3.2		
Vegetable . . .	28 = 434.0	1.08 = 16.7	0.15 = 2.3		
Non-nitrogenous	16 = 248.0	0.69 = 10.6	0.09 = 1.3		

It is here seen that on an animal a much greater quantity of urea is excreted than on a mixed diet, and least of all after non-nitrogenised food has been taken. These results are in accordance with those of all other observers, except that the total quantities are greater.

Some suppose that urea comes in no case directly from the excess of absorbed food, but only indirectly from that portion of it which has undergone metamorphosis in the tissues (Bischoff, Voit, Parkes). If such be in reality the case, it appears to me very extraordinary that when living on a purely animal diet a person should excrete a larger proportion of urea than when living on mixed food, the mixed being the most nourishing diet of the two. Again, if their views be correct, why is it that exercise, which is well known greatly to increase the metamorphosis of the tissues, is not found materially to affect the daily elimination of urea? Thus, Von Franque excreted in twenty-four hours:—

Diet and exercise.	Urea in 24 hours.		For every lb. of wght.	
	grammes.	grains.	grammes.	grains.
Mixed, with moderate exercise	37.983	= 588.73	0.218	= 3.379
Mixed, with much exercise	37.877	= 587.09	0.217	= 3.363

Actually less urea after much exercise than he did on his ordinary average exercise. (c) On the other hand, Dr. Ed. Smith found that prisoners excrete 36 grains more of urea when at hard work than when doing nothing, which, he adds, is 19 grains above what they pass on light labour.

Again, we find that Bischoff in his experiments on dogs observed that they passed most urea when fed on eggs, muscle, and gelatinous substances, and that it increased in proportion to the quantity of food given. These facts all tend to the conclusion that a portion of the urea excreted by the kidneys comes from the excess of food, independent of the metamorphosis of tissue. That all the eliminated urea does not come from this source no one seeks to affirm, for there is abundant evidence against such a supposition. For example, starve an animal as you may the urea will never entirely disappear from the urine. It can only be reduced to a certain point and no further. Schmidt, Frerichs, Bischoff, and myself have observed this in dogs, and Lassaigne, Scherer, Von Franque, and others have made similar observations on the human urine. The last-named gentleman starved himself during forty hours, and still found 19.35 grammes (299.9 grains) of urea in his twenty-four hours' urine. On experimenting on the effects of tartrate of antimony as a slow poison, I found that the urine of dogs, reduced to perfect skeletons, contained such an amount of urea that it crystallised on the simple addition of nitric acid without any concentration whatever.

The amount of urea passed by an animal during starvation is greater, if he has been previously well fed, than if he has only received a sufficiency of food to prevent his losing weight (Bischoff), which fact probably accounts for Dr. Von Franque passing so much during the time he was without food.

Prout thought that the urea came chiefly from the gelatinous tissues, and Von Franque thinks it comes chiefly from the muscles, but neither of these tissues has been found to contain urea. It is true that Städeler and Frerichs found a considerable quantity of urea in the muscles of cartilaginous fishes; but that proves little, seeing that they detected it in almost all the organs. My idea is, that *urea is not the special product of any one particular tissue or organ, but the united product of all nitrogenised effete matter.* Bechamp and Picard assert that they have converted albumen and other azotised substances into urea by slow combustion with permanganate of potash, and although subsequent experimenters have not been equally successful, we must accept their statement as a fact until the contrary is proven.

Part of the urea may also be formed in the blood by the decomposition of uric acid. This is rendered highly probable, for two reasons—Firstly, Neubauer found on giving rabbits from two to three grammes (31 to 46½ grains) of uric acid with their food the quantity of urea excreted in the twenty-four hours was augmented from 2.1 to 4.2 grammes (32.5 to 65.1

(c) So contradictory are the results of different observers, that further experiments are necessary before the question can be settled; the observations, too, in order to be exact, must only be made on the urine during the time the exercise is being taken, and not over the whole twenty-four hours, as the effect of rest and sleep may counterbalance the result produced by the exercise. I am myself strongly inclined to the opinion that exercise increases the elimination of urea, but cannot venture positively to assert it in consequence of the contradictory evidence furnished us by so many observers. (Draper, Lehmann, Franque, Smith, Hammond, Ranke, etc.)

grains); and, secondly, when uric acid is acted upon by permanganate of potash it is transformed into several substances, one of which is urea.

We have now to consider how the elimination of urea is influenced by other than animal foods. In the first place, water increases it. The more water we drink, *ceteris paribus*, the more urea we excrete, most probably for the reasons already given when speaking of the influence of water on the urinary solids. Common salt also produces an augmentation in the excretion of urea (Böcker, Bischoff). Coffee has an analogous effect. I found this to be very decidedly the case in one of my friends, Baron G., aged 57. The daily average of urea excreted by him was 17.28 grammes (267.84 grains), whereas after he had restricted himself to nothing but coffee (without milk or sugar) and dry bread during forty hours he passed 25.3 grammes (382.25 grains) of urea per twenty-four hours.

This diet had an equally striking effect on the amount of water eliminated. His usual average was 1290 cubic centimetres (41 ozs.), and on the day in question it rose to 1895 cubic centimetres (60 ozs.) per twenty-four hours. This result is contrary to the observations of Böcker and Hammond, who found, on taking an excess of coffee with their ordinary diet, that the daily excretion of urea diminished. But this probably arose from their taking the coffee in the usual way, sweetened with sugar, for there are certain foods which greatly diminish the elimination of urea, and among them sugar holds the foremost rank (Böcker, Bischoff, and Voit). Starch has also a marked effect in diminishing the amount of urea, and I believe that fat may be placed in the same category, for, notwithstanding the statements made to the contrary (Böcker and Bischoff), the results of Botkin's experiments on dogs are conclusive regarding the decided diminution of urea which takes place when fatty matters are added to the food. This opinion is further strengthened by the observations of Beneke, who found that cod-liver oil lessens the amount of urea passed by the human subject. In fact, my idea is, that all nitrogenised foods augment, and all non-nitrogenised foods diminish, the amount of urea eliminated by the kidneys. Even gelatine, the nitrogenised substance which of all others is supposed to possess the least nourishing properties, has a decided effect in increasing the daily excretion of urea.

I have entered thus fully into the physiology of urea in consequence of being aware that unless the influence of diet, age, and sex be borne in mind while studying its fluctuations during disease, our labours will be unattended with any practical benefit; while, on the other hand, if these factors are duly considered, we cannot fail to reap important advantage from the knowledge thus acquired, for just as we have seen that its amount in normal urine represents, to a certain extent, the wear and tear of the frame, and is consequently an index to the health of the individual, so also in disease it furnishes us with precisely similar and even more important data; for the amount of urea in the urine enables us not only to judge of the tissue consumption, and, through it, of the severity of the affection, but is at the same time a direct clue to treatment, showing us whether our remedies should be directed to the restraining or encouraging tissue metamorphosis.

MEDICAL CHARITIES.—The following munificent sums have been left to the undermentioned Medical Institutions by Admiral Octavius Vernon Harcourt, of Swinton Park, Bedale, Yorkshire, who has made charitable bequests to the extent of £36,000. The will, which has just been proved in York, directs that the various sums be paid free of duty. The following metropolitan charities benefit to the extent of £1000 each—viz., St. Mary's Hospital, Paddington, St. George's Hospital, Hyde Park, the Cancer Hospital, Chelsea, the Charing Cross Hospital, and the Middlesex Hospital. Similar sums are also bequeathed by the late gallant admiral to the York County Hospital, the Leeds Infirmary, and the Idiot Asylum, Earlswood; making a total of £8000 to Medical charities alone.

GRANT OF ROYAL CHARTER TO THE SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.—This Society, founded in 1788, and now giving, in half-yearly and other relief, about £2000 a-year, has, within the past week, received a Royal Charter of Incorporation, and has become the Society for Relief of Widows and Orphans of Medical Men, the name having been shortened a little. The anniversary dinner is on May 28 next, at the Albion Tavern, Aldersgate-street; the President, T. A. Stone, Esq., in the chair.

THE OPTICAL DEFECTS OF THE EYE.

A COURSE OF LECTURES DELIVERED DURING THE SUMMER OF 1862 AT THE

Surrey Ophthalmic Hospital,

By J. ZACHARIAH LAURENCE, F.R.C.S., M.B.
Univ. Lond.,

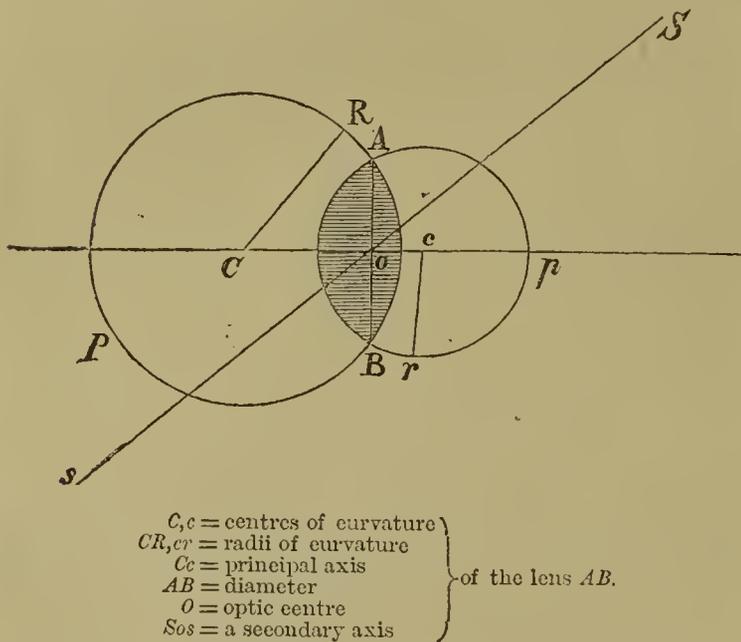

Surgeon to the Hospital.

PART I.—OPTICAL CONSIDERATIONS.

(Continued from page 361.)

We shall now proceed to the, for our purpose, most essential part of the subject—viz., to the consideration of the properties of optical lenses.

FIG. 5.

C, c = centres of curvature
 CR, cr = radii of curvature
 Cc = principal axis
 AB = diameter
 O = optic centre
 Sos = a secondary axis

The double-convex lens is represented in section *A*, Fig. 5. It is formed by the apposition of segments of two spheres. With the centre *C* and radius *CR*, describe the circle *CRP*, and with the centre *c* and radius *cr*, describe the circle *crp*; the part *AB*, common to both circles, represents the vertical section of a double-convex lens. *C, c* are the centres of curvature *CR, cr* radii of curvature of the lens. A line *Cc*, drawn through the two centres, is called the principal axis; the line *AB*, perpendicular to the axis, the diameter; the centre of this line *O* is the optic-centre of the lens respectively; whilst lines passing through *O*, as *Sos*, are secondary axes of the lens.

In the convex lenses in general use for spectacles, the radii of curvature of the two surfaces are equal. We then have a double equi-convex lens (*AB*, Fig. 6.)

FIG. 6.

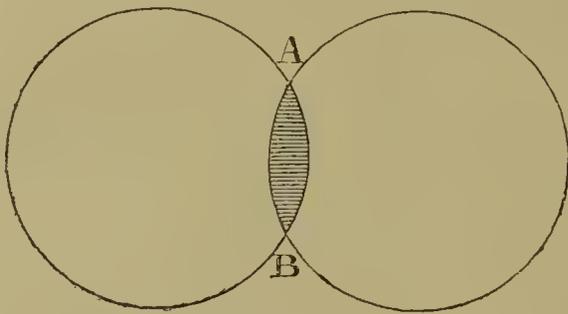

FIG. 7.

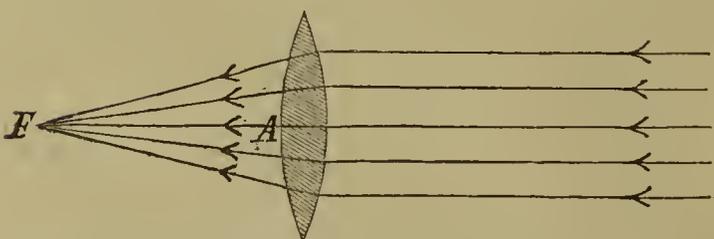

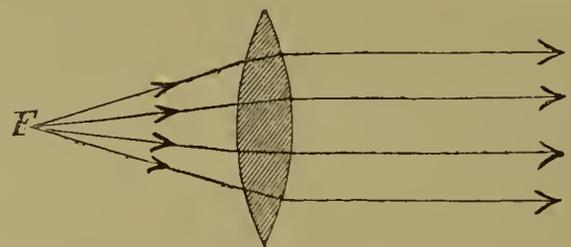

Fig. 7.—*FA* = principal focal length, in an equi-convex glass lens equals the radius of curvature.

Parallel rays (*i.e.*, as I have before mentioned, such as emanate from luminous objects at a distance from the lens—prac-

tically, I find experimentally that for a lens of about an inch and a-half diameter, this distance is anything beyond four feet) entering one surface of the lens, are found, on their exit from the second surface, to have converged to a point at a fixed determinate distance from the lens.

This point *F* (Fig. 7) is the *focus* of parallel rays—the *principal focus* of the lens, or, briefly, the focus of the lens. The distance of this point from the contiguous surface (strictly speaking, from the optic centre) of the lens, *FA*, is the *principal focal length* of the lens, or, briefly, the *focal length* of the lens. This, in the case of an equi-convex glass lens, equals the radius of curvature. Thus we speak of convex lenses of 2, 3, 5, 8, etc., inches focal length, or, as they are commonly termed, 2-inch, 3-inch, 5-inch, 8-inch, etc., convex lenses—meaning thereby that such lenses have the property of converging parallel rays to a focus, uniting them to a point, at distances from the lenses of 2, 3, 5, 8 inches respectively. (d) To make a practical application of our knowledge:—A person comes to you with a pair of convex glasses, but he has forgotten their focal length, and you wish to find this out; all you have to do is to see at what distance the image of any distant object (such as of objects in the street, of the sun, etc.) is formed most distinctly on a sheet of paper. Measure the distance of the lens from the image, and you at once have the required information.

FIG. 8.

Vice versa: rays of light which diverge from a point *F* (Fig. 8), situate at the focal length of the lens, issue from the other side in a state of parallelism. Many light-house lanterns are constructed on this principle, the light being placed at the focus of a convex lens. (e)

I must here mention a well-known property of convex lenses, which is necessary to the right understanding of what follows. If an object be placed behind a convex lens at a less distance than its focal length, an erect magnified image of the object is perceived by an eye placed in front of the lens. Now, the shorter the focal length of the lens, the greater its magnifying power—*e.g.*, a 2-inch lens magnifies more than a 4-inch lens. In reference to their respective magnifying powers, then we should be wrong in designating the first lens as 2, the second as 4, which would imply the second were “stronger” than the first; but the more correct nomenclature is to call the first lens a $\frac{1}{2}$, the second a $\frac{1}{4}$, the latter fraction being less than the former. In further illustration, therefore, of the “powers” of lenses by fractions you see that, *e.g.*, a lens of $\frac{1}{12}$ is one that unites parallel rays to a focus at a distance of twelve inches from its surface, a lens of $\frac{1}{24}$ at a distance of twenty-four inches, and so forth; and, moreover, to use the vernacular expression, that the $\frac{1}{24}$ th lens is, in regard to its magnifying power, not so “strong” as the $\frac{1}{12}$ th lens.

Designating, then, in this way convex lenses by fractions, of which the numerators are 1, and the denominators the focal lengths of the lenses, let me announce to you a most important proposition, that the optical effect of a combination of lenses in contact, both as regards the power of magnifying, and as regards the distance at which parallel rays impinging on the first lens are brought to a focus by the combination of lenses, is always given by adding the several fractions, which express their respective powers, together. The resultant fraction represents the power of the single lens, which is optically equivalent to the whole set. Thus, suppose we wish to know the focal length of the combination of an 8-inch and of a 5-inch convex lens, placed together, we have, $\frac{1}{8} + \frac{1}{5} = \frac{13}{40}$

(d) I strongly recommend all persons who wish thoroughly to understand the subject of these lectures, to actually perform themselves all the experiments which are adduced. A set of trial lenses, and a few stands to hold them, etc., constitute all the apparatus required.

(e) I may here call attention to an important fact—viz., that, in the German and French trial-lenses, the focal lengths are given in Paris inches, whereas English opticians give theirs in English inches. 12 English inches = about 11½ Paris inches; so that, *e.g.*, if we find a patient requires a 22½-inch glass of the German trial-glasses (now in very general use amongst English oculists), we should order him a 24-inch English glass.

nearly. The equivalent single lens is a 3-inch lens. Parallel rays impinging on such a combination will be focussed at a distance of three inches. (f)

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASE OF OBSTRUCTION OF THE BOWELS,

ENORMOUS DISTENSION OF THE ABDOMEN—PARACENTESIS
CÆCI—DEATH—SECTIO CADAVERIS—STRICTURE OF THE FIRST
PORTION OF THE RECTUM.

With Clinical Remarks by Professor LAYCOCK.

W. S., aged 45, a shoemaker, residing at Cupar Fife, was admitted to Paton's Ward, Edinburgh Royal Infirmary, under the care of Dr. Laycock, on January 18, 1864. Patient states that he has enjoyed good health, and is of regular habits.

State on Admission.—Circulatory System.—Pulse 84, fair volume and strength; cardiac sounds normal, impulse imperceptible. Respiratory System.—Normal. Voice thick and husky, and has been so for the last month, according to the patient's statement. Nervous System.—Sleeps well; pupils contracted; complains of occasional pain all over the abdomen, and of constant pain, increased by pressure, at the junction of the right inguinal with the umbilical and hypogastric regions. Has pain sometimes in the calves of the legs. Has occasional numbness and weakness in the left arm. Integumentary System.—Is of the neuro-vascular diathesis. Skin warm and moist. The abdomen is enormously distended, and very tense when palpated. There is no scrobiculus cordis, and the integuments about the umbilicus are much stretched. Percussion elicits a loud tympanitic note of low pitch. At the umbilicus the circumference of the abdomen measures thirty-four inches. No herniæ detectible. Genito-urinary System.—Urine dark amber colour, deposits mucus, feebly acid reaction, sp. gr. 1.025, contains no albumen nor sugar; purpurin and indican in large amount with slight excess of phosphates present. Digestive System.—Tongue dry and clean, but rough, with arborescent fissuring. Papillæ large and prominent. There is thirst and anorexia. Bowels have not acted freely since the 9th inst. On the 10th had a small, hard stool. For some weeks past he had noticed his stools to be small and hard at times, and occasionally of natural character. Remembers to have passed a small, thin portion of fæces on December 8 last, and of late he has noticed a jelly-like streak on the motions. Has had frequent desire to defæcate, but without result.

History of Present Attack.—On the evening of January 9, after working at his trade all day, he set out to walk to Cupar, a distance of six miles. Had taken his meals that day as usual. He states that after walking about a mile he suddenly felt a severe pain about his navel, which "doubled him up." He continued to walk on for three miles, when he rested at the house of a friend for a short time. He next went on to Cupar, and sought relief from a druggist, who treated him for "gravel" with antibilious pills. The bowels acted several times next day, but not freely. The pain continued, and proper Medical treatment obtained. Calomel and opium was prescribed that night and castor oil to be taken the following morning. No relief was obtained, so the same treatment was again adopted. Patient thinks there was a small stool on the 11th or 12th. During the week sinapisms were applied, purgative powders given, castor oil and turpentine, emetics, enemata of various kinds, including tobacco, senna and salts, warm baths, full doses of opium with repeated enemata failed to relieve the pain or unload the bowels. Bougies passed into the rectum at times allowed some flatus to pass. The application of ice in an ox bladder gave relief to the pain and distension. On the 18th his Medical attendant recommended him to this Hospital. He came by train, but was able to walk from the station to the steamer, and from the steamer to the train on this side of the Forth. On admission, as no herniæ were discovered and no stricture was to be felt on digital examination per rectum, the case was sent to the Medical wards.

(f) If one or more of the lenses is a concave one, we must subtract the fraction or fractions representing these lenses. Thus the equivalent lens of a combination of an 8-inch convex and a 16-inch concave lens equals $\frac{1}{8} - \frac{1}{16} = \frac{1}{16}$ equals a 16-inch convex lens. If the 8-inch lens were a concave one, and the 16-inch lens a convex one, the equivalent concave lens is given by the formula: $-\frac{1}{8} + \frac{1}{16} = -\frac{1}{16}$, a 16-inch concave lens, the resultant fraction being negative.

Treatment, etc.—An opiate and foetid enema was given at once, and a grain of opium ordered to be taken in the form of a pill every fourth hour. No solid food to be taken. Milk and lime water for common drink, with 4 oz. of brandy and ice *ad libitum*. Palpation and galvanism to be employed over the distended abdomen. This was carried out for an hour and a-half, the tension being relieved, and the intestines being caused to contract. In the course of the evening the patient vomited watery bilious fluids, and had occasional singultus. Decubitus chiefly dorsal, with knees slightly drawn up.

19th.—Had a pretty good night. Is in the same condition. Pulse 84; good volume and strength. Tongue dry and rough, clean. Seen by Dr. Laycock. Nutrient enemata of beef-tea to be given three times a-day with brandy. An opiate and terebinthinate epithem to be laid over the abdomen. No solid food to be taken into the stomach. The opium to be continued every four hours. Was galvanised over the abdomen, and palpated for half an hour, with relief, in the evening.

20th.—Had a restless night. Pulse 100; good volume and strength. Right pupil dilated. Passed flatus after an enema of beef-tea. Occasional singultus and watery bilious matters are vomited. Patient sucks ice and finds it very grateful. Injections to be given with brandy, and the pills to be continued. In the evening the abdomen was galvanised and palpated for half an hour. The following draught was given, with relief to the flatulent distension:—Æth. chlor. æth. sulph. sing., ℥xl.; ex aquæ, ℥i. Urine plentiful, excess of phosphates, and diminution of chlorides with much indican. Dr. Laycock examined the rectum to-day with the finger, and observed that there was great dilatation of the bowel immediately beyond the sphincter. The apparently normal calibre of the gut could just be felt by the tip of the finger.

21st.—Passed a better night. Pulse 80, moderate volume, becoming soft; pupils both contracted; tongue dry, with arborescent fissuring; singultus occasionally; passed some flatus during the day. The pills to be discontinued. A wine-glassful of beef-tea to be taken by the mouth, and a little jelly. Half an ounce of ether to be added to each injection of beef-tea and brandy. He takes in the day brandy ℥iv., with ice. Galvanism and palpation employed in the evening. Flatus passed after the enemata.

22nd.—Had a restless night. Does not feel so "fresh" to-day. Pulse 80, rather small, and compressible; tongue dry, and fissured as before; right pupil dilated to-day; a little flatus passed, and in the evening there was a small powdery motion, of a scammony powder colour, probably *débris* of enemata, though it had a fæcal odour; vomiting watery matters and whitish masses, which are found to consist of tessellated epithelium cells and mucus corpuscles. Injections continued. To have pil. opii. gr. v., hac nocte (opii., gr. j.). With a view of affording relief to the patient, if no other indication was afforded, Dr. Laycock proposed to perform Sir Henry Cooper's operation, and tap the caput cæcum coli with a large trocar to evacuate the flatus and feculent matter. If the bowel were pinned up to the abdominal wall by long acupuncture needles, the operation would be more feasible, and the gut would be prevented from retracting after it had collapsed. Thus, an artificial anus would be established.

23rd.—Feeling weaker to-day. Pulse 84, rather small, and soft; tongue dry, with a yellowish-brown thin crust upon it; skin hot and dry; watery vomiting, with flocculent masses in it, and singultus occur at intervals; passed twenty ounces of urine in the last twenty-four hours; some flatus passed to-day; abdomen continues very tense and tympanitic; right pupil dilated. He complains of griping pains about the navel. To have brandy, ℥iv., and port wine, ℥iv. per diem. To-day, by Dr. Laycock's directions, the Resident-Physician (Dr. Duckworth) introduced the forefinger of the left hand into the rectum to the point where it narrowed, and guided along it a flexible œsophagus tube. This was passed on beyond the finger till it came in contact with some obstruction. About seven inches of the tube was inserted. No pressure was made, but an injection of beef-tea, brandy, and ether was next forced into the tube. This was, however, rejected as fast as it was pumped in. Omit pil. opii. hac nocte.

24th.—Had a restless night. Pulse 88, of rather better strength; tongue dry and rough. Passed twenty ounces of urine in the last twenty-four hours of same character as when last examined. The fact of an abundant quantity of urine being passed helped to corroborate the diagnosis of the stricture being low down in the intestine. Abdomen greatly distended. Patient looks somewhat emaciated in the face, and has a slight icteric tinge in the conjunctivæ. Is very

anxious for some operative procedure to be undertaken. Accordingly, Dr. Laycock having percussed out the course of the colon, which extended into the infra-mammary regions on both sides, and up to the level of the fourth rib on the right side, thrust a large four-bladed trocar into the caecal region. Although the patient was well under chloroform, the hypertrophied oblique muscles of the abdomen seized the canula so firmly that the trocar could only be withdrawn with difficulty. Meantime a large quantity of flatus escaped, and the distension subsided. About a drachm of brownish fluid came welling through the canula; it had no faecal odour. No faeces passed; the canula was then tied into the wound and plugged. A large opiate epithem was laid on the abdomen. The pulse was 88 after the operation, full and soft. The needles were not employed to catch up the bowel, as it was thought not unlikely that some adhesion had already taken place between the peritoneal surfaces, since the patient complained of pain about this region, and it was feared too that the ileum might be punctured.

Seven hours after the operation, Dr. Laycock examined the canula, and passed a probe through it. It was found occluded; he therefore withdrew it, and the wound was brought in contact by two points of silver wire suture. A large opiate epithem was then applied to the abdomen and a grain of opium given by the mouth.

25th.—Patient had a good night, and no pain in the abdomen. He expressed himself as being much relieved by the operation. Pulse 88, moderate volume and strength. Tongue just moist, arborescent and longitudinal fissures upon it, with dirty white fur. Vespere.—Patient complains of pain in the region of the umbilicus and over the right side of the abdomen. There is great distension again. Pulse 112, moderate volume, soft. To have Pulv. opii, gr. j., form. pil. Brandy and ice continued. Opiate epithem to the abdomen.

Was restless till 2 a.m. on the 26th. Slept for a short time, but the breathing became hurried and feebler. He died at 6 a.m., quietly.

Section Cadaveris Thirty-one Hours after Death.—There was a slight icteric tint in the conjunctivæ, and over the body generally. Incisions were made from the xyphoid cartilage to the umbilicus, and from this point two incisions were carried down to the centres of Poupart's ligaments. A quantity of foetid gas escaped on cutting into the peritoneum. On reflecting the flaps, the intestines were seen to be discoloured. The caecum and colon were greatly distended, so as to hide the stomach and liver (*vide* Fig. 1). There was adhesion by recent

FIG. 1.

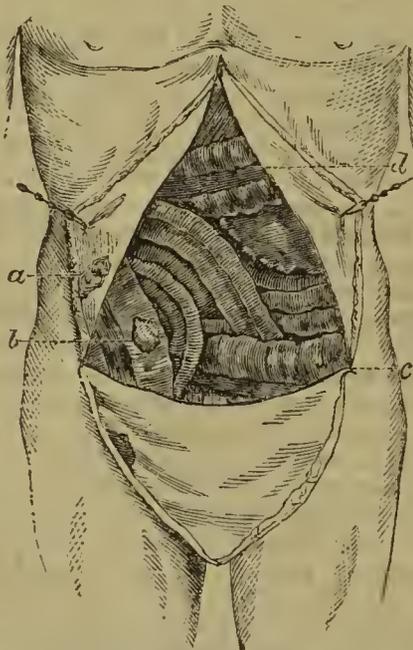

FIG. 1.—Appearance of Abdominal Cavity. *a*, Point of puncture of abdominal wall; *b*, point of puncture of caecum repaired by effused lymph; *c*, sigmoid flexure of colon; and *d*, transverse colon distended with flatus.

soft lymph between the abdominal wall and the caecum, and on raising up a patch of this from the gut, the cicatrix of the punctured wound was brought into view. Some of the lymph in this situation was vascular, and had been evidently exuded for some time. The colon lay in the infra-mammary region, on the right side, up to the level of the fourth rib. The sigmoid flexure in its lower portion was so distended as to occupy the entire brim of the pelvis. The intestines were removed care-

fully; in the small portion nothing beyond congestion and discoloration was observable. On separating the sigmoid flexure, which, with the entire mass of the colon, was filled with faecal matter, from the left iliac fossa, and cutting through the meso-rectum, a strictured portion of the gut was detected. Immediately below the sacral promontory, the dilated extremity of the sigmoid flexure became suddenly contracted. The rectum was next removed entire. It appeared as if the bowel had been strangulated at the point of stricture, by the gut being somewhat twisted upon itself (*vide* Fig. 2).

FIG. 2.

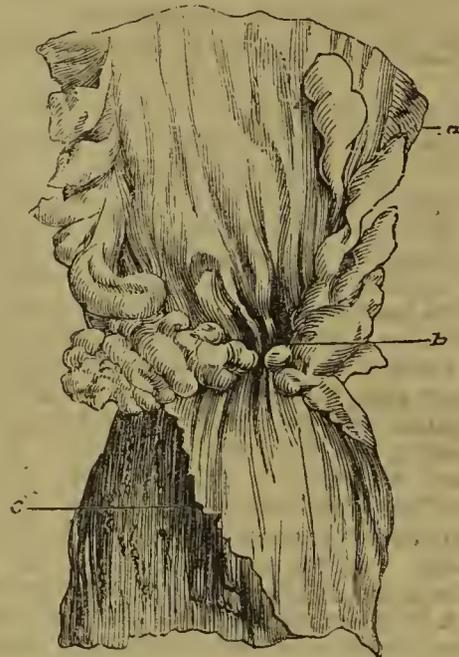

FIG. 2.—External Twisted Aspect of Stricture. *a*, Distended portion of colon; *b*, site of stricture, with adherent appendices epiploicae; *c*, rectum with its developed muscular fibres.

On laying open the colon, foetid gases escaped and a large quantity of faecal matter. Hard lumps were impacted in the caecum. The capacity of this portion of the distended gut was ascertained by filling it with water, when it was found to contain 222 fluid ounces, or a little under a gallon and a-half. The strictured portion permitted water to pass through it *guttatim*, but in the condition and position of parts during life it is improbable that the gut was pervious. On cutting through the stricture, the mucous membrane appeared dark and highly congested: there were valvular folds upon it, and dark oedematous processes looked towards the rectal side (*vide* Fig. 3).

FIG. 3.

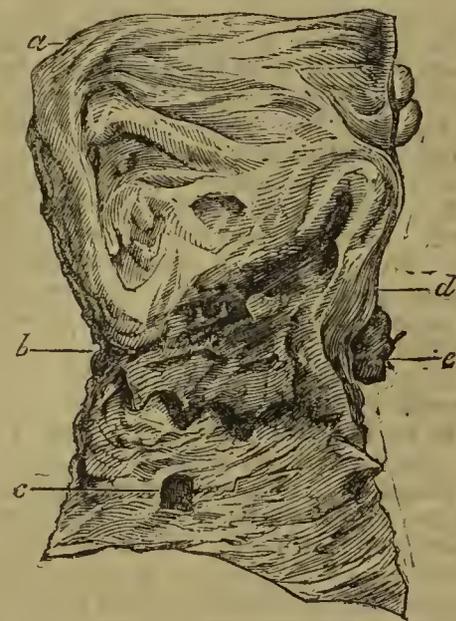

FIG. 3.—Internal Aspect of Colon and Rectum at the Site of Stricture. *a*, Dilated portion of colon; *b*, stricture, showing the dark mucous membrane drawn into folds; *c*, dilated portion of rectum and cicatrix of an ulcer; *d*, hypertrophied muscular coat of colon; *e*, portion of meso-rectum.

The muscular layer of the colon was greatly hypertrophied above and at the point of stricture. The fibres were pale.

The meso-rectal vessels and fat were contracted and indurated by chronic inflammatory changes. Microscopic sections of the different portions were made, and the nuclei of the muscular fibres were seen to be greatly increased in number. A large number of cells were discovered having several nuclei in their interior. They were probably the results of chronic inflammation in the part, being devoid of any specific character. In the course of the colon and rectum were numerous cicatrices of old ulcers, in one of which the stricture had probably originated. The liver was healthy; weighed 3 lb. 3 oz. Spleen, small and shrivelled, otherwise healthy in structure; weighed $2\frac{3}{4}$ oz. Kidneys healthy; right weighed 6 oz; the left, $5\frac{1}{2}$ oz. Thorax not examined.

Remarks on the Case by Professor Laycock.—Cases of obstruction of the bowels are amongst the most difficult and anxious that you will be called upon to treat. There are a variety of causes tending to its production, amongst which, as being the most important, may be mentioned spasm, volvulus, or intussusception, the presence of foreign bodies in the intestine, and stricture of some portion of the gut. Of these, the first is apt to be paroxysmal, but this condition may last for thirty-six or forty-eight hours, or even longer. Bands of organised lymph sometimes entangle loops of intestine and strangle them. Foreign bodies may lodge in the cæcum or appendix vermiformis, a sudden shock sometimes dislodges them and they are cast, incrustated with phosphates, into the ileo-cæcal valve. The rectum at its commencement and the sigmoid flexure of the colon are the parts of the intestinal tract most obnoxious to stricture. In this case I was led to diagnose stricture low down in the bowels for several reasons. In the first place the patient told us that for the last month or so before his admission here he had habitually passed small knotty masses of fæces, with slime attached to them. This fact led me to suppose that there had probably existed for some time a chronic inflammatory condition of the lower portion of the intestinal canal. Again, careful percussion proved the presence of the distended colon in the infra-mammary regions. Further, when a nutritive enema was administered by means of an œsophagus tube passed up per rectum till it encountered obstruction, it returned as fast as it was injected. Throughout his stay in the Hospital he passed an abundant amount of urine, and this would probably not have occurred had the stricture or intussusception existed far up on the small intestine. There was one circumstance, however, which militated against the stricture hypothesis—namely, the fact of the sudden painful seizure at the onset of his sufferings. The initiatory symptoms were characteristic of volvulus rather than stricture. Perhaps the gut got twisted at this moment. Pain at the umbilicus was complained of. This is significant, however, of other affections than ileus, and I am inclined to believe that intra-abdominal pain is not unfrequently referred to the umbilical region, in the same way that the irritations of vesical calculi are referred to the end of the meatus urinarius in the penis, or the tickling in the bronchi, which in some forms of bronchitis is felt in the neck. At all events, pain at the umbilicus does not of necessity imply affection of the parts immediately below this point, unless it be situated there exclusively, and in such a case the ileum would most probably be involved. If the pain occur in the right iliac region we may fairly infer that the ileo-cæcal valve or cæcum is affected, and all the more if our patient be of the female sex, since women are more liable than men to perityphlitis and disease of the ileo-cæcal valve. Now, this man's pain, doubtless, arose from the stricture situate within the pelvis, although it was referred to his umbilical region. With regard to the treatment of these cases of obstinate obstruction of the bowels, the first canon is—to do the patient no harm. Thus the practice of administering purgative drugs is much to be condemned. If the bowels fail to act after one or two doses of castor oil, it is better to desist from further efforts in this direction. The next step is to paralyse the bowel, and this is best done by repeated doses of solid opium in the form of pill. In this way all spasm is relieved, should it exist, and natural processes are permitted to go on without any injurious interference. Sometimes copious stools follow. Opiate epithemata to the abdomen are likewise grateful and of good service. Upon the plan adopted for feeding the patient much of his comfort will depend. No solid food of any kind is to be given, nor any of a nature likely to leave *débris* in the bowels. Thus nutrition must be carried on mainly *per rectum* by means of injections. A fair quantity of liquid aliment may be taken by the mouth, such as a few cupfuls of essence of beef, with wine, or liquid animal jellies. Ice in morsels is likewise useful, and always

grateful; it allays thirst, and often relieves the flatulent gastric distension so common in these cases. The enemata should consist of strong beef-tea, with whipped-up eggs and brandy, or the brandy may advantageously be alternated with half an ounce of ether, should there be urgent distension or spasm in the bowels. The bilious vomiting which occurs in cases of obstruction is not necessarily a bad symptom: it is really beneficial to the patient, as the bile is carried off from the system, and not retained to be absorbed into the blood. Nor, indeed, is stercoraceous vomiting of so grave import as is generally imagined, for in this way accumulation in the bowels is diminished, and pressure is removed from the upper side of the obstructed bowel, while at the same time the painful distension is relieved. In this case there was bilious vomiting, but no stercoraceous matter was ever rejected. The patient, in spite of all treatment, was not relieved of his prominent symptom. The enormous distension of the abdomen was constant; and the pressure exerted by the abdominal organs upon the diaphragm, heart, and lungs began to induce exhaustion and distress. Though free from pain in so marked a degree, and with such little disturbance as there was, palliated to the utmost, there remained but one chance to afford the prospect of direct relief; and this was the operation of paracentesis of the cæcum. I proposed, therefore, to perform this operation, having an excellent precedent for it in a case which occurred a few years ago in the practice of my friend, Sir Henry Cooper, of Hull. This operation has several noteworthy points. It entails but little injury to the parts concerned; the relief afforded by the evacuation of the flatus is immediate, and may ultimately be complete if fæces also pass; and should it even fail in accomplishing this, the patient is not in a worse position after the operation than before. In this case the cæcum and colon were so loaded with fæces that on the collapse of the distended portion the weight of the gut caused it to slip away from the trocar, and thus only a small aperture was made. It would have been better had the sigmoid flexure of the colon been pinned up to the abdominal wall and punctured, rather than the cæcum. Nature indicated what she would have done had the circumstances been more favourable, for there were plastic adhesions in the course of formation between the cæcum and abdominal walls, and had the canula maintained connection between the bowel and the lips of the wound, in course of time a serviceable artificial anus might have been established and dilated. It is necessary to employ a very large trocar, such an one as is employed in opening ovarian cysts. No fæces came through the canula, because the opening into the bowel was not large enough for the hardened solid masses. How vain in this case it would have been to perform gastrotomy and search for the site of obstruction, was amply shown by the great difficulty experienced in reaching the seat of stricture post-mortem without wounding the intestine.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

WESTMINSTER HOSPITAL.

CLOSURE OF THE JAWS FROM CICATRICES ON BOTH SIDES OF THE MOUTH—TREATMENT BY INTERNAL DIVISION AND THE USE OF METALLIC PLATES UPON THE ALVEOLI—SATISFACTORY RESULT.

(Under the care of Mr. CHRISTOPHER HEATH.)

In the *Dublin Quarterly Journal* for May, 1863, Mr. Heath described the causes and treatment of closure and immobility of the jaws, and reported two cases treated in the Westminster Hospital—one by himself, in which Esmarch's operation of division of the lower jaw was successfully practised; and the other by Mr. Holt, in which division of the cicatrices and the after use of metallic shields contrived by Mr. Clendon (late Surgeon-dentist to the Hospital), were followed by the best results. In that case, however, the contractions were on one side of the mouth only, and it might, therefore, have been treated after Esmarch's plan, which consists in producing a false joint in front of the cicatrix; but in the case we report to-day the contractions were on both sides of the mouth, and that procedure was, therefore, inadmissible.

The treatment by internal division and the use of shields is much more painful and wearisome for both patient and Surgeon than the method by division of the jaw (where it can be applied), and it will be seen that it was necessary to administer chloroform every time the mouth was interfered with. Mr. Heath has lately performed Esmarch's operation in another case, with the most promising results, and would prefer that operation to that by internal division in all cases where only one side of the jaw was affected.

Isabella McN., aged 18, admitted into Arden ward December 15, 1862, under Mr. Heath, with closure of the jaws and mouth by cicatrices.

History.—When five years old she had measles (?), and is supposed to have taken mercury, and, a few months after, it was noticed that the cheek was contracting, so that when 6 years old the jaws were firmly closed. When about 7 she was admitted into the Dundee Infirmary, and some operation was performed, by which she was benefited for a short time, but the jaws were soon as firmly closed as before. When about 11 years old she was admitted into the London Hospital, under Mr. Luke, who divided the cicatrices and opened the jaws with a screw. She was in the Hospital three months, and was slightly benefited for a time. Eighteen months after this was again admitted, and the same operation was repeated, oiled lint being introduced beneath the cheek, and wedges inserted between the teeth to keep them apart. The parents took considerable pains to keep the wedges in and to make her move her jaws, but the contractions soon recurred, and for the last two years and a-half the jaws have been firmly closed.

Present Condition.—The mouth is smaller than usual, owing to contractions at the angles. She can show the incisor teeth, and the upper ones are firmly closed over the lower. The cheeks are firmly bound down to the alveoli from the angles of the mouth, and there is no power of separating the jaws at all, but she can move the lower jaw a little from side to side. She introduces her food through an aperture on the right of the incisor teeth, where a tooth has been lost. She is plump and well-nourished, but has not menstruated for five months.

Operation.—December 16.—The patient having been put under chloroform, Mr. Heath proceeded to dissect up the cheek from the alveoli by passing a knife from the mouth. The bands of cicatrix were exceedingly firm, and were found to pass not only between the gum and the cheek, but between the gums themselves, and these required free division before the mouth could be opened at all, and then only by the help of a screw. A small wedge of wood was extracted from between the teeth, where it had been for some months. Oiled lint was carefully stuffed between the alveoli and the cheek and the patient put to bed. ℞ Tinct. opii., ℥xxx.

18th.—The pledgets of oiled lint were removed, and the mouth well washed out. She could open her mouth for a short distance, but the movements were necessarily painful. Lint soaked in myrrh lotion was placed inside the cheek.

20th.—Chloroform having been again administered, Mr. Clendon, the dentist to the Hospital, attempted to take models of the mouth, but found that the aperture was so small and the space between the teeth so contracted that it was almost impossible to obtain a satisfactory mould. The teeth appear to have been only partially developed, with the exception of the incisors, which also are so loose as to offer little support to a shield.

22nd.—Mr. Clendon took moulds of gutta percha of the outer surface of the jaws as some guide for the formation of temporary shields.

25th.—The House-Surgeon was called up last night to the patient, who was bleeding freely from the left side of the mouth. He plugged the cheek with fresh lint, which arrested the hæmorrhage. A second hæmorrhage occurred in the afternoon, and the blood came from quite the back of the mouth, between the cheek and alveolus on the left side. Mr. Beadles, House-Surgeon, finding that a coagulum had formed which had stopped the hæmorrhage, left it undisturbed.

26th.—Mr. Heath saw the patient, who was rather reduced by the bleedings, but thought it better not to disturb the clots for another day. Ordered, wine, ℥vij.; beef-tea.

27th.—A severe arterial hæmorrhage occurred this morning, and was arrested by clearing all clots and syringing the mouth with cold water. Wine, ℥xij.; beef-tea, eggs.

29th.—No more hæmorrhage has occurred, but the patient has become somewhat anæmic. Mr. Heath thought it would be safer to postpone any further interference with the case for a week, so as to allow her to recover fully from the loss of

blood. The mouth to be simply syringed out with warm water and myrrh lotion.

January 5, 1863.—The patient having been put under the influence of chloroform, Mr. Heath carried his finger freely between the cheek and the alveoli, breaking down the soft adhesions which had begun to form. Mr. Clendon then removed some stumps of teeth and all the incisor teeth (except one of the upper centrals), which were loose. Mr. Clendon then succeeded in taking more satisfactory models of gutta-percha, from which the shields might be made.

7th.—Under chloroform, silver shields were fitted upon the alveoli, the edges of which passed between the alveolus and cheek, gutta-percha wedged in between them.

10th.—Fresh shields with deeper sides were inserted under chloroform. The remaining incisor tooth came away, and several stumps were removed.

14th.—Bone wedges were adapted to the shields to keep the jaws apart and to permit of greater cleanliness than was possible with the gutta-percha. To use a lotion of the chloride of soda frequently.

21st.—Under chloroform Mr. Heath made a thorough examination of the mouth, and found everything in a satisfactory condition so far. The sulcus on each side of the mouth has considerably increased in depth, and the finger can be carried between the gum and cheek as far back as the wisdom teeth on each side. The mouth is kept well open by the bone pieces, and the absence of incisor teeth gives plenty of room in front. Mr. Clendon extracted several stumps, and then took fresh moulds of the mouth. The old shields and bone pieces were then inserted.

28th.—Under chloroform the shields were removed, and having been re-lined with soft gutta-percha, were replaced. The mouth opens very satisfactorily, and the soreness is diminishing.

February 4.—Under chloroform fresh shields with deeper edges were introduced, which kept the mouth widely open.

12th.—Some little swelling about the right eye has come on during the last day or two, but is gradually subsiding under fomentations.

28th.—The patient is able to move the jaws to a slight extent, even with the shields in the mouth, and the case seems to be going on satisfactorily. The shields were removed under chloroform (having been *in situ* three weeks), and were lined with some fresh gutta-percha, so as to fit more accurately to the alveoli. The mouth has increased in size, and the sulci on each side of the alveoli are much deepened.

March 4.—The shields were removed under chloroform, and the bone wedges cut off, their places being supplied with moveable wedges of hard gutta-percha, so as to permit the patient's removing them when eating, and thus to exercise the jaws. The granulations in each cheek were touched with nitrate of silver.

25th.—Under chloroform the shields were removed, and new ones substituted with deeper edges in front, so as to free the lips from their attachments, which were divided with a scalpel.

30th.—The lips are more mobile than before, and now that the soreness of the first few days has worn off, the shields are more comfortable than the old ones. Wedges of beech-wood were substituted for the gutta-percha. There is a clear inch between the shields when the mouth is fully open.

April 18.—Under chloroform the plates were removed, and as it was found that the right lower wisdom tooth raised the shield so much as to prevent proper closure of the mouth, it was extracted by Mr. Clendon. Fresh shields were introduced in order to obtain a correct mould of the bite, and the old shields were then replaced.

May 13.—Under chloroform Mr. Heath screwed open the mouth with a screw-gag placed between the plates, and found the space obtained very satisfactory, and the bands of tissue much less firm than they were.

20th.—The above operation of screwing was repeated.

June 3.—Under chloroform the shields were removed, and fresh ones with artificial teeth fitted to them were inserted. The space already obtained is satisfactory, and movements of the lips are very free.

17th.—The "bite" of the teeth not being quite satisfactory, the upper piece was removed under chloroform, the old shield being temporarily replaced.

24th.—The upper piece having been modified and replaced, the bite proved very satisfactory.

July 28.—The patient went home to Dundee, as Mr. Heath thought time alone was required to perfect the cure. She wears the plates with perfect comfort, and can eat crust. The

space between the artificial incisors is three-eighths of an inch, but from one plate to the other, including the artificial teeth, one inch.

Mr. Heath has lately heard from Dr. Crockatt, of Dundee, that the patient continues in a satisfactory state, and is able to open the mouth as well as when she left town.

GUY'S HOSPITAL.

THREE CASES OF OBSTRUCTED LABOUR—FORCEPS AND CRANIOTOMY EMPLOYED IN FORMER LABOURS IN EACH—DELIVERED READILY BY VERSION.

(Under the care of Dr. J. BRAXTON HICKS.)

Case 1.—Coarctation of the Brim—Version by Dr. Hicks' Method—Labour induced by Dilating Elastic Bags, and completed in Two and a-half Hours—Child Alive—Mother Recovered.

This patient had had four children; the first two were very small, naturally born; the third delivered by craniotomy; the fourth by forceps, alive, by Dr. Hicks, who advised her to have labour prematurely induced at seven and a-half months in the next pregnancy. This, however, she neglected to do till nearly full term, when she consented. Dr. Hicks thought it useful to take advantage of even a short time, and to try delivery by the foot. It was decided by him to change the presentation while the uterus was quiescent. Accordingly, on March 13, 1864, the cervix was dilated readily by elastic india-rubber bags, so that in an hour the cervix was fully dilated. Chloroform was now given; version easily by combined external and internal method; membranes ruptured, and the foot drawn in vagina. Chloroform was then withdrawn, and the uterus began to act. In half an hour after it was in fair rhythmical action, and had expelled the breech. A dose of scalle was given to secure its full action after, and the child was gently drawn down during the pains. When the head was engaged in the brim, the traction was increased, and once detention ensued for four minutes, owing to the prominent sacrum; the head, however, gradually passed through, and the difficulty was over. The child soon began to breathe, although the funis was not pulsating quite five minutes before birth.

The whole affair was over in about two and a-half hours from the commencement of the dilatation to the delivery of the head. The placenta came away naturally. The mother and child are doing well.

Case 2.—Semi-Elastic Solid Tumour in Cavity of Pelvis, lessening its Antero-posterior Diameter One-third—Craniotomy in Former Labours—Version in Early Labour by Dr. Hicks' Method—Delivery of Dead Child—Recovery.

In this patient there is a tumour, semi-elastic, extending from tip of cæcæx upwards three inches, spreading laterally halfway round on each side. In the former labour forceps were tried, but they failed to bring down the head, in consequence of the pressure of the head from above causing bulging so as to reduce the antero-posterior diameter to about half. The child was delivered by craniotomy. She was advised to have premature labour induced at seven and a-half months upon a future occasion. This, however, she neglected, and when she was seen on March 13, 1864, she was in labour. Dr. Hicks having determined to employ foot presentation, version was accomplished by the combined external and internal version readily under chloroform, and the foot brought into vagina. The chloroform was suspended, and the pains soon came on vigorously. The body descended shortly, but the head was detained long enough to take away the chance of a living child, but infinitely easier than the former craniotomy. She recovered rapidly.

Case 3.—Equally Small Brim—Large Head—Forceps found Dangerous—Version—Delivery of a Dead Child—Recovery.

This patient had had eleven labours, in all of which the child was born dead, excepting in one which was premature. In three craniotomy, in three forceps. The cavity and outlet were very full sized; the brim was remarkably small in every direction. She had been in labour twelve hours on March 25, 1864. Head at brim five hours without progress. Forceps were put on, but as it was found that they would have seriously pressed on the brim they were withdrawn, and version was employed instead by the old method. There was much difficulty in effecting the descent of the breech, owing to hour-glass constriction of uterus. This being at last overcome by gentle traction, the head was again engaged at the brim.

Steady traction for two minutes caused it to come through, but it was dead, having probably been so for some time. She progressed favourably.

Dr. Hicks remarked that induction of labour at the eighth month and delivery by foot presentation would, in all probability produce a live child.

ST. GEORGE'S HOSPITAL.

TWO CASES OF ULCERATION OF ARTERIES.

(Under the care of Mr. HENRY LEE.)

THE first of these was that of a married woman, named Eliza M—, 53 years of age, whose arm was amputated for disease of the wrist on October 29, 1863. Some phagedænic ulceration followed the operation. She died on December 2, a very large quantity of blood having been found in the bed. On examining the arm, a deep cavity was found to exist on the inner side of the arm, from the surface of the stump to within an inch of the elbow joint. This cavity was filled with recent coagula, which evidently had come from an opening in the ulnar artery an inch and a-half from its origin.

The second case was one of ulceration of the artery, in which no corresponding opening existed in the skin. A lad, named F—. On Good Friday, 1860, he was kicked on the knee-cap, which caused him some pain for two or three days. Nothing further occurred until May 25 of the same year, when the right ankle became swollen, and in two days more the swelling reached to the knee. There was no pain nor difficulty in walking. He was admitted into St. George's Hospital on the 29th of the same month. The whole of the right leg and thigh were then swollen from serous effusions in the cellular tissue. The patella was raised by effusion into the knee joint. There was no pain, nor discolouration of the skin. On the 30th, the swelling was much less, but some swelling continued on June 14. He now left the Hospital; but the leg continued slightly more swollen than natural. It did not inconvenience him, and he was able to go about his work. On November 10, 1863, the whole leg again began to swell whilst he was at work, and in the evening the boot could scarcely be removed. The stocking was found saturated with serous fluid, and on its removal the skin had given way at two points—viz., at the upper and outer part of the thigh and at the point of the great toe. On November 12, he had great pain in the popliteal space. There was pain on pressing the articular cartilages against each other. The principal swelling was now above the knee on the inner side. A grooved needle introduced at this point allowed serum only to escape. On November 13 there was some redness about the knee-joint, less pain on pressing the articular cartilages. On November 17 the swelling had increased in the whole thigh and leg. A grooved needle again introduced allowed the escape of some sero-purulent fluid. On November 21 swelling of leg increased. On December 21 an incision was made above the knee, and a large quantity of bloody fluid was evacuated. From this time a very large quantity of fluid was discharged daily, partly from the wound above-mentioned and partly from an opening which occurred spontaneously below and to the outer side of the knee. The fluid thus discharged gradually became more fetid, and the proportion of blood which it contained became gradually greater. The patient died on January 5. Nearly the whole of the thigh was occupied by a large blackened cavity, through the centre of which the femur passed down, covered by blackened periosteum, but denuded of muscles. The femoral artery and several of its branches were exposed and dissected. On injecting water into the femoral artery it passed in a fine stream through a circular aperture in one of its branches. This aperture was either an ulcerated opening in the side of a vessel, or else the ulceration has extended round a smaller branch at its origin, so as to separate it completely from its attachment. The abscess in the thigh communicated with the knee-joint and extended into the calf of the leg. The articular cartilages of the joint were gone, and the bone was roughened and covered with lymph. The other organs were healthy, with the exception of a part of the lower lobe of the left lung, which was solidified.

ARMY MEDICAL APPOINTMENT.—Miss Mary C. Walker, M.D., arrived here last week with orders to report to Dr. Perrin for duty. She has been appointed to Colonel M'Cook's brigade, and has just left for Gordon's Mills, where the brigade is stationed. The young lady is said to thoroughly understand her Profession. She is very pretty.—*Chattanooga Gazette.*

SATURDAY, APRIL 16.

ARMY MEDICAL MATTERS.

AT that period of our lives when we possessed two great enemies always menacing us,—the nursemaid and the Doctor—the former would threaten us with physic from her coadjutor in wickedness, the Doctor, or would occasionally try to beguile us into silence, if not goodness, by a fairy tale.

Now that we can gaze upon “young knickerboekers” of our own nursery, we may have lost the pleasures arising from an open-mouthed absorption in their recital, but we have preserved sufficient “greenness” to feel gratified with the fictions, while we can recognise the homely truths which underlie them.

Well we remember the “Prince with the Nose.” A king succeeds, after many efforts, in stamping upon a cat’s tail, by which he broke an enchantment, liberated a lovely and captive princess, who—with that rapid consummation of happiness only to be found in these stories—speedily became his wife. We learn that the aforesaid cat changes into an infuriated man, and threatens the happy pair with a son and heir who shall have a nose, and no mistake.

In due time a little prince came, and he had every feature in lovely proportion except the nose, which covered half his sweet face. The queen-mother was consoled by her ladies. The nose was not nearly so large as it seemed; it would grow smaller as the prince grew bigger, and if it did not, a large nose was indispensable to a hero. All great men had great noses, as everybody knew. The little prince was, in due time, told all kinds of amusing stories, in which the main element consisted in making out that all the men with large noses were good people, and those with small noses bad ones. The prince was surrounded with portraits of big-nosed ancestors, and all persons with a diminutive form of this feature were banished. To possess an enormous nose was the climax of a man’s ambition, as it was the sure way to his success in life. Babies had their noses pulled then on principle by their fond parents; and as the long, well-developed nose was the mark of the “swell” of that day, the “snub” was an unmistakable indication of the snob. Well, we read how the prince grew up in this kind of thing, and, in process of time, fell in love with a charming young princess, whose only drawback was her small nose (a fact which the sophists of that day soon managed to prove was the right thing for a woman, and quite consistent with the prevalent belief); how the being whose feelings had been outraged by the aggression on his tail soon found out how matters stood, and treacherously carried off the beautiful princess; how the determination to rescue her led the prince into a land of normal-nosed inhabitants; how a garrulous old fairy raised his cholera by her remarks on the size of his nose, and politely requested him to turn his head a little, as his nose cast such a shadow on her plate; how the prince saw his lady-love, but could not get at her for the length of his said nose, and how he at length exclaimed, “Well, my nose is too long,”

and thereupon how all obstacles to his happiness were instantly overcome. The old fairy—as old ladies are apt to be—is very candid, and tells him “You ought to be much obliged to me. I might have talked for ever on the subject of your nose, and you would not have believed in its length till it became an obstacle to your own inclinations.” The story comes to us as fresh as ever, and the truths it teaches—like all stories worth the telling—lie upon the surface, and are not limited to children only.

With a little mental readjustment we can adapt it to the conduct of many people in the present day. We take one illustration. The authorities persist in saying that the Army Medical Department has no grievances; then that the grievances are much less than stated, and will cease as the department grows; then they introduce all the men they can who are of their way of thinking, and banish all others; then they declare that all the *good* Medical officers have no grievances and all the bad ones have, and so it goes on; but, spite of all they can do, people will perceive and assert the truth, till the Army Medical Department is almost in the state of a derelict ship.

We suppose that the authorities must sooner or later make the discovery, by a process something akin to that of the prince, for no amount of talking will ever convince them. They are beginning to find by experience that the ugly features in the Army Medical service have become as evident as the nose on one’s face. Their last shift has brought them a very slight accession. Here and there a man under 30, who has not found the paths of private practice to be the ways of pleasantness and profit, has boldly entered Whitehall, and desperately taken the street to the Director-General’s office in search of these things.

Seeing that an army can’t exist without Medical men, looking to the fact that Doctors are becoming much less numerous than of yore, and of far better education and social stamp, the sooner the authorities read what everybody else can see the better for themselves and the pockets of the taxpayers. In the meantime, as soldiers will get sick and Doctors must be had, we have learned that a new plan may be adopted to get them. We heard the rumour some time ago, but did not refer to it because we did not credit it. However, it has been stated as having a foundation in fact. It is rumoured, then, that the gap is to be filled by means of civilians and acting Assistant-Surgeons. A member of the Medical Department may be years abroad, longing for the home which he may now never see, until he is placed upon permanent or temporary half-pay, for the civil element will, we suppose, perform the Medical duties of the home stations. Should this be true, it is as lamentable as it is unjust.

If the Government authorities would only have the courage and candour to meet the evils face to face, they would be saved all the present difficulty, which will only gather additional force for every day that it is put off.

It must be confessed that “the nose is too long.” That is the disagreeable truth.

So long as there is the probability of serving in all climates for twenty or thirty years on the pay and position of an Assistant-Surgeon, so long as the duties comprehend what they now do—the monotonous courses of rifle practice, the degrading work of branding, the clerical work, and the restraints on all liberty of action in the discharge of those duties—there is not much chance for the Army’s obtaining its share of the really well-educated, gentlemanly, zealous, and able-bodied young men from our Medical universities. Until some reforms are made, and we may take the two temperate letters by an Army Surgeon, which lately appeared in our columns, as expressing the direction which those reforms should take, it is very unlikely that the Army Medical Service will be as popular as the other walks of life open to the rising Physicians and Surgeons.

In the meantime, to expect men to compete for posts which are going-a-begging, and which others are daily resigning,

bears on the face of it a ridiculous misconception; and, on the other hand, to introduce a number of men as acting Medical officers without any examination is an unjust and miserable expedient, is brimful of evils, present and prospective. On one or other of these horns the authorities now find themselves, and seem very likely to remain.

THE WEEK.

GENERAL GARIBALDI.

WE are glad to be able to present our readers with the following authentic Surgical account of the present condition of the illustrious foreigner:—The wound in General Garibaldi's leg has been entirely and soundly cicatrised for three months or more, and the only indication of the injury is a dimple on the inner side of the ankle where the ball entered. There is no sinus and no discharge, and as the parts are thoroughly cicatrised, there is, in all probability, nothing present in the shape of a foreign body or piece of necrosed bone. The main symptoms from which the General is at present suffering are the effects of long-continued inflammation, represented by considerable stiffness and want of motion about the ankle. There is limitation of movement in various directions, and, in all probability, there is a pretty firm ankylosis of the ankle joint itself. There is, however, a considerable capacity of motion in the tarsus. By the aid of a stick the General can move the limb freely. From this account it is clear that no active Surgical treatment is needful.

PARLIAMENTARY.

ON Thursday, April 7, in the House of Lords the Malt for Cattle Bill was read a third time and passed.

In the House of Commons the event of the evening was Mr. Gladstone's financial statement. The main points in the budget of 1864 are doubtless well known to our readers, and we have only to congratulate them on the prospect of a reduction of 1d. in the pound income-tax, and of about one-third of the tax on sugar. The sugar tax is still to be discriminating instead of uniform, a mode of taxation which favours the introduction of the coarser varieties of sugar. The objection urged to a uniform duty on unequal qualities is, that in effect it would afford protection to the growers of pure sugar in Mauritius and elsewhere, and to foreign refiners. Mr. Gladstone has therefore decided on preserving the present system, which is at least equally a system of protection to the producers of the inferior qualities. It can scarcely be doubted on which side the interests of the general public lie. But it would be ungracious to criticise too closely a budget which has so much to recommend it.

On Friday, April 8, Mr. Gregory called attention to the condition of the scientific institutions of Dublin which are assisted by Government aid.

Sir R. Peel said the Government were prepared to agree to the appointment of a Select Committee to inquire fully into the character of these institutions.

On Monday, April 11, in the House of Commons, the debate on going into Committee upon the Government Annuities Bill was resumed. Sir M. Farquhar's amendment was ultimately agreed to, and the bill was ordered to be referred to a Select Committee.

The House then went into a Committee of Supply on the Army Estimates.

Upon the vote of £5,708,983, for general staff and regimental pay, allowances, and charges, a long debate took place, in the course of which Mr. O'Reilly instituted a comparison between the cost of the British and French armies, in all the details of the charges, which showed that, in all of them, with the exception of Medical attendance and appliances, those of the British army were nearly double those of the French army, calculated per man of the respective forces.

In the course of his general reply, Lord Hartington gave details relating to the effects of the Limited Enlistment Act. There were two points touched on in his Lordship's speech

which are of Professional interest. One was the reduction of mortality in the army. He said:—

“By the returns of 1850, 1851, and 1853, it appeared that the annual deaths in the army were over 29 per thousand, while according to the same returns of ten years subsequent, 1860, 1861, and 1862, the deaths were reduced to 18 per thousand, showing in the death vacancies of the army a reduction of 11 per thousand. Now, the average number of men serving during the last years was 195,730, and the difference of the two rates of mortality would cause in these numbers an annual saving in death vacancies of 2,200 men. He was quite aware that they could not attribute all that saving to any particular cause. No doubt, the improved sanitary and Medical regulations had done something, and he hoped a great deal; but the great bulk of the saving of 2,200 in the death vacancies annually was to be attributed to the fact that in 1860, 1861, and 1862 we had a much younger class of men than in 1850, 1851, and 1852. After our army had suffered great losses in the Crimea and the Indian mutiny, a very large number of young men joined it. Still it was quite evident that the army was, to a certain extent, composed of younger men, and, therefore of a class of men less likely to die rapidly. In that view he was borne out by some Medical statistics which had been drawn up, from which it appeared that in the army the number of deaths of men under 30 years of age was 17 per 1,000, while of men between 30 and 40 it was 28 per 1,000. In India the comparison was still more striking; for there the mortality of men under 30 was 39 per 1,000, and of men between 30 and 40 it was 74 per 1,000. It was clear, therefore, that in an army composed of younger men the mortality was less than among older men.”

If this deduction be true, it militates to a certain extent against the belief that the constitution becomes fortified by exposure against the various deteriorating influences to which the soldier is subjected. The higher rate of mortality is not amongst the young lads who are sent raw to India and the colonies, but amongst the tried and seasoned soldiers who have completed a large portion of their service. The other subject referred to by the Marquis of Hartington was the slowness and difficulty with which men are obtained for the army. His observations show that the relaxation of the law which made the Surgeon responsible for the expenses of a recruit rejected after examination has been wrung from the authorities, not by the remonstrances of the Medical Department, but by the fact that the Surgeons have discharged their duty so scrupulously that they have rejected too large a number, and the service has accordingly been starved for want of men. His Lordship said:—

“Much of that slowness was attributable, he believed, to the stringency of the Medical regulations, which threw the whole travelling expenses of a recruit rejected by the regimental Surgeon upon the Surgeon who had originally passed him. The consequence of that regulation was that the Surgeons attached to the recruiting staff were over careful in passing recruits, and in order to encourage recruiting so as to obtain the ordinary number it was intended to relax the regulation he had referred to, and to reduce the standard by one inch.”

The authorities have been taught two lessons by experience—first, that in the matter of passing recruits it is possible to err on the side of too much care as well as in the opposite direction; and secondly, that the service is really better off when it trusts to the honour and rectitude of its Medical officers in the performance of their duty than when they are placed under an arbitrary and oppressive system of pains and penalties.

The votes on the Army Estimates were agreed to.

Lord Hotham again introduced the subject of the Crawley court-martial. He contended that the court-martial need not, and should not, have been held in this country, and that the expense and scandal might have been avoided. The points of Professional interest connected with the court-martial were not touched on.

Mr. Gregory moved for a Select Committee to inquire into the condition of the scientific institutions in Dublin.

On Tuesday, April 12, in the House of Lords, Lord Westmeath moved the second reading of the bill empowering the judges to add flogging to the punishment awarded by the law in the case of persons acting as accomplices in criminal assaults on women.

After some discussion, the bill was read a second time.

Lord Carnarvon moved for copies of the correspondence relative to George Hall convicted of murder at Warwick and

respired on March 13. After commenting on the facts connected with the cases of Townley, Wright, and Hall, he said that he approved the final decision in the case of Hall, but thought the Secretary of State ought not to shift his responsibility upon a power so uncertain and capricious as public opinion.

The Lord Chancellor took on himself all the responsibility of the decision as to the disposal of Townley after his removal to a lunatic asylum. He had also been consulted by Sir G. Grey in the case of Hall, and, taking only the legal view of the evidence, he had advised the decision announced in the first communication to the Birmingham magistrates. But he, nevertheless, felt glad that Sir G. Grey subsequently revoked that decision on other than legal grounds, as there were, no doubt, circumstances in the case that in general opinion reduced the murder to homicide of the degree of manslaughter, and the execution of the criminal would have shocked the community. Every allowance should be made for the peculiar position of a Secretary of State who succeeded to the office with all its traditions and rules of proceeding that had grown up in a long series of years. He exercised a power that under the present system must be considerably affected by personal disposition. A stern man would probably resist a pressure to which one of gentler temper would yield. The prerogative of the Crown must of course be maintained unimpaired, but he wished the Secretary of State could be assisted in his decisions by some authorised body that could act on more distinct principles. The whole subject was difficult and important, and deserved the serious attention of the Legislature. As to the motion, he would give Lord Carnarvon every information on the case, but the communications to him were almost private letters, which it would not be expedient to publish.

The motion was withdrawn.

In the House of Commons, Captain Jervis brought the subject of the grievances of the officers of the late East India Company's service under notice. As the debate turned almost entirely on the effect which the recent change has had upon the position and advantages previously enjoyed by the "combatant" part of the service, it does not require our notice. The only reference to the Medical branch of the service was made by Mr. Bass, who asked "whether anything was to be done to remedy the grievances of the Medical officers in India." To this Sir Charles Wood gave the vague and unsatisfactory reply that "the case of the Medical officers had to receive an entirely separate consideration." We believe that the Government will before long find out that the subject of the Medical Department in India will need consideration in another sense than that in which the Secretary of State for India spoke. In the Indian army it is said there are about 100 vacancies, and it is utterly improbable that under the policy the Government are at present pursuing they will get any Medical officers to fill them. In the old days of the East India Company there were always double as many candidates as vacancies, in the Assistant-Surgeons' list. But the East India Company, whatever were its shortcomings, had a knack of keeping faith with their servants.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XI.—FEBRUARY 25.

Anatomy of the Chimpanzee Continued.—The scapula is of an elongated and narrow form, compared to that of man, and has a very clearly defined articular surface on the acromion for the clavicle. The last-named bone much resembles in its curves and general form the human clavicle. It articulates very obliquely to the manubrium sterni, so that the outer rises greatly above the level of the inner extremity, causing the characteristic high shoulders and apparent shortness of the neck, for, contrary to what is generally supposed, the cervical region is not really shorter proportionately to the trunk than in man. The humerus, radius, and ulna closely resemble the same bones in the human subject, with the alterations of proportion already noticed. The radius is rather more curved, giving a wider interosseous space. There is no essential difference in the structure of the carpus from that of man, the

bones have the same number and relations to each other, but they present slight differences of form and proportion. The trapezium is a smaller bone, and its articular surface no longer presents the characteristic saddle-shape found in man, but is a simple, oval, convex facet, in relation to the comparative small size and less important function of the thumb itself. The fingers are of much greater length, compared with the breadth of the hand, than in man, and the phalangeal bones are more curved. These modifications of the hand of the chimpanzee show that it is an organ less adapted for administering to the will, exercising the sense of touch, and the multitudinous purposes to which it is put in man, but have clear reference to its principal purpose as a scansorial organ.

The pelvis differs greatly from that of man. Though the whole animal is smaller, the pelvis is absolutely of greater length. The iliac bones are much narrower in proportion, and the whole has little of the basin-shape characteristic of the human pelvis. The front surfaces of the ilia are certainly somewhat concave, and traces of the sigmoid curvature of the upper margin are visible. The sacro-iliac angle is more acute than in man, not exceeding 70°. The pubic symphysis is singularly long, and the union of the bones very complete.

The antero-posterior diameter of the pelvis greatly exceeds the transverse diameter, contrary to what generally obtains in man, and another important point of difference, and approximation to the lower monkeys, is the eversion of the tuberosities of the ischia. The femur is of small size, but not otherwise unlike that of man; the internal condyle, however, scarcely projects further than the external. In the ankle-joint, the astragalus is embraced firmly by the projecting malleoli; but the lower articular surface of the tibia, instead of being horizontal, slopes obliquely upwards to the outer side. In the foot, the extremely different proportions of the tarsus, metatarsus, and digits from those of man have already been alluded to; the metatarsal segment being rather the shortest of the three. The various bones of the tarsus have fundamentally precisely the same number, form, and relations, but the differences in detail are numerous. The hinder process of the calcaneum is much less developed than in man, and its tuberosity is single and narrow at its inferior extremity—circumstances which greatly impair the efficiency of the foot as an organ of support. The scaphoid and cuboid bones rotate freely on the astragalus and calcaneum, and it is on account of this mobility, and not from any peculiarity of the ankle joint, that the outer side of the foot comes to the ground first when walking, and that the soles naturally turn inwards when the foot is at rest, or in climbing. The phalanges of the toes exhibit a certain concavity of the under surface, but not so marked as in the fingers. But the greatest peculiarity of the foot, and one which makes it pre-eminently adapted for grasping boughs in climbing, is the position and mode of articulation of the great toe. This is one of the most interesting examples in nature of a very slight modification of the structure of parts essentially the same producing a vast change in their function. The change is in the articular surface of the entocuneiform bone—a change the converse to that which takes place in the trapezium. The result is that the toe is freely moveable, though not in the same direction as the others, being opposable to them, and the peroneus longus muscle, having precisely the same origin and insertion as in man, has its function reversed, and instead of steadying the leg from a fixed point below, becomes a powerful adductor of the great toe, affording prodigious grasping power to the foot.

Leaving the skeleton, Professor Huxley passed to the consideration of the muscular system, confining his observations to the upper and lower limbs, of the muscles of which he had lately, in conjunction with Mr. Flower, made a new and careful dissection. There are certain muscles which the chimpanzee possesses, which are not found in man. There are,—1. A muscle passing from the transverse processes of the upper cervical vertebræ to the outer end of the clavicle, called "levator claviculæ" by Tyson, and "trachelo-aeromial"

by Duvernoy. This muscle, however, does not seem to be always present even in the Chimpanzee. 2. The "dorso-epitrochlear" of Duvernoy, a muscular slip passing from the tendon of insertion of the latissimus dorsi to the elbow. 3. The "scansorius" of Trail, arising from the edge of the ilium, and inserted into the great trochanter, a powerful internal rotator of the leg. 4. A very small muscular slip, arising from the calcaneum, apparently detached from the abductor minimi digiti, and ending in a tendon inserted into the base of the fifth metatarsal bone, which might be called "abductor ossis metacarpi quinti." Now, these muscles, though stated to be absent in man, are not wholly unrepresented, either normally or exceptionally. 1. A separate bundle has been seen to pass from the mastoid process to the extremity of the acromium, detached from the trapezium, and representing to a certain extent the trachelo-acromial of the inferior mammals. 2. According to Henle, the triceps extensor of the arm has constantly a tendinous slip from the latissimus dorsi, constituting an interesting approximation to the dorso-epitrochlear. 3. A distinct muscle arising in front of the gluteus minimus near to the sartorius, and either joining the tendon of the gluteus or inserted separately into the femur, and so resembling the scansorius of the apes, has been observed in man. 4. Although not hitherto noticed in anatomical works, Mr. Wood has frequently seen in the human foot a muscle precisely corresponding to that above described under this head.

There are certain muscles which are developed in man, and which either are, or are commonly said to be wanting, in the chimpanzee. These are—1. The extensor primi internodii pollicis; 2. The peroneus tertius. Instances of the absence of both these muscles in man have been met with—the latter, especially, is very variable. The transversus pedis and the extensor indicis have both been said to be absent in all apes; but, on the contrary, they are really well developed in the chimpanzee, and as we shall afterwards see, in other members of the group. The flexor accessorius was absent in the specimen recently dissected, but it has been found by other observers.

Certain muscles differ from the same muscles of man in their origin. The soleus rises only from the fibula by a tendinous head. The flexor brevis of the toes arises partly from the calcaneum and partly from the under surface of the tendon of the long flexor, the division for the fourth and fifth digits having the latter origin. This remarkable simian modification is, however, met with occasionally, and in a limited manner, in the human foot, the muscles furnishing the perforated tendon for the fifth toe having been seen to arise from the tendon of the long flexor, apart from the remainder of the short flexor.

FROM ABROAD. — ENGLISH AND FRENCH STATE-MEDICINE —
THORACENTESIS IN PLEURISY—REGENERATION OF BONE.

A REMARK made by a reviewer of Mr. Simon's Report to the Privy Council, writing in a recent number of the *Union Médicale*, is worthy of notice as indicating a point too often forgotten among ourselves. Loud are the encomia which some of us are in the habit of passing on the elaborate official organisations which exist on the Continent, as contrasted with our own more humble and less comprehensive arrangements; but the comparison is not always carried far enough for the appreciation of results, or the conclusions arrived at might prove rather different. The observations of the reviewer would apply still more forcibly to our registration reports, returns similar to which, as regards completeness, accuracy, and importance, are to be found nowhere, either in Europe or America. "It is not," he observes, "that public or administrative Medicine is as well organised in England as it is in France, but our neighbours know better how to utilise their institutions, incomplete though they be. With us organisation is carried even to luxury, for we have Physician-Inspectors of Mineral Waters, Physicians of Epidemics,

Sanitary Physicians in the East, Vaccinating Physicians, Medical Verifiers and Inspectors of Deaths, Medical Inspectors of Foundlings;—all these radiating from central institutions, as the Academy of Medicine, or the Consulting Committee of Public Hygiene, or from the local councils of Hygiene and Salubrity of the different departments and arrondissements—all, however, leading to no general and united whole, such as that which we have now under consideration. The Academy of Medicine publishes annually general reports on epidemics, mineral waters, and vaccination; and several, but not the greater number, of the Councils of Hygiene likewise publish the result of their labours; but there is an absence of connection and co-ordination among these; and it is thus impossible to educe from them a general statement of the condition of the public health in France like that furnished with respect to England by Mr. Simon."

Continuing the discussion on paracentesis in pleurisy at the Surgical Society (*Med. Times*, March 26, p. 344), M. Hérard terminated a long discourse with these conclusions:—1. Thoracentesis is formally indicated whenever danger of suffocation arises. 2. In chronic effusions a complete cure may be obtained by its aid, accompanied or not with iodine injections; but this is exceptional, the ultimate result being in general unfavourable. The fluid reaccumulates, and the patient in the end succumbs, and sometimes more rapidly than if no operation had been performed. 3. In acute pleurisy with moderate effusion, thoracentesis does not offer any marked advantages, and is generally a useless operation. 4. In recent pleurisy with great effusion it is indicated, even when there is no intense dyspnoea. It cures quicker than any other means, and usually prevents the occurrence of sudden death, which is not infrequent in pleurisy. M. Hérard, although he would not hesitate to operate in an urgent case after the fourth day, considers that the period between the ninth and the eleventh day is that in which there is the greatest hope of expansion of the lung without reproduction of the effusion. Even until the second month this chance continues great; but later, a tentative puncture should be made, in order to ascertain whether the lung still dilates, only completing the operation in the affirmative. M. Moutard-Martin believes that in hyperacute pleurisy, in which the effusion takes place very rapidly, the operation is the more successful the nearer it is performed at a period between the seventh and eleventh day. M. Béhier declares that he has never met with any ill effect, whether immediate or remote, resulting from this operation, which, indeed, can scarcely be called an operation, especially when compared with the results which it gives rise to. We must not be in too great a hurry to operate, for a puncture made on the fourth day runs a risk of being followed by a reproduction of the fluid. From the ninth to the eleventh day is the best period. In chronic pleurisy, the operation, even with iodine, fails, and the chronic stage may commence as soon as the second month. In recording cases of sudden death from pleurisy, M. Béhier believes that co-existing pericarditis has sometimes been overlooked. M. Chauffard directed attention to the importance of employing active measures in the early stages of pleurisy, as bleeding, diuretics, especially nitre, and exutorics, and in most cases the necessity for paracentesis will be superseded. The period at which it should be performed must depend much on the individual, but it will be usually advisable to wait until the ninth or eleventh day. M. Gaillard feels convinced that the danger of thoracentesis has been made too little of, and refers to a case of his own, in which the patient operated upon at 8 was dead at 4. M. Woillez, while far from considering the operation usually a dangerous one, cannot admit the absolute innocuity claimed for it. Not only has fatal syncope supervened in some cases, but in others the lung has been perforated by the trocar, this explaining the pneumothorax which sometimes persists after the operation. The statistics of the seventy-five operations performed by Dr. Bowditch show that fatal results are by no means infrequent. These statistics M. Béhier regards as

valueless, comprising as they do an indiscriminate collection of cases bearing no resemblance to each other. The danger of the operation should not be exaggerated so as to diminish the frequency of its performance, for numerous patients die at the fourth or fifth month whom paracentesis might have saved.

M. Goupil observed that upon an examination of twelve cases of sudden death from acute pleurisy, he finds that in the majority this has not been due to syncope, but to some complication such as pericarditis, emboli, or coagula in the heart; that the accident has occurred almost as often in moderate as in excessive effusion; and that it takes place generally at so late a stage that premature recourse to thoracentesis is not requisite. M. Goupil is not an opponent to the operation, for he has often performed it; but he thinks that it is especially useful when the effusion is abundant, and when inflammatory accidents are no longer present. He has resorted to it with advantage from the fifteenth to the twentieth day, when by means of percussion and auscultation and the use of the cyrtometer (which he regards as a very useful means) the effusion is found to be on the increase or to remain stationary. It is here a proper operation; not that the fear of sudden death should induce its performance, but the failure of other methods of treatment.

M. Ollier, of Lyons, communicates to the same Society some additional results of his interesting investigations on the regeneration of bone. Although the fact of this regeneration has now been definitively acquired and appropriated by Surgical science, yet such regeneration does not take place in all bones in the same manner, being more constant, easy, and rapid in the long than in the flat and the short bones. One general and essential condition of the regeneration is the preservation of the periosteum, hundreds of experiments and observations having shown that this will not occur when this membrane has been completely removed. The reproduction of the diaphysis of long bones is admitted by all; but M. Ollier's preparations show that the epiphyses are no less truly regenerated, although a much longer time is required. The regeneration of the flat bones has been wrongfully denied; for by means of the external periosteum derived from the frontal bone, M. Ollier has been enabled to construct a new nose possessed of complete osseous solidity; while the internal periosteum of the cranium, the dura-mater, has in his experiments also given rise to ossification. Again, the mucous periosteum of the nasal fossæ, palate, etc., will also produce osseous substance; but to do this it requires a long space of time, as five, six, seven, or eight months, before the reproduction takes place. The short bones may also be reproduced, M. Ollier having succeeded with the calcaneum, cuboid, etc., in animals. In all these regenerations the new bone sometimes acquires greater dimensions than the original bone. M. Ollier has never found in the course of the operations of resection or bony extirpation which he has performed any practical difficulty in preserving the periosteum—not even in the case of bones with aufractuositities like the jaw. The conditions under which regeneration becomes possible are the youth, good constitution, and favourable hygienic condition of the patient; and the thickness, resistance, and adhesion of the periosteum to the osseous tissue. In cachectic or scrofulous subjects the regeneration takes place imperfectly or not at all. The thickness and resistance of the periosteum constitute a most important sign as to its reproductive power, and the condition of the membrane will accurately indicate beforehand whether success, and what amount of it, is likely to attend the operation. The general conclusion M. Ollier arrives at is, that not only is osseous regeneration possible in man, but that it takes place more easily in him than in animals.

MEDICAL BENEVOLENT COLLEGE.—We are glad to see that the approaching anniversary dinner of this excellent Institution will be presided over by Sir Charles Locock. Peers of the realm have hitherto occupied the chair, and we thank them for the aid given; we are now gratified to see a member of our Profession announced for the Twelfth Annual Festival, and we call upon our brethren to add their names to the stewards' list, thus testifying their respect for the Chairman, and their unabated zeal to further the continued success of their College.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF WOLVERHAMPTON.

(Continued from page 404.)

In my last paper I described the Infirmary of Wolverhampton. With that I bring to a close the history of the Medical institutions. For the relief of the sick there is no Dispensary, and no other Hospital in the town.

MEDICAL SOCIETIES.

There was a Medical Society in Wolverhampton some time since which at first promised well. It was established in the year 1861, but after a few months of existence it languished, and is now, I believe, defunct. The members met at each other's houses, and papers were read and discussed. It is a great pity that an undertaking promising so much for science should have thus decayed, for assuredly there is not a town in the United Kingdom that presents a finer field for Medical observation and research. If I might venture to assign a practical reason for the failure of the Wolverhampton Medical Society, I should name the fact that the meetings were held at the houses of the members. For such a society to thrive the place of meeting must be central, the ground neutral, and the organisation perfect. There must be a president annually elected, and each office must carry with it its due meed of honour and distinction. Then a wholesome spirit of fair competition is set up, in the absence of which, science, not less than commerce, either sinks into a monopoly—a dying thing that torments the world with its agonies—or ceases altogether to exist, a better fate.

PAROCHIAL MEDICAL PRACTICE.

The town is divided into four districts, the salaries of the Medical officers varying from £50 to £75 a-year. To the districts may be added the Workhouse, for which a stipend of £130 a-year is paid to the Medical officer. The whole district of Wolverhampton, however, is divided into seven parts, and is attended by the following Medical officers:—W. Dunn, Esq., H. Hancox, Esq., D. Shelswell, Esq., G. N. Smith, Esq., D. Best, Esq., W. M. Hancox, Esq., J. Harthill, Esq., and H. Gibbons, Esq., the Surgeon to the Workhouse.

The rates of payment and amount of labour are shown as follows:—

	Population.	Average.	Annual Fee.
Mr. Dunn's District	10,020	807	£ 8 54 8
Mr. H. Hancox's District	14,463	807	72 4
Mr. Shelswell's District	12,258	807	54 0
Mr. Smith's District	13,248	807	74 0
Mr. Best's District	11,763	848	77 4
Mr. W. M. Hancox's District ..	11,763	848	76 0
Mr. Harthill's District	16,789	5,585	97 8
Mr. Gibbon (for Workhouse) ..	About 600	—	130 0

Vaccination is the only extra allowed.

THE UNION WORKHOUSE.

This institution affords room for 824 inmates. The number now in the house is about 600. Aged men and able-bodied women form the chief of the numbers of the adults. The diet of the inmates is a little above the regulation standard. In the sleeping apartments the cubic space allowed to the healthy adults is 300 cubic feet, and to the sick 500. The ventilation of the wards and rooms is free and simple. The air enters the wards from without by free openings near the floor, and escapes at the ceiling by openings in the centre guarded with perforated metal. Ventilation is also effected by means of the windows. A projecting section is allowed inwards from the centre of the window: this projection, which opens above obliquely, and allows the air to ascend to the ceiling, something like the hopper plan of ventilation by Mr. Peter Hinckes Bird, works well, and is worthy of further application. The ventilation was reported to me as most efficient, and I have every reason to believe the statement. I also learned that no epidemic disease had ever originated in the house, and that the numerous cases of epidemic disorder brought into the house do not spread, but appear immediately to come under control. (a)

(a) In so far as I could see, the arrangements of the Workhouse were very good; but I regret that in the course of my round with the Master, who was most anxious to show me every part, the chairman of the Board of Guardians interposed, and objected to my further progress. According to his view, a visitor might see, but ought not to make any comment on what was to be seen; and as I could not bind myself to any promise of

CLUB PRACTICE.

Club practice prevails extensively. The principal clubs are the Odd Fellows, Foresters, Hearts of Oak, and various small benefit societies. Burial clubs are very numerous. The pay to Medical men in the club practice varies from two shillings per head per annum to five. The Odd Fellows and Foresters are those that pay best. There are several other societies of a more general character. For instance, there is a Wolverhampton branch of the "Liverpool United Legal Friendly Burial Society," of which society there are upwards of 26,000 members. There is also a branch of the "Liverpool Victoria Friendly Society," which society pays its Surgeons the munificent sum of two shillings for the certificate of the health of a joining member, and fines them £1, with dismissal for any subsequent offence, if it can be proved that they have admitted any person who was labouring under any disease or complaint at the time of examination. A rule somewhat similar belongs to the Burial Society. "The People's Universal Life Assurance and Sick Fund Friendly Society" holds its chief office at Wolverhampton, and allows three shillings per head for the year's Medical attendance on members. It also allows a special fee, varying from two shillings and sixpence to ten shillings and sixpence, for special examinations for assurances, the fee being regulated by the amount of assurance. Lastly, there is a "United Life Assurance and Sick Benefit Society," which has an "infantile assurance branch," for securing to children fixed sums at various ages, on payment of one penny per week.

LITERARY AND SCIENTIFIC INSTITUTIONS.

There is no literary and scientific institution at present in Wolverhampton, but there is a school of art, and a reading-room fitted up with great taste, and containing a large collection of books.

CHARITABLE INSTITUTIONS.

There are various charitable institutions in Wolverhampton, viz., Mitchell's Charity, the Free Grammar School, Thorneycroft's Charity, the Orphan Asylum, and the Ragged Schools.

The *Free Grammar School* was founded in 1508 by Sir Stephen Jenning, Lord Mayor of London, and a native of Wolverhampton.

Thorneycroft's Charity.—Mr. Thorneycroft was the first mayor of Wolverhampton, in 1848. To signalise his year of office he invested £1000 in the name of trustees, who have re-invested it at 5 per cent.; the income is applied annually on November the 9th in providing blankets and flannels for the poor of the borough; tickets for the distribution are given by the mayor, aldermen, rector, and trustees.

The *Wolverhampton Orphan Asylum*, situate on Goldthorn-hill, was instituted on April 1, 1850. It is a noble building, commanding, I think, one of the finest prospects that could be seen from any centre. The asylum receives at the present time 80 children, namely, 58 boys and 22 girls. The founder of it was Mr. John Lees, who left to it a legacy of £1800. The charity is intended for those children who have either lost both parents, and have no friends to support them, or for children who have lost their father, and whose mother is unable to support them. No diseased, deformed, or infirm child, or child of unsound mind, or a child born out of lawful wedlock, is deemed eligible. Not more than one child of the same parents, father or mother, is allowed to be on the foundation at the same time; and no child who has been at any time in the union or parish work-house, or on whose behalf parochial aid has been received (except for temporary relief) is admitted. Fatherless children, of either sex, wherever resident, without means equal to their support, whose parents have been in respectable circumstances, are considered to have a special claim to the benefits of the charity.

Mr. and Mrs. Marsh, the Secretary and Matron, were so kind as to show me every part of this building, with great care. Some parts of it are as yet incomplete, and large dormitories are undergoing preparation, but the arrangements

that nature, I left. A stranger, in making inspection by courtesy, has no alternative in a position so painful except to forbear pledging himself to any specific course. He cannot walk blindfolded, and there is an end of that question. But it is a great point whether such a policy of exclusion is sound. I think it is not. If an inquirer speak falsely, how easy is it to show his falsity by reference to the data. If he speak correctly, of what use is it disputing his truth; and how much more important to remove the causes that have called forth his criticism! I have felt it right on all occasions not to do more than simply ask permission to see; and in every case, except the one above-named, the most perfect liberty has been given to me; nay, in many cases I have been invited—owing to the very independence with which these papers have been written—to inspect institutions which claimed to be considered as open to criticism in every form. The idea of exclusion, in fact, suggests, rightly or wrongly, the further idea that something exists which would not bear the light.

are most perfect. The school-rooms are spacious and well ventilated. The diet is of the best description; and the children seemed one and all to be as happy as they were healthy. The only objection I could see, in fact, was in the dress. It was a fancy—I had almost said a caprice—of the benevolent founder to introduce the Blue-coat School dress; and this has been done, surely not to the advantage of the charity. In an institution of this kind it is time for all badges of dress to be removed, otherwise the charity is clothed in livery and lost in its purity.

THE RAGGED SCHOOLS.

The ragged school is held in a plain, but rather large, building. The land on which the school is erected was presented by the Duke of Sutherland, the late Mr. Thomas Perry having surrendered some leasehold interest to allow the scheme to proceed. The object of the schools is to reclaim and instruct destitute and neglected children of both sexes. A master and mistress reside on the premises, and the schools are open on every day, except Saturday, from two o'clock until four in the afternoon, and from seven until nine in the evening. I found the children at work in a large schoolroom, and for the character of the school the arrangements seemed very good. They would compare well with those of the London ragged schools.

SANITARY CONDITION OF WOLVERHAMPTON.

POPULATION.

The Poor Law Union includes four townships, with a population, in 1861, of 126,894. The true borough of Wolverhampton, or municipality, had, in the same year, a population of 60,838; while in the more extended or Parliamentary borough, in which is classified four large parishes, viz., Bilston, Sedgely, Willenhall, and Wednesfield, the population amounted to 147,646. The increase of population in the last few years has been very great. In the year 1831 the Parliamentary borough had a population of 68,508; in 1841 this had increased to nearly 95,000; in 1851 it reached 119,748; and from 1851 to 1861 27,898 persons were added. The people are now lodged in the borough in about 13,600 houses. In the first years of this century this number represented the actual population.

VALUE OF LIFE.

The following tables from the Registrar-General's Returns, previously described, supply full information as to the value of life in Wolverhampton:—

Average Annual Rate of Mortality in Wolverhampton from all Causes, at different Ages, to 100 Living, during the Ten Years 1851-60.

	Males.	Females.
All ages	2·845	2·673
Under five	11·022	9·937
Five to ten	1·017	·925
Ten to fifteen	·564	·489
Fifteen to twenty	·638	·582
Twenty to twenty-five	·778	·845
Twenty-five to thirty-five	·907	·969
Thirty-five to forty-five	1·364	1·282
Forty-five to fifty-five	2·096	1·593
Fifty-five to sixty-five	3·669	2·925
Sixty-five to seventy-five	7·456	6·619
Seventy-five to eighty-five	15·753	15·563
Eighty-five and upwards	26·600	22·838

The value of life in Wolverhampton, as compared with all England, is, for males, 2·845 against 2·305, and for females, 2·673 against 2·132.

The mortality of children under five years of age is alarming: it stands as 20·959 per cent. against 13·517 for England altogether; but it will be instructive to give the facts entire.

WOLVERHAMPTON AND ENGLAND.

Relative Mortality per cent. at different Ages, including both Sexes.

	Wolverhampton.	England.
All ages	5·518	4·437
Under five years	20·959	13·517
From five to ten	1·942	1·693
„ ten to fifteen	1·053	·994
„ fifteen to twenty	1·220	1·407
„ twenty to twenty-five	1·623	1·736
„ twenty-five to thirty-five	1·875	1·949
„ thirty-five to forty-five	2·646	2·463
„ forty-five to fifty-five	3·689	3·316
„ fifty-five to sixty-five	6·594	5·786
„ sixty-five to seventy-five	14·075	12·399
„ seventy-five to eighty-five	31·316	28·101
„ eighty-five and upwards	49·438	59·964

It will be seen from this table that the value of life in Wolverhampton is below the average up to the age of fifteen; from fifteen to thirty-five it is above the average; from thirty-five to eighty-five it again sinks, but appears to rise at eighty-five and upwards: this latter appearance, however, probably is delusive; it may be due to the circumstance that there are proportionately a smaller number of persons at that advanced age left to die in Wolverhampton.

The excessive mortality of children in this English town demands serious investigation. The remarks made in my last paper relative to the prevalence of syphilis will account in the main for the mortality. Why the value of life should rise from fifteen to thirty-five I cannot explain; its fall during the advancing years of manhood is more easily accounted for, as arising from overwork, and destruction of the organism from irregular life, amongst the lower classes. The subject is further elucidated in the subsequent tables showing causes of mortality.

MORTALITY FROM DIFFERENT CAUSES.

The average annual rate of mortality in Wolverhampton from all causes to 1000 persons living is 28, or three above the average of Staffordshire as a whole. Excepting Manchester, St. George's-in-the-East (London), and Leeds, there is no town in the kingdom that presents a higher death-rate. The fluctuations from year to year are very remarkable. Calculating the population as numbering at present 63,000, the rate of mortality in 1863 stood as 28 $\frac{2}{3}$ per 1000, by the side of 24.8 per 1000 in 1862.

Average Annual Mortality in Wolverhampton from Different Causes to 100 Living, from 1851 to 1860.

	Males.	Females.
All causes.	2.845	2.673

Births Compared with Deaths of Males and Females.—1861.

Males, births of, 2601; deaths, 1473; births over deaths, 1128. Females, births, 2546; deaths, 1303; births over deaths, 1243; total births, 5147; total deaths, 2776; total births over deaths, 2371.

1863.—(Municipal Borough.)

Number of births during the year, 2552; number of deaths during the year, 1804; excessive births over deaths, 755.

WATER SUPPLY.

The water supply is from two sources, from wells and from the supply of the Wolverhampton New Water-works Company, founded in 1855. The water of the town naturally supplied is abundant and good; in summer it is very cold, and in all seasons is well charged with gas, and is bright and sparkling. The company's supply is derived from a brook at Cosford, in the county of Salop, nine miles from Wolverhampton; this is the main source, but supplementary supplies are pumped from borings through the red sandstone at Tettenhall and at Goldthorn Hill. The water is conveyed through iron pipes to a reservoir at Tettenhall, which holds about fourteen millions of gallons; it is pumped from Tettenhall into the town.

On Goldthorn Hill is a second reservoir, which takes what the town does not want; this reservoir holds about a million and a-half of gallons, and acts as a store. There is no filtration of the water. The supply pressure is sufficient to cover all the houses, the average pressure being about 60 lbs. The present pumping per year is at the rate of four hundred and thirty millions of gallons.

In many houses there is no ready water supply: the inhabitants seek for it at pumps in the street; water is in this way used over and over again to save carriage. The Board of Health has given orders to several owners of houses having no water supply to provide the necessity.

The character of the water supplied to Wolverhampton may be gathered from the subjoined analyses:—

(To be continued.)

PHOSPHORUS PILLS IN NERVOUS AND CHLOROTIC AFFECTIONS.—M. Tavignot, in the neurosis of the lachrymal nerve, which is often mistaken for lachrymal obstruction, has found phosphorus highly useful. He has long been in the habit of using this substance in nervous, chlorotic, and scrofulous affections, preferring it in many cases to iron, iodine, or cod-liver oil. The formula is as follows:—Ol. amygd., 4 grammes; phosphor, 5 centigrammes. Dissolve in the water bath, in a vessel which is full and secured with emery, and then add almond soap, 4 grammes, and 9.8 of an inert powder, so as to divide into fifty pills. Each pill contains $\frac{1}{10}$ th grain of dissolved phosphorus, and from two to four should be taken daily.—*Chémie Méd.*, April.

REVIEWS.

Advice to a Mother on the Management of her Offspring and on the Treatment of their more urgent Diseases. By PYE HENRY CHAVASSE, F.R.C.S., etc., etc. Seventh edition. London: Churchill and Sons. 1864. Pp. 316. Price 2s. 6d.

POPULAR Medical books demand, as we have often said, quite as much critical notice as books do which are addressed to ourselves. If purely Medical books contain blunders they are coolly discussed, and whatever does not bear the stamp of truth either finds no favour with Practitioners, or after a short trial is quietly dropped. Not so with popular books, whose errors, if any, are greedily absorbed by the public, and are added to that mass of ignorance and prejudices which are the most formidable foes to the Medical Practitioner. Whoever writes for the Profession may say what he chooses; whoever writes for the public should remember that he is one of a body whose reputation should not be compromised. The first fault to be avoided is egotism. Mr. Chavasse is not altogether free from this vice in his account of scarlet fever, where, with much good sense, there are statements which we think egotistical and mischievous. He says he has not lost more than one case of scarlet fever during the last fourteen years, although he has had "numerous" cases, many most severe. He gives rules, of which he premises that "if the scarlet fever be not malignant," they will be almost invariably successful. There is great virtue in *if*.

His plan is, during the first four or five days, to keep the room cool; to have the windows open, and admit fresh ventilation; then, when the skin becomes cool, to close the windows, wrap the patient warmly, and take great care against cold for at least a month. Of this part we can speak with unqualified praise. Secondly, he applies a poultice of barm and oatmeal to the throat; but surely other applications we could name are equally efficacious and less nasty? Thirdly, he gives sulphuric acid in the well-known infusion of roses—a practice we entirely commend. "But," says Mr. Chavasse, "my belief is that the sulphuric acid mixture is a SPECIFIC in scarlet fever—as much so as quinine is in ague and sulphur in itch. I have reason to say so, for IN NUMEROUS CASES I have seen its immense value." We will leave Mr. Chavasse and Dr. Charles Witt to fight out the question of the specificity of acids and of ammonia. We will take the liberty of reminding both that scarlet fever, unless of the malignant variety, is a disease which naturally tends to recovery, and that good nursing is of far more consequence than the "specific" of either Practitioner. For food, Mr. Chavasse gives low diet at first, fruits, etc., and denies broths and stimulants. Lastly, he altogether denounces aperients. He says in awful terms, "DO NOT ON ANY ACCOUNT FOR THE FIRST TEN DAYS USE ARTIFICIAL MEANS TO OPEN THE BOWELS." "THE ADMINISTRATION OF PURGATIVES IN SCARLET FEVER IS A FRUITFUL SOURCE OF DROPSY, DISEASE, AND DEATH." Then follows a hazy passage:—"The irritation of aperients on the mucous membrane may cause the poison of the skin disease to be driven internally to the kidneys, the throat, the pericardium (bag of the heart), or the brain." Mr. Chavasse is evidently an accomplished billiard player; he fancies that if a pill be aimed at the bowels it will rebound, hit the skin, knock off the eruption, and pocket it in the bag of the heart. We don't see the sense of Mr. Chavasse's denunciations. What does he mean by a "purgative?" If he means something that shall cause the patient to rise half-a-dozen times to pass watery, griping stools, we agree with him; but as for refusing a simple aperient pill, or teaspoonful of magnesia with lemon-juice, to unload the bowels, we say it is a monstrous and cruel folly. And here is made evident one source of mischief of books of this sort, which only the greatest delicacy and conscientiousness on the part of the writer can avert. Mr. Chavasse—who leaves out, by the bye, all mention of the necessary processes of cleansing and syringing the throat and nose—speaks as if all cases of scarlet fever were alike. As if all patients could bear a starving regimen for the first few days, and as if none might dislike sulphuric acid or require an aperient. He ignores the fact that in many epidemics scarlet fever does not begin with one or two days of chill and languor, but with a sudden attack of vomiting, and that many patients have the headache wonderfully relieved by an aperient. All we desire to say is, that Mr. Chavasse's sentiments about aperients in scarlet fever have a want of

breadth and freedom of view about them, and are contrary to those of most practical men of our acquaintance. Give us a box of mild pills and a supply of good Bordeaux wine and cold water, and we would undertake to match the results of any "specific" treatment in any number of cases of scarlatina.

The present edition has the advantage of some practical notes, added by Sir Charles Locock; but, notwithstanding this important aid, it seems to be a little behind the day in some points. For example, Mr. Chavasse says:—"I have known some careful mothers who use no pins in the dressing of their children; they have tacked everything that requires fastening with a needle and thread." We are surprised that Mr. Chavasse speaks of this as the practice of *some* only. Here is another point:—"I know some careful mothers who have accustomed their children after the first few months to do without napkins." The fact is, that the old-fashioned, nasty plan of letting a baby defæcate into a napkin, and lie soaking in its filth till it pleases the nurse to change it, is quite obsolete in well-ordered nurseries. The youngest baby may be *held out* at regular times, and, if healthy, soon will learn to avoid the making nasty messes in napkins.

The remarks on wet-nursing and feeding of infants, and the reprobation of all artificial food for five or six months, savour of theory more than of experience. Few mothers can maintain their baby entirely, and if they do it with difficulty, should lighten the task by a little artificial food. All that is said about children living on milk till they have teeth to eat meat is contrary to general experience. Late development of teeth is an argument for meat.

The recommendation to let slight diarrhœa go on three or four days is hardly safe. "There is no better light for a nursery than the old-fashioned tallow candle." Surely Price's patent candles stink less? Mr. Chavasse supposes that children's legs become deformed because they are put too soon on their feet. We should say, because they have been fed on too sloppy a diet. He decidedly disapproves of perambulators; and, we don't hesitate to say, deserves to be laughed at for his objections. He dislikes fires in bedrooms. He commends singing, but repeats the old-fashioned cry against wind instruments, which are less trying, and equally healthy. The exertion of the lungs is the same; that of the larynx is saved. He advises parents to put on a blister to the throat in croup—a savage remedy. He seems to have a horror of aperients in all shapes, and recommends figs and various messes for the cure of constipation, forgetting that a clean mild pill excites far less irritation than does stale retained fæculent matter. He recommends July and August as the best months for sea-bathing; most of us prefer September and October. He indulges in the wonted sermon about young ladies' evening dresses and balls, and affects to believe that a "considerable portion" of the deaths from consumption are due to such causes. *Quere*: Amongst young women, who die the most often of consumption—they who go to balls with naked shoulders, or the class that don't? Can he prove what he says, that "hundreds die of consumption" from going to balls? He objects to soup for dinner, because the stomach can digest solid more readily than liquid food. He asks "what are the causes of so many young ladies of the present day being weak, nervous, and unhappy?" and thinks that unless great alterations take place the women of England will become physically deteriorated. This is like other complaints made by the *laudator temporis acti*, who forgets that his grandmother said the same in her day, and her grandmother before that.

There is in Mr. Chavasse's work a great deal of very useful information very clearly put; and we may say that the author is generally happy when he gives the common sentiments of the Profession in his own pungent, argumentative way, and less happy, in our opinion, when he introduces pet notions of his own. He is a little too egotistical, too fond of introducing the name of God in largest letters, and, like most popular writers, too finical in his diet rules, though much less so than some of his brethren. Between the two extremes, it is much safer that children should be overfed than underfed; but a strict adherence to the rules of popular Medical books generally causes parents to choose a monotonous, insipid, and insufficient diet, from which the children are saved by their own appetites, or by the good sense of their nurses. Certainly, for older children Mr. Chavasse's diet rules are liberal; and, although we have taken the liberty of expressing our opinion freely on the points in which the work is, in our judgment, erroneous, yet on the whole it is well written, with good sense and high principle, and is a valuable work for a young mother to read.

The Stream of Life in our Globe: its Archives, Traditions, and Laws, as Revealed by Modern Discoveries in Geology and Palæontology. A sketch in untechnical language of the beginning and growth of life and the physiological laws which govern its progress and operations. By J. L. MILTON, M.R.C.S. London: Hardwicke. 1864. Pp. 620.

AN ambitious book, truly! Beginning with most ancient chaos, when the surface of our earth was an ocean of molten granite seething like the Atlantic in a gale, it gives in popular language an account of each stage of progress and development, both of the globe and of the living beings which inhabit it, and concludes with speculations on the future fate of the earth, and the probability that we shall be swallowed by the sun, and expire in a conflagration. It embraces all human knowledge. Geology, with its kindred science of palæontology, which pre-supposes a thorough acquaintance with the history of the three kingdoms of nature; anthropology and archæology; mythology and tradition wherein lie embalmed the vestiges of the earliest history or the glimpses of the pre-historic condition of our race; the science of language, with its inseparable companion ethnology; Max Müller's researches and Rawlinson's on the early arrow-headed inscriptions; the doctrine of species, with Mr. Darwin's views of the battle of life and selection of species; laws of life; life in the blood; life in the nerves; theories of disease and remedies; life of giants; life of men of genius; life of the waters; life in the stars;—such are the contents of this volume, of which the plan is admirable, but of which the execution adequately would be impossible, unless with the united force of Humboldt, Herschel, and Owen. Much of it is amusing, and gives intelligible pictures of the early history of our globe. There is also much curious information collected regarding the early history and traditions of our race. All of it is readable; and it is highly creditable to a member of our Profession that he should have conceived such a plan, and have accumulated the great amount of information necessary for carrying it out. If we say that he is at times not very deep, and a little flippant, or that his criticisms are deficient in good taste and in force, we point to faults venial and unavoidable. What we do complain of is, that, with multitudes of facts and information at his command, he should occupy a large portion of his space with a hazy chapter or two on the nature of disease, of the vital force, etc., and of the "nerve theory" of life and disease which he holds instead of the "blood theory." Such matter is useless to the public and injurious to us. It is disappointing, too. We look for philosophy, and find "shop." The "Stream of Life" would have been a much better book if the writer had shown his MS. to a "candid friend" who would have pruned it a little, and cut out all those portions which would imply that the author's notions on the nature of disease and vital force, etc., are better than those of his brethren. Mr. Milton's faults are those of taste chiefly. He has imagination and erudition, and we hope will give us other, fuller, and more refined books in time.

An Elementary Text-book of the Microscope, including a Description of the Methods of Preparing and Mounting Objects, etc. By J. W. GRIFFITH, M.D., F.L.S. With 12 coloured plates, containing 451 figures. London: Van Voorst. 1864. Pp. 185.

A CAPITAL book. Short, clear in style, logical in arrangement, and containing such a course of instruction, both on the nature of the microscope and on the method of preparing and viewing objects, and this arranged in such order that any intelligent student who sets to work to teach himself, or any Professor who uses it as a class-book to teach others, cannot fail of acquiring or imparting a good systematised mass of microscopic knowledge, and of the general nature of the vegetable and animal kingdoms as well.

The Prescriber's Analysis of the British Pharmacopœia. By J. BIRKBECK NEVINS, M.D. Lond., etc. London: Churchill and Sons. Pp. 91. Price 2s. 6d.

The Prescriber's Companion. By ALFRED MEADOWS, M.D., etc. London: Henry Renshaw. 1864. Pp. 152.

THESE are two capital little books, and as it is impossible to say that one is better than the other, and as the plan and contents of each vary somewhat, the best advice we can give our readers is to purchase them both. They are easy reading, and each will yield much more in value than it cost. Dr.

Nevins' valuable little work is chiefly, as its name implies, an analysis of the British Pharmacopœia; and its leading feature is a clear and short demonstration of the changes which have been made in it of the ancient-accustomed formulæ. It is very neatly done, although it lacks an index. Dr. Meadows' "Companion" is fuller, and possesses a pretty good index, and contains the British formulæ themselves, without going into the changes which have been made in them from the foregoing ones. It also contains the other drugs in common use, which the compilers of the British Pharmacopœia have not included. Hence any one who desires to know in what respects the new formulæ differ from the old, whether L., or E., or D., will find what he wants in Nevins; but he who cares not for the old L., or E., or D., but wants a good guide to the new British *simpliciter*, will find himself suited by Meadows. And in these hard times it is worth noting that either of them is much handier, cheaper, and more useful to the prescriber than the British Pharmacopœia itself.

Notes on the British Pharmacopœia: showing the Additions, Omissions, Changes of Nomenclature, and Alterations in the various Compound Preparations, with the Doses of those Medicines which are comparatively New. By A. S. HASELDEN, Pharmaceutical Chemist, etc., etc. London: Hardwicke. 1864. Pp. 82.

THIS book, like those of Dr. Nevins and Dr. Meadows, will be an acceptable guide to the Practitioner, who may desire to know wherein the British Pharmacopœia differs from either of its predecessors. We have looked it through, and pronounce it clear and accurate, and, as the alphabetical order prevails, it is easy of reference.

The British and London Pharmacopœias Compared, with a Posological Table. By GEORGE BARBER. London: Simpkin and Co. Pp. 38 and 27.

THIS is yet another handy little book, containing very much matter in small space. It seems easy of reference, but is rather rich in *errata*.

PROVINCIAL CORRESPONDENCE.

EDINBURGH.

MARCH, 1864.

MY last contained a laudatory remark upon our climate. I regret to say it cannot now be repeated, as the rain seems never weary, the gutter of fœtid fluid containing an emulsion of every filth imaginable, but by euphuism termed the "water of Leith," is roaring a yellow flood under Stöckbridge and disturbing the unused fishing-boats at the harbour. Some regret this rainfall. I do not. The uncleansed streets are receiving their yearly washing; the heaps of filth which accumulate in our neighbourhood and are considered healthy are no longer to be seen, and perhaps fever may diminish in consequence. I had purposed to round this sentence off in a becoming manner, but was called out, and as I passed through Jamaica-street saw every drain-grating piled with fæces; garnished with intestines of fish and other domestic contributions to the welfare of my Profession.

The plan of class-examination being steps to graduation seems to have fallen into abeyance. The extramural school readily took up the idea; but the Professorial body declined to recognise their testimonies in favour of industrious and overwrought students. This must necessarily have affected those who take advantage of the privilege offered by the patrons of the University years ago to admit pupils of the private classes to examination for the M.D. degree. But I would fain hope that the difficulty may be got over, and the rational and, if I may use the term, humane suggestion of Mr. Syme may be carried out ultimately. So far as I have been able to see into Medical education here, but two objects govern teachers and pupils—the one make it their business to teach, the others to learn. I never saw a teacher, however great his eminence, treat a student *de haut en bas*, and certainly never a student take advantage of the great man's kindness, Mr. Syme teaches how to operate for fistula in ano as carefully as he explains how to tie the iliac. Professor Simpson will explain how to use the female catheter with least annoyance to

the patient, and pass on to the most complicated manœuvres in obstetrics. Begbie will spend hours, stethoscope in hand, drilling young ears to the music of the cracked-pot sound; and when we return to the clinical wards, Laycock is there, with many thoughtful faces round a bed, clearing away for them difficulties by showing how an accurate arrangement of details, like the lenses in a microscope, may concentrate light on some obscure disease. His nomenclature has lately been scoffed at a little; but he whom the Oxford undergraduate calls "Mr. Flaccus, a well-meaning, but mistaken Italian gentleman," made this remark:—" . . . ego cur acquirere pauca si possim invidere? Cum lingua Catonis et Enni sermonem, patrium ditateverit et nova rerum nomina protulerit? licuit *semperque* licebit signatum præsentem notâ producere nomen." (Please read the next dozen lines, as I forget them; but do not skip): "Multa renascentur, quæ jam cecidère cadentque. Quæ nunc sunt in honore vocabula, si volet usus. *Quem penes arbitrium est et jus et norma loquendi.*"

Mr. Syme has excised a knee-joint successfully. I was going to say something, when my eye caught the "Essay on Diseased Joints" lying before me, an essay which was published when your correspondent had not an articulation, vocal or mechanical. But considering the enmity shown to it for several years, his now performing the operation is the grandest tribute to its merit any one has yet given. In doing so he has not contradicted one word in that remarkable essay; and I also believe it will do away with much bitterness between other great Surgeons. "Even the ranks of Tuscany can scarce forbear to cheer."

Dr. Gillespie has removed the head of the femur, and it should be remembered that through good and evil report of the operation just alluded to he has stedfastly supported it.

They tell me that Professor Simpson is publishing a work on acupressure. I have seen this plan tried and succeed, and I can only offer my affidavit that it stops bleeding, saves a great deal of trouble, and that whoever cuts my leg off is perfectly welcome to substitute pins for ligatures; indeed, I think that I should prefer them. I wish to ask a question—How many resident Medical officers in Hospitals die every year? The mortality in Scotland has been very great. In one Infirmary, I believe, *nine* have died in succession of fever. And, alas! how many of our clinical clerks die of it; and of those self-abnegating students who trudge the Cowgate and Westport, spend their money, their time, their lives, the happiness of the homes they shall never more see, for dispensary patients? I intended to mention some names, but they are too many. No one will ever convince me that Providence intended such a waste of talent and good. Let the dead bury their dead. If Edinburgh *will* have fever, let her pay hardy, strong men to doctor her. If students must learn that "they can only watch the symptoms," let them find out that suggestive fact in the Infirmary, surrounded by proper means for reducing the chances of contagion to a minimum.

Mr. Mackintosh has favoured the public with a pamphlet on "Mad Doctors, etc." As you are aware, he lost his last action against Drs. Lowe and Smith, of Saughton Hall Lunatic Asylum, where he was confined several years ago. His case is a good instance, I believe, of how early and judicious surveillance and Medical treatment may restore the reason, but it is also a warning to Medical men not to sign certificates of lunacy. I do not believe one person connected with that case has not suffered more or less by it, as Mr. Mackintosh seems determined that the memory of an event in his life which all would wish to forget shall be kept green. He prosecuted his lawyer, Mr. Hugh Fraser, W. S., to whose firmness and kindness he probably owes his life, and most certainly his restoration to sanity. Mr. Fraser's well-known benevolence and sensitiveness of the feelings of others were too well known for any one to imagine that he had dealt ungenerally by any young man. No one knows better than your correspondent of many instances in which this gentleman has befriended young men, simply because they needed help. Well, Mr. Mackintosh lost that action, and another against Dr. Graham Weir. I do not generally suffer from nervousness—a Dutch gardener's pulse is as difficult to quicken—but when at the end of the trial the Lord Justice General Macneil gave Mr. Mackintosh a bit of his mind, I felt as if about to be hung, and sincerely sorry for Mr. Mackintosh. There have been ever so many trials since, and all against Mr. Mackintosh, but still he writes and publishes. Though successful in their defence, all his Doctors must have lost money, and the single fee they may have received for their opinion burnt a large hole in their pockets. On Wednesday, war raged in the Medico-Chirurgical Society

after a paper by Dr. Andrew Wood upon "Medical Education." I had hoped the question had been settled, but here are two Members of the Medical Council disputing about the very rudiments of the subject.

Dr. Laycock declared there had been no substantial increase in *subjects* of study during the last thirty years, and that the Hall and College at that time required, with two exceptions, as many courses as Edinburgh for the degree. But whereas they would be attended in two years, in Edinburgh are extended over four years. He said the subjects of study, judiciously varied, strengthened the intellect. He would wish a moral training for the student, so that he would love truth, hate bigotry, be ready to learn, and slow to abuse. Prof. Laycock thought two new courses might be added to the curriculum for the higher honours. One is the history of Medicine, and, in mentioning it, he paid Dr. J. W. Begbie a compliment, who gives a course in summer. The scandalous results of recent trials have shown the necessity of a thorough scientific knowledge of Medical psychology and mental diseases. The deliberate falsehood of Mr. Syme's "student" was rated in such a way that there is great curiosity excited to know the young gentleman and hear him count to 100.

Any one who knows students must at once see the danger of encouraging a contempt for the rules, which they must follow with greater or less exactness; but still there was much truth in Professor Syme's lecture; and the only remark I can make upon it is the one you sometimes hear from a patient listener after a facetious friend has told him a Joe Miller—"I *think* I've heard something like that before." Talking of Miller, his namesake, our Professor of Surgery, is about to open the Chalmers' Hospital here. It is a pretty little place, and I believe well arranged. Dr. Halliday Douglas, learned in heart sounds, is the Physician.

Prince Alfred must be rather tired of being King of Edinburgh. He is advertised, run after, and worshipped in a way which only a nation who cultivate "*booing*" could accomplish in the time. As he attends Playfair's ten o'clock lecture, his admirers congregate about eleven. Shakspeare said something about *Divinity* hedging a *King*—why, I saw a whole class of divinity students hedging a Prince the other morning. Times are looking up for Royalty. *Vivat Regina!*

GENERAL CORRESPONDENCE.

PROPOSED TESTIMONIAL TO MR. GRIFFIN.

LETTER FROM MR. W. PROWSE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you be good enough to find room in your journal to inform the Poor-law Medical officers throughout the country that a subscription has been set on foot by me for a testimonial to Mr. Griffin for his long-continued and unwearied exertions in our behalf? It is now nine years that he has laboured with such unremitting attention to our cause. Every one of us must admit that he deserves our highest commendation, and is worthy of a gratitude that should show itself in a substantial manner. We must open our purses as well as our hearts, and present him with some fitting acknowledgment for all the trouble he has taken and the work he has so willingly performed on our account. This is our plain duty, as true and honest men—a duty that we owe not less to ourselves than to him, and we shall be much to blame if we disobey the voice of conscience in this matter, and prove ourselves neglectful of an obligation so imperative. I am, &c.,

WM. PROWSE,

Surgeon to the Union House and District.

Amersham, Bucks, April 7, 1864.

N.B.—Subscriptions to the Poor-law Medical Reform Association should also be forwarded as early as possible to Mr. Griffin.

[The proposal of Mr. Prowse will meet, we doubt not, with warm support from the Profession. Few men have devoted themselves so disinterestedly and have laboured so perseveringly in the interest of their Medical brethren as has Mr. Griffin. We shall be most happy to receive subscriptions to the Griffin Testimonial Fund at the office of the *Medical Times and Gazette*, 11, New Burlington-street.]

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

THURSDAY, MARCH 2.

Dr. OLDHAM, President, in the Chair.

THE following gentlemen were elected Fellows of the Society: F. J. Butler, M.D., Winchester; Thomas Chambers, L.R.C.P., London; Edward Fussell, M.B., Brighton; Samuel N. Harrison, Patrington, Hull; Edward Jackson, M.B., Sheffield; W. N. Price, Esq., Leeds; A. G. P. Wilks, M.D. Cantab., Guy's Hospital.

Dr. HICKS read a report on two cases of monstrosity exhibited by himself and Dr. Gervis at a former meeting of the Society.

CASE OF FATAL UMBILICAL HÆMORRHAGE IN AN INFANT.

Dr. GRAILY HEWITT related the particulars of a case of hæmorrhage from the umbilicus. The mother of the patient, a weak, ill-nourished individual, was delivered of a female child at about the eighth month, in the British Lying-in Hospital. She had previously lost a child, a few days old, from bleeding at the mouth, ears, and rectum. At birth the infant was weakly and the circulation languid; moreover, in the course of a few hours, the child became jaundiced. The second day after birth a very slight appearance of blood was noticed at the insertion of the cord. On the third day hæmorrhage set in, and when seen by Dr. Graily Hewitt had lasted for upwards of an hour. The child was then excessively pale and moribund. Further loss of blood was prevented by application of a ligature *en masse*, but the infant died about an hour afterwards. The blood exuded as from a sponge, at the junction between the cord and the abdominal wall. Post-mortem examination showed great congestion of the liver, and slight hæmorrhagic effusion into the peritoneal cavity. There was no ulceration of the stump of the cord inwards through the abdominal wall. Dr. Graily Hewitt alluded to a series of cases of this affection published by Grandidier. In a large proportion of them jaundice was observed, as in the above case; and in a few the existence of a hæmorrhagic diathesis was well marked. The treatment carried out in the above case had been found most successful in the hands of others—namely, the use of the ligature *en masse*. The mortality from this affection had been found to be very high—namely, 83½ per cent.

A paper, by W. TYLER SMITH, M.D., was read on

EIGHT ADDITIONAL CASES OF OVARIOTOMY.

The notes of twelve cases have already been presented to the Society.

Case 13.—Multilocular Tumour of the Right Ovary—Operation—Recovery.—E. H., aged 33, unmarried. Abdomen forty-two inches; growth rapid. Operation, June 16, 1862. Incision, four inches. Tumour composed of two principal cysts, full of purulent matter. Cysts tapped first. Pedicle secured by silk, divided and allowed to drop into the pelvis. Tympanitis and sickness severe on third day; relieved by calomel, turpentine, etc.; iced water and milk. In October following quite well.

Case 14.—Multilocular Tumour of Right Ovary—Ovariectomy—Recovery.—Mrs. B., aged 54. Weak and emaciated; size great. Has lived in West Indies. Operation, October 13, 1862, under chloroform. Extensive adhesions on right side. Numerous cysts with gelatinous contents. Large incision. Pedicle allowed to drop into pelvis. Wound healed by first intention. Convalescence tedious. Large doses of opium, to which she had been accustomed, necessary. Now in better health than she had been for years.

Case 15.—Multilocular Tumour of Left Ovary—Operation—Recovery.—E. B., aged 32. Much emaciated. Measured forty-two inches round. Pedicle returned into pelvis after operation performed in usual way, under chloroform. At night, enema with laudanum, the only medicine given. Took stimulants early. Excellent recovery in less than a month.

Case of Ascites with Malignant Tumour, supposed to be Ovarian—Operation—Death.—Patient 43 years of age; had had thirteen children; youngest fifteen months old. Had gradually increased in size since birth of child. Measured forty-eight inches round. No unusual pain. Pulse good; not much emaciated; complexion not like that seen in malign-

ant disease; considerable œdema of abdominal walls. A tumour, believed to be ovarian, felt through ascitic fluid on left side. Incision being made, a tumour was found firmly adherent to abdominal walls. It was removed, as also the ascitic fluid. Other tumours of malignant character then found connected with intestines and other structures. Patient never rallied. Death four hours afterwards. Numerous cancerous tumours found in omentum, etc. Ovaries diseased, but small.

Case 16.—Multilocular Tumour of Left Ovary—Operation—Recovery from Operation—Death Three Weeks after from Bronchitis.—General health bad; subject to bronchitis. Operation, April 15, 1863. Strong adhesions on left side. Pedicle returned into pelvis. At end of fortnight sat up daily. She was removed on May 5, at her own request, to the Hospital. She ate a good breakfast on May 6, but died almost suddenly late on the same day. Extensive emphysema of both lungs, and thickening of bronchial tubes. Pedicle and ligature enclosed in a sac formed by coagulable lymph.

Case 17.—Multilocular Cyst of Left Ovary—Operation—Recovery.—Mrs. B., aged 43. Enlargement of the abdomen noticed for six years. Operation, June 26. Tumour, one large cyst, with gelatinous contents. Adhesions considerable. Pedicle treated as in the foregoing cases. Left for the country on July 30.

Case 18.—Multilocular Cyst of Left Ovary—Operation—Recovery.—Tumour growing for eighteen months; measurement forty-six inches. Tumour very adherent. To a small vessel of intestine wounded in separating the adhesions a metallic ligature applied. Pedicle treated as above. No bad symptoms.

Case 19.—Multilocular Colloid Tumour of the Left Ovary—Operation—Death on the Sixth Day.—Miss S., aged 58. Tumour growing a year. Tapped a month previously. Tapping now again necessary; and a fortnight afterwards, having again filled, ovariectomy was decided on. Many adhesions. Tumour made up of large masses of colloid. Pedicle very small. Some hæmorrhage from tearing the pedicle, and it was secured with great difficulty. The patient rallied after becoming very exhausted, and took food well. On the fifth day bad symptoms set in; and death occurred on the following day.

Case 20.—Multilocular Tumour of Left Ovary—Operation—Recovery.—Miss M., aged 39. Tumour growing two years. Much emaciated from bronchitis. Perfect recovery from the operation, which was performed in the usual way. Is now in excellent health.

The author remarked that of the 20 cases 16 had recovered, or 80 per cent.; that is, excluding Case 16, in which death occurred from bronchitis three weeks after operation; including this case the cures were 75 per cent. He had now returned the pedicle into the pelvis in 10 cases, and with most satisfactory results. In all the poor women operated upon the disease incapacitated them from work; in the others, the operation could not have been delayed without risk to life.

The PRESIDENT considered that in cases of doubtful diagnosis the operation of tapping was advisable, as preliminary to the other operation.

Dr. TYLER SMITH thought that in the case alluded to by the President no positive information would have been obtained by tapping. The diagnosis was extremely difficult in some cases. In the particular instance in question there was extreme œdema of the abdominal walls, and he thought it probable that such œdema might be found in other cases to be associated, as it was in this case, with malignant disease. In answer to a question from Mr. Cumberbatch, Dr. Tyler Smith stated that he preferred non-metallic ligatures for securing the pedicle.

Mr. SPENCER WELLS said that the question raised by Dr. Tyler Smith as to the mode of securing the pedicle was one of the most important which could be considered by the Society. He had followed Dr. Tyler Smith's practice in five cases. From the first no conclusion could be drawn, as the patient would probably have died had the pedicle been secured in any other manner. Two of the other four had recovered more quickly than they probably could have done under any other proceeding, although in both there was more evidence of sthenic peritonitis than was often seen where the clamp was used. In two other cases the patients died of diffuse peritonitis, and he (Mr. Wells) thought they might have done better if the clamp had been used. In one no post-mortem could be made. In the other, the ligature and the tissue it enclosed were surrounded by a sort of capsule formed by two

coils of small intestine adhering together and to the pedicle by recent lymph. It was a matter of some doubt whether such a condition might lead eventually to intestinal obstruction, and be more objectionable than the adhesion to the abdominal wall which followed the clamp. His (Mr. Wells') own impression of the three modes of dealing with the pedicle was, that when the pedicle was long the clamp was the safest and best mode; but that when the pedicle was short, it was better to cut off the ligatures short and return the tied pedicle than to leave the ends of the ligature hanging out through the abdominal wall. In reference to the question of the diagnosis of cancer, he had never met with a case of cancer in the abdomen which had not been diagnosed without operation. The diagnosis of cancer of the peritoneum was not difficult. In one case cancer of the right kidney was easily recognised, and was found after death to weigh 17 lbs. In two other cases of cancer of the ovary—one of the left ovary and one of both ovaries, with a large quantity of ascitic fluid—the diagnosis was easily made out after the preliminary tapping suggested by the President, and was proved to be correct after the death of the patient. In neither of these cases was there much œdema of the abdominal wall, and he (Mr. Wells) differed completely from Dr. Tyler Smith in his opinion that this œdema could assist us in making out whether an abdominal tumour was innocent or malignant.

Dr. GRAILY HEWITT mentioned a case in which he had observed very extensive œdema of the abdominal parietes, together with great œdema of the lower extremities, and in which the abdominal tumour present, and which reached above the umbilicus, was constituted by the urinary bladder enormously distended with urine. It was evident, therefore, that œdema of the abdominal walls could not be depended on as a sign of malignant disease.

Dr. J. BRAXTON HICKS wished to ask Dr. Tyler Smith whether he had found any subsequent untoward result from the dropping in of the ligature. Although this practice had been shown by the results to be apparently unattended with danger, and possessed many advantages, still the ligature had possibly to be accounted for at some future day. He considered the perfection of ovariectomy would be nearly gained by doing without any ligature at all. He believed it would be possible, by firmly compressing the pedicle for an inch or so by a serrated clamp or some such apparatus, to condense the tissues so firmly as to completely prevent bleeding. The pedicle could then be dropped into the pelvis. He threw out this suggestion, because he had found in examining tissues after the use of the écraseur that it was nearly impossible to unravel them; and he thought if the width of the compressor were increased, no bleeding would result.

In reply, Dr. TYLER SMITH stated that he had every reason to be satisfied with the results of the plan of dropping the pedicle into the pelvis after securing it by ligature, and he could with confidence recommend it as being probably safer and certainly more convenient than the other plan. He should be very glad to have an instrument such as that suggested by Dr. Hicks for dividing the pedicle if it could be relied on for preventing hæmorrhage.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 15.

Mr. PRESCOTT HEWETT, President.

(Continued from page 407.)

Dr. BARKER brought forward a specimen of
HYPERTROPHY OF THE HEART.

The left ventricle was the one chiefly enlarged, and Dr. Wale Hicks had found that many of its fibres had undergone fatty degeneration. The heart weighed twenty-five ounces; he brought the specimens, not on account of the extent of the disease, but on account of the peculiarity that the patient had had no symptom of heart disease until five weeks before his death, and after admission there were no very positive symptoms. There were no sounds, the apex could not be felt, and there was no pulse. There was no obstruction, and the kidneys were healthy.

Mr. ERNEST HART exhibited a specimen of
DEPRESSED FRACTURE OF THE SKULL FROM A PATIENT WHO
HAD HAD NO HEAD SYMPTOMS.

It was removed from the body of a patient who was thrown from a coach twenty-one years ago. The outer table of the parietal bone was fractured, and driven inwards in the centre

of the fracture. The internal table was not broken to nearly the same extent, but was fractured in the centre. Repair had taken place to a very considerable extent, and as there had been no motion, there was no callus. The history gathered from the Surgeon who attended the patient at the time of the accident was to the effect that the symptoms had been very slight. He was insensible for half-an-hour. Then he slowly recovered, and had no further symptoms. Mr. Hart added that there were two similar specimens in the museum at Fort Pitt.

The PRESIDENT said there was one also in the museum of the College of Surgeons.

Mr. TEEVAN remarked that he had made a number of experiments which all clearly showed that when a foreign body passed completely through one side of the skull the aperture of exit was always larger than the aperture of entry, and this, too, whether the force passed from within or from without. Mr. Hart's specimen seemed apparently to contradict this proposition, inasmuch as the line marking the boundary of the fracture in the external table was much more extensive than the corresponding line marking the fracture in the internal table. But it must be remembered that in this case the head merely struck the ground, and that consequently the latter had only driven inwards a portion of the skull, and had not itself passed into the interior. The case, therefore, was entirely different from that of the passage of a foreign body into the head.

Dr. CRISP exhibited

MICROSCOPICAL PREPARATIONS OF THE OXYURIS VERMICULARIS
IN MEN,

for the purpose of showing the extraordinary number of eggs in this entozoon, and more especially to call the attention of the Society to the mode of expulsion of the ova of the worm, which he believed he was the first to notice. When the female worms are expelled from the body, a white spot is seen with the naked eye, about a third the length of the body from the head. On placing the worm under the microscope, this white spot is found to be composed of a pile of eggs, which are expelled by an artery-like contraction of the oviduct. This process of expulsion is often continued for three or four hours, when the oviduct is nearly emptied. Assuming that the ova in each worm amount to 5000, the number in some persons would reach to a million or more.

Dr. CRISP also exhibited specimens of the

STRONGYLUS FILARIA IN THE LUNGS OF THE LAMB AND THE CALF, with a wax cast of the lungs of the former for the purpose of showing the immense number of these parasites, which block up the air-tubes, and in this way occasion the death of a great many lambs and calves in this country. Dr. Crisp said that in a few instances he had observed the same process of expulsion of the ova in the strongylus filaria as in the oxyuris, in a few instances; but there was this curious difference between the eggs of the two worms, that whilst in the former the young were generally matured, in the latter no appearance of an embryo was visible.

Dr. GIBB exhibited a drawing of

ACUTE EPIGLOTTIDITIS,

occurring under his care in January last, in a gentleman, aged 31, who had phthisical disease. The voice had been gradually going for ten days, and two days before he was seen by Dr. Gibb, dysphagia, with fluids, set in. The laryngoscope revealed the epiglottis enormously swollen, projecting upwards and backwards in the form of a bright crimson red tumour, like an immense plum. It was immovable unless in the movements of the tongue, and could be seen readily at the back of the mouth without even introducing the laryngeal mirror. The larynx was clear and free from disease, the inflammation and swelling being confined to the epiglottis. Under treatment, local and constitutional, the more urgent symptoms had subsided in five days, and a good recovery ensued.

THE ACORUS CALAMUS AS A PREVENTIVE OF INSECT DEPREDATIONS.—Dr. Schultes observes that much use was made by the older naturalist travellers in the East of the powder of the root of *acorus calamus* as a preservative against insects, and that he has found it of the highest utility for the protection of herbaria against the ravages of the *annobium panniceum*. Some of the powder is to be occasionally strewed over the plants, and this insect, beetles, etc., at once desert the spot wherever its smell is perceptible. For the same reason it is a valuable means of preserving zoological collections from insect depredations.—*Buchner's Repertorium*, 1863, No. 8.

OBITUARY.

DR. ROBERT MAYNE.

THE Medical Profession in Dublin has just sustained a very heavy loss—a loss which has called forth in Ireland as lively an expression of sympathy as did the untimely death of Dr. William Baly, some years since, in the English Metropolis. On Thursday, April 7, Dr. Robert Mayne fell a victim to that deadly enemy of the Irish Physician—typhus fever. Like Baly, Dr. Mayne won his way to eminence by the sheer force of innate work and energy, and had only during the last few years begun to reap the fruit of his early labours, when suddenly he is taken from among us. As a writer, Dr. Robert Mayne will be probably best known out of Ireland as the author of the admirable article on the "Optic Nerve" in the *Cyclopædia of Anatomy and Physiology*, to which he also contributed the article "Perinæum." His numerous papers in the *Dublin Quarterly Journal of Medical Science* and *Dublin Hospital Gazette* gained for him the great reputation as a practical Physician; of these, he himself considered those on "Pericarditis," "Cerebro-Spinal Arachnitis," and "Dysentery" as met with in Irish Workhouses the most valuable, and we believe his judgment to have been correct. But of late years his numerous contributions to the Pathological Society of Dublin (of which he was President at the time of his death) proved him to be a Physician remarkably endowed with the power of observation as well as a profound pathologist. As a teacher, Dr. Mayne was eminently successful; in lecturing, his language was clear, and his method of dealing with his subject exhaustive; his style, although quite unstudied, was vigorous, free from dogmatism, and full of that earnest stress which kindled a like earnestness in his pupils. His mind, early trained in anatomical and physiological research, and at a later period devoted to the cultivation of pathological science, was well suited to undertake the duties of bed-side teaching; indeed, we do not think that as a clinical teacher Dublin has met with so great a loss since the death of Graves.

No man envied Dr. Robert Mayne's success; his brethren looked with pride on a man who had reached the highest walks of his Profession without ever quitting the path of the strictest honour. The natural amiability of his character gave him the power of attaching to himself in close affection those who came in contact with him. Perhaps, however, his unaffected simplicity formed the most striking feature of his character. Where will he be most missed?—in the social circle, where his cheerful laugh was ever foremost to greet the sallies of humour, while his presence forbade a word that was unkind, and repressed the first approach towards a jest that was coarse? or at the bedside of sorrow and sickness, where his energy, his vigour, his power of inspiring confidence were only equalled by the kindness of his nature, his gentleness, his almost womanly tenderness?

At the early age of 53 years, having done more than attained success, having deserved it, he was followed to the tomb by a large concourse of persons who had admired his simple, honest ways, and who cordially lamented his untimely death. His remains were borne to their last resting-place by his pupils—a touching tribute to the memory of their honoured master which caused a tear to start into many an eye that witnessed it.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 12th inst., and when eligible will be admitted to the Pass Examination:—

Algernon Ewen, Henry Weekes, John Gill, Jabez Thomas, Robert Stuart, W. H. Butler, J. H. Walters, B. C. Gowing, R. B. Nowell, and S. W. Bushel, Students of Guy's Hospital; O. W. Berry, A. R. Verity, A. Fenning, T. S. Dowse, and H. J. Foulds, of Charing-cross Hospital; R. P. Simpson, H. A. Husband, and Edward Bryan, of St. Bartholomew's Hospital; G. A. Brown, J. Oakley, and R. M. Hickman, of King's College; C. J. Harris, C. W. Huet, and J. C. Worthington, of the Middlesex Hospital; E. C. Shopfree, William Hoffmeister, and W. C. Cass, of University College; J. F. Sargent and W. J. Land, of St. Mary's Hospital; Richard Ley, London Hospital; W. B. Coghlan, St. Thomas's Hospital; W. A. Parsons, Birmingham; and W. E. Richardson, Leeds.

On the 13th inst. :—

J. T. Langley, William Iliffe, G. F. Webb, T. L. Place, A. C. Farrington, H. C. Rogers, Theodore Fennell, H. R. G. Rust, and Edwin Renshaw Students of St. Bartholomew's Hospital; Henry Denne, Henry Morris, H. S. Taylor, G. R. Raine, and Joseph Batteson, of Guy's Hospital; E. M. Spooner, E. S. Wright, Disney Sharp, and Alfred Walker, of the London Hospital; R. S. P. Griffiths, N. B. Major, and F. G. Atkins, of St. Mary's Hospital; Howard Barrett, G. C. Searle, and F. W. Underhill, of St. George's Hospital; J. B. Kerswill and W. J. Todd, of King's College; Alfred Jones and John Swindale, of the Middlesex Hospital; T. H. Tidswell, of the Charing-cross Hospital; F. B. Nunnely, of University College; C. G. M. Lewis, of Birmingham; J. H. Hughes, of Dublin; T. R. King, of Edinburgh; and George Bambridge, of Leeds.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 7, 1864 :—

William George Beardsall, Worksop, Notts; Arthur Roberts Firth, Richmond, Surrey; Henry Rayner, St. Thomas's Hospital; Joseph Bower Siddall, St. Thomas's Hospital.

As an Assistant :—

James Williams, Wokingham.

The following gentlemen, also on the same day, passed their First Examination :—

Franklin Gould, King's College; William Iliffe, St. Bartholomew's Hospital; George Wareup Malim, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANSTIE, FRANCIS EDMUND, M.D., M.R.C.P., Assistant-Physician to the Westminster Hospital, to the Chair of Materia Medica and Therapeutics in Westminster Hospital School.

BAKER, SLADE J., M.R.C.S. Eng., has been pointed Surgeon to the Berks County Hospital at Abingdon.

BARKER, EDWARD, M.D., F.R.C.S. Eng., has been appointed Lecturer on Surgery at the University of Melbourne.

CLEMENTS, G., Mr., has been appointed Resident Clinical Assistant at the Middlesex Hospital.

EADES, RICHARD, M.A., M.B., has been appointed Lecturer on Materia Medica, Therapeutics, and Medical Botany at the University of Melbourne.

GRIMSHAW, THOMAS W., M.B., T.C.D., has been appointed Junior Physician to the Cork-street Fever Hospital, Dublin.

HARRIS, WILLIAM, M.D., has been elected House-Surgeon to the Bristol General Hospital.

HARRISON, GEORGE W., M.R.C.S. Eng., has been appointed Assistant House-Surgeon to the Birkenhead Borough Hospital.

HOLYOAKE, THOMAS, M.R.C.S. Eng., has been appointed Junior House-Surgeon to the Royal Infirmary, Liverpool.

KENNEDY, HENRY, M.B., T.C. Dub., has been appointed Physician to the Cork-street Hospital, Dublin.

LEACH, J. C., Mr., has been elected Assistant House-Surgeon to the Bristol General Hospital.

LOWE, EDGAR, M.R.C.S. Eng., has been appointed Medical Officer to the County Gaol, Worcester.

MACADAM, JOHN, M.D., has been appointed Lecturer on Chemistry and Practical Chemistry at the University of Melbourne.

NASH, GEORGE, B.V., M.R.C.S. Eng. has been appointed House-Surgeon to the Liverpool Royal Infirmary.

PHILIPPS, A., M.R.C.S. Eng., has been appointed Resident Surgeon to the Manchester Workhouse.

PHILIPSON, GEORGE H., M.B. Cantab., has been elected Physician to the Royal Victoria Hospital for the Blind, Newcastle-upon-Tyne.

SHORT, JOHN, L.R.C.S.I., has been elected one of the Medical Officers of the South Dublin Union.

SOPER, ROBERT W., M.R.C.S. Eng., has been appointed House-Surgeon to the Loughborough Dispensary.

TRAVERS, ROBERT, M.B., T.C. Dub., has been elected Professor of Medical Jurisprudence in the University of Dublin.

WHARTON, JAMES, L.K.Q.C.P.I., has been elected Surgeon to the Fever Hospital, Cork-street, Dublin.

DEATHS.

BEAUMONT, JAMES, Surgeon, at Wetherby, Yorkshire, on March 31, aged 75.

COLBY, T. Y., Surgeon, at Bayswater, on March 22.

COLLIGAN, WILLIAM W., L.R.C.S. Edin., at Johnstone, Paisley, N.B., on April 2, aged 31.

COLLYNS, CHARLES PALK, M.R.C.S. Eng., at Dulverton, Somerset, on April 7, aged 70.

HEADLEY, W. C., Surgeon, at the Lunatic Hospital, Lincoln, on March 15, aged 82.

HILDYARD, ISLE G., M.R.C.S. Eng., at Louth, Lincolnshire, on March 30.

DR. LIVINGSTONE.—Her Majesty's steamer *Rapid* has arrived at Table Bay from the eastern coast of Africa. She brought the welcome intelligence that Dr. Livingstone was alive and well. On January 5 the *Rapid* arrived at the Louba mouth of the Zambesi, expecting to find Livingstone and his party, to take them on to the Cape. On communicating with

the Portuguese station-house there, they found there was a letter addressed to the senior naval officer from Bishop Tozer. It was dated "Murchison Falls, December 21," and stated that Dr. Livingstone had come back from his expedition up country, and arrived at the foot of the Murchison Falls in November, and they intended to come down the river as soon as the water rose sufficiently to get the *Pioneer* down. Dr. Livingstone, the Bishop, and party were well in health. The mission party also intended to leave the country, as it appeared an unsuitable field, and would return to England by the Cape; the Bishop and one of his clergymen, however, were to go and visit the Governor of Mozambique. There were no letters for the Cape. The *Rapid* brought down 187 prize negroes taken from a slaver.—*Graham's Town Journal*.

THE LATE EXAMINATION FOR THE ARMY MEDICAL DEPARTMENT.—As might have been expected, the late desperate attempt to obtain candidates for the vacant Assistant-Surgeons in the army has proved an utter failure. Although the bait was thrown far and wide, and any unsettled, unemployed man, possessing the necessary qualification, and being under 30 years of age, was solicited to make application, only fourteen candidates were obtained. Of these three were physically disabled, four were rejected as Professionally incompetent, and the remaining seven were accepted. In the Indian and British armies together there are now nearly two hundred vacancies. When it is too late the authorities will perhaps become alive to the folly of the course they are pursuing. We can assure them that they will never make the service a popular one, and never obtain an influx of highly-educated Professional gentlemen as candidates, until they grant those reforms in the matters of pay, retirement, position, and duties, which have been so frequently insisted on in this Journal.

SANITARY REFORM IN INDIA.—Letters received by the last Calcutta mail state that the Bengal Government is taking active measures to abolish the native custom of throwing the bodies of the dead into the River Ganges, and of burning dead bodies at the Mintollah burning ghât, whence the sickening fumes are wafted over the city of Calcutta. These reforms have raised a storm of opposition amongst the Hindoos. The correspondent of the *Times* writes:—"In other respects judicious endeavours are being made to purify the capital. The health officer has been making a 'hygienic survey' of the town—a thing hitherto unheard of. The filthiness of this place, the loathsome stench that fills nearly every street, the utter neglect of cleanliness and decency among the native population surpass belief. The only mystery is that Europeans are able to live here at all. The city is ten times as dirty as the bazaars at Cairo, and smells fifty times nastier than Cologne. There is likely at last to be an improvement in it; but the cooperation of the natives ought to have been secured in the first instance, instead of their opposition being aroused."

KEW GARDENS.—Many improvements in the gardens are in progress or contemplated. The duties of the Department of the Herbarium are rapidly increasing, owing to the demands made upon it by various departments of the Government, the receipt of large collections from important Government expeditions, the applications for advice from persons proceeding to take charge of plantations of tea, cinchona, cotton, coffee, etc., and the redoubled activity of the colonies in the publication of their *Floras*, which, though paid for by the Colonial Government, can only be prepared at Kew, or by persons in direct and constant correspondence with its Herbaria and Museums. The *Flora* of the British possessions in India is to be proceeded with upon the same plan as the colonial *Floras*, and has been commenced in the Herbarium by Dr. Thomson. Very satisfactory reports are received of the success of the introduction of cinchona plantations in India, in the establishment of which Kew has had so large a share. In the nurseries on the Neilgherrie hills there were, in December last, nearly 260,000 plants, of which more than 66,000 were planted out; one was nearly ten feet high. The bark has been analysed, and the result is entirely satisfactory. There are 8000 plants in the Darjeeling plantations, Himalaya, and 22,000 in Ceylon. Steps have been taken at the request of the Government of South Australia to introduce the cork tree into that colony; a large quantity of young plants have been raised in the pleasure-ground nursery for transport, to be sent out this spring in a growing condition in glazed cases. Large collections of semi-tropical trees and shrubs have been sent, at the request of the Admiralty, to the once desert island of Ascension, the upper parts of which are now clothed with trees and shrubs, chiefly

derived from Kew. The most satisfactory accounts are received of the thriving condition of these plants, and the consequent rapid increase of the fertility, water supply, pasture land, and vegetable produce of the island. The Bermuda grass especially, which was sent from Kew several years ago, has now become the staple fodder of the place.

THE DISPUTE BETWEEN DR. BULLEN AND SIR ROBERT KANE.—The grave charges made by Dr. Bullen, Professor of Surgery at Queen's College, Cork, against Sir Robert Kane, the President of the College, were investigated by order of the Government, at the usual triennial visitation of the College, which took place on April 12. The visitors were the Lord Chancellor, the Bishop of Killaloe; Dr. Corrigan, President of the College of Physicians, and Dr. Colles, President of the College of Surgeons. One of the charges brought by Dr. Bullen against the President was, that he urged Dr. Bullen to join him in making a report which would ascribe the burning of the building to the ultramontane party in Cork. Dr. Bullen appeared by his counsel—Mr. Barry, Q.C. Sir Robert Kane declared that the charges made against him were false and unfounded, and that he desired the fullest investigation. Mr. Barry then read the following letter from Dr. Bullen, dated April 12, and addressed to Sir R. Kane, President:—"Sir,—In a communication which I addressed to his Excellency the Lord-Lieutenant on the 29th of July, 1863, I enclosed to him memoranda, purporting to represent conversations held between you and me relative to the burning of the Queen's College, Cork. These memoranda were not committed to writing for a considerable interval after the conversations referred to, nor until, as I am now convinced, a lapse of time and intervening events had effaced from my mind an accurate recollection, and substituted erroneous impressions of what had passed between us. At the time I made the statements to his Excellency I believed in their accuracy, but am now satisfied that I was entirely mistaken, and that you are perfectly justified in your denial of the statements, which I now entirely withdraw. The excitement produced by the public discussion of these matters has since led me to prefer charges against you which are altogether unfounded, and which I beg also to retract in the most unqualified manner. I deeply regret what has occurred, and beg to offer you the most ample apology for any annoyance which these transactions may have occasioned you.—Denis B. Bullen, M.D., Professor." The *Times*' Correspondent adds:—"The reading of this letter called forth enthusiastic cheers from the students and the citizens present. The Lord Chancellor stated that, having received that full, explicit, and unqualified assurance of the incorrectness of his statements from Dr. Bullen, their function was at an end. It was for the Government, not for them, to take action upon the letter, which he would lay before the Lord-Lieutenant. He expressed his gratification with the satisfactory result at which they had arrived, and hoped that the future progress of the institution would be equal to that which it had hitherto maintained, gratifying to all connected with it, and reflecting credit on the country at large."

BETHLEHEM HOSPITAL.—On Saturday, April 9, an adjourned special meeting of the Governors of Bethlehem Hospital was held at Bridewell Hospital, Bridge-street, Blackfriars, under the direction of Mr. F. O. Martin, Inspector of Charities, respecting the site of the Hospital; Mr. Alderman Copeland, M.P., in the chair. The chairman said the Commissioners in Lunacy having recommended to Sir G. Grey that the Hospital should be removed from its present site to the country, to make room for St. Thomas's Hospital, the Governors were prepared with a great deal of evidence which they should offer to Mr. Martin in favour of the present site. Mr. A. M. Jeaffreson (the secretary) read a communication from Mr. Lawrence, Surgeon to the Hospital, and senior Surgeon to St. Bartholomew's Hospital, which stated that the Commissioners in Lunacy sought to obtain the assistance of Sir George Grey in order to enforce an arrangement which was most repugnant to the Governors, forgetting that their power, as far as Bethlehem was concerned, was simply confined to that of visiting. Without any examination on his part, the Home Secretary endorsed the strange proposal for taking down one of the handsomest and best constructed Hospitals in London. The present site of Bethlehem was perfectly suited in healthiness either for lunatics or as a general Hospital. Instead of being confined, the site of the Hospital was remarkably open. He disapproved entirely the recommendations of the Commissioners in Lunacy. The opinion of Dr. Goode was read. He was in favour of the present site

from his personal experience of ten years. At present it enjoyed many advantages, and the Hospital, instead of being hemmed in by buildings, was peculiarly free and open. If the Hospital was removed ten or twenty miles into the country, how were the patients to be removed to the Hospital? The sanitary condition of the neighbourhood was good. The site was healthy, and the position good, and he hoped that the Hospital would be maintained in its present condition. Dr. Wood, one of the Medical officers of St. Luke's Hospital, and formerly of Bethlehem Hospital, said no good reason had been advanced why the Hospital should be removed. Bethlehem was one of the finest buildings in London, and taking the grounds of Bethlehem, with its eleven acres and 200 patients, and Hanwell, with twenty-eight acres, farm of seventy-seven acres, and 1600 patients, there was considerably more space at Bethlehem per head than at Hanwell. The Hospital was singularly and exceptionably healthy. When cholera was raging in London, and people were dying literally at the very doors of the Hospital, not a single case happened among the inmates. Mr. Martin, the inspector, asked whether it was possible to have an institution in the country in connexion with the Hospital. Mr. Johnson, the treasurer, said to a small extent they had already sent patients to the seaside. After some further evidence had been taken, a vote of thanks was passed to the chairman, and the meeting was adjourned.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

A Foreign Verdict on a Question of Professional Honour.—L'Union Médical, of April 7, after speaking of the alleged refusal of the civil Medical Practitioners of Foggia to render aid to their military brethren in an epidemic of typhus, and of the condemnation of their conduct by the whole Medical press, and of the unanimous generous spirit with which the whole of *l'Italie Médicale* protested against it, and came forward to fill the gap, thus delivers its verdict upon the Birkenhead case:—

“Quel contraste avec nos confrères d'outre-Manche, dont le flegme à l'annonce d'un fait analogue, et plus répréhensible peut-être, ne s'est pas troublé le moins du monde; le *Medical Times* seul en a pris souci, et encore est-ce pour faire pièce au petite *British*, qu'il prend directement à partie pour lui reprocher à ce sujet ses tendances mercantiles. Voici le fait: Une femme de Birkenhead est prise des douleurs de l'enfantement avant terme, le 8 mars, à neuf heures du soir, sans avoir retenu personne pour l'assister. On patiente jusqu'à minuit et demi, mais, à ce moment, il n'est plus possible d'attendre, et le mari court chercher un médecin. Il frappe à la porte d'un, de deux, de trois, et successivement jusqu'à six, mais en vain; l'un est indisposé, l'autre est vicieux, celui-là est occupé ailleurs, un quatrième ne répond pas, et celui-ci—je ne le nommerai pas—va jusqu'à dire, oh, *shame! shame!* qu'il ne se dérangera que si on lui apporte une guinée pour le payer d'avance. A bout d'adresses, le pauvre homme revient au premier médecin, espérant, comme il est quatre heures du matin, que son indisposition sera dissipée. Il l'adjure, au nom du ciel et de l'humanité, de venir sauver la vie de sa femme. Celui-ci se rend, en effet, aussitôt près d'elle, qu'il trouve sans pouls par suite d'une hémorragie abondante et qui expire instantanément. Et voilà comment le *coroner*, appelé à constater ce fait révoltant, l'a rendu public dans le *Liverpool Mercury*, et mis ainsi les médecins de Birkenhead à l'index.

“Leur conduite est évidemment injustifiable. Le médecin doit d'abord secourir en pareil cas, sauf à demander, à exiger même ses honoraires ensuite. C'est le meilleur moyen de montrer que nos services ne sont pas légalement dus, comme on est trop disposé à le croire partout. Des membres du jury dans l'examen de cette triste affaire, ont ainsi demandé que des mesures coercitives puissent être dirigées contre les médecins récalcitrants. Exiger rigoureusement la rémunération de nos services est la meilleure manière de répondre à de telles prétentions, mais il n'est ni juste ni digne d'agir autrement.”

THE SCOTTISH REGISTRATION ACT.

The Medical students of Glasgow have addressed the following memorial to Lord Palmerston, the Lord Rector of that University. Its object will meet with the sympathy of the whole Profession in all parts of the United Kingdom. The Scottish Registration Act was an insult to the Medical Practitioners of Scotland, which could never have been perpetrated had the Profession been properly represented in Parliament:—

“The Right Hon. Viscount Lord Palmerston, K.G., M.P., etc., etc., First Lord of Her Majesty's Treasury, and Lord Rector of Glasgow College.

“The memorial of the undersigned students attending the Medical classes in the College of Glasgow,

“Most respectfully sheweth,

“That memorialists desire to draw your lordship's attention to an unseemly anomaly in the law affecting the registration of deaths in the United Kingdom.

“That an Act for Regulating the Registration of Deaths has been in operation in England for 30 years. That the professors in the colleges and universities of England, and the members of the Medical Profession generally, are expected to render their professional services for the public interest, by granting certificates of the cause of death, without fee or reward. That it has never been thought expedient to employ coercion by legal statute to compel the Practitioners of England to give their professional assistance gratuitously in this matter—such a course being wholly opposed to the genius of the British Constitution, and irreconcilable with English ideas of justice and the rights of property or of professional labour.

“That in 1854 an Act for the Regulation of the Registration of Deaths in Scotland was carried through Parliament. That in dealing with the Medical Profession in the Scotch colleges, and the Profession generally of Scotland, a widely different course was pursued to that which had been followed with the English. The occupants of the Medical chairs and the members of the Profession were not estimated as being entitled to be classed with, or put on a footing of equality with their English brethren. It was deemed necessary to institute a system of penal terror—fine or imprisonment, inflicted at the instance of the criminal officers of the Crown, under which the professional labours of the Medical men of Scotland could be exacted for the public interest.

“That during last session of Parliament Sir Robert Peel, her Majesty's Principal Secretary for Ireland, carried an Act to Regulate the Registration of Deaths in that country. That on introducing his measure the Secretary for Ireland stated in the House of Commons that he had consulted the President of the Royal College of Surgeons of Ireland, and other competent authorities, whether the ‘Scotch compulsory system’ would be suited to and borne by their countrymen, members of the Medical Profession; but he had been given to understand that it would be vain and futile to attempt to force so obnoxious a system on the Irish—that any such overture would be met with scorn and contempt—that nothing but full equality with the English, and that in every particular, would be submitted to. Government acted on this advice, and the Irish Registration Act is free from the unjust, invidious, and humbling enactment existing in the Scotch.

“That memorialists are confident your lordship is not aware that so invidious and uncalculated for a distinction injuriously affecting the status of the Medical Professors and Practitioners of Scotland exists, therefore they think it necessary to draw your lordship's attention to it, and to state that, if this unseemly condition of matters be permitted to continue, the prospects of the young men educated in the Universities here will be materially injured. The inference to be drawn from the above-recited Acts of Parliament unanswerably is, that the teachers under whom the youth of Scotland are trained are morally and otherwise inferior to their class in England and Ireland, incapable by example or precept to bring up their students otherwise than in such a manner that, when they enter the Profession of their adoption, they will be found not entitled in the eyes of the law to be placed on a footing of equality with their co-practitioners of England and Ireland.

“May it therefore please your lordship to introduce into Parliament such a measure as will repeal the compulsory section of the Scotch Registration Act, and thus place the Medical Professors on equal footing throughout the United Kingdom,

“And your lordship's memorialists, as in duty bound, will ever pray.”

COMMUNICATIONS have been received from—

Dr. GRAILY HEWITT; MEDICAL SOCIETY OF LONDON; ANTHROPOLOGICAL SOCIETY; Mr. JOHN ROBERTSON; HARVEIAN SOCIETY OF LONDON; ROYAL INSTITUTION; Dr. JAMES C. L. CARSON; IN DUBITE EST; Dr. J. FERRIER CLARKE; Dr. R. DUNDAS THOMSON; Dr. MOORE; PROFESSOR WHARTON JONES; Mr. BARTH; APOTHECARIES' HALL; C. K.; Mr. THOMAS B. BOTT; Mr. W. A. HARRISON; PHARMACEUTICAL SOCIETY; Mr. W. PROWSE; NEMO SIBI VIVAT.

BOOKS RECEIVED.

Laryngoscopic Medication, or the Local Treatment of the Throat, Larynx, and Neighbouring Organs. By Louis Elsberg, A.M., M.D. New York: W. Wood and Co. 1864.

** On the whole, a useful and readable digest of the subject. The following list of topical remedies is the author's contribution to American go-ahead-ism:—Acids, acetic, pyroigneous (either alone or with creosote water), tannic (especially with belladonna), chromic, nitric, and other mineral acids; aconite tincture with glycerine; atropine solution, and belladonna tincture; alum, bromide, and chloride of ammonium; benzine; borax; iodide and chloride of bromine; sulphate of cadmium; catechu tinct.; capsicum tincture; chlorine; ozonised chlorine; cannabis indica tincture; chloroform; codeine tincture; conin solution in sweet almond oil; aluminated sulphate of copper, nitrate of copper; creosote; digitalis tincture; ergotine solution; erygeron oil; eupatorium; gelsemium tincture; geranium tincture; glycerine; hyoscyamus tincture; iodine in various combinations; iodoform solution in oil; sesquichloride of iron tincture, perchloride solution, persulphate sol.; chloride of lime solution; iodide of lead, also tannate and sulphate; myrrh tincture; acid nitrate, argento nitrate of mercury, iodide, mild and corrosive chloride; iodochloride of mercury; morphine solution and opium tincture; cod-liver and olive oil; bromide, cyanide, iodide, and hydrargyri iodide of potassium; bichromate, chlorate, iodate, nitrate, and permanganate of potash; Filho's caustic, and Vienna paste in stick; rosin; common salt; sanguinaria; senega; iodide of silver and potassium; stramonium; strychnine; sugar; tar; turpentine; veratrum tincture; acetate, chloride, iodide of zinc, sulphate of zinc and alum, sulphate of zinc and morphia, etc.” Surely any prospective laryngoscopist must be satisfied with an armamentarium such as this! What the author has not told us is how and when to use them, and which are altogether useless.

The Glasgow Medical Journal. April, 1864. Glasgow: W. Mackenzie.

** A writer in this Journal subjects Dr. Forbes Winslow's evidence in the Townley case to a more severe criticism than we have ventured upon. He says “the conclusions of Dr. Forbes Winslow, when compared with the observations on which he bases them, have not unjustly given rise to the most unmingled astonishment. If this man Townley was mad in the sense that he was not responsible for his act, what crime of the kind will in future be incapable of defence?” He adds:—“It is scarcely our business to speculate as to the origin of these comprehensive theories in the mind of the distinguished Physician in question, but it may not be irrelevant to go so far as to assume that when a man is constantly examining cases of real or supposed insanity, a period arrives when his own judgment is in a certain degree affected by the continual practice which he has to undergo.” This is about the mildest of the insinuations of the writer of the article.

Annals of Military and Naval Surgery and Tropical Medicine and Hygiene—Vol. I., 1863. London: John Churchill and Sons. 1864.

** A condensation of Medical Blue-books, etc., likely to be in demand among officers of both services.

Edinburgh Medical Journal. April, 1864. Edinburgh: Oliver and Boyd.

** Dr. Andrew Wood furnishes us, in this number, with a mild protest against Mr. Syme's extravagances in relation to the reform of Medical education. That students are wearied, annoyed, and disgusted by much in the present system there is no question, and Dr. A. Wood's suggestions for their relief are many of them of real value, inasmuch as he maintains the importance of a complete curriculum, while divesting it of much of its tedium.

Edinburgh Veterinary Review. April, 1864. Edinburgh: Maclachlan and Stewart.

** Officers of health and Veterinarians are not the only people concerned in the prevention of the spread of disease among live stock, and consequently in the attempted legislation upon the subject. The "Cattle Diseases Prevention Bill," introduced into the Commons by Mr. Bruce, has been referred to a select committee—the best thing that could be done with it in the present state of public opinion. Those who may wish to hear the views held by its advocates and opponents will find in this number of the *Veterinary Review* several discussions and papers respecting it.

Bulletin de l'Académie Royale de Médecine de Belgique. Second Series. No. 9. Bruxelles. 1863.

** We can commend to such of our readers as are not yet familiar with the operations of the Calabar bean an excellent paper on the subject by M. Warlomont, which is the principal article of interest in this number.

Quarterly Journal of Microscopical Science. April, 1864. London: John Churchill and Sons.

** This number contains a paper "On the Germinal Matter of the Blood, with Remarks upon the Formation of Fibrin," by Dr. Beale, which demands a more extended notice.

Annual Report of the Bourton-on-the-Water and Cotswold Village Hospital. January, 1864.

** The rules, subscribers, and third annual report of a useful institution, where patients pay for their support, and the Union Medical officer is not defrauded. An enclosed sheet gives brief details of thirty-eight cases brought to a conclusion, and two still in the Hospital. 261 out-patients are also tabulated. There appear to have been no deaths during the year.

A Guide to Geology. By John Phillips, M.A., etc. Fifth Edition. London: Longman and Co. Pp. 314.

** The completeness of this small work is marvellous. It lays before the student, in few and clear words, all the existing doctrines of modern geology, and the relations of geology proper to the kindred sciences of natural history, mineralogy, and chemistry.

Handbuch der Lehre von den Knochenbrüchen. Von Dr. E. Gurlt, Professor der Chirurgie an der Königlichen Universität zu Berlin. 2. Theil. 1. Lieferung.

** This is a second part of the comprehensive and exhaustive treatise on Fractures by the learned Professor of Surgery in the Royal University of Berlin. The former part was reviewed in our columns in 1862, vol. i., p. 247. The present part contains 368 pages of text and 31 admirable woodcuts, illustrating fractures of the vertebrae, ribs, rib-cartilages, sternum, os hyoïdes, and laryngeal cartilages. It is a perfect museum of references to all recorded cases of rare fractures.

A Vindication of the Present State of Aural Surgery. By a Member of the New Sydenham Society. London: John Churchill and Sons. 1864.

** A pamphlet which our readers, like ourselves, will probably have received individually. It reviews Kramer's Aural Surgery, recently translated by the New Sydenham Society, in a very unfavourable manner. Beyond this, it is rather difficult to see the object of an anonymous publication of the kind.

Sketch of the Early History of the Medical Profession in Edinburgh. By John Gairdner, M.D. Edinburgh: Oliver and Boyd. 1864.

** This is an address delivered at a *conversazione* in the hall of the Royal College of Surgeons of Edinburgh in January last. It appears to follow up a similar communication made four years ago. It is as interesting as might be expected, but hardly admits of analysis, from its consisting mainly of extracts from records and historical minutiae.

Montpellier Medical Journal Mensuel de Médecine. March, 1864.

** Three original memoirs on malignant pustule, puerperal fever, and hemeralopia, as observed among the crew of the *Pallas*, a French frigate, when in the Pacific Ocean, sustain the credit of a periodical to which we are already indebted. A review of a work on the outbreak of yellow fever in France, at St. Nazaire, is followed by a particularly lively and amusing monthly chronicle.

Modern Leicester. Part 2. A Lecture delivered before the Leicester Literary and Philosophical Society. By John Barclay, M.D., F.R.C.P. Leicester: W. P. Cox.

** This plain-spoken, admirable address is one example of the civilising effect of our Profession. It is fortunate for the Leicester people that they have so acute and eloquent a critic amongst them. We reserve for another occasion his remarks on the Leicester Infirmary.

Biographical Sketch of Sir Benjamin Brodie. By Henry W. Acland. London: Longman and Co. 1864. Pp. 30.

** Reprinted, with a few alterations, from the obituary notices of the Royal Society. An elegantly written account of Sir Benjamin's life and character.

The Quarterly Journal of Science. No. 2. April, 1864. London: John Churchill and Sons.

** This periodical is likely to take a high position among its congeners, judging from the two numbers which have appeared. We are glad to be able to say a good word in its favour. Among the papers which will interest our readers most is one on "the Fossil Skull Controversy," a continuation of Dr. Carpenter's contribution on "the Conservation of Force Applied to Physiology," and one by Dr. Voelcker on "Milk and Dairy Arrangements."

Archives of Medicine. No. 14. By Lionel S. Beale. London: John Churchill and Sons. 1864.

** In addition to the other excellent papers, there will be found here the first of a series on "Recent Contributions to the Study of Continued Fever," apparently intended as an antidote to the objectionable parts of Dr. Christison's address at the Edinburgh meeting of the Social Science Association.

Rapport sur l'Assainissement des Fabriques ou des Procédés d'Industries Insalubres en Angleterre. Par M. Charles de Freycinet.

** We desire to direct the attention of Medical Officers of Health and others interested in improving the health of workpeople and the neighbourhoods around manufactories to this volume. The author, we know, took great pains in investigating the subject when in England last year. The Report is published by the French Government, and although the matters discussed are regarded from a Continental point of view, the book is well worthy of perusal. We suppose it may be obtained through any of the foreign booksellers.

Evening Thoughts. By a Physician. Third Edition. London. J. Van Voorst. 1864.

** A little book containing plenty of suggestions for the thoughtful.

The British and Foreign Medico-Chirurgical Review. April, 1864. London: John Churchill and Sons.

** An excellent number of a periodical which never falls to mediocrity.

Statistical Tables of the Patients Treated in Guy's Hospital, 1863. By John C. Steele, M.D.

** The continuance of these tables by Dr. Steele will, in time, furnish a valuable series for the Medical Statistician.

VITAL STATISTICS OF LONDON.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	30.023 in.
Mean temperature	44.5
Highest point of thermometer	61.4
Lowest point of thermometer	35.0
Mean dew-point temperature	38.8
General direction of wind	Variable.
Whole amount of rain in the week	0.63 in.

APPOINTMENTS FOR THE WEEK.

April 16. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Frankland, "On the Metallic Elements."

18. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Mr. Teevan, "On Some Injuries to the Skull."

19. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Captain Burton, V.P.A.S.L., and C. Carter Blake, F.G.S., "On Skulls from Annaborn, in the West African Seas." John Thurnam, M.D., F.S.A., "On the Two Principal Forms of Ancient British Skulls."

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Professor Helmholtz, "On Conservation of Energy."

20. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

HUNTERIAN SOCIETY, 8 p.m. Mr. C. Bader, "On the Case of Opacity of the Cornea by Gonorrhoeal Inoculation."

21. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Dr. Cock, "On Laryngismus Stridulus."

ROYAL INSTITUTION, 3 p.m. Professor Helmholtz, "On Conservation of Energy."

22. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. Professor Blackie, "On Lyeurgus."

DINNEFORD AND CO., PHARMACEUTICAL CHEMISTS,

Beg respectfully to inform the Medical Profession that they are now Dispensing Physicians' Prescriptions
with the

PREPARATIONS OF THE NEW BRITISH PHARMACOPŒIA,

except when otherwise indicated by the Prescriber.

172, NEW BOND-STREET, LONDON.

Pulvis Jacobi ver, Newbery's,

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

The Best House for Second-hand Instruments.

Where there is the Largest Stock in London, is Mr. WILLIAM LAWLEY'S, 78, FARRINGDON-STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases at 8s. 6d. and 10s. 6d. each.

Photographic Lenses, Opera Race Glasses, and Telescopes, by the best London Makers.

Catalogue of Cameras and Lenses, also of Pocket and Dissecting Cases, forwarded on receipt of Postage Stamps.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "*Pharmaceutical Journal*," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "*Times*," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

THE ORIGINAL CHLORODYNE.

INVENTED AND MANUFACTURED, IN 1844, BY RICHARD FREEMAN.

By the decision of Vice-Chancellor Sir W. Page Wood, R. Freeman is entitled to the SOLE right to use the word Original as a prefix to the word Chlorodyne.

The large and still-increasing demand which the Inventor has for this therapeutic is evidence of the high estimation in which its properties are held by the Profession generally; and on a recent occasion a number of eminent London Physicians and Surgeons of long standing in the Profession, and who hold public appointments, made affidavits to the fact that Freeman's Original Chlorodyne is a more certain and reliable, a more valuable and a preferable, preparation to that of any other maker's. It is offered to the Profession as the best preparation of the kind, and at a price which allows the poorest sufferer to enjoy its extraordinary beneficial effects.

MANUFACTURED BY THE INVENTOR,

RICHARD FREEMAN, PHARMACEUTIST, KENNINGTON-ROAD, LONDON, S.;

And Sold by all Wholesale Druggists, in Actinic Glass Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d. each.

ORIGINAL LECTURES.

LECTURES
ON THE CONSERVATION OF ENERGY.

By Professor HELMHOLTZ.

DELIVERED AT
The Royal Institution
ON APRIL 12, 1864.

LECTURE III.

LADIES AND GENTLEMEN,—In my last lecture I explained the arguments which are derived from modern observations on the nature of the sun, from which we are to conclude that the sun is an intensely heated body. I also endeavoured to prove that this idea is not at all in disaccord with the observations relating to the form of solar spots. We saw, likewise, that the small degree of density of the sun can be explained only by the very high temperature of that body; and that the light coming from the body of the sun is far more intense than any light we can obtain by terrestrial means—that it is 150 times more intense than the light of lime made to glow by a jet of oxygen and hydrogen, the so-called Drummond's light. The most intense we can produce by terrestrial means is that of an electric arc between two charcoal-points; but the intensity of the sun-light is three or four times greater. As to the intensity of the light, we can only give estimates, not accurate measurements; but the quantity of heat which is given out by the sun can be measured exactly. Such measurements have been made by the French physicist, M. Pouillet. He collected carefully the rays of the sun which are received by a surface of metal of definite size, and the heat produced by the rays was conducted to water, which was thus warmed. In this way he was able to measure how much the temperature of the water was raised by a given quantity of solar heat; and this was the result:—Supposing every square foot of terrestrial surface to be covered with one pound of water, the solar rays falling upon that surface being converted into heat, and this heat used to raise the temperature of the water, the temperature would be raised during one second of time by 0.06° Centigrade. This supposes that the surface is exposed perpendicularly to the solar rays. Now let us imagine a sphere [illustration], the centre of which is the sun, and the radius of which is the distance from the earth to the sun: the sun radiates its heat in all directions, and every square foot of this sphere receives the same amount of heat as every square foot of terrestrial surface which is exposed perpendicularly to the sun's rays; so that we can calculate the whole amount of heat which is given out from the sun, by multiplying the total number of square feet by the quantity of heat given out to one square foot. Such calculations have been made by M. Pouillet, and they have given this result. The quantity of heat emitted by one square foot of solar surface during one hour is equal to the heat which can be produced by burning 1500 lbs. of coal. You see that is a very great amount of heat. It would be impossible to burn such a quantity of coal on one square foot of terrestrial surface during one hour: the temperature of burning coal would not be sufficient to give so great an amount of combustion.

Now, I showed in my last lecture that heat can be converted into mechanical power; therefore, as we see that the surface of the sun gives out a most astonishing and enormous amount of heat, we must infer from this fact that an enormous amount of mechanical power goes out from the surface of the sun. We shall see that even the small portion of heat which is given to our earth is sufficient to produce all those great alterations, meteorological changes, the circulation of water, and so on. From the results of Mr. Joule's experiments, I have calculated the mechanical equivalent of this quantity of heat, and I find that it is 7000 horse-power for every square foot of solar surface. In this case we need not take notice of the time, because horse-power is a certain quantity of work done during a certain period of time. You see, then, that every square foot of the surface of the sun produces an enormous quantity of work, or the equivalent of an enormous quantity of work. It is not possible that such an amount of work can be produced without equivalent loss of other natural forces, because we have seen that power and energy cannot be produced from nothing; that they can only be obtained by changing the energy of other natural forces into the particular forms which we wish to pro-

duce. We must ask, then, what may be the sources of this enormous amount of solar heat? First, it might be supposed that there is a combustion going on over the surface of the sun. We know that by chemical processes a great amount of heat can be produced, and we may therefore ask if the sun is not fire, and if such an amount of heat cannot be produced by chemical means? Now, if we were to produce heat by the combustion of the elements of which our earth is composed, and we wished to produce the greatest amount of heat possible from the smallest mass, the most advantageous way would be to take hydrogen and oxygen, the two gases which are the component parts of water, and to burn them. They give a flame of a very high temperature, and they give the greatest amount of heat that can be obtained by a definite quantity of matter. If, then, they were mixed in that proportion which would give the greatest amount of heat that can be produced by chemical combination—if we supposed the whole body of the sun to be composed of oxygen and hydrogen, so combined as to form water, then the whole mass of this water would be heated to 3777° Centigrade. We have seen that the loss of heat is very great. Suppose the whole body of the sun to consist of water, the loss of heat going on during one year at the surface of the sun would cool this quantity of water by $1\frac{1}{4}^{\circ}$ C. Now, if we had such a mass of water produced by the combustion of oxygen and hydrogen, and heated to the temperature I have mentioned, this heat would be sufficient to supply the amount given out by the sun for 3021 years. Supposing, then, hypothetically a combustion going on such as would be most fitted to produce a great amount of heat, and to give out the heat which the sun loses every year, this would not make up for the loss of the sun's heat for more than 3000 years. Now we know thoroughly from human history that the sun has given out the same amount of heat (perhaps more in former times) for nearly 6000 years, and we may be sure that the time is far greater. We must conclude, then, from these results that chemical combinations are not at all adapted to produce such an amount of heat as the sun gives out every year. In order to derive the whole heat of the sun from chemical combinations, we ought to suppose that in the sun exist chemical elements of quite another nature than those of our earth—elements which have a power of affinity superior to the affinities of our terrestrial elements. But we know by the researches of Kirchoff and Bunsen that a great number of the elements of our earth exist in the sun; therefore it is very probable that the composition of the body of the sun is not so very different from the composition of the mass of the earth. We cannot, then, suppose that the heat of the sun is produced by a chemical process, and that the sun is of the nature of fire. One might presume that the sun contains already a very great amount of heat; that it gives it out and is cooled by degrees. But you will see the cooling per year would be $1\frac{1}{4}^{\circ}$ C., and even this under the most favourable supposition—namely, that the whole mass of the sun was composed of water. Water, among all terrestrial bodies, has the greatest capacity for heat. All other terrestrial bodies would be cooled more than water by the same loss of heat; and we may be sure that if the sun gave out a store of heat already existing in its interior, the cooling would be greater than $1\frac{1}{4}^{\circ}$. Now, the facts made known by human history prove that the temperature of the sun has not been sensibly diminished, and therefore that the cooling during historical times cannot be perceptible. We could perhaps suppose that the temperature of the sun is so great that even a loss of 3000° or 5000° is not perceptible; its temperature might be several millions of degrees; but this seems rather a bold and dangerous supposition. It is not very probable that the sun gives out only heat pre-existing in its interior. It is more probable that there are means to produce new heat. If the sun is losing heat, and becomes cooler, then it must contract, like all other heated bodies which contract if they are cooled. Now, the contraction of so great a mass would cause the outer layers of the sun to approach to the centre; they would sink down under the influence of gravitation; the heavy bodies thus sinking must necessarily do work, and that work cannot be lost. In such a case the work could only be converted into heat; and we may inquire—how great would be the quantity of heat produced by the mechanical work resulting from the contraction of the sun by the force of gravitation? You know that a heavy body falling to the earth produces heat, and in the same way the outer layers of the sun, if they approach the centre, must produce heat. This heat is, indeed, very great. We can calculate the amount of it, because we know by the researches of Mr. Joule the equivalent of mechanical power expressed in heat. If the sun contracts

only so much that its diameter is diminished by the 10,000th part of its length, we shall get an amount sufficient to compensate for the loss of heat for more than 2000 years. If we suppose that the body of the sun contains the same substances as the body of the earth, then we must conclude that if the sun is cooled down to the same temperature as the earth, it will have at least the same density, or probably even a far greater density, because the gravity of the sun is far greater, and the attraction of this enormous mass to its outer surface is far greater than the attraction of the mass of the earth to its surface. But supposing that the sun could only contract to such an extent that its density would become equal to the density of the earth, then we should have heat produced by this contraction, and the amount would be nearly sufficient for the sun to give out heat and light of the same amount as at present for 17,000,000 years. So that you see, the force of gravitation operating on the surface of the sun, and the amount of this work converted into heat, would give a quantity far greater than can be produced by the strongest of our chemical affinities. This may appear an astonishing result, for the force of gravitation operating on the surface of our earth appears to be much less than the power of chemical combinations in producing heat or other kinds of mechanical energy. If we raise a weight to a very great height, even to the height of a thousand feet or more, and let it fall, it will only give so much heat as to raise its own temperature one or two degrees; and you know that the power of steam-engines, in which the energy is produced by the chemical combination of coal with oxygen, is far greater than the power of water-mills or the power of such weights as we are able to raise to a height by human force. Therefore, here on the surface of our earth chemical forces have a far greater amount of energy, and are capable of producing far greater effects, than mechanical means, than the force of gravitation as far as we can apply it. When one pound of carbon is burned, it produces so much heat that 8080 pounds of water can be warmed one degree Centigrade. One pound of carbon combines with $2\frac{2}{3}$ pounds of oxygen. Now, suppose that the heat produced in this way is used for lifting up the weight of carbonic acid produced by the combustion, that weight would be raised 580 English miles—the seventh part of the radius of the earth. You see that we are quite unable to raise any weight by mechanical power or by the power of the human body to such a height as it can be done by the energy developed by the combustion of carbon, by the combination of carbon with oxygen. Therefore, the energy developed by this combination, the energy which is used in our steam-engines, is far greater than the energy of similar masses when acting in a mechanical way.

Now suppose that carbon was burned on the surface of the sun, and we had to raise the weight of the carbonic acid from that surface: it would be raised by the energy produced by the combustion 20 miles only, because the force of gravity on the surface of the sun is so much greater than that on the surface of the earth. But when you compare this distance with the distances of the inter-planetary spaces, it is infinitely small; as it is when compared with the distance of the earth, or even with the diameter of the sun. You see, therefore, that the force of gravity, working through these enormous distances of the inter-planetary spaces, may be said to produce far greater amounts of energy and of heat than chemical combination, although for our terrestrial conditions chemical forces are far stronger and mightier than the force of gravity. The heat, then, given out by the sun may be produced by the contraction of the sun and by the force of gravity working during the contraction.

Several philosophers—first, Dr. Mayer, afterwards Mr. Waterston, and then Professor William Thomson—have upheld another theory, that the heat of the sun could be produced by a fall of meteors. You know that meteors and falling stars are bodies swarming through inter-planetary spaces, which sometimes come into our terrestrial atmosphere, are then heated, become glowing and luminous, and sometimes fall to the ground. They are chiefly composed of iron and several other minerals. It is not necessary that I should go into a further description of meteors, because soon after my own lectures Mr. A. Herschel will give you a special account of them. I can now only speak of those points which have reference to force. The velocity of these meteors is very great. Of course the calculations and measurements of their distance, height, and velocity are not very exact; but we have results approaching the truth. Their velocity is about the same as—sometimes greater than—the velocity

of the earth in its way round the sun, which is 23 English miles per second. Now, this velocity is lost if the meteors fall to the earth—first, by friction, and afterwards by the impact on the ground: it cannot, however, be lost completely, but must be changed into another form of energy—it is changed into heat. This heat makes the body itself luminous and glowing; and when meteors have been found soon after their fall, they have been very hot, at least on their surface; they have also occasioned several fires; they have burned houses; and in the year 1618 the Palais de Justice, in Paris, was burned by a meteor. These cases seem not to be so rare as one would be inclined to suppose; Arago has given a list of them from some modern observations, and has found that, in the six years from 1840 to 1846, there were not less than five such cases in France alone. Now, we cannot doubt that the heat by which these meteors are heated is produced by friction, and by the compression of the atmosphere when they dip into it with such enormous velocity. We can produce the same result even with a less amount of velocity. I have here a piston adapted to the interior of a glass tube, and a little amadou fastened at the end of it. Now, when I compress very quickly, the atmospheric air contained in the interior, it becomes so heated that the amadou begins to burn. [Experiment.] You see, even with the small power of my arm, I can compress the air so much that it sets the amadou on fire; and, of course, the far greater velocity of meteors produces a far greater heat. The observers I have named were obliged to suppose that there are great swarms of meteors falling down on the surface of the sun, and producing solar heat. It was principally Professor William Thomson who discussed this hypothesis, and showed that it is not at all impossible to maintain such an idea. Indeed, the quantity of meteors falling into the sun must be very great—of course, far greater than the quantity falling on the surface of our earth; and the diameter of the sun would increase very sensibly during a long time: but the diameter is so great that it would require a much longer series of accurate observations than has yet been made, to perceive the increase. According to the calculations of Professor William Thomson, it would continue 4000 years before the diameter of the sun could be increased by one-tenth of a second of angle; and this could be recognised only by astronomical observations of the greatest degree of perfection. But there is another difficulty which was discussed by the same philosopher, relating to the attraction of the sun to the earth. If the mass of the sun increases, the attraction which drives the earth and all the other planets to the sun also increases; they would, therefore, be obliged to go more swiftly round the sun, and the length of the year would be lessened. This result would be avoided by supposing the whole amount of the meteors falling subsequently into the sun to be enclosed within the orbit of the earth. But lately M. Leverrier, in Paris, has made accurate observations and calculations about the motions of the planet Mercury, and he has found that they do not agree with the hypothesis that there is a perceptible mass of meteors in the interior of the orbit of this planet. Professor William Thomson has retracted his former conclusions, and no longer supposes that the whole amount of solar heat is produced by meteors; but it may be, nevertheless, that a sensible amount may be produced in that way. The period of time, then, through which the sun could give out the same amount of heat as at present will be lengthened a great deal if this supposition, that meteors are falling to the sun, is right. You see, therefore, that we already know processes by which the loss of heat which goes on along the surface of the sun can be made up through a period of time compared with which the length of human history is infinitely small, and that many generations of human beings must succeed each other before the diminution of the heat of the sun is perceptible.

In connection with these ideas respecting the nature of the sun, it is very interesting to remark that some recent astronomical observations have shown that there are dark fixed stars on the firmament. We cannot see them; we can perceive their existence only by several incidental observations. It is well known that on several occasions new stars have appeared on the firmament. In the "Cosmos" of Humboldt twenty-six such cases are given; the latest is one given by Mr. Hind in 1848. The most brilliant phenomena of this kind were the new stars observed by Tycho Brahe in 1572, which remained in the firmament two years; and the star of Kepler, observed in 1604, which remained till March, 1606. The star of Kepler was brighter than Sirius; it was one of the brightest stars in the firmament, but its light became by degrees feebler till it

vanished completely. The position of these stars remained quite unchanged, so that they were evidently fixed stars. We see, then, that stars have existed which have glowed and given out light for some time, but at present are dark. I have already cited the instance of the dark companion of Sirius. The existence of such a star very near to Sirius, and nearly equal in its mass, was concluded from the motion of Sirius itself. Fixed stars which move through the cosmical spaces can only go on in a straight line if there is no other mass in their vicinity which attracts them; but if there is such another mass, they go on in a curved line, or they circulate round their common centre of gravity, and then they go in curved lines. Now, the motion of Sirius was in such a curved line, and, therefore, it was necessary to suppose that there was a dark mass in its neighbourhood. Indeed, this companion of Sirius has been found as a very feeble star,—not quite dark, but giving a very feeble light proportionately to its mass, which, as I have said, cannot be so very inferior to that of Sirius. It seems also that the intensity of the stars of the first magnitude has been altered even during the times of history. Ancient observers assert that Aldeboran was the greatest and brightest star in the firmament; at present, it is not so bright as Sirius, and it seems to have lost a part of its light.

We must ask now if a loss of the mechanical power of the solar system goes on at present, so that new quantities of heat can be developed. The theory that meteors falling into the sun keep up its heat supposes that mechanical power belonging to the motion of celestial bodies is lost. Mechanical power can be lost only by friction or by impact. Friction cannot be opposed to the motions of the celestial bodies if the interplanetary space is vacant. But it is very doubtful if it is vacant. There must at first be the mass of luminiferous ether; the mass cannot be zero; it cannot be vanishing, because the vibrations of the ether have a certain *vis viva*, a certain energy, and the energy of such a motion is always the product of the mass of the moved matter with the square of the velocity; therefore, if the mass of luminiferous ether were infinitely small, its motion could be no source of energy. In this way even a minimum can be calculated, and we may say that the mass of luminiferous ether, which is enclosed in a volume like that of our earth, cannot be less than 3000 lbs. of matter. This is the calculation made by Prof. W. Thomson. There is, then, a medium in the interplanetary space which has a very small density,—the space is not quite vacant. Now, if we consider the loss of motion in a space filled with a resisting medium, it is clear that the motions of the planets cannot go on to eternity; they must approach, by degrees, to the central body.

I showed you in my second lecture the motion of a small, heavy ball of iron round a large sphere. To-day I have a lighter ball, made of ivory, the motion of which is more impeded by the resistance of the air than was the ball of iron; and you will see if I put this ball into the same kind of motion round the sphere, it will soon approach it, coming nearer and nearer, and at last falling upon it. Now, we know that the motion of the planets has not diminished in a sensible degree within the time of human history. The length of our year, measured by days, is the same as it was in the time of ancient Greece, and at the time when the Chaldeans made their astronomical observations. There is, however, a small body belonging to our system—(the comet of Encke, the smallest of the bodies visible from the earth, and the motions of which we can calculate)—which goes round the sun in little more than three years; and it has been observed that it gradually approaches the sun, and that the time of its revolution becomes shorter and shorter,—not very much, indeed, for in 1786 the time was 1208 days, and at present it is 1204 days. This shows that the comet approaches the sun, and that at last it must fall into the sun. We may conclude from these observations that the density of the resisting medium is not great enough to alter in a sensible degree the motion of the larger planets which have a very heavy mass, but that it is quite sufficient to alter the motion of bodies of smaller masses in the same way as the motion of this little ball has been altered by the resistance of the air.

Then we have another sort of friction going on in the celestial bodies—that is, the motion of the tides. Our ocean is moved by the attraction of the moon and the sun. I need not describe the motion of the tides: you all know it, because you have all been on the sea-shore, and the motion of the tides is very great along the coast of England. The ocean rises and sinks twice every day, and the motion is produced by the attraction of the moon and the sun; it is resisted by friction

in the breaking of the waves against the shore, and by the friction against the bottom of the ocean. We have here a motion that goes on, and the energy of which is perpetually diminished by friction. We must conclude that, by the friction of the tidal waves, heat is produced at the expense of gravitation which attracts the moon to the earth. It is true we have not yet been able to prove that the friction of the tides has any sensible influence upon the motion of the earth. But when we ask what will be the final result of this friction, we find that the length of the day must be augmented by it till it becomes equal in length to one month, to a revolution of the moon; and the final result will be that the earth will always turn the same side to the moon, just as the moon now turns always the same side to the earth. We find the same condition in reference to the satellites of the other planets. It is very probable that this peculiar position of the moon has been produced by tidal waves, which may have been very great at former times when the moon was a fluid melted mass, and exposed to tidal waves of far greater intensity than we observe at present. The loss, then, of mechanical energy going on in our system at present is very small indeed; but it is not zero. Now that the masses of the interplanetary space are all collected together into a small number of planets and satellites, the loss cannot be very great; but if we suppose that formerly this space was filled with a greater mass, that the temperature of the celestial bodies was higher, that they were more vaporous, and that greater atmospheres existed than now, the loss must have been greater.

We come at last to the question as to the origin of the heat of the sun and of the internal heat of a planet like our earth. I may remark here that an hypothesis concerning the first origin of our planetary system was formed by LaPlace. He endeavoured to explain only by this hypothesis the peculiar circumstance, that all the planets go round the sun nearly in the same plane—not exactly, but nearly, and all in the same direction; that they all rotate round their axis in the same direction, and that all the satellites go round their central planet in the same direction. There is only one exception with regard to the planets and satellites; the satellites of Uranus go round the planet nearly in a perpendicular direction. All the other bodies go round their central body in the same direction. This peculiar circumstance shows that these bodies did not come together from different parts of the universe, but that they must be connected by their origin—that the directions of their motions must have a common cause and a common origin. LaPlace explained these circumstances by the known hypothesis, that at first the mass of the sun and planets was spread out through the universe in the shape of mist, or perhaps a sort of dust, or as a shower of meteoric stones (they all give the same result)—that this mass was contracted by the force of gravity, which drew all the single parts to a common centre; and that these united into a ball of mist, and the more they approached and became condensed the more was their rotatory motion increased. We may suppose that they had at first a very small amount of rotatory motion, but in proportion as they approached the sun this motion was increased; and if the mist formed at first a spherical ball, it would be flattened by the centrifugal force into an ellipse, and the centrifugal force would drive away principally those parts which were at the greatest distance from the axis of rotation, therefore the equatorial part of such a nebular mass would be separated from the original mass by the centrifugal force. They might be united sometimes into a coherent ring like the ring of Saturn, or this ring of mist might be separated into several masses, giving a swarm of meteoric stones like that which gives the regular appearance of falling stars on our earth; or it might be divided into a smaller number of planets like those between the earth and Mars; or it could be united into a single planet. This hypothesis, invented only to explain the agreement in the direction of the motions of the planets, also explains the origin of the solar heat and the interior heat of our earth. This result was not at all known to LaPlace, and it is very remarkable that his hypothesis explains far more things than he himself supposed. For of course, if such a great mass were spread out through the spaces of the universe, and its single parts were to come together under the influence of gravitation, with a certain velocity, the destruction of their velocity, if they were united into a coherent mass, would give heat. The masses ought to become incandescent by being united, and we can calculate the amount of heat which would be produced by bringing together all these substances that form at present the mass of

the sun. This amount is so great that a quantity of water equal in mass to the body of the sun would have been heated by 22,000,000°, if all this heat could be collected at the same time in the interior. Of course, during the time when the mass was being united, a great part of the heat would leave and go out into space in the form of solar heat—rays of heat and light; but you see that an enormous amount of heat could be generated in this way. I have said, therefore, that we cannot be sure if the interior of the sun is not heated to such a degree that even the cooling by 3000° or 6000° is nothing in proportion, and does not sensibly diminish the temperature of the interior of the sun. You see that in this way the forces of gravitation, working through the great distances of interplanetary space, may produce results which are not at all comparable with those which are produced on our earth, where we are under very different conditions.

I am sorry that I have not been able to go more especially into the effects produced by solar heat in the inorganic actions on the surface of the earth. The time is rather short for so extended a subject, but I will try to refer to it in my next lecture, when I shall have to speak particularly of the effects of solar heat on vegetable life.

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University
College Hospital.

LECTURE III.

(Continued from page 419.)

PATHOLOGICAL RELATIONS OF UREA.

Disease has an important influence on the amount of urea excreted by the kidneys. In some diseases it is abnormally increased; in others it is as strikingly diminished. Thus in all febrile affections, with one exception, namely, yellow fever, it is increased. In typhoid, for example, Parkes found as much as 57 grammes (833.5 grains) passed in the twenty-four hours; and Vogel, in one case, the enormous quantity of 78 grammes (1209 grains), all, or nearly all, of which, seeing that the patient was on low diet, must have come from the tissues. In typhus, febricula, and remittent, the urea is likewise found to be increased, though not to such an extent as in typhoid. The same remark is equally applicable to the different forms of exanthemata, as well as to inflammatory affections, such, for example, as pneumonia and meningitis. In the case of chronic cerebritis, already alluded to under a different head, I found the urea as high as 57.42 grammes (890 grains), and as the patient recovered it fell to 46.5 grammes (720.7 grains), and still later to 37.1 grammes (574 grains) in the twenty-four hours.

In some cases of epilepsy Dr. Sieveking found the urine so loaded with urea that the simple addition of nitric acid to the non-concentrated liquid caused an immediate formation of crystals of the nitrate. In one of his cases, in which I estimated the quantity, I found it amount to no less than 50 grammes per thousand. Unfortunately, no exact analyses have as yet been made on the twenty-four hours' urine of epileptics, but from the observations of Hensen it seems that although the urea may be increased during the seizure, it is in general diminished when estimated over the twenty-four hours.

Sanger found the daily excretion of urea diminished in cases of paralytic idiocy.

In a case of pyæmia, Vogel found 80 grammes (1240 grains) of urea; and Ringer has made the interesting observation that the quantity excreted stands in a certain relationship to the temperature of the body; for both in the hectic of phthisis, and in the paroxysms of ague it increases with the rise, and diminishes with the fall of the animal temperature. Scarlet fever is, however, an exception to the rule.

In diabetes the amount of urea is greatly increased; on one occasion I found 70 grammes (1085 grains) passed in the twenty-four hours, and that too in the case of a gentleman nearly 50 years of age.

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

The average amount yielded by the twenty-nine analyses of diabetic urine now before me is 47 grammes (728.5 grains)—still a large excess over the normal excretion. But this is, I believe, in a great measure due to the rich animal diet. In a case of accidental diabetes accompanying paralysis, following upon a fall on the back of the head, instead of an excess there was an actual diminution of the urea. The man, a strongly built and otherwise healthy labourer, passed only 19.99 grammes (308.4 grains) of urea a few days after the receipt of the injury, while he was passing 36.89 grains of sugar; whereas during the period of convalescence, three months afterwards, when the sugar had disappeared from his urine, he passed 24.7 grammes (382.8 grains). The quantity of the urine in the first instance was 952 c.c. (30 oz.), of a specific gravity of 1.017; and in the second, 915 c.c. (29 oz.), of a specific gravity of 1.023.

In diabetes insipidus (polydipsia) I have found the urea enormously increased. On one occasion a man, aged 56, passed 84.63 grammes (1311.76 grains) in the twenty-four hours. At the same time the urine amounted to 4030 c.c. (130 oz.).

There are a few diseases in which the excretion of urea appears to be diminished before the attack. Gout (Böcker) and asthma (Ringer) may be cited as examples.

In cholera, the quantity of urea in the urine, both absolutely and relatively, is very small. The total quantity of urea excreted in the twenty-four hours, in some cases, does not amount to more than 4 grammes (62 grains). As soon as the attack begins to pass off, the urea commences to increase, and during convalescence it may even be much greater than in health. 70 grammes = 1085 grains (Buhl).

The question which here suggests itself is, whether the decrease of urea in the urine of cholera is simply due to diminished elimination or to an absolute decrease in its formation? I am inclined to believe that the chief cause is the latter—viz., lessened formation, for while I can find no reason for its non-elimination, relatively to the amount of urine, if it be actually present in the blood, I see a potent one for its non-formation in the low temperature so characteristic of cholera. (We previously saw that in hectic and ague the urea rises and falls with the increase and diminution of animal heat). Diminished formation cannot, however, be said to be the cause of the small amount of urea excreted in Bright's disease and some other affections.

In the experiments made conjointly by Gegenbauer and myself on the blood and urine in albuminuria, we found the daily excretion of urea on one occasion as low as 3.3 grm. (51 grains) and this was clearly due, not to diminished formation, but to arrested elimination. The more albumen excreted, the less was the amount of urea; the less albumen excreted, the greater was the amount of urea in the urine.

	November 5.		November 17.		December 7.	
24 hours.	Grammes.	Grains.	Grammes.	Grains.	Grammes.	Grains.
Urea .	3.3 =	51.15	5.4 =	83.70	10.9 =	168.95
Albumen .	9.5 =	147.25	2.9 =	44.95	1.6 =	24.80

In cases of Bright's disease the urea is not only diminished in the urine, but is in excess in the blood. It may even make its appearance in all the fluids of the body. In dropsical exudations, in the humours of the eye, in the serum of the ventricles of the brain, in the milk, as well as in the vomited matters. On one occasion I found the blood of a patient who died of uræmic convulsions from Bright's disease quite acid (twelve hours after death), and in the serum taken from some large bulke on the chest and thighs urea was detected in considerable quantity. It may here be mentioned that in yellow fever the urea, in like manner, appears to accumulate in the blood, so that in those cases it is not the formation, but only the excretion which is arrested. Dr. Porcher says that in some of the urines in the Charleston yellow-fever epidemic of 1846 there was an entire absence of urea. But this statement must be taken with a certain degree of reserve, as his mode of analysis was not sufficiently delicate to admit of his detecting small quantities of urea.

Most of the patients died with symptoms of uræmic poisoning.

(To be continued.)

MUNIFICENCE.—Under the will of the late Eneas Mackintosh, Esq., of Montague-square, which has been sworn under £160,000, the Middlesex Hospital funds will benefit to the amount of £1000.

ORIGINAL COMMUNICATIONS.

ON THE EXTERNAL USE OF RED IODIDE (BINIODIDE) OF MERCURY IN CHRONIC GLANDULAR, AND OTHER TUMOURS.

By MICHAEL THOMAS SADLER, Jun., M.D. Lond., etc.

THE value of biniodide of mercury in bronchocele when used as an external application is now pretty generally recognised, and it has probably been used still more largely and more frequently in Veterinary Surgery to reduce splints and other periosteal swellings in horses. I have not, however, seen any reference to its power in reducing glandular and other tumours in the human subject, and have therefore ventured to call attention to it, in the hope that Surgeons may be induced to give it a trial. I have used it for the last eighteen months in a great number of cases with the greatest benefit, and have seen swellings of many months' and even years' standing melt away in a few weeks. Perhaps it would be better for me to give a brief account of two or three cases, only premising that the number might easily be largely increased.

Case 1.—A child about 10 years of age was brought to me with a swelling just below the knee, about the size of a small hen's egg, which had been growing for many weeks, and began to alarm the parents. I ordered her to have a little of the ointment (containing sixty grains of the red iodide in an ounce) rubbed in every night, omitting a night or two when the skin began to turn red. In about a fortnight I saw her again, and found that the swelling had entirely disappeared.

Case 2.—A Medical friend requested me to see with him a woman who had had for ten or twelve years a slowly-growing and painful tumour in the left axilla; it was the size of a large fist, and pressed so much on the nerves as to cause great pain on every motion of the arm, so that she was unable to earn her living, which, being a poor widow, was a serious matter for her, so that she was anxious to have it removed if there was no other way of curing it. I suggested a trial of the biniodide of mercury, used as above, for a fortnight. At the end of that time the patient informed us that there was no improvement, and that she wished to have it removed. On exposing the armpits the diminution in size was so evident as to strike all who saw it, and the woman herself admitted that it was her impatience to be well which had induced her to deny the improvement. She was persuaded to give the ointment a little longer trial, and in another fortnight presented herself in a state of great alarm on account of what she said was the appearance of a second tumour. Examination, however, proved that the continued shrinking of the swelling (formed by enlargement of a number of glands which had coalesced) was beginning to separate it into its component parts. The poor woman went away somewhat comforted, and when I saw her a few days ago I found that a knot of rather enlarged glands was the only trace of the original tumour, and I have little doubt that even this trace would have disappeared had she not for some weeks discontinued the use of the ointment.

Case 3.—A gentleman of gouty family and constitution consulted me on account of a painless swelling in the situation of the bursa patellæ, rendering kneeling on that knee very uncomfortable. I requested him to rub in a little of the red ointment every night. He did so, and in the course of a few weeks the swelling had so much diminished that he could kneel without the slightest discomfort. The inconvenience being completely removed, he ceased to trouble himself with the remedy, so that I cannot report an entire removal of the swelling, but see no reason to doubt that a little longer perseverance with the ointment would dissipate the remaining thickening.

I have taken up sufficient of your space with cases, and will only add a few words on the manner in which I have used the remedy.

I have almost invariably used it without the exhibition of any other medicine, so that whatever benefit was produced must have been due to it alone. I have generally ordered it as an ointment containing sixty grains in an ounce of simple ointment; but believe that half that strength is better for persons with delicate skins, as it sometimes causes a sensation of burning pain when used too freely.

It should not be allowed to blister the skin, and when redness is produced it seems best to omit the rubbing for a night

or two. It seems most useful in strumous swellings of the glands, but, as case 3 shows, is also of use in gouty swellings.

The only ill effect that I have seen is the burning pain sometimes caused, and that inconvenience may apparently be avoided by using a weaker ointment.

Barnsley.

THE READIEST METHOD OF LARYNGOSCOPIC AND AUTOLARYNGOSCOPIC INVESTIGATION.

By THOMAS JAMES WALKER, M.D. Lond.,

Surgeon to the Peterborough Dispensary and Infirmary; formerly Assistant-Physician and Pathologist to the Queen's Hospital, Birmingham.

ALTHOUGH the reports of cases successfully diagnosed by aid of the laryngoscope, which weekly appear in the Medical journals, prove that the value of this instrument is becoming known, and that the number of those working with it is steadily increasing, doubtless many members of our Profession are deterred from making the attempt to employ the speculum in the diagnosis and treatment of laryngeal disease, by their ignorance of the instruments which it is actually necessary that they should obtain, and by their unwillingness to encounter the considerable expense which, from the numerous complicated instruments described as laryngoscopes, they believe to be requisite, before they are provided with the necessary means for obtaining a view of the larynx.

Although one object of this paper is to describe an instrument which, as I have now modified it, is an addition to those among which the would-be laryngoscopist finds himself so confused, I hope to be able to show that, with a very simple apparatus, and at a comparatively small cost, the Practitioner may not only have the power of investigating any diseased larynx which may come under his notice, but also may have the opportunity of acquiring, by practice upon himself, that manual dexterity and familiar acquaintance with the normal appearance of the parts which experience alone can give.

The actual laryngoscope is, as most of the readers of this paper probably already know, simply a small reflector, which is held in the back of the throat in such a position as to throw the light down into the larynx, and in which the larynx, when thus illuminated, is reflected, and its image seen by the operator. This mirror is manufactured of various forms and sizes; I am in the habit of using two sizes of the round mirror, one about an inch and a quarter in diameter, and this I employ whenever it is admissible; and another, the diameter of which is half an inch less, for examining the throats of children and others, when it is not practicable to use the larger one.

With the large mirror a tolerable view of the larynx may be obtained, even on a dull day, by placing the patient opposite a large window, with his head in such a position that no shadow falls on the back of the palate, against which the mirror is held so as to reflect the diffused daylight down into the trachea; and the parts are still better illuminated by making the patient bring his mouth near to a bright gas jet or a lamp, and reflecting the light by the large mirror in a similar manner; but from neither of these sources do we get a sufficiently bright light for illuminating the larynx with the small mirror, for the investigation of delicate changes of structure, such as are often met with, nor for examination of the larynx in those cases where, from circumstances incidental to the case, but a small proportion of the light employed can be thrown into the larynx. The most perfect illumination is obtained by allowing the sunlight to fall directly on to the patient's face, so that it shall reach the laryngoscope, when held in the back of the pharynx, or, if the sun is high above the horizon, by reflecting the rays on to the face from a common looking-glass placed a little below the level of the patient's mouth, on a table, window-sill, or whatever may be convenient; but, as sunlight is not always available, it is necessary that we should have some accessory apparatus for concentrating artificial light, when we are desirous of making a minute inspection of the larynx on a dull day.

This concentration is usually effected by means of a concave reflector; but after having used for some time the reflectors of Semcleder, Czermak, etc., and having tried the improved forms which Dr. G. Johnson and others have devised, and which are erroneously called their laryngoscopes, I unhesitatingly recommend the form of globe condenser represented in

the engraving, and which, when mounted as I shall describe, in addition to many advantages which it possesses as regards its illuminating powers, constitutes the most convenient form of apparatus for demonstrating and observing the larynx either of a patient or of the operator himself. The engraving is taken from a photograph, and the various heads are represented in the position which they actually occupied when every one of the five persons, including the patient, had a full view of the interior of the larynx.

The part of the instrument which is essential for concentrating the light is the glass globe (*a*), which is about six inches in diameter, and is filled with water, thus constituting a powerful concentrating lens. (A little corrosive sublimate may be dissolved in the water to prevent the growth of confervæ on the interior of the globe, necessitating frequent change of the water.) This globe is supported in a steel frame about 22 inches high, being attached to a crossbar (*b*), which slides upon the upright rods (*cc*), so that it can be moved up and down, and fixed at any level desired, by means of the thumb screws (*dd*). When the globe is placed immediately in front of a lamp, an Argand gas burner, or any other source of light, it concentrates the rays so as to throw a most brilliant light upon any object placed in front of it, the light being most brilliant at a distance of from twelve to twenty inches from the globe.

With the instrument thus constituted, and without the additional mirror which I shall now describe, I have long been in the habit of working. I have described its application in the *British Medical Journal*, and I have demonstrated its advantages over all the reflecting instruments to a large number of my Medical brethren. These advantages are,—1st. That from a flame of the same size a more brilliant light is obtained with the globe-condenser, than with any of the reflecting condensers commonly used. 2nd. That the apparatus being independent of the head of the operator, he is able to move and to bring his eye nearer to, or further from, the mouth of his patient, without interfering in any way with the illumination; whilst, on the other hand, with the reflectors which are attached to the head of the operator, there is but one position in which the operator must hold himself in order that the light may fall upon the face of the laryngoscope, any movement on his part withdrawing the light; nor, indeed, can the operator bring his eye nearer to the mouth of the patient, so as to observe more accurately the laryngeal image, without diminishing the intensity of the light. 3rd. The beam of light thrown on to the patient's face by the condenser is so wide, that he may move his head very considerably without withdrawing the face of the laryngoscope from the illuminated field. It is not, therefore, necessary to follow up the movements of the patient's head with the concentrating apparatus; the facility for doing which, when a mirror is used for the method of concentrating light by reflectors, as an advantage by some of those who advocate this plan. But to the advantages which the apparatus thus possesses as a mere illuminating apparatus for the examination of the larynx of another, must be added the great one, that when constructed with the small mirror (*e*) (*vide* engraving), it constitutes the most convenient form of apparatus for autolaryngoscopy. A small plane mirror, $3\frac{1}{2}$ inches long by $2\frac{1}{2}$ wide, is attached to a

sliding arm (*f g*) by a stiffly-working hinge at the corner (*f*); this hinge allows of the mirror's being inclined at any convenient angle, while it can be placed higher or lower on the stand by sliding the supporting arm up or down the upright rod (*e*), and fixing it in the desired position by the thumb-screw (*g*). If this mirror is placed immediately in front of the lower part of the globe, and made to incline at a convenient angle, the person whose throat is under observation can, by casting his eyes downwards, obtain in it a perfect view of the

laryngoscope, and the image reflected in it; at the same time, two or more on-lookers can, by placing their heads on a level with that of the person under observation, and looking into the mirror, get the same view of the fauces, the laryngoscope, and the laryngeal image, without in any way interfering with the view of the observer, who, seated opposite to the patient, holds the laryngoscope in position in the fauces, and looks directly into it through the open mouth of the patient. In the wood-cut a fifth person is represented, who, like the operator, looks directly into the laryngoscope; and it is evident that several other spectators, without either interfering with the transmission of the light from the lamp, or interposing any part of their body between the mirror (*e*) and those who are looking into it, might place themselves in a position in which

they could see into the patient's mouth, and get a view of the larynx. Now, as there is a certain amount of manual neatness and dexterity in the management of the speculum, as well as a practical acquaintance with the normal appearance of the parts, required before a Practitioner can, without much inconvenience to his patient and some trouble to himself, acquire all the information which the laryngoscope is capable of affording in a case, the importance of having an instrument which facilitates his acquiring these requisites by practice upon himself cannot be overrated. It is true, that with no other instrument but the throat speculum and a dexterously-managed looking-glass, it is possible to obtain a view of one's own larynx; but, even to the practised laryngoscopist, this method presents difficulties, and these to the novice would appear almost insuperable.

I must refer my readers to the papers which I have published in the *British Medical Journal* for rules for the examination of the larynx by direct sunlight, without the aid of any other instrument than the laryngoscope itself; but this is without doubt the readiest method of examination when sunlight is available—indeed, in nine out of ten examinations which I make I employ no other instrument than the larger-sized laryngoscope, reflecting by it either the diffused daylight admitted through a window, a ray of sunlight thrown directly on to the patient's mouth from a small looking-glass, or at night the light from an ordinary gas-jet; but, in order that none of my Medical brethren may be deterred from employing that which I regard as the readiest method for autolaryngoscopic examination, as well as, under certain circumstances, for the examination of others, from not fully comprehending the mode of employing the globe condenser, I here subjoin some short rules, both for self-observation and the examination of others, by its assistance; and, as self-observation should be the first practice, I give directions for this first. It is better that the concentrated artificial light should be employed in a darkened room; but this is not absolutely necessary: thus, at the moment that the photograph was taken from which the engraving is copied, the light obtained from the lamp and condenser was so good that a perfect view of the larynx was obtainable by all the observers, although the daylight was, of course, strong enough for the photographer's purpose.

Rules for Auto-laryngoscopic Examination by the Laryngoscope and Dr. Walker's Globe-condenser.

1. Place your lamp or other source of light upon a table, a little way from the edge, and immediately in front of it place the condenser and stand, the back of the small mirror being directed towards the lamp.

2. Seat yourself in front of the table facing the lamp and condenser; when upright in your chair, your face should be about on a level with the globe, and twelve to eighteen inches distant from it.

3. Now, by means of the thumb-screw *g* (*vide* engraving), fix the mirror just below the globe, and incline it at such an angle that, when seated erect with your mouth open, you can, by casting your eyes down, see in it the reflection of your pharynx.

4. Observing your face in the small mirror, you now, if necessary, alter the level of the globe-condenser, so that the bright stream of light shall fall on the lower part of your face. The adjustment of the level of the condenser is effected by loosening the thumb-screws (*dd*) with the right and left hand respectively, using them as handles to raise and depress the crossbar and globe, and tightening them when the globe is at its proper level.

5. Now open the mouth as widely as possible and protrude your tongue (it may be necessary to draw the tongue forward with the finger and thumb, using a napkin to prevent its slipping). You will now perceive in the mirror (*e*) whether you have fully exposed the fauces, or whether the tongue is in contact with the roof of the mouth. If the fauces are not exposed, draw a deep breath through the mouth, and you will perceive that the tongue is immediately depressed, and a very little practice will enable you to keep it so.

6. The fauces being fully exposed, you will now alter the inclination of your head, or slightly readjust the level of the condenser, so that the light falls on to the soft palate, the shadow of the tongue just resting upon the edge of the velum. When the light is properly adjusted, you close your mouth.

7. Take the laryngoscope between the thumb and two first fingers of the right hand, warm it, and test its temperature on the back of your hand, lest you burn your mouth.

8. The mouth being now opened and the tongue drawn forward with the finger and thumb of the left hand, protected by a napkin, all kept well out of the way to avoid throwing a shadow on the fauces, you introduce the laryngoscope with its face downwards, and steadily press its back flat against the soft palate and uvula, raising these slightly, but being very careful to avoid touching the posterior wall of the pharynx. The laryngoscope must be held so that it may be introduced without bringing any part of the hand in front of the mouth.

9. Should the introduction of the instrument induce a tendency to retch, draw a deep breath, pronounce in a prolonged note the vowel sounds *a* or *ah*, and you will thus conquer this tendency.

10. Hold the mirror in the fauces with its face directed downwards and forwards, not to either side; alter its inclination, so as to bring the various parts of the larynx into view; while by coughing, laughing, or cachinnating and articulating vowel sounds in high and low notes, you cause the parts to vary their position, and study the actions which most readily bring into view the different parts of the larynx.

By referring to the engraving at the commencement of this paper, it will be seen that, by the directions given above, the observer is made to take the position which the patient occupies in the group there delineated; and should he be anxious to demonstrate his larynx to others, this can readily be done if they will arrange their heads, some of them round the globe condenser, so as to look directly into the laryngoscope, and others round the observer's head, looking, as he does, into the small square mirror attached to the condenser.

In examining the larynx of a patient, it may not be desirable that he should himself see what is going on, in which case the little mirror will be turned so that he cannot see into it; but very frequently, and especially in the practice of rhinoscopy, it is desirable that the patient should be able to study the movement of his fauces and tongue, so as to keep them under control; and then the following directions must be followed:—

To Examine the Larynx of a Patient with the Laryngoscope and Walker's Globe Condenser.

1. The lamp and condenser being arranged as directed for self-observation, seat your patient erect in a chair facing the lamp, with his head distant about eighteen inches from the condenser.

2. Adjust the mirror so that the patient sees his opened mouth, and, if necessary, alter the level of the condenser as directed in the foregoing rules, so that the light falls upon the patient's mouth.

3. Seat yourself facing your patient, and at his right hand, so as to avoid coming between him and the light.

4. The patient's fauces being exposed and illuminated according to the directions for self-observation, you take his tongue between the forefinger and thumb of the left hand,

guarded by a napkin or handkerchief, and draw it forward, while with the right hand you introduce the laryngoscope, warmed, and its temperature previously tested on your own cheek, into the mouth. The instrument is to be held between the thumb and the two first fingers, the little and ring finger resting against the cheek of the patient, so that the mirror may be held steadily against the soft palate.

6. Carefully avoid bringing the head too much in front of the globe condenser when you are looking into the laryngoscope, and carry the right hand well over to the left side of the patient, so that no part of it casts a shadow on to the fauces.

The directions given for self-observation will show the other points to be attended to in examining the larynx of a patient; and as I have already, in the papers published in the *British Medical Journal*, given more minute and complete rules for all points connected with laryngoscopic examination, excepting the use of the small mirror attached to the globe-condenser, I do not deem it necessary to repeat them here. The main points to which I wish to draw the attention of the readers of the *Medical Times and Gazette* are:—

1st. That much useful information may be obtained as to the state of the larynx with no other instruments than the small round speculums, of which each laryngoscopist should have at least two sizes.

2nd. That the best and simplest means of concentrating artificial light for laryngoscopic purposes is, by the use of a small glass globe of water, such as my globe-condenser, a plain water caraffe, or some other substitute.

3rd. That the arrangement of the globe-condenser figured in the engraving constitutes not only the most convenient instrument for concentrating light, but also is the best apparatus for the practice of auto-laryngoscopy, and for laryngoscopic demonstration.

4th. Consequently, that, in my opinion, a Practitioner possessing two round laryngoscopes, the globe-condenser, and a small palate spatula, for examining the posterior nares. Eustachian tubes, etc., which I have not here described, is provided with all the instruments, and these the best, necessary for observing his own larynx, and making himself master of the art of laryngoscopy; for observing the larynx, air-passages, etc., etc., of his patients; and for demonstrating these to others. Finally, I may add that, although some of the advantages which I claim for my method may not be allowed by those who have been long in the habit of employing the concave reflectors, there is one which is undeniable, namely, the comparative cheapness of the apparatus. Mr. Matthews, of Portugal-street, manufactures the stand, as I have described it, at a lower price than that at which any of the concave reflecting mirrors are sold, and at about a quarter of the price to which a laryngoscope, reflecting concentrator, and a special apparatus for self-observation, would amount.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

THE LONDON HOSPITAL.

EXTRACTS FROM

A CLINICAL LECTURE

ON

CASES OF DISLOCATION OF THE FOOT BACKWARDS, WITH FRACTURE OF THE FIBULA.

(By Mr. HUTCHINSON.)

GENTLEMEN,—The effects produced by injuries at or near the ankle-joint are exceedingly varied. I select for our consideration to-day a single group of them—those, namely, in which there is a partial dislocation of the foot backwards. This is comparatively a very rare accident, and you will find but little detailed information respecting it in systematic works. We have at present in "Sophia" Ward a good example of it. The attention of the Profession has also been specially drawn to this form of injury by an action for malpraxis against a Surgeon which was tried a few weeks ago. I shall also have to mention the case of a gentleman now under my care in private.

Most of you are familiar with the common accident known as Pott's fracture; how that in it the foot is twisted outwards

so that it rests on its inner edge, the fibula being broken a little higher than the joint, and the internal lateral ligament torn through. It involves, as Mr. Pott described it, the complete fracture of one bone, the complete rupture of one ligament, and a partial dislocation. The amount of displacement may vary very greatly; in some cases it is extreme, in others but slight. Now in the typical "Pott's fracture" the displacement of the foot is simply outwards. In a few exceptional instances, however, we find a modification of this, the foot being turned outwards, but also thrown backwards too. In these cases we still have the fracture of the fibula and the rupture, partial or complete, of the internal lateral ligament.

A case in which, a few weeks ago, a Surgeon was dragged as defendant into a court of law, was one of this kind. The following were its chief facts:—A bricklayer, wheeling on a plank, slipped off, and injured his foot. The Surgeon consulted recognised the true nature of the case, and reduced the dislocation. The foot became displaced again, and was again reduced. The man proved an unruly patient, frequently undoing the splints, and the result was that he got well with his heel projecting far behind, and his tibia resting on his scaphoid bone. The jury very properly found that the Surgeon was in no way responsible for this result. My friend Mr. Bryant, who was engaged on the trial, informs me that the man at present (eighteen months after the accident) has his heel drawn much upwards, and that his facility in walking is very limited. The fragments of the fibula, as is usual in such cases, are united at an angle, the lower fragment slanting upwards and forwards.

Mr. D., a stout, muscular man, first consulted me about eight months ago. It was then four months after his accident. A glance at his foot at once showed the nature of the injury he had received. The heel projected backwards, the tendo-Achillis presented a strongly-marked curve, and the tibia appeared to rest on the middle of the instep. On examining the outer maleolus, I found it in its proper position, but on a plane an inch and a-half behind that of the inner one. From the tip of the outer maleolus upwards, the lower part of the fibula slanted forwards, and at a distance of about three inches there was the callus of a united fracture, the upper and lower fragments having come into apposition at an obtuse angle. The inner malleolus had not been broken, nor was there any evidence of fracture of any part of the tibia. The following are the measurements of the two feet:—Right foot (injured one), from tip of inner maleolus to end of great toe, $6\frac{1}{4}$ inches; left foot, ditto, $7\frac{1}{2}$ inches; difference, sound foot $1\frac{1}{4}$ inch the longer. Right foot (injured one), from tip of one maleolus, round the heel, to the tip of the other, $9\frac{1}{4}$ inches; left foot, $7\frac{3}{4}$ inches; difference, injured foot $1\frac{1}{2}$ inch the longer.

It is important to mention in this case that Mr. D., after the accident—which was sustained in stepping backwards out of an omnibus—with some assistance actually walked home. In all probability he greatly increased the displacement by this achievement. I cannot learn that any attempt to reduce the dislocation was made in his case. Let us mark that, in contrast with the bricklayer's case, Mr. D.'s heel is not drawn up, and further, that he now enjoys very fair use of his foot. The other day, he walked a distance of two miles to my house, and he regularly follows his occupation as a commercial traveller.

The patient now before us, Mrs. N., is a stout, flabby woman, the subject of albuminuria and liable to "seizures," in which she loses her sight. In one of these she fell down stairs with her right leg doubled under her, and was on the same evening brought into the Hospital with a fractured fibula and displacement of the foot outwards and backwards. Mr. Spencer, who admitted her, tells me that he had great difficulty in reducing the displacement outwards, the skin being very tense over the inner maleolus and the bone threatening to come through. It was not found practicable to wholly remedy the displacement backwards, although it was effected to a great extent. Very efficient pressure was necessary to keep the bones in place. Mr. Spencer, whose skill and care I cannot too much praise, placed the limb on its outer side on a well-padded leg and foot splint, and then secured a second splint on the inner aspect of the tibia, so as to make very firm pressure just above the inner malleolus in a direction outwards. Even at the end of a week if this inner splint were removed the end of the tibia would at once rise. Of course, the limb was laid on its outer side and the knee well bent. We were very anxious, considering the woman's state of health, lest her soft tissues should not bear with impunity the pressure which was absolutely necessary to retain coaptation, but fortunately

no ulceration took place. The result you now see. It is about two months since the accident; the ankle is still somewhat swollen, the external maleolus is too far behind the level of the internal one, and the tibia is a little too forward on the instep. She will, however, eventually have a most useful foot. Let us remark that in this case again the heel is not in the least drawn up. We must remember that the displacement was complicated, the foot being both outwards and backwards, which rendered the obtaining of perfect adjustment most difficult.

About four years ago I had under care in "Mary" Ward a woman of middle age, who had sustained a somewhat similar injury. In this case, however, there was but little displacement outwards. I did not see the patient till a week after the accident, and then the skin was in such a state from contusion that it was out of the question to attempt replacement. A week later, when the swelling had somewhat subsided, we put her under chloroform and made attempts at reduction with all the force that was justifiable, but without effect. The fear that the skin would give way induced us to desist. The woman left the Hospital with her tibia still resting at least half an inch too far forwards, but the heel was not drawn up, and no doubt she would soon be able to walk firmly.

And now, gentlemen, with reference to the diagnosis of this form of partial dislocation, let me beg of you to always bear in mind in practice the remark with which our lecture opened, that the effects of injury about the ankle joint are exceedingly varied. In every instance note most carefully the contour of the limb, and examine the points of bone; never assume that the case conforms itself to any recognised type, for it is very possible that it may not do so. Do not too hastily rest content with the discovery of one lesion,—as, for instance, fracture of the fibula. Remember that fracture of the fibula is a complication common to several different forms of injury. Great swelling usually occurs very quickly in these cases, and the contour of the foot and the prominences of the bone are much concealed. If the displacement backwards be considerable, you will usually recognise it easily by the prominence of the heel, the bow-like concavity of the tendo-Achillis, and the shortness of the foot anterior to the tibia. If it is only in slight degree, however, the diagnosis may be exceedingly difficult. Carefully estimate the relative position of the two maleoli, and ascertain whether the inner one is on a plane too far forward as regards its fellow. Note also whether the lower fragment of the fibula slants backwards. If there is any material displacement, this slanting obliquely backwards of the lower maleolus is almost certain to be present. The anterior border of the tibia will generally be concealed from observation by the swelling. In patients under the age of eighteen it is very possible that a separation of the lower epiphysis of the tibia may simulate a dislocation of the foot at the ankle-joint. Of this we have a good instance in the case of a lad now in "Richmond" Ward.

A correct diagnosis once made, the displacement backwards is not, as a rule, difficult to reduce. Flex the leg at the knee, and then, having the tibia held backwards by an assistant, firmly draw the foot forwards. It may facilitate reduction to extend the foot at the ankle, but bear in mind that when replacement is once effected the foot must be carefully kept at a right angle to the leg. In a few cases, however, reduction has been difficult or impossible. Sir Astley Cooper records one in which he could not succeed, and I have mentioned one above in which, at the end of a fortnight, even with the assistance of chloroform, I was quite unable to alter the position of the bones. The reason of this difficulty is not always clear. Should it appear to depend on spasm of the calf, section of the tendo-Achillis may be advisable.

In most cases, however, the real difficulty occurs in retaining the bones in position after reduction has been effected. There are but two means of which you can avail yourself in accomplishing this end—first, and by very far the most important, is direct pressure; and secondly, the relaxation of muscles. Now, the only muscle that you can relax with safety is the gastrocnemius, and of this you can relax only the upper heads where they arise from behind the condyles of the femur. The greater part of the muscles which extend the foot, inasmuch as they arise from the tibia or fibula below the knee, cannot be relaxed in the least by any amount of flexion at the latter joint. The only way to relax them would be to extend the foot at the ankle; and this must not be thought of, since it would put the tibia and astragalus in the very best position for again slipping. When we consider the anatomical fact to which I have adverted, it is really almost surprising

that we should be able to gain anything by bending the knee; nevertheless, I believe practical Surgeons are unanimous as to the great advantage thus obtained. Mr. Poff, as is well known, considered this the main point. You will, therefore, bend the knee. Next a back splint, well padded, must be adjusted as a support for counter-pressure; then a splint in front of the tibia, or in front of the inner side, as the case may be, must be applied and firmly secured with straps. In the course of about a fortnight the tendency on the part of the bone to rise will probably cease, and the pressure may be relaxed or laid aside. During this period you will, of course, attend to the splints with the utmost anxiety and care. The state of the soft parts should be inspected almost daily in order to avoid sloughing from pressure; but an assistant should always at the time carefully hold the limb to prevent displacement. Sloughing is your Scylla—re-displacement your Charybdis; and between the two it will require great judgment to steer safely. I am well aware that you may read in books the strongest invectives against thus attempting to secure bones in place by direct and forcible pressure. All that I can reply is, that such invectives seem to me wholly without practical basis. There are many cases in which relaxation of muscles will not secure coaptation, and in which pressure will. With due caution pressure may be employed quite safely. In a few the only alternative is the allowing your patient to remain with an unreduced dislocation, and to leave his bed a cripple. Even in those instances in which, whether from the age and state of health of the patient, or the bruised condition of the soft parts, it may be impracticable to employ the means recommended, and you may be compelled to leave the displacement unreduced, there is still one important point requiring attention. I allude, of course, to the position of the heel. If the patient recovers with his heel retracted upwards, his foot will be of much less use to him than if he had the tarsus at right angles with his leg, the latter merely resting too far forwards. The cases I have adduced, more especially that of Mr. D., prove that the latter condition is quite compatible with good power of progression. In the class of cases now alluded to, therefore, the tendo-Achillis ought certainly to be divided, and the foot, if it cannot be kept forwards, at least kept in due position under the leg. Do not defer this in the belief that you can subsequently cut the tendon, and thus remedy the talipes equinus, for this hope may prove delusive, owing to the fact that the fibula is always broken, and that its lower fragment passes with the os calcis, and thus becoming united at right angles to its upper part, may entirely prevent subsequent efforts at replacement.

MIDDLESEX HOSPITAL.

CASE OF PHTHISIS COMBINED WITH EPILEPSY—DEATH—AUTOPSY—TUBERCLE IN THE BRAIN AND LUNGS.

(Under the care of Dr. GREENHOW.)

J. W., aged 50, butler, admitted an out-patient June 20, 1862. Very pallid, and of unhealthy aspect. Had been in good health until he took cold in the month of March previous, from which time he had suffered from pain in the chest near the right nipple, and from dry, hacking cough. Slight dullness on percussion, and deficient expansion of upper right side of chest, where also the respiration is harsh and tubular, but free from moist sounds. Patient complained of headache and vertigo.

August 29.—Much improved in general health, and cough gone, but physical signs as before. Still complains of headache.

November 21.—Has been out of town since last report. Headache and vertigo have been persistent. Pulse 78; feeble. Pupils of equal size. Has very slight cough and dyspnoea. No appreciable change in the physical signs.

February 5, 1864.—Presented himself after an absence of more than a year, during the greater part of which time he had not been troubled with cough or dyspnoea, but had never been free from headache. While in the country had had three fits on the morning of November 30, 1863, which came on without warning, and in which he became unconscious, fell down and was convulsed, with slight foaming at the mouth. Did not recover his recollection for many hours, and was not perfectly himself until the following day. Memory has been impaired since these fits, which are the only ones he has ever had. Has also since then suffered frequently from cramp in the feet, and constantly, day and night, from dull, heavy, frontal headache, but no longer has vertigo. Has no paralysis,

numbness, nor formication. Is still of pallid and unhealthy aspect. Sleeps badly. Pulse 86, feeble. Has been suffering again since Christmas from cough and dyspnoea, and now presents the physical signs of phthisis in both lungs. Urine slightly albuminous.

March 1.—Acute bronchitis having supervened, patient was admitted into Hospital, where he gradually sank, and died on March 13. While in Hospital he was very sleepless, exceedingly sensitive to noises, and frequently incoherent.

Autopsy, Sixteen Hours after Death.—Head: Skull-cap extremely dense and thick. Inner surface marked with deep pits along the mesial line corresponding to large Pacchionian bodies. Dura mater somewhat firmly adherent to the bones. Arachnoid over the hemispheres opaque, in patches. A large amount of sub-arachnoid fluid. Depressions between the convolutions very deep. On the inner surface of posterior lobe of right hemisphere, situated at the bottom of a deep convolution and firmly adherent to the grey matter, was a firm, spherical, opaque, yellow body, the size of a small nut, which, under the microscope, had all the characters of tubercular matter. The membranes at base of brain normal in appearance, except at one point at the commencement of the left fissura Sylvii, where there was a small opaque granule beneath the arachnoid, resembling a tubercle. The substance of the hemispheres was firm and very vascular. The ventricles contained about two drachms of serum. The rest of brain normal. Weighed 48 oz. *Thorax:* On the right side the lung was firmly attached to the thoracic walls at every point; on the left the pleura was free from adhesions. The right lung was completely solid throughout, and was much broken down in removing it from the chest. It was studded from apex to base with very minute yellow granules, set close together, giving it a finely granular appearance; here and there, especially in the lower lobe, there occurred a space where these were absent, and there the lung appeared to be in a state of red hepatisation. At the apex were two or three small, irregular cavities. The left lung was much more bulky than the right, and its borders and surfaces emphysematous in parts. On cutting into it, the upper part was solidified by yellow tubercle, and contained some small cavities. The lower part of the upper lobe and the lower lobe showed numerous circumscribed circular patches, where the lung was studded with minute yellow granules, as on the right lung, and here and there were small patches of hepatisation.

HEREFORD INFIRMARY.

REPORT OF A CASE OF TRAUMATIC TETANUS TREATED BY ACONITE AND NICOTINE.

(Under the care of Mr. CAM.)

FOR the following case and remarks we are indebted to Mr. Beavan, House-Surgeon:—

Thomas L., aged 37, a gentleman's servant, on the 20th of February last met with an accident from a thrashing-machine which deprived him of the index, and portions of the middle and ring fingers of the left hand, the laceration extending about an inch into the dorsum and palm. The wound had been dressed by a Surgeon, and he was admitted into the Infirmary on February 22, when the sutures were removed and replaced by adhesive plaster. He was in his usual health, and the hand looked well.

On March 1, the tenth day after the injury, he complained of stiffness between the shoulders, and on the 3rd took to his bed. He was then flushed and perspiring, and troubled with dyspnoea. A dose of calomel and colocynth was administered, and a free evacuation of the bowels followed. On the evening of the next day (4th) the stiffness had extended to the jaw, and he had had some muscular twitches. Two grains of calomel and a quarter of a grain of opium were given every four hours during the night.

5th.—This morning his symptoms were much more marked, the teeth were clenched, the corners of the mouth retracted, giving to the countenance a peculiar smile; the cervical muscles rigid and prominent; lumbar and abdominal muscles hard. He had pain at the pit of the stomach extending to the back, and frequent but not severe opisthotonic spasm; deglutition not seriously impaired; the skin was bathed in perspiration; pupils contracted; pulse 120; respiration 34 per minute; mind calm, and free from extreme anxiety. Wine and beef-tea *ad libitum* were ordered, and half a grain of extract of cannabis indica given every three hours, the dose being increased to a grain hourly, and finally to two grains.

6th.—Has had a bad night; the spasms continue, especially on the approach of sleep. Ordered eight minims of Fleming's tincture of aconite immediately, to be followed by four minims every hour. 8 p.m.—The spasm and rigidity have somewhat diminished, the former affecting chiefly the muscles of the hip and thigh. He lies with the lower extremities semi-flexed; pulse 100—96; pupils natural. He takes food at intervals.

7th.—Has slept a little during the night; spasms unaltered; pulse 104; respiration 32. The dose of tincture of aconite increased to six minims hourly, and an aperient administered consisting of one drop of croton oil and ten grains of extract of colocynth, which acted freely. 9 p.m.—Rigidity much less; spasms in lower extremities frequent, but not very painful; slight opisthotonos; pulse and respiration unchanged; suppuration in wound much diminished. He has felt some tingling of the fingers to-day for the first time.

8th.—A good night, with more sleep than heretofore; the spasms are weaker; pulse 84; surface warm and perspiring; pupils natural. At 5 p.m. the dose of tincture of aconite increased to eight minims hourly. 6 p.m.—Pulse 100; respiration 32; the spasms are rather more violent; tingling of hands and feet continues.

9th, 1 a.m.—The spasms are stronger than they have been before, and appear to cause him intense pain. He cries loudly when they come on. At half-past twelve eight minims of the aconite were administered, and now ten additional minims—these large doses not having the effect of controlling or even weakening the violence of the attacks. At half-past one a drop of nicotine dissolved in spirits of wine and added to two tablespoonfuls of wine, was given. His pulse was then 120; respiration, 32. In less than five minutes his eyes closed, and he became more tranquil, breathed more freely, and within twenty minutes fell into a sound sleep of one hour's duration. 2 a.m.—Pulse, 108. 3 a.m.—Pulse, 92. He is able to put out his tongue. Sweating continues, but clammy, and devoid of snuff odour. 5 a.m.—He took a second drop of nicotine. 9 a.m.—Has had three or four hours' sleep, is refreshed, and complains but little of pain. 2 p.m.—During the morning he had frequent slight spasm, but slept at intervals. Rigidity of upper and lower extremities, and masseters continues. Pulse, 100; pupils natural. Given one drop of nicotine. 4 p.m.—Nicotine repeated. 10 p.m.—Pulse, 140; respiration 36—40. Has rambling delirium; the arms are curved; spasms continue, and affect the right arm more than the left.

10th, 10 a.m.—Pulse, 120. Abdomen covered with a pustular-looking eruption. Lower maxilla falls as he dozes; but he is unable to open his mouth. He died at 11 this morning after severe convulsion.

Remarks.—The above case appears to confirm the observations of Professor Haughton, of Dublin, on the use of nicotine in tetanus. It can, scarcely, however, be said to have afforded a fair test of the value of that alkaloid, inasmuch as it was not employed until the ninth day from the commencement of the symptoms, and when the disease was in active progress. Its influence over the severe spasm and its capability, in some cases at least, of alleviating acute suffering and procuring sleep will, I conceive, place it in a high rank among those means by which this fatal disease is henceforth to be combated. It may not be unworthy of remark that the treatment with aconite was during the early period satisfactory; and that much of that peculiar resistance to the specific action of powerful agents which characterises this disease was manifested during the exhibition of the latter remedy.

SUICIDE IN A CHILD.—A little girl, twelve years of age, of very excitable disposition, living at Havre, having been scolded by her parents, went and purchased some vitriol and drank it off. She soon became the subject of dreadful suffering, and notwithstanding every means tried, died in about six hours.

A GOOD HOSPITAL IMPROVEMENT.—It has been decided that in all the Paris Hospitals wards shall be established, in which all patients not confined to their beds may be allowed to assemble and pass their time in talking, or in the pursuit of the recreations which may be authorised. Not only will this measure prove of great service to those capable of availing themselves of it, but also to those who are unable to leave their beds, who by the absence of their more fortunate comrades will be able to enjoy more repose and tranquillity than is now possible. This arrangement has been for some time in satisfactory operation at the magnificent Marine Hospital at Brest.

SATURDAY, APRIL 23.

LUNATIC DIETARIES.

WE ought to treat the subject of lunatic asylum dietaries as a branch of Hospital dietetics. Thus much being premised, we may proceed to say that up to a certain point the insane, as confined in asylums, are not all such as require the daily prescription of a special dietary. There is that in common with the majority which enables the Physician to lay down a dietary calculated for the use of all those who are free from specific complication, who are not in the usually-received sense "ill." The insane are really the subjects of disease, whose most general character is depression of vital energy, weakness, or imperfect nutrition. Hence it is that the inmates of an asylum must be supplied with food not only nutritious in quality, but abundant in quantity. Not only must there be found thereat all that is needful for the maintenance of life and health of the healthy, but for the restoration of force in the debilitated. This is the physical, the chemical view, if you please, to take of the matter; but there is another aspect in which it is to be regarded—namely, the psychical. Nothing is trivial in the arrangements made for the insane—so many are the paths pursued by the mind, so little to be anticipated the associations between external events and the consequent course of ideas in the morbid intellect. Whatever is calculated to inspire a feeling of disgust—whatever is inconsistent with cleanliness or decency—whatever is likely to shock the sensibilities of the class to which the patient belongs, should be religiously proscribed in an asylum for the insane; and, on the other hand, whatever is fitted to inspire a notion of comfort, to promote cheerfulness, to foster the proprieties of life, to lure away from unhappy thoughts, to implant ideas of a pleasing nature—with these things should the managers of asylums strive to surround their charge.

Having before us the diet tables of several of the county asylums for pauper lunatics, we shall first of all occupy ourselves with these. It will be seen that they are numerous enough without engaging too much of our space to give a fair idea of the sort of treatment which the insane poor receive in this respect at these institutions. In addition we have received from Dr. Down the dietary of the Asylum for Idiots at Earlswood.

In order to present the matter in the most intelligible form, we have represented in the following table the quantity of each article of diet supplied weekly to male patients in the different asylums, without distinguishing, except in the column for remarks and in the appended notes, the different meals at which they are given. This omission the reader will have no difficulty in filling in. And here is it to be remarked that it is a matter for regret that in the diet tables of the asylums the meat supplied is not always represented in weight as cooked and free from bone. It throws a difficulty in the way of calculating the supply when "uncooked meat" or "uncooked

meat including bone" is mentioned. We have endeavoured to overcome it by the use of a table, resulting from certain experiments on the loss of weight sustained by meat in various modes of cooking given by Dr. Steele in the paper we formerly quoted, and which he read before the Association for the Promotion of Social Science last year. We reprint this table, then, here by way of parenthesis as our warrant for deducting as a fair average from the stated supply of "uncooked meat" one-fourth of its weight, and from "uncooked meat, including bone," one-third.

	Original Weight.	Loss in Cooking.	Loss in Bones, etc.	Total loss.
	lbs. oz.	lbs. oz.	lbs. oz.	Per cent.
Baking in close oven	126 4	24 8	8 2	25.8
Roasting with gas	87 0	29 0	6 8	40.0
" before a fire.	128 8	38 8	10 4	39.8
Boiling.	156 0	30 8	9 6	29.3
	477 12	122 8	34 4	32.8

Again, we may state, in explanation of our table, that where

Irish-stew or meat-pie are mentioned as the dinner for the day, we have calculated the supply of meat to each patient at two ounces, where any larger amount is not actually placed in the tables. This quantity is small, but appears to be about the average, the difference in total weight of pie or stew being made up with potatoes and other vegetables, the liquor of a former day's boiling of meat, and pie-crust. The following is the receipt for pie and stew followed at the Northampton Asylum, which may be taken as an example of the way in which those dishes are prepared in most of the rest:—"Meat-Pie.—2 oz. of uncooked meat, 12 oz. uncooked potatoes, 5 oz. of flour, with dripping. Irish-Stew.—2 oz. meat, 10 oz. uncooked potatoes, seasoned with pepper, salt, and onions. The liquor of the previous day's boiled meat is added to the Irish-stew." As solid meat appears in these dishes, we have included the days on which they are given for dinner, usually once or twice in the week, each of them, as among the "meat days." The column relating to "quantity of meat" will mostly give some idea of the frequency with which pie and stew are given.

Table showing the Weekly Allowance of different Articles of Food and Drink in Sixteen Asylums.

Name of Asylum.	Number of Meat days (including Stew or Pie). Soup days.	Weekly quantity of Meat (cooked) in ounces.(a)	Weekly quantity of Bread in ounces.	Weekly quantity of Pudding (Suet or Rice).(e)	Weekly quantity of Vegetables in ounces.(f)	Weekly quantity of Beer in pints.	Weekly quantity of Tea or Coffee, in pints, or Cocoa with Milk and Sugar.	Weekly quantity of Milk Porridge, or Strabout, in pints.	Weekly quantity of Cheese in ounces.	Weekly quantity of Butter in ounces.	Weekly quantity of Solid Food, including Piecrust, Oatmeal, and calculating Irish Stew as solid; 1 pint of Porridge calculated as 2 ounces of Meal.	Remarks.
Hanwell	7 —	28(b)	104	20	64	7(g)	10½	—	14	—	240	Dumplings on five days of the week, instead of bread at dinner. There is no butter on diet-table of males, but females have 3½ ozs. weekly in lieu of cheese.
Colney Hatch	7 —	29	104(e)	14	64	7(g)	7	—	14(c)	—	235	Tea, 1 pint daily, given to females at supper in lieu of beer; males only have tea in the afternoon, if employed, as an extra. Butter as at Hanwell, except that employed males get a little with their bread at tea.
Somerset	7 —	34	116(e)	16	144	3½(g)	21	—	—(e)	7	317	No bread stated as given with meat dinners except with stew. Male patients sometimes have milk-broth for breakfast in lieu of coffee, and those who have this have no butter.
Stafford	5 2	24	148(e)	20	At discretion.	10½(g)	7	—	14(c)	—	295	Females have tea, 1 pint daily, in lieu of beer for supper. Butter as at Hanwell.
Sussex	7 —	26	114(e)	12	56	3½(g)	14	—	—(e)	3½	227½	No butter at breakfast.
Lincoln N. & E. Rid. of Yorkshire.	6 1	23	96(c)	12	52	3½(g)	11	3	—(e)	3½	212	Ditto.
Northampton	6 1	21	112(d)	—	Ad lib.	2½(g)	Unde-fined.	10½	14	Unde-fined.	264½	Ditto. No milk mentioned, and butter only at supper for females, in lieu of cheese.
Durham	7 —	31	99	—	36	4½	14	—	—	7	201	On two days in week either meat pie or suet pudding.
Worcester	4 2	18	91	8	60	—	8	13½	—	2½	214½	Vegetables other than potatoes on Sundays only.
Wiltshire	3 2	18	116(e)	24	Unde-fined.	3½(g)	14	—	1(c)	7	231	Occasionally fish and fruit puddings.
Nottingham	4 1	19½	98(c)	32	32	9½(g)	7	—	14(c)	3½	199	Females have butter in lieu of cheese at supper.
Bristol	4 1	19	117(c)	32	44	3½(g)	17½	—	1(c)	4½	227½	Patients may have milk-porridge in lieu of tea or coffee and butter; a salad once a week.
Prestwich	7 —	29	120(c)	—	80	3½(g)	14	—	—(e)	7	236	No bread at dinner except on two days in week, with Irish stew; fruit pies or puddings when in season.
Belfast	6 1	23	114(c)	—	80	3½(g)	7	10½	—(e)	2½	248½	The extra bread, cheese, and beer for employed patients is given at breakfast and dinner.
Idiot Asylum, Earlswood.	3 3	18	104½	—	See Remarks.	—	—	14	—	—	150½, or 390	Patients may have 344 ozs. of potatoes in lieu of 48½ ozs. of bread at dinner, and in winter they have 20 pints of milk stirabout in lieu of 56 ozs. of bread. Employed patients have meat dinners five days a week, and 10 pints of milk additional per week.
Mean	7 —	24½	108½	21	65	5	—	—	—	3½	228½	

(a) Calculating each dinner of stew or pie as containing 2 ozs. of meat, and allowing for loss in cooking to extent of one-fourth where quantities are stated in uncooked meat, and to extent of one-third when bone is included.
 (b) Fruit and rhubarb pies in place of meat pies now and then in the season.
 (c) Bread and cheese at lunch for employed patients extra.

(d) Idiots and employed patients have broth, bread, and vegetables for lunch extra.
 (e) To this may be added for each asylum about 10 ozs. or 12 ozs. of piecrust.
 (f) Stews and pies also contain vegetables.
 (g) Extra beer at lunch for employed patients, and at some asylums in the afternoon also, ½ pint each time.

In order to discuss the subject before us as distinctly as possible, we will consider it under the following heads, asking ourselves as we proceed how far the dietaries for lunatics can be called "liberal."

1. Average Quantity of Solid Food.—Without entering precisely, then, into the amount of nitrogenous, carbonaceous,

or fatty matter supplied, we may say that, on the average, the quantity of food supplied cannot be regarded as insufficient for the maintenance of health. Basing a theoretical dietary upon the formula of Vierordt, Dr. Guy, in a paper recently communicated to the Statistical Society, thus states it as per week:—Bread, 112 oz.; potatoes, 56 oz.; and oatmeal,

56 oz., or 224 oz. of solid food, with 7 pints of milk; and he has shown that with prisoners health may be maintained merely upon a diet of bread and potatoes—where the quantity of the two together amounts to about 300 oz. per week. In the Stafford Gaol the allowance quoted by Dr. Baly was 196 oz. of bread and 112 oz. of potatoes. For a man in health Dr. Letheby represents a physiological dietary as consisting of 140 oz. of bread, 84 oz. of meat, and 3.5 oz. of butter—equivalent to 227½ oz. of solid food. Now it will be seen that the mean allowance of solid food in the lunatic asylums in the table is 245½ oz., or from 16 oz. to 18 oz. in excess of these theoretical dietaries.

2. *Varieties as to the Amount of Solid Food given in Different Asylums.*—This is not only great, but difficult to account for. The highest amount is 317 oz. in the Somerset Asylum; the lowest among the English asylums is 199, in the Wilts. The Belfast Asylum stands alone, but the 390 oz. of bread, potatoes, and oatmeal, with 10 pints of milk, is in excess of Dr. Guy's "scientific" dietary, and also of that which has been found sufficient to maintain prisoners in Stafford Gaol. Of the English asylums there are only three where the amount of solid food supplied is less than 227½ oz., viz., Lincoln, 212 oz.; Northampton, 201; and Wilts, 199. The most abundant dietaries are those of Somerset, 317 oz.; Stafford, 295 oz.; and North and East Riding of Yorkshire, 264½ oz.

3. *Meat* is an essential element of a "liberal" diet, not only because it contains a large amount of nitrogenous and fatty matter in a small bulk, but because custom has associated one meal of animal food with the diet of the majority of English people. And in an asylum for the insane such habits must be regarded. Besides, Medical experience goes to show that it is an article of diet peculiarly suited to improve the strength and enrich the blood of the debilitated. Hence it should constitute a part of the food of the majority of the insane every day. There should be no "banyan days" in lunatic Hospitals; and the fact of this article being deficient in quantity in any dietary would place that asylum by so much lower than others in the scale of "liberality." Taking, now, the sixteen asylums on the table, we find that in seven meat, in greater or less quantity, and in one form or another, is given daily at dinner; in five it is given on six days of the week; in one on five days only; in three on four days only; and in two on three days only. The mean weekly quantity is 24½ ozs. (cooked and free from bone), and the extremes of quantity are 34 ozs. in the Somerset Asylum, and 18 ozs. in the Durham, Worcester, and Belfast Asylums. The asylums which supply their inmates with it most liberally are the Somerset and Northampton (31 ozs.), Bristol and Colney Hatch (29 ozs.), Hanwell, Prestwich, and Earlswood (28 ozs.), Sussex (26 ozs.), and Stafford (24 ozs.). With respect to those who do not give solid meat every day, it is right to say that, on the "maigre diet" days, soup is given in four asylums, but at Durham and Belfast there is one day, and at Worcester, Nottingham, and Wilts Asylums there are two days, on which neither meat nor soup appears on the table at dinner. In the last-named asylum, which we have already mentioned as that which gives the smallest amount of solid nutriment, we must add that on the one day when soup is given it consists merely of the liquor of the boiled meat, with peas and vegetables. If the boiled meat, then, given the day before is good for anything the animal element in the soup can only be analogous to the "point" with which the Irishman is said to qualify his meal of potatoes. It is very clear to us that the diet-table of this asylum at least demands reform.

4. *Cheese* is supplied to the patients to the extent of nearly a pound a-week in the two Middlesex asylums in which there is meat at dinner daily, and in three others—viz., Stafford, North and East Riding of Yorkshire, and Wilts—in which meat is not given every day. Considering the large percentage of total nutriment, three-fourths nitrogenous, contained in the sort of cheese used in asylums, the deficiency in meat appears fairly made up—that is to say, chemically; but cheese is not an article which weakened stomachs can always readily
