manage; for the most part it is given to males only at supper, and a lunch of bread and cheese to the workers in addition. It would be well, we think, if it could be done conveniently, to give to males the option of cheese or butter at supper.

5. *Bread* is supplied on an average to the extent of 108½ oz. weekly, the quantity varying from 148 to 91 oz. in the county asylums. At Earlswood it is 84 oz. This being the "staff of life" is the basis upon which, of course, all dietaries are built up; and hence we must expect to see the quantity supplemented, when small, by additional quantities of other nutritious food, of which wheat-flour, oatmeal, or rice form the principal constituents, in puddings or porridge. In the column relating to porridge each pint may be taken to represent 2 oz. of meal. Where meat is supplied abundantly, there the quantity of bread, pudding, and porridge is, of course, less—so much is not requisite; and where the meat is supplied in smaller quantity we find these elements of diet mostly larger. Still there are exceptions to both these observations. Thus in the Somerset and Stafford asylums, where the diet is very liberal, 132 and 168 oz. respectively of these articles are supplied per week; whereas at Durham, which stands the lowest as respects meat, stands lowest also as respects these equally important articles of food, only 105¾ oz. of them being given. Nor do we find from the table that persons who are employed get any addition. Bread should always be given with meat dinners, except where the dinner is meat pie. The addition is an appetising one, and adds with nearly all people to the enjoyment of a meal. With most people, in idea, at all events—and this is an important matter with the insane—it makes all the difference between "dining" and "feeding." Now, at Hanwell, Bristol, Lincoln, and Somerset, bread is only given when stew or soup forms the staple of the meal. On one occasion the Commissioners in Lunacy found that the patients had no bread even with their soup at the Warwick asylum, and very properly ordered the addition. At Hanwell dumplings are substituted for bread on five days of the week.

6. *Butter* is rarely supplied to male patients; the females in asylums almost universally have it in place of cheese at supper, but neither males nor females get any to moisten their bread at breakfast in the asylums on our list, except at Northampton, Stafford (females only), Durham, Somerset, Worcester, Welts, Nottingham, and Earlswood. In some of the others, indeed, milk porridge constitutes the breakfast; but there still remain those at Hanwell, Colney Hatch, Lincoln, Sussex, and Stafford (males) who have dry bread with their cocoa or coffee. This should be amended. Seven ounces a-week of butter is a very fair allowance for one person, and it is that given to male patients at Somerset, Northampton, Worcester, and Bristol, where cheese is not supplied. Other asylums which allow cheese give much less, and two—viz., Durham and Prestwich, who give no cheese—supply also the smallest quantity of butter in lieu of it, viz., 2½ oz. weekly—far too little.

7. The supply of *vegetables* of all kinds is abundant at nearly all the asylums. Somerset, liberal in everything else, is the most liberal here also. The Wilts Asylum gives least vegetables, only 32 oz.; and the Northampton 36 oz.; but the scale of liberality is also in both these institutions very low. The quantity in both these instances is much too small. There can be no excuse in county asylums for stinginess in respect of farm and garden produce. Salads and rhubarb pies, or puddings, when in season, should also appear on the dinner-table of every asylum occasionally. The large quantity of potatoes which, with milk, oatmeal, and meat, is given at Belfast is adapted to the ordinary diet of the people, and the whole forms a diet far more liberal than the lower orders of the Irish usually enjoy at home. Its great fault is its uniformity.

8. *Beer* is another element of a liberal diet which the Commissioners in Lunacy are in the habit of recommending. Durham, again, is here illiberal, giving none. The rest on our list allow on an average five pints per week. Hanwell

and Colney Hatch allow seven pints, and Wilts nine and a-third. As Wilts, in other respects, is not remarkable for over-feeding its inmates, it is a matter of some curiosity to us to know the strength of the "malt" supplied. The absence of beer at dinner at Durham was commented upon by the Commissioners in 1861.

Tea and coffee or cocoa are supplied, with a sufficiency of milk and sugar or molasses, to the inmates of all the county asylums.

Our space, which we have already drawn upon very largely, will not permit us to enter into the subject of the dietaries of any but the county establishments. We can only say that, while in the best of the private asylums the diet table is abundant and unexceptionable, there are many respecting which grave faults are found by the Commissioners, as will be seen by any one who will take the trouble to look through their Annual Reports.

The arrangements of the meals in the county asylums demand a few remarks. All the patients who are in a position to do so take their meals together in the large dining-hall; and the advantages of this rule in promoting their comfortable serving are great, so long as the practice is not pushed too far for the purpose of vain display. When taken into the wards or galleries, the dinner is apt to be cold, and the meal not being taken under the eye of the superintendent is sometimes served in a slovenly manner. In 1861, indeed, the Commissioners found that at the Durham Asylum the patients, even in the dining-hall, had to eat their dinner without either knife or fork. At Colney Hatch, in the same year, they had to complain that the table-cloths were not changed often enough for cleanliness; and on visiting one of the male wards, where thirty-five patients were at dinner, they found that they had neither knives, forks, nor spoons, and learnt upon inquiry that for upwards of six months past they had been in the practice of eating their food with their fingers, and this although there were spoons in store in the ward. This was a ward in which, that year, a patient was strangled by another, unobserved by the attendants. At the Somerset Asylum, whose dietetic arrangements we have already frequently mentioned with commendation, a band plays during meal time. The arguments in favour of comfort and liberality in asylums for the insane may be stated in the words of Dr. Conolly:—

"Another particular," he says, "which is of consequence to all persons is especially so to insane persons in asylums: a supply of good and well-cooked food, liberal in quantity, punctually served. The monotony of asylum life is relieved by the certainty of comfortable meals at regular hours. Pauper patients may be habituated to making some personal preparations for the dinner-table, and patients of the higher class may readily be induced to dress for dinner. Insane people require a somewhat full diet, by which the body is nourished and the mind satisfied. The manner in which the meals are conducted is of great importance. . . . To be well clothed, to have a comfortable bed, and sufficient food every day may, of course, be considered as having peculiarly comforting effects on pauper patients, too long accustomed to scanty fare and miserable lodging and wretched clothing. They often come to the asylum half starved, and good food is not unfrequently of far more consequence to them than medicine of any kind."—(*On the Treatment of the Insane.*)

These are the sentiments of one who had a regard to his charge as sick people whom he was to cure if possible, or to relieve if he could not cure. The following extract from a letter to the Commissioners in Lunacy represents the economical views of a committee of management:—

"The Visiting Commissioners in Lunacy do not appear sufficiently to bear in mind the fact that the Colney Hatch Asylum is established for pauper lunatics only, and that many luxuries and appliances suggested by them are quite unsuited to that class of patients, and could not be provided but at a cost which would be most justly complained of by the parishes chargeable for their support, and which would, even if granted to the patients during their residence in the asylum, tend most materially to aggravate the distress of those discharged as recovered, who, on return to their houses and former condition would have to forego those comforts which by long use had become almost necessities."

It is difficult to see the extent to which a line of argument such as this would not conduct its originators if it were pushed to its legitimate results.

In all asylums the Medical officers have, as we are assured, unbounded liberty in modifying the diet for individual patients—the extent to which it is exercised we believe to be considerable. The last annual report of the Hanwell Asylum contains a table showing the extra diets ordered on the last day of each month. The articles enumerated embrace nearly every dietetic luxury that can easily be imagined as entering into a public Hospital. The Asylum contains about 1500 patients, and of these more than a third are constantly in receipt of some one or more of the extras mentioned. Dr. Down, too, has kindly furnished us with the diet list of Earlswood for October 9, and here we find that, while 118 patients dining in hall were on ordinary diet, thirty-nine were on what is there termed "full diet," which differs from that stated in our table in containing an excess of nearly all the ordinary articles supplied at each meal. Minced meat, rice pudding, porter, and wine were supplied to several patients also who needed it. Thus far, then, the Lunatic Asylums agree in the main with ordinary Hospitals for the sick.

THE WEEK.

GENERAL GARIBALDI.

WE think it our duty to lay before the Profession an authentic account of the circumstances under which Garibaldi came under the Professional care of Mr. Fergusson. In the latter part of last summer that gentleman was consulted in his case, and the idea was entertained of Mr. Fergusson undertaking the journey to Caprera. Garibaldi, however, improved, and the project was abandoned. Six weeks before Garibaldi arrived in England Mr. Fergusson was again applied to by the General's friends, and it was arranged that during his visit he should have the benefit of Mr. Fergusson's opinion and advice. Accordingly, on the General's arrival at Stafford House, he immediately consulted Mr. Fergusson. It will be seen, therefore, that instead of Garibaldi's "visit to this country being quite unconnected with any seeking or necessity for Medical or Surgical opinion or treatment," the professional services of Mr. Fergusson were engaged for Garibaldi a considerable time before his arrival. The necessity for professional advice is completely proved by subsequent events. The continuous strain of body and mind to which the popular hero has been subjected has had such an effect on him as to induce Mr. Fergusson to interfere, and the consequence has been that Garibaldi has determined to curtail his visit. In another column will be found Mr. Fergusson's letters on the subject to the Duke of Sutherland and Mr. Seely. Of course we need scarcely say that the reports which have been circulated of there having been political reasons for the General's early departure are entirely founded on newspaper *canards*. The real fact is that he has been undergoing an amount of physical and mental labour and excitement since his arrival, for which he is completely unfitted by his state of health, and which could not be continued without positive danger. With regard to the condition of the injured limb, we have good authority for stating that in Mr. Fergusson's opinion there is bony ankylosis of the ankle-joint. There is at present no power of flexion or extension in that joint. There is some capability of lateral movement in the joints of the tarsus, which with time and use will in all probability be increased, but free motion in the ankle-joint itself cannot under the circumstances of the case be expected. Another report, however, on Garibaldi's case has been published in the form of a letter to the *Times* newspaper, by Professor Partridge. The amiable and accomplished Professor of Anatomy at King's College has, it will be remembered, from the beginning viewed Garibaldi's case through a medium of roscate hue. For the benefit of those of our readers who repose confidence in Mr. Partridge's opinion, we reprint his

letter elsewhere. Its former part would be to us entirely incomprehensible, were it not that during the past week all England, from the high-born dames of the West-end salons down to the street Arabs of St. Giles's, has been light-headed with the Garibaldian fever, and we can only suppose that Mr. Partridge, on his visit to Stafford House, was attacked by the general epidemic. We hope that our French brethren will remember this when they read the statement that Garibaldi is indebted for his successful cure to the Italian Surgeons.

NEW REGULATIONS RESPECTING ASSISTANT-PHYSICIANS AND ASSISTANT-SURGEONS AT KING'S COLLEGE HOSPITAL.

OUR readers in general, and especially those who had their education in King's College, will be glad to hear that at a late meeting of the Committee of the Council of the College it was determined—we believe unanimously—that the appointments of Assistant-Physician and Assistant-Surgeon to the Hospital should be made permanent. It is well known that a few years since the experiment was tried of increasing the staff of assistants to the Hospital, and of making these appointments temporary merely; the term of office varying from three to five years. A great deal of dissatisfaction was produced amongst the old King's College men by this step, and it was hoped that so soon as this just feeling was known the promoters of this innovation would rescind their resolution; unfortunately, however, the Council remained obstinate, and the consequence was that a great injury was done to the character of King's College as a Medical School. Some of the very best men educated there refused temporary appointments, and those who had influence in regulating the future education of young men exerted themselves to prevent them from entering the classes, consequently, the number of pupils greatly diminished, much to the regret of the old friends of this justly-famed school. It is now, however, seen that the experiment in question has failed to increase the usefulness and reputation of King's College as a place of Medical education, and the Council have wisely determined upon a step which all who have watched the progress of events during the last few years foresaw must be taken sooner or later. It is to be hoped that all the irritation and unpleasant feeling which has of late years existed will subside, and that henceforth King's College will hold the same position it formerly did as a Medical School amongst the members of our Profession and the public at large.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XII.—FEBRUARY 27.

Anatomy of the Chimpanzee Continued.—Professor Huxley commenced by stating that since his last lecture Mr. John Wood had shown him drawings which he had made of a true "levator claviculæ," and also of an "abductor ossis metacarpi quinti" occurring in the human subject. He then proceeded to the consideration of certain muscles of the chimpanzee, which differ essentially in their insertion from the corresponding muscles in man. These are,—1. The pectoralis minor, which varies much in insertion in different chimpanzees which have been dissected; in Duvernoy's specimen it was attached to the coraco-clavicular ligament; in Wilder's, to the coracoid process on the right side, and the great tuberosity of the humerus on the left; in the one lately dissected by Professor Huxley and Mr. Flower it joined the tendon of the supraspinatus muscle. In man its insertion is not constantly into the coracoid process. 2. The flexor longus pollicis of the chimpanzee presents a remarkable deviation from that of man. Arising in the usual manner, it gives a very slender tendon to the thumb, and a much larger, stronger tendon, which is the perforating flexor tendon of the index finger. The flexor profundus digitorum supplies only the third, fourth, and fifth fingers; in the palm of the hand the two tendons are closely united. The nearest approach to this arrangement which has been observed in the human subject is seen in those cases in

which the flexor pollicis longus has given a slip to the tendon of the flexor profundus which goes to the index finger. 3. The gluteus maximus departs considerably from that of man, the nature of the departure chiefly having relation to the different attitude assumed by the chimpanzee. It is small and flat, causing little prominence of the buttock, and from its lower edge the muscular fibres are continued down on the outside of the thigh as far as the external condyle of the femur. This part was described by Duvernoy as a separate muscle, under the name of "ischio-femoral." 4. The two long flexors of the toes, the flexor hallucis and the flexor digitorum, cross each other as usual, and then divide into several tendons, the former supplying the hallux and the third and fourth digits, the latter the third and fifth digits; at their point of division they are partially blended together. It will be recollected that when describing these tendons in the human foot, it was demonstrated that the flexor hallucis joined in the supply, to a variable extent, of the second, third, and fourth toes, so that difference in the arrangement of these tendons in man and the chimpanzee is only a difference of detail.

There are certain muscles which are single, or nearly so, in man, but which are more or less divided into two in the chimpanzee. 1. The extensor minimi digiti appears to be constantly divided in the chimpanzee, one tendon going to the fourth, and the other to the fifth digits. This is, however, a not uncommon exceptional condition in man. 2. The extensor ossis metacarpi pollicis is a more or less completely double muscle in the chimpanzee, one tendon being inserted into the trapezium, and the other into the base of the metacarpal bone of the thumb. In man, as we have seen, the tendon is commonly divided for some distance from its insertion. 3. The tibialis anticus undergoes the same change in the chimpanzee—the division of the tendon observed commonly in the human foot being carried up into the muscular fibres, sometimes quite to their origin, so that the anterior portion has been described by Cuvier and other anatomists as a distinct muscle under the name of abductor hallucis longus. 4. In the interossei of the hand, the division which was noticed in man at their anterior extremity, one tendon being inserted into the base of the first phalanx, the other into the extensor tendon, is carried to a greater extent, each interosseous muscle of the human hand being represented by two distinct muscles in the chimpanzee, having in both cases precisely the same insertions.

The general result of this sketch of the myology of the limbs of the chimpanzee as compared with those of man, is to show a certain difference between the two, but in almost every case the differences found in the chimpanzee are either exaggerations of arrangements existing normally in man, or they are arrangements which are met with in him occasionally as varieties.

Some questions now remain of much interest, and about which much discussion has taken place of late. Is the terminal division of the fore-limb of the chimpanzee properly to be called a hand? and secondly, is the terminal division of the hind-limb to be called a foot or not? These questions have acquired their interest thus:—Tyson, a hundred and fifty years ago, struck by the great external resemblance of the hinder limb with its opposable thumb to a hand, remarked that these animals might be called "quadrumanous." The term was afterwards made use of in a technical sense by Blumenbach, Cuvier, and others, and it has frequently been said that the great distinction between man and apes was, that the former possess two hands and two feet, and the latter four hands. In the consideration of this question, it will be necessary first to settle the basis of the argument. If the grasping power conferred by an opposable digit be taken into consideration, we must call the terminal division of the hind limb of a bird or an opossum a hand equally with that of a monkey; but morphological analogies cannot be decided by physiological function, only by an exact comparison of the

essential anatomical characters. We have seen that the terminal division of the fore-limb of the chimpanzee resembles the hand of man in all its essential muscular arrangements: it has, 1, long flexors and extensors; 2, a distinct extensor indicis; 3, an opponens pollicis; 4, the divaricators fundamentally disposed as in man. It differs from the hand of man in, 1, the union of the flexor pollicis and indicis; 2, the absence of an extensor primi internodii pollicis; 3, the division of the extensor ossis metacarpi; 4, the division of the interossei. The first and third are in some sense an approximation to foot arrangements; the second and fourth are special aberrations; but on the whole the differences are very unimportant, as compared with the great resemblances admitted on all sides; and, therefore, the term "hand" may properly be applied to this part in the chimpanzee.

If we examine in the same way the myology of the terminal division of the hind limb, we find it agreeing with the foot of man in the following characters:—1, the presence of a short flexor and extensor; 2, the intermingling of the long flexor tendons; 3, the presence of a peroneus longus; 4, the absence of a special extensor of the fifth digit; 5, the absence of an opponens hallucis, and presence of an opponens minimi digiti; 6, the single tendon of the interossei inserted into the first phalanx; 7, the presence of a transversus pedis; 8, the occasional presence of a flexor accessorius. On the other hand, there are the following deviations from the arrangement of the foot in man:—1, the more extensive division of the tibialis anticus; 2, the absence of the peroneus tertius; 3, the presence of a special abductor ossis metacarpi quinti; 4, the frequent absence of the flexor accessorius; 5, the origin of part of the short flexor from the deep flexor tendons; 6, the looseness of union of the flexor hallucis and flexor longus digitorum tendons, and the slight difference of their distribution; 7, the different distribution of one of the dorsal interossei. The greater part of these differences are, as we have seen, either differences of degree or occur as occasional varieties in the human foot, and they have no manner of weight when compared with the great resemblances; they are certainly not relatively greater than those found between the hand of man and the hand of the chimpanzee. Therefore, the same process of reasoning which induces us to call the terminal division of the fore-limb of the chimpanzee a "hand," must also compel us to call the corresponding part of the hind-limb a "foot." If we revert to the osteological structure we shall find that the argument acquires even greater weight, and we must conclude that there is not the smallest ground for applying the term "four-handed" to the apes, if it is meant to imply by that term that there is any structural difference between their foot and that of man.

PARLIAMENTARY.

In the House of Lords, on Thursday, April 14, the bill empowering the judges to order flogging, in addition to imprisonment, in the sentences of accomplices in criminal assaults on women, passed through committee, after a short discussion.

In the House of Commons, Mr. Bazley asked the Secretary of State for India how many candidates for employment in the Medical Department for India were presented, and how many were the vacancies at the time of the competitive examination in January last, and again how many at the recent examination?

Sir C. Wood was understood to state, in reply, that for two or three years there had been no examination of candidates for the Indian Medical service.

On Friday, April 15, in the House of Commons, in answer to various questions on the subject of the new museums at South Kensington, Mr. Cowper said that thirty-two sets of designs for the new buildings had been sent in by public competition. Those designs were now hanging up in the Royal Gallery, where they were accessible at any time to hon. members. The judges would consist of five persons. Three of them would be architects of acknowledged reputation and experience, who were not at present practising their profession. One would be a painter, and the fifth would be an amateur.

The proposed building was to occupy one front of the site lately occupied by the Exhibition, and there would be space enough to receive the Natural History Collection of the British Museum, and also the contents of the Museum of Patented Inventions, if it should be ultimately determined to remove those inventions to Kensington. But the first thing would be to get designs for the building, and the use to which the building should be put would be a matter for further consideration.

In reply to a question respecting Burlington House, Mr. Cowper said he believed that he would soon be able to lay on the table an estimate for erecting a National Gallery in the garden of Burlington House, which was one-half only of the site.

Mr. Crawford's motion advocating a uniform and fixed duty on sugars was lost by a majority of 133 to 17.

In the House of Commons on Monday, April 18, the House went into committee on the Penal Servitude Acts Amendment Bill. Upon the 4th clause, Mr. Hunt moved to add the words:—"If any holder of a licence, who shall be at large, shall fail to report himself to the chief police-station of the borough or district where he shall be on his arrival therein, and subsequently on the first day of each month, or shall change his locality without having previously notified the same to the police-station to which he last reported himself, he shall be deemed guilty of a misdemeanour, and may be summarily convicted thereof, and his licence shall be forthwith forfeited."

This amendment was opposed by Sir G. Grey; but after a long debate it was carried on a division by 148 to 120.

The remaining clauses were agreed to with a few amendments.

In the House of Lords on Tuesday, April 19, Lord Clarendon, referring to certain rumours relating to the departure of General Garibaldi, denied it was hastened by any representations on the part of the French Government. The Emperor perfectly understood the character of the reception Garibaldi had met in England, and the causes of the popular enthusiasm. No inquiries whatever had been made on the subject. As to the pending Conference on the affairs of Denmark, no concessions had been asked from the English Government, the Emperor of the French wishing that on all questions that might arise a cordial understanding should exist between the two countries.

Upon the report of amendments to the Punishment of Rape Bill,

The Earl of Carnarvon moved an amendment providing that the infliction of corporal punishment in the case of attempts to commit the offence should be discretionary with the judges, instead of compulsory, as it stood in the Bill.

The Lord Chancellor and Lord Wodehouse supported the amendment, and, after a short conversation, it was agreed to.

The report was then agreed to.

In the House of Commons, in reply to a question put by Mr. D. Griffith, Lord Palmerston also contradicted the report respecting the return of General Garibaldi and its causes. He believed, he said, that his visit would be curtailed, but solely out of regard for his health, which had suffered since his arrival in England.

FROM ABROAD.—VIOLATION OF PROFESSIONAL SECRECY IN FRANCE—THE OIDIUM OF THE VINE AS A POISONOUS AGENT.

THE conviction of a Medical man in France for betrayal of Professional secrecy (*Medical Times* March 26, p. 344), and the infliction of a heavy fine, with a long imprisonment, must not, it seems, be taken as a usual procedure. It has, in fact, excited some consternation in that country on the part of Medical Practitioners, which has elicited an explanation that this is an exceptional instance of severity due to the very bad conduct of the person inculpated. This Dr. Z., it seems, being much in the habit of suing his patients for their bills, contracted an acquaintance with M. N., a clerk of the office whence the writs issued, and became the attendant of himself and wife for some not very serious ailments. When N. asked him for his bill, the Doctor replied that he was well pleased to accept the good services he had rendered him in bringing the actions as remuneration for his services. However, N. having left the lawyer's office, and thus ceased to be useful to Z., the latter immediately sent him in a bill of 300 francs for attendance alleged to have been given him on

account of syphilitic affections. N., indignantly denying the fact of his ever having had syphilis, refused payment, except as far as regarded 50 francs for attendance, which he acknowledged to have received for other affections. Thereupon the Doctor summoned him before the Tribunal, and the revelations made in the document he caused to be issued, and left with the porter of the house, constituted the charge of breach of Professional secrecy. In this he stated that he had attended N. for two successive attacks of syphilis, as also his wife for syphilis, contracted from her husband. N., totally denying the truth of the statement made, brought the Doctor before the Tribunal, charging him with defamation and with betrayal of Professional secrecy. At the hearing of the case, he emphatically denied that either he or his wife had been ever the subject of this disease, while the Doctor affirmed the veracity of his statement. The Tribunal, in giving its decision, stated that another procedure must be taken with respect to the charge of defamation; but pronounced the accused guilty, even on his own showing, as regarded the divulgence of Professional secrets. M. Chaudé, a Paris advocate, much accustomed to Medical cases, thus explains the bearing of the law in this matter:—"The grand principle of an obligation of secrecy, which is an honour to the Profession of Medicine, does not, however, present any obstacle to just demands. When, as too often happens, a patient, forgetful of the services which have been rendered him, refuses the legitimate remuneration, the Practitioner has assuredly the right to carry his demand before the tribunals; but he must confine himself in his statement to the indication of the sum which is due to him for his attendances, without entering into any detail as to the affections treated. Doubtless, as the fees recoverable must be fixed in relation to the importance of the diseases, it may be necessary, in certain cases, to inform the judges with respect to the nature, course, and duration of such diseases, or the importance and number of the operations practised. These details must then be confided to the advocate who has been selected by the Practitioner, who, like himself, is obliged to secrecy. Informed by his agency, the Court is enabled to reconcile the necessities of the defence with the law of secrecy, and decide with a full knowledge of the circumstances. In this case, it is Justice herself who demands the revelations, which, given with discretion, cannot be regarded in the same light as violations of secrecy. It is no divulgence made with the intention of doing harm, or with culpable thoughtlessness, the object being to overcome an unjustifiable resistance, and cause the triumph of a just pretension."

We all know the destruction which the *oidium* has caused among the vines for many years past, and, according to a communication made by M. Collin to the Academy of Medicine, it may determine in man all the symptoms of true poisoning. In the three cases which he relates, the persons while cutting vines affected with *oidium* produced a slight incision in the skin; and in all the same symptoms resulted. In a few days, shivering, loss of appetite, and fever with remissions set in. The cut, at first quite insignificant, soon assumed a bad aspect, and eventually became gangrenous, the limb itself being œdematous. The most remarkable circumstance was that the mouth became covered with *muguet*, which modern researches have shown to be a cryptogamous production, and which has, indeed, been termed by M. Gubler the *oidium* of the mouth. M. Collin has instituted some experiments by the inoculation of animals with *oidium*, the results of which will be communicated.

A LADY has been lecturing the members of the Brighton Literary and Scientific Institution on the impropriety of using "Baking Powder," a well-known compound of carbonate of soda and tartaric acid, instead of eggs. If this substance is really employed instead of eggs and butter, the persons who eat the pastry so made must be very indifferent judges of good living, if they do not find out the difference; but we believe that the addition of a very little of this powder, if nicely neutralised, to the crust of an apple dumpling is rather an improvement than not.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF WOLVERHAMPTON.

(Continued from page 432.)

DRAINAGE.

The drainage of the town at the present moment is very imperfect. Surface drainage is general, and cesspools are abundant. Naturally, the town is well placed for drainage, being on a sandstone rock, and being situated so high that the flow from the drains is easy. There are also several outlets for the escape of water, while the sandstone acts as a filter for the removal of a large portion of the mere watery part of the sewage. Such errors as exist in the drainage of Wolverhampton will shortly be rectified. There is now a proposed plan for the complete drainage of the town. The plan has been inspected by Mr. Rawlinson on the part of the Government, and approved of by him; and sanction has been obtained from Sir George Grey for effecting a loan of £37,000, repayable by instalments, extending over a period of thirty years, for the purpose of carrying out the scheme.

The sewage of the town has been to a certain extent utilised, for the Town Council have for some time past had an arrangement with a firm of contractors (Messrs. Deans and Son) for the removal of night soil, etc., and this firm has disposed of the sewage to a large extent for application to agriculture. Last year, however, the Sanitary Committee, with the sanction of the council, entered into a contract with the Wolverhampton Manure Company for the removal of manure. The conditions are somewhat singular. The contract is for a term of fifteen years, dating from Lady-day, 1864. The removal, cleansing, etc., is to be effected by the contractors to the satisfaction of the Local Board, for which services the Board is to pay the contractors £500 for the first year of the term, £400 for the second, £300 for the third, £200 for the fourth, and £100 for the fifth year; for the remaining ten years no payment is to be made. The contractors have power to determine the contract at the end of any one year, upon giving the Local Board three calendar months' notice in writing. The Committee congratulate the Council that by this proceeding £1050 will be saved for the first year. I should think that the Wolverhampton Manure Company will congratulate itself also for many years. One would like to know something about the shares of so promising a society.

SITE—CLIMATE—METEOROLOGY.

I have already stated that the town is situated on a sandstone rock. The soil is gravelly, with points at which clay is presented. Respecting the climate, it is at times damp, but much less so than Stafford and the neighbouring towns. The temperature is very variable, and the winds are often bleak and cutting. Meteorological records have not been kept until quite recently. They are now being preserved by Mr. Thrustans, a member of the Meteorological Society, and a well-known meteorologist; but I regret that his observations do not extend over a sufficient time to allow him to state anything positively as to the meteorological condition of the district. He has, however, organised a series of reports, which appear monthly in the *Wolverhampton Chronicle*, and which promise to be exceedingly useful. No observations have been taken with reference to climatic influences on disease.

VENTILATION.

But little attention has been paid to the ventilation of private houses or of the public buildings. In the Agricultural Hall, however, there is carried out an original and simple mode of ventilation, consisting of shafts in the roof of the building, across each of which is a septum of wood, which can be made to open, by means of a cord, into four parts. This mode of ventilation is said to be very effective.

STREETS.—DWELLINGS OF THE POOR.

Considering the irregular way in which the town of Wolverhampton has been built, the streets are much more commanding than might be supposed. In most cases they are wide and open, and as a general rule they are exceedingly well kept. The roadways are macadamised; the footways are paved, and kept in good order. I may remark that iron kerb is becoming more and more in use in Wolverhampton in the sideways, and appears to answer well, being durable, and affording a surface that allows the water rapidly to escape. The local Board is now very active in bringing the whole of

the streets of the borough into an efficient state of repair. The streets of the town are well lighted with gas. The dwellings of the poor are much superior to those that are met with in most of our agricultural districts; but I learn that amongst the poorer classes the internal management is bad, and that the rooms are filthily dirty. Overcrowding, moreover, prevails to a great extent, with the evils consequent upon it.

DIET OF THE PEOPLE.

Amongst the working classes animal diet is sought after, especially pork. We may say, indeed, that, as regards animal food, pork is the staple. After pork, tea and bread form the chief articles. These are taken nearly at every meal, and the very poorest live on them almost exclusively. Butter is a luxury; it is supplemented usually by lard or dripping. Cheese is also a luxury amongst the poor, and fish, with the exception of herrings, is little in demand. I have already referred to the luxurious habits of the colliers during their days of "play." The Irish poor, who abound in Wolverhampton, retain all their taste for the food of the Emerald Isle. The flesh of the "unclean animal" tempts them but little, so long as potatoes and butter-milk are within reach.

PROSTITUTION.

Prostitution is rife in Wolverhampton. 265 women are known to the police as professed prostitutes. Of these, 30 are under 16 years of age. During the past year no fewer than 5 prostitutes have been added to the streets whose ages are under 16. There are no fewer than 97 brothels or houses of ill-fame. Venereal diseases are exceedingly prevalent, and extend amongst both sexes beyond the classes of those who inhabit, and of those who frequent, the brothel; for, as we have already seen, there are large numbers of unmarried women in the town who live with men, and who cannot be called prostitutes in the strict sense of the term, but who contract diseases, which originally came from the brothel, of the men with whom they cohabit. The number of questionable houses, including the brothels, amounts altogether to no less than 240.

PUBLIC-HOUSES AND BEERSHOPS.

The number of licensed victuallers in the borough is 215; of beer-house keepers (to be drunk on the premises), 225; of beer-house keepers (not to be drunk on the premises), 12; of licensed refreshment houses, 28; of wine retailers (to be consumed on the premises), 7; of wine retailers (not to be consumed on the premises), 13. In all, 490; or 1 salesman of alcohol to 128 inhabitants.

CORONERS' INQUESTS.

The number of inquests held during the year ending September 30, 1863, was 77. 56 of these were held on males; 21 on females. 31 males and 14 females were adults; 25 males and 7 females were children. The verdicts returned were—murder, 1; accidental death, 33; natural causes, 31; suicide, 3; manslaughter, 4; indefinite, 5. The number of cases of suicide was reduced one-half in 1863 as compared with 1862.

CRIME AND CRIMINALS.

995 males and 351 females were proceeded against summarily last year, and 1023 depredators, offenders, and suspected persons were known to be at large during the year. Of persons apprehended and proceeded against by summonses before the justices during the year ending September, 1863, there were 1168 males and 373 females. Of these prisoners two were sent to reformatories and twelve were whipped.

EPIDEMICS AND ENDEMICS.

No accurate records have been kept bearing upon the epidemic or endemic diseases of the town of Wolverhampton. Scarlet fever is exceedingly prevalent, as well as measles. Five years ago diphtheria broke out and spread with great violence and rapidity; one Medical man—Mr. Edwards—fell a victim to it; since that time it has scarcely been seen in the place.

Typhus and typhoid fevers are comparatively rare. Cholera visited Wolverhampton both in 1849 and 1854. The Wolverhampton district, indeed, was marked by Dr. Farr in the Registrar-General's report on the mortality of cholera, as the "Wolverhampton cholera field." In this field he included a space of twelve miles square at the southern extremity of Staffordshire; and in this space, during the epidemic of 1849, no less than 3275 persons died of cholera and diarrhoea. In the actual district of Wolverhampton the deaths amounted to 137 in 10,000. In the entire district of Willenhall, the population of which is 11,863, 160 males and 121 females were destroyed, and 167 persons fell victims between the 1st and

12th of December. The greatest number of cases occurred where drainage, sewerage, ventilation, and water were most wanted; and the classes amongst whom the disease prevailed most were labourers, locksmiths, miners, bootmakers, and keymakers. The whole of the deaths registered in the Wolverhampton parliamentary district, embracing in 1851 a population of 104,158, were from cholera, in 1849, 1365; and in 1854, 80. The deaths from diarrhoea were 243 in 1849, and 312 in 1854.

Small-pox has recently prevailed in Wolverhampton in the epidemic form, and has been rather severe.

VACCINATION.

The practice of vaccination is not confined exclusively to the Parochial Medical Officers; but every Medical man who does vaccinate must have a permit from the Board of Guardians proving that he is a recognised vaccinator, otherwise he cannot receive fees. The fee is only 1s. 6d. per case. As a whole vaccination might be performed more efficiently, but the Medical men experience great difficulties owing to the facts that popular prejudices against vaccination are very strong, and that the Board of Guardians have not, until of late, enforced the law rigidly in respect to vaccination.

ETIOLOGY.

We have seen, in speaking of the practice of the Hospital, that the prevailing diseases in Wolverhampton are consumption, rheumatism, grinders' phthisis, lead colic and paralysis, stone, chorea connected with heart disease, and tapeworm. We have since seen that certain of the epidemics have a constant home in this town. Few accurate data exist that would lead to any safe inference as to the precise causes of all these diseases. The grinders' consumption we naturally trace to the exposure of the subjects of it to foreign material spread out in the air in fine particles. The lead paralysis we trace to the uncleanly habits of men who are working in lead. The epidemics we follow to their specific poisons; but, respecting the origin of the other disorders, obscurity prevails. It is interesting, however, to observe that chorea, which is a common disorder, appears to connect itself very closely with endocardial disease and with the rheumatic constitution. Still more interesting is the apparent and obvious connection between the consumption of large quantities of pork and the occurrence of tapeworm to so considerable an extent. I was anxious to ascertain whether amongst the members of a community, which may in truth be called a pork-feeding community, *trichina* disease had ever been seen; but I could obtain no evidence bearing upon the point. All that I could learn was that a rheumatoid affection of the muscles and urticaria were frequently seen as forms of disease. Of course it is more than possible, considering the *trichina* disorder has been so recently differentiated from various forms of so-called muscular rheumatism, that cases of trichiniasis may have occurred over and over again; and it is almost impossible to suppose from what we now know, that such cases have not occurred. Any way, in Wolverhampton there is perhaps the best field in England for new and important investigation regarding the disorder in question, and it is to be hoped that our Medical brethren there will soon report to us various important facts bearing upon the whole subject.

I cannot bring to a close the Sanitary History of Wolverhampton without referring to the very earnest labours of the Sanitary Committee of the Town Council. Their report, from which I have drawn many facts, is quite a statesmanlike document, and their activity during the year has been unceasing. In 1863 their inspectors gave notices against 100 nuisances; the town ditches were cleansed; whitewashing and cleansing were carried out on a large scale in the courts and streets; the sale of diseased meat was suppressed as thoroughly as could be done; the slaughter-houses were carefully inspected; attention of the owners of small house property was called to the desirability of an efficient supply of pure water; arrangements were made by the committee with Messrs. Wildsmith and Gaunt for the prevention of noxious and offensive vapours arising from the manufacture of their artificial manures; the Act of Parliament of last Session for the regulation of bake-houses was considered and ordered to be carried into effect; and a vigorous effort was made in the report of the committee to secure for Wolverhampton a Medical Officer of Health.

MEDICAL BIOGRAPHY OF WOLVERHAMPTON.

The Medical Biography of Wolverhampton is very shortly written. I cannot ascertain that any man who has added

anything really important to Medical scientific literature could be claimed by that town as an inhabitant, or as native born. My learned friend, Mr. Garner, of Stoke-on-Trent, has, however, supplied me with one or two facts of some interest, to which I may refer.

Dr. William Gibbons, M.D.—Dr. Gibbons is said by Mr. Garner to have been born at Wolverhampton, and to have left £500 to the Wolverhampton Charity School in the year 1728. The place and the date of his death are unknown. Dr. Gibbons has the reputation of having been the first man to introduce mahogany into this country.

Dr. Wilkes, M.D.—Dr. Wilkes resided during the last century at Willenhall. A large ancient mansion, close to the Grand Junction Railway, was the residence, Mr. Garner relates, of this eccentric man, one of the most celebrated of his locality. Wilkes appears to have been what is now called a hydropath, and over a medicinal spring hard by his house he placed this inscription:—"Fons oculis morbisque cutaneis diu celebris. Anno Domini, 1728." In this department of pseudo-medicine, Wilkes followed another eminent Staffordshire man, the Physician to Charles II., Sir John Flower, who, near to Lichfield, established actually a hydropathic establishment, to which the good people of his day flocked, as the people of these days have flocked to Grafenberg and Malvern.

In tracing out the Medical History of Wolverhampton, we have learned many valuable truths; not so many as ought to have been yielded to us by such a place, truly, but still many. And, above all, this one great truth, which, in time, will be reckoned as pertaining alike to statesman and Physician,—that disease and crime rest on the same basis, that one cannot exist without the other, and that to remove one is to remove both. *The diseases, the mortality, the population, and the meteorology of a district being known, deduce from those facts the amount of crime perpetrated by the said population.* That will be the question which will one day be put to the student,—a question which he will have to answer accurately, and which even now could be answered approximately.

ADDENDUM ON LITHOTOMY IN THE WOLVERHAMPTON HOSPITAL.

I am indebted to Mr. Nesbitt, the Senior Surgeon to the Wolverhampton Hospital, for the following table giving the lithotomy practice for four years—viz., from 1860 to 1863. In the table published on April 9, only two years of practice was rendered:—

Total Number of Cases of Stone in the Bladder admitted into the South Staffordshire General Hospital, from January 1, 1860, to December 31, 1863.

Males	25
Females	2
Total	27
Lithotomy (lateral).	21
Lithotriety.	1
Total	22

Cured. 19
Died. 2
Cause of Death. Exhaustion and secondary hæmorrhage.

Average of deaths 1 in 11
" age 16
" weight of stone ʒij.ss. (3½ dr.)
" duration in Hospital 50 days

Three cases died in Hospital before operation. Females, 2. Urethra incised in both—one recovered and one died of traumatic peritonitis.

The stones are chiefly lithic, and of the whole number (27) 16 are from the town of Wolverhampton; 8 from the mining districts around; and 3 from the agricultural districts.

Table Showing the Comparative Prevalence of Stone in the Bladder at Different Ages, with the Result of Operation, whether by

No.	Age.	Lithotomy,			or	Lithotriety.		
		Cured.	Relieved.	Died.		No.	Age.	Cured.
5	5 yrs. and under	5	—	—	1	47	1	
7	5	10..	6	—	—	—	—	
8	10	20..	8	—	—	—	—	
0	20	30..	—	—	—	—	—	
1	30	40..	1 Fem.	—	—	—	—	
2	40	50..	2	—	—	—	—	
0	50	60..	—	—	—	—	—	
2	60	70..	—	2	—	—	—	
0	70	80..	—	—	—	—	—	
Total 25		22	—	3	1	—	1	

Occupation had no effect in the production of stone.

Note on the Medical Staff of the Wolverhampton Hospital.

The name of Mr. Coleman, as Senior Consulting Surgeon, was accidentally omitted in the list of officers.

REVIEWS.

Dichter und Aerzte. Von Dr. RAPHAEL FINKENSTEIN, etc. *Poet and Physician; a Contribution to the History of Literature and the History of Medicine, with practical examples and critical remarks.* By Dr. RAPHAEL FINKENSTEIN. Breslau. 1864.

DR. RAPHAEL FINKENSTEIN has thought that he would be rendering a service to the future historians of literature and of physic by bringing into a small compass an account—illustrated with copious extracts—of all the poetry written by Physicians, and of all other poetry which, though not written by Physicians, yet has a bearing upon Physic. His little book contains accordingly much that is amusing, and a good deal that casts a light both upon the manners of various ages, and the progress of Medical opinion. That the number of the votaries of Esculapius who have also wooed the Muses is no inconsiderable one, is well known; but the list before us expands into a really formidable length, which makes us regret the more that there is no index attached whereby we might accurately gauge the numbers. We have our suspicions, also, of its completeness, for, on looking through it attentively, more than once, we have not observed the name of Akenside, though he does not omit to include Oliver Goldsmith among his *Medici*. One gratifying circumstance we may note, that among the poems upon the Doctors, of which there are a goodly number, the laudatory overshadowingly surpass the depreciatory. How far a judicious selection on Dr. Finken-stein's part may have contributed to this result we cannot say, and need not too scrupulously inquire. To judge by his volume, however, probably, next to the fair sex, the Medical Profession have been most bepraised, and we note with gratification that this laudation is expressed in many tongues. A grateful Arabian sets forth his wonder at a predecessor of Dr. Bright in terms which we (from the German version) venture thus to render:—

"Such Godlike help as Ibn Corra gives
Can any other to the sick man give?
By grace of Godlike wisdom he revives
The vanished art to make the dying live
As Jesus, Mary's Son, by simple word
Restored the dead, so he, with perfect ease,
And without effort, can new life afford,
And banish the foul demons of disease.
I did but show my urine, and his skill
At once discerned my secret malady
Deep hid 'twixt ribs and heart. Nor human ill
Is there, nor can be, but Ibn Corra's eye
Perceives, as spots look gross on polished steel."

It is probable that Ibn Corra had not "sent in his account," or that the Arabian College of Physicians in those days were stringent in their bye-laws, for as we read here in the original Latin,—

"Three faces has the Doctor: longed for, he
Appears angelic; giving ease, divine;
But let him, long delaying, ask his fee,
His horrid visage Satan's doth outshine."

The poetic literature of syphilis is represented at length, in all its ghastly fun; we gladly pass it by, observing only that fun seems a dominant element in the poetico-Medical mind, as from the prevailing *bon-homme* of the Profession might have been expected. Yielding to the genial atmosphere in which we find ourselves, we are tempted to undertake the impossible task of translating a pun,—

"Would you grow slowly old, these precepts store:
Mess like a Doctor—take no Doctor's mess;
Physic, as food consumed, consumes the more;
Food used as physic will as surely bless."

Explorations in the Interior of the Labrador Peninsula, the Country of the Montagnais and Nasquapee Indians. By HENRY YOULE HIND, M.A., F.R.G.S., Professor of Chemistry and Geology in the University of Trinity College, Toronto, etc., 2 vols. London: Longmans. 1863.

WE extremely regret that the demands upon our space do not permit us to express more than the very great pleasure which these volumes have given us, with the strongest recommendation to our Medical and scientific readers to order them from their library or book-club. In giving an account of his

adventures through wild regions unexplored by the European, the writer gives abundance of details respecting the Indian tribes, their manners, habits, and capacity, and the causes which slowly, but surely, are bringing them to extermination. Their mode of life is incompatible with that of a civilised race; moreover, they die of influenza when they settle among the missionaries of the coast. The accounts of huge tracts of "burnt country," in which the destruction of the existing vegetation by fire condemns the ground to long-continued barrenness, the mosquitoes of the lakes and swamps, the disappearance of animals hunted for their fur, and the traditions of the ancient wars of extermination amongst various tribes of Indians, all give the book a melancholy charm. The account of night blindness, which affects men after hard work on monotonous diet, and seems allied to scurvy, includes some incidents more thrilling than those in any romance. As for the Indians, they seem children of a larger youth, and their development to have stopped short of the "measure of a perfect man." Mr. Hind believes their physical strength and stamina to be below that of Europeans; they have all the vices of overgrown children, as gambling, licentiousness, and improvidence. Yet it is a melancholy thing that the poor creatures fade away visibly. These volumes are illustrated with capital woodcuts and chromolithographs. They are full of information about Labrador, which perhaps in the next generation may be visited by our children for a summer residence, and may have deer and salmon preserves as Scotland has now.

GENERAL CORRESPONDENCE.

AN OUNCE OF QUININE ADMINISTERED BY MISTAKE.

We most readily give insertion to the following letter, which has been placed at our disposal by Dr. Clapton, of St. Thomas's Hospital:—

DEAR DR. CLAPTON,—It has often been a matter of reflection to me how imperfect is our knowledge of the action of the various substances employed in medicine, when used in health and in disease, and how greatly this branch of Medical science needs improvement. I am brought to admit that the reason proceeds, on the one hand, from the complicated state of our organisation, in consequence of which the effect is modified by the simultaneous influences of many organs, and by a variety of circumstances not under our control; and that, on the other hand, there is still a great want of acquaintance with the properties, and, I dare say, with the affinities of the various substances to the organs and tissues of the human frame.

The first difficulty may certainly be almost insuperable; the last imposes on each of us the duty of communicating to our Medical brethren what may be of interest to them, especially in regard to those remedies most commonly employed. This same consideration influences me in transmitting to you a singular fact which occurred here lately. It is as follows:—

Dr. Hayler, a military Medical man, visited in barracks a soldier, suffering from a relapse of ague, and administered to him a small dose of sulphate of quinine. At the same time, he directed a man to fetch one ounce of the same remedy from the Hospital, in order that he might have it in readiness for any emergency. The man received the bottle; but, supposing that it was ordered for the patient just mentioned, he took it to him. In the presence of their comrades, they put the whole into a cup, adding sufficient water to make a paste of it; and the patient, although he found the medicine uncommonly bitter, did not leave off until he had taken it all.

Dr. Hayler, on learning that this enormous dose had been taken, at once visited the patient. The most careful investigation left no doubt of the fact; but, with all that, *incredibile dictu*, except a complete deafness and a kind of stupor, no other bad effect ensued, and no antidote was administered. He was directed to the Hospital, where he remained a week under observation, and left the establishment in the best state of health. The ague disappeared, probably never to return. I saw the man myself; he is a Swiss, named Albitz, aged 30, of small stature, and of a strong constitution.

It was not to be supposed that there was any important adulteration of the remedy in question, as all these preparations are subjected to a chemical investigation before they are admitted in the Hospital Dispensary.

Now, I do not intend to discuss the various points in respect of which this fact offers a peculiar interest, leaving the application of it to yourself. I merely hope that its publication may tend to diminish the popular prejudice still existing against this powerful and highly important remedy,—a prejudice which sometimes prevents us from using it. Professional men and patients may both learn once more how often symptoms, which we are so frequently led to consider the effect of quinine, ought rather to be attributed to the malady itself than to the medicine employed.

It would certainly be a difficult matter in this case to determine how much of the entire ounce was absorbed, and brought into circulation. A most careful inquiry as to the excreta for several days following its assumption would have facilitated an approximation of the amount. As this examination was not made, we can only infer, from the slight symptoms experienced by the patient, that a portion only of the quinine was absorbed. Though, therefore, I would not willingly encourage larger doses than we usually give, we may still feel induced by the present case to administer moderate doses in various affections besides ague, where the use of quinine is indicated. As, for instance, in remittent fevers, we need not wait too anxiously till evident intermission, remembering the *occasio præceps*; so in certain cases of typhoid fever, and in acute rheumatism, we may, perhaps, more frequently try it, less deterred by the fear of increasing a supposed inflammatory condition, or of promoting severe nervous excitement. I recollect some cases of phthisis pulmonum where I gave daily a few grains of quinine, guided by the observation that the fever in these individual instances was in no proportion to the local disease.

I am afraid, dear Dr. Clapton, I have taken up too much of your valuable time by giving you so long an account. Make what use of it you think proper, and shorten it as you please, only let the fact be known. I am, &c.

Rome, December, 1863.

DR. TAUSSIG.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 12.

Mr. PARTRIDGE, President.

A PAPER, by Mr. SAMUEL SOLLY, was read, on

FOUR CASES OF INTESTINAL OBSTRUCTION, IN THREE OF WHICH THE COLON WAS OPENED IN THE LEFT LUMBAR REGION (AMUSSAT'S OPERATION).

The writer of this paper, after acknowledging the value of Mr. Cæsar Hawkins's contributions to the subject, proceeded to detail his own experience. The operation of opening the colon in the loin, in properly selected cases, he believed to be neither dangerous nor difficult; nor was it contraindicated by the occasional passage of small quantities of fæculent matter. The results, moreover, of the operation were far from unfavourable even where the stricture was due to malignant disease, and the relief afforded was so instant and decided as in the interest of humanity imperatively to call for Surgical interference. The first case, that of a labourer, aged 28, was one of rectal cancer, advancing with unusual rapidity, and dating only five months from admission. At the onset, diarrhœa, with slimy and bloody motions, was followed by intermittent symptoms of obstruction, which before long became constant. On admission, the abdomen was frightfully distended; the rectum did not admit the passage of even a small elastic catheter. Three days after, the descending colon was opened in the left lumbar region. Much flatus escaped, but hardly any fæces until some hours after the operation. This was followed by rapid improvement in every respect. Sixteen days later the patient left his bed, wearing a tent in the wound, and continued in fair health for three months, when chronic peritonitis set in, probably from extension of the primary disease, and slowly advanced to a fatal termination. The second case, that of a railway clerk, was of eighteen months' standing. It had been very gradual in its access, and palliated during the last month by passage of rectum bougies twice a week. On admission, the symptoms, both local and general, were very severe. At the operation much fæculent matter was evacuated, and the relief obtained was very de-

cided, lasting for six weeks, when sudden collapse, partially due to mental causes, was very rapidly followed by death. Post-mortem examination was refused. The third case had occurred very recently. A bank cashier, aged fifty-four, of active and temperate habits, had begun about a year previously to suffer from constant tenesmus, with from five to seven evacuations daily; these were on three or four occasions accompanied by blood. Seven months later he consulted the author, and extensive carcinoma was found partially occluding the bowel. During the following five months he could evacuate the bowel without much distress; but at the commencement of the present year complete obstruction took place, accompanied by great distension of the abdomen, for which, ten days later, he was admitted into St. Thomas's Hospital. On admission he complained of dyspnoea and retching, but without actual vomiting. A nodular mass could be felt projecting into the rectum, hard and inelastic, almost obliterating the canal. The following day an incision was made midway between the last rib and the iliac crest, horizontal, with a slight inclination upwards and outwards, from three inches and a half to four inches long. The erector spinor was partially divided, and then the quadratus lumborum inwards, on a director, to the extent of an inch and a half. The abdominal fascia was similarly treated, leaving the bowel exposed; this was fixed by means of two silk sutures to the edges of the wound, and the gut opened transversely by means of scissors. Very little blood was lost, and three pints of liquid faeces came away, with intense relief. During the afternoon more liquid faecal matter was discharged per anum. On the following day the pulse was 86; he had slept well, and eaten a chop for dinner. The wound showed no inclination to close, and slight prolapse of the bowel was easily checked by an oiled sponge plug. For six days he did very well, except that there was a tendency to the formation of bed-sores. Thirteen days after the operation he sat up two hours daily, and seemed better, faeces passing both by the wound and anus. But on the twenty-first day collapse, vomiting, and swelling of the face came on, followed by great dyspnoea and extensive mucous crepitation in the chest, which increased so rapidly as to carry him off in a few hours. At a post-mortem examination, tubercle was found in both lungs, which were oedematous, with much injection of the bronchial tubes. The caecum was distended by gas, and was adherent to the sheath of the right psoas muscle, in which was an abscess extending to its origin, containing several ounces of thin fetid pus. There was a free opening in the descending colon, where it was uncovered by peritoneum, and its edges were adherent to the wound. The sigmoid flexure contained solid faecal matter. The rectum was embedded in a firm mass of infiltrated tissues, adherent to the pelvis posteriorly and to the bladder in front. The deposit was firm, fibrous, and juicy. A softer growth projected inwards round the whole circumference of the bowel, so as almost entirely to obstruct it; below the tumour was an ulcerated surface of the intestines, two or more inches across, where the coats of the bowel were entirely destroyed. The scirrhus mass under the microscope showed fibrous tissue, with cells of various sizes, mostly round, and containing minute oil globules. The liver contained several masses of scirrhus, most of them presenting traces of central degeneration. The fourth case resembled the preceding up to a certain point, where it diverged in consequence of the operation not having been performed, and the patient dying rapidly from rupture of the bowel. W. C., aged 55, a member of the College of Surgeons, was a ruddy and robust man, of very active habits, subject to no illness except occasional attacks of gout. In April, 1863, he had a severe attack of what he termed colic, for which his father-in-law, a retired Practitioner, successfully treated him. Even at that period Mr. Solly saw reason to diagnose stricture of the large intestine, though the patient attributed his symptoms to gout, and did not formally request his advice until two months later. On a first visit he was in great pain, and the abdomen was so tender as to preclude close examination. Palliative treatment mitigated the symptoms for a fortnight, and then the author was again hastily summoned to Tunbridge Wells. Examination of the rectum by means of the finger and a soft bougie revealed an obstruction at its upper part. The abdomen was intensely distended with flatus, although small quantities of faecal matter were once or twice evacuated. It was suggested to open the descending colon in the left lumbar region, but postponed for the opinion of an eminent Surgeon, who came to the conclusion that it was not desirable. Accordingly Mr. Solly unwillingly relinquished the proposal under protest. Within twenty-four hours the

patient died in great agony, with symptoms of ruptured bowel. On post-mortem examination, the abdomen was tense, and prominent above the umbilicus. The lower part of the descending colon presented a small perforation, from which half an ounce of faecal matter had escaped. There were no signs of recent peritonitis; and the intestines were healthy except at the sigmoid flexure, where a mass occupied the interior of the gut, of a scirrhus hardness, measuring over three inches across. Several pulpy, lobulated portions of this occupied the calibre of the tube, fitting into each other like cogs of wheels. No other morbid condition was found. Before opening the abdomen a trocar had been introduced at the spot where the proposed operation would have been performed, and its point was found in the intestine an inch and a-half above the diseased mass. In commenting on this case, it was noticed that death had obviously been the result of obstruction, not of any rapid malignant growth, and that life would undoubtedly have been prolonged by the operation for an indefinite period. Moreover, the valvular form of the obstacle was pointed out, and the possibility of the original channel becoming pervious when the accumulation above was removed by operation, as had actually occurred in the third case. Lastly, attention was directed to the fact, already noticed by Mr. Quain in his work on this subject, that obstruction might be complete and prove fatal even when the autopsy did not exhibit total occlusion of the intestinal canal. (A drawing of a portion of the intestine in this case was exhibited.)

Dr. BELL rose for the purpose of making a few remarks on the interesting paper which had just been read, not only from the impression that in advocating a new operation or mode of treatment it was of the utmost importance that the data on which we proceed should be correct and well founded, but because one of the cases (the fourth) referred to by Mr. Solly occurred in a patient of his (Dr. Bell's), in regard to which he thought he could give such information as would enable the Society to come to a just conclusion on the subject. This patient came under his care in the month of March, 1863, suffering from dyspeptic symptoms; these were relieved, and he then went on a visit to some friends, where he over-exerted himself, and he returned worse in health than when he left home. He called on Dr. Bell soon after his return, and left a message saying he wished to see him. Dr. Bell in consequence saw him on May 6, and, from his sufferings, was induced to examine him in the recumbent posture, when he discovered a tumour, of the size of a cricket-ball, about three inches below the umbilicus and rather to the left of the median line. The tumour could be readily distinguished from the folds of the intestine by percussion, which, owing to the tenderness, required to be done with great gentleness. He was surprised to find that Mr. Solly's report was totally at variance with the facts of the case as they came under his (Dr. Bell's) observation in the course of his attendance on the patient, during which he saw him once or twice a day. Peritonitis appeared on the 10th of the month, and on the 11th he was surprised, on making his afternoon visit, to find Mr. Solly sitting in consultation with the father-in-law of the patient: he was not aware that he had been sent for. Immediately on his entering the room, Mr. Solly told him he had resolved to operate on the patient, which he (Dr. Bell) decidedly opposed. He certainly felt aggrieved by the statement that had the operation been performed the patient would still have been alive; for Dr. Ferguson, after carefully examining the patient, fully corroborated his (Dr. Bell's) view of the case, and said distinctly that the operation was not justifiable, and never could become so during the lifetime of the patient. The same opinion was given by Mr. Fergusson, who considered the great risk was that the patient would die on the table. During the whole course of the case the bowels were frequently moved by enemata. He (Dr. Bell) left to Dr. Wardell the description of the post-mortem examination, which fully bore out the correctness of his opinion. With regard to the diagram on the wall, it was the most fanciful production he had ever seen: it resembled nothing human.

Dr. COPLAND had been consulted in two or three cases of obstruction of the intestines as to the advisability of performing an operation for their relief. In every case he recommended the introduction of a long flexible tube as high up as possible into the passage. This had been successful, although the operation for artificial anus had been about to be commenced. The patients lived some time afterwards. He inquired whether in the four cases related by Mr. Solly this plan had been resorted to previous to the operation.

Dr. WARDELL said that on May 7 Dr. Bell desired his

opinion on the fourth case related in the paper read by Mr. Solly, and that he gave it as being one of a malignant tumour pressing upon some part of the large bowel. The history and symptoms all warranted this conclusion. The patient's friend, Dr. Branson (consulting Physician to the Sheffield Infirmary), consulted with them on the 9th, when he fully and entirely agreed with them. On that day a large injection was given, which thoroughly cleared out the colon, but did not remove the tumour in the left hypogastrium, which was round, hard, and the size of a cricket-ball. Acute peritonitis set in. On the 11th, Mr. Solly was telegraphed for. On his arrival, to Dr. Wardell's astonishment, he wished to perform the very serious operation for artificial anus, which he (Dr. Wardell) stoutly opposed, because the colon was unquestionably well-nigh empty; because he regarded the case as one of acute peritonitis, caused, it is true, by contraction, but not occlusion of the passage; because it was almost certainly cancer; because fecal matter could pass of the size of walnuts; and because he conceived his chance of life greater by Medical than Surgical treatment. Dr. Ferguson, of London, came down on the 27th, when he confirmed the diagnosis, and was utterly against the operation. Mr. Fergusson was also summoned, and on the 29th he deliberately gave it as his opinion also that opening the colon was not warrantable.

Dr. Wardell was now proceeding to read the post-mortem examination published by Dr. Bell, when the President reminded him that time was very short, and as others wished to speak, he must request him to omit reading it, but make a statement.

Dr. WARDELL then distinctly affirmed that the description given in the paper just read was most incorrect. Mr. Trustram denied the existence of peritonitis, when there were pints of serum (which ran out on the table), bands of lymph, agglutinated and injected intestines. The colon contained but little fecal matter. The rupture was not a slit, but punched, round, the result of ulcerative absorption. The calibre of the bowel was much encroached upon by annular nodules of colloid cancer, but not occluded. Fæcal matter continued to be passed of the size of walnuts. He maintained that it was not a case for operation, and Dr. Ferguson and Mr. Fergusson still endorse this opinion. With regard to the drawing on the wall, he most emphatically declared that no sketch was ever taken of the morbid parts; that it was a thing of fancy, or exaggeration, and most unlike the diseased appearances which the autopsy revealed.

Mr. TRUSTRAM had been called in to this case after a course of fruitless medication had been employed. He had no doubt there was some mechanical obstruction, and had doubts whether an operation might be successful, because he believed, as did the patient, there might be an obstruction higher up, in addition to the one which was present in the rectum. This opinion was fortified by the very great distension which existed about the umbilicus. He (Mr. Trustram) was anxious that the reputation of the operation should not be perilled by its performance in a case which in some respects presented such an unfavourable aspect. With respect to the post-mortem examination, he could positively state that there were no signs of recent inflammation, though there were marks of an old attack of peritonitis. The quantity of fluid was very small, and there was a little fæculent matter in the colon. The drawing on the wall was a rough, but not inaccurate representation of the affected part. He had attempted to pass a bougie in this case, but had not persevered in the effort for fear of mischief. No tube had been inserted for the same reason. Mr. Solly had advised the operation, and he (Mr. Trustram) now believed that if it had been performed when first suggested the patient might have been alive, and have been present to hear his own case read! (A laugh.) He (Mr. Trustram) knew that there was a cancerous mass in the rectum, as cancer-cells had been found on a bougie which had been introduced. Cases of this kind he believed would be more or less successful as they were performed at an early or late period. He had seen cases lost by delay.

Mr. CURLING wished to make some observations on Mr. Solly's paper, but had no desire to enter upon the personal matters which had been introduced into the discussion. And yet he ought not, perhaps, to shrink from offering some opinion on the propriety of an operation in the fourth case. So far as he could arrive at a conclusion from the account which had been given, he thought that had the lumbar colon been opened at the time of Mr. Solly's first or second visit life might have been prolonged, but that on the last occasion it was too late for operative interference. He reminded Dr. Copland that these

were not doubtful cases of obstruction, but ascertained cancerous strictures; and a long tube, unless used with great care, was very liable to penetrate the peritoneal cavity. He had seen one instance in which this had occurred. The *Transactions* of the Society were rich in cases of lumbar colotomy, and Mr. Caesar Hawkins had collected and analysed a large number of cases. Since then the operation had been performed in a great many instances. He had himself done it five times, and assisted in three other cases; and he viewed it as one of the established operations of Surgery. But what he had heard on that occasion led him to think, with Mr. Solly, that Amussat's operation was not sufficiently appreciated by the Profession, and that its difficulties and dangers were much exaggerated. He took exception to the remark of Mr. Solly, that the operation was called for in properly selected cases—meaning cases only of intestinal obstruction. Surgery had, he considered, advanced beyond this, and there were other conditions in which the colon might be opened in the loin with great relief to the patient. He dwelt on the miseries of cancerous disease in the rectum, the incontinency, scalding evacuations, and the passage of fæces through the vagina and by the bladder and urethra. These miseries might be removed by the formation of an artificial anus in the loin. The operation could be performed even when the colon was not distended: in three of the cases in which he had operated the colon was contracted. An anus in the loin was not so inconvenient as was commonly supposed. A case was related in the Society's "Transactions" in which this operation had been performed in South America, by Pennell, in 1849. The stricture in the rectum was not malignant, and the patient recovered, and some years afterwards came over to this country, when he (Mr. Curling) had an opportunity of seeing him, and could bear testimony to the slight inconvenience occasioned by the aperture. The operation had already been adopted in some few cases for the relief, chiefly, of the distressing symptoms of cancer. He had himself done it in one instance with benefit, and regarded the operation as a step in advance and as a boon to the suffering patient.

Dr. WYNN WILLIAMS, in justice to provincial Surgery, wished to state that the first two operations for artificial anus in this country were performed by Mr. Clement, of Shrewsbury. In one instance the patient survived the proceeding for three years. Eight-seven plum-stones were found in one of the cases; these would not have been removed by the introduction of a tube.

Mr. SOLLY, in reply, said that he had no personal feeling in the matter, which he had treated simply on its scientific merits. He had not in either of the cases detailed introduced a tube, as recommended by Dr. Copland; in all cases of cancerous disease such a proceeding was attended with danger. He had certainly examined the last case with a bougie, but he did not attempt to pass it through the obstruction in consequence of the peril which it involved. Dr. Wardell had stated that the patient had been in bad health for some time; but he (Mr. Solly), having had an intimate knowledge of him for thirty years, could positively state that until within a few days of his death he was well and robust.

DISCHARGE OF A PORTION OF THE ILEUM PER ANUM.—Dr. Bare relates the case of a woman who, jumping from a fence, felt something give way in the abdomen, causing severe pain. When he saw her four hours afterwards, the pain, seated below and to the right of the umbilicus, had become excruciating, the skin being cold and clammy, the pulse thready and 122, and the thirst incessant. Believing this to be an example of intussusception of the ileum, Dr. Bare studiously avoided all means calculated to increase peristaltic action, gave large doses of opium and morphia, with an occasional blue pill. Demulcents, with laudanum, were also injected. On the third day the bowels were evacuated by means of a more stimulating injection, and the abdomen being distended, a large blister was applied. On the fifth day, air passed through the intestines. On the seventh day, castor-oil and laudanum were given; and from the eighth to the tenth days, excessive diarrhœa prevailed, requiring acetate of lead and opium. The patient's strength was kept up by injections of chicken-broth; and on the thirteenth day a portion of intestine, about thirteen inches long, was discharged. From this time the patient gradually recovered, and six months after only suffered from indigestible food as it passed the stricture.—*American Quarterly Journal*, October, p. 561.

OBITUARY.

THE LATE DR. CARLYON, OF TRURO.

TRURO has lost the most beloved, the most venerated, of her sons. No one at all familiar with the place and its history could doubt that these terms can apply only to Dr. Carlyon. We have long regarded with something of the tenderness that attaches to the memory of the dead this now departed representative of a generation of whom scarce another is left; and we owe it to ourselves as well as to him whose departure from among us we lament, to devote a few lines to the history of one so conspicuous for public and private virtues, and so dear to our whole community.

Dr. Clement Carlyon, a scion of an ancient Cornish stock, was the youngest son of the Rev. John Carlyon, of Truro, and of Miss Mary Winstanley, of Braunston Hall, Leicestershire, and was born on the 22nd of April, 1777. His father had been a Fellow of Pembroke Hall, Cambridge, and had gained high honours there. He was offered valuable preferment in a distant county, which he declined, although non-residence was allowed, because he did not consider himself strong enough for the full performance of its duties; and he passed a happy and useful life in Truro, whilst bringing up most excellently a large family of sons and daughters.

Clement Carlyon, like his brothers, was educated at the Truro Grammar School, then most successfully conducted by the Rev. Dr. Cardew, where he had for companions, among many others afterwards distinguished, the illustrious philosopher and chemist, Sir Humphry Davy; Henry Martyn, the missionary; and Prebendary Kempthorne, the well-known Chaplain of the Bishop of Gloucester. Each of the two last attained the pre-eminent position of Senior Wrangler, at Cambridge, and all these maintained in after life their friendly intercourse with their schoolfellow, Carlyon. He proceeded, like these great men, at once from Truro School to College, and he went out as Tenth Wrangler in 1798. In the same year he was chosen a travelling bachelor, an appointment to which the annual stipend of £100 was then attached, with the condition that three years should be devoted to foreign travel, and that an account of what had been noticed should be periodically given in Latin letters to the University. During these journeyings, which embraced the whole of Central Europe, and extended to the northern parts of Sweden, he had for his principal companion the late Dr. Parry, son of the famous physician of Bath, and brother of Sir Edward, the Arctic navigator; and their excursions were frequently shared by the poet and philosopher, Samuel Taylor Coleridge. Of him, and of other remarkable men with whom he was more or less associated abroad at that critical period of the world's history, the close of the last century and the beginning of the present, he has recorded many interesting personal traits in the volumes of his "Early Years and Late Reflections," a work of his elder leisure, which includes his reminiscences of Sir Walter Scott, Mr. Abernethy, and other celebrities of that day, with whom he was brought in contact during his medical studies in Edinburgh and London. Dr. Carlyon was elected to one of the valuable Fellowships of Pembroke Hall, soon after he took his B.A. degree, and he held it till his marriage, in 1806, to his cousin, Eliza, a daughter of Mr. Carlyon, of Tregrehan. Before this conclusion of bachelor life, he had proceeded from the degree of M.A., to that of M.D., and settled as a Physician at Truro, where he speedily acquired the confidence of a large circle of society, including many of the principal families of Cornwall—a confidence which was rendered permanent by the remarkable combination exhibited in his character of the highest qualities of the friend and the gentleman with those of the Medical adviser. He was in truth a model Physician of the old school, a shrewd and quick observer of symptoms, full of ready resource for their treatment—clear and prompt in judgment—delicate in tact—and, above all, large and warm in heart—so that all his powers moved in active concert for the service of his patient. In 1827 he published a pamphlet on the "Endemic Typhus Fever of Cornwall," in which the principles of sanitary science, of late familiarised to the public mind through so many channels, but then quite novel, are enforced with the greatest clearness of detail and weight of argument. Before this time Dr. Carlyon had become one of the Physicians to the Cornwall Infirmary, a field of usefulness to the poor in which he delighted; and his services there were but justly estimated by the governors when on his retirement in 1849 they pre-

sented him with a very valuable and suitably inscribed salver. In connection with this Hospital, and by every available channel, he urged forward with exemplary zeal, from its first introduction, the practice of vaccination. He withdrew almost entirely from private practice about the same time when he gave up his public Medical appointment; but his interest in his Profession, in its study as well as appliances, continued always lively; and down to his latest years many a poor sufferer has been indebted to his assiduous skill, bestowed on local as well as general maladies, for recovery or relief.

Dr. Carlyon now employed his greater leisure in the diligent promotion of the useful and charitable institutions of his town and county, for both of which he was a magistrate. To the Lunatic Asylum, at Bodmin, he devoted particular attention. In the working of the Truro Savings Bank, in whose establishment he took a leading place, he was always greatly interested, and little more than a month before his death he presided with unimpaired vigour over the latest important meeting of its managers. In the municipal affairs of Truro he had always taken a very active part, and five times he filled the civic chair; a fact recorded on his marble bust, the excellent work of Burnard, placed in the Council Chamber, in 1849, after the completion of those handsome halls, over the erection of which he presided during three successive mayoralties. The town owes mainly to his efforts the memorial column and fine statue of the traveller Lander; and the poor are entirely indebted to him for the cottages connected with the Truro Friendly Society, which he founded.

Those literary pursuits which "Rome's least mortal mind" has called the delight of old age, also engaged much of Dr. Carlyon's later years. He held a facile and graceful pen, and his writings reflect the same qualities of mind and character which we have described as belonging to him in social life. We have mentioned his "Early Years and Late Reflections," perhaps his most interesting and valuable work, certainly that which best exhibits his individuality, as it is there the records of his life, as well as of his thoughts, are to be found. His "Precepts of Health" is a pleasant and forcible exposition of his experience, in confirmation of the maxims of old Louis Cornaro, well supported, assuredly, by the hale and cheery aspect of the author.

Dr. Carlyon was a truly religious man. In his early days his faith had stood firm among the sceptics and scoffers of the school of Voltaire, and it was the mainspring of his life throughout, maintaining its action so habitually as to be part and parcel of his common every-day nature, and to mix itself, even at the last, without any appearance of effort, with his consciousness that his end drew near—a cheerful, steady light of simple Christian confidence, which doubtless did much to render what it was his

"Death-like sleep,
A gentle wafting to immortal life."

Under this paramount influence, he devoted almost all his more recent publications to religious topics. He was strongly attached to the Church of England, but thought he saw, in certain of her formularies, occasions of stumbling to the weak; and he wished the Surgical knife to be applied to these, as he considered them, morbid excrescences. His "Scripture Notices and Proofs" was his earliest, and is his most considerable effort in this direction; several shorter essays followed it, and the latest of these, bearing the appropriate title of "A Last Attempt," has only just come out of the printer's hands. In this connection we cannot but allude to the full flow of Christian sympathy with which he welcomed the efforts of all true-hearted labourers in the Gospel field, though beyond his own particular pale; to the services of Wesley and his followers, past and present, he especially rejoiced to pay his cordial tribute.

Dr. Carlyon was a rather strong politician in his prime of life—a good old Tory—and he fought well as a partisan. He made, however, but few enemies—in fact, he was a good friend, but he was not a good hater—and he lived to be almost a reformer. He was fond of the country—of nature altogether—of his farm, of his dog and gun, but especially of his fishing-rod. The last year of his life witnessed successes of this veteran Waltonian. He was a whole man, body as well as mind. He did not concur with some respectable people who regard sports and amusements as unbecoming the gravity of mature age and learned professions, or as puerile interruptions to the pursuit of gain.

To such a man, whose chief desire is to be useful and to be loved, a town of moderate size has some advantages over

those populous cities in which the larger prizes of ambition are to be won, but where it is not possible for any individual to see a friend in almost every one he meets, bound to him by some kindness or courtesy received. Such was Dr. Carlyon's position in Truro, and as a fatherly friend will he be missed—as the embodiment, too, of what was most worthy our respect in the past age and our love in the present.

Dr. Carlyon must be considered to have had a happy life in all that best constitutes happiness. Of his outer world we have said something; his domestic relations we believe to have been in every way blest. What he was to the world outside he was in more than double measure by his own hearthstone; and we know that his love has been well returned. The wife whom he married in 1806 was parted from him little more than two years ago, and of their numerous family not one has been taken from them. They lived to see their children happily settled, and their descendants to the fourth generation. We may be allowed further to express the satisfaction which all around us feel in common with ourselves that it was permitted to him whom we mourn to enjoy, as a bright gleam in his evening sky, the recognition of the merits of his son-in-law, Dr. Harold Browne, in his elevation to the Bishopric of Ely, with the hearty approval of the whole Church—we may say, the whole nation.

Dr. Carlyon has died at the ripest age, within a few weeks of eighty-seven, but without decay of faculties or anything like decrepitude. His benignant smile had not lost its glow, nor had his cordial “manly voice been turned again towards childish treble.” Alas, that we must know them no more! He will, before these feeble sentences are printed, have been followed to the grave by the benedictions and gratitude of the poor, and the unmixed esteem and love of every class:

“He was a man, take him for all in all,
We shall not look upon his like again.”

—From the *West Briton and Cornwall Advertiser*, March 11.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a General Meeting of the Fellows, held on Monday, April 18, Augustus Ward Clement, 78, Upper Berkeley-street, formerly an Extra-Licentiate of the College, was duly admitted a Member. At the same meeting, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Henri Victor Bertin, 26, Alpha-road, Regent's-park; Jean Baptiste Blanchot, M.D. McGill College, Montreal, Quebec, Canada; John Legge Currie, 42A, Charterhouse-square; Henry John Hunt, 18, Portugal-street, Lincoln's-inn-fields; Charles Perks, Lichfield; George Edward Pyle, Middlesex Hospital; Alexander Waugh, Corsley, Warminster; Connell Whipple, Plymouth; William Samuel Wilson, 34, Hereford-road North, Bayswater; Sedley Wolverstan, Plymouth; Edward Miles Coverdale Hooker, Hadlow, Tunbridge; and Andrew Nash, Jamieson, Victoria, Australia.

The following gentlemen were reported by the Examiners to have passed the First Part of the Professional Examination for the Licence:—

Allen Fennings, Charing-cross Hospital; William Iliffe, St. Bartholomew's Hospital; Frederick William Humphreys, Guy's Hospital; Josiah Court, Guy's Hospital; Richard S. P. Griffiths, St. Mary's Hospital; Hamilton de Tatham, St. Mary's Hospital; Franklin Gould, King's College; Gifford Ransford, St. George's Hospital; George Arthur Kenyon, St. George's Hospital; Walter Lattey, St. George's Hospital; Howard Barrett, St. George's Hospital; William S. Wilson, Westminster Hospital; and John George Frederick Wilford, Guy's Hospital.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their First Professional Examinations during the April sittings of the examiners:—

P. O'Neill, Castledermot; David Young, Perth; James Vince Worthington, Lancaster; Frank Godfrey, Salisbury; Thomas Wardleworth, Lancaster; Edward M'Craith, County Cork; William Young Veitch, Coundon; Aubrey Wicks, Cambridge; Henry Cornish, Taunton; William Chisholme, Edinburgh; William E. Steel, Blaenarvon; John Mickle, Douglas; David J. Walsh, County Cork; George L. Carriek, Constradt; William Duguid, Elgin; A. H. Allshorn, Enfield; Patrick Kynock, Roxburgh; William J. Elmslie, Aberdeen.

And the following gentlemen passed their Final Examinations, and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh:—

Francis Codman Ropes, London; William Lawton Eames, County Cork; David Topham, County Cavan; John Crerar, Perthshire; James Jamieson, Bowden; James M'Caul, Edinburgh; Alexander Laing, Aberdeen; William Dunbar Cosgrove, Aberdeen; William Stuart, Ayrshire.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a Meeting of the Court of Examiners on the 14th inst., and, when eligible, will be admitted to the Pass Examination:—

Edwin Atherstone, J. F. Plomley, J. W. Smith, John King, E. F. J. Cole, F. J. Greening, F. S. Mainsty, R. F. Nell, Frederick Marshall, and Fenwick Metcalfe, Students of King's College; J. E. Eaton, David Sharp, A. C. B. Melhado, R. A. Rix, R. G. Roper, and W. J. Wane, of St. Bartholomew's Hospital; C. V. Helsdon, V. E. Noel, and J. F. Cadle, of the Middlesex Hospital; John Ruby, F. H. Ward, and H. H. Birtwell, of St. Thomas's Hospital; W. J. Burt and F. K. Hampshire, of St. George's Hospital; R. P. Goodworth and Rees Llewellyn, of the London Hospital; Campbell Fair and Daniel Costelloe, of Dublin; Henry Sainsbury and William Thomas, of Birmingham; G. P. Bate, of the Westminster Hospital; and S. J. Hulme, of Manchester.

The following passed their examination on the 19th inst, viz.:

Messrs. Francis Bateman, G. F. Maberly, J. T. Jacques, Henry Rundle, J. O. Adams, Lytleton Hallett, A. Mc J. Tindall, J. W. Hembraugh, and L. H. Reid, Students of St. Bartholomew's Hospital; Clarence Visiek, C. F. C. Foxon, G. S. Watson, C. E. Hocken, William Bruorton, and F. M. B. Sims, of St. George's Hospital; Augustus Müller, S. J. Knott, Thomas Leah, N. T. J. Haydon, and W. Le G. Denziloe, of St. Mary's Hospital; R. S. Smith, Charles Kelly, Geoffrey Hett, and A. F. Hill, of King's College; F. E. Manby, W. M. Knipe, J. S. T. Perkins, and James Haslam, of Guy's Hospital; G. O. Spencer, A. H. Martin, and W. A. Stuart, of University College; H. M. Body, and R. Y. V. Packman, of Charing-cross Hospital; C. G. Firmin, Middlesex Hospital; and Samuel Oldham, of Manchester.

On the 20th inst. :—

Herbert Lucas, H. G. Budd, Clement Palmer, Henry Whiting, G. J. B. Stevens, Joseph Riley, H. C. Smith, and William Hawett, Students of Guy's Hospital; G. F. Pritchard, A. A. Corte, J. H. Wright, E. C. Evans, and J. F. Hussey, of King's College; Richard Pughe, Thomas Flower, R. M. Williams, and W. G. Jones, of the Middlesex Hospital; J. A. White, W. F. P. Davies, W. A. Renshaw, and J. H. Worsley, of Manchester; O. T. Gronow, J. H. Webb, and H. de Tatham, of St. Mary's Hospital; C. A. Brigstocke, Joseph Goodall, and Robert Robinson, of St. Bartholomew's Hospital; H. C. Wigg and R. D. Logg, of University College; George Aekroyd and T. E. G. Bywater, Leeds; W. G. Sutcliffe, Charing-cross Hospital; and James Hickinbotham, of Birmingham.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their First Professional Examinations during the April sittings of the examiners:—

Cuthbert H. Robinson, Yorkshire; John D. Lytle, Maghera; John Adolphe Moniot, Penang; Horatio D. S. Compigne, Gosport, Hants; Peter M'Arthur, New York; James Smith, Dumfries; George A. Christie, New Brunswick.

The following gentlemen passed their Final Examinations, and obtained the Diploma of the College:—

Alexander Gordon Miller, Edinburgh; James Hunter, Ayrshire; Wm. Bruce, Edinburgh; Samuel M'Crea, County Down; Andrew David Ducat, London; Eugene Valentine MacSwiney, County Cork; George Bridges Mouat, Stirling; John Miller, Edinburgh; Andrew Barrie, Glasgow; William Henry Semple, Stranraer; Samuel Wordsworth Poole, Edinburgh; John Burke Gaffney, County Roscommon.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 14, 1864:—

William George Vawdrey Lush, Wilton, near Salisbury; George Lamb, Hull; James Thomas McMahon, Rochester-terrace, Camden-town; Andrew Rowan, Station-terrace, Hull; Thomas Clave Shaw, Stockport.

The following gentleman, also on the same day, passed his First Examination:—

Thomas Franklin Lloyd, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLINGHAM, Mr. JAMES, has been elected Assistant-Surgeon to St. Mark's Hospital.

CARTER, THOMAS A., M.D. Edin., has been appointed Physician to the Leamington Hospital.

COOPER, ALFRED, M.R.C.S. Eng., has been elected Assistant-Surgeon to St. Mark's Hospital.

ELLERTON, J., M.D., has been appointed House-Surgeon to the North Riding Infirmary, Middlesborough-on-Tees.

HARRISON, REGINALD, M.R.C.S. Eng., has been appointed Demonstrator of Anatomy at the Liverpool Royal Infirmary School of Medicine.

IRVINE, GEORGE R., M.D. St. And., has been appointed Assistant Medical Officer to the Rainhill Lunatic Asylum, near Liverpool.

MALLAM, H. P., M.R.C.S. Eng., has been elected Medical Officer for the Workhouse and Industrial School, Oxford.

PHILIPPS, ALFRED, M.R.C.S. Eng., has been appointed House-Surgeon to the Manchester Workhouse.

ROBERTS, ROBERT, M.R.C.S. Eng., has been elected Surgeon to the Festiniog Hospital.

ROCHE, R., L.A.H. Dub., has been appointed Apothecary to the Workhouse of the Listowel Union, Co. Kerry.

WILLET, C. V., M.R.C.S. Eng., has been appointed House-Surgeon to the Great Northern Hospital.

WILLIAMS, WILLIAM, M.R.C.S. Eng., has been elected Surgeon to the Festiniog Hospital.

YOUNG, ADAM, L.R.C.P. Edin., has been appointed to the Commission of the Peace for the Borough of Boston, Lincolnshire.

DEATHS.

BLACK, THOMAS HENRY, M.R.C.S. Eng., at Marcus-square, Newry, Co. Down, on March 30.

BOULTON, JAMES, L.S.A., at Stone, Staffordshire, on April 1, aged 56.

DIXON, F. B., M.D., at Hackney, N.E., on April 4, aged 50.

DUCAT, CHARLES, M.D., late of H.E.I.C. Service, at Hastings, on April 18.

HERBERT, JOHN, L.F.P.S. Glasg., at Airdrie, Lanarkshire, on March 29.

McCOMBE, THOMAS SHERIFF, L.F.P.S. Glasg., at Antrim, Co. Antrim, on April 12, aged 38.

MINTER, MICHAEL, M.D., at Mount Moriac, Geelong, Australia, on January 31, aged 57, formerly of Folkestone, Kent.

PARKS, JOHN, M.R.C.S. Eng., at the Wyld, Bury, Lancashire, on April 10, aged 57.

PERFECT, THOMAS W. CHAMBERLAINE, M.R.C.S. Eng., at Hammersmith, near London, on April 13, aged 88.

PORTER, GEORGE M., L.S.A., at Caistor, Lincolnshire, recently.

SMITH, JAMES C., Assistant-Surgeon 1st Battalion 19th Foot, at Ferozepore, India, on February 13, aged 31.

TURNBULL, W., Surgeon, Madras Service, at Aldroughy, on April 8.

THE REPRESENTATION OF FINSBURY.—There promises to be a sharp contest for this borough on the resignation of Sir Morton Peto. Besides those gentlemen's names which have already appeared, and whose claims are put forward for the seat about to be vacated, that of Dr. Lankester is mentioned; and we hear of a meeting having been held at which that gentleman's merits were discussed, and many promises of support were given.

PROFESSOR PARTRIDGE AND GARIBALDI.—The following letter appeared in the *Times* of April 18:—

To the Editor of the Times.

"Sir,—I saw General Garibaldi, by appointment, at Stafford House yesterday morning, and I am able to state, for the comfort and reassurance of the numerous friends who are interested in his welfare, that his visit to this country is quite unconnected with any seeking or necessity for Medical or Surgical opinion or treatment; this statement is due also to the able Italian Surgeons to whose unremitting care and skill (aided by his own excellent constitution and abstemious, active habits) the General is indebted for his successful cure.

"The fact is that General Garibaldi's health, which had been somewhat impaired by the long confinement of his wound so as to render a change of air and scene desirable, is now quite restored, and he looks and declares himself to be in excellent condition.

"The limp, and use of a stick in walking, are owing to a remaining stiffness of the ankle-joint, and of the sheaths of the surrounding tendons; but as the articulation retains some degree of movement, and the foot is in a good position—at right angles with the leg—it is not improbable that with time, care, and moderate exercise, the joint will become, so to speak, more supple, and that eventually, though a certain degree of lameness must always exist, a useful and active limb will be obtained. With regard to the present condition of the leg and foot, there is no swelling nor inflammation of either, the wound has quite healed, is free from discharge, and though the scar is a little tender, and requires the protection of a slip of plaster, there is no present sign of abscess, nor of the existence of more particles of dead bone to come away. The foot, indeed, is turned a little inwards, but it has been so ever since the injury; and this is owing to the loss of support to the foot derived from the inner ankle, the bone of which was broken by the shot, and was afterwards cast off, or exfoliated.

"The General is able to bear the whole weight of his body upon the injured limb, which is quite free from pain, except after over-exertion in standing or walking.

"I am, Sir, your obedient servant,

RICHARD PARTRIDGE.

"17, New-street, Spring-gardens, S.W., April 15.

"P.S.—Those of my Professional brethren who feel an interest in the Medical and Surgical history of the General's case will find it fully detailed in the pamphlets of Drs. Ripari and Basile, published at Milan and Palermo respectively, and copies of which I have presented to the libraries of the College of Surgeons and of the Medical and Chirurgical Society."

GARIBALDI'S DEPARTURE.—We reprint the communications from Mr. Fergusson to the Duke of Sutherland and Mr. Seely, which decided the friends of the gallant soldier to permit him to shorten his visit:—

(Private.)

(Copy.)

"16, George-street, Hanover-square, April 17.

"My Lord Duke,—I see by the papers a gradually-extending list of places which General Garibaldi has promised to visit during his brief stay in this country, and have reason to know that the list is rapidly increasing.

"As the General has done me the honour of consulting me regarding his health, I take the liberty of stating to you, as one of his warmest English friends, that I should greatly dread the effect of so much continued excitement as these intended visits imply. I doubt if the strongest could endure as much, and if you have any influence with the General (as doubtless you must have) I implore you to do your best to set aside much of this intended fatigue, as already I have noticed occasional indications of fatigue; and, considering the usual habits of my illustrious patient, I must say that I should dread the effects upon both his constitution and his limbs, for the sound one must suffer in the efforts to save the wounded, and were he to suffer in health in the way referred to, it would be a cause of deep grief to your Grace and to his admirers and friends, not only in England, but throughout the world.

"I have marked this note 'private,' but should your Grace feel impressed with what I have stated, you may show it to the General and to others interested.

"I have the honour to remain,

Your Grace's most obedient servant,

WM. FERGUSSON.

"To his Grace the Duke of Sutherland."

"16, George-street, Hanover-square, April 18.

"My Lord Duke,—With reference to my communication of yesterday, I beg to state that I have had an interview with General Garibaldi this morning, and have spoken with him directly on the subject. He admits that he is fatigued, and he certainly does not appear so fresh as when he arrived from the Isle of Wight.

"On several occasions he has spoken of the excitement and bustle around as being so different from all about him in the ordinary tenour of his life, and this morning he referred particularly to mental exhaustion from excitement more than to physical weakness.

"I certainly cannot take it upon me, as a professional man, to say that he is unfit to undertake any of his engagements in this country; but I have no hesitation in stating my firm conviction that by much work of the kind he would incur great and serious risk. Such, I believe, is the General's own opinion on the subject, and, if doubts remain, it might be advisable to call a consultation of several eminent professional men in London.

"I have the honour to remain,

Your Grace's obedient servant,

WM. FERGUSSON.

"His Grace the Duke of Sutherland."

"16, George-street, Hanover-square, April 16.

"My dear Mr. Seely,—I see by the papers that the General is engaging himself in all directions. The fatigue would be enormous. No Professional man could answer for it, unless, indeed, it were to say that it would kill the strongest. I have written to this effect to the Duke of Sutherland, and, as General Garibaldi is in a manner your guest more than of any other man, and as you have displayed to me so kindly an interest in his health, I wish to say that I think it incumbent on you and his other friends in England to suggest some such course as shall turn him from the fatigues these various provincial visits imply.

"Believe me, yours very sincerely,

"Chas. Seely, Esq., M.P."

WM. FERGUSSON.

A MISAPPROPRIATION OF PUBLIC FUNDS.—The prosecution in the Court-Martial upon Surgeon-General Hammond has recently closed without establishing one of the charges set forth in the indictment against him. It is to be regretted that a quarter of a million of the public money should have been thus expended in a vain attempt to blast the reputation of an officer whose administration of one of the most important Government Bureaux has challenged the admiration of the Medical Profession of this and foreign countries.—*American Medical Times*, March 26.

THE JACKSONIAN PRIZE.—The Council of the Royal College of Surgeons has just awarded the above prize to Dr. Morell Mackenzie, of George-street, Hanover-square, a member of the College, for his essay on the "Pathology and Treatment of Diseases of the Larynx." It is stated that there were no competitors for the other Jacksonian prize on the "Normal and Pathological Anatomy of the various Synovial Bursæ connected with the Muscles and Tendons of the Upper Extremity." There are three Jacksonian prizes to be awarded this year for the best essays on the following subjects—viz., "Club Foot: its Causes, Pathology, and Treatment;" "The Diseases of the Ankle-Joint, and of the Joints and Bones of the Tarsus, requiring Surgical Treatment; and stating the Treatment, including Operative, most suitable in each Case, with the Results thereof;" and "The Malformation, Diseases, and Injuries of the Fingers and Toes, with their Surgical Treatment. The Dissertation to be Illustrated by Preparations and Drawings." The Collegiate Triennial Prize subjects must be sent in before Christmas-day next. The following is the subject for competition:—"The Structural Anatomy and Physiology of the Lymphatic Vessels and Glands (the Anatomical Distribution not being required); the Communications (if any) between the Lymphatics and the Blood-vessels to be Demonstrated; and the Influence (if any) which the Lymphatic Vessels or Glands Exercise on the Fluid they Transmit, to be Elucidated. The Dissertation to be Illustrated by Preparations and Drawings."

A NEW FEVER NEST.—We have noticed the death of five of the ten resident Physicians of Bellevue Hospital who contracted the fever, and now have to record the fact that three more are prostrated by this disease. The Medical Board of that Hospital have taken the alarm, and urged the Commissioners to erect a Fever Hospital upon one of the islands under their charge. The Commissioners have moved in the matter, but, with characteristic disregard of their Medical advisers, have erected a barrack in one of the least ventilated and most public corners of the grounds at Bellevue.—*American Medical Times*, April 2.

ACCIDENTAL POISONING.—On Monday, April 18, the Liverpool borough coroner sat for the purpose of accepting bail for Mr. Richard Poole (assistant to Messrs. Clay and Abraham, pharmaceutical chemists), against whom a jury, on Saturday, returned a verdict of manslaughter. He had caused the death of Mr. John Lingard, a Liverpool tradesman, by making up a prescription with strychnine instead of James's powder. The coroner exhibited a number of bottles (Thouger's patent) which had been forwarded to him that morning, the object of the patent bottle being to prevent accidental poisoning. The bottle, or rather its label, the coroner said, had been approved by Dr. Lankester, in whose opinion he concurred. The ordinary dispensing label is surrounded by sandpaper, and a portion of the bottle covered by the same material, which, being felt by the dispenser or patient in handling the bottle, at once shows that it contains some dangerous preparation. At the inquest on Saturday, Mr. Bird, a Liverpool chemist, exhibited his safety poison bottles and corks to the jury and to the Medical witnesses who had given evidence in the case. Mr. Bird's contrivance would seem to be still more effective than that of Mr. Thouger. It consists of a stopper or cork, having sharp, angular points, which cannot be removed without inflicting considerable pain upon the hand, unless the dispenser puts down both the dispensing glass and the medicine bottle. By this contrivance, any one using the bottle would be so distinctly reminded that it contained poison, that a mistake could not occur even in the dark.

CONVICTION OF AN ILLEGAL PRACTITIONER.—On Saturday, April 12, at the Worship-street Police-court, Mr. Edward Tucker Jenkins, of 159, Lever-street, St. Luke's, was charged at the instance of Mr. James Ireland, a Medical man, with having unlawfully pretended to be a Physician, Doctor of Medicine, and Surgeon. Mr. Sleight, the barrister, instructed by Mr. T. W. Rogers, jun., of 70, Fenchurch-street, conducted the prosecution, and Mr. Nind, from Mr. Abbott's offices, appeared for the defence. Mr. Sleight said he appeared there to conduct a prosecution against the defendant, who was charged in the summons issued against him with having on certain days and times held himself out and professed to be a Physician, Doctor of Medicine, and Surgeon, thereby implying and leading the public to believe that he was legally and properly registered as such. He should be able to prove by evidence that this defendant had for some years carried on the business of a Doctor of Medicine and Surgeon both in the

New North-road and also in Lever-street, St. Luke's; that he had issued cards with that designation, calling himself "Dr. Jenkins, Surgeon and Accoucheur, 150, Lever-street, late John's-row, and at 11, Great Prescott-street; advice gratis from 9 to 11;" and that at his private residence he intimated he was at home from ten o'clock till ten o'clock, so that he must be there all night, while he also had a brass plate on his door calling himself a Surgeon and Accoucheur. He was thus ostensibly carrying on the Profession of a Surgeon, Doctor of Medicine, and Accoucheur, while he was not on the Medical Register at all, and had no title whatever to any such designation. He should now prove all that he had stated, and would call upon the magistrate for the infliction of the full penalty of £20. Mr. Nind said that, notwithstanding the serious results alleged to have been likely to follow his client's practice, no proof of a single case of such consequences had been adduced. He should be able to prove, from documents he held in his hand, that the defendant was a man of ability, and worthy the confidence which had been placed in him. It was true that he was not licensed or registered; but his father, who had been in the profession for years, was so. The defendant had been assistant also to his father, who had just died. In addition to all this he had letters from Messrs. Partridge, Ferguson, Tanner, and Lyons, of King's College Hospital, speaking of his diligence, readiness, and intelligence while assistant-dispenser there, showing he had the good opinion of all the Medical officers, and numerous other testimonials, expressing a conviction of his perfect competency as a Medical man. He attributed the prosecution to jealousy on the part of the Medical Profession. But he could not defend his client's conduct. However, the defendant intended shortly to pass an examination at Apothecaries' Hall, and he hoped that before twelve months expired he would legally be upon the register. Mr. Sleight warmly protested against such an unjustifiable imputation upon the Medical Profession as that just made of jealousy of the alleged success of the defendant. Immediately on hearing the announcement of the defendant's father's death he was about to rise and withdraw his pressure for the extreme penalty, and even now he wished to do so, in consideration of such a domestic misfortune. He and his clients would therefore be satisfied with any penalty the Bench might think would meet the case, and, so far from there being any feeling beyond vindicating the honour and the respectability of the Profession, they would not ask for any costs, not even those of the summons. Mr. Nind expressed his client's appreciation of this friendly act, and Mr. Leigh sentenced the defendant to a penalty of £5.

THE annual meeting of the Manchester and Salford Sanitary Association was held in the Town Hall, King-street, on April 6. The Bishop, who occupied the chair, paid an eloquent tribute to the memory of the late Alderman Neild. He said that the Manchester and Salford Sanitary Association exercised the most salutary influence in different branches of the community. He had read the report and the valuable papers of Dr. Angus Smith, Mr. Ransome, Mr. Royston, and Dr. Morgan with instruction, and with that instruction, said the Bishop, for which I confess I am always most grateful, for I felt I was not only made a wiser man by the information they gave, but a better man by the tone with which that information was communicated. Dr. Morgan read the report for 1863, which concluded by urging the establishment of an institution for the training of nurses for Manchester and the surrounding neighbourhood. It is intended that a certain proportion of these nurses shall, after suitable instruction in their duties, discharge the office of district visitors among the poor, imparting to them useful information on such subjects as the training and management of children and the preparation and cooking of food. Mr. Malcolm Ross said that every one who looked at the reports of the association must be struck with the self-denying labours of so many Medical men in the furtherance of the cause of sanitary improvement. It was a most gratifying thing that those who might be supposed to live by a contrary course should give so much of their time and services to the prevention of disease, which, to a certain extent, was the staff of their own existence. Mr. Thomas Turner said that a great desideratum towards the prevention of zymotic diseases, small-pox, measles, and scarlet fever was the means of separating infected from uninfected persons. It might surprise some to hear that, in the visitation of the sick suffering from small-pox, families had been found who obstinately persisted in refusing to allow their children to be removed from home, and who, indeed, kept the fact of the illness as quiet as possible, to prevent any interference. A

letter had been published suggesting the propriety of establishing a reception-house for children under 10 years of age, but he said that they must go higher than that if they wanted an institution likely to do good and to prevent the spread of contagious diseases. The Bishop, in conclusion, said it was his lot at a very early period of life to be associated with some of the most eminent of the Medical Profession. I remember, said he, the majestic form of Henry Cline; I remember Abernethy and those of that school, many of whom took kind notice of me in my boyhood days. I cannot say from that time to this that I have known any Profession whose self-denial, whose noble liberality, whose willingness and anxiety to sacrifice almost anything for the benefit of their fellow-creatures, has surpassed the members of that Profession. (Applause.)

THE BATTLE FOR LIFE BETWEEN THE NEW AND OLD WORLDS.—The first number of a new Journal, called the *Scientific Record*, contains some curious facts as to the naturalisation of European plants and animals in the New World. It would appear that, as in the case of the human inhabitants, there is a law that the new-comers should eventually take the place of the native denizens of the soil. "W. T. Locke Travers, Esq., F.L.S., an active New Zealand botanist, thus writes from Canterbury:—'You would be surprised at the rapid spread of European and other foreign plants in this country. All along the sides of the main line of road through the plains a *Poligonum aviculare* called "Cow Grass" grows most luxuriantly, the roots sometimes two feet in depth, and the plants sometimes spreading over an area from four to five feet in diameter. The dock *Rumex obtusifolius*, or *R. crispus*, is to be found in every river bed extending into the valleys of the mountain rivers, until these become mere torrents. The water-cress increases in our rivers to such an extent as to threaten to choke them altogether. In some of the mountain districts, where the soil is loose, the white clover, *Trifolium repens*, is completely displacing the native grasses, forming a close sward. In fact, the young vegetation appears to shrink from competition with these more vigorous intruders.' Dr. Hooker says that he has in vain urged on his colonial correspondents the importance of systematically recording and collecting facts on this important subject. Every problem of the geographical diffusion of plants is directly interfered with by these intruders. Mr. Darwin is the only author who has had the boldness to approach the subject. 'This great naturalist,' says Dr. H., 'believes that the facts hitherto observed favour the supposition that, in the struggle for life between the denizens of the Old continents and the New, the former ones are pre-potent; and he attributes this to the longer period during which they have been engaged in strife and the consequent vigour acquired. European weeds have established themselves abundantly in N. America, Australia, and New Zealand, but comparatively few plants of these countries have become naturalised, and ultimately complete weeds in England. We may hence infer why it is that the indigenous plants of St. Helena and Madeira show no tendency to increase, whilst European and African trees, shrubs, and herbs are rapidly covering those islands.' The rapid propagation of European animals is no less remarkable than that of plants. J. Haart, Esq., Government geologist, Canterbury, writes as follows to Mr. Darwin:—'The native (Maori) saying is, "as the white man's rat has driven away the native rat, so the European fly drives away our own; and as the clover kills our fern, so will the Maories disappear before the white man himself." It is wonderful to observe the botanical and zoological changes which have taken place since Captain Cook first set foot in New Zealand. Some pigs, which he and other navigators left with the natives, have increased and run wild in such a way that it is impossible to destroy them. There are large tracts of country where they reign supreme. The soil looks as if ploughed by their burrowing. Some station-holders of 100,000 acres have had to make contracts for killing them at 6d. per tail, and as many as 22,000 on a single run have been killed by adventurous parties without any diminution in their number being discernible. Not only are they obnoxious by occupying the ground which the sheep farmer needs for his flock, but they assiduously follow the ewes when lambing, and devour the poor lambs as soon as they make their appearance. Another interesting fact is the appearance of the Norwegian rat. It has thoroughly extirpated the native rat, and is to be found everywhere growing to a very large size. The European mouse follows closely, and what is more surprising, where it makes its appearance, it drives to a great degree, the Norwegian rat away. Amongst

other quadrupeds, cattle, dogs, and cats are found in a wild state, but not abundantly. The European house-fly is another importation. When it arrives it repels the blue-bottle of New Zealand, which seems to shun its company. But the spread of the European insect goes on slowly, so that settlers, knowing its utility, have carried it in boxes and bottles to their new inland stations.' 'It must be long,' says Dr. Hooker, 'before facts enough to theorise upon can be collected. Meanwhile, the inquiry appears to be, perhaps, the most interesting and important in all biology, and as such, it is most earnestly desired that all who are favourably circumstanced to pursue it, will do so both systematically and carefully.'"

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Poor-law Medical Reform Association.—Mr. Griffin, Weymouth, requests us to inform the Poor-law Medical Officers that in *Knight's Official Advertiser* of the 15th inst. it is stated:—

"The Select Committee (Poor Relief, England) continued to meet on Tuesdays and Fridays until the Easter recess, and have now resumed their sittings. The members alone are present when the Committee are considering their report, and the resolutions agreed to will not be made known until they are formally reported to the House. In all probability the Report will be issued early next month."

Since April 1, Mr. Griffin has received the following subscriptions in aid of the funds of the Association:—

Jay, F. F., Depwade, 5s.; Davies, F., Pershore, 10s.; Whiteman, R. H., Wandsworth, 5s.; Banks, P. H., Bedford, 5s.; Thomas, J. L., Carmarthen, 2s. 6d.; Stainthorpe, T., M.D., Hexham, 5s.; Terry, H., jun., Hardingsstone, 5s.; Percival, W., Hardingsstone, 5s.; Spicer, N. W., Chard, £1 1s.; Moreton, S. E., Great Boughton, 10s.; Clarke, J., Barnstaple, 5s.

Varieties of Salt.—Some persons abhor the taste of salt; others empty a saltcellar at dinner, and take some with everything they eat—sweets, pastry, fruit, and even coffee. Great salt-eaters have their favourite kinds of salt, of which they are as fond as some persons are of a special vintage of wine. Most people are contented with the ordinary table salt, the cheapness and excellency of which is a thing to be thankful for; but the fastidious *halophilist* will give sixpence a pound for Maldon salt, crystallised in their square, dry flakes, which crunch pleasantly in the mouth, whilst others prefer Lymington salt, with its little deliquescent cubes, and strong briny taste. The difference in flavour between this and the common table salt is remarkable; and any one who has to prescribe for a bad appetite may gain his patient's goodwill by recommending him so homely a luxury. Celery salt, flavoured with the powdered seeds of that plant, is much relished by some people. For pickling purposes, the stronger deliquescent salts known as Bay salt, St. Ube's, etc., are preferred. For bathing purposes also, these salts, which contain other marine elements besides the mere chloride of sodium, and which consequently attract moisture from the air, and have a fuller bitter, and even acrid taste, give to the water in which they are dissolved a more crisp feeling and refreshing smell. A variety of salt is now largely advertised and sold for bathing purposes by the Messrs. Tidman, which we have had tried in our own nursery, and believe that it makes a very agreeable and tonic bath.

Dinner of the Licentiates in Dental Surgery.—Mr. Harrison may be assured that any misrepresentation of his views was quite unintentional. We have not space to publish his letter in *extenso*, but give the following extract, which doubtless fairly represents the views of a highly educated man and F.R.C.S.:—

"Let Licentiates in Dental Surgery be called and registered what they are, and what they are content to be, and it would be found neither probable that they would attempt any practice which was beyond the proper pale of their department of the Profession, nor possible that they should succeed if they did attempt it—as, independently of the legal difficulty which would in such case be in their way, it is simply impossible for any man who attempts to practise both General Surgery and Dentistry to succeed to any extent in either. I take it upon myself to assert this thus confidently because I am thoroughly conversant with the requirements of both these departments of practice, having enjoyed in the course of my Professional career large practices in both; and, I may add, that if proof were wanted to confirm this assertion, it is to be found in the fact that, among those Dentists who possess the full qualifications of Member or Fellow, there is not one who attempts to combine the general practice of Surgery with his speciality."

The Hôtel Dieu and St. Thomas's Hospital.—Saint-Thomas Hospital est aussi parvenu définitivement à se placer. C'est le cas d'appliquer la devise: Mieux vaut tard que jamais. Après le choix successif de Surry Gardens, de Bethleem, de Newington Church et de bien d'autres sites, celui de Stangate sur les rives de la Tamise, vient d'être approuvé par la Chancellerie. Parmi les considérants du jugement, dont le bon marché de 2,375,000 fr. pour le terrain seulement est l'un des principaux, la salubrité du lieu est invoquée en se basant sur celle de l'Hôtel-Dieu de Paris. Voilà, certes, un honneur pour cet établissement ne devait guère attendre; l'Hôtel-Dieu pris pour modèle! Et puis, il y a Seine et Tamise, et celle-ci ne peut guère être comparée à celle-là au point de vue de la salubrité.—*L'Union Médicale*, April 7, p. 39.

The Pigmy Fossil Elephant of Malta.—More remains of this animal have been discovered by Dr. Leith Adams, F.G.S., in extensive excavations lately made by that gentleman among the cavern deposits and breccias near Crendi. One of the chief points with reference to the fossil elephant found in Malta is the small size of its teeth, which, coupled with other characteristics, leaves no doubt that it was not only distinct from any living or extinct species, but was, as regards dimensions, a pigmy compared with them. It is supposed not to have been larger than a lion. Such relics, together with the bones and teeth of hippopotami, etc., which of late years have been met with in great abundance in different parts of Malta and Gozo, tend to show that these islands are but fragments of what may at one time have been an extensive continent, in all probability connected with either Europe or Africa, or both. At all events, the physical geography of this portion of the Mediterranean must have changed very much since the above-mentioned animals wandered over our islands. To those who take an interest in the wonderful discoveries made by geologists of late years, it is worthy of notice that teeth and bones of the living elephant of Africa, and another larger fossil species, together with the hippopotamus, have been lately discovered by Baron Anca in the Palermo caves; thus showing that in all probability no less than three descriptions of elephants and two species of hippopotami frequented an area embraced within the southern point of Sicily and Malta, and during the post-pliocene period, when we find the earliest traces of man's existence. None of the latter have yet been met with in Malta. But there is every probability that flint implements and such like will turn up, as they have done in the Sicilian caves, more especially now that the attention of scientific inquirers has been earnestly directed to this important subject. Without the invaluable testimony afforded by the remains of the quadrupeds above mentioned, there are downcast fragments of the strata and faults along the shores of Malta, which testify to the submergence of the land. Besides, the subaqueous plateau, named Adventure Bank, uniting Sicily to Africa by a succession of ridges not more than forty to fifty fathoms under water, points to the former contiguity of that island and the continent of Africa. So marked is the latter that Sir C. Lyell has asserted that Sicily might be re-united to Africa by movements of upheaval not greater than those which are already known to have taken place within the human period in Sardinia, where the bed of the sea has been elevated 300 feet since man inhabited that island.—*Malta Times.*

Historical Notice of Raphides as Natural Characters.—In the current number of the *Ann. Nat. Hist.* is a thoughtful paper on this subject, by Mr. Gulliver, from which the following extract will show what a novel and fruitful field of research lies open for cultivation before the eyes of our country readers. In the natural sciences, the study of difference or contrast is more difficult and scarcely less important than the study of resemblance or analogy; and the complaint of Lord Bacon of the comparative neglect of difference in anatomy is still as pertinent as in the time of the great Chancellor. Since the discoveries of Schleiden and Schwann, important advances have been made in both directions, including the valuable characters afforded by the bone-cells and intimate structure of the teeth of animals, as expounded by Quekett, Nasmith, and Tomes; and Mr. Gulliver had long ago shown (*App. to Gerber's Anat.*, 1842) that there are animals which may not only be distinguished by their red corpuscles alone from other species of the same order, but from every other order of the vertebrate subkingdom; nay, that the most universal single diagnostic between the two chief subdivisions of that subkingdom is in the blood; that is to say, while a nucleus regularly exists in the red corpuscle of oviparous Vertebrates, that nucleus is as regularly wanting in the red corpuscle of Mammalia; and hence the terms Vertebrata Pyrenæmata, and Vertebrata Apyrenæmata, as more particularly explained in the reports of the author's College lectures (*Medical Times and Gazette*, 1862-3, and Hunterian Oration, 1863). Excepting the diagnosis of a few orders by the woody tubes and pollen, we find little use made in systematic botany of the distinctions afforded by the intimate structure of vascular plants. Hence the orders, genera, and species seemed to require further research, especially as regards the characters which might appear in modifications of size, form, structure, and functions of the cells, and in the properties of the juices. The latex (*Medical Times and Gazette*, February 14, 1863, fig. 11) and cells of the hairs, pollen, etc., were sometimes found available in this way. But these observations had not gone far before examples occurred of the truth of Schleiden's remarks as to how little hope there is, without a study of the fundamental principles of development, of much further aid to systematic botany from mere anatomy. After a while, however, Mr. Gulliver proved that anatomy would occasionally extend our good diagnoses between allied vascular plants, as he exemplified in Juncaceæ and Hymenophylleæ. It was not before a large accumulation of his notes had been examined that Raphides were thought of in this point of view, for they had not even been particularly looked after, and were merely noted whenever seen, long before their significance as characters was suspected. But when every one of those notes of Raphides had been picked out, it was very unexpectedly discovered that the plants in which they occurred would sometimes come under certain orderly arrangements. Thus, not a single species belonging to the orders Balsaminaceæ, Onagraceæ, and Galiceæ was without its note of Raphides, while in no single instance were they noted in the next allied orders; and conversely, a single order (as Hydrocharidaceæ), in which Raphides were regularly wanting, would be surrounded by orders in which Raphides were as constantly abounding. Then, repeated experiments

and observations proved that raphis-bearing is an essential and intrinsic, plain and characteristic phenomenon throughout the life of certain species, pervading its healthy frame from the seed-leaves and young buds to the ovule and ripe fruit. Accordingly, the conviction arose that such observations, among the infinite details of Nature, might add to our knowledge of the affinities and contrasts of plants, and of their true position in her system. Among the most remarkable of the results is the fact that whenever Raphides afford a diagnostic, it is so much more fundamental and universal than any other single character yet in use that mere fragments of two plants, at any period of their growth, may be sufficient to show the difference.

OBSTETRIC GUIDE HOOK.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me, for the sake of your readers who have corresponded with me in respect of your report of the proceedings of the Obstetric Society, to say, that the "Guide Hook," on the use of which I communicated through the kindness of Dr. Graily Hewitt a paper to the Society, is made by, and may be procured of, Messrs. Weiss and Son.

I earnestly commend the instrument to the notice of every accoucheur, and shall be greatly favoured by the experience of any who may make use of it.

Bury St. Edmunds.

I am, &c.

SAMUEL NEWHAM.

MR. GLADSTONE'S GOVERNMENT ANNUITIES BILL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have heard through reliable sources that inquiries have been made of Parochial Medical officers as to what fee they would accept to examine assurers for the Government annuities, supposing that Mr. Gladstone's bill should become law. Now, I think if the parochial Medical officers are to be the examiners, to the exclusion of the generality of Medical men, it is high time that men of influence in the Profession should look into the matter, and offer some opposition to such a manifest injustice. If Government is to become a gigantic assurance company, let them act with the same liberality as the other companies, leaving the assurers the option of being examined by their usual Medical attendant.

I am, &c.

FORTITER IN RE.

INHALATION OF GAS FUMES IN WHOOPING-COUGH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your last issue of the *Medical Times and Gazette* you notice that "several children suffering from whooping-cough at Calais have been taken to the gas works of that town, and caused to inhale the fumes which are disengaged during the purification of the gas by lime." This you head a "New Cure for Pertussis." It may be new to you and the people of Calais, but it is not so to the inhabitants of the town in which I reside. The lower classes especially, when they find that their own, or the doctor's treatment, or Dame Nature does not produce a cure, frequently take their children to the gas works. This proceeding here, as in Calais, has a good repute.

TUMOUR (NODE?) AT THE BACK OF THE PHARYNX TREATED BY IODIDE OF POTASSIUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A similar case having been reported from King's College Hospital, perhaps you will consider the enclosed worth publishing.

I am, &c.

JAS. FERRIER CLARKE, L.R.C.S.I., L.C.P.I.

Farnworth, near Bolton, April 11.

Mrs. S., aged 52, consulted me at the beginning of July last for an indolent ulcer on her leg, and at the same time complained of difficulty of swallowing. On looking into the mouth the back of the pharynx appeared bulging forwards, the uvula resting against it. This tumour was hard, but not painful to the touch. She acknowledged to having had venereal some twenty years ago, for which she was salivated, and two years ago had "lumps" (nodes?) on her tibia. I ordered her three grains of iodide of potassium (increased gradually to six grains) three times a day, and painted the tumour with tinct. iodinii. This treatment was continued till the end of September, when the tumour had almost entirely disappeared.

TURNING BY EXTERNAL MANIPULATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was called at six o'clock on the morning of February 23, 1864, to attend Mrs. — in her fourth confinement. She had been ill from the previous evening, but did not think it necessary to send for me any sooner as the pains were not very strong. On examination, I found the os uteri well dilated, and the membranes protruding freely, but there was no presentation within my reach. I had no doubt from the internal as well as from the external examination that it was a cross birth. The pelvis was very roomy, and the previous confinements were speedy. In consequence of a late illness of a formidable character, the lady was in a very unfavourable condition for bearing the operation of turning, and as there was nothing urgent, I waited for nearly three hours. At the end of that time there was not the slightest change in the case, and I requested the assistance of another Practitioner. On consultation, it was agreed to wait half an hour longer to allow of greater relaxation of the os externum, and also in the hope that nature might rectify the position of the infant, as the labour had come on six weeks before the expiration of the ninth month. In the meantime, however, Dr. Hicks' observations on turning by external manipulation came to my recollection, and I determined to try to put them in practice. I found the child lying fair across with the head in the right side and the breech in the left. It was very easily moved across the pelvis, as no part of it had entered the brim. I thought it better to make a breech case of it, and therefore I carried up the head with the one hand and pushed down the breech with the other. This was done in the interval of the pains, and whilst the uterus and abdominal parieties were relaxed. The infant floated round so nicely in the waters that I brought it into a straight line with the inlet of the pelvis with the greatest possible ease. I held it steadily in that position till a pain came on, and the breech at once descended into the pelvis. Although the lady knew nothing of the nature of her case or of my operation, she at once exclaimed that the child had turned in the womb. The birth was completed in a few minutes, and the patient made a most excellent recovery. When I first read Dr. Hicks' remarks on this plan of turning, they made

so little impression upon me that they escaped from my memory. I thought the operation could not be performed without dangerous violence, and did not intend to try it, and therefore dismissed it from my thoughts. When I came to put it in practice, however, I found it so easy of accomplishment that I was surprised beyond measure. No injury could possibly result from such trifling manipulation; and in this instance I have little doubt, from the unfavourable condition of the lady, that it was the means of saving the life of my patient. I am, &c.
Coleraine, Ireland, April. JAMES C. L. CARSON, M.D.

THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you permit an old subscriber to state what he believes to be the real grievances of the officers of the Medical Department in the Army?

1st. Faith is not kept with them. Warrants, regulations, or circulars are never faithfully carried out, excepting when they prove to be prejudicial to the interests of the officers.

2nd. That the same measure is not meted out to the officers of this Department as to those of others, nor to all the officers of this Department alike.

3rd. That appeals coming from Medical officers are never met in proper spirit, or fairly and impartially decided.

4th. That either the bias of the present Director-General is against the Department, or that his authority is, like that of the rest of his brethren, not recognised. The latter is my opinion.

5th. That the military status of Medical officers, staff or regimental, is never freely and frankly accorded. This prejudice obtains in the War Office, Horse-Guards, and every branch of the service, and the infection has spread into civil life.

6th. That even in their own Hospitals their authority is much too limited. All the servants belonging to the Hospital should be under the direction (mind, not military command) of the Medical officers.

7th. That the few prizes in the Department are monopolised by a party, while the labour falls on their less-favoured brethren.

8th. That it is very difficult to get leave of absence, and the difficulty is increasing.

9th. That the pay of the Surgeons on promotion is too small, and their service before retirement too long.

10th. That promotion "for merit," so-called, is prejudicial to the Department, disheartening to the majority, and productive of no benefit to the service. I am, &c.

April 12.

AN OLD SUBSCRIBER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Horse-Guards circular of the 9th ult., which expresses the opinion of the Secretary of State as to the impropriety of imposing fines on Medical officers who have passed recruits, may be accepted as a proof that the grievances of Medical officers are not altogether groundless, and that the dearth of candidates is beginning to compel attention to the state of the Army Medical Department.

Since the discussion of this subject in your columns, another step has been taken in the right direction, forage allowance being now granted as an appanage of rank, in accordance with the terms and intention of the Royal Warrant, and not given or withheld according to the nature of the duty which the Medical officer may happen to be performing.

Although the duties of Medical officers are in every respect more onerous and responsible than those of commissariat officers, the latter are better paid, and their promotion to the higher grades is more speedy and certain, while retirement at the age of 55 is not compulsory, but prudently left to the discretion of the Commissary-General.

The pay of Assistant-Surgeons should, as recommended by a correspondent in your issue of the 19th ult., be increased after fifteen years' service; promotion would be quickened by affording a retirement at twenty years; the scale of half-pay after twenty-five years' service should be augmented to 21s. per diem, and the retirement of Medical officers at 55 years of age should not be compulsory, unless inefficiency has been certified by a Medical board.

Were these alterations brought into immediate operation, their value and significance would appear at the next examination of candidates. I am, &c.

April 15.

MERCURY IN SYPHILIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—When a member of our Profession advocates his opinions in a spirit of candour and fair play, with the sole object of eliciting truth, for his enthusiasm we commend him; but when the opinion of others is treated with irony and sarcasm, and his own supported by an exaggeration of what is in favour of, and a *suppressio veri*, as to what is against it, he lays himself open to the just rebuke of candid men. Under which of these categories has Dr. Drysdale placed himself?

In support of his unmitigated denunciations against the use of mercury in syphilis he has brought forward a host of authorities, whose practice is diametrically opposed to their being quoted in any such way.

Mr. Syme gives mercury in syphilis and other diseases, and salivates in it. See his "Principles of Surgery."

Fricke's simple treatment (so-called) in the Hamburg Hospital was, in 1827, the following:—Saline baths, 14; zinc, 38; emit. tartar., 103; corrosive sublimate, 302; nitric acid, 314; soap, 330. That is to say, mercury was deemed necessary, and employed in about one-third of the cases.

The brothers Desruelles collected 25,000 cases in Rennes and Val de Grace, and after this enormous experience, and being advocates of the simple treatment, came to these conclusions:—

After all treatments there are relapses, consisting in diseases of the anus, skin, mouth, throat, nasal fosse and osseous system, though more severe after the mercurial.

The mercurial treatment does not determine all the diseases attributed to it by the exclusive partizans of the simple treatment.

In certain circumstances the mercurial medicines are of use to assure the success of the cure, etc.

Mr. Prescott Hewett (*Lancet*, Feb. 20, 1864.) says, "By far the greater number of cases of these diseases (caries and necrosis of the bones of the skull) are connected with scrofula, and much more commonly still with syphilis and the careless administration of mercury. In the two cases just admitted, the disease of the bones owes its origin to the syphilitic poison."

The Swedish Council of Health have shown that diseases of the osseous system do occur, though less frequently, after the simple treatment; and they add, "there are cases where mercury is useful, but then we ought to administer it in small doses, and make patients take a soothing diet."

Mr. Rose found that one out of every three of the sores treated without mercury was followed by secondaries.

Thus, Sir, it appears from Dr. Drysdale's own authorities, that the sequelae of chancre are similar in kind and equal in proportion under any and every treatment, but milder in those cases in which mercury is not abused. But what enlightened member of the Profession, I ask, uses mercury in this way now?

I hope with Dr. Drysdale that this important subject will be thoroughly ventilated, and I doubt not that the following remark of the late John Pearson, treated by Dr. Drysdale in his work on "Syphilis," with undeserved irony, will prove pertinent as ever:—"When mercury is under the direction of an unskilful man, it will fail of effecting a cure more frequently than it will succeed. The complaint will be generally exacerbated by it, and rendered more intractable than if no mercury had been given." I am, &c.

Maida-hill, April, 1864.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.800 in.
Mean temperature	48.9
Highest point of thermometer	68.5
Lowest point of thermometer	33.4
Mean dew-point temperature	41.4
General direction of wind	Variable.
Whole amount of rain in the week	0.06 in.

APPOINTMENTS FOR THE WEEK.

April 23. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Prof. Frankland, "On the Metallic Elements."

25. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.
MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion.

26. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. John Campbell, Esq. (Islay), and Sir Justin Shiel, K.C.B., "On the Celtic Languages and Races."
John Lubbock, Esq., F.R.S., "On the Danish Coast-fords."
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. Morell Mackenzie, "On the First Laryngoscope as Invented by Dr. Benjamin Babington in 1829." Mr. Thomas Bryant, "On Stone in the Bladder of a Female—Urethral Dilatation."
ROYAL INSTITUTION, 3 p.m. Professor Blackie, "On Homer."

27. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

28. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.
ROYAL INSTITUTION, 3 p.m. Professor Blackie, "On Homer."

29. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 8 p.m. Professor Williamson, "On the Existence of Atoms."

ORIGINAL LECTURES.

LECTURES
ON THE CONSERVATION OF ENERGY.

By Professor HELMHOLTZ.

DELIVERED AT
The Royal Institution
ON APRIL 14, 1864.

LECTURE IV.

LADIES AND GENTLEMEN,—I can give only a very short summary of the influence which heat produces on the inorganic processes on the surface of our globe. We have seen that the sun contains a great store of heat, and that it produces always new quantities of heat. The other bodies of our system, the planets and their satellites, have been fluid masses—melted masses: so, at least, we may suppose, with a great degree of probability. The principal proof of this supposition is the spherical and slightly flattened form which all the planets and their satellites exhibit, and which our own globe also shows; for this form is exactly that which fluid masses, under the attraction of their own gravitation, and under the influence of rotation round their axis, always assume. We find this form in all the bodies of our system; and from this we may infer that they were formerly in a fluid state, and we know no other mode by which they could become fluid than by heat. As for our own earth, we have evidence of the interior heat independently of its form; for we have but to make a deep hole into the earth, to go down into mines, or to sink a thermometer into a hole bored for discovering the minerals of superficial strata, and we find that the temperature increases with increasing depth. This increase of temperature has been found all over the surface of the earth, wherever borings have been made through the soil, or mines have been sunk. We find also the rate of increase very similar in different parts of the earth. It varies between 60 and 110 feet for 1 degree of the centigrade scale, the average being 1 degree to 95 feet. Now our mines, some of them, go down to the depth of 2000 feet. The well at Grenelle has been bored to the extent of 1800 feet, and the fountain at Rehme, in Westphalia, is 2100 feet. To this depth we find always the same increase of temperature. It is quite constant. We find a still greater increase of temperature in the hot springs of water coming from a greater depth. All the hot sources of water which are spread over the surface of the earth are most probably heated only by going through these warmer and deeper layers of the soil. The deeper the outlet for such a source, the higher is the temperature. The temperature of these springs of water goes up to boiling-point, and some of them even higher. They cannot, of course, keep that higher temperature at the surface of the earth; but we find it at a greater depth. My colleague, M. Bunsen, has shown that this is the case with the geysers in Iceland. The water of those fountains is heated to a higher temperature than boiling-point. As soon as the water comes to the level of the earth, and is not hindered by great pressure, it is changed into vapour, and gives those great explosions of vapour by which the column of water is sent up to a great height. A still higher degree of temperature we find in the ejections of the volcanoes, whose masses of minerals are sometimes thrown out glowing and melted, and having a temperature of 1500 or 2000 degrees. They have been melted in the interior of the earth, and we know no other cause for their heat than the interior heat of the earth. Now, we do not need to suppose that there is any source of new heat in the interior of the earth,—that new heat is produced there. It is very probable that we have there only the remnants of an original store of heat; for so large a body as the earth, if its surface is consolidated, will cool but very slowly. We see this slow cooling even in smaller masses—masses of lava thrown out by volcanoes. It has been observed in some of the currents of lava at Etna, in Sicily, that their interior was glowing and red hot seven years after they were thrown out, and at a time when the surface was completely cooled and covered with cryptogamic plants; and one of the great currents of lava thrown out in the year 1787 gave out hot vapours of water fifty years after it had left the interior of the mountain. Therefore, even these relatively small masses of minerals, which compose these currents of lava, are cooled very slowly; and

we may infer that the cooling of so large a body as the earth, composed of similar substances, must be very slow. The rate of cooling can be calculated, not with great accuracy, but with a sufficient degree of accuracy for our purpose. Observations have been recently made on the temperature of the interior of the rocks near Edinburgh; and Professor William Thomson has calculated the conducting power of these rocks for heat, and how much time would be required for the surface of the earth to arrive at its present temperature, on the supposition that the whole earth consisted at first of a melted mass of these same rocks. Of course, the different minerals of the earth show a great variety of chemical composition and of conducting power, so that this calculation can give no great degree of accuracy; but it is sufficient to show what a great number of years would be required to cool the earth to its present state of temperature on the surface. According to the calculations of Professor Thomson, if we suppose that the surface of the earth was consolidated when it arrived at a temperature of 2000 degrees centigrade, then, from that time, 24,000,000 years would be required for cooling it down to the present state. You see, then, that no new heat is necessary to be produced in the interior of the earth. The old store of heat comes out so slowly through the superficial layers, that it has been kept for many millions of years; and many millions of years will elapse before a sensible diminution of the heat of the interior of the earth can take place. At present the quantity of heat which leaves the surface of the earth, and which is taken from this original store of heat, is very small. As long as there is a difference of temperature between the superficial strata and the deeper strata of the earth, heat must go out, and must be conducted from the interior to the surface, and leave the surface by radiation; but this quantity is exceedingly small. According to the calculations of Fourier, which agree very well with the later calculations of Professor William Thomson, the quantity of heat which comes from the interior of our earth to the surface is sufficient only to melt during one year one inch of ice, supposing a stratum of ice to be spread over the whole surface of the earth; and the mean temperature on the surface of the earth is increased by the heat which leaves the interior by only the seventeenth part of a degree centigrade; so that this interior heat of the earth, as regards the common phenomena of our weather and climate and temperature, is quite unimportant.

Now if you will look to a great mass like the earth, and suppose that it has been formerly melted and then cooled, it is clearly not possible that a mass of brittle and rigid material like the rocks which compose the surface of our earth, would cool down quietly without altering its shape and dimensions. Every mass which is cooled contracts. When a melted mass passes into a solid state, it can either contract, like the greater part of the minerals of our earth, or it can expand like water. You know that when water is enclosed in a bottle, if it is cooled and becomes ice, the bottle is broken by the expansion of the ice; but the greater number of melted bodies which are solidified by cooling do not expand, they contract. Now suppose that the earth has been a melted glowing ball, which has been cooled on its surface, then the surface of the earth ought to come to its present temperature very soon, because the conducting of the heat from the interior must be very slow as soon as the surface is solidified. We may therefore suppose that in the first thousand or ten thousand years after its solidification, the surface of the earth was very nearly of the same temperature as at the present time, but the interior would be cooled down by very slow degrees, and in cooling it would contract more and more. There would, then, be a solid covering, and an interior mass (it might be fluid or solid) which contracted; and the spherical shell would be too large for the interior mass, in proportion as the latter was condensed, and contracted, and therefore the exterior covering could not remain a complete spherical shell without distortions and changes of level. We see this going on in every melted mass. If a great mass of metal is cast into a mould, or wax, fat, and other bodies which can be melted, and which we use to fill moulds to get casts, all these bodies either contract or expand when solidified, and afterwards, in cooling, they contract. The mass which flows at first into the mould is not quite sufficient to fill it exactly if it is cooled. Therefore, in every such case peculiar arrangements must be made, that new parts of the fluid mass may enter the mould. Various contrivances are used for this purpose, according to the materials which are employed in the casting. If no new material can enter into the mould, you will get no accurate cast from the

mould, but the cast will have holes, depressions, and so on. We may suppose that the same thing must have happened when the earth cooled; and we find, indeed, by the researches into the geological structure of the surface of the earth, that a long series of changes of level has taken place since the time when the first layers of the surface were solidified—that the surface of the earth has been broken many times, that new masses have come out from the interior; that some parts have been raised and others depressed, not only once, but many times; and so a very complicated structure of the surface of the earth has been produced, and this complication is so great that it is often extremely difficult to separate the different levels and elevations of the different geological ages. The same processes are going on at the present time, for we find regular changes of level in many parts of the earth. Thus, Mr. Darwin has proved that the American chain of the Andes along the coast of South America is rising from the water, not quietly, but at intervals of five, ten, and twenty years earthquakes occur, during which a constant elevation takes place of the coast line to the extent of four, five, six, and eight feet. You find the coast lines along the mountains rising to a height of nearly a thousand feet. Then we know that there is a constant elevation at present going on in Scandinavia, by which the Baltic shore is raised every century four or five feet, and the shore of Norway, which looks to the German sea and to the Atlantic, is raised still more, and it can be shown that the interior chain of mountains rises more than the coast lines. England is rising at its western shore and sinking at its eastern shore, very slightly indeed, in the same way as the western shore of France is rising from the water. I quote these few examples only, but the number of such observations is very great. We see, then, at present changes of level going on, either quietly, so that they can be discovered only by very accurate observations, or sometimes with great disturbances, producing earthquakes; and I think we may with great probability suppose that these changes of level, which are quite of the same kind as the changes of level in past geological epochs, have the same cause, and are produced by the slow cooling of the interior of the earth, by which it contracts more and more, and becomes less adapted in its form to its solid covering. At present, therefore, the temperature of the surface of the earth and the air depends only on the quantity of heat coming from the sun, and the loss of heat by radiation from the surface of the earth—radiation into infinite space. The rays of the sun are distributed in very unequal degrees over the various parts of the earth; they fall nearly perpendicularly to the tropical zone, to the parts near the equator; they touch the surface only near the poles. The equatorial regions are, therefore, heated very much, and the polar regions do not receive much heat; but they lose as much during the night, by radiation into the sky, as the equatorial regions.

Now, by this inequality of temperature a great number of motions are produced. First, there are the motions of the air: you all know that heated air is lighter than cooled air; you see this by daily experience in your chimneys. The air heated by burning the coals rises through the chimney because it is expanded, and is lighter than the colder air, which sinks down as the other rises. We can show this still more clearly by a simple experiment. We will fill a little paper balloon with heated air produced by a spirit flame, and as soon as it is filled you will find that the difference of weight between the expanded interior air and the cooler exterior air in the room will be sufficient to take the balloon up to a considerable height. (Experiment.)

You know that the air is heated along the equatorial regions of the earth and is cool nearer the poles, where it is in contact with the cooler surface of the earth and the ice which abounds in those regions. Therefore the air of the equator will strive to go to the upper regions of the atmosphere, while the air of the poles will sink to a lower point. In this way a motion is produced. The hot air strives to expand in the higher parts of the atmosphere, and is distributed over the surface of the earth, flowing from the equator to the poles, while the colder air from the poles goes to the equator, filling those places which are left by heated air. We have thus on the surface of the earth the same process going on which you observe every day in your chimneys. The equator is like the chimney of the earth where we have the greater heat. The cool air flows from the poles to the equator, and the hot air goes along the upper portion of the atmosphere from the equator to the poles. Now this motion of the air is changed by the rotation of the earth itself. If the earth were at rest, we should only have one

current of air going along the meridian line to the equator, and another going back in the same direction at a greater height to the poles; but the air which goes from the poles to the equator goes from parts where the velocity of the rotation of the earth is not very great, to other parts where the velocity of rotation is greater. The velocity at the equator in the daily movement of the earth round its own axis is about 1500 feet in a second; but the same motion at the Shetland Islands is only one half—750 feet in a second. At London the velocity is very nearly 1200 feet. Now, the air going from the poles to the Shetland Islands has originally no rotatory motion, and therefore it must appear at the Shetland Islands like a current of air going back; and the more south the air comes, the more it is retarded when compared with the motion of the earth. To show you this, I will make a chalk line along the meridian of this globe from the pole to the equator, at the same time turning the earth just as it moves in its daily course round its axis, and you will see that the result is a curved line. The air goes, then, in this direction. Now, if I draw another line from the equator to the poles, moving the earth in the opposite way, you will see the curved direction which it takes. (Illustration.) The air, then, which comes from the poles to the equator does not come from north to south, but, as you see, from north-east to south-west; therefore, the current of air which goes to the equator appears to us like a north-east wind, while that coming from the equator to the poles appears like a south-west wind. This is the principal system of winds along the surface of the earth. It is not much disturbed in the tropical zone, where it passes under the name of trade winds; but in our region of the earth and in the temperate zone it is disturbed very much by the unequal distribution of land and water, and by the different temperature produced by the currents of the ocean, by mountain chains, and so on. We are living in the regions of the earth where the warm equatorial streams come from the upper regions to the lower; and on the whole surface of Europe we have an unstable equilibrium between the colder and warmer wind. The colder currents are winds coming from the north-east, and you know that they are cold indeed. The warmer currents come from the south-west, also from the west and north-west, because the warmer air that comes down does not quite lose the greater velocity which it acquires at the equator when it leaves the surface of the earth. In the higher regions of the atmosphere the friction is not so great, and the air can retain its original velocity better than on the surface of the earth; therefore these higher currents coming down have commonly this velocity of the equator, and they appear like westerly winds; so that in Europe westerly winds predominate, because not only the equatorial streams, but even some northerly streams, have retained the western direction. Now, this principal system of winds is very much disturbed by local circumstances, so that it is very complicated in our region; but in the equatorial regions the system of trade winds is very regular, and the temperature, the weather, and the fall of rain are more regular than they are here.

The same motions go on in the water, where we have the same difference in temperature. Water is expanded by heat, and comes up to the surface of the ocean, while the colder water goes down. We have, therefore, in the water the same sort of currents, not only currents going from north to south along the bottom of the ocean, and streams going from the equator to the pole, but these are deflected in the same way by the rotation of the earth; so that we have along the equator in the Atlantic a current having the direction of trade winds from East to West; it then cuts against the coast line of South America, is deflected to the Mexican shore, and comes out again at the point of Florida. There it is much condensed by the peculiar forms of the land. It comes out through the narrow straits of the Bahama Islands, and then forms the renowned gulf-stream, which goes along the western shore of North America, and back in the direction of the polar currents from west to east; it is thus directed against the coast of Europe, and principally against the coast of Ireland, so that we have in this part of our own coasts a warm current of sea-water spread out: one part is deflected along the coast of Europe to go down to Africa and return in its former way; the other part goes to the coast of Ireland, Scotland, and Norway, into the polar regions, and returns to Baffin's Bay, where it is completely cooled. You know that the peculiar climate of the British Islands depends upon this warm current of water, which gives a great quantity of humidity. It is this which has given them the peculiar name of the Green Islands, so that for vegetation they are renowned

throughout the whole of Europe. It is not possible to have such meadows and lawns on the Continent of Europe, where we have not the same degree of humidity.

Then we have another circumstance which makes these phenomena more complicated. Water as it is warmed passes off in vapour; and therefore the warm air which rises along the equator from the surface of the ocean and from the wetted surface of the earth is saturated with vapours, and these vapours are deposited and separated from the air in the form of fog, or mist, or rain, or clouds, where the air is cooled, and then water falls down again to the surface of the earth; so a continuous process of distillation goes on through our atmosphere, by which the water is carried to the surface of the land. Now, the coolest parts of the atmosphere are the higher parts, and therefore we have a deposit of water and rain principally where the warm humid air is obliged to rise to the higher parts of the atmosphere by chains of mountains, and this is why chains of mountains are the principal collectors of rain over the surface of the earth. You all know, if you have made any excursions to mountainous districts, that the weather is very inconstant there; that there is much more rain there than in any part of the level land. The water deposited from the air in the mountains goes down from them in the form of rivulets and rivers back to the sea, or it is collected in little lakes, from which it is removed by evaporation. Sometimes it is collected on the top of the mountain in the form of snow, which then is condensed into ice and forms glaciers. The water coming down to the surface of the earth through the fissures of the rocks washes out a great number of the soluble substances of the rocks and carries them to the ocean. These soluble substances, salts of different kinds, remain in the ocean, because the water from the ocean is lifted again only by evaporation, by distillation. All the soluble substances, therefore, are collected in the ocean; and wherever we have little lakes in desert plains, where there is no flow of water by which it can be removed to the ocean, we find the water saltish, because the salt is collected there. Besides this chemical decomposition of the rocks going on under the influence of water, the water also acts by mechanical power, particularly if it is converted into ice in the fissures of the rocks, when it splits the rocks and carries down the fragments in its course to the level land and to the ocean. These particles of the rocks which are separated are either great stones, or fine sand, or the finest powder which remains suspended a long time in water when it is in motion, and is deposited only when the water comes to a state of repose. In this way also at present new layers, either of broken stones, or of sandy soil, or of fine clay, are constantly produced over the surface of our earth, wherever water can bring these substances down from a higher level. This process, which has been of such great importance in the formation of the geological structure of the surface of the earth, is going on at present continuously.

Now, you see even from this very short and incomplete survey of the influence of heat, how great a variety of effects is produced by this single cause. All the motions of the earth, the winds, the rain, the weather, the snow, the phenomena of glaciers and rivers, the geological deposition of new layers of earth, even the electric processes in our atmosphere, are produced in this way by this one cause—by the heat of the sun coming down to the surface of the earth.

The more you look into the special processes, the greater the variety of these phenomena; but we have still a greater variety of phenomena depending upon the energy communicated to our earth by solar rays, if we look at the processes of vegetable and animal life, and principally the processes of vegetable life, which are under the direct influence of the solar rays. When the seed of a plant is developed to its full growth, you have at first in the seed a very small quantity of combustible matter. This quantity of combustible matter is increased as the plant develops. Take the small seeds of our trees, and then look at the trees when in full growth, and you will see what a great quantity of combustible matter is brought together by the process of vegetable development. When we burn a seed, with its small quantity of combustible matter, we do not get much heat by it; but if the seed is developed into a great tree, we have a large quantity of fuel, and we can produce a great quantity of heat by burning it, and derive a great quantity of mechanical power, or other kind of energy, by the heat produced in this way. You see, therefore, that the plants during their life collect a great store of energy. We may ask, what is the source of this energy? Now, first we have to put the question, what are the materials which are used by plants to construct and organise their bodies? Chemical investigations

into the composition of vegetable substances have shown that the greater part of these substances which are collected in the body of plants are composed of three elements only—carbon, hydrogen, and oxygen. There is relatively a small quantity of nitrogenous substances, which is, indeed, of very great importance for other purposes, but it is small; and if we consider the plant only as fuel, as we shall do to-day, we need not refer to the nitrogenous substances. All those substances, as wood, starch, sugar, oil, gum, and other substances which we find in the body of plants, and which compose the greater part of the weight of its solid components, are composed of the three materials which I have mentioned. Now, it can be proved, with reference to the substances of wood, starch, fat, sugar, and the vegetable acids contained in plants, that the carbon, hydrogen, and oxygen which compose them are taken by the plants from carbonic acid and from water. Carbonic acid contains carbon and oxygen, and water contains hydrogen and oxygen; therefore these two combinations, carbonic acid and water, can really afford all the chemical elements which are wanted for vegetable life. But we know that if we have a quantity of fuel, say wood or oil, which contains carbon and hydrogen, and burn it, a great store of energy is changed to heat; that the energy of the chemical affinity of carbon to oxygen, and of hydrogen to oxygen, is lost by burning these substances. It is lost if carbon and oxygen are united into carbonic acid, and if hydrogen and oxygen are united into water. When we wish to restore this quantity of energy, as it is really restored during the life of the plants, we must have some other external source of energy which is capable of giving back the energy lost by burning the fuel; therefore, if plants take in carbonic acid and water, which no longer contains any quantity of chemical energy, and if the plants convert these substances into combustible substances, a new store of energy is collected in the plants, and there must be a source of this energy.

Now, the observations upon vegetable life have shown that plants can only grow under the influence of solar light; and that as long as solar light, and principally the more refrangible parts of solar light, the blue and violet rays, fall upon the green parts of the plants, the plants take in carbonic acid and exhale pure oxygen. The experiment can be made in a very simple way. We have here a bottle containing a quantity of common water, which has been saturated a little—not completely—with carbonic acid, just sufficient for the process of vegetation. We have put into the water a quantity of water-cress—green leaves—and closed the bottle, as you see. Then we have a glass tube going down into a little vessel filled with water, so that the water cannot flow out from the bottle. The bottle was exposed to the influence of solar rays yesterday afternoon, and from this morning till the commencement of my lecture. We now see that in the upper part of the bottle a great quantity of gas has been collected, and we may suppose that the greater part is oxygen, perhaps mixed with a certain quantity of carbonic acid taken with the water. Now, if I turn the bottle upwards and place a piece of lighted paper in the tube, we shall be able to see the nature of the gas. (Experiment.) A better method of collecting the oxygen is to bring the whole plant into an enclosed space of air, and to keep up the current of air which conducts fresh quantities of carbonic acid to the plant. Then, by analysing the air, one can get better measurements of the quantity of gas changed by vegetable life. We find, then, that plants decompose carbonic acid and give out free oxygen only under the influence of solar light. Therefore, we must ask if solar light can give the energy which is wanted to produce these effects. I have already remarked that only the blue and violet rays are capable of producing this effect upon plants; and it can be shown that these rays are, indeed, completely absorbed by the leaves of the plants, so that the solar light which has passed through green leaves in full development is no longer capable of exerting any chemical influence. This can be shown by a very simple experiment. I have here two screens of dark paper covered with glass plates. I have in the middle of one screen a piece of common writing paper, rather thick letter paper, not very transparent; and in the middle of the other screen a green leaf of a plant, and behind them I have put a small piece of photographic paper, so that by exposing these to the daylight the solar light penetrates through the paper and through the leaf to the photographic paper. These have been exposed only to the daylight of this lecture-room; but I have no doubt the result will be sufficiently apparent. If I remove the piece of letter paper, you will see a dark surface on the photographic paper, which

is the photographic image of the hole in the dark screen; but if I remove the leaf, you see that the photographic paper is quite white: it has not been altered, although it has been exposed under the leaf during the whole time of this lecture. You will see that the white paper and the leaf are transparent very nearly in the same degree; so that the intensity of the light which went through the white paper is very nearly the same as that which went through the green leaf; but the green leaf absorbs completely all the chemical rays of the solar light, while the white paper does not absorb them. You will observe, if you look at photographic pictures of landscapes, that the green leaves are commonly very dark—unnaturally so. This is one of the great difficulties of photography when applied to landscapes. You see here some instances where the leaves are very black, while other parts of the pictures are light. If you wish to have a good photographic effect, you must take your picture from that side of the leaves which is illuminated, as in the picture before you, where you see the leaves are not so dark, the light being reflected. In this other picture, where the leaves are so dark, the tree has been illuminated from behind, and the light coming from the leaves has passed through them, and has, therefore, been completely bereft of its chemical rays; so that it has no effect upon the photographic paper. This is a very interesting phenomenon, and it shows how completely the plants are able to take in these chemical rays of solar light; and these rays are the only sources which the plants have for collecting new sources of energy.

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University
College Hospital.

LECTURE III.

(Continued from page 446.)

URÆMIA.

Uræmic poisoning is a subject of such grave importance to the Medical man that I must say a few words regarding it. There can be no doubt that urea is a powerful irritant poison. When injected into the veins of animals it rapidly induces fatal convulsions. It is not necessary, as some have imagined, that the urea should be decomposed in the blood in order to produce its toxic effects. On the contrary, I believe that urea is a far more dangerous poison than the substance into which it is decomposed, namely, the carbonate of ammonia. Both are, however, poisonous, and they frequently manifest their action together, for although we may, perhaps, have uræmic without ammoniacal poisoning, we cannot have the latter, as the result of disease, without its being in some measure associated with the former.

True uræmia depends on the arrested elimination of the poisonous material by the kidneys; true ammonæmia on the re-absorption into the circulation of the decomposed secreted product.

Uræmia may occur in the course of any disease in which suppression of the renal secretion takes place. It is therefore superfluous to specify the diseases in which it may occur by name.

Carbonate of ammonia poisoning occurs in its least complicated form in those cases where the urea, although secreted, is retained in the urinary passages until it is decomposed, and the products of its decomposition are reabsorbed into the blood. Just as was formerly said the normal ingredients are reabsorbed from the bladder, when from any cause the urine is retained for some length of time in that viscus. The conditions under which it most commonly occurs are therefore:—

- 1st. Sacculated kidneys.
- 2nd. Dilatation of the ureter and pelvis of the kidneys.
- 3rd. Renal abscess.
- 4th. Paralysis of the bladder.
- 5th. Enlarged prostate with retention.
- 6th. Stricture with retention; or, indeed, retention from any cause whatever,—all that is required to induce ammonæmia

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—*Ed. Med. Times and Gaz.*

being the retention of the urine in the body sufficiently long to allow of the decomposition of its urea. It is quite surprising, indeed, in how very short a time retained urine may become ammoniacal. (b)

In Mr. Marshall's case of exfoliation of the bladder, which has during the last year given rise to so much discussion, the urine contained such an abundance of carbonate of ammonia that it effervesced exactly like a seidlitz powder when I added to it a few drops of acid.

The symptoms which distinguish ammonæmia from simple uræmic poisoning have been recently carefully pointed out by Jacksch (1860).

In ammonæmia the urine is ammoniacal when passed. The breath and perspiration are ammoniacal. The mucous membrane of the mouth is dry and shining. The complexion is sallow, and there is increasing emaciation. No dropsical symptoms are present. Convulsions are rare, but intermittent ague is frequent. Moreover, although in the acute form of the disease both vomiting and diarrhœa may occur, in chronic cases, which are much more common, these symptoms are always absent. Death is in general preceded by coma, varying from a few hours to several days in duration.

It is thus seen that the symptoms, as well as the pathology of ammonæmia, present striking features of difference to those of pure uræmia. The most characteristic of the latter being the vomiting, and diarrhœa, the convulsions, and coma. The treatment of the two cases is in several particulars equally different.

In the first place, ammonæmia arising, as it generally does, from directly remediable causes, is much more frequently under our control than uræmia. For example, when the ammonæmia is due to the simple retention of urine in the bladder repeated catheterisation is usually followed by a speedy cure. In no case is uræmia within the reach of instrumental interference. Its most remediable form is when it arises from some temporary incapacity of the kidneys to perform their office; as in suppression of the urine after scarlet fever, or in idiopathic nephritis. Here we can do good by relieving the congestion of the kidneys by cupping or leeching the loins; and when the patient is too weak for such active measures, by the application of dry cupping-glasses, poultices, and the free use of the air-bath. In most other particulars, the two diseases are to be treated alike; and when neither offers us a chance of permanent cure we can in general alleviate the sufferings, and prolong the life of the patient by reducing the formation, as well as by hastening the elimination of the urea. This may be accomplished by a proper selection of food and medicine.

The remedies which enable us to control the formation, and hasten the elimination, of urea are the following:—Whenever there is an excessive tissue waste, as indicated by an augmented excretion of urea, without any very apparent cause, the citrate of quinine and iron appears to be a most useful remedy. Sigmund has observed that digitalis diminishes the elimination of urea; and Kletzinsky, that benzoic acid has a similar effect, but in a much greater degree. The last-named observer states that the daily excretion of urea may actually be reduced to 2.5 gm. (38.75 grains), by benzoic acid, in the short space of twenty-four hours. The acetate and phosphate of soda, as well as colchicum, act in a similar manner (Parkes). On the other hand, we have several remedies which increase it. Thus, Sigmund found that cubeb and cantharides have this effect; and Parkes has noted that atropine augments its elimination. If we wish to diminish the urea by means of the diet, all that is necessary is to administer arrowroot, sago, tapioca, and other such starchy foods, well sweetened with sugar; and when a more nourishing diet than this is demanded, cream, cod-liver oil, or any other fatty matters that may be considered suitable to the particular case, will have an equally good effect in reducing the amount of urea. On the other hand, when it is deemed advisable to increase it, animal soups, eggs, milk, jellies, and other nitrogenised matters, together with a fair portion of common salt, will answer the purpose. To these may be added coffee, but without sugar.

In concluding my remarks on urea, I have to remind you how useful a knowledge of its daily excretion is in prognosis. Thus, it will have been gleaned from what has already been said regarding the amount of urea in the urine during the course of disease, that if, in cases of fever, such as typhoid and typhus, or of the exanthemata, such as small-pox and measles, or of inflammatory affections, such as pneumonia and meningitis, a decrease in the daily elimination of

(b) Urine becomes much more rapidly ammoniacal in than out of the body, in consequence of the animal warmth favouring its putrefaction.

urea is observed, it may be regarded as a most favourable sign for the prognosis; for no sooner does a change for the better take place in these affections, than an immediate diminution in the amount of the urea is observable. During convalescence, the quantity is frequently below the normal standard. Whereas, in cases tending to a fatal termination, even in spite of the true febrile symptoms having passed away, the daily excretion of urea still remains high. Hence this sign may be a valuable and truthful guide when all others fail. If, on the other hand, in those diseases in which the excretion of urea is known to be abnormally small, such, for instance, as paralysis, cholera, or the different forms of albuminuria, an increase in its amount during the course of the case is noticed, it is an equally favourable sign for the prognosis; while, on the contrary, any further reduction in the amount of the eliminated urea cannot be otherwise regarded than a most untoward event, as, even when the other symptoms have improved, it is an almost infallible index of approaching danger.

METHOD OF ESTIMATING THE AMOUNT OF UREA.

All that now remains for me to do is to show you the quickest and best method of ascertaining the quantity of urea contained in any given specimen of urine. This I believe to be Liebig's method,—for the employment of which furnish yourselves with the two following solutions, and prepared paper:—

1st. Liebig's standard solution of the proto-nitrate of mercury.(c)

Dissolve in strong nitric acid by the aid of heat 77.2 grammes (1196.6 grains) of dry oxide of mercury, sufficiently pure to leave no residue when volatilised on a platinum spatula. Evaporate the solution to the consistence of a syrup, and then dilute it up to 1000 cubic centimetres with distilled water. If any precipitate of basic salt should form, add a drop or two more of the acid till it is redissolved. One cubic centimetre of this solution precipitates 0.01 gramme (0.15 grain) of urea.

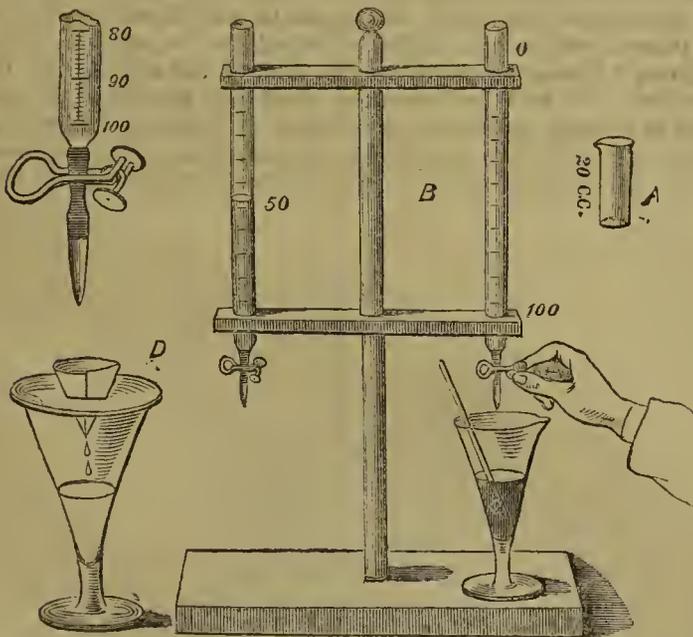

2nd. Baryta solution.

Mix one part of a cold saturated solution of nitrate of baryta with two parts of a cold saturated solution of caustic baryta, and then reduce the mixture to one-half its strength by adding an equal amount of distilled water.

3rd. Impregnate a sheet of ordinary white filter paper with a saturated solution of carbonate or bicarbonate of soda; dry, and cut it into strips six inches long and one inch broad. These may be kept in readiness in a wide-mouthed, stoppered bottle.

The next point is the requisite apparatus, the whole of which is represented in Fig. 8.

FIG. 8.

- A. A glass measure holding exactly twenty c.c. when full to overflowing.
- B. A stand containing two Burettes graduated in cubic or half cubic centimetres.
- C. C. Two glasses, made specially of a conical form, in order to act as a support to
- D. A glass filter-holder, like a candle ornament, only larger.
- E. A filter.

(c) The standard solutions are to be obtained from Schacht and Hilgenberg, 38, Houndsditch; Bullock and Reynolds, Hanover-street, Hanover-square.

By using the above apparatus and proceeding in the manner I am now about to show you, one can easily make a quantitative analysis of urea in ten or fifteen minutes. I need not waste your time by explaining in what the superiority of the mode of procedure consists, as those who are in the habit of making these analyses will at once observe its practical advantages; while to those to whom the subject is new, it signifies not whether it is precisely the same or totally different from the ordinary methods, so long as it is the quickest and best.

Fill glass A as I now do to overflowing with urine; empty it into one of the conical (C) glasses; again fill it to overflowing with the baryta solution, which will precipitate all the sulphates and phosphates, and add it to the urine. Stir the mixture well, and then leave it for a few minutes at rest, while you take a filter, fold it in four, moisten it with distilled water, and insert it into the holder (D) placed over the other conical glass. Having done this, pour the mixture of urine and baryta solution into it, and while the filtering is going on fill one of the Burettes (B) with Liebig's standard solution to the level of the first graduation. Place ready on the stand one of the soda papers.

You perceive that a considerable quantity of pure liquid has now filtered through the paper. You need not wait till the whole has passed through, but at once fill the A measure with the filtrate to overflowing, throw away the remainder, and return these 20 c.c. of mixture, which of course contain 10 of urine, to the glass. Now add to it a few drops of nitrate of silver, in order to precipitate the chlorides, for as long as any soluble chloride is present the nitrate of mercury will give no precipitate with urea. (Many do not remove the chlorides unless they are in large quantity, as in ordinary cases they can scarcely be considered to interfere with the experiment.) I now add a drop or two of carbonate of soda solution to the liquid, in order to be perfectly sure that it is alkaline—in acid solutions the precipitate of mercury and urea ($\text{NO}_5, \text{Ur} + 4\text{HgO}$) does not form—and at once proceed gradually to add to it the standard solution until all the urea is precipitated, and there remains a slight excess of the standard solution in the liquid. This is known by a drop of the mixture producing a yellow stain on falling on the soda paper. Whenever this coloration is detected, the analysis is completed, and the quantity of urea in the twenty-four hours' urine is ascertained by the following calculation:—You perceive that we have used 50 c.c. of the standard solution to precipitate the urea in 10 c.c. of urine, and 50 c.c. of the standard solution is equal to 0.5 gramme (7.5 grains) of urea; consequently as the patient passed 800 c.c. of urine in the twenty-four hours, we multiply the 800 by 0.5, and divide the result by 10, the quantity of urine analysed. The product represents the quantity of urea excreted in the twenty-four hours.

$$\frac{800 \times 0.5}{10} = 40$$

namely, 40 grammes (620 grains).

N.B.—*Albuminuria*.—In albuminous urine the urea cannot be estimated till after the albumen is removed. In order to do so, acidulate the quantity of urine to be operated on with a few drops of acetic acid. Boil it rapidly for a minute or two over the spirit lamp, and then place it aside to cool. When cold, the coagulated albumen will be found deposited at the bottom of the vessel, and the clear supernatant liquid can either be filtered or decanted. It is now ready to be operated upon as above.

Albumen may also be separated from urine by passing the liquid through a filter filled with crystals of sulphate of soda. These have the power of arresting the albumen.

Diabetes.—The presence of sugar in the urine in no way interferes with the analysis of urea.

Mucus.—When urine contains a large quantity of mucus or other deposit, only the clear supernatant liquid is to be employed in testing for urea.

ST. ANDREW'S UNIVERSITY.—GRADUATES' DINNER.—The Doctors of St. Andrew's University hold an anniversary dinner at the London Tavern on Tuesday next; Dr. Richardson in the chair. This, the first dinner of the kind, is sure to draw together a large number of the many influential Medical representatives of the University. The presentation of a testimonial to Dr. Day will form part of the proceedings. We hope the event will pass off as successfully as the graduates can wish.

THE OPTICAL DEFECTS OF THE EYE.

A COURSE OF LECTURES DELIVERED DURING THE SUMMER OF 1862 AT THE

Surrey Ophthalmic Hospital,

By J. ZACHARIAH LAURENCE, F.R.C.S., M.B.
Univ. Lond.,

Surgeon to the Hospital.

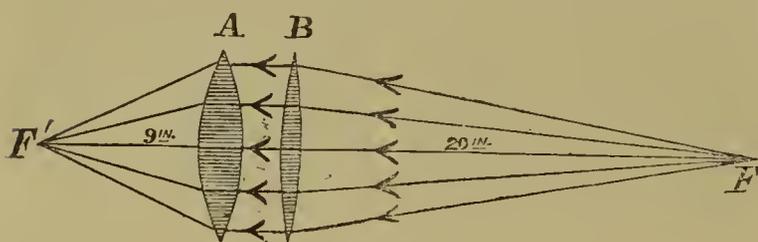

PART I.—OPTICAL CONSIDERATIONS.

(Continued from page 421.)

We have now considered the optical effect of a convex lens on parallel rays, such as emanate from objects at any distance greater than four feet from the lens. But suppose the object situate at any less distance, but greater than the principal focal length, from the lens, then the rays of light which proceed from each luminous point are no longer parallel, but divergent. It will now be found the lens still retains its power of re-uniting the rays to a point—of focussing them. But the focus is now further off the lens than the principal focus. I think I may explain this result by a very simple demonstration. Take the case, *e.g.*, of a 6-inch convex lens. Such a lens unites parallel rays to a focus at six inches. Suppose, however, the rays of light, instead of being parallel to, diverge from, a luminous point, say, twenty inches distant from the lens, then, as I have before said, they would, after passing through a 20-inch lens, issue parallel. Now, a 6-inch lens may (according to the proposition before announced) be considered as equivalent to the combination of a 20-inch lens and a 9-inch lens; for $\frac{1}{6} = \frac{1}{20} + \frac{1}{9}$ (nearly). So that we may assume that that part of the 6-inch lens which is equivalent to a 20-inch lens has been employed in converting the ray diverging twenty inches from its surface into parallel ones; these then strike that remaining part of the 6-inch lens which is equivalent to the 9-inch lens, and are, therefore, brought to a focus at nine inches from this latter. So that the final result is, that rays diverging from a luminous point twenty inches from a 6-inch convex lens are brought to a focus at a distance of nine inches from its surface. (a)

Fig. 9 illustrates the presumed theory graphically:—

FIG. 9.

B = 20-inch lens } Together equivalent to a 6-inch lens.
A = 9-inch lens }
F = a luminous point, twenty inches from B.
F' = focus of combined lenses, nine inches from A.

As the luminous point approaches nearer and nearer to the lens, the focus of the emergent rays moves further and further off, till, as I have before said, when the luminous point arrives at the principal focus of the lens, the emergent rays are not united to a focus at all, but issue parallel to one another.

We are now prepared to understand how a convex lens possesses the power of forming an *image* of an object placed in front of it. As I have before explained, every object in nature may be considered as composed of an infinite number of points, either in themselves luminous or rendered so by reflected light, every such luminous point emitting a pencil of rays, either divergent or parallel, according to the distance of the object from the surface on which the rays fall. If the rays of any one pencil are made to again converge, the luminous point from which they in the first instance emanated is, so to say, again reproduced at their point of union (focus). In this way, each luminous point of the object having its optical representative, an "image" of the object is formed. We understand, then, by the term "image" of an object, its

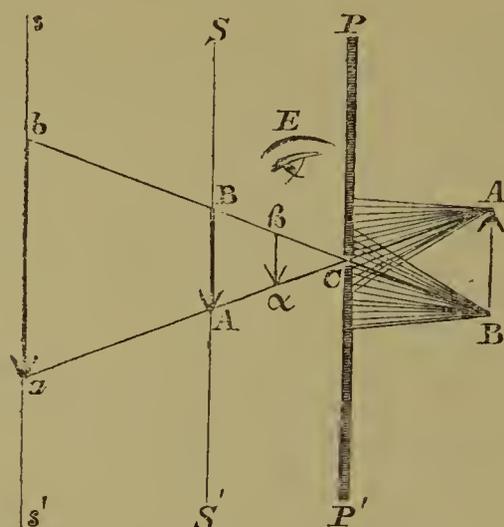

(a) We may hence deduce the practical rule: To find the focus of rays diverging from any given distance from a convex lens of known focal length, subtract from the power of the lens the fraction whose numerator is unity, and whose denominator is the distance of the object from the lens; the resulting fraction reduced to a fraction whose numerator is unity gives in its denominator the distance from the lens to which the rays will be converged to a focus by the lens.

optical reproduction. An object has certain physical properties: its extension in space, its power of affecting our sense of touch. It may possess heating or electrical attributes, and, as a rule, always has an optical existence. Certain bodies, however, such as gases, having neither any inherent nor acquired luminosity, may be said to have no optical existence; at any rate, as far as our means of ascertaining any such existence extend, although they may have certain optical properties, such as the power of refracting or polarising the light emitted from other bodies. If you regard yourself in a looking-glass, you see yourself optically reproduced, but not in any other sense; your image conveys to you no direct information of any other physical properties you may possess; you cannot, hence, directly infer whether your flesh is hard or soft, whether your body feels hot or cold, whether you are in any particular electrical state, etc. Your image in the glass is your optical reproduction, and nothing more.

If in a plate of metal a minute aperture is drilled, and on one side of the plate an object (the flame of a candle) be placed, whilst on the other side is held a sheet of paper, an *inverted* image of the flame will be observed on the paper. To understand this result, we must premise that light travels only in straight lines. Look at the sky through a flexible tube; bend the tube, and the sky will no longer be perceived.

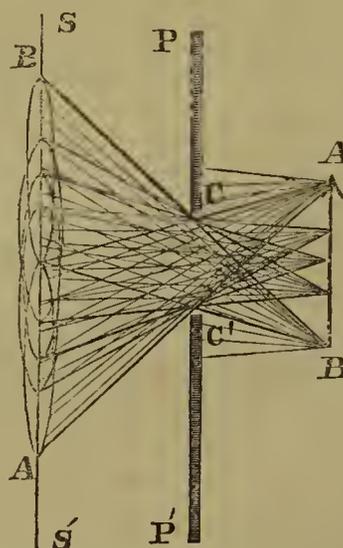

Let *AB* (Fig. 10) be an object from every point of which a

FIG. 10.

pencil of divergent (or parallel, as the case may be) rays proceeds (only those which proceed from the top and bottom of the object are represented in the figure), *PP'* a plate of metal perforated at its centre *C*, so as to admit of but a single ray of light passing through it, *SS'* a sheet of paper. A single ray, as *AA'* and *BB'*, from each point of the object will strike the paper, and hence, being reflected to the eye, *E*, of an observer, a distinct *inverted* image, *BA'*, of the object will be perceived. It will be remarked, that the inversion of the image is caused by the fact that rays of light only travel in straight lines. (b) A simple inspection of the figure shows that if the sheet of paper is as far behind the aperture in the

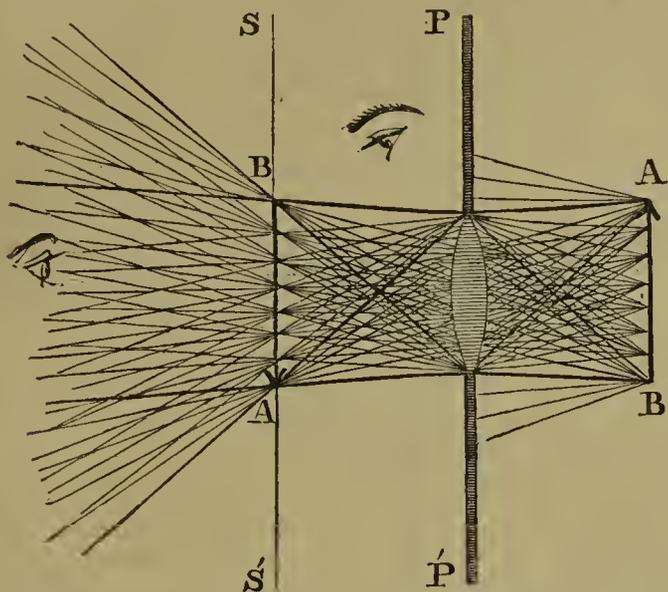

FIG. 11.

(b) In such an elementary exposition as the above, I ignore the inflexion of light.

plate as the object is in front of it, the image (*BA*) will be equal in size to the object; if closer, less (*βa*); if further off, greater (*ba*). As of all the rays that diverge from each luminous point of the object only one of each pencil strikes the paper (the rest being cut off by the opaque plate of metal), it follows that the image will be greatly inferior in brightness to the object. If we, as in Fig. 11, increase the aperture in the plate, more rays of the pencils from each point of the object are received on the paper, but each point of the object is no longer represented by a point, but by a *circle* (the section of each conical pencil of rays) on the paper; these circles ("circles of confusion") from contiguous points necessarily overlap, hence the image is no longer a faithful optical representation of the object, but appears blurred and indistinct. In other words, we have lost in definition what we have gained in brightness by the enlargement of the aperture in the plate. Suppose we now

FIG. 12.

in the enlarged aperture *CC'*, place a double convex lens, then the rays of each divergent pencil, from every luminous point of the object, will be reunited by the power of the lens into a corresponding luminous point in the image, and we shall obtain all the advantages of distinctness of definition combined with a due degree of luminosity in the image. (Fig. 12.) An eye in front of the paper will perceive an inverted image of the object by reflected light; if an aperture be made in the paper, an eye placed behind the aperture will see an inverted image of the object, suspended, as it were, in the air (an "aerial image"), formed by the rays of the convergent pencils which produce the image, diverging again after their reunion. If the object be at a considerable distance from the convex lens, of course the image will be formed at its principal focal length; after the object is about four feet from the lens, as it approaches nearer, so the image recedes, and at the same time becomes larger. A little reflection shows these facts to be an immediate consequence of what has been already said regarding the foci of convex lenses, and the optical effects of a minute aperture.

I now wish to direct your attention to some phenomena which are the direct consequences of what has preceded, and which are of great importance in the physiology and pathology of the optical apparatus of the eye.

If we place a candle-flame at a considerable distance from an 8-inch lens, a screen placed eight inches behind this latter will exhibit a distinct inverted image of the flame; if we now bring the flame closer to the lens, say, to fourteen inches from it, this approximation of the object is accompanied by a corresponding recession of the image (*c*); if the screen still remains at 8", only an indistinct, blurred, *quasi* image of the flame will be seen; but by placing a 14-inch lens next to the 8-inch one, we re-obtain a perfectly distinct (larger) image of the flame on the screen. The *rationale* of this is very simple; the 14-inch lens has the effect of rendering parallel the rays which diverge from each luminous point of the object fourteen inches in front of it: these parallel rays impinging on the 8-inch lens are then focussed at eight inches—the original position of the screen. Of course, for the two (14- and 8-inch) lenses we may substitute a single 5-inch one; for $\frac{1}{14} + \frac{1}{8} = \frac{1}{5}$ (nearly). As we

(c) In fact, the distance behind the lens at which a distinct image of the flame is formed is 19", so that the screen must be moved eleven inches further back for the observation of a distinct image.

shall see further on, this is precisely what occurs in the human eye, in the act of accommodation for near objects.

The converse experiment is important in the theory of myopia. The flame being at a considerable distance off, and the screen being at eight inches from the 8-inch lens, substitute for this latter a 5-inch one: no distinct image of the flame then appears on the screen. Now place a 14-inch concave lens next to the 8-inch convex one, and a distinct image on the screen is at once produced. After what has preceded, the equation, $\frac{1}{5} - \frac{1}{14} = \frac{1}{8}$ (nearly), sufficiently explains the above result.

In all the cases we have been hitherto considering, the rays of light which converge to form the image actually meet, and may be received on a screen; or, if we remove this latter, the aerial image may, by a little attention, be seen suspended in the air, as it were—to be an "aerial image," as it is termed. But as soon as the object approaches the lens to a distance anything less than the principal focal length of this latter, a remarkable change ensues; the image all at once transplants itself to the same side as the object, and simultaneously becomes erect. (Before, it was on the contrary side of the lens to the object, and inverted.) This image, however, cannot be received on a screen. It is not, as in the case of the inverted image, a *real*, but only an *imaginary* (virtual) one; or, if I were to designate the real image as a *physical*, I should call the imaginary a *physiological* one. (d) If this course were one of pure optics, I should now bring before you the subject of concave lenses; but as these find their application in myopia, I shall defer speaking of them till I come to that part of our subject.

ORIGINAL COMMUNICATIONS.

CASES OF SOFTENING OF THE BRAIN AND SPINAL CORD.

By JOHN W. OGLE, M.D., F.R.C.P.,

Assistant-Physician to, and Lecturer on Clinical Pathology at, St. George's Hospital.

THE cases of softening of the nervous centres which are contained in this contribution are all of a simple or uncomplicated nature, as I have with a purpose excluded all such as are connected with other affections of the nervous structures, as injuries, extravasation of blood, tumours, morbid deposits and cysts, abscesses, secondary deposits, inflammatory conditions of the membranes, etc., and also such as are met with in general morbid states like fever. The co-existence of such conditions may well be considered as complications. I shall not omit to include among the present list of cases such instances of softening as are of the nature of secondary deposits, and also such as are obviously or apparently the result of disease of the heart or of the *blood-vessels*, whether of those which supply the nerve-tissues, viz., the arteries (including cases of so-called embolism and also cases of alteration in the walls of the arteries) (e); or of those which carry the blood from the nerve tissues, viz., veins and sinuses within the cranium (including thrombosis). I find it personally convenient in the first instance to record the cases, and to leave such commentaries as they may suggest, and such inductions as may arise out of their consideration, until after they shall have been related. In doing this I shall as much as possible observe a uniform order, giving firstly the previous histories of the cases, then passing on to the progress and course of the symptoms, and lastly describing the appearances found after death. All these details I shall record with as much brevity and conciseness as a due regard to perspicuity will permit.

I.—SOFTENING OF THE BRAIN.

Case 1.—Elizabeth S., aged 57, was admitted into St. George's Hospital July 31, 1844. Had been often attacked by a sensation of fulness and distress at upper part of abdomen,

(d) A convex lens used as a magnifier, in the sense referred to in the text, is simply an artificial addition to our accommodation, which enables us to view the object under a greater angle than we otherwise could do, and in combination with a mental reference of the image to a further plane of projection than the object itself really occupies. This explanation will first be rendered clear by subsequent explanations.

(e) It will be seen that there are cases in which, in certain places, a thickening of the parietes of the arteries carrying blood to the brain had become so excessive that the tube of the vessels was to a considerable degree obliterated, and in which the passage of the blood must, of necessity, have been interfered with in consequence.

with spasmodic pain—generally during the night. A purge brought away much lumpy fæces, and she improved.

August 4.—Another spasmodic attack.

5th.—Spasmodic dyspnœa came on, lasting all night; complained of a sensation of sinking at the præcordial region; a blister gave no relief. Dyspnœa continued until the 7th, when another spasmodic attack occurred, followed by death in a few hours.

Post-mortem Examination.—Cranium: Clear sub-arachnoid fluid, also fluid in ventricles, which were dilated; posterior part of corpus callosum and of fornix softened; arteries of the first and second order at base of brain very atheromatous and brittle, and in many cases the deposit contracted the tube to a very considerable extent. Thorax: Lungs hepatized; left ventricle of heart hypertrophied, and its valves containing interstitial deposit; whole aorta highly atheromatous. Abdomen: Kidneys highly diseased.

Case 2.—Thomas H., aged 40, was admitted into St. George's Hospital, January 10, 1844. Of full plethoric habit, with short neck. Intemperate. Had had a fit of "apoplexy" four days before admission, for which he was bled, so regaining his consciousness. Admitted sensible, but with almost entire loss of speech; limbs of right side paralysed—the arm being the worst; face flushed; heart's sounds natural, and also pulse; tongue moist, but loaded and pushed to the right side, though it could be moved in any direction. Was purged and blistered at the nape of neck. He improved in speech and in everything else until the 29th, when severe headache came on. He had never had headache before. Diarrhœa set in with much debility and tendency to syncope. In the evening of the 29th the patient had another sudden attack, and lost his speech entirely, but when roused was quite conscious. Pupils contracted; eyes suffused; conjunctivæ injected. Skin hot but moist; tongue dry and furred; pulse very small and unsteady. Was again blistered at nape of neck, and mist. cretæ with brandy ordered. The diarrhœa ceased, but the pulse became more unsteady. He sank and died on the 30th.

Post-mortem Examination Seventeen Hours after Death.—Cranium: Cerebral veins very prominent; much clear fluid in sub-arachnoid tissues and in ventricles; arachnoid and pia-mater slightly thickened; brain watery; "puncta" on section large and numerous; the left corpus striatum presented a dirty yellow part one inch and a-half by one inch, in size, having a few small puncta in different parts. This portion was very soft, in some places quite diffuent, and was surrounded by a thin stratum of vascular brain-substance; otherwise the surrounding tissues were quite healthy. Thorax: Aortic valve and flaps thickened—two of them united, and having soft red fibrin masses attached. Lungs rather œdematous. Abdominal organs natural.

Case 3.—Louisa B., aged 38, was admitted into St. George's Hospital May 8, 1844. Had had dropsy following rheumatic fever, with diseased heart and kidneys, dyspnœa, cough, and expectoration, and pain near the heart. On admission, heart's impulse extended over too large a surface, its second sound obscuring the first, and too loud. Urine albuminous. Severe pain in the legs came on, attended by some loss of power, which was relieved by sinapisms. Pain in the head followed, coming on during, and awaking her out of, sleep. The next day the left side became suddenly paralysed, but she remained conscious, though a state of stupor came on; could be roused to answer questions. The right pupil was dilated, the left contracted. Coma preceded death, which occurred on the 23rd.

Post-mortem Examination Twenty-eight Hours after Death.—Universal œdema of the surface. Cranium: Slight sub-arachnoid serum in ventricles, which were of natural size; membranes transparent; convolutions of brain slightly flattened. Middle lobe of brain at outer surface of the right corpus striatum to the extent of one and a-half inches, softened and quite pulpy, and of a purplish colour. Here both grey and white substances of the brain were of the same purplish hue; no blood was found to be extravasated. Thorax: Heart dilated and hypertrophied; left valve-flaps slightly thickened; slight pleuritic adhesions. Lungs condensed; in one lung a mass of yellow firm matter, containing numerous blood-vessels, was found. Abdomen: Kidneys diseased; one containing deposit like that found in the lung. Spleen contained several similar deposits.

Case 4.—John D., aged 40, was admitted into St. George's Hospital August 5, 1845. Intemperate. Two days before admission had had an apoplectic fit, having had transitory promonitory symptoms five weeks before, but no treatment. Fell down in convulsions, with stertor, followed by hemi-

plegia of the right side. Had been bled to ζxvj . A turpentine injection given, and calomel and croton oil, bringing away much fœcal matter. Insensible for some time, but afterwards it was found that sensibility of the skin on the right side remained; the mouth drawn to the left. Left ptosis: Pupils acting well and equally. Could not speak, but appeared sensible, signifying when he wanted to pass urine or fæces; nervous and suspicious, and refused to put out tongue; there was almost constantly slight twitching of the voluntary muscles; aspect heavy. Slept much; appetite good; pulse 65, soft; bowels costive; urine 1019, acid, not albuminous; was cupped to ζxvj .; bowels kept open with medicine. Became very delirious for two or three hours, but subsequently quieter. Convulsive movements increased; foamed at mouth, and passed evacuations involuntarily. No squinting, but occasional stertor. Became quieter after ice was applied to the shaved head and injections given. Cried much on seeing his wife. Tendency to twitchings remained. The ung. hyd. rubbed in. Became weaker; pulse 100; gums sore. Back requiring water-bed; gradually sank and died August 31.

Post-mortem Examination.—Cranium: Left cerebral hemisphere collapsed and very soft, and with feeling of fluctuation. Membranes covering were opaque, congested in patches, and having on them occasional particles of lymph in some places. Left hemisphere, on section, very pink; very diffuent in places, especially about the corpus striatum and outer part of the thalamus opticus. Two-thirds of the hemisphere involved. Corpus callosum and fornix softened. Thorax: Lungs containing frothy serum. Heart soft, flaccid, with dilated cavities.

Case 5.—Sarah W., aged 37, admitted into St. George's Hospital January 15, 1845. Six months previously was suddenly affected with giddiness and partial hemiplegia of the left side; did not lose her senses or the use of limbs so as to fall. In a fortnight she quite regained power; but since then had had pain at the right side of her head, occasional numbness of the surface of the left side of her body, and constant violent palpitation. Feet swollen; within the last fortnight cough and dyspnœa; never had had rheumatism.

On admission there was slight cough, much dyspnœa, and slight mucous expectoration; much headache, chiefly on the right side, and palpitation; heart's action irregular, not violent; pulse very weak, irregular, hardly perceptible; sounds of heart, with loud murmur, most distinct over aortic valves and along the aorta; crepitation over all the lungs; bowels costive; urine acid, not albuminous. Purgatives, sedatives, and anti-spasmodics given. Sleeplessness came on. Palpitation, and fainting, and orthopnœa supervened. Symptoms became aggravated. Left arm and both lower limbs became anasarctous and dyspnœa distressing; remained generally half delirious until death, which occurred March 30.

Post-mortem Examination.—Cranium: Much sub-arachnoid fluid; brain natural, except one portion of the size of a half-penny on the outside of the right lateral ventricle, which was decidedly softened and partially broken down. Thorax: Much pleural fluid; lungs gorged; bronchi dark and livid; heart's walls thin; cavities dilated; mitral flaps rather thickened; aorta dilated above valves. Abdomen: Organs natural.

Case 6.—S. S., admitted into the Hospital July 22, 1845. She was in good health when married, July 1. On the 6th had pain in the head, which shortly became very much worse, and she got up, insisting that she had had a fit; had been delirious; the evacuations involuntary; blister applied to the neck; and medicine given.

On admission face flushed, skin hot, especially head; pupils much dilated, but acted, though sluggishly; pulse 120; tongue dry and clean; unconscious, but answering questions when roused, and following people around her with anxious looks; speech imperfect; voice weak; when asked about pain pointed to her head; abdomen soft and flaccid, but pressure gave pain; no vomiting; no petechiæ on the skin; no albumen in urine; lungs congested; cough, with thin sputum; chest well expanding on deep inspiration. Ordered twelve leeches to temples. Salines, with calomel and rhubarb, given to-day, and subsequently ζii . wine. Improved so as to speak to those about her, and even passed evacuations consciously; the pupils acting better. Later on she became delirious after a bad night, and jerking at the bed clothes and muscæ volitantes came on. Bark, ammonia, and wine given. Bed sores came on; tongue dry; refused food; delirious four days before death, which occurred August 7.

Post-mortem Examination.—Small quantity of clear fluid was found in the sub-arachnoid tissues; but the ventricles were

not dilated, nor containing more fluid than usual; fornix and back part of corpus callosum diffuent; whole of brain and cerebellum blanched and somewhat softer than usual. Thorax: Lungs with emphysema anteriorly; posteriorly œdema and congestion; other organs natural; no blood in heart's cavities; abdominal organs natural.

Case 7.—Thom. T., aged 12, was admitted February 18, 1846. Had been ill five weeks with rheumatic (?) pains in limbs, but never redness or swelling of joints; always "hot and thirsty," but had not perspired. Lost flesh and appetite. Restless until a few days ago, when he became drowsy, and pain came on in the left side of the chest, attended by slight hæmoptysis.

On Admission.—Face suffused. Screamed when touched. There was a rolling of the head in bed. Sordes on teeth; tongue brown, furred, dry; skin hot; pulse 108, quick, but regular; heart's sounds and action natural. Bowels costive. An enema was administered and wine given.

Became violently delirious in the evening, and subsequently screamed much. When roused he put up his hand to the left side of his chest. Cal. and opium and effervescing salines given; and subsequently the wine was increased. He died two days after admission.

Post-mortem Examination.—Cranium.—Cerebral membranes were vascular. The septum of ventricles and fornix very softened, and broken up in places. Other parts of the brain were natural. Thorax.—Lungs hepatised, and containing tubercles. Heart healthy, excepting that a slight number of recent fibrinous granulations were found on the valves of the heart.

(To be continued.)

TYPHOID FEVER IN CONNEXION WITH PREGNANCY.

By E. E. DAY, M.R.C.P. Lond.

THE occurrence of fever, of whatever kind, in connection with pregnancy is always a matter of serious anxiety to the Medical attendant, and is often attended with fatal results to the patient. When such an attack comes on at an early period of pregnancy, miscarriage, with its accompanying dangers, generally ensues; but if not, the fœtus generally suffers, and it is small and imperfectly developed, or it may bear the marks of the disease having affected it in its intra-uterine life, as in the case of small-pox. Last autumn a child was born in King's College Hospital, with two pits on the face, which were evidently the effect of small-pox from which the mother had suffered in the preceding summer.

When an attack comes on at a later period, premature labour will generally result, and then may follow either a more severe form of the primary disease, or it may change its type and become puerperal fever, with all its local affections—*e.g.*, uterine phlebitis, pelvic abscess, etc. Or it may happen that the fever-poison so paralyses the nervous system that the patient sinks in a state of coma.

The influence on the child will vary. In some cases, if the woman be close to her time, the uterus may take on contractile action and expel the child quickly; in such cases the child may live, but if it remains in utero some little time during the progress of the disease the blood which should nourish it has become poisoned, and the child will die without any sign discoverable by post-mortem examination to account for its death.

Lastly, the disease, being slight in character, may commence, continue, and terminate with little effect in the uterine system.

In the case which I am about to relate the disease seems to have roused parturient action and destroyed the child, but after that to have had no influence in retarding the natural recovery, as far as the confinement was concerned.

Mrs. P. was confined on March 11, 1864, under the following circumstances:—

She was 30 years of age, was married, and had had several children. Six weeks ago she had a child seized with typhoid fever, for which she applied to the Carey-street Dispensary, from which institution it was attended at its own home. A fortnight after that, a second child was taken ill, and was sent to Guy's Hospital; a week after, a third child was attacked, and it was sent into King's College Hospital.

On Sunday, March 7, the mother, who was, as far as she could tell, eight months and a week gone in pregnancy, after

being tired out with nursing the first child, was seized with shivering headache and loss of appetite. This continued Monday and Tuesday. On Tuesday evening labour set in, and she was confined, after a natural but tedious labour, on Thursday evening of a dead child. The placenta did not come away, but was removed by the student in attendance. The breasts gave no trouble. When they began to fill they were covered with belladonna plasters. The lochia went through their natural course.

On Saturday, when I first saw her, her pulse was 140; tongue white in the centre and surrounded by red papillæ; head aching; uterus well contracted, not tender; several rose-coloured spots were scattered over the abdomen, which was only slightly tympanitic. She was taking ammonia and chloric ether. I ordered beef tea thickened with arrowroot, 6 oz. of port wine, and the following draught every four hours:—Acid. nit. hydrochlor. dil., ℥xx.; liq. cinchonæ, ℥xv.; water, ℥j. Mix. In the evening, before she had taken any of this medicine, she was seized with violent diarrhœa and was purged nine or ten times. This was arrested by opium and catechu.

15th.—The bowels were only open once yesterday. Pulse 120. Urine normal. Lung sounds natural, except a little wheezing.

17th.—Yesterday and to-day the bowels have been relaxed. Pulse 120. Ordered tinct. krameriæ, ℥j.; decoct. hæmatoxyli. ℥j. Ft. haust. post sing., sedes sumendus.

19th.—The bowels were only open once to-day. Appetite better. Pulse 100. To continue the nitro hydrochloric acid.

From this time she recovered well.

The only other point which strikes one in connexion with this case is the importance of removing the mother from the causes which may have given rise to the fever, or at least of sending all the children away from her. For want of this precaution many a mother has been sacrificed by nursing her sick children.

CLINICAL NOTES AND OBSERVATIONS.

By F. A. BULLEY, F.R.C.S.,

Senior Surgeon to the Royal Berkshire Hospital, Reading.

CONTRACTION AND THICKENING OF THE PALMAR FASCIA — PERMANENT FLEXURE OF THE FINGERS.

RICHARD B., aged 52, a labouring man from the country, was admitted into the Hospital December 22, 1863, on account of a contraction of the left ring finger, which had become so firmly bent into the palm as to render the hand almost useless. The least attempt to extend it caused great pain. The contraction was occasioned by a tense projecting band of firm hard tissue, which extended from the first phalanx of the finger backwards nearly as far as the carpo-metacarpal joint. The other fingers were similarly affected, but not in so great a degree, by a puckered contraction of the integument of the palm, which was everywhere converted into a brawny inelastic structure, in which the subcutaneous cellular tissue, as well as the aponeurosis underneath, appeared to be involved. The same kind of change was commencing in the opposite hand, but had not yet produced any permanent flexure of the fingers. The disease had been coming on about eight or nine years; and he dates its commencement to repeated attacks of rheumatic inflammation, particularly affecting the knuckle joints, which had become stiffened and incapable of complete extension for some time before contraction commenced in the palm. He had been subject to rheumatic affections all his life, and had been two or three times under treatment in the Bath Hospital, but latterly he had been comparatively free from the disease.

Thinking the deformity might be at least partially removed by an operation, I divided the projecting band as well as the whole of the contracted tissues in the palm of the hand, which immediately allowed of the straightening of the fingers to a great extent, but not completely, the hindrance to complete extension being evidently due to the old rheumatic stiffness of the knuckle joints. The fingers were afterwards kept extended on a flat hand splint, and at the end of a month he had so far recovered the use of his hand as to be able to be discharged from the Hospital, the hardened tissue of the palm having almost entirely disappeared.

Some difference of opinion formerly existed as to the origin and nature of this peculiar kind of contraction. By some it

was believed to be the consequence of that horny condition of the palm which is induced by hard labour, but as the disease has been found to occur in persons who have never been subject to this cause, some other reason may be safely assigned for its occurrence. In the instance which I have related, as well as in one or two other cases of the same kind which have come under my notice, I have reason to believe that the affection has commenced in the contraction of the carpo-metacarpal joints through a kind of chronic rheumatic arthritis especially affecting them, and that thus the palmar aponeurosis, becoming slackened by the gradual approximation of its attachments, has undergone the particular kind of shortening upon itself, with consequent condensation of tissue, which I have described.

P.S.—I omitted to mention that on the division of the contracted parts, the tendons underneath, [together with their sheaths, were found to be quite free from contraction, and had evidently been not at all concerned in the disease.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

HOSPITAL FOR EPILEPSY AND PARALYSIS.

CLINICAL REMARKS ON CASES OF DEFECTS OF SIGHT IN DISEASES OF THE NERVOUS SYSTEM.

(Cases under the care of Dr. HUGHLINGS JACKSON.)

It is of as much importance to the Physician to distinguish the various kinds of amaurosis occurring in brain disease for their value as symptoms, as it is to the ophthalmologist for treatment as diseases of the eye. Dr. Hughlings Jackson recently made some remarks on this subject at the Hospital for Epilepsy and Paralysis. He said, that as six of the nine cranial nerves—the optic, third, fourth, fifth, sixth, and portio dura of the seventh (for the orbicularis and tensor tarsi)—had more or less to do with sight, a knowledge of diseases of the eye was of the very utmost importance in the investigation of intracranial disease.

Defects of sight were more frequent in diseases of the nervous system than defects of all the other special senses put together. Of defects of smell he knew little or nothing, and next to nothing of defects of taste; but he had inquired carefully as to defects of hearing, and had found deafness to be much less frequent than blindness, and when present it was often due to organic disease of the ear and attended by discharge. Complete blindness was, he said, very commonly met with, but complete deafness was a very rare symptom in brain disease in his experience. Defects of hearing ought, he said, to be studied by Physicians for the same reason as defects of sight, viz., for their value as symptoms. The watch ought to be used to each ear, as a patient might not be aware that hearing on one side was impaired. It need scarcely be said that a common simple cause of slight deafness was wax in the external auditory meatus; and therefore, in noting impaired hearing, we ought to be careful that we were not putting down a symptom which really had no bearing on disease of the nervous system.

Dr. Hughlings Jackson then gave examples of the very great variety of causes of blindness in brain disease, and he submitted that to put down "amaurosis" as a symptom, without further description, was far from being precise. To begin with, the so-called amaurosis following diphtheria was not amaurosis, even in the loosest sense. It was in physiological language a loss of accommodation, and in anatomical language a paralysis of those branches of the third nerve which pass through the lenticular ganglion. Dr. Jackson said that diphtherial paralysis differed from all other kinds of paralysis with which he was acquainted in seeming to have a great preference for those branches of nerves which pass through the ganglia of the sympathetic. For instance, in the so-called diphtheritic amaurosis the whole of the third nerve was not paralysed, but only those branches which pass through the lenticular ganglion. The facial was not paralysed, but those branches of nerves given off by Meckel's ganglion to the palate. Next as to the otic ganglion. Hearing was practically not affected at all in the general run of cases, as the accessory muscles of the ear have far less to do with the functions of the organ of hearing than the ciliary muscle has with sight. But in one case, that of a well-educated Medical man, notes of which had

been furnished to Dr. Hughlings Jackson, there was slight defect of hearing. It was not enough to render the patient unable to converse, but, to use the patient's expression, it "rendered music unintelligible." Next there was in this case, too, defect, not loss, of taste, due probably to an affection of the branch of the facial (the chorda tympani), given off to the submaxillary ganglion. Again, it is well known that slowness of pulse is a very dangerous symptom in heart disease. It is possible that this, too, is due to an affection of the sympathetic, as the heart receives much of its nervous endowment from its cervical ganglia.

It will be remarked, too, that the paralysis of the ciliary muscle in diphtherial paralysis is generally on both sides, for diphtheria is a general disease. When, on the contrary, a patient comes for mydriasis and paralysis of the ciliary muscle on one side, we suspect his disease to be actually local, and not merely the local manifestation of some general condition. There is generally some paralysis, however slightly marked, of the other muscles supplied by the third nerve, or they become paralysed afterwards. Indeed (after making allowance for the fact that the pupils are in many people in good health of different sizes), a difference in size of the pupils is of great help to us in localising disease. Thus, in the early stage of tubercular meningitis we may know that a child has acute tuberculosis by other signs, and a change in the relative size of the pupils enables us to diagnose further that active disease is beginning or progressing in the head. But when in such a case the pupils are equally small or equally large, we cannot speak so decisively as to there being local disease at the base. Hence, until we get physiological symptoms, as an alteration in the size of the pupils or strabismus, the diagnosis of tubercular meningitis is sometimes not easy. Or, in other words, the diagnosis in the early stage is difficult. Dr. Wilks says that he never saw a case of tubercular meningitis in an adult which was not in the early stage taken for fever.

Again, the effect of diphtherial paralysis on sight showed how different was disorder of function of the organ of vision from derangement of its mechanism from real amaurosis, in which the true visual part—the optic nerve—was diseased. And the slight deafness in the case of the Medical man quoted was probably due to an analogous disorder of the mechanism of the organ of hearing by paralysis of the branches to the internal muscles of the ear, through the sphenopalatine or otic ganglia, rather than to an affection of the auditory nerve itself. So, too, as regards taste, the little change was most likely the result of some affection of the chorda tympani, than of the gustatory.

The next illustration was that of a family in which there were five children. The eldest, a girl, had had iritis in infancy. [Of Mr. Hutchinson's twenty-three cases of infantile iritis, five were males, sixteen females, and in two the sex was not known.] The three next had amaurosis. Of these three amaurotic children, the first and third (the second and fourth in the family), were paralysed. In one, a girl aged 15, there was partial hemiplegia; in the other, a boy aged 9, complete paraplegia. The amaurosis was, in all these cases, found to depend on bygone choroiditis, the irides being perfectly clear. That the choroiditis was syphilitic was rendered probable by the fact that the eldest showed marks of iritis in both eyes, and was, Dr. Hughlings Jackson thought, rendered certain by the fact that the two eldest of the amaurotic children had the form of teeth described by Mr. Hutchinson. Now of course, in the early stage, the exact diagnosis that the amaurosis was due to syphilitic choroiditis would have been of very great value for treatment, and even when the changes were settled into hopeless permanence, a knowledge that they were due to syphilis would have been of great value as a symptom, when the paralysis began, and it began *gradually, after* the amaurosis. For Dr. Hughlings Jackson thought it would be worth while to raise the question whether in such cases the paralysis might not be due to new syphilitic disease of the pia-mater, a membrane somewhat analogous to the choroid which had already suffered. At all events, it is clear that for scientific purposes the nature of the amaurosis in these affections of the nervous system ought to be made out. It was, in the case just mentioned, the local manifestation of a constitutional taint, and not a special symptom of disease of the nervous system, and it might help us to gain a better idea of the kind of tissue disease within the head. Then, too, in writing the clinical history of diseases of the nervous system, an ignorance of the conditions producing the amaurosis would lead us wrong. Amaurosis and paraplegia are not unfrequently found together, but the case of the boy in the family just mentioned

was the only one Dr. Hughlings Jackson had seen in which the amaurosis was due to choroiditis.

Next, apoplexy of the retina, which occurred so often in Bright's disease, but which Dr. Hughlings Jackson had once seen in a young and healthy man, was of great importance as a symptom as well as an eye disease. Dr. Jacob long ago alluded to this local apoplexy as a precursor of a cerebral one, and Dr. Hughlings Jackson related two instances in which apoplexy of the retina was preceded and followed by cerebral apoplexies. The retinal degeneration found in chronic Bright's disease ought, he fancied, to be studied by Physicians. It was of great value as demonstrating that we had something more to deal with than kidney disease. The eye was to be looked on as a field for the study of diseases of tissue as well as an organ for important functions.

There was, Dr. Hughlings Jackson said, another form of amaurosis in brain disease which he had now seen a good many times. The following were, speaking generally, the ophthalmoscopic appearances described from one case lately under his observation:—For about three times the size of the optic disc was a patch which obscured the natural disc. It was in parts white and in parts of a brick-red and spattered with blood. Generally no arteries could be seen in it, but the veins were bulky and were irregularly seen, as they seemed to struggle their way through the patch to the centre of the disc.

This kind of amaurosis had been found in tumours of the brain. Dr. Hughlings Jackson said he had seen it once in a case of apoplexy of the middle lobe in a young man, in apoplexy of the anterior lobe in a young woman, and in several cases of cerebral tumours in different positions. He had now under care a case in which, with paralysis of the third nerve on one side, and hemiplegia on the other, this condition was found; and a similar case had recently been pointed out to him by Mr. Ernest Hart. It was difficult to account for the production of this kind of amaurosis, but it had not, Dr. Hughlings Jackson thought, been yet much studied, at least in England, perhaps for this reason: that such cases come under the care of the Physician—to whom the amaurosis is but one symptom of severe brain disease—rather than of the ophthalmic Surgeon, who sees amaurosis as a disease of the eye rather than as a symptom of intra-cranial disease. It was, however, a symptom which deserved more study, and was to be found more often than was supposed towards the end of many acute intra-cranial affections. Dr. Jackson used the last vague expression advisedly, as the exact significance of the symptom had not been made out.

In nearly all cases of blindness attending cerebral disease there were ophthalmoscopic signs when the blindness had continued for some time. The condition generally found was white atrophy. It was very difficult, Dr. Hughlings Jackson said, to form any rational idea of the order of the symptoms in such cases, as, clinically, white atrophy was found in association with almost all kinds of disease of the nervous system, even with paraplegia of the lower limbs only. The most striking thing was that both eyes were nearly always affected. Dr. Hughlings Jackson could only remember a few cases in which the atrophy of the optic nerve was on one side. A few months ago a patient attended for giddiness, and just mentioned that for two years he had been blind of one eye, the right. He had had much advice, and did not come for the eye disease, but such a symptom was not to be lost. The optic disc was atrophied, the arteries and veins small, and he had a loud mitral murmur. He was assured that the blindness was due to the heart, and perhaps the giddiness too. He did not attend again, having had an attack of hemiplegia. Here, no doubt, the blindness was due to embolism.

In another case, Dr. Hughlings Jackson said he had seen blindness of one eye and hemiplegia, but he unfortunately has no note of any examination of the heart. A case like the following evidently belongs to quite a different category:—A young healthy patient is struck on the head, becomes very deaf, and has blindness of the right eye, paralysis of the right third and of the fourth nerves. The optic disc is white and glistening. Again, a young and healthy patient is struck on the head, has discharge of blood from the ears (but no deafness) and from the nose. He is left for dead. He gets rid of the severe symptoms, and comes for amaurosis of the right eye. In the first case, several orbital nerves being implicated, the lesion was clearly about the entrance of the nerve to the orbit, and it is extremely probable it was so in the other.

There is a peculiar defect of vision called hemiopia due to disease of one optic tract, which, of course, injures the sight of

both eyes. Dr. Hughlings Jackson said that he had only seen two cases of this kind—one under the care of Dr. Brown-Séquard, and one when he was Clinical Assistant at Moorfields. In Dr. Brown-Séquard's case the patient had paralysis of one third nerve and partial paralysis of the other, and hemiplegia. As the patient squinted, he knew that he had lost the sight of half of each eye. But in the other case Dr. Jackson had seen, the patient did not know that he had lost half the field of vision of each eye, as the good half of one covered the lost half of the other. The patient under the care of Dr. Brown-Séquard died imbecile, and was, before his death, completely blind. The difference in the ophthalmoscopic signs in the period of half-blindness and of total blindness was most interesting. During the condition of hemiopia, the discs were quite normal; but when total blindness came on, both were quite white. It seemed, then, that during the hemiopia there was enough function to keep up the nutrition of the optic disc; but that when, from further disease (probably encroachment to the commissure, or to the opposite optic tract), the function being then entirely lost, the nerves atrophied.

But, as before said, the common form of amaurosis in brain disease is that in which are found the ophthalmoscopic appearances of white atrophy. It is well known that blindness is found associated with disease of almost any part of the brain; but sometimes with other symptoms it was of great help to locate disease. For instance, Dr. Hughlings Jackson had under his care a boy about 12 years of age, who has double amaurosis, a head twice its natural size, and some time after these symptoms loss of power in all his limbs. In such a case it seemed all but certain that there was a tumour of the vermiform process of the cerebellum pressing on the corpora quadrigemina, causing the blindness, and on the vena Galeni, causing hydrocephalus, the dropsy of the ventricles, just as pressure on the portal vein causes ascites. In another case a patient had double amaurosis and great fulness of the veins of the lids, so that the Surgeon, under whose care she was at first, called the disease varicocele of the orbits. She had also constantly pain which she described as being "in the eyes far back in the head." A tumour was found at the autopsy situated at the sella Turcica.

This last case, too, showed well the usual clinical history of the common form of amaurosis—viz., vomiting and intense pain in the head. The vomiting was "purposeless," and the pain was frequently at the back of the head. But this clinical history was common to cases of blindness, from the most diverse causes. For instance, in apoplexy of the middle lobe, tumours of the cerebellum, and tumours of the hemisphere.

In a few cases Dr. Hughlings Jackson fancied he had been able to be more precise as to the seat of the cause of the blindness.

He had under his care four patients who had had convulsions on the left side of the body and double amaurosis. Of course, it was in most cases difficult to be sure as to the exact range of the convulsions. But in one he had seen the patient in the attack, and in the others there was more or less paralysis on the side said to have been convulsed, confirming the patient's statement. The following was the best of the four cases:—

The first part of the notes of the case was taken at the first visit. Geo. —, aged 30, was admitted, under the care of Dr. Hughlings Jackson, 1862, for epilepsy. A few days before, whilst riding in an omnibus, he had a quivering in the left side of the tongue and left side of the cheek. At the same time the eyes "became dim and sparkled." This continued for seven minutes, and then he, having left the omnibus, found that the left arm was "pulled right up." Next he slipped down, and then became insensible, he thinks for about half an hour. He could tell nothing about his condition in the fit. In a little time he was able to walk from the police station, where he had been taken, to a cab.

Six weeks before he had had a little working in the left side of the mouth for about ten minutes. This was the only suspicious symptom until the attack for which he came.

His general health was good, except that he had pains in the limbs, worse at night. For this he had been attending Mr. Hutchinson, who had given him iodide of potassium. Two years ago he had had chancres, followed by buboes. He had, however, except the pains in the limbs, had no other suspicious symptoms.

It will be seen that the parts affected in the fit are those supplied by the right middle cerebral artery. This vessel supplies the corpus striatum, hence the affection of the limbs; both optic nerves, hence the affection of sight; and the hemi-

sphere, hence the insensibility following the two above-named symptoms in the paroxysm.

Some months afterwards Dr. Hughlings Jackson, not having seen the patient after the first visit, sought him out, and found him blind of both eyes and paralysed on the left side of the face and the left arm. The leg was scarcely affected. Indeed, the hemiplegia was just that which Dr. Hughlings Jackson pointed out in some cases of supposed embolism of the middle cerebral artery.

There was another little fact in this case which rendered the idea of the epilepsy and paralysis being in a definite arterial region more plausible, viz., that the sight of the *right* eye was completely lost, and that there was still partial vision of the other. The right optic tract which sends fibres to both retinae is supplied by the right middle cerebral artery, so that the fibres going from this tract to the left eye would be damaged, and also the fibres going from it to the left optic tract would be so also. Again, the right optic nerve formed by parts of both optic tracts would be affected, as it also is supplied by the artery on the right side.

This holds good for another of the four cases, but in the remaining two the condition is exactly the opposite; the eye on the side of the convulsed limbs is the worse. This, of course, bears strongly against the hypothesis; but Dr. Hughlings Jackson thought there was enough plausibility to render it desirable to investigate further. He thought from several circumstances that epileptic seizures occurred in arterial regions of the brain, rather than in its physiological divisions—in regions of nutrition and not in regions of function; and he thought that the frequent occurrence of amaurosis in brain disease was to be explained by the fact that the optic nervous system from the corpora quadrigemina to the retinae passed through several arterial regions, and that just as hemiplegic paralysis follows hemiplegic epileptiform seizures, so amaurosis follows temporary defects of sight in various kinds of epileptiform attacks.

Dr. Hughlings Jackson has already observed that whenever loss of speech occurs with hemiplegia the hemiplegia is on the right side. A note on this subject will be found in this journal for January 30, but Dr. Jackson has now had under observation about twenty-eight cases, and he still thinks it plausible, if not highly probable, that the cause is embolism of the left middle cerebral artery. He intends, then, to investigate the sequence of symptoms in the paroxysm, and the subsequent mental condition of a patient who has epileptiform convulsions on the left and right side respectively.

Some cases of epilepsy begin by alteration in smell. It is the so-called aura. If epilepsy occurs in arterial systems the spasm should in such cases begin in the range of the anterior cerebral artery; and, if limited to that arterial system, there would be no muscular spasm—no local spasm of one side at least—as this artery does not supply any part of the motor tract.

MIDDLESEX HOSPITAL.

CASE OF SLOWNESS OF PULSE FROM CARDIAC DISEASE (NARROWING OF MITRAL ORIFICE, WITH HYPERTROPHY AND DILATATION OF LEFT VENTRICLE?).

(Under the care of Dr. GREENHOW.)

A. P., aged 32, sawyer; admitted an out-patient March 20, 1863. Had been obliged to discontinue his occupation some time previously, on account of palpitation of the heart and of debility. Pulse 48, feeble and irregular; cardiac dulness increased to twice the normal extent, the extension being in all directions, but more especially towards the left side; perceptible bulging of chest in cardiac region; heart's action irregular; to right of left nipple downwards both sounds are heard almost free from murmur, but feeble; a loud diastolic blowing murmur heard to the left of, and a little below, the nipple; there is neither anasarca nor albuminuria. \mathcal{R} Tinct. ferri sesquichlor., \mathfrak{mxx} .; sp. ether chloric, \mathfrak{mxxv} .; aq. menth, \mathfrak{zj} . M. ter die sum.

April 10.—Slight improvement in general health, but no change either in frequency or character of pulse; diastolic murmur continues; palpitation still troublesome. Emplastrum belladonnæ reg. cord.

(Patient remained under observation till the middle of May, but, though his general health decidedly improved, the frequency of pulse never varied, being always exactly 48 per minute.)

KING'S COLLEGE HOSPITAL.

CASE OF EXCISION OF THE KNEE-JOINT— SUBSEQUENT AMPUTATION—RECOVERY.

(Under the care of Mr. WOOD.)

A MAN, aged 28, of a highly-scorfulous constitution, as marked by enlarged glands and extensive scars about the neck and under the jaw, was admitted into King's College Hospital in August, 1862, for a swelling of the knee-joint, with sinuses below the patella communicating with bare bone at the internal tuberosity of the tibia, but not passing into the joint. The sinuses were laid open, and portions of the bone gouged out without any implication of the joint itself. Afterwards, by the aid of perfect rest and constitutional treatment, the swelling of the joint subsided, the sinuses closed, and he was discharged. He then went to his work, which was heavy and exposed. In April, 1863, he was again admitted with an aggravation of the swelling in the joint, and the formation of more sinuses. The joint was much swollen and very tender. It became evident, after some further treatment, that the joint was now entirely disorganised. On May 9, excision of the knee was performed, the sections of both femur and tibia being sufficiently satisfactory to render it probable that a recovery might ensue with the retention of the limb. The bones were in perfect coaptation, and kept throughout in a very good position and quite unmoved. As the wound healed, however, abscesses formed in the popliteal space, and about the sheaths of the hamstring tendons, which, though freely and carefully opened, burrowed and left sinuses in all directions. He continued to have very fair general health throughout. Finally, he was sent down to the Margate Hospital for sea-air and bathing, remaining there four months. The number of sinuses, however, continued to increase, and the ends of the bones continued moveable upon each other. In February last he was again admitted into King's College Hospital, and at his own request and desire amputation was performed. This was effected in the lower third of the thigh by oblique flaps, so formed as to avoid the diseased jelly-like mass about the sinuses, and to give the best possible drainage to the wound. The flaps united entirely by adhesion, except around the ligatures. These came away entirely in about eighteen days, the femoral ligature being the last to separate. The result three weeks after the operation was a very good square stump, with the cicatrix placed well behind the end of the cut femur, and with no tenderness on pressing firmly over the end of the femur. The specimen showed good broad and level surfaces of apposition at the cut ends of the tibia and femur, with weak fibrous connection over the greater part of their extent; numerous sinuses about the lower and back part of the joint extending in all directions; most of them communicated with a portion of diseased bone upon the projecting portion of the inner condyle left after excision. In this was an opening passing through the condyle, and connected with a sinus passing along the posterior surface of the femur as high as the incision made in amputation. The top of this sinus was left in the flap, but since the operation it has entirely dried up. The cancelli of the diseased bone found at each operation were filled by solid lymph, and presented the yellow, bloodless appearance and friable bone-texture of this species of caries. The synovial textures around the great tendons were also thickened, gelatinous, and suppurating. The muscles of the calf were in a state of fatty degeneration.

MIGRATION OF THE FANG OF A TOOTH.—M. Delestre related to the Paris Medical Society the case of a lady upon whose palate, opposite the first large molar (which was missing), and at about a centimetre from the edge of the gum, was observed a small rounded, blackened loss of substance, which seemed as if it had been punched out. Various Surgeons who had seen it had regarded it as caries of the maxillary bone, and treatment had been employed in vain. M. Delestre found, on examination with a probe, that there was not the crepitation produced by contact with caries, and that a certain amount of mobility existed. Passing in a delicate forceps, to his great surprise, he withdrew the fang of a tooth, about a centimetre in size, which, proceeding from the first molar, had evidently proceeded through the substance of the maxillary bone, and become placed perpendicularly to the palate. The patient remained entirely well.—*Union Méd.*, No. 142.

SATURDAY, APRIL 30.

MEDICAL MEN IN PARLIAMENT.

THE Imperial Parliament very rarely dies a natural death; its appointed term of existence—seven years—is almost always cut short by some political convulsion; and a little time ago there appeared to be considerable danger that the present Parliament would be brought to a sudden and untimely end by one of those fortuitous concurrences of atoms on the wrong side of the House of Commons which lead falling Ministers to “appeal to the country.” Immediate danger seems, however, to have passed away, and possibly Parliament may make a good end, and die in its bed. Even that rare occurrence, however, is so far from being a remote event that the air already begins to grow thick with the sounds of coming contests for the honour of seats in a new House of Commons. Aspiring politicians, rising barristers, ambitious men, and “pure patriots” of all shades of politics, are beginning to bestir themselves, and to look out for chances of obtaining the honour and glory of the M.P.; and even members of our quiet Profession are spoken of as likely to come forward and solicit the sweet voices of the people. And why should they not? Are there any reasons why our Profession should not be represented in the national legislature? It would be easy to give plenty of excellent reasons why it should be. Sanitary Medicine would then have efficient and recognised exponents in the House, and all measures for the care of the public health intelligent and authoritative critics; the Medical services would have advocates of Professional experience and knowledge, and the Profession at large would be directly supported and defended. Great gain would undoubtedly accrue to the general weal, and not improbably some benefit to ourselves from our having a direct voice in the legislation of the country. What, then, can be said against it? We remember that when once, in our hot-headed days, we had warmly engaged in a political discussion, we were “advised” by an eminent barrister present, himself an ardent politician, that “Medical men knew no politics.” Officers of the army and navy have, in times of peace, at least, plenty of leisure to devote to politics, and the mimic strife of party seems congenial to their professions. The clergy, even, generally take their full share in politics, and though they cannot sit in the House of Commons, it is said that to be a warm and decided partisan has not a little helped in gaining promotion in the Church. Perhaps, however, this has passed away, and we may hope that now political activity has, with “inability to construe the Greek Testament,” and some other mundane qualifications, ceased to be an important aid to ecclesiastical preferment. For the aspiring barrister politics and a party are essentials; the only road to the highest honours of his profession lies through the House of Commons; to reach them he must perforce engage in the strife and tumult of St. Stephen’s. But our duties are with the sick and the suffering; our paths lead to the quiet and calm of the sick chamber;

politics are uncongenial to Medical men, and can bring no professional advancement, gain, or honour to any one of us. It may be said, and very truly, that a man may be a most useful member of Parliament without being a politician; but then he must, to gain any weight with the House, devote to it an amount of time and labour that would be to most Medical men professional ruin. To avoid the latter he must hold an entirely exceptional position in the Profession. He must have made such a fortune as renders him independent of practice, and yet retain health and energy sufficient for the wear and tear of Parliamentary life; or have inherited such a fortune after years of practice—for we want no representative who is merely nominally a Medical man. Or he must have some special kind of practice that leaves him at liberty many hours of the day, and that during the busiest time of the year. Or, again, he must hold some public Medical appointment which frees him from private practice; or, finally, he must be known to have made sanitary science or State medicine his special study, and be willing to make large sacrifices of Professional success for the public good. How very few men can be found who can be placed in any of these categories we leave others to calculate. Still, there is no doubt that fit candidates can be found—independent men, of experience, knowledge, and learning, of some eminence in the Profession, and men who will devote themselves, not to party, but to mankind. But where are the constituencies that will elect them? How are the “sweet voices” to be gained by a man who is no politician, and pledges himself to no party? Abroad, as in Germany and Italy, Virchow and others are influential in the Parliaments of their countries; but they are there as party-politicians, and we have no wish to see their example followed here. Our more happy country does not require men of scientific and liberal education to fight the battle of liberty. We heartily desire to see Medical men in Parliament; we believe their presence there would be a great gain to the nation, and a great advantage to the Profession; but we do not wish to see them as politicians. Their platform, to borrow an American expression, must be science and knowledge, with moderately liberal politics, but no extreme views of any kind. Let men of fitting standing in the Profession, and holding such views as these, come forward, and they shall have all the support we can give them, and they would, we believe, be warmly supported by the whole Profession; but we confess that unless they are taken by the hand by some enlightened layman with predominating influence in some borough, or until we get a Reform Bill giving us what have been contemptuously termed “fancy franchises” and “constituencies,” we should have but small hopes of their success.

We have heard of two members of our Profession as likely to present themselves at an early period as candidates for seats in Parliament—Dr. Lankester and Dr. B. W. Richardson; we have heard them both spoken of as possible candidates for the seat which, it is rumoured, Sir Morton Peto will shortly vacate. They are both well-known men of science; the one has been a special, early, and persevering teacher of hygiene, the other holds an important public appointment; both would earnestly and honestly employ their great abilities and high scientific acquirements for the advantage of the Profession and the good of the public. We hope that such men would not woo in vain, but we also earnestly hope that they will not both woo the same love.

A CONTINENTAL VIEW OF THE “FEE QUESTION.”

WE have several times of late had occasion to bring the question of Medical fees and their recovery under consideration in this journal. The question is not an insular one. It concerns the Profession wherever its members are established in civilised countries. Human nature is everywhere the same, and gratitude for benefits received is exhibited just as rarely and just as frequently under one sky as under another. “My dear Doctor,” who is sincerely welcomed and willingly fee’d,

at the time that his services are most urgently needed, is very apt to be received with coolness when his patient has recovered, and a demand is made, or about to be made, upon the purse. The history of the "ten cleansed" and the one thankful finds its parallel every day and everywhere. Our Continental *confrères* have thus the same difficulties to contend with as ourselves. Devoted to a profession, humane, self-denying, beneficent, divine, they, like ourselves, must live by it respectably; and, while maintaining this right, meet ingratitude with the dignity becoming those who walk—albeit, at an infinite distance—in the very footsteps of Him who "went about doing good" and "healing the sick." How far this dignity is compromised by Medical men rushing to a law court for the recovery of their just remuneration, and what remedy for an acknowledged evil might be adopted in the opinion of some of our Gallic neighbours, may be gathered from the report of the General Commission of the "Association des Médecins du Rhône" recently published in *L'Union Médicale*. The members of the Commission were MM. Diday, J. Bonnet, Bachelet, and Rougié; the last is the legal adviser of the Association; the other names are well known to all readers of French Medical literature. The two questions proposed to them were:—1. By what means may the fees of Medical men be placed on a level with the dignity and the necessities of the Profession? and 2. How the general Commission of the Association ought to interfere in this respect? It was felt that, while for many years past the price of all the necessaries of life had risen, the traditional fees of the Profession had remained stationary; and hence the first proposition they undertook to consider was the establishment of a fixed tariff of charges to be calculated according to the importance of the service rendered and the position of the patient. As it happened, such a tariff would have been inoperative, because illegal; the Commission, however, do not regard this legal impediment with regret; for, besides being inefficacious, they consider that it would have been contrary to the true interests of the Profession. "The palm from the 'concours,' brilliancy of talent, authority the result of long practice, or studies of a special character—in fact, a variety of circumstances, sometimes even chance circumstances, inspire the public with exceptional confidence. Will you compel," they say, "those who are its object to bow beneath the yoke of a tariff? Are there not between such persons and their patients relations that escape the conditions of customary remuneration? Will you make an exception? But, then, for the benefit of whom? What authority shall determine the persons to be comprised by it? And, if there are exceptions which must be left to the determination of those who shall consider that they ought to apply to themselves, what becomes of the force of the regulation? Will the public sanction your decision?" "With patients who appreciate your devotion, no tariff is necessary; such as these know that the fees they pay do not free them from their obligation to you, and their gratitude survives the remuneration." And as to the other class, it is held that "they would deny your capability of appreciating their situation and of determining the extent of their obligation." The second proposition considered was to invite the members of the Association to augment their present rate of fees by about a fourth; but it was felt that similar objections applied to this as to the first proposition. Putting aside, then, all propositions in which a definite tariff of fees is involved, the Commission proceed to state the positive results they have arrived at. "The first result," they say, "to obtain is that no member of the Medical body should compromise his dignity, his interest, and that of his brethren, by practising Medicine at reduced prices." "When your benevolence is appealed to, a free field is open for it, and every one knows that it is largely exercised. . . . But when you are not called to relieve misfortune, you have a certain right to be remunerated for your services according to their extent and the position in life of the sick. If by a lamentable carelessness a Medical man neglect to obtain this remuneration from those who can give it; if from other less excusable

motives he contents himself voluntarily with fees less than those which are generally demanded, he not only does a wrong to himself, but discredits the practice of the Profession in general—he depreciates the services of his brethren, and contributes to maintain their estimation at the level of a lamentable inferiority." . . . "It is better to refuse all remuneration for the past, and even all service for the future, than to compromise equity and propriety by the acceptance of beggarly fees." A further result of the deliberations of the Commission is the proposal that the Association should constitute itself a quasi court of equity in all questions of remuneration which may arise between its members and their patients, and that no appeal to a public court of law should be made except under its sanction, and until all the chances of a friendly solution have been tried in vain. The Commission anticipate that thus by degrees there would arise such a series of precedents as will guide the members in the exercise of their Profession, and enlighten the public upon the real value of the services it renders. They say:—

"We cannot conceal from ourselves the fact that in general the public tribunals only experience a painful impression when a Medical man brings before them a claim for his fees. Do not be surprised or hurt at this. An assimilation between the two liberal professions *par excellence*, Medicine and the bar, is very natural; and if the Chancellor of Aguesseau has been able to say of the Order of Advocates that it is as ancient as the magistracy, as noble as virtue itself, as necessary as justice, what might not be said of Medicine, the devotion of which had its commencement with the sufferings of humanity, only to find its end with their termination?"

Let our readers recall for a moment the views upon this important, but unpleasant, subject which we have over and over again expressed, and they will not be surprised that we should simply leave the opinions thus propounded by the Association des Médecins du Rhône to the honest judgment of the Profession in England. We have amongst ourselves an association whose boast it is that it embraces amongst its members not only the *élite* of the Profession, but its hard workers in Hospitals, prisons, Poor-law unions, and private practice among persons of all classes in every county and every town through the length and breadth of our country. We say, then, to the British Medical Association, "Go and do likewise!"

THE ARMY MEDICAL SERVICE.

THE systematic way in which all questions affecting the interests of the Medical Profession are ignored by Government bodies is truly surprising. In our last number we recorded a glaring instance of this. Mr. Bazley asked a question of Sir Charles Wood about the number of candidates which were appearing for the Indian Army Medical Department. An answer to this disagreeable question was ingeniously evaded by a quibble. Since the amalgamation of the Indian with H.M.'s army no separate examinations have been held for the Medical Department of the former. We presume that anything and everything is fair in politics as well as in war. Sir C. Wood knew well enough what was meant; he and his colleagues understood only too well what a damaging admission would have to be made by a frank answer; and he was too wary a soldier not to fall behind the cover of a quibble. Whenever an honourable Member of the House of Commons does venture upon a question of Professional interest—which is seldom enough the case, Heaven knows—it is ten to one that he is himself sufficiently acquainted with it to serve any useful purpose. The War Office and Horse Guards have it all their own way; and nothing short of an absence of any candidates at all will suffice to convince them that *that* way is not pleasing to the Medical Profession. The shifts and expedients to which they have been driven are so many confessions of the weakness of their cause. After fishing in vain in London preserves, they contented themselves with the few specimens of average fish they could obtain in Ireland. That failing, they betook themselves to the millstreams; and as they could not have

salmon they contented themselves with sprats. The last haul did not sink the ship, for it amounted to seven only.

We will supply Mr. Bazley with an answer to his question. For about two years the number of candidates for the so-called *competitive* examinations have invariably been less than the number of vacancies, and of late the supply has been by dribblets only—a little in excess, certainly, of the resignations. It is notorious that the Army Medical Department is extremely unpopular, and the Indian part of it still more so. We receive, in common with other Medical journals, a goodly array of letters from Medical officers, and they are wonderfully alike. No one can miss their meaning, and it is the same with what we hear verbally from the same sources.

And now it is with regret that we direct our readers' attention to the fact that advertisements have appeared for Acting Assistant-Surgeons for temporary service in the United Kingdom. It is with a feeling of indignation that we record these expedients; but we fancy this must be the last, for it surpasses the others in folly and injustice. To Dr. Gibson it must be humiliating to have to advertise, as it were, the great unpopularity of the Department over which he presides; to the soldier it is wrong, in that our troops will now be committed to the tender mercies of men whose chief qualification will be their having reached maturity without having secured any success; to the Government it is a scandal that, when every avenue to the public service by competition is choked with candidates, the Army Medical Department should be obliged to *abolish all* competitive examinations; and to the Medical officer it is a hardship and injustice that he should have to undergo the banishment from home which this threatens.

As soon as the authorities meet the evils which undeniably exist in the Medical Department in a fair and candid manner there will be no need for all these shifts, and we hope that the Director-General and every one in authority will urge upon them the only course which can bring success. Every day the task before them increases in difficulty.

THE WEEK.

ILLNESS OF DR. T. K. CHAMBERS.

THE illness of Dr. T. K. Chambers, Physician to St. Mary's Hospital, has excited so much sympathy in the Profession, that we shall not be violating the reserve with which the misfortunes of less conspicuous men should be treated, if we record that which is well known to every member of the Profession in London. It seems that he had suffered for exactly ten days from popliteal aneurism; on the 11th day, the 27th April, the aneurism burst; the leg became rapidly distended with extravasated blood, spite of the compression kept up on the artery by a relay of Medical students; the limb was amputated at 6 p.m. by Mr. Paget, in the presence of Dr. Acland, Dr. Gull, Mr. Cæsar Hawkins, and Mr. Arnott. Mr. Potter, of St. George's Hospital, gave chloroform. We are glad to say that on Thursday morning Dr. Chambers was going on favourably.

TRINITY COLLEGE, DUBLIN, v. THE KING AND QUEEN'S COLLEGE OF PHYSICIANS OF IRELAND—DECISION OF THE MASTER OF THE ROLLS.

It will be remembered that in this case a petition was presented by Trinity College for the purpose of obtaining a decree declaring that the Irish College of Physicians are not entitled to confer the degree of Doctor of Medicine upon their Licentiates. The case was argued last term, and a full report of the pleadings on either side appeared in this journal. The Master of the Rolls, after taking full time to consider the case, has now delivered judgment. We must confess that we greet his decision with satisfaction. To give a non-academical corporation the power of conferring an academical degree by the mere act of examining for their licence would be to introduce

a fresh element of confusion into the ranks of the Profession, and to increase the heartburnings and jealousies amongst the existing examining bodies. The Members and Fellows of Colleges of Physicians are entitled by long usage and courtesy to the style and title of "Doctor," but only Universities and the Archbishop of Canterbury can give a man a right to use the magical affix of M.D.

The following is a condensed report of the judgment:—

"The Master of the Rolls now gave judgment, granting the prayer of the petition, and holding that, under the true construction of the charter of the College of Physicians of 1692, its licentiates had no authority to use the title of Medical Doctor unless the same were conferred upon them by one of the Universities. His Honour went at great length into the history of the College of Physicians, and in conclusion said that it was surprising that a body consisting of such eminent men should allow itself to be so misled as it had been. Whilst he only expressed the general opinion that a licentiate of the College of Physicians stood as high as any gentleman holding the degree of Doctor of Medicine from a University, he would say that if the heads of the College had read the charter of 1692 in its simplest sense, and in the absence of legal interpretation, they would have come to the conclusion that they had no right to confer degrees. By a singular accident he had this morning received from her Majesty's Stationery Office, London, a copy of the Medical Register for the year 1864, compiled by the General Medical Council, and which contained the names and designations of all the Medical Practitioners of the United Kingdom. In this document he found the names of the witnesses who had been examined on the part of the College of Physicians, some with the designation 'Doctor,' and others with that of 'Bachelor' of the University of Dublin, but only, so far as the College of Physicians was concerned, with that of 'Licentiate.' He was called upon, in fact, by the respondents in the present suit, to set aside this public document, compiled, as it had been, under the directions of an Act of Parliament; but the circumstances of the case would not warrant him in doing so, and he was therefore obliged to declare that nearly nineteen out of every twenty gentlemen of the Medical Profession in Ireland, who were licentiates of the College of Physicians, were not entitled to add 'M.D.' to their names. If he were wrong in this judgment, there was ample opportunity of setting him right; but his present impression was that his opinion was in accordance with the true construction of the charter which had been relied upon."

REPORTERS AT THE GENERAL COUNCIL.

THE General Council of Medical Education and Registration have resolved that reporters be admitted to attend their proceedings. We are sorry for it. The proceedings of the Council have not been very fruitful in results as yet, and now that the members, instead of confining their attention to the merits of the matter before them, may have their thoughts directed to the effect of their speeches upon the public, we have less hope than before. Through the crowded state of our columns this week, we regret that we are obliged to postpone our report both of the minutes and of their deliberations.

PREVALENCE OF SKIN AFFECTION IN THE METROPOLIS.

THE number of cases of anomalous skin eruption, at present, in some districts of London is so great as almost to constitute an epidemic. In some cases the eruption resembles roseola, in others lichen urticatus, in others it puts on a rubeoloid character. The symptoms are red patches, especially on the face and extremities, mixed with pimples, itching and tingling, some headache, but no sore throat, and no catarrhal symptoms. Many experienced Practitioners say that they have been puzzled to give a name off-hand to the eruption.

PARLIAMENTARY.

IN the House of Commons, on Thursday, April 21, in reply to a question put by Mr. Kinnaid, the Chancellor of the Exchequer stated the proceedings which had given rise to what he termed "the absurd rumours" as to the reasons

of the curtailment of the visit of General Garibaldi, declaring the "ridiculous stories" which had been circulated on the subject to be entirely destitute of any shadow of foundation.

The Select Committee on the Government Annuities Bill having been nominated, Sir M. Farquhar moved that the committee have power to send for persons, papers, and records.

The Chancellor of the Exchequer opposed this motion, urging a variety of objections to taking evidence before a committee upon such a measure, for which the Government was responsible, an inquiry that would throw over the bill till another session.

A sharp debate followed, in the course of which

Lord Palmerston observed that the real question was whether the bill should be entirely thrown over, for that would be the effect of the motion if it were carried. It would be much fairer to move its rejection at once.

Upon a division the motion was negatived by 127 to 104.

In the House of Lords on Friday, April 22, the Earl of Ellenborough, in introducing a bill on the subject of remission of death sentences, said that recent proceedings had shown the absolute necessity of a change in the present practice at the earliest possible period. It was most desirable that the greatest weight and authority should be given to decisions in regard to sentences of death, whatever they might be. It was not right that the life of a man should depend on the particular views or temperament of the Home Secretary, and that the whole responsibility of deciding should be cast upon that functionary alone. Looking back to his own experience, dating now about thirty-five years ago, of the ancient course of proceeding, he recollected when the Recorder of the City of London used to present a report on capital sentences for the decision of the Government. In that case all the members of the Government, with the addition of the Chief Justice of the Queen's Bench, were summoned to attend the Sovereign. The King was present at these meetings, and took part in the discussions which arose. He knew that His Majesty George IV. regarded this duty as one of the most important which he had to discharge. He had no recollection that in those days, under any circumstances, distrust was manifested concerning the decisions arrived at. On the contrary, they seemed to give general satisfaction. That course of proceeding continued until the accession of her present Majesty, when it was deemed expedient, and he did not dispute the expediency, to render it no longer necessary for a youthful Queen to be present at the consideration of such questions. He remembered very well, however, that the Duke of Wellington, while consenting to the alteration, lamented that at the very commencement of a female reign it should be necessary to change the course of proceeding which had continued for so many years. The penalty of death no longer attached to certain crimes which it was then held improper to bring under the notice of a youthful Queen; and that reason for the new system had therefore ceased to exist. At the same time, he did not propose to place any additional burden on Her Majesty; but, recollecting the value of the solemn proceeding of the Sovereign in Council with regard to decisions or sentences of death, he thought it desirable that it should be revived, with the condition that the presence of the Sovereign should not be insisted upon. If the principle of the Bill met with approval, he trusted the Government would adopt it, for he felt it was more appropriate that the responsibility of such a measure should rest on them than on an individual peer. If on the other hand, the Government would not accept the bill, he hoped that at the earliest opportunity they would submit some proposal of their own on the subject, better than that he now tendered. He was satisfied that the practice of the law ought to be amended, so that the utmost authority and weight should attach to decisions in regard to capital sentences, and that the whole responsibility should not be thrown on the Home Secretary alone. Unless the country was made to understand that entire confidence could be placed in the decisions on these questions, there would be some danger of our being forced to abandon a punishment which he believed to be necessary in the interests of society. (Hear, hear.)

The bill was then read a first time.

Lord Derby moved that it should be an instruction to the Committee on every Metropolitan Railway Bill to require the several companies to provide cheap transit to and from London, every morning and evening, for the labouring classes. He only wished to lay down a principle for the guidance of the Committees, the details of time and distance to be determined by the circumstances of each case.

After a short discussion the motion was agreed to.

In the House of Commons, Sir C. Wood, in answer to a question by Lord Stanley, said that no despatches had been received from India on the subject of the order prohibiting the native custom of burning the dead on the banks of the Hooghly, and the only information he possessed was derived from private sources. The cholera had been exceedingly prevalent at Calcutta lately, and the greatest possible alarm had been created there in consequence. The question was therefore taken into consideration of what was to be done to check the spread of the disease, and an order was issued to prevent the throwing of dead bodies into the Hooghly. Anything more disgusting than the sight of the dead bodies floating up and down that river could hardly be imagined, and it was thought most desirable to prevent that practice. With regard to the burning of dead bodies, he did not believe that any order on that subject had been issued; but there was, he thought, a proposal that means should be provided for the burning of dead bodies at a short distance from Calcutta. He had reason, however, to know that, if the objections to it were as strong as was represented by some persons, that proposal would not be persevered with.

In the House of Commons on Tuesday, April 26, Lord R. Montague moved for a Select Committee to inquire into any plans for dealing with the sewage of the metropolis and other large towns, with a view to its utilisation for agricultural purposes.

Sir J. Paxton was of opinion that the inquiry would be of no use.

After a few remarks by Mr. J. Miller and Mr. Caird, the motion was agreed to.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XIII.—MARCH 1.

The Anatomy of the Chimpanzee continued.—The larynx of the chimpanzee has all the essential parts of the same organ in man, every cartilage, ligament, and muscle being represented, with only differences of detail in form and proportion. There is, however, connected with it a very singular exaggeration of a structure existing in man, the so-called *sacculus* of the larynx. This undergoes on the left side a most remarkable enlargement in the adult chimpanzee, forming a pouch which extends beneath the sterno-thyroid and sterno-hyoid muscles, into the anterior triangle of the neck, and even projecting into the axilla. The function of this great air-sac is entirely a matter of speculation at present.

The chimpanzee has the same dental formula as man—viz.,

$$i \frac{2-2}{2-2}, c \frac{1-1}{1-1}, p \frac{2-2}{2-2}, m \frac{3-3}{3-3} = 32$$

The teeth agree with those of man in some of their most characteristic features. Of the incisors, the median pair in the upper jaw, and the outer pair in the lower jaw are the largest; the upper premolars have two cusps, of which the external is the most developed; the lower premolars have two cusps united by a transverse ridge; both the upper and lower molars have the same pattern as those of man, but in a marked and exaggerated form. The teeth also present the following differences from those of the human subject:—The arrangement of the alveolar arch in both jaws vastly exaggerates the peculiarity found in the lower races of man, the sides being quite parallel, or even slightly concave externally; the absolute size of the teeth is greater in the chimpanzee than in man; the upper canine especially is much larger, particularly in the male sex, where it is prominent and pointed as in the carnivora, though only used as a weapon of offence and defence, not in securing prey. The lower canine, though smaller, projects above the others of the series, and its axis is obviously anterior to the upper one, and there is an interspace to receive it between the latter and the contiguous incisor. The anterior premolars of the lower jaw present a certain declivity of the front edge, which is an approach to the very peculiar form of this tooth in the lower apes. The premolars of the upper jaw are implanted by three, those of the lower jaw by two fangs, thus presenting a considerable difference in this respect from the

human subject. In their mode of wear the teeth present peculiarities observed in the lower races of men, the incisors bite directly one against the other, and become ground to a flat surface, and the outer edge of the lower, and the inner edge of the upper molars first show signs of attrition.

In the deciduous dentition we have the essential human characters repeated, with remarkable differences of detail. The first canines are proportionally small, projecting but slightly above the remainder of the series. The pattern of the milk molars of the upper jaw is as in man; in the lower jaw, however, it differs considerably, the posterior tooth especially having only four cusps instead of five. In the order of succession there is a difference from that observed in man. The great canine, appearing to require longer elaboration, does not come into place until after the molar series is complete.

The soft palate has a well-developed uvula. The tongue is very like that of man, except that the circumvallate papillæ, instead of being arranged like a V, are like a T, with the top turned forwards. The salivary caruncle beneath the tongue in the middle line is lengthened out to a point, presenting an indication of the greatly-developed "sublingua" of the lower apes and lemurs. The stomach and cæcum closely resemble those of man in form, and there is a long vermiform appendage. The great vessels arise from the aorta in precisely the same manner as in man.

Of the brain a remarkably excellent account has lately been published by Mr. Marshall, the statements in which Professor Huxley had himself been able to verify in a recent specimen. The largest brain of an adult chimpanzee, judging from the size of the interior of the cranium, is less than half that of the smallest normal human subject, and as shown by casts that were exhibited, very much less than half that of the average Australian or African brain. In Mr. Marshall's young chimpanzee the brain weighed 14 oz.; that of a European child at a corresponding period of dentition being 38 oz. The form of the brain differs from that of man, in being less convex in the parietal region, but more particularly in the great diminution of the anterior portion, which is cut away laterally so as to bring it to a point in front, and greatly excavated beneath in the supra-orbital region. The general divisions of the brain into segments are the same as those before given in the lecture on human anatomy. The olfactory segment bears a striking resemblance to that of man, being thin and flat, and received into a groove on the under surface of the frontal lobe. The cerebral hemispheres agree with those of man in the manner in which they cover all the other parts, so that on looking at their upper surface no portion of the olfactory lobes or cerebellum are to be seen. According to Mr. Marshall, the amount of overlap of the cerebrum behind the cerebellum is greater proportionately to its length than in the average human brain. If we adopt the old division of the hemisphere into three lobes, anterior, middle, and posterior, we find them all represented in the chimpanzee's brain, and agreeing with the definitions given of them in human anatomy. The five lobes of the outer surface, as defined by Gratiolet, can also be distinctly traced. The central lobe, or island of Reil, though more simple, has the same form and is sulcated on the same fundamental pattern as in man. The other lobes present all the sulci and gyri previously described in man, with the following differences of detail:—The principal character by which the Bosjeswoman's brain was seen to differ from the European's is here greatly exaggerated; the gyri are much larger in proportion to the brain, are less complex or subdivided, and present more bilateral symmetry. The fissure of Sylvius is less inclined; the fissure of Rolando is placed further forward than in man; the insula is no longer completely covered by the temporal lobe in front; of the annectent gyri only the second, third, and fourth appear on the surface; the first is folded upon itself, giving rise to the external perpendicular fissure, a peculiarly simian character. On the inner face of the hemisphere every gyrus and sulcus seen on the human brain can be traced, the principal differences being

the smaller mass of brain lying above the corpus callosum and the forward inclination of the internal perpendicular fissure.

In the interior anatomy of the brain may first be noticed the smaller proportionate volume of the corpus callosum, although it has all the same parts and general form as in man. The septum lucidum is exceedingly thick, and the precommissural fibres well developed. The lateral ventricles are, in proportion to the size of the brain, as large or larger than in man, and have the same general form. The anterior cornu sends no prolongation into the olfactory lobe. The descending cornu contains the hippocampus major, which frequently shows digitations upon its terminal part; the posterior cornu has the same form and extends as far back as in man, and contains within it a well-developed hippocampus minor and collateral eminence, having the same relation to fissures on the surface as in man, as can be most readily demonstrated by transverse sections. No hard bodies have as yet been found in the Pineal gland. There are two distinct corpora albicantia. The cerebellum is singularly like that of man, but is larger in proportion to the cerebral hemispheres; in Mr. Marshall's chimpanzee it was as 1 to $5\frac{3}{4}$, in man as 1 to $8\frac{1}{2}$. Both the width of the cerebellum, and of the nerves coming off from the base of the brain are proportionately greater than in man. Finally, the entire absence of these intervals between the pons and the anterior pyramids called "corpora trapezoidæ," found in the lower mammals, may be noted.

FROM ABROAD—SENSATIONAL SURGERY IN FRANCE—ARTERIAL
ULCERATION FROM ABSCESS.

A KIND of "sensational" Surgery seems to be becoming prevalent in France, which we hope will not find imitators among ourselves. Recently (*Med. Times*, March 12) we narrated the dramatic incident of four or five Medical students succeeding each other in performing insufflation by the mouth after tracheotomy in a case of diphtheria. So laudable was the procedure deemed that the Director of Hospitals tendered its performers his formal thanks, and said that he was certain that they would never want imitators. Now, another story is going the round of the papers, amidst salvos of applause. A man at St. Quentin having been seriously bitten by a dog, was taken to the house of Dr. Gobet, who, to the justifiable astonishment of the patient's companions, at once applied his mouth to the wound, and began sucking like an infant at the breast, only leaving off in order to breathe; after dashing away the blood which befouled his lips and face, he again renewed the process. Next, having cauterised the wound, he thus addressed his patient:—"Depart, my friend, with your mind at ease as regards the consequences of the bite. Whatever may be the condition of the dog which has bitten you, you have nothing to fear. All danger is at an end, for I have removed whatever impurity may have lain in the wound. Once more, you have nothing to fear!"

M. Dolbeau related an interesting case to the Society of Surgery. A young lady, 16 years of age, habitually of good health, had an abscess on one of the cervical glands, which, having been opened, continued to discharge just like an ordinary abscess, when, about the seventeenth day, large quantities of blood began to issue forth. When M. Dolbeau was called in to her she had lost a large quantity, and seemed moribund. Having made a long incision in the course of the sterno-cleido-mastoid muscle, he turned out an immense accumulation of coagula, and found an open artery, which he took for the thyroidean branch of the carotid, and endeavoured to secure it. This was impossible, on account of its extreme friability, and he therefore determined to tie the external carotid, which, amidst the inflamed tissues, was a work of some twenty minutes, during which he every instant expected to see his patient expire. The vessel once secured, however, all hæmorrhage ceased, and the girl rapidly recovered, no secondary hæmorrhage ensuing. M. Chassaignae observed that this case reminded him of an

instance of an abscess which supervened upon an amygdalitis in a man from eighteen to twenty years of age, the spontaneous opening of which was followed by a hæmorrhage, which proved rapidly fatal. Now, if in this case, in place of its being left to nature, a Surgeon had intervened, the responsibility of the accident would have been laid to his account. Cases of ulceration of arteries through the agency of purulent collections are less rare than is supposed. M. Morel-Larallée met with such in a case of abscess of the axilla which he had opened. At the end of three months a copious and obstinate hæmorrhage occurred, whether arterial or venous could not be determined. It, however, stopped after a while, and the patient recovered. M. Trelat could not see how the Surgeon could be rendered responsible in these cases, as the hæmorrhage does not usually occur for a more or less long time after the opening of the abscess. He has met with two such cases. In the one, a woman, the subject of suprahyoidæan abscess, was seized a month after this had been opened with hæmorrhage, to which she succumbed; and in the other, a young man also died from hæmorrhage, which came on a fortnight after a deep-seated abscess of the thigh had been opened. M. Morel Lavallée observed that a regard for Surgical responsibility required that it should be well known and admitted that these hæmorrhages by no means only come on after a long period, but may occur at any time after the opening of the abscess. M. Giraldès pointed out that several cases like that of M. Dolbeau are related by Hodgson. These abscesses of the neck usually occur in children and young persons after scarlatina angina, which induces ramollissement and suppuration of the glands, the vessels of the vicinity sometimes participating in the change. M. Marjolin, in corroboration of what had fallen from M. Giraldès, observed that it is by no means rare to observe in children hæmorrhage in the vicinity of abscesses of the neck as well as in the vicinity of the axilla and groin; and such hæmorrhage is not only found at a distant period, but may occur at the time of opening the abscess, whether this be spontaneous or practised by the Surgeon. Sometimes an enormous quantity of coagula is discharged with the pus, and the bleeding may recur again and again with great obstinacy, resisting all means for arresting it. It is of the highest importance that this should be known in relation to Surgical responsibility before the tribunals. M. Bauchet saw in M. Velpeau's practice an arterial ulceration produced by an enormous abscess at the upper part of the thigh. Nothing unusual ensued on the opening of the abscess, but next day an alarming hæmorrhage occurred, rendering the ligature of the femoral artery necessary.

LEPROSY IN INDIA.

It will be in the recollection of many of our readers that attempts have lately been made, both in Germany and England, to obtain extensive and reliable information as to the pathological history, geographical distribution, and causation of leprosy (*Lepra Arabum*, *Elephantiasis Græcorum*). With this end in view, Professor R. Virchow, of Berlin, appealed in 1862 to Physicians, historians, and travellers to afford him materials for composing a history of leprosy. A portion of the information he obtained has appeared in the eighteenth volume of Virchow's *Archives*. But, as he states, there are still important gaps to be filled up, even in the history of leprosy in Europe, and accordingly in April of last year he issued a fresh request for information on the subject. In his letter dated April 18 he states that he has obtained scarcely any details with regard to the state of lazarettos in Austria, and that next to nothing is known in reference to the history of the disease in Westphalia, Hesse, Hanover, Oldenburg, Holstein, and Eastern Prussia. There is also almost an entire absence of information with regard to the Slavonic countries. If it be true, as Richter asserts, that leprosy first appeared in Russia in 1426, a period when it had assuredly begun to disappear in other European States, this fact would alone be a valuable addition to the current knowledge of its history. In

August, 1862, at the request of the Duke of Newcastle, the Royal College of Physicians of London appointed a committee to collect information. The committee drew up a series of interrogatories which were sent to the various Medical authorities both in our Eastern and Western colonies. We have before us as the first fruits of the harvest of information which may be expected, the replies furnished by Assistant-Surgeon Dr. H. V. Carter, of the Jamsetjee Jejeebhoy Hospital. Dr. Carter's contributions on this subject are especially valuable, as for several years he has paid considerable attention to it, and has had a wide and fruitful field for observation. Dr. Carter states that leprosy is well known in most, if not in all, parts of India; that it prevails extensively in the Bombay Presidency, and that it presents itself under three forms or varieties. (1.) The first is an eruption on the skin, probably allied to *Lepra* (*Græcorum*), and accompanied by anæsthesia. This form has not been accurately distinguished by writers, but it is probably the *Leuke* of the Greeks, the *Baras* or *Beres* of the Arabs, and, perhaps, the *Barat Lebena* of the Hebrews. To it belongs the *White Leprosy*, or *Shvet-kusta* of India. (2.) The second variety is characterised by "anæsthesia of the skin of the face, ears, and extremities; followed in the latter case by atrophy, interstitial absorption, and, occasionally, ulceration of the benumbed parts, notably of the fingers and toes." This is the most frequent form. It is the *Guleet-kusta* or *Sunbahiree* of the Hindoos, and has been described as anæsthetic leprosy or articular leprosy. (3.) The third form is marked by tumefaction or tubercular thickening of the skin. It principally attacks the face and extremities, but is less marked on the trunk. This variety is best known and has attracted most attention in the west, but it is not the commonest in India. It is the *Tubercular Leprosy*, the *Elephantiasis*, *Leontiasis* of the Greeks, the *Lepra* of the translators of the Arabian writers, the *Jezam*, *Da-al-asad* (lion disease) of the Arabs, and the *Ructa-kusta*, *Ructa-pitia*, *Maha-viadhi* of Hindoos. Dr. Carter considers the second form to be the typical and most invariable, but he asserts that all three are but varieties of one common affection; they seldom occur separately, being almost always combined at certain stages; different members of the same family may be affected with each, they occur under the same circumstances and in the same locality, and a parent, the subject of one variety, may transmit another to his offspring. On the subject of premonitory constitutional symptoms ushering in the affection, Dr. Carter's experience is at variance with some other observers. He states, as the result of his inquiries, that there are no special or invariable premonitory phenomena. What the patient sees is generally his first intimation. The tubercular form appears soonest to lead to a fatal issue, evidencing perhaps a deeper taint than the more common or anæsthetic variety. The eruption alone does not seem materially to shorten life. Taking the disease as a whole, its duration may extend to twenty years, but from five to fifteen years is probably the usual period. In the town of Bombay the mortality seems to reach its maximum at about the age of thirty years. The male sex furnishes the most frequent cases of leprosy. The proportion of males to females is said to be about four to one. Leprosy principally attacks the native races. The mortuary returns of Bombay for 1860 show that the greatest number of deaths from the disease had occurred amongst the native Christians, next amongst the Marathas and low-caste Hindoos, particularly the latter; then follow the Mussulmans, the Parsees, and the vegetable-feeding Hindoos, whilst no case was furnished by the Jewish and European populations.

Although no caste is exempt, leprosy principally affects the lower orders of native society; the greater number of lepers are from small hamlets and rural districts, but many are from the towns. These districts are principally on the sea board, but the disease is also found inland, and Dr. Carter does not believe it to be essentially connected with sea coast residence. Neither is it limited to low land, as it occurs in the high districts of the Deccan, but Dr. Carter thinks that it seldom arises *de novo* in cool and dry localities. With regard to the effects of hygiene and mode of living, it does not appear that those affected have, previous to the appearance of the disease, been under influences different from their neighbours. Dr. Carter thinks that leprosy is a cachexia comparable in some respects to the syphilitic and strumous. Like the latter, it is clearly hereditary. There is no direct evidence that it is dependent on, or connected with, syphilis; but Dr. Carter strongly suspects that the two diseases are essentially related. Leprosy, however, does not appear to be transmissible by sexual intercourse, and Dr. Carter knows of no reliable evidence which

would prove it contagious. He is inclined to think that the disease may be on the decrease. He believes it to be a constitutional affection having a local manifestation, and no more spontaneously curable than syphilis or struma. With regard to the causes of the disease, he thinks they require to be investigated *de novo*, and suggests that a special commission be appointed to investigate them. Dr. Carter, from the data he has collected, places the following districts in order of furnishing the greatest number of cases:—1. The Concan generally; 2. Guzerat; 3. The Deccan and table-land; 4. Rajpootana; 5. Kattiawar; 6. Kutch; and 7. Scinde.

The preceding are the principal points of interest contained in Dr. Carter's valuable report. If the inquiries instituted by the Royal College of Physicians succeed in eliciting equally reliable information in other quarters, that body will have conferred a real benefit on scientific medicine.

REVIEWS.

The Insane in Private Dwellings. By ARTHUR MITCHELL, A.M., M.D., Deputy-Commissioner in Lunacy for Scotland, etc. 8vo. Pp. 97. Edinburgh: Edmonston and Douglas. 1864.

THE object of this treatise is stated to be to exhibit the condition of the insane in private dwellings; to show the extent of proper treatment, which can be found in such establishments, for a certain class of them; and to prove the necessity which exists of providing for the accumulation of chronic cases in asylums an outlet which shall meet the requirements of humanity and economy.

It seems that the Scotch law, differing from that of England and Ireland, divides the insane not confined in asylums into two classes, according as they are supported by their own means and those of their friends, or as they derive maintenance wholly or partially from parochial boards. Their number in January, 1862, was estimated at 3628, of whom 1887 were non-paupers, and 1741 paupers. About 44 per cent. of all the insane in the country are thus provided for. Those who board with strangers at their own cost are required to be under the sheriff's warrant on certificates of insanity from two Medical men; they are visited at stated periods by officers of the Board of Lunacy. It is unfortunate that an excellent provision should be systematically evaded, so that not more than one in fifteen are in conformity with the Act. Those who live with relatives are even less under the control of the Board; but where the insanity requires coercion, and has lasted above a year, the house-occupier or Medical man is required to inform the Commissioners of the detention. From inquiries made by the Board, the writer is led to the conclusion, with which our readers will entirely concur, that "it would be an act of the highest philanthropy to create and endow, by public subscription or by the munificence of an individual, a middle-class institution in which such patients could be received at low rates of board, paid, of course, by themselves or by their friends." A powerful and sad picture is drawn of the way in which many lunatics "travel down to pauperism, dragging their whole family with them," and it is plain that what is best for the insane poor is best in the end also for the pockets out of which they are supported. A series of cases follows illustrative of these statements; many of them are of the most melancholy and startling character, fully confirming what has recently attracted so much notice in the public journals.

The pauper insane in private dwellings are those whose residence in the district asylum has been dispensed with by the Commissioners; they are under their supervision, and formed in 1862 33 per cent. of all the pauper insane. Their condition was found to be better than that of their non-pauper fellow-sufferers, though with some exceptions, of which details are given.

Very remarkable facts are stated as to the frequency with which imbecile women have borne children. The writer shows that it is only to be prevented by more careful surveillance, and remarks that "the unseemly event of an idiotic woman becoming pregnant is not to be obviated solely because it is a scandal to public morality, but for the further reasons that it propagates the deepest of human misfortunes, and imposes a heavy burden upon society."

This valuable work concludes with a long chapter, in which it is shown most conclusively, as it appears to us, that the transference of many lunatics, especially such as are

in a chronic and incurable condition, from asylums to private dwellings, is the best thing to be done for themselves and also for the country at large.

Annals of Military and Naval Surgery and Tropical Medicine and Hygiene; being an Annual Retrospect embracing the experience of the Medical Officers of Her Majesty's Armies and Fleets in all parts of the world. Vol. I., for the year 1863. London: Churchill and Sons. 1864. Pp. 376.

THIS retrospect, if carried on as it has been commenced, will be to the Military and Naval Surgeon what the annual volumes of Ranking and Braithwaite are to the civil Practitioner. It is intended to take some note of every important paper or book bearing upon their special fields of practice. The subjects treated of are arranged in an order corresponding to the several military or naval stations. There is probably a practical convenience in this; at all events, there is a precedent for the arrangement, inasmuch it is that adopted in the Medical Blue-books, and has the advantage of showing separately the health-history of each command. The volume concludes with a series of obituary notices.

It is not a book to be reviewed at any length; it is sufficient to say that the matter of the present volume appears to be well selected. We have no doubt this annual retrospect will be very acceptable to that section of our Profession for whose benefit it is chiefly designed.

On the Nature, Pathology, and Treatment of Puerperal Convulsions. By RICHARD HODGES, M.D., F.R.C.S. Churchill and Sons. 1864. Pp. 96.

THIS is a very fair essay upon the subject. There is nothing new in it, but, for all that, the book may be of service to a good many who require to be taught what is old and established doctrine. The author tells us that his object in writing the book was to record his experience of the success of the treatment by early bleeding. The section on treatment, however, is simply written in the didactic style common to ordinary text-books, and we miss those narrations of cases or statistics which are naturally looked for in a work put forward on the ground which has been assumed by Dr. Hodges.

The Roman or Turkish Bath, together with Barège, Medicated, Galvanic, and Hydropathic Baths. By JAMES LAWRIE, M.D., L.R.C.S.E. Edinburgh: MacLachlan and Stewart. 1864.

It has been remarked that English Medicine inclines towards the exclusive or excessive ingestion of therapeutical agents by the mouth, while our French neighbours have been over-liberal in patronage conferred on the opposite extremity of the gastro-intestinal tube. Whatever be the truth of this assertion, there can be no doubt that the agitation raised in favour of Turkish baths has brought into very desirable prominence the importance of the skin as an emunctory and as a means of sound Medical treatment. The writer of the present work joins in a laudatory chorus, which from familiarity is now perhaps verging on contempt. In an introductory chapter he treats us to some venerable arguments in favour of hot-air baths. Although he denies their novelty, he assumes that they are generally esteemed novel, and proceeds to show how "useful discoveries are frequently opposed at first and their discoverers denounced," Harvey, Ambrose Paré, Jenner, Professor Simpson, and David Urquhart, Esq., being his typical martyrs to truth. It is unlucky that this line of reasoning may be applied to the wildest or most pernicious schemes which ever excited the instinctive opposition of popular common sense.

Chapters follow devoted respectively to the history of the bath and to a description of its nature. Then we have its varieties in different countries and its physiological action. We are introduced to the "seven millions of pores" which we carry about with us. Some rather hazy philosophy suggests a similarity in action between hot air and mercury, and the section concludes by hoping "that another Isaac Watts will arise to sing in moral songs the praises of the bath, and to describe the busy bather, and how he improves each sweating hour, and gathers oxygen all the day from every opening pore." Dr. Jonathan Green, Culverwell, some Irish peasant girls, John Bunyan, and other great authorities testify to the uses of the bath—an appliance, indeed, of which we never before suspected the latter worthy. Clemens Alexandrinus,

however, comes to the rescue of his saintly brother, and Hippocrates somehow reinforces the latter dignity.

The bath is strongly advised as a cure for drunkenness, and penitent letters from reformed patients attest its success. Moreover, its prophylactic and therapeutic benefits are incalculable. A long chapter is devoted to answering objections to the bath, and incidentally to severe strictures on a Scotch Medical editor, who has incurred the author's displeasure. From the author's case-book also we are favoured with an example of the power of Turkish baths in reducing obesity. A corpulent mother of several children under their influence became so much thinner that "no one could look upon her beautiful person without fancying to himself that the immortal Milton must have had his mental eye fixed on such a grand specimen of humanity when he wrote of our first mother (!)—

"Grace was in all her steps, heaven in her eye;
In every gesture dignity and love."

"The lady was much delighted," adds the writer, and no wonder. Indeed, a concluding chapter is mainly devoted to gratitude. Letters are given in full from noblemen, gentlemen, majors-general, and doctors; one of the latter signs himself "Physician and Surgeon Cosmopolite," and in his concise opinion we may sum up the book. "I have taken Turkish baths," says this citizen of the World, "in every part of the world where they have been instituted, from Cairo to Sydney, and I consider Dr. Lawrie's bath is unsurpassed for neatness, comfort, and moderation of charges."

We make no demand for inserting this advertisement.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

APRIL 15.

"ARMA VIRUMQUE CANO," freely rendered, as I have heard, by some desperate schoolboy into "an arm and a man with a cane," might be the motto for the history of an occurrence which has lately occasioned an immense amount of interest here, Professional and non-professional. I mean the attack made on Dr. Rowe last Saturday week. Dr. Rowe had been engaged to a young lady, who, by the decisive act of marrying another gentleman, brought this engagement to a close. Certain letters, written by the lady during her engagement, and a locket remained in the possession of Dr. Rowe. These, it seems, Mr. Brice, the young lady's husband, was set upon having. On Saturday, April 2, he determined to bring matters to an issue, and with this view he provided himself with a letter from Mrs. Brice demanding the return of her correspondence, etc. He was further fortified by the company of an able-bodied friend, Scot by name, but Irish by nativity, carrying in reserve an *argumentum ad hominem* which took the form of a horse-whip. The proceedings commenced by the demand that Dr. Rowe would surrender the letters, etc. Dr. Rowe refused. Mr. Scot bolted the door, Dr. Rowe took up the fire shovel. Mr. Scot, with the preliminary announcement that the following "was the way they managed those things in Ireland," rushed on Dr. Rowe, and Mr. Brice looked calmly on while a struggle took place, the result of which was, that when at last an inspector of police found his way in, Dr. Rowe was on the floor, insensible and bleeding from the nose and mouth, and Scot standing over him, whip in hand, "perspiring very much, as if from recent exertion." The two cowardly ruffians were then marched off to Bridewell. Bail was allowed in consequence of a gross misrepresentation of the facts having been made to two magistrates, but the culprits were soon rearrested, and have remained in custody up to the present time, for Dr. Rowe, in addition to a fracture of the fibula, had received such injury to the chest that up to Monday, April 11, he was not out of danger. I trust, however, that he may soon be safe.

At the meeting of the Medical Society, held on March 3, Mr. Lowndes showed the ankle-joint of a man, aged 44, which had been removed at the Great Northern Hospital, in consequence of strumous disease. The operation was performed on February 24, and Dr. Simpson's plan of acupressure was employed, instead of tying the arteries. Three needles only were used, and the wound was closed by sutures tolerably deeply passed. Forty-eight hours after the operation the needles were removed; there was no hæmorrhage, but there was a discharge of pus when some of the sutures were cut. On March 2 he was doing well, and seemed better than a

patient who had had her leg amputated, in consequence of the effects of a railway accident, a week before. In her case, although only two ligatures were used, they kept up a constant irritation, and could not be removed till the fourteenth day. The joint, when opened, was found denuded of all articular cartilage. The astragalus was extensively carious, and the surfaces of the astragalo-scapoid articulation were intensely red and ulcerated. Syme's operation had been contra-indicated by the very unhealthy condition of the integument.

Mr. Higginson, as an instance of the evil effects sometimes following the use of ligatures, mentioned a case of his own, in which twenty vessels were tied, and in which he believed that the profuse suppuration, kept up to a great extent by the presence of that number of threads in the wound, contributed not a little to bring about a fatal result.

Dr. Grimsdale then communicated to the Society a case of ovariectomy, in which, unhappily, acute peritonitis came on, and the patient died. In the discussion which followed, several members spoke on the importance of the publication of *all* cases of this operation. I can corroborate the statement that there have been several in this town which have not yet been made public.

At the next meeting Dr. Nottingham mentioned some peculiar effects which he had seen apparently due to working teak wood. It seems that enlargement of the glands of the neck, hypertrophy of the scrotum, and various skin eruptions were very frequent among those who were employed in working this wood. Its sawdust has a peculiar smell, something like that of tannin. He thought that the phenomena mentioned might be due to the amount of silicon which this wood contains. Dr. Nottingham also showed the body of an anencephalous child, born, at the full period, on March 11. The parents were healthy. The father a German, aged 28, the mother an Irishwoman, aged 22. The child was of full size, it breathed well, so that the skin acquired the ruddy tint seen in healthy newborn infants, and it lived for thirty-six hours. The pulse as well as the respiration was normal. The head looked much as if, after the removal of the top of the skull in a post-mortem examination, the skin had been stitched up without replacing the bones. This bag of integument ended in a sort of topknot, about the size of a walnut, very like a cock's comb in substance, but of a deep port wine colour. The true skin appeared to stop short at the circumference of this mass, but a delicate membrane like conjunctiva was continued from it over the mass. The osseous margin of the imperfectly developed base of the skull could be distinctly traced through the membranes, which contained little if any fluid. Unfortunately no post-mortem examination was allowed. The child never made any noise, but Dr. Nottingham found that it sucked when he put his finger to its lips. He found the child in a cold room, and apparently not much cared for. One case he knew of in a country village in which a poor little anencephalous monster was born so frightfully deformed, and was rendered so doubly hideous by constant convulsions, that the people, believing it to be "possessed" treated the unfortunate little being by a process "the reverse of artificial respiration" which effectually cured its convulsions.

In three cases which Dr. Nottingham had seen, about seven years since, there had been an opening in the top of the membranes, through which the finger could be passed.

Mr. Bailey mentioned a case in which an infant, on whom craniotomy had been performed, was not only born alive, but lived on, with a cicatrix in the scalp, and a somewhat deficient intellect.

On March 31 the Society was mainly occupied in the discussion of Dr. Imlach's resolution respecting services rendered in emergencies, which has already been published in your columns.

With regard to midwifery cases among the poor, it was resolved to communicate with the committee of the "Ladies' Charity" to ascertain whether they could make any provision for cases of this kind. This valuable society already provides the poor with the attendance of skilled midwives, and, if necessary, with that of the Medical men attached to the Charity. If its managers could establish stations in different quarters of the town, at each of which a trained midwife should be within call, such sad cases as that at Birkenhead might be prevented. Considerable care would be required to prevent impositions being practised on such an institution; better, however, that many undeserving people should be attended than that one poor woman should be left to die without help.

APRIL 21.

P.S.—In reference to Dr. Rowe's case, I may mention that on Monday, the 18th inst., the prisoners Brice and Scot were again brought up. Dr. Rowe was stated to be out of danger, but unable to attend; and the prisoners were again remanded, no bail being taken.

GENERAL CORRESPONDENCE.

HOSPITAL MORTALITY.

LETTER FROM DR. J. S. BRISTOWE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The personal discussion between Dr. Farr and myself is, I presume, at an end; but the question of the healthiness of British Hospitals cannot be allowed to rest where it is. Both Dr. Farr and Miss Nightingale have recently brought accusations against the healthiness of these institutions, resting ostensibly on mortuary tables which Dr. Farr has prepared. It is primarily necessary, therefore, that the meaning and value of these tables should be clearly understood.

Dr. Farr's statistics are contained in a letter of his published in the Twenty-fourth Annual Report of the Registrar-General, and put forward by himself as evidence in support of his accusation in your journal of February 27. In that letter are contained two tables, of which the following one is the more important:—

Principal General Hospitals in England and Wales, 1861.

	Number of Hospitals.	In-mates.	Average Number of Inmates in each Hospital.	Deaths.	Mortality per Cent.
Total Hospitals	80	8535	107	6220	72.88
Hospitals containing—					
300 inmates & upwards	5	2090	418	2101	100.53
200 and under 300	4	913	230	838	91.78
100 and under 200	22	2898	132	2041	70.43
Under 100	49	2634	54	1240	47.08
Mortality of general population					2.16

His conclusions from these tables are given in the closing paragraphs of his letter. These I append:—

“In the meantime it is evident from the tables that the mortality of the sick who are treated in the large general Hospitals of large towns is twice as great as the mortality of the sick who are treated in small Hospitals in small towns.”

“It remains to be seen whether the mortality in small Hospitals is not twice as great as the mortality of the same diseases in patients who are treated in clean cottages.”

In other words, it remains, in Dr. Farr's opinion, to be seen whether the mortality in large Hospitals is not four times as high as it should be; whether, in fact, three out of four deaths occurring in them are not the direct result of Hospital influences!

Miss Nightingale, in the recent edition of her “Notes on Hospitals,” referring to a modified form of Dr. Farr's tables, which she publishes, says:—

“However the great differences in the death-rates may be explained, it cannot be denied that the most unhealthy Hospitals are those situated within the vast circuit of the metropolis; that the next lower death-rate takes place in Hospitals in densely populated, large manufacturing and commercial towns, and that by far the most healthy Hospitals are those of the smaller country towns.”

Miss Nightingale uses “death-rate” and “unhealthiness” as equivalent terms, and emboldened by this confusion continues as follows:—

“Facts such as these—and it is not the first time they have been placed before the public—have sometimes raised grave doubts as to the advantages to be derived from Hospitals at all, and have led many an one to think that in all probability a poor sufferer would have a much better chance of recovery if treated at home.”

There are, as Dr. Farr has shown, two methods by which the death-rates of Hospitals may be calculated. The first method is that which is in common use, and consists in ascertaining for each Hospital the ratio between the number of patients treated to a termination and the number of deaths

which have occurred during a period of twelve months. Thus:—

Total No. of Patients per annum.	Total No. of Deaths per annum.	Death-rate.
p	d	$\frac{100 d}{p}$

Advantages of this method are, that the actual number of patients who have been under treatment is a vital element in the calculation, and that the death-rate being deduced from numbers which can be ascertained with perfect accuracy need not itself be otherwise than perfectly accurate. But the principle on which this death-rate is obtained is so different from that on which the death-rate of the whole population is obtained that the respective results admit of no sort of comparison. The death-rate, in fact, is the death-rate of diseases treated in Hospitals, and not the death-rate of the Hospital population.

The second method is that which Dr. Farr has adopted in the letter to which reference has been made. In principle it is identical with the method by which the general mortuary tables are deduced, and by it the results for Hospitals and for the general population become like quantities, and admit of being dealt with accordingly. The method as applied to the population is this:—The estimated average daily population for a year is compared with the actual number of deaths which have taken place during the year, and thence by a simple arithmetical process the proportion of deaths to every hundred of this average population is ascertained.

Average Daily No. of Population.	Total No. of Deaths per Cent.	Death-rate.
A	D	$\frac{100 D}{A}$

So in regard to Hospitals and other institutions, the death-rate is obtained by comparing, for each of them, the total annual number of deaths with the estimated average daily number of inmates for a year, instead of (as in the former case) with the actual number of persons who have been inmates during that period. The principle of this mode of ascertaining the death-rates of the populations of Hospitals and other institutions is undoubtedly mathematically correct; and by adopting it in his calculations, Dr. Farr has obtained the results given in the table which I have quoted.

The figures, as they are put in that table, with scarcely a word of technical explanation, do indeed look astounding. While the death-rate of the general population is scarcely more than 2 per cent., that of some Hospitals exceeds a hundred per cent.! That Dr. Farr understands the mathematical meaning of his figures no one will doubt; but that the majority of his readers understand them neither in this sense nor in any other, and are utterly misled by them, is certain. Let us, therefore, for the sake of illustration, apply Dr. Farr's method to a few hypothetical cases.

If, out of a fixed population of 10,000 persons, 200 die in the course of a year, the mortality of the population will be at the rate of 2 per cent. But if, during this supposed year, these same 10,000 persons had been successively inmates of an institution with 2000 beds, and the 200 deaths had happened within the walls of this institution, the result would have been for the institution a death-rate of 10 per cent. And again, if these same 10,000 persons had been on similar conditions inmates of an institution with 1000 beds, or of one with 500 beds, the mortality of these institutions would have become respectively 20 per cent. and 40 per cent.

	Average No. of Inmates.	Deaths.	Mortality per cent.
Institution with 2000 beds	2000	200	10.0
” ” 1000 ”	1000	200	20.0
” ” 500 ”	500	200	40.0
Population of 10,000 persons		200	2.0

Now, in these figures we have actually placed before us, on a uniform plan, the respective death-rates of the several supposed institutions, but we have absolutely no hint from them in reference to the number of persons who have been inmates of these institutions, or to the relative duration of their sojourn therein. We have assumed in each case that the 200 deaths occurred among 10,000 persons, and on this assumption the average length of stay would have been in the first case 73 days, in the second 36.5 days, and in the third 18.25. But the death-rates of the institutions are obviously wholly independent of these important facts, and whether these institutions had received 5000 or 10,000 or 20,000 inmates in the course of the year, their death-rates (provided 200 persons had

died in them) would still be expressed by the figures above given. Dr. Farr may think this consideration wholly unimportant; he may assume even, as he seems to assume, that the mean average term of treatment is the same, or nearly the same, for all classes of Hospitals. But as a matter of fact, the mean term of treatment varies very greatly indeed, and is, as a rule, much longer (a) in the small rural Hospitals, which he regards as comparatively healthy, than it is in Metropolitan Hospitals, which he stigmatises as highly insalubrious; and, what is yet more important, it is greater for Surgical patients, in whom the death-rate is naturally low, than it is for Medical patients, in whom the death-rate is naturally high; (b) and it is considerably greater for patients suffering from subacute and chronic affections, which mostly yield a low mortality, than it is for fever (c) and other acute cases, among which the mortality is always extremely heavy; so that if a fever-house in which the average length of stay is twenty-two days be compared with a Surgical Hospital of the same size in which the average length of stay is forty-four days, the double proportion of relief which the former has been enabled to afford would have, in Dr. Farr's figures, no other effect than that of doubling its apparent relative insalubrity.

Has Dr. Farr, we ask, in drawing conclusions from his tables, really overlooked the different relative severity of cases admitted into his different classes of Hospitals, the different relative length of stay of their inmates, the different numbers of patients treated in them in relation to the numbers of constantly-occupied beds? Has he no suspicion that his death-rate is determined almost wholly by these causes?

When comparing his average unit of a metropolitan Hospital population, who dies once, and a little bit more, in the course of a year, with the average unit of the general population, of whom $\frac{1}{50}$ th part dies per annum, has it not struck him that this unit has to undergo during the year (on his own showing) (d) ten serious illnesses or accidents, while many a healthy man never in the whole course of his life labours under more than one serious illness—the illness of which he dies? Or, when comparing his average units of different Hospitals, has it not struck him that his unit of one Hospital runs the gauntlet of risk to life from accident or disease ten times, while his unit of another Hospital runs it only five times; that his unit of one Hospital suffers from ten serious attacks of dangerous illness, while his unit of another Hospital undergoes ten trivial ailments?

Again: Has Dr. Farr calculated the birth-rates of lying-in Hospitals on the same principle, and attempted to draw deductions from the results? A lying-in Hospital, with ten beds habitually occupied, would yield at least 120 children per annum—a birth-rate of 1200 per cent. The average maternal unit brings forth a litter of twelve. Would Dr. Farr, who assumes that his death-rates of Hospitals are a measure of the unhealthiness of Hospitals, assume that the birth-rates of lying-in charities are a measure of the procreative influence of Hospital air? I have a suspicion that he would attribute the high birth-rate to the fact that a considerable number of women were delivered in proportion to available beds; that the charity effected in proportion to its means of accommodation a large amount of benefit; but I have also a suspicion that he would look on the whole calculation as a mere playing with figures.

Further: Has Dr. Farr thought of comparing the recoveries (escapes, if he will) per cent. in his various Hospitals with the deaths per cent.? A method of calculation which is good for

(a) In the small Hospitals at Colchester and Ipswich the average term of treatment is over sixty days. In the paper on "Hospital Statistics" published in the Statistical Society's *Transactions*, the average term is shown to have been—for St. George's, twenty-seven days; for the London Hospital, twenty-nine days; and for Guy's, thirty-five days.

(b) The following figures show the mean duration of treatment of Medical and Surgical cases for several institutions taken at random:—

	Surgical. days.	Medical. days.
St. Bartholomew's	44	28
St. Mary's	35	26
Glasgow	37	29
Adelaide (Dublin)	38	26

(c) The average duration of treatment in several fever Hospitals is as follows:—

	days.
London Fever (1861)	25
Glasgow	27
Greenock	21
Cork-street, Dublin	18
Hardwicke, Dublin	17

(d) Dr. Farr says in his letter "the mean term of treatment varies in different Hospitals; in many it averages 36.5 days, or the tenth part of a year."

determining the one point is, of course, equally good for determining the other. The death-rate varies from 47 to 100.5 per cent.; the recovery-rate (using Dr. Farr's own data) varies from 899.5 to 953 per cent.! These results do not, of course, invalidate Dr. Farr's figures; but they so far invalidate his conclusions that they might justify an enthusiast of an opposite bias in adducing the recovery-rate as a proof of the admirable healthiness of the very institutions which Dr. Farr condemns on account of their insalubrity.

If Dr. Farr had made his calculations about Hospitals in a tentative spirit, with the object of ascertaining whether they were likely to lead to any useful results, he would have acted in a way to which no exception could have been taken; if, when he had obtained his results, he had published them, and had at the same time pointed out clearly all their imperfections, and that, even had they been perfect, they would still have afforded no test at all of the relative healthiness of Hospitals, but possibly some test of the relative severity of cases admitted into Hospitals, his labours might have been regarded as trivial, but no complaint could have been made; but when both he, and Miss Nightingale under his guidance, not only publish such results, but themselves draw from them the inference, and try to mislead others into the belief, that the unhealthiness of Hospitals is in proportion to Dr. Farr's death-rates of Hospitals, we are bound to protest against the whole matter as an unfounded and mischievous delusion.

I am, &c., J. S. BRISTOWE.

2, Queen-square, Westminster, April 26.

P.S.—I hope ere long to have the opportunity of discussing other points connected with the death-rates and healthiness of Hospitals.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF DUBLIN.

THE last meeting of this Society for the Session 1863-64 was held on Saturday, April 23, in the Anatomical Theatre of Trinity College. In consequence of the recent lamented death of the President, Dr. Mayne, the chair was taken by Dr. McClinton, one of the Vice-Presidents. Interesting communications having been made by several members,

Dr. McCLINTOCK said: Gentlemen,—Before proceeding to the business which properly belongs to this, the last day of our session, I must advert to the sad occurrence which has led to my occupying the President's chair. Under other circumstances, I would esteem this a rare distinction; but to stand in the place of one so highly valued and deeply lamented, I feel to be an honour bringing with it more of pain than gratification. The Council of your Society, anxious to mark their strong appreciation of Dr. Mayne's talents, and their sense of the great loss which the Society has sustained by his untimely death, have passed the following resolution, which it is my duty to lay before you, and sure I am that it will meet with the cordial acceptance of all present, from the youngest to the oldest:—"That this Council feels called upon to express its sorrow at the loss which the Pathological Society has recently sustained by the death of its excellent and beloved President, Dr. Mayne; a loss, moreover, not confined to this Council or this Society, but one which the Irish Schools of Physiology and Pathology have such abundant reason to deplore. The Council trust that the example of this distinguished man, and the history of his life and labours, will keep alive and will forward the interests of the healing art wherever it is cultivated as a science, and followed as an enlightened and honourable Profession." Gentlemen, it is the first time in the history of this Society—now twenty-five years in existence—that its President has been removed by death. We have thus been deprived of our highest officer, but, more than this, we have lost in Robert Mayne one of our earliest, ablest, and most zealous contributors. To speak of him as his merits deserve, or as my own feelings prompt me, would occupy too much of your time, nor could I do anything like justice to the subject. We all knew him to be a first-rate anatomist, a profound physiologist, an admirable pathologist, a close observer of the laws and phenomena of disease, and, as a result of all these, a most accomplished Physician. With such attainments he assuredly deserved our admiration and respect. Along with these he possessed qualities which caused him to be held in affectionate esteem by us all; for he possessed an open-hearted frankness and buoyancy of disposition which always made him a wel-

come companion, and which lightened every toil in which he was a sharer. All his actions were marked by undeviating honesty of purpose, whilst in his intercourse with Medical brethren of every age and rank his conduct was regulated by the highest standard of Professional honour. Gentlemen, we meet here week after week to rescue the secrets of disease from the cold grasp of death. Even this dread enemy of our race is made subservient to the advance of our noble science. But, alas, to-day we are forcibly reminded how irresistible is his power, and how impotent our efforts to withstand his assault. The man who had done so much towards unveiling these secrets has himself been vanquished! By an inscrutable decree of Providence, Robert Mayne has been struck down in the midst of a bright career, and when about to enjoy the well-earned reward of years of intense application and thorough devotion to Professional pursuits. He has missed the reward for which he strove so manfully, so honourably; but earnestly do I trust he has reached that goal which, after all, is the highest, the worthiest, the noblest object of our hopes and aspirations! It would, perhaps, be out of place here to review, or even to analyse, the several essays and monographs of which our late president was the author. They all are fresh in your memory, and are appreciated by you as they deserve. I shall, therefore, do little more than enumerate them. His maiden essay—that, namely, on Pericarditis—was published, as most of you know, when he was yet a mere student. It not only bears that stamp of accurate observation and sound deduction which characterise all his Medical writings, but it contained some original observations of very great clinical value. This essay gave a presage of the future man, and in it one can plainly see the germs, and more than the germs, of those talents by which his after fame and success were attained. To Todd's Cyclopædia of Anatomy and Physiology he contributed two articles, one on the Optic Nerve, and the other on the Perineum, both of which are worthy of being placed side by side with any of the essays in that incomparable work. Subsequently Dr. Mayne published in the *Dublin Journal of Medical Science* most carefully drawn up papers on epidemic dysentery, on chronic dysentery, on varicose aneurism, and on cerebro-spinal arachnitis. The distinguishing features of these papers is their eminently practical character. They bear the impress of truth and afford convincing evidence of a mind thoroughly trained to Medical reasoning and largely stored with well-digested facts. Dr. Mayne's most numerous contributions, however, were in the pathological branch of Medicine. There can be no manner of doubt but that his connection with this Society early led him to that close study of pathology which gave a sound basis to his Medical knowledge, and by which we have all from time to time so largely profited. The various communications which he made to this Society amount to no less a number than sixty. As most of you are aware, they were chiefly illustrative of diseases of the vascular, pulmonary, and cerebro-spinal systems, and of the pathology of fever. He always spoke to the purpose, and by closely comparing the morbid changes with the symptoms and physical signs which the case had presented, he seldom failed to make his observations interesting and instructive to all who heard him. It is worthy of being here recorded that his last contribution to Medical science was a communication to this Society not many days before he was seized with that malady under which he sank; and further, by a remarkable coincidence, that communication had reference to the pathology of the very disease to which he fell a victim—a disease that may well be called the scourge of our Profession. It can safely be asserted that his numerous and valuable contributions to this Society would in themselves be enough to establish his renown, and to give him an honourable place among the most distinguished names on the roll of our members. His fame will long endure; his worth none of us can forget; and the force of his example will, I trust, long be felt.

Dr. McClintock then announced that the Society's gold medal for the present year had been awarded to the author of the subject announced at the commencement of the session, "The Pathology and Diagnosis of Diseases of the Ovaries," who had assumed the name of "de Graaf," and, on breaking the seal of the letter containing his real name, this gentleman was found to be Mr. Austin Meldon. Mr. Meldon having presented himself, the chairman said he had great pleasure in congratulating him on being the successful competitor for the prize. His treatise possessed not merely comparative merit, but it possessed merits of a positive kind. It displayed a vast deal of research; it was replete and rich in clinical illustration,

and great judgment and care had been shown in the arrangement and classification of its contents. It gave him much pleasure, therefore, to be the medium of conveying to Mr. Meldon the Pathological Society's gold medal for this treatise—a medal which he had justly earned by his industry and diligence; and with such a proof of Mr. Meldon's talent and diligence while yet a student, he confidently ventured to predict that in future years, if health and opportunity be permitted, he would prove himself a successful contributor to the advance of Medical science, that he would reflect honour on the society which had thus early encouraged and rewarded his diligence, and show himself a pillar of the Dublin School of Medicine. (Applause.)

The Society then adjourned till November next.

MEDICAL NEWS.

UNIVERSITY OF ABERDEEN.—APRIL 22.—At the late Graduation Term, the following Candidates, after the usual Examinations, received Degrees in Medicine and Surgery:—

DEGREE OF M.D.

Samuel Davidson, M.A., Wartle, Rayne, George Dickson, L.R.C.P. and S., Edinburgh, William Gregory Van Dort, Colombo, Ceylon, and John Gray M'Kendrick, Aberdeen, honourably distinguished; James Copland, M.A. Ed., Edinburgh; John Dunlop, L.R.C.P. and S. Ed., Lanarkshire; John Fraser, Grantown; William Grant, Methlic; James Foote Henderson, Aberdeen; James Ledingham, M.A., Aberdeen; William James Smith, Kintore; George Charles Henry Wigan, M.R.C.S. Eng., L.A.C., Bristol; George Yeats, Aberdeen.

At the same time, the following were promoted to the Degree of M.D.:—

James Ross, M.B. (H. Hon.), and M.C. (H. Hon.), Aberdeen, and James Clark, M.B., Aberdeen.

DEGREE OF M.B.

George MacIver Campbell, M.A., Old Aberdeen, and Robert Alexander Farquharson, M.A., Ballater, honourably distinguished; George Andrew, M.A., Huntly; Theunis Johannes Botha, Cape of Good Hope; Charles Burnett, Alton, Hants; Stewartson Clark, New Pittsligo; Alexander Duncan, M.A., Aberdeen; James Hector, Aberdeen; Robert Keith, Keithhall; Robert Davidson Kemp, Aberdeen; Godfrey Alexander Macrae, North Uist; Alexander Minty, Kennethmont; John Murray, Woodside; William Paterson, M.A., Aberdeen; Peter Shepherd, Leochel-Cushnie; William Henry Stewart, Grantown; Thomas Watt, M.A., Aberdeen.

DEGREE OF M.C.

Robert Alex. Farquharson (highest honours); George MacIver Campbell, Samuel Davidson, William Gregory Van Dort, John Gray McKendrick, and William Paterson, honourably distinguished; George Andrew, Thennis Johannes Botha, Charles Burnett, Stewartson Clark, James Copland, John Fraser, William Grant, John Gray, James Hector, James Foote Henderson, Robert Keith, Robert Davidson Kemp, James Ledingham, Godfrey Alex. Macrae, Alexander Minty, John Murray, Peter Shepherd, William James Smith, William Henry Stewart, Thomas Watt, George Charles Henry Wigan, George Yeats.

At the same time, the following were declared to have passed part of their Examinations:—

William Scott Aitken, Frederick P. Atkinson, Alexander Campbell, John M. Campbell, William Duncan, Owen Evans, George Findlay, James E. Fowler, William Robert Gordon, Alex. Lyall Grant, James Grant, Edward Gray, Alfred Orlando Jones, George King, John Knox, John Macpherson, Josiah W. Matthews, John S. M'Gowan, Robert Moir Milne, Alex. Gordon Mitchell, Edwin B. Muskett, David Nicolson, Archibald G. Robertson, John Robson, James Rodger, Robert John Scott, Robert Shiels, John Simpson, Alex. B. Strahan, Charles James Trenerry, John Whyte, Alfred Harold Wheldon, James Williamson.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on April 26—viz.:—

John Sidney Turner, Seaford, Sussex; Nyssian Holman Lower, Lewes, Sussex; Henry Viant, Totton, near Southampton; Thomas Haywood Smith, Alcester, Warwickshire; Robert Chapman Gibson, Fyfield, Ongar, Essex; John William Hayward, Seasalter, Kent; and Edward Peter Shorland, L.S.A., Westbury, Wiltshire, Students of Guy's Hospital. Frederick Henry Appleby, East Retford, Notts.; and Alexander Bruce, Albert-terrace, Regent's-park, University College. Joseph Bower Siddall, L.S.A., Morton, Derbyshire; and Wm. Boyle Coghlan, M.A., Queen's Univ., Ireland, Manchester, of St. Thomas's Hospital. Edgar Athelstone Browne, Notting-hill; and Alexander Clement Rayner, Bedford, of the Charing-cross Hospital. Henry George Benvenuto Harris, Coombe Down, Somerset; and John Frederick Foster, Guernsey, of St. George's Hospital. George Benson Baker, Southport, Lancashire, St. Mary's Hospital; Henry William Freeman, Bideford, Devon, of the Middlesex Hospital; Albert James Wallis, Cambridge, of St. Bartholomew's Hospital; Edward M'Conkey M'Creedy, M.B., Trin. Coll. Dub., Birmingham, Dublin; Robert Morris Mecklejohn, Bombay, Edinburgh; Thomas Bond, North Petherton, Somerset, of King's College; and John Reuben Bathurst Dove, Falfield, Berkeley, Gloucestershire, London Hospital.

The following were admitted members on the 27th inst., viz.:

Messrs. Spencer Henry Simpson, Stowmarket; William McCandlish, Glasgow; William George Vawdrey Lush, L.S.A., Wilton, near Sailsbury; James Walbridge Snook, Wellington, Shropshire; George Vincent Lang-

worthy, Modbury, Devon; John Powdrell, L.S.A., Farndon; Allen Wear-
ing, Lancaster, and Albert Comberbach Reade, Congleton, Students of St.
Bartholomew's Hospital; John Henry Salter, Arundel; Alfred Ensor,
Dorchester; George Henry Madeley, Kensington; Richard Wheeler
Haines, L.S.A., Broomsgrove, and Joseph Snape, Liverpool, of King's
College. Henry Couling, Kingston Bagpuize; Charles Frederick Long,
L.S.A., Ipswich, and Thomas Robert Nason, Nuneaton, of Guy's Hospital.
Edward Maundrell, Calne, Wiltshire; Thomas Henry Green, Saffron
Walden, and William Spooner, Southampton, of University College.
Charles Adcock, Birmingham, and William Bullus, West Bromwich, of
the Birmingham School. William Yates, Richmond, Westminster
Hospital. Laurence Corban, Cork; Ebenezer Snell, Plymouth, Middle-
sex Hospital; John Henry Hughes, M.D., Queen's University, Ireland,
Armagh, and Charles Davidson, Orkney.

APOTHECARIES' HALL.—Names of gentlemen who
passed their Examination in the Science and Practice of
Medicine, and received certificates to Practise, on Thursday,
April 21, 1864:—

Richard Istance, Carmarthen; John Edmund Gunning, Surbiton,
Surrey; Joseph Carter Neynoc Murphy, 75th Regiment; John William
Devereux Bain, Brunswick-terrace, Blackwall.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the
Publishing-office, as early as possible, information as to any
new Appointments that take place.

ADAM, JAMES, M.D. St. And., has been elected Assistant Medical Officer
to the Female Department of the Middlesex County Lunatic Asylum,
Colney Hatch.

ANDERSON, Mr. W., Univ. Glasg., has been appointed Assistant to the
House-Surgeon of the Northampton General Infirmary.

BULLEN, F. D., L.R.C.P. Edin., has been appointed Assistant Surgeon to
the North Charitable Infirmary, Cork.

COLEMAN, EDWARD H., M.R.C.S. Eng., has been appointed Consulting-
Surgeon to the South Staffordshire General Hospital, Wolverhampton.

CUBITT, GEORGE R., M.R.C.S. Eng., has been appointed Medical Officer
for the Workhouse of Stroud Union, Gloucestershire.

EVERSHEDE, A., M.R.C.S. Eng., has been appointed Medical Officer for the
Workhouse of Ampthill Union, Beds.

HUGHES, JAMES STANNUS, M.D. Glasg., has been appointed to the office of
Inspector of Lunatics under the Court of Chancery in the Northern
Districts of Dublin.

LITTLE, FREDERICK, M.R.C.S. Eng., has been elected Resident Medical
Officer to the Jersey General Dispensary.

SOMERVILLE, J. E., M.D., has been elected Coroner for the West Riding of
York.

SOUTHEY, REGINALD, M.B. Oxon., has been elected Physician to the Royal
General Dispensary, Bartholomew-close.

WATSON, HORACE N., M.D., has been elected House-Surgeon to Queen
Adelaide's Dispensary, Wilmot-square, Bethnal-green.

DEATHS.

ALSTON, HUGH M., M.D. Glasg., at Dalry, Ayrshire, on April 10, aged 49.

BREMNER, ALEXANDER, M.R.C.S. Eng., at Keith, Banffshire, on April 9,
aged 73, formerly Surgeon in the Army.

CUMPSTONE, WILLIAM, M.R.C.S. Eng., at Market Rasen, Lincolnshire, on
April 13, aged 28.

HAMILTON, ROBERT, Surgeon, at 1, Princes-road, Liverpool, on April 21,
aged 78.

HARRISON, JOHN SWEETING, M.R.C.S. Eng., at Braintree, Essex, on April
20, aged 77.

HAWORTH, G., M.D., at Brunswick-street, Oxford-road, Manchester, on
April 8, aged 41.

MCGILL, WILLIAM, M.D. Edin., at Grove House, Tunbridge, on April 21,
aged 51.

MATHER, HORATIO, C.M. Glasg., at Earlstown, Newton-le-Willows, near
Warrington, on April 20.

STATTER, EDWARD, L.S.A., at Morecombe Bay-villa, Bare, near Lancaster,
on April 6.

WALLACE, ROBERT, L.R.C.P. Edin., at Eglinton-street, Glasgow, on
April 9.

WE hear that Dr. Bullen, the Professor of Surgery at
Queen's College, Cork, has resigned his chair in deference to
the expressed wishes of the students.

MR. TIDD PRATT, the Registrar-General of Friendly
Societies, has been designated to the office of general manager
of the insurance department of the office about to be created
by Mr. Gladstone's Government Annuities Bill. It is under-
stood that the salary attached to the appointment will be
£5000, with the option of simultaneously holding his present
appointment of Registrar. Dr. Farr will be the actuary, at a
salary of £2500; but it is understood that this new appoint-
ment will not interfere with the holding of his present office.
—*The News*.

AN INGENIOUS APPLICATION OF ELECTRICITY.—Mr.
Cornelius, of Philadelphia, has just perfected an ingenious
mean of lighting gas by means of electricity as it issues from
the ordinary burner. The little apparatus required forms an
ornamental appendage to the gas bracket or chandelier, and is
always ready for action; so that matches and tapers may be
entirely dispensed with. By a very gentle friction of two
surfaces a delicate spark of electricity is generated by the
movement of the gas from the burner. The apparatus consis-
s of a small brass conical cup, with an inside lining of
lamb's wool and silk, into which is loosely fitted a plug of
hard rubber, surmounted by a knob or handle. The slight
friction caused by simply lifting this plug from its bed in the
cup generates sufficient electricity for the purpose. This is
conducted by a delicate copper wire or chain covered with
silk to the orifice of the burner, where it is discharged from a
platinum point through the jet of gas, and instantly ignites it.
Nothing can be more simple and beautiful, while the cup and
chain are a decidedly ornamental addition to the bracket.—
American Med. Times, No. 15.

ODONTOLOGICAL SOCIETY.—At the last monthly meeting,
held on the 4th inst., Edwin Saunders, Esq., F.R.C.S., in the
chair, a number of casual communications were made on
various models then presented to the Society's museum. The
Secretary then read a paper, by H. Kyan, Esq., of Preston,
on the "Extraction of Teeth and Roots as a Preparation for
the Introduction of Artificial Substitutes." The author con-
sidered that the presence of roots in the mouth impaired the
breath, that they could not bear pressure without disease, and
prevented a uniformity in the resisting surface of the gum,
thereby causing unsteadiness of the artificial substitutes. His
experience led him to adopt the practice of extracting all
teeth and roots which were liable, even remotely, to occasion
future trouble. The discussion that followed elicited the
opinion of the Society to be in favour of conservative Surgery;
and that, as a rule, it was far more desirable to preserve than
to extract all teeth and roots. The thanks of the Society were
accorded to Mr. Kyan, and a paper, by S. Cartwright, Esq.,
on "Some Forms of Irregularity and their Treatment," was
announced for the next meeting.

SHOULD any one desire to calculate the amount of each of
the essential elements of a physiological dietary, we will present
him with the means of doing it himself by the following extract
from a table given by Dr. Letheby in a paper which he read
before the Society of Arts a few years ago, and which repre-
sents the nutritive value of different kinds of food:—

Substance, 100 parts.	Water.	Fibrin and albumen.	Starch, sugar, etc.	Fat.	Salts.	Carbonife- rous.	Nitroge- nous.	Total nutri- ment.
Human milk (the standard of com- parison).	89	3.5	4.2	3.0	0.2	11.4	3.5	14.9
Cows' milk	86	4.5	5.0	4.1	0.7	14.8	4.5	19.3
Beef and mutton	73	19.0	..	5.0	2.0	12.0	19.0	31.0
Cheese (skimmed)	44	45.0	..	6.0	5.0	14.4	45.0	159.4
Butter	15	83.0	2.0	99.0	..	99
Wheat flour	15	11	70	2.0	1.7	74.8	11	85.8
Oatmeal	15	12	62	6.0	3.0	76.4	12	88.4
Peas	13	22.0	58.0	2.0	3.0	62.8	22.0	84.8
Wheat bread	44	9.0	49.0	1.0	2.3	51.4	9.0	53.7
Potatoes	74	2.0	23.0	0.2	0.7	93.5	2.0	25.5
Green vegetables	86	2.0	4.0	0.5	0.7	5.0	2.0	7.0

As respects "the nutritive equivalent of foods," as they may
be termed, the following extract may be useful:—"If we
were to ask how much meat, bread, rice, and potatoes
may be substituted for each other to supply the 2000
grains of nitrogenous matter which are daily expended on an
adult human body, the theoretical answer is—24 ounces of
the first, 51 of the second, 65½ of the third, and 228½ of the
fourth; but these quantities contain very unequal proportions
of carboniferous matter, and hence their effects on the animal
system is also very unequal—to say nothing of the fact that in
the act of appropriating them different amounts of labour
would be demanded from the different digestive organs. So
also in endeavouring to construct a table of nutritive equiva-
lents for the carboniferous matter contained in different foods,
attention must be paid, not merely to the relative proportions
of fat, starch, and saccharine material, but also to the respira-
tory powers of these substances; for it is known that 10 parts
of fat have the value of 24 of starch, or 25 of cane sugar, or
26 of fruit sugar, or 27 of spirit, or 77 of lean flesh; and
experience shows us that these are the proportions in which
they may be substituted for each other."

A. VETERAN OCULIST.—It is stated in the *Weiner Medizinische Zeitung* that among these senior specialists Mr. Bowman works indefatigably still for science, notwithstanding a practice he can hardly get through, and even the eighty-five-years-old Laurence is still as active as ever, and occupies himself with especial preference in all the discoveries and observations of Donders. Mr. Laurence has just evidenced the active zeal which animates him in the production of an excellent brochure "On the Progress of Ophthalmic Surgery," since the introduction of the ophthalmoscope. It is scarcely necessary to add that the gentleman here mentioned is *not* the Senior-Surgeon to St. Bartholomew's Hospital, but Mr. J. Z. Laurence, the Senior-Surgeon to the Surrey Ophthalmic Hospital.

MR. O. FERRALL has published a useful tract on the cure of anthrax by pressure. With respect to the mode of applying compression to an anthrax, he says, it is very easy of accomplishment if the principle be kept in mind—to maintain and promote the capillary circulation. The compression must be firm, and must begin at the periphery of the swelling and gradually approach its centre. I cover the swelling with straps of plaster drawn tightly from the neighbouring sound parts, and they by traction exert a firm degree of compression on the swelling. When the skin of the sound parts is thus drawn together, it will by its own elasticity in the act of recovering its position with respect to subjacent parts, produce a distinct and appreciable amount of compression on the swelling. The dressing should be removed every day, and it is invariably observed by the dresser that the pus oozes freely from the centre during the process, and the slough begins and continues to project until it comes away altogether. It is not, however, to the shape or medication of the plasters that I attach any importance. Simple oblong strips of plaster can be made to effect the object, if applied so as to produce a steady, equal, and firm compression of the parts. I may add, that I have found a coating of well-made collodion of considerable service from its contractile properties. The old method by crucial incision is always painful, often inefficient, and occasionally fraught with danger to life. The new method is not only painless in its application, but actually relieves the pain existing at the time; it is effectual in arresting the progress of the disease, and the process of cure is more speedy and complete.

THE enormous and rapidly-increasing demand for meat which characterises the food-markets of these days has reacted in a remarkable manner upon the nature of the animals that supply it. Formerly the animals that furnished pork, mutton, and beef, were allowed to attain the age of three years old and upwards before they were considered to be "ripe" for the butcher: but now sheep and pigs are perfectly matured at the early age of one year; and two-year-old oxen furnish a large quota of the "roast beef of old England." The so-called improvement of stock is simply the forcing of them into an unnatural degree of fatness at an early age; and this end is attained by dexterous selection and crossing of breeds, by avoidance of cold, by diminishing as much as possible their muscular activity, and lastly, and chiefly, by over-feeding them with concentrated aliments. . . . The habits of animals, and the nature of their food, affect the quality of their flesh. Exercise increases the amount of osmazome, and consequently renders the meat more savoury. The mutton of Wicklow, Wales, and other mountainous regions is remarkably sweet, because the animals that furnish it are almost as nimble as goats, and skip from crag to crag in quest of their food. The fatty mutton, with pale muscle, which is so abundant in our markets, is furnished by very young animals forced prematurely into full development. Those animals have abundance of food placed within easy reach, and their muscular activity is next to *nil*; the result is, that their flesh contains less than its natural proportion of savoury ingredients. It is the same with all other animals. The flesh of the tame rabbit is very insipid, whilst that of the wild variety is well flavoured. Wild fowls cooped up, and rapidly fattened, lose their characteristic flavour; and when the domesticated birds become wild, their flesh becomes less fatty, and acquires all the peculiarities of game. . . . The meat of animals brought very early to maturity is seldom so valuable as the naturally developed article. Lawes and Gilbert state that portions of a sheep that had been fattened upon steeped barley and mangels, and which gave a very rapid increase, yielded several per cent. less of cooked meat, and lost more, both in dripping and by the evaporation of water, than the corresponding portions of

a sheep which had been fed upon dry barley and mangels, and which gave only about half the amount of gross increase within the same period of time. . . . On the whole, then, we may say of the improved system of fattening stock, that it produces a maximum amount of meat on a given area of land; that the meat so produced is, except in rare cases, perfectly wholesome; that it is capable of supplying the ingredient—fat—which is almost wholly absent from a vegetable diet; and, finally, that it places animal food within the reach of the working classes.—*Professor Charles A. Cameron in the "Edinburgh Veterinary Review."*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

The Greenwich Squabble.—We think Dr. Moon is quite justified in circulating his statement amongst his Professional brethren, although the higher course might have been to have treated the affair with the contempt it deserves. We see every reason to repeat the intimation we made in our number for March 5, that if a Court-Medical were held at all Dr. Purvis should be the defendant, and not Dr. Moon. The case lies in small compass. Dr. Purvis was in attendance on a lady in July last, when he was asked to meet Dr. Moon in consultation. He refused to do so. This was mistake the first. Of course the patient sent for Dr. Moon, as she had a perfect right to do, and Dr. Purvis ceased his attendance. Instead of letting the matter drop, and acquiescing good-humouredly, Dr. Purvis wrote in November to Dr. Moon, complaining that Dr. Moon had impugned his diagnosis and treatment, which, according to the evidence, Dr. Moon did not. He also complained that Dr. Moon had done wrong in supplanting him with the patient, than which, on his own showing, a more preposterous charge could not be made. He also, during the patient's lifetime! asks to be present at her post-mortem examination—a thing which makes one's blood run cold. However, the patient died on December 14; and a *post-mortem* was held next day, at which Drs. Moon, Pallfrey, Duncan, and Purvis were present. They found disease of womb and tubercular infiltration of the lungs. It was agreed that this result of the inspection should be communicated to the relatives by Dr. Moon; and it was so. But here occurred an act of carelessness on Dr. Moon's part, which is the only thing that can be alleged against him, and which is quite inexplicable. In the certificate which he gave the Registrar of Deaths, he ascribed the death to *neuralgia* and *acute phthisis*, omitting *carcinoma*, which he had written first in the fly-page, and which he says he left out through haste and inadvertence. Certainly it is difficult to conceive of any corrupt motive which could have actuated him, or of any difference that the omission could have made to any one. The family had been informed of the whole truth. Dr. Purvis's original diagnosis of uterine disease had been justified. Dr. Purvis, however, who seemed to have been in a state of chronic discontent, accused Dr. Moon—

1. Of having unprofessionally superseded him on the 10th July last in having seen the patient and administered medicine at the time he knew he was in attendance.
 2. Of having attributed to him an error in diagnosis and unskilful treatment.
 3. Of having given a certificate which was untrue.
- Dr. Purvis then had the audacity to summon by circular, dated Jan. 21, a meeting of all the Medical Practitioners of Greenwich, to be held on the 27th, in which circular he speaks of a "misunderstanding of a very serious character," which materially affected his Professional character, the facts of which he desired to lay before a collective meeting of Practitioners of the neighbourhood, as a better course than bringing it before a legal tribunal. He summoned Dr. Moore to attend this meeting, without furnishing him with a proper specification of the charges, and without obtaining his consent to the adjudication of the so-called "Court-Medical." Of course Dr. Moore refused to attend or acknowledge the jurisdiction of this Court. Nevertheless, the meeting was held, and the Practitioners present proceeded to entertain the question! In so doing they were unmistakably wrong. They should have offered their services as arbitrators; and in case of Dr. Moon's refusal, might have taken further steps; as it was, to call themselves a "Court," and proceed in the defendant's absence, was a mistake. However, the "Court" did sit, the two first charges were withdrawn, and a paper was signed by Dr. Moon's friends, expressing regret at the error in the certificate. There the matter ought to have ended. The proceedings were private. But there followed a set of the meanest and most disreputable proceedings possible. A statement of the case was allowed to appear in the *Lancet* of January 30, of which we say unfeignedly that a more unfair and nonsensical statement is impossible to be conceived. Then followed publications and notices in the local journals, which drew forth editorial remarks which ought to have made the propagators of these scandals blush; and, *proh pudor*, handbills! are said to have been circulated, all against Dr. Moon, whose conduct (with the exception of that certificate, which was no business of Dr. Purvis's) seems quite irreproachable. Let us ask, in conclusion, do we wish the public to think of us as a set of fractious, narrow-minded, spiteful old women? Are they to give

us credit neither for such education as enlarges the mind nor for pursuits which raise us above the meanest gossips? Are they to conceive of us as allowing our petty egotisms and jealousies to be distracting our minds amidst the scenes of sickness and distress in which they fondly hope to obtain our unruffled, unbiassed, single-minded counsel? Are they to think that we would sooner let a patient—"my patient" again—go on in torture rather than consult with a junior Practitioner? If so, by all means let us have more of these squabbles, and make the most of them; but don't let us complain that patients have no faith in physic, or, rather, that they despise the practitioners thereof, as they infallibly must.

TESTIMONIAL TO MR. GRIFFIN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me to acquaint my Professional brethren the Poor-law Surgeons that five of the six Medical officers of this (the Amersham) union have now subscribed five shillings each to the two funds, making twenty-five shillings in all. The remaining officer is very ill, and has not been applied to. Now, there are 650 unions in the country, and if each union furnished a proportionate amount to the above, we should have in possession the very respectable sum of £812 10s.—an ample supply for both the purposes we require, viz., the expenses of the Reform Association and the testimonial to our chairman. The subject of a testimonial has now been submitted to the consideration of gentlemen for more than a month in the pages of the Medical journals, and I regret to say that the great mass of my Professional brethren have not as yet exerted themselves in favour of this object. Surely this is an opportune a moment for doing something in the way of thanks—and, I will say, of recompense—for the nine years of continued and unrelaxed efforts of Mr. Griffin to gain, both for the poor and ourselves, something like justice at the hands of the Government. Were the scheme which he proposes to become law, it would be a social and economical benefit to all classes of the community. That he has not succeeded in obtaining this measure of justice is no fault of his, but is rather to be laid to our own charge, and is no argument against our presenting him with the very inadequate acknowledgment which I lately proposed, and which I would fain see carried out. I cannot doubt but that gentlemen are of one mind in this matter, and that they are both able and willing to give their money towards this most desirable object. To do this completely and satisfactorily, it is only necessary that some one of the Medical officers in every union in the country should put his shoulder to the wheel, and call upon, or write to, his brethren, requesting their assistance in so just and equitable a proceeding; and, when the collected sums shall have been forwarded to the offices of one or other of the weekly Medical periodicals, the thing would be in great measure accomplished.

I beg, therefore, to call upon gentlemen to act without further delay. Mr. Griffin has performed his part in doing our work ably and well; we are, or ought to be, much indebted to him. It is now our bounden duty to offer him some token of our esteem and gratitude. Let us not fall short of our obligations, but do it generously and without stint.

I am, &c.

Amersham, Bucks, April 26.

WM. PROWSE.

INHALATION OF ARSENIC.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Being desirous of trying the effect of smoking arsenic in tubercular disease, would any of your readers kindly inform me, through the medium of your journal, the most approved means of inhaling that substance, as I am completely at a loss how to proceed. I am, &c.

Glasgow, April 20.

INCONNU.

HYPERTROPHY AND ULCERATION OF THE LABIA MAJORA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will any of your readers oblige me by giving me in your next number some hints as to the treatment of a troublesome case of scrofulous ulceration of the labia majora, along with which is great hypertrophy? I have tried various local stimulants without effect, and am now hesitating whether to excise the parts, or destroy the diseased tissues by some caustic. If I must adopt the latter, I should like to know which escharotic is best suited for such a case. I am, &c.,

M. D.

THE "BRITISH MEDICAL JOURNAL" AND OPHTHALMOLOGY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A leading article in the *British Medical Journal* of the 16th instant is devoted to an attack upon the *Ophthalmic Review*. The article in question contains statements that are untrue, and that I ask leave to contradict, in the interests of truth and science.

The writer says that "Dr. Mackenzie, Mr. Wharton Jones, and Mr. Dixon are quoted to show how unpardonably ignorant they have shown themselves of the ophthalmoscope through their published writings." If this sentence were transposed into sense and English, so as to express the probable meaning of its author, it would still be without foundation. The *Ophthalmic Review* does not contain one single word which could even imply a charge of ignorance against Dr. Mackenzie or Mr. Wharton Jones, who are only mentioned on account of the historical interest which attaches to the slight value they were, at one time, disposed to assign to the ophthalmoscope. I believe these gentlemen would cordially agree with the general spirit of the article in which they are referred to; and their names (especially the honoured name of the venerable Dr. Mackenzie) do not need my protest in order to free them from the ridiculous imputation cast upon them by your contemporary.

The astounding misstatement I have quoted casts into shade some half-dozen minor inaccuracies, equally culpable, but not equally important. The critic refers to Dr. "Rainey" and to "Schamenburg,"—persons of whom I have never heard. He states that Mr. Hulke's book is useless, and implies (falsely) that this statement is a quotation from the *Ophthalmic Review*. He places within inverted commas the words "modest and

sagacious Helmholtz," implying (falsely again) that these words are quoted from the same source.

The critic displays, however, an amount of ignorance that cannot be altogether feigned. He seems really not to know what sort of proportion the cultivation of ophthalmology in Germany, during the last few years, has borne to its cultivation in other countries. He is wroth at the names of "German Surgeons" mentioned in the review, and complains that "the doings of French Surgery" are scantily noticed. Among the "Germans" he enumerates Wecker. It will comfort him to know that Dr. Louis Wecker, in spite of his German surname, is a Professor in Paris, and a French author of no small celebrity.

I do not address myself to the *British Medical Journal* upon this question, because I think such gross and extraordinary carelessness places a journal, as it would place an individual, beyond the pale of ordinary courtesy. Is it possible that the tone lately assumed by the publication in question depends rather upon design than upon incapacity, and that its managers entertain a wish to supply, by any means, an "organ" for the expression of the sentiments and opinions of the least instructed portion of the Profession in this country? A while ago, there was a cry for "cash payments and no Professional liberality," and it would seem that "British ignorance, and down with the furriners," is now to be used in its turn.

I am, &c.

THE AUTHOR OF THE ARTICLE, "ENGLISH OPHTHALMOSCOPIC LITERATURE," IN THE "OPHTHALMIC REVIEW."

POISONING BY MUSSELS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall be glad by your giving the accompanying case a place in your Journal, if you deem it worthy of it:—

A few evenings ago I was called to see a young woman who had, whilst eating a plain supper, been induced to taste a boiled mussel, and about half an hour afterwards was seized with vertigo, pricking and burning pain in the tongue and eyes, which began to swell, producing a sense of suffocation. I attended as quickly as possible, when I found her in the following condition:—Face of a bright crimson colour, enormously swelled, the eyes being scarcely visible; tongue so much enlarged as to prevent protrusion and interrupt the articulation; body thickly covered with large patches of scarlet colour intensely irritable; breathing hurried; pulse small, weak, and very rapid; general depression of vital powers, etc. She complained of pain in the epigastrium, headache, and great thirst. Whilst speaking to her, syncope suddenly came on, the extremities became very cold, body bathed in cold sweats, and pulse almost imperceptible; after a few minutes she rallied sufficiently to be able to take an emetic, which produced good effect. Small quantities of hot brandy-and-water were then administered with great relief to her pain, and after about an hour the symptoms gradually subsided, and she fell into a quiet sleep. The next morning the face was still much puffed, and some few patches remained on the skin, but she had no pain; she took a warm aperient, and the following day had regained her usual good health.

Although instances of the deleterious effects of fish undergoing putrefactive change are not uncommon, I think symptoms of such severity as the foregoing are not often seen; that they were due to idiosyncrasy, and not to any unwholesomeness of the mussels, there can be no doubt, as four other persons partook freely of them with impunity, and my patient assures me that she only ate one, as she did not like the taste of them. There can be no question as to the importance of a speedy evacuation of the contents of the stomach in such cases, and the administration of stimulants to relieve the consequent depression, recovery so quickly ensuing as to render further treatment unnecessary. Cases of this kind may be of importance in a Medico-legal point of view.

"NEMO SIBI VIVAT."

AMYLENE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It may interest one of your subscribers who makes inquiry about amyleno to state that since the date given by him amyleno has been used pretty extensively at Berlin, but does not seem to possess any greater safety than chloroform. Amylene has an unpleasant smell, too, of naphtha, not desirable in the sick room: it is very difficult to prepare, and in some examinations of the so-called amyleno used by the late Dr. Snow, it was found to contain large portions of amyl alcohol and free chlorine. I stated that fact in 1859, and I was not astonished to find Dr. Thudicum, in the "Oration" of the Medical Society of London last month, stating that he had discovered the same thing, so that there has been really very little pure amyleno experimented with at all in London. I remember one particular specimen, made at University College Hospital, and used extensively by Mr. Erichsen for some weeks; it seemed nearly devoid of smell, had a bland oily taste and appearance, yet, though I watched its administration with special care, as also the administration of the impure specimen, with chlorine, etc., at King's College, I cannot say that either exhibited any novel peculiarity, when compared to cautious small doses of chloroform. The patient readily regained consciousness under amyleno, but because the patient was not deeply anaesthetic at all; the reason being that the amyleno was more or less mixed with chlorine, amyl alcohol, etc. Dr. Thudicum, indeed, stated in his late address that the latter is highly poisonous! Aldehyde (in some measure analogous to amyleno) has also been extensively administered by Poggiale and others as an anaesthetic, but it excites embarrassing dyspnoea, constriction of the throat, and cough; it produces marked anaesthesia; and the late Dr. Snow told me it was to obviate these symptoms he directed attention away from aldehyde to amyleno, and once or twice expressed a wish to me that I should follow up both these anaesthetics if possible, as there are certain good points about them, as being fugacious in their effects, yet so perfect as anaesthetics for short operations, as on the eye, to wit, where chiefly they have been used in Germany. Aldehyde (if we are to believe Mulder), not alcohol, is the active agent in champagne, together with other delicate metamorphoses of amyleno and fusel oil, hence its slight intoxicating qualities.

The odour of all the so-called amyleno of the shops is such that it cannot be recommended in midwifery practice; some describe it as like onions: it is, perhaps, a mixture of this smell of onions and that of the naphtha of a very new india-rubber coat. Such "comparisons are odorous," but still we have to consult the *bienseances* in the sick room, and nothing that I have tried is so valuable and agreeable at the same time, as a quiet extemporised mixture of chloroform and eau de cologne on a handkerchief, without the balloons and amyleno parachutes figured even in the

last edition of the Gower-street Manual that invariably frighten patients. I have sometimes thought that amylene or nitrous ether, the latter especially, which lessens pain while preserving consciousness, acts beneficially on the cerebellum or pons, by exciting, for instance, in midwifery good uterine action and taking away pain; but the Royal Society now tells us all our theories on the cerebellum are wrong, and we must rest satisfied with watching the analysis of various cerebral actions by chloroform, and especially its influence so specific on the sensory ganglia. The cerebellum has no co-ordinating power or control over the sexual faculty at all, though some supposed actions of chloroform are visible in that direction, and of pure amylene, perhaps, we know very little.

The number of accidents from amylene have been painfully numerous, perhaps due to the free chlorine with which it was impregnated. Even in these days of inhaling oxygen and nitrous oxide, which are theoretically supposed to cure certain diseases, we cannot be too cautious in changing from chloroform to amylene; we should rather encourage the fullest study and observation of chloroform, for the more it is studied, the safer it becomes, especially in midwifery, where amylene, as your correspondent supposes, was at one time supposed to have some advantages, not since realised.

C. K.

ON THE USE OF COD-LIVER OIL.

By JNO. ATCHERLEY, L.R.C.P. Edin. by ex., M.R.C.S. Eng., etc.,
Surgeon to the Liverpool Dispensary.

THERE is no medicine which more frequently thwarts the intention of the Medical man than cod-liver oil; this arises from the insuperable loathing which so many patients have to its taste and smell, or to the difficulty of retaining it on the stomach, or of digesting it in sufficiently large doses if so retained, creating a painful eructation and constant feeling of nausea, thereby destroying the appetite, and depriving both patient and Physician of the aid of a valuable agent.

I have made use of the subjoined menstruum for its ready exhibition during the last ten years, without, I truly believe, having heard of a single complaint of its disturbing the stomach, or of its being in any way offensive to the most fastidious palate; both the taste and smell of the oil are so completely disguised by being reduced to a smooth, pleasant, and digestible emulsion, that patients are surprised on being told that there is any oil in the composition they are taking:—

Take the yolk of one egg; powdered sugar, two ounces; orange flower water, one ounce; cod-liver oil, three ounces; essence of bitter almonds one drop. The egg and sugar should be well rubbed together in a mortar, the essential oil then dropped in, the orange flower water gradually added, and lastly the cod-liver oil, little by little, and the whole intimately mixed. One or two drachms of brandy will preserve it from change for weeks if required to be kept so long; the manipulation is so simple that patients or their friends are able to make it themselves.

22, St. James's-road, Liverpool, April 25.

COMMUNICATIONS have been received from—

MR. JAMES S. BRAZILL; MR. SWANN; APOTHECARIES' HALL; INCONNU; WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON; DR. THUDICHUM; DR. JOHN ATCHERLEY; MR. C. VASEY; MR. W. PROWSE; JUSTITIA; HARVEIAN SOCIETY OF LONDON; ROYAL INSTITUTION OF GREAT BRITAIN; UNIVERSITY OF ABERDEEN; ODONTOLOGICAL SOCIETY; DR. MOON; DR. W. B. HERAPATH; DR. J. S. BRISTOWE; HUNTERIAN SOCIETY; "GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION;" "M.D.;" MR. R. FREEMAN; THE "CARMARTHEN WELSHMAN."

BOOKS RECEIVED.

Theory of Heat. By A. A. Harrison, M.B. Macmillan and Co. 1864.

* * The object of the author is "to show that the motion of the particles of matter, which must be caused in the processes of combustion and friction, is sufficient of itself to account for many of the phenomena of heat. Secondly, to raise the question, whether it is not sufficient to account for all? And thirdly, to mention some of the simplifications resulting from the supposition that this is the real nature of heat."

Remarks on a Proposed System of Sea Transport for Troops employed in India and China. By Charles A. Gordon, M.D., C.B., Deputy-Inspector-General of Hospitals. Serampore. 1864.

* * * The object of Dr. Gordon's suggestions is the establishment of a sanitarium at or near Japan for invalids from the troops serving in China, and the more rapid removal home from our Eastern possessions of such as it seems necessary should return.

The Transversalis Pedis in the Foot of the Gorilla. By W. Thomson, Victoria, Australia. Reprinted from the *Australian Medical Journal*. January, 1864.

* * * The general conclusion of the author is "that that theory which would deny the possibility of a derivative origin of a higher order of beings from the gorilla must be erroneous, in as far as it is deduced from the alleged absence of the *transversalis pedis* muscle."

Thirteenth Annual Report of the Wilts County Asylum for 1863.

* * * Contains a record of a remarkable death from "Rupture of the spleen." The organ weighed 4 lbs. Av. "The exciting cause of the rupture appears to have been mental emotion, of the character of groundless fear."

On the Present System of Medical Education in England. By George W. Callender, F.R.C.S. London: Spottiswoode and Co. 1864.

* * * This is another reply to Mr. Syme. The author advocates a minimum of alteration in the present system.

Summary of the Principal Points of Evidence relating to the Medical Relief of the Poor. By Richard Griffin, M.R.C.S. 1864.

* * * Mr. Griffin is indefatigable in the task he has undertaken. This pamphlet consists of a series of replies to the evidence given by Mr. Cane before the Select Committee of the House of Commons on Poor Relief in 1861.

Lectures on the Laryngoscope. Part I. By Philip C. Smyly, M.D. Dublin: Fannin and Co. 1864.

* * * A reprint of Dr. Smyly's very clear and able lectures from the *Dublin Medical Press*.

The Senses and the Intellect. By Alexander Bain, M.A. Second Edition. London: Longman and Co. 1864.

* * A good many alterations have been made in this work in order to bring it up to the present standard of physiological and mental science.

On Diabetes and its Successful Treatment. By John M. Camplin, M.D. Third Edition. By James G. Glover, M.D. London: John Churchill and Sons. 1864.

* * This little book has passed successfully through two editions, and the third had been prepared by the author before his death. All Dr. Glover has had to do with it has been to see it through the press.

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 23, 1864.

BIRTHS.

Births of Boys, 1033; Girls, 967; Total, 2000.

Average of 10 corresponding weeks, 1854-63, 1847-5.

DEATHS.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.909 in.
Mean temperature	53.3
Highest point of thermometer	73.8
Lowest point of thermometer	35.5
Mean dew-point temperature	40.3
General direction of wind	Variable.
Whole amount of rain in the week	0.00 in.

APPOINTMENTS FOR THE WEEK.

April 30. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Frankland, "On the Metallic Elements."

May 2. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

ODONTOLOGICAL SOCIETY, 8 p.m. Meeting.

ROYAL INSTITUTION, 2 p.m. Anniversary Meeting.

3. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Life."

4. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

HUNTERIAN SOCIETY, 8 p.m. Mr. Couper, "On a Case of Vertical Dislocation of the Patella."

5. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Dr. Sisson, "On the Origin and Nature of Syphilis."

ROYAL INSTITUTION, 3 p.m. Mr. Hullah, "On Music (1600-1750)."

6. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of the Council.

ROYAL INSTITUTION, 8 p.m. Professor Roscoe, "On Indium, &c."

WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Practical Evening, for Cases and Specimens."

DINNEFORD AND CO., PHARMACEUTICAL CHEMISTS,

Beg respectfully to inform the Medical Profession that they are now Dispensing Physicians' Prescriptions
with the

PREPARATIONS OF THE NEW BRITISH PHARMACOPŒIA,

except when otherwise indicated by the Prescriber.

172, NEW BOND-STREET, LONDON.

Pulvis Jacobi ver, Newbery's,

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

The Best House for Second-hand Instruments.

Where there is the Largest Stock in London, is Mr. WILLIAM LAWLEY'S, 78, FARRINGDON-STREET, CITY.
Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases at 8s. 6d. and 10s. 6d. each.
Photographic Lenses, Opera Race Glasses, and Telescopes, by the best London Makers.
Catalogue forwarded on receipt of Postage Stamps.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz, 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

THE ORIGINAL CHLORODYNE.

INVENTED AND MANUFACTURED, IN 1844, BY RICHARD FREEMAN.

By the decision of Vice-Chancellor Sir W. Page Wood, R. Freeman is entitled to the SOLE right to use the word Original as a prefix to the word Chlorodyne.

The large and still-increasing demand which the Inventor has for this therapeutic is evidence of the high estimation in which its properties are held by the Profession generally; and on a recent occasion a number of eminent London Physicians and Surgeons of long standing in the Profession, and who hold public appointments, made affidavits to the fact that Freeman's Original Chlorodyne is a more certain and reliable, a more valuable and a preferable, preparation to that of any other maker's. It is offered to the Profession as the best preparation of the kind, and at a price which allows the poorest sufferer to enjoy its extraordinary beneficial effects.

MANUFACTURED BY THE INVENTOR,

RICHARD FREEMAN, PHARMACEUTIST, KENNINGTON-ROAD, LONDON, S.;

And Sold by all Wholesale Druggists, in Actinic Glass Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d. each.

ORIGINAL LECTURES.

LECTURES
ON THE CONSERVATION OF ENERGY.

By Professor HELMHOLTZ.

DELIVERED AT
The Royal Institution
ON APRIL 19, 1864.

LECTURE V.

LADIES AND GENTLEMEN,—The law of conservation of force has had a peculiar importance for physiology. Ever since the sixteenth century nobody has doubted that even the most complicated processes of inorganic nature were produced and directed by forces which acted in a merely mechanical way, following the law of blind necessity; nobody has supposed that the clouds, and winds, and rain, or the physical processes and chemical processes in our laboratories were produced by forces acting with any degree of arbitrariness or spontaneity; but the processes in living beings, in animals and plants, are so far more complicated, and go on under so different conditions, and are so easily modified by the slightest influences, that it seemed rather doubtful that the processes of the bodily life of plants and animals could be directed by forces following such simple laws as the physical and chemical forces of inorganic nature. Such a supposition appeared, perhaps, too bold to be made by former physiologists. One supposed that the processes of animal life were directed and governed by a peculiar principle or agent. It was called by different names—the vital principle, the vital force, and so on; and it was supposed to be more similar in its nature to the soul of man than to the inorganic forces; at least, the characteristic qualities of this vital principle were supposed to be such as can only be ascribed to a soul. It was well known that physical and chemical forces are effective also in the interior of living bodies. Physiologists saw that the body is subject to gravitation—that it has its weight, and that this weight cannot be taken away by any influence of the vital process. And the more they looked into the interior mechanism of the physiological processes, the more they found that the known forces of chemical affinity, and the forces of hydraulic pressure, and the force of electricity were acting also in the interior of our nerves, and muscles, and organs. The common supposition was, that the vital principle which governs the whole body has the faculty of binding or loosening the effect of the actual forces—that it has the power arbitrarily to impede the actions of these forces, or to let them go on; and in this way it would be possible to produce a series of actions and processes which could not go on under the common laws of inorganic forces. We must say that the progress of physiology was very much retarded by these opinions, because, of course, if one was of the opinion that such and such a process of the living body was brought forth, not by conditions and forces acting of necessity in the way in which they acted, but that there was a sort of arbitrary choice between different ways, and that the vital principle had the faculty of meditating, of choosing different ways for its action, and determining at last that it would act in such and such a way,—if one held such suppositions, of course every explanation of these actions which went further into the mystery of these processes—every real explanation—was impossible; and physiologists were obliged, or thought themselves obliged, to observe only the facts as far as they could. The modern great development of physiology depended principally upon the supposition, that in the interior of living beings those same forces were acting which we know already to be acting throughout organic nature. Now, it was necessary to define the difference between these two opinions with regard to the nature of the vital principle, to define them as accurately as it could be done, in order to come to a clear insight into the nature of organic life. It has thus arisen that two physiologists, Dr. Mayer at first, and some time later myself, came to the same law of the conservation of energy, which had been found already from other technical and physical considerations by the engineers and physicists. It was the aim of our investigations to find a character of inorganic forces which gave the possibility of determining exactly if in the interior of the living animal body other forces were acting than those of inorganic nature, or forces subject like those of inorganic nature to the

laws of blind necessity, without arbitrariness in their manner of acting, and without spontaneity; and really the law of conservation of energy has determined such a character of natural forces as is not consistent with the so-called vitalistic theory of organic life—with the supposition that forces are acting in the interior of our body, the action of which can be arbitrarily impeded or freed. You will see easily that if it was possible, by the action of the vital principle, to take away the force of gravity for some time from our limbs, and then again to let it free, so that it produced its action, then we could use the force of gravity to attract our arm to the earth and produce work by that; and then we could again take away the force of gravity from our arm, and raise the arm without doing any work at all, and then, again, let the force of gravity act, and let the arm again sink down and again do work. If this theory of the vitalistic school was right, then the organism would be capable of producing work of an infinite amount from nothing. You see, therefore, that by the law of the conservation of energy it can be determined if the forces acting in the living body are subject also to the same kind of laws as the forces in inorganic nature; it would not follow that in the interior of the living body other natural forces may not be acting than in the inorganic world. There might be, perhaps, a peculiar kind of imponderable matter, like ether or electricity, acting in the interior of living beings; but as soon as those forces are subject to the same kind of laws as the inorganic forces, if the actions produced by such hypothetical imponderable matter depend only on the conditions under which they were acting, and not upon any arbitrariness or any spontaneity, then they would be subject to the law of conservation of force, and that would have the same effect.

Now, we have seen already that by the life of plants great stores of energy are collected in the form of combustible matter, and that they are collected under the influence of solar light. I have shown you in the last lecture that some parts of solar light—the so-called chemical rays, the blue and the violet which produce chemical actions—are completely absorbed and taken away by the green leaves of plants; and we must suppose that these chemical rays afford that amount of energy which is necessary to decompose again the carbonic acid and water into its elements, to separate the oxygen, to give it back to the atmosphere, and to collect the carbon and hydrogen of the water and carbonic acid in the body of the plant itself. It is not yet possible to show that there exists an accurate equivalent proportion between the power or energy of these solar rays which are absorbed by the green leaves of the plants, and the energy which is stored up in the form of chemical forces in the interior of the plants. We are not yet able to make so accurate a measurement of both these stores of energy, as to be able to show that there is an equivalent proportion. We can only show that the amount of energy which the rays of the sun bring to the earth is completely sufficient to produce such an effect as this chemical effect going on in the plants. I will give you some figures in reference to this. It is found that in a piece of cultivated land producing corn or trees, one may reckon per year and per square foot of land .036 lb. of carbon to be produced by vegetation. This is the amount of carbon, which during one year, on the surface of a square foot in our latitude, can be produced under the influence of solar rays. This quantity when used as fuel and burnt to produce carbonic acid, gives so much heat that 291 lbs. of water could be heated one degree of Centigrade. Now, we know the whole quantity of solar light which comes down to one square foot of terrestrial surface during one second, or one minute, or one year. The whole amount which comes down during a year to one square foot is sufficient to raise the temperature of 430,000 lbs. of water by one degree. The amount of heat which can be produced by fuel growing upon one square foot during one year is, as you see from these figures, a very small fraction of the whole amount of solar heat which can be produced by the solar rays. It is only the 1477th part of the whole energy of solar light. It is impossible to determine the quantity of solar heat so accurately that we could detect the loss of so small a fraction as is absorbed by plants and converted into other forms of energy. Therefore, at present, we can only show that the amount of solar heat is sufficient to produce the effects of vegetable life; but we cannot yet prove that there is a complete equivalent ratio.

Animals, and some cryptogamic vegetables which live in the dark, take in those combustible substances which are produced by plants, and take in oxygen, and combine them again in

their body into carbonic acid and water. All the food which animals take in is derived from plants. Some animals feed directly on plants; other animals eat those herbivorous animals; so that the food of the carnivora is derived, in the last instance, from the vegetable kingdom. Cattle which eat grass, and digest it in their ample stomach and very complicated bowels, are, indeed, only collecting those small proportions of albuminous matter of starch and sugar which are contained in the grass, and which are too widely distributed and mixed up with matter which our own organs could not digest; therefore they collect for us those particles of food which are contained in the leaves of plants, trees, and grass, and so on. In connexion with this circumstance, that all the food of animals is taken from the vegetable kingdom, I may mention that the chemical composition of the bodies of plants and animals shows a very wonderful agreement which is really astonishing, if one has looked hitherto only to the great difference of external appearance, and even to the great difference of taste—to the great difference which the interior parts of plants and vegetable food and animal food offer to our senses. But the principal part of the mass of animal food and vegetable bodies is composed nearly of the same materials. The chemical molecules of which the bodies of living beings are composed have a very complex composition. I have here the chemical formulæ of several of the principal compounds which are contained in living beings. You know that chemists have called an arbitrary mass of hydrogen the unit of hydrogen. It is an arbitrarily chosen quantity, and is represented by the letter H, and the quantity of oxygen which combines with this hydrogen is called the equivalent of the unit of hydrogen, and is expressed by the letter O; and the quantity of carbon connected with one equivalent of oxygen, and forming carbonic oxide, is expressed by the letter C. Now, the greater part of the substances contained in vegetable and animal bodies is composed of these three elements. There is a fourth element, nitrogen, which combines with the others which I have named, the equivalent of which is expressed by the letter N. We have here the chemical formula for water. It is an equivalent of hydrogen to one of oxygen. In carbonic acid we have one of carbon and two of oxygen. In ammonia, which is the principal source for affording the nitrogen to plants, we have one of nitrogen with three of hydrogen. These are very simple ratios. I have also the chemical formulæ for some compounds of our food and of vegetable and animal bodies. Here is the composition of grape sugar, which is contained in grapes and in honey, and which can also be produced from starch. We have here sugar made artificially from starch, and also honey-sugar, extracted from honey. The formula of this sugar is far more complicated— $12\text{ C}, 12\text{ H}, 12\text{ O}$. Cane-sugar is nearly the same— $12\text{ C}, 11\text{ H}, 11\text{ O}$. Cane-sugar is usually crystallised, as you know, in large crystals, as in candy sugar. Starch is the principal compound contained in flour and potatoes, and it is this that makes the flour of different kinds of corn and potatoes so valuable as food. The composition of starch is $12\text{ C}, 10\text{ H}, 10\text{ O}$. You see, therefore, that these substances, which are the simplest of their kind, have a far more complicated formula, and present far larger numbers, than the compounds of inorganic chemistry. You see here the formulæ of fatty substances, the principal fats which are found in different organic bodies. Many of the seeds of plants contain fat; it is deposited there as a kind of food for the young plant; it is, indeed, the most concentrated kind of food which we can get—at least, for giving carbon and hydrogen to the organic body. You see here numbers higher than a hundred— $114\text{ C}, 110\text{ H}, 12\text{ O}$ —which is the formula for stearine. These two fats, stearine and palmitin, are solid in the common temperature; while this olein is fluid. Fluid and solid parts are commonly so mixed up in the interior of the body that the mixture is of a soft nature, neither quite solid nor quite fluid. In cold-blooded animals and plants we find a greater amount of olein, and in warm-blooded animals we find a greater amount of stearine and palmitin. Then we have an extended mass of nitrogenous substances, which form principally the matter of which the animal body is built up. You see here the chemical formula of albumen—one of the principal combinations of that kind. It has a far greater number of atoms than inorganic combinations; yet this formula is the simplest to express its composition. These substances we find spread throughout the whole kingdom of animals and plants. The principal mass of vegetable bodies is composed of substances containing the class called hydrates of carbon, because hydrogen and oxygen are combined in the same proportion as in water. We have here sugar, starch, gum—sub-

stances of which the cells are formed in vegetables—gum made from starch, and dextrine, and gum arabic, and other substances of similar composition, several of which can be transformed into each other. Thus we can transform starch, which is insoluble in cold or warm water, by boiling it with sulphuric acid into this kind of gummy substance—dextrine, or starch-gum; and boiling it further with sulphuric acid we get at last starch-sugar, which is identical with grape-sugar, or the sugar of honey. So the common cane-sugar can be transformed into grape-sugar. Nothing is altered by this transformation but the amount of those elements which are the elements of water. These substances are found also in the body of animals, not in great quantity, but you find them everywhere in small quantities. There is a rather large quantity of sugar contained in the liver of men and animals. Another kind of sugar, the so-called Inosite, is contained in flesh; and some traces of sugar we find also in the blood, and in the yellow part of the egg. Then we find a peculiar substance, which is very similar to the starch of plants, in the liver; and in the liver the same transformation is going on continuously that we can produce artificially. The starchy substance is transformed into sugar, which passes into the blood, and is afterwards burnt in the lungs. We find small traces of these substances also in animals; and our food contains always great quantities of these substances, sugar, gum, starch, as often as it is taken from the vegetable kingdom. Fats and oils are found in vegetables, but, as I said, principally in the seeds of plants, where they are a store of food for the new plant which is to grow from the seed. They are far more diffused in animal bodies, which contain always a great store of fats. Albuminous substances form a large proportion in the composition of the animal body. We find albuminous substances, like the so-called albumen, in the egg, in the blood, in the flesh, in the brain, in the glands, and so on; and we find the same substance in those parts of vegetables which are still growing and developing, the construction of which is not quite finished. Therefore, all the green parts of plants which are vegetating contain small quantities of albuminous matter. A greater quantity of albumen, or of similar substances, is deposited in the seeds of plants; and therefore the seeds of plants are of peculiar importance for our food. They are the richest food which animals and men can get from the vegetable kingdom, because these nitrogenous substances, of which we want to have a great amount, are diffused only in small quantities in the other parts of vegetables. It appears very improbable that this same matter, albumen, which we know so well in the egg, should be contained also in other substances which we use as food; but it can be easily shown that it is also contained in flesh and flour. I have here a quantity of wheat flour which has been infused in water and standing some days. The water has been taken away and cleared by filtration. Here is also a quantity of flesh, beef, cut into small pieces; it has also been infused with water, which has been separated by filtration. You see, it is coloured by the red pigment belonging to the substances of the flesh. Here, in a third vessel, we have some water mixed with albumen taken from eggs. I can easily show you that all these fluids contain albumen. You know that the characteristic property of the albumen of eggs is, that it is soluble in water, but that when the solution is boiled the albumen is coagulated and becomes insoluble in water. You know that eggs when boiled become solid; the albumen cannot afterwards be dissolved in water. This is a very characteristic property of albumen which is not found in any other substances; so that we can use this peculiarity to recognise the presence of albumen in any mixture of organic fluids. All that we have to do is to boil it. The reaction does not always take place, if the quantity of albumen is very small, and if there is a small quantity of alkali in the fluid; we make the reaction more certain if we add a small quantity of nitric acid. Nitric acid also produces a peculiar effect on the albumen and similar substances by colouring them yellow; and this yellow colour is exalted if we saturate the nitric acid by some ammonia. You observe that this liquid containing the albumen of eggs becomes turbid and opaque as I heat it. I now add some nitric acid, and you see that the water is coloured a light yellow. By pouring in some ammonia to saturate the nitric acid, the light yellow is changed into an orange. Now, I take the liquid containing the soluble substances of wheat flour; I add the nitric acid to it, and you see it becomes opaque; and if I boil it, we have the same yellow colour as before. You have here the proof that common wheat flour contains a quantity of albumen, which can be dissolved

by water. The albumen contained in the flour of corn is of great importance as food for men and animals, because in this way we get a certain amount of albuminous substance to build up the organs of our bodies. This is the substance which we call albumen, or the white of egg, because we have it in its purest form in the egg, and because it is mixed with other substances in other organs of the animal body or the body of plants. You will observe it is the same with the fluid from the flesh. We cannot make the experiment to produce the yellow colour, because the fluid is already coloured red, and the natural red colour becomes black by nitric acid. You observe that there is a deposit of coagulated albumen on boiling; indeed, if we take a piece of beef, and pour cold water upon it, and then put it upon the fire to boil, a white substance is separated on the top of the pot, which is taken away by the cook. This substance is coagulated albumen.

Now, these peculiar substances, which are of so complicated a composition, and of which organic bodies are built up, are also remarkable for their great alterability, if that is a correct expression. They are changed by the slightest influences. Inorganic compounds are very stable. You cannot destroy water but by very effective means and very powerful forces, such as the force of a galvanic current, or very intense heat, or very intense chemical affinities; but these compound bodies, which are of so complicated a composition, can be destroyed by very slight influences; and this is the great difficulty of chemical investigation into their nature. They may be compared with a building composed of a great many loose stones. I have here, as you see, a number of cubes, which represent chemical atoms. They may be so placed together as to form a very solid compact mass, or I may pile them one above the other, so that they are only just in equilibrium, and the slightest touch will cause them to fall down. Now, you may suppose that the molecules of sugar, fat, and albumen, which contain more than two hundred elementary atoms, are built up in that way, like an artificial building of loose stones, put together in a very unstable equilibrium; so that a very slight influence, any attraction of one of the atoms by some foreign matter, will destroy the whole construction of the molecules, so that they fall in pieces, or the single parts become united into simpler and more stable compounds, such as carbonic acid, and water, and other simpler combinations. This peculiarity of organic compounds is exhibited principally by these peculiar chemical processes which we call fermentation and putrefaction. We have here such a case of fermentation. In this vessel there is a solution of sugar. If the solution of sugar is alone in a closed vessel, without mixing with any other substance, we may keep it for several days, or weeks, or months; the purer the sugar is, the longer it remains unaltered when it is dissolved in water. I have put to the sugar not a very strong chemical agent, but a little yeast, which contains at first the cellular tissue of plants,—it is, indeed, a minute plant—some starch, sugar, and albuminous matter. Under the influence of the albuminous matter which is contained in the yeast, the sugar begins to be destroyed and to be decomposed into carbonic acid, which goes away, and which you see has filled the tube of glass, and alcohol. Now, if we take the formula of grape sugar—twelve carbon, twelve hydrogen, twelve oxygen—and if we let four equivalents of carbon be burnt with eight parts of oxygen of the sugar itself, there will then remain eight equivalents of carbon, twelve of hydrogen, and four of oxygen; and that is like two equivalents of alcohol, the formula of which is $4C, 5H, O + HO$. Therefore we have here some internal combustion of the sugar; some of the carbon of the sugar burns with some of the oxygen, and the rest which remains is alcohol. I beg you to observe that the decomposition of the sugar goes on under the influence of albuminous matter. It would require an extremely small quantity of yeast to destroy the whole of the sugar if we had time enough. If we take more yeast the decomposition will go on more swiftly. This fermentation of sugar will give us a very good illustration of the processes going on in the living body, of which we have to speak in the next lecture.

You see, then, that combustible substances—indeed, substances of quite the same nature as those contained in our body—are introduced with our food, which contains sugar, starch, fat, and several albuminous matters. The number of albuminous matters contained in the vegetable kingdom is very great; there are many different kinds of them. Thus we have gluten and albuminous matter produced during the fabrication of starch; casein, which is contained in milk, and is the principal substance of cheese; and we have here dried the albumen of eggs. These are introduced into our stomach

and there dissolved by a kind of fermentation going on under the influence of the gastric juice, and afterwards taken up by the blood-vessels and the lymphatics. In the same way, the sugar which is introduced into our digestive canal is dissolved and absorbed by the vessels. Starch is transformed at first, by the influence of saliva and the secretions of the bowels, into grape sugar, and is afterwards absorbed in its soluble form. Fats are only finely divided in our stomach and intestines; they are divided into very fine drops, which are mixed with the watery masses contained in the bowels, and are taken up into the lymphatic vessels. They are brought into the same form as that in which they are contained in milk. Milk, indeed, is a fluid, a watery solution of sugar and casein, in which a great number of small globules of the fat of butter are suspended. Milk, therefore, represents the state of the fine division of the fats in which they are taken up by the lymphatic vessels. They are not carried immediately into the circulation of the blood, because they are obliged to pass through different glands. The blood-vessels of the intestines are collected together into one great trunk, which carries the blood into the liver, and all the blood which contains these digestive substances is obliged to pass at first through the liver. It appears that some of the substances so taken up are retained in the liver, and pass only gradually in small quantities into the blood before being used further. The substances which are taken up by the lymphatic vessels are carried through the so-called lymphatic glands of our abdomen, and are there transformed in a peculiar way, and afterwards they pass through the great lymphatic vessels into the blood. So at last all those combustible substances which we take up as food are carried into the blood, and by the blood to all parts of our body in which the blood-vessels are spread out.

Now we take in not only combustible substances, but also gas. Oxygen is taken in by the lungs, which are of a spongy texture, and contain a great number of very fine blood vessels, through which the blood flows. The blood which comes through the lungs is of a very dark colour, such as you see in this vessel. I have here a small quantity of the blood of an ox in a vessel filled with carbonic acid. The blood has taken up the carbonic acid, and you see how dark the colour is. I have another vessel filled with oxygen, into which I have put the same kind of blood, and you will observe that the colour is scarlet red. This difference is produced by the two gases. If I put the dark blood into a vessel filled with oxygen, you observe that it becomes light; and if I put the lighter blood into another vessel containing carbonic acid, you see that it assumes a darker hue. You see, therefore, that blood is able to take in quantities of gas, and that the nature of these gases contained in the blood is indicated by the change of colour. I can show you that these gases contained in the blood can be separated again by means of an air-pump: for, as soon as the air is removed, you will observe that gas bubbles rise from the blood. [Experiment.]

CLINICAL LECTURE ON FLEXIONS AND VERSIONS OF THE UNIMPREGNATED UTERUS.

By W. O. PRIESTLEY, M.D.,

Professor of Obstetric Medicine in King's College.

GENTLEMEN,—The uterus, both in its unimpregnated and gravid condition, is liable to certain deviations from its normal position; and I propose in this lecture, without going at length into the whole details of the subject, to make a few practical remarks on flexions and versions of the womb, in connexion with the case of a patient under treatment in the Hospital.

I may explain that the displacements of the entire organ, backwards or forwards, are termed respectively retroversion and anteversion, according as the fundus uteri is thrown posteriorly towards the sacrum, or anteriorly towards the symphysis pubis, the os and cervix lying in the opposite direction. The instances in which the womb is bent upon itself, after the fashion of a chemical retort, posteriorly or anteriorly, are called distinctively retroflexion and antelexion. The symptoms and treatment of all are, with certain modifications, practically the same, but for various reasons it is desirable to distinguish between them.

The existence of these displacements is often traced back to labour or miscarriage, or to some attack of uterine congestion, which rendered the fundus heavier than its supports could

bear. Occasionally a fibroid tumour in the uterine walls, or an ovarian tumour above, bears down the entire uterus lower into the pelvis than its normal site, and at the same time flexes the fundus on the cervix. In some instances where there is no enlargement, mere relaxation of the ligaments, combined with habitual constipation, is sufficient to account for the deviation of position; while in others, the first symptoms are attributable to a fall or other accident. There is reason to believe that, in some cases, anteflexion in the adult is owing to the persistence of an earlier degree of development, the uterus in the fœtus and during infancy being commonly found anteflexed.

The study of uterine displacements is avowedly a difficult one, and the mind of the student cannot but be perplexed by the different and, indeed, antagonistic opinions entertained by writers of authority regarding them. Thus, while some distinguished teachers hold that deviations in the position of the uterus are a fertile source of pain and inconvenience to patients, another refuses to recognise as pathological facts the existence of such mal-positions; and an eminent Professor of Surgery, not long ago, in alluding to them, evidently regarded them as the creations of ingenious Practitioners, intended to amuse fanciful and credulous patients. The reason of this divergence of opinion is no doubt partly traceable to the very variable symptoms experienced by patients who are the subjects of these affections. Observation clearly proves that some patients who have flexion or version of the womb suffer little or no inconvenience from it; the existence of the displacement perhaps being discovered accidentally. In others, the amount of suffering associated with displacement is very great, and seems altogether out of proportion to the supposed pathological cause. Constant and depressing pain in the lower part of the abdomen and back, shooting down the lower limbs, and leading the patient to believe she cannot walk; difficulty and pain in defæcation; irritation of the bladder, or retention of urine; sympathetic nausea and chronic vomiting; headaches, and neuralgia in distant parts of the body; dysmenorrhœa and menorrhagia in varying degrees, and various hysterical phenomena. These symptoms may be present singly or together,—the presence or absence of any one of them not always being distinctly traceable to the variety of displacement which is present. I have seen more than one case of retroflexion in which the patient suffered from obstinate chronic vomiting, and such severe continued pain in the hypogastric, iliac, and sacral regions, that progression became almost impossible; she could at last no longer be persuaded to leave her couch, and became a permanent invalid. The suffering face and emaciated lower limbs seemed to preclude the idea that any effort on her part could have overcome the indisposition to move; and yet no other cause could be ascertained beyond the malposition of the womb.

My own observation does not enable me to state whether the displacement of the fundus backwards or forwards produces the greater inconvenience, but retroflexion and retroversion are more frequently observed than anteflexion and anteversion, and retroflexion is more commonly met with than retroversion. The order of frequency is mainly to be accounted for by the anatomical arrangement of the parts. The freedom of the posterior wall from attachments and supports renders the fundus more liable, particularly when it is enlarged, to be borne backwards by the superincumbent weight of intestines, and to be pushed further downwards into the retro-uterine cul-de-sac by the transit of fecal matter through the rectum. The anterior wall, on the other hand, is better supported by the arrangement of its ligaments and by its attachment to the bladder; and we may readily suppose that the filling of the bladder in the ordinary performance of its functions, by exercising pressure upwards and backwards, has a natural tendency to rectify anteversion and anteflexion when they are accidentally produced. Again, the more frequent occurrence of retroflexion than of retroversion is explained by the greater mobility of the fundus as compared with the cervix, which is sustained by dense ligaments both anteriorly and posteriorly.

It is by no means easy to account for the varying amount of discomfort associated with flexions and versions of the uterus, and the difficulty is increased by its having been remarked that the same train of symptoms may be associated with other and dissimilar affections of the organ, and that not unfrequently when the displacement had been remedied the inconveniences supposed to be produced by it were not removed. The knowledge of these facts has led M. Scanzoni and Dr. West in his excellent book on the "Diseases of Women" to suggest that, in the majority of instances, the

symptoms were less owing to the displacement *per se* than to some superadded morbid changes in the structure of the womb itself. The reason why one patient suffers little or nothing from uterine flexion or version, while another experiences such grave local and general disturbance of the system, being that in the one case the uterus though displaced remains healthy; in the other there is not only misplacement, but besides uterine congestion or inflammation with its results, or some other form of uterine disease.

The patient in King's College Ward whose presence there has led me to bring this subject before you, in some measure illustrates and confirms this position.

On her admission the uterus was not only flexed, but enlarged, and exquisitely tender to the touch, and she had such local and general discomfort that she was quite incapacitated from following her avocations. As the congestion and tenderness subsided under appropriate treatment, the symptoms became less urgent, and she is about to leave the Hospital in all respects much improved, but with the womb still in a great degree flexed. At first the pain inflicted merely by a digital examination was so considerable that it was not deemed advisable to perfect the diagnosis by the introduction of the uterine sound, and the fundus uteri in its bent position was so immovable as to create a suspicion that it was bound down by fibrinous adhesion in the retro-uterine cul-de-sac. At a later period, however, when the use of the sound became justifiable, I was enabled to lift up the uterus into its natural position, but it fell back again as it commonly does, almost immediately after the withdrawal of the sound.

The explanation offered by M. Scanzoni and by Dr. West, while it meets the difficulty in a considerable number of instances, nevertheless does not apply to all cases. A certain number of patients apparently suffer much from the results of uterine displacement without having the womb in any degree enlarged or even sensitive to the touch, in whom, indeed, the uterus seems endowed with a less degree of sensibility than under ordinary circumstances—the introduction of the sound and other manipulations being borne better than in health. In patients with retroflexion it has been supposed that the fundus uteri exerts painful pressure on adjacent parts, and particularly on the sacral flexus of nerves, thus affecting the nervous supply of the lower extremities. But we must look further than this for the cause of suffering in some of those who suffer most from retroflexion without disease of the uterus; and this I believe is often to be found in the condition of the ovaries. The same relaxation of tissue which permits retroflexion favours also prolapsus of the ovaries into the retro-uterine cul-de-sac, and when the uterus falls backwards on account of increased bulk and weight, it is very likely to pull down the ovaries with it. Overlaid thus, singly or together, by the retroflected womb, their circulation is impeded; they are apt to become congested and enlarged, and are still further irritated by the contents of a constipated bowel, and by the effects of accidents to which they are exposed in this abnormal position. The frequency of pain referred to the ovarian region in the subjects of retroflexion has been often remarked, and it has been repeatedly noticed how often prolapsus and congestion of the ovary are associated with retroflexion. In many of these cases pressure with the index finger on the uterus may give comparatively little pain, but the slightest touch of the ovary produces a paroxysm of suffering, followed, perhaps, by aching for some time afterwards. I have fancied that instances of this kind might be compared with those of neuralgia of the testicle in the male subject. Prolonged and severe pain in this gland has a very large proportionate influence in impeding nutrition, and in producing physical discomfort and mental wretchedness. Whether this analogy holds good or not, I have no doubt that the distressing symptoms in some cases of retroflexion are rather due to a morbid condition of one or both ovaries associated with displacement, than to the displacement itself, or to displacement combined with some morbid condition of the uterus.

* * * * *

For the purposes of diagnosis the uterine sound is of great value. By carefully passing it into the womb we may ascertain the direction of its cavity, and in many cases by its assistance be able to raise up the fundus, thus restoring the uterus to its natural position, and causing the tumour formed by the displacement to disappear. In this way we are able to distinguish flexions and versions from other pelvic tumours to which they may bear a resemblance. Certain cautions are, however, necessary in using the sound. Thus, it is certainly

better to be content with the diagnosis so far incompleated than to persist in using the uterine sound when its passage would inflict much pain at the time and suffering afterwards. Moreover, it should be remembered that whenever the deviation has been of long standing the uterus may have become tied down in its abnormal position by inflammatory adhesions on its peritoneal surface. This is well shown in a preparation of retroflexion recently presented to King's College by Dr. Day. Under these circumstances we may ascertain by the sound the direction of the uterine cavity, but to use such force as to break up the adhesions with the object of restoring the uterus to position would be to inflict grievous and perhaps fatal injury. Further, Virchow, Scanzoni, and others have pointed out that in cases of prolonged retroflexion, the cervical canal becomes extremely contracted at its upper extremity, and this contraction obstructs the introduction of the sound. The difficulty in passing the sound in some instances arises, no doubt, from the canal being bent upon itself in the general displacement of the womb, and we may often materially assist the passage of the instrument by lifting up the fundus with the finger, and thus lessening the degree of incurvation. But the authorities named have shown that in protracted cases there is an organic narrowing of the canal at the situation of the os uteri internum, produced by atrophy of the posterior wall at the seat of flexure. The wasting of the uterine substance at the point indicated is probably owing to the continuous pressure which has been exercised upon it, and the womb is here sometimes reduced to such a degree of tenuity that a sound might readily be pushed through it in attempting to reach the cavity, unless this pathological fact be borne in mind and proportionate care exercised. One patient I have seen who for years had suffered from retroflexion, and in whom I had reason to believe that not only atrophy of the posterior wall had been produced, but that wasting had further resulted in permanent shortening of the uterine cavity. The displacement had apparently been produced by a fall from a horse. I saw her in consultation some time afterwards, and passed, with difficulty a sound two and a-half inches into the uterine cavity. Two years later she had not improved, but was then a confirmed invalid; and, on examination, it was found impossible to introduce the sound quite two inches. A subsequent use of sponge tents, by which the canal was well opened, and its condition carefully ascertained, proved that the womb had undergone a general atrophy, its walls were everywhere very thin, and it was further proved that the difficulty in introducing the sound, which had been attributed to some contraction of the canal, was really due to organic shortening of the uterine cavity, consequent, probably, on absorption and shrinking of the posterior wall.

(To be continued.)

ORIGINAL COMMUNICATIONS.

RADICAL CURE OF INGUINAL RUPTURE.

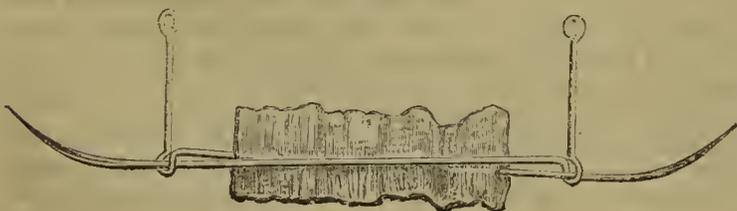

By JOHN WOOD, F.R.C.S.

Operation by Pins.—This operation I use in cases of congenital hernia, and those of small size in lads and young men. In such cases, when the hernial canal is narrow, its sides yielding, and easily and completely approximated, there is no need of any intervening substance to fill up the hernial gap. The tissues also are thin and comparatively unaltered, and permit of an accurate examination, by the finger, through them when invaginated into the canal.

The apparatus used in this operation is very simple, and no incision through the skin is required.

The pins I employ are of various sizes—from three to five inches long, hardened at the point, but made in the shaft so that they will bend a little rather than break off short.

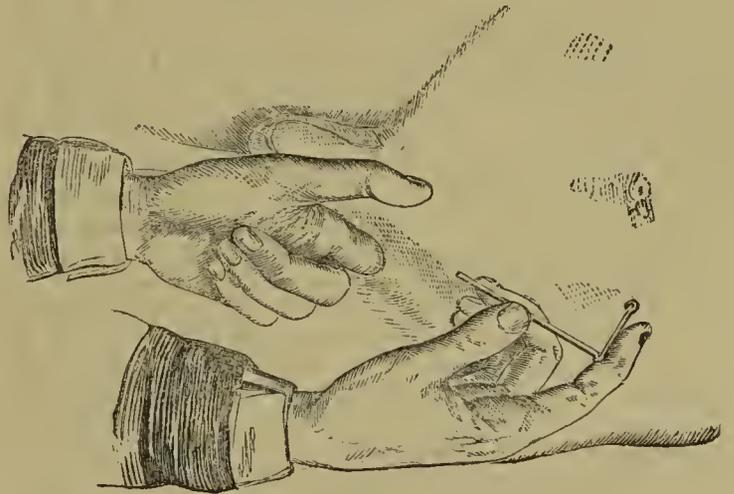

FIG. 1.

They are spear-pointed, curved boldly near the point like a suture needle, flattened on the concavity, with slightly cutting edges, and with a rounded shaft. At three or four inches from the point the shaft is bent into a right angle and twisted into a loop large enough to receive the point of a fellow needle. The projecting end is about an inch long, terminating in another loop for the purpose of being held by the dressings. See Fig. 1. When applied, the pin should be held by the middle of the shaft between the thumb and long finger, the end of the forefinger being placed upon the bent extremity. They are applied in opposite directions through the structures intended to become adherent, and are pinned through and through like an ordinary toilet pin. Each point is then passed through the angle loop of the fellow pin, and the ends then rotated in opposite directions, so as to twist up the confined tissues, and fixed by straps of plaster and pads.

The patient being laid on his back with the knees and shoulders raised, the scrotum is first invaginated into the canal, and the relative positions of the cord, the conjoined tendon, and Poupart's ligament carefully noted. In small cases this can be most conveniently done with the little finger. The finger should be carried as far up as possible, so as to fill in front of it the lower border of the internal oblique muscle, and to the inner side of it the conjoined tendon. The skin of the groin being then drawn directly inwards by an assistant, the needle is carried with its concavity outwards and downwards through the tissues directly upon the inside of the nail of the invaginating finger (see Fig. 2). The point

FIG. 2.

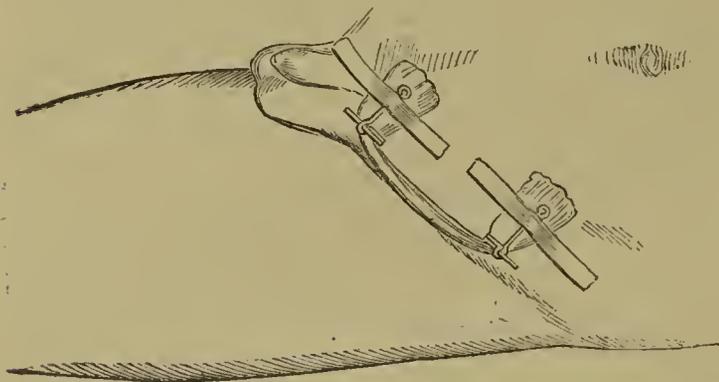

then turned downwards towards the pubis, and pushed steadily after the invaginating finger as it is slowly withdrawn, protecting the needle on the outer side. As the needle passes over the pubis it is made to take up the fibres of the internal pillar attached to that bone, grazing the bone as it does so. The needle and finger must be kept fairly together, the two last fingers of the hand resting firmly upon the groin over the deep ring. This gives steadiness to the hand, and, at the same time, by its pressure, keeps the bowel out of the canal. The point of the pin is then to be cut off with a pair of pliers. The second pin is then taken, and its point, with the concavity directed forwards, passed into the aperture through which the first emerges in the scrotum. The invaginating finger is then placed below it, and passed up into the canal, carrying the pin before it till it touches the middle of the back surface of Poupart's ligament. Through this the pin is then pushed upwards and outwards till it can be seen to raise the skin (see Fig. 3). This is then drawn inwards by

FIG. 3.

the assistant until the point of the pin can be pushed through at the same place at which the first pin entered. The pins are then locked, after which the point of the second pin is to be cut off conveniently close, and one of the bent ends of the pins twisted over the opposite side and held down by a pad of lint and a strap of adhesive plaster. A strip of oiled lint is then twisted round the pins where they lock, so as to protect the skin from their pressure somewhat (see Fig. 4). The whole is then retained by a pad and spica bandage.

FIG. 4.

In this operation the conjoined tendon and inner pillar are transfixed by the first pin, which thus traversed the inner and hinder part of the hernial canal and sac, while the outer pillar is fixed at Poupart's ligament by the lower pin. The whole of these parts, with the hernial sac, are twisted together by the revolution of one pin round the axis of the other, so that the hinder wall is drawn forcibly forwards and outwards, and the front walls backwards and inwards till the canal is firmly closed. The cord lies behind the pins, closely embraced by the twisted tissues. Adhesion takes place between the parts in their new position, following up closely (if the case does well) the slow ulceration in the course of the pins. These are kept in a week or ten days, according to the amount of fibrinous effusion which takes place in the canal. About that time a thick firm mass of deposit occupies the course of the pins, excluding the bowels, filling up the sac, and uniting all the twisted tissues into a solid mass. When the pins are withdrawn, simple water dressing or a poultice may be applied. As the wound heals, a stout pad should be applied over the dressings, and held in its place by a bandage firmly applied. When the openings have sufficiently healed, a horseshoe-pad truss should be applied, with a bit of cotton wool or lint between it and the skin to protect the tender skin. Until this time the patient should be kept in the recumbent position. After the truss has been applied, he may be suffered to get up.

If, in the course of the treatment, the testicle becomes much swollen, all bandages and pressure should be removed, and cold water or evaporating lotion applied. Some degree of swelling of the testicle is beneficial, rather than otherwise, as showing a sufficiently close embrace of the cord, and, consequently, obliteration of the canal. The pins usually are withdrawn with great ease and very little pain. The patients ordinarily suffer so little, that food is taken in the usual way a day or two after the operation. I seldom find it necessary to employ a stricter regimen than milk diet for the first few days. As the wound heals, an allowance of wine or beer may be permitted, and the general health of the patient supported as much as possible, to ensue a more vigorous reparative formation in the parts.

In some cases I have applied the pins transversely to the canal, especially where, as in cases of a large size and direct kind, the rupture shows a tendency to emerge behind the cord, lifting it forwards and pushing it outwards. In some of these very large cases it has been necessary to repeat the operation in order to meet this tendency. Wire has also been applied transversely under these circumstances. It is important in such cases to make the deeper pins or wire touch or graze the upper border of the pubis, over which the rupture emerges. By establishing a bridge of adhesion there, this tendency is better counteracted.

In the case of a child, aged 3 years, now in the Hospital, a very large rupture, reaching half-way down the thigh, and totally unmanageable by any kind of truss, has been very successfully treated. No impulse whatever is now felt on crying, and the large sac can be felt doubled up in the scrotum, and forming a hard tumour, connected above with the pillars of the ring and canal. The child's health and appearance

have positively improved during the time that he has been under treatment. I have found it very advantageous in this and other large cases to keep the child's head and shoulders laid a little lower than his body and legs. This diminishes much the force with which the rupture presses from above upon the newly-formed adhesions. In these large cases the ring truss pad, described in a former paper, will be found to give a more direct and efficient support to the adhesions. At the same time it does not press upon the structures which fill up the hernial gap in the abdominal walls. The sides of the inguinal canal and the pillars of the superficial ring, already closed up by the operation, are kept in position by the pressure of the ring or horse-shoe truss-pad. The first complete closure and obliteration is effected by the operation, and the truss, by supporting properly the newly-formed tissues, during some months after the operation, completes the cure.

I have kept cases treated upon this plan in view for two or three years, the rupture remaining perfectly cured up to the present time, without any truss being worn after the first six or eight months. The growth and development of young subjects assist powerfully in rendering the resistance to re-protrusion more efficient as time elapses, during which the bowel is effectively excluded from the canal. The very large cases of the two brothers Dunn (47 and 48 in my work on Rupture), operated on in June, 1862, remain, according to a letter from the father received a short time ago, perfectly cured up to the present time.

I may here mention that, as I am anxious to obtain, as far as possible, correct statistics of my cases of radical cure, I should be glad to receive information that may have been directly verified by any of my readers as to the failure of any of my cases, specifying the name and address of patient, date of operation, and whether one of my trusses had been worn.

It is the interest both of the Profession and of the public to have the utmost light thrown upon the results of an operation for the cure of a deformity which has baffled the efforts of Surgery for the last thousand years or upwards. I should be also very glad to know the results that have been obtained by any of my professional brethren, both in this country and abroad, who have given these methods of operating a fair trial. I would emphasise a *fair* trial, because many operations have been done based upon the principles, wholly or partly, which I originally laid down as necessary for the cure of rupture, but altered by modifications according to the fancy of the operator, many of which (from the accounts I have received) have influenced the results of the operation very materially.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

CASES OF TYPHOID AND TYPHUS FEVER, ESPECIALLY WITH REFERENCE TO THE CONDITION OF THE URINE.

(Communicated by WM. DUNNETT SPANTON, late Resident Obstetric Assistant House-Surgeon to the North Staffordshire Infirmary.)

Case 1.—R. T., aged 21, single, was admitted under the care of Dr. Goodfellow on November 19, 1861. He has been a carman for six years, and has always been healthy. Ten days before admission he did not feel well, and had an attack of diarrhoea. This was followed by rigors, vomiting, anorexia, drowsiness, and headache, and soon afterwards by cough and expectoration of thick mucus. The diarrhoea continued up to the time of admission, accompanied with pain in the abdomen. The urine was diminished in amount. No cause could be assigned for the illness.

On admission, the countenance was febrile; skin hot, on the chest covered with numerous rose-coloured "typhoid" spots. There was no pain in abdomen, no tenderness on firm pressure, nor gurgling. Some meteorism was present, most marked in the right iliac region. Bowels loose; tongue dry, florid at edges and tip, furred along the centre; resp. 23, calm; occasional cough, with expectoration of frothy mucus; sibilant and sonorous rhonchi all over the chest; pulse 112 sitting up, 98-100 when lying down, small, easily compressed; heart sounds healthy; no headache, deafness, *muscae volitantes*, nor tinnitus aurium; urine acid, loaded with urates. Ordered to

have milk diet and beef tea, and to take a pill containing sulph. copper and opium every six hours, also one pill of two grs. each of Dover's powder and hydr. c. cretâ at bed-time.

November 20.—Slept fairly, rambling a little. Complains of slight headache, and is a little deaf sometimes. Some fresh "typhoid" spots have appeared on the abdomen, others have disappeared. Bowels open once, motion dark ochre coloured, containing blood; resp. 28; pulse 104, firmer. Urine dark orange coloured, loaded with urates, very acid; sp. gr. 1022, containing 51.26 grs. solid matter in 1000 grs.; urea 23.28 grs. in 1000 grs. Chlorides almost absent. Sulphates in moderate quantity. Under the microscope nothing abnormal. Ordered to continue the pills, and to have applied over the abdomen a poultice of linseed with a little mustard.

21st.—Slept fairly; no headache; no fresh spots, former ones disappearing. One bloody motion since yesterday. Respiration 36. At the base of the left lung fine crepitation is heard, and there is some dulness on percussion; elsewhere over both lungs sibilant and sonorous rhonchi as before. Pulse 96; urine high-coloured, clear, acid, specific gravity 1023, twenty-six ounces from 7 p.m. yesterday to 7 p.m. to-day, containing 53.59 grains solid matter in 1000, 668.80 grains in the whole; urea 51.04 grains in 1000, 387.35 grains in the whole; no albumen, abundance of carbonates, small amount of sulphates, scarcely a trace of chlorides. Ordered to continue the pill with the addition of pulv. ipec. one grain; to have a draught of acetate of ammonia and oxymel of squill every six hours, and two teaspoonfuls of castor oil immediately.

22nd.—Rather better; spots fading; two dark, ochre-coloured motions after the oil, free from blood; respiration 32; pulse 96-100, soft, jerking. To have four ounces of wine daily, and to have some carbonate of ammonia added to the draught.

23rd.—Slept well; numerous fresh spots over sides of abdomen; one bloody motion last night, one bilious to-day. Respiration 32; pulse 96, dicrotous.

25th.—Not so well; lips and teeth covered with sordes; tongue covered with thick, dry, brown fur, and fissured; no pain in abdomen; a bilious fæculent motion passed in the night; respiration 34; fine crepitation at base of both lungs; pulse 88; urine high-coloured, clear, acid, sp. gr. 1024. To continue the copper and opium pill, and to take a draught containing quinine, sulph. acid, and tincture of cardamoms every eight hours. To take some strong beef-tea and an ounce of wine alternately every hour.

26th.—Urine copious, high-coloured, bilious-looking (giving no reaction of bile with nitric acid), sp. gr. 1027. A trace of albumen.

27th.—Better; less rambling and somnolency; skin perspiring; some fresh spots; those which came out three days ago are fading; tongue cleaner, moist; one motion this morning; respiration 36-40; expectoration tinged with blood; pulse 100; urine high-coloured, clear, acid, sp. gr. 1027, 30 oz. in twenty-four hours; solids 62.90 grs. in 1000, 905.76 grs. in whole; urea 22.30 grs. in 1000, 321.10 grs. in whole.

28th.—Urine in twenty-four hours 20 oz., acid, sp. gr. 1028, a trace of albumen; solids 65.24 grs. in 1000, 626.30 grs. in whole; urea 16.78 grs. in 1000, 161.08 grs. in the whole.

29th.—Improved; spots disappearing; tongue cleaner; respiration 28; pulse 78; urine in twenty-four hours 20 oz., amber-coloured, acid, clear, containing a trace of albumen, carbonates, phosphates, and chlorides abundant; solids 65.24 grs. in 1000, 626.30 grs. in the whole; urea 18.50 grs. in 1000, 177.60 grs. in whole.

December 2.—Much better; sleeps well. All spots are gone. No abdominal pain. Bowels open once daily; motions solid. Tongue moist; very florid. Respiration 25. Expectoration quite free from blood; scanty. Loose subcrepitant rhonchi heard at base of lungs. Pulse 94, small, weak. Urine in twenty-four hours, 26 ozs., acid, sp. gr. 1025, free from albumen; solids 58.25 grs. in 1000, 736.28 grs. in whole; urea 16.00 grs. in 1000, 199.68 grs. in whole.

4th.—Improving daily. Sleeps naturally. Appetite returning. One loose motion to-day. Respiration 18-20. Pulse 90. To have meat daily, and half-a-pint of bitter ale. To take a teaspoonful of castor oil every morning.

6th.—Going on favourably. Tongue clean. Bowels open last night. Appetite good. Respiration 18. Pulse 112, easily compressed. Urine of yesterday in twenty-four hours, 18 ozs., amber coloured, acid, sp. gr. 1024, free from albumen; solids 55.92 grs. in 1000, 483.15 grs. in whole; urea 17.18 grs. in 1000, 143.56 in whole.

9th.—Sleeps well. Appetite remains good. Skin natural. Bowels confined without the castor oil. Respiratory sounds healthy. Pulse 92, small.

17th.—The motions for the last four days have been covered over with florid blood, though firm and otherwise natural. General condition much improved.

24th.—Discharged well.

Case 2.—T. B., aged 21, single, admitted under the care of Dr. Goodfellow, on November 12, 1861. Has been a piano-forte maker for five years; temperate; always healthy. Three days before admission (November 16), when he went to work, felt very sick. Soon after this rigors followed. In the course of the same day diarrhœa came on, with epigastric pain, anorexia, and vertigo, which have gradually increased. He had no headache, nor epitaxis. On admission he was unable to walk; countenance dull and heavy; the lips incrustated; skin hot and dry. Several "rosy spots" on abdomen and back, disappearing on pressure. Marked meteorism. Bowels relaxed. Tenderness on pressure over whole abdomen, most severe in right iliac and right hypochondriac regions. No gurgling. Tongue dry, thickly coated in centre, florid at tip and edges. Thirst and anorexia. Respiration 28. Respiratory sounds healthy. Slight dry cough. Pulse, in sitting posture, 120; lying down, 88, full. Complains of headache, often severe, but inconstant. Slight deafness. No tinnitus nor muscæ volitantes. Urine acid, amber coloured, loaded with urates, sp. gr. 1026, free from albumen. Ordered to have milk diet and beef-tea, and to take a draught of acetate of ammonia every six hours.

November 20.—Slept little; no delirium; headache and deafness continue. Some tinnitus aurium and muscæ vol. at times. Several fresh spots on abdomen; tenderness continues. Bowels open once, loose. Respiration 28. Pulse 88, dicrotous. To have spirit lotion applied to the forehead; to take a pill containing two grains each of hyd. cum cretâ and Dover's powder at bed-time, and two teaspoonfuls of castor oil in the morning.

21st.—No delirium; no headache; no deafness; nor tinnitus. Still much tenderness and meteorism of abdomen; bowels open once to-day, motion loose bilious, free from blood; Tongue moist, less coated. Respiration 36. Pulse 88, full, very soft. Urine to 7 p.m. yesterday in twenty-four hours, 26 oz., orange coloured, acid, thick with urates; no albumen; solids 58.25 grs. in 1000, 736.28 grs. in whole; urea 46.56 grs. in 1000, 581.05 grs. in whole.

23rd.—Slept well; no headache. Spots marked on the 20th still visible; all others have disappeared. Bowels open twice yesterday, motions dark, loose, and fæculent. Tongue still coated, fissured, pale at tip. Abdomen still tender on pressure; slight meteorism. Respiration 27. Expectoration some slightly rusty mucus, which yesterday was bloody. Slight dulness at both bases; no crepitation audible. This was probably merely temporary congestion. Pulse 70, soft. Urine in twenty-four hours, 25 oz., light amber-coloured, acid; sp. gr. 1027; no albumen; solids 62.90 grs. in 1000, 754.80 grs. in whole; urea, 34.20 grs. in 1000, 410.40 grs. in whole. To take a draught containing quinine, sulphuric acid, and gentian every six hours, and four ounces of sherry daily.

25th.—Improved; sleeps well; no headache; skin moist. One spot only remains. Still slight pain in abdomen on pressure; no meteorism. Bowels open once to-day, motion firm, dark, free from blood. Respiration 26. Pulse 68-70, weak. Urine in 24 hours, 29 oz., light amber-coloured, acid; specific gravity 1018; solids 41.94 grs. in 1000, 648.05 grs. in whole; urea 27.00 grs. in 1000, 375 grs. in whole. To continue the draught and wine.

28th.—Better; gums very spongy; no spots. No pain in abdomen, unless pressed. Slight gurgling in right iliac region. Bowels not open for two days. Tongue much cleaner, moist. No appetite. Respiration 28. Pulse 72. Urine in twenty-four hours, 38 oz., acid, straw-coloured; sp. gr. 1010; solids 23.30 grs. in 1000, 424.99 grs. in whole; urea 20.04 grs. in 1000, 365.52 grs. in whole.

December 2.—Much improved. Skin warm, acting well. Still slight tenderness of abdomen. Bowels not open since November 29. Tongue moist, clean. Some appetite. Respiration 22. Pulse 74, moderately full. Is able to be up a little. To have meat diet, 4 ozs. sherry, half a pint of bitter ale, and a draught of Chiretta, bicarbonate of potash and rhubarb three times a-day. Also to take a teaspoonful of castor oil immediately.

5th.—No pain in abdomen. Bowels open after oil and daily since. Appetite good. Respiration 30. Pulse 74,

small, weak. Slight dyspnoea. Urine in twenty-four hours, 34 ozs., acid, clear, straw-coloured, sp. gr. 1026. Solids, 60.58 grs. in 1000, 988.66 grs. in whole. Urea, 20.28 grs. in 1000, 331.06 grs. in whole.

11th.—Not so well. Last night the pain in abdomen became severe, and the patient was giddy and faint. This, however, has nearly gone. Bowels open once a-day; motions firm. Respiration 26. Pulse 100. Complains of some headache.

24th.—Since the 11th there has been a steady improvement, and he was discharged to-day well.

ROYAL MATERNITY CHARITY.

CASES OF PLACENTA PRÆVIA.

(Under the care of Dr. BARNES.)

Case 1.—*Partial Placental Presentation—Funis and Shoulder—Turning.*

NOVEMBER 23, 1862.—A. B., in ninth labour, at term. The liquor amnii escaped in very large quantity three hours before Dr. Barnes was called. No presentation was felt. At 10 p.m. Dr. Barnes passed his hand into vagina to determine presentation; the cervix was fully dilated; a bunch of funis was hanging through the os; the right shoulder was over the os internum; the face a little to the left of the brim; the child very moveable. The right knee was seized by pressing the breech firmly down upon the forefinger of the operator's left hand, which was passed just inside the cervix. Version was then easily effected by drawing down this leg and pushing up the head from the brim by the palm of the operator's right hand applied externally. Delivery was quickly effected by traction upon the child, combined with pressure on the uterus. To this speed the safety of the child was due. It was born asphyxiated, but respiration was excitable, and was excited. The placenta was cast. The mother appeared to suffer no pain throughout. Child, a boy, of full size. The cord was inserted on the margin of the placenta, just over the os uteri. There had been considerable præ-partum hæmorrhage. This had entirely ceased when Dr. Barnes examined and found the cervix dilated, although there was no pressure of membranes or fœtus upon the cervical zone capable of closing the vessels, as was proved by the following facts:—1. There was a shoulder presentation; 2. The funis was prolapsed, and was not compressed, for the child was born alive; 3. The fingers passed the cervix with ease.

Case 2.—*Placenta Prævia—Arrest of Hæmorrhage by Escape of Liquor Amnii—Birth of Live Child.*

February, 1853.—A pluripara, being near term, was taken with copious flooding at night. The midwife ruptured the membranes; the liquor amnii escaped, and the head was pressed upon the cervix. When seen by Dr. Barnes, the cervix was dilated to size of a crown piece; the head was presenting, and there was no hæmorrhage. Concluding that by uterine contraction alone the placenta had been detached from the orificial zone, and that the case was thus reduced to one of natural labour, there being no urgency, Dr. Barnes advised trusting to nature. The child was delivered alive spontaneously six hours afterwards.

Case 3.—*Placenta Prævia—Artificial Detachment of Placenta from Orificial Zone (Dr. Barnes' Method)—Turning.*

January 8, 1864.—C. D., patient in tenth pregnancy, at term. The last two labours were preceded by flooding. She has had repeated hæmorrhages during the last fortnight. To-day more free from hæmorrhage; very little pain. The midwife found the os opening, and some hæmorrhage, at 10 p.m., and sent for Dr. Barnes. He found the patient very weak; pulse scarcely felt; very anæmic; no pains; cervix expanded to three inches diameter; a flap of placenta extending over the orifice; the membranes unbroken, although it was said some water had escaped. There was no hæmorrhage, and no tension of the membranes. Dr. Barnes detached the placenta freely all round the orificial zone as far as the finger could reach; and opened the membranes just on the margin of the placenta with a steel pen. The head presented. There being no uterine action—paralysis of the uterus is, in fact, a very common attendant upon placental presentations, and one great motive for artificial delivery—it was determined to turn. A knee was seized by aid of external pressure; the cord was felt pulseless; version effected by pushing the head up from without away from the brim. A full-sized male child was delivered in ten minutes; still-born. The placenta was cast; it was of

large superficies. The part which had been over the os was lacerated; the cord sprang from this edge. The mother did well.

Case 4.—*Placenta Prævia—Artificial Detachment of Placenta from Orificial Zone—Turning.*

April 17, 1864.—A. M., pluripara estimated in seventh month. She was taken with profuse flooding yesterday, and this returned still more severely to-day. Dr. Barnes saw the patient at 10.30 a.m., found her very anæmic, pulse feeble, surface cool, cervix scarcely admitting the finger, vagina full of clots, hæmorrhage still, cervix fully an inch and a-half long, a flap of placenta partially loosened lying over the os uteri internum, which was very rigid. The placenta was further detached from its adhesion to the posterior aspect of the orificial zone by the finger; the head was presenting; there was no uterine action, and therefore no security against further hæmorrhage; it was therefore determined to accelerate labour. The medium-sized bag was passed and distended with water; the cervix held it firmly, pressure being exerted along the whole cervical canal, and especially upon the ora internum and externum; dilatation, admitting three fingers, was effected in half-an-hour, and some slight uterine action was excited. The largest-sized bag was then placed; in fifteen minutes more the rigid, imperfectly-developed cervix was sufficiently dilated to admit the passage of a premature child without violence. Turning was effected by the bimanual method easily, and the child was extracted in fifteen minutes, the os internum yielding slowly to the head. The child, which did not exceed the development of six months' gestation, was still-born. The placenta was cast, the uterus contracting well when the child was extracted. The flap of placenta that had presented was infiltrated with effused blood, and a clot adhered to the margin. The mother recovered well.

These cases illustrate several of Dr. Barnes's views as to the physiology and treatment of placenta prævia.

Cases 1 and 2 prove that there is a physiological limit to the hæmorrhage marked by the detachment of the placenta from the cervical or orificial zone; that it is not necessary to separate the placenta beyond this zone; that the detachment being completed from this zone, and the hæmorrhage being stopped, the portion of placenta remaining adherent to the lateral and fundal zones of the uterus may preserve the child, and enable it to be born alive either by turning, as in Case 1, or by the natural powers, as in Case 2.

Case 3 proves the safety and utility of artificially detaching the placenta from the orificial zone, and the indication to deliver by turning when the uterus is paralysed.

Case 4 illustrates a point much insisted upon by Dr. Barnes—namely, that profuse and even fatal hæmorrhage may occur before the os uteri is dilated; that hæmorrhage does not necessarily render the cervix soft and dilatable, and that active measures may, therefore, be called for to accelerate labour at a time when the cervix would not admit the hand to pass for turning without the infliction of severe and even dangerous violence. In no class of cases is the value of the water cervical dilators more decided. In this case the uterus was put in a condition for the safe transit of the child in an hour, notwithstanding the great rigidity attending the imperfect development of the organ at six months' gestation.

APOTHECARIES' HALL OF IRELAND.—The annual examination for the Council's prize of five guineas was held in the Board-room on Monday and Tuesday, May 2 and 3, the subject for the present year being "The Chemical Physiology of Man: the Chemical Changes which take place in the Human Body in Health, with special reference to the Functions of Digestion, Respiration, and Nutrition." Mr. E. W. Collins obtained the prize; Mr. Joseph Kenny, Medical scholar, Catholic University, was awarded the certificate.

DRASTIC PURGATIVES IN PUERPERAL FEVER.—Professor Breslau, Director of the Zurich Obstetrical Clinic, relates 64 cases in proof of the great advantage attending the administration of drastic purgatives in the true Hospital puerperal fever, even when prevailing epidemically or endemically. Their use should be commenced within the first twenty-four hours, and continued at short intervals until the purgative effect is produced. The presence of an acute general or circumscribed peritonitis, oophoritis, or salpingitis, must not deter the Practitioner from their use, as they constitute the best antiphlogistics, while their employment does not prevent other means, such as leeches, cataplasms, etc., being simultaneously resorted to.—*Archiv. der Heilkunde*, 1863, Nos. 2 and 6.

Medical Times and Gazette.

SATURDAY, MAY 7.

THE MEDICAL COUNCIL.

Our Medical Parliament met for the Session of 1864 on Monday, April 25, and the first subject discussed was Dr. Andrew Wood's Annual—"That reporters be admitted to the meetings of the General Medical Council." As we anticipated, the motion was this year carried; in a rather curious, complicated manner, as our readers will learn from the Minutes, but it was carried, and all the speeches made in Council may now be published, as well as the results of those speeches.

The Council, after much hesitation, decided most rightly on employing a "reporter for the Council;" as public reporters are admitted to the debates, it is most important that an authorised version should be provided.

The discussion on the subject occupied a sitting and a-half, so that this privilege has cost the Profession, as the *British Commercial*—we beg its pardon, the *British Medical Journal*—is very properly careful to inform us, about £250. This must have been nearly the cost for this Session only; it is a pity the calculation was not more accurately and fully carried back, so as to embrace all the golden hours given to the subject from the time when Dr. Andrew Wood first made his motion; for a knowledge of the exact money value of getting the Council to "sit in the presence of the Profession" might help us towards feeling enthusiastic over Dr. Andrew Wood's victory. At present, though we have tried to think big things about it, we confess to having failed most woefully. We care vastly more to know what men do in council than what they say; what men vote for or against, than for their reasons for the faith that is in them. Nothing would be more easy than to utter a quantity of "tall talk" on the subject, but the occasion does not appear to us to call for or to justify it. The outer world is most cruelly indifferent, and simply ignores the great fact that the hall of our convocation is open to it; not Jupiter, neither the great nor the lesser, nor any of his rivals, has cared to grace the reporters' gallery; we cannot learn that even the smallest, the most lean and hungry for news, among the dailies or weeklies of the secular press has claimed admission to it.

We are quite ready to allow that it is only right and just that the Medical Parliament should meet in public, and that the exclusion of reporters would be "alien to the genius of British institutions," etc., and we believe that men will be more careful and guarded in speech, and more deliberate in forming their opinions now that they have to speak in the presence of the Press; but we do not anticipate much pleasure, or satisfaction, or benefit from the perusal of their speeches; and the specimens we so far have of them do not exceed our anticipations. One of our contemporaries has given us, with a great flourish of trumpets, Dr. Andrew Wood's speech on introducing his resolution—reported in full before reporters were admitted, by the bye. It is, perhaps, a clear and not

unfair *resumé* of the arguments for and against the resolution; but we should have been somewhat puzzled to account for our contemporary's high-flown praise of it, had we not observed that Dr. Andrew Wood had had the sagacity to discover that that contemporary is "the leading journal of the Profession." "Caw me, and I'll caw thee," is an excellent principle, and is appreciated as well this side of the Tweed as beyond it; it is only natural to put on our most rosy-hued magnifiers when reading the speeches of appreciating friends. We trust, however, that it will not become a habit with speakers in the Medical Council to quote by name any of the journals; such a proceeding will do anything but add weight and dignity to the debates, and savours strongly of flunkeyism.

One thing we have learnt from the published speeches of our representatives which we should never have suspected—namely, that the great end and being of the Medical Council, its "final cause," is the use of "moral suasion." We are quite sure the Profession never dreamt that all their years of anxiety and agitation, all the vast expenses they have incurred, and are still incurring, were only to result in the acquisition of a "Moral Persuader!" We cannot believe that many of the members of the Council entertain so low and weak a view of its duties and powers. If they do, we may at once bid "farewell, a long farewell," to all ideas of any greatness of results from its deliberations, to all hopes of an improved and uniform system of Medical education, or of any real advantage whatever from its existence. The utmost to be expected will be a series of futile and vacillating compromises. Dr. Andrew Wood "abhors compromises," while Mr. Arnott complains that the spirit of the old Covenanters still flourishes north of the Tweed; to which Dr. Alexander Wood retorts that such ideas are "natural to a naturalised Scotchman in England. Whenever he heard a man abuse Scotland, he was sure that that man's grandfather was a Scotchman." Our readers may not be impressed with any great notion of dignity and worth by debates carried on in this spirit, but let us be thankful for a little amusement. Compromise there must be in carrying out such work as the Medical Council has in hand, and we willingly make allowance for the great and manifold difficulties it has to contend with, but "il y a fagots et fagots;" and after an existence of five years the Profession has a right to look for something better from the Council than compromises which are absolutely neutral and emasculate, or, at the most, only make confusion worse confounded. Look at that incarnation of compromise the British Pharmacopœia! Speaking with reference to it last year, we observed—"Come when it may, it will be received with a chorus of discordant criticism." We were wrong—we openly confess it; for never was a work greeted by such an universally accordant cry of dissatisfaction and objurgation. From the late President of the Council downwards, throughout the Profession, it meets with only hostile criticism and dislike, and is, not quietly, put on one side, while men go on using the Pharmacopœias of the Colleges. Our great "persuader" will assuredly fail in getting us to swallow this one of its productions by any arts of "moral suasion" it can employ.

The Council has appointed a Committee, which we are glad to see consists of only four members, to prepare a new edition of their Pharmacopœia; and this Committee is to appoint "an editor or editors;" we trust they will keep to the singular number in this respect. The Committee is to supervise the labours of the editor, and the Council the labours of the Committee, so that there will be verge and scope enough for the conflict of opinions, without a plurality of editors to start with.

On Wednesday the Council resolved itself into a Committee on Education, and has since then been chiefly occupied with this subject. The speaking has been most copious, and the actual work done proportionately small; nearly every inch of ground has been hotly disputed, and it is not always easy to discover what was the difference between the

disputants. The ball was opened by Dr. Storrar, who proposed "that the Committee proceed to consider, one by one, the recommendations of the Council, relating to General and Professional Education and Examination." As the object was to get a general committee on education to work, this resolution has a most natural, simple, sure-to-pass aspect; but Mr. Syme met it by the amendment "that the Committee do now proceed to consider the whole subject of Medical Education and Examination, with the view of preparing a Report for the guidance of the Licensing Bodies." Dr. Storrar naïvely remarked that he could not see any difference between the original motion and the amendment, and we suspect most readers of the Minutes will find the same difficulty; however, the Committee were sharper sighted, for a debate followed, which occupied the greater part of the day. The real object of the amendment seems to have been to ignore entirely all the former work of the Council on the subject, to throw over altogether the existing regulations, and begin *de novo*. It is impossible for us to treat our readers with the various speeches at length, but Dr. Storrar proposed to take the existing "recommendations as a sort of catalogue of the various questions which are conveniently placed before us for the arrangement of our discussion;" and he was anxious that the Council should do their spiring very gently, and remember that they could only "recommend," and were utterly destitute of any authority or power to prescribe or enforce "rules."

Mr. Syme considered that when the recommendations were agreed to by the Council they intended to enforce them, but, as was well known, when one of the examining bodies had rebelled against them the Council had shrunk from enforcing them, that "last year it was agreed that the period of force had ceased" (we did not know it had ever existed), "and the age of persuasion begun;" that, therefore, it would be a waste of time to consider the recommendations. He proposed to recommence with a "tabula rasa."

Dr. Andrew Wood seconded the amendment, and made a vigorous speech in support of the powers of the Council. The object of the Act which created them "was to remove invidious privileges which existed previously, to do away with injurious monopolies, and to put all parties on an equal footing, but at the same time to establish a means of enforcing a certain, fair, and just amount of education and examination throughout the kingdom;" but when the College of Surgeons had refused to adopt their recommendations the Council had vacillated. Had they carried the matter then before the Privy Council "they would have been in a condition to say exactly what their powers were. It was said they had no powers. They had never tried their powers. Had they gone before the Privy Council they could have forced them to do what they wished, and so they could have enforced the regulations and have established uniformity. Failing this, they might then have either used 'moral suasion' or have taken a bolder and more straightforward course: they might have gone to Parliament to get the proper powers. . . . Let them no longer recommend, desire, and do nothing, but take the steps the act enabled them to take, or if the present act did not give them power, let them get a new one."

Dr. Wood's mention of the College of Surgeons called up Mr. Arnott, whose speech, however, can hardly be considered a defence of his College, as it consisted mainly of a charge of intolerance against some of the members of the Council; to this we have already alluded. He warned them against going to the Privy Council. "If you frame resolutions and go to get them sanctioned, look what you do. You put the control of the whole Medical system of England out of your own hands, and give it to the Privy Council. And who is the authority with regard to the Privy Council? Do you think the Privy Council care a rush for you? They will ask the man who happens to be their Medical adviser, and you are in their hands. I will advise you to hesitate before you adopt that course of going to the Privy Council."

Dr. Acland thought it very unfortunate that there was so great a tendency to throw discredit on their past proceedings. A great deal of time and labour had been expended on these recommendations. "Their late President (Mr. Green) had bestowed great attention on them, and had paid great attention to educational questions, and was known to be a skilful thinker (if he might say so) in that department of knowledge." He thought a great deal of time had been wasted, and hoped that the resolutions might be adopted without much further observation.

Eventually the original motion was carried.

Dr. Storrar then moved the first recommendation—"That all students pass an examination in general education before they commence their Professional studies." This again excited a long discussion; and Dr. Acland, "to meet the wishes of the various speakers," moved the following amendment:—"That all students pass an examination in subjects to be included under the head of general education prior to the date from which the commencement of their Professional studies is to be reckoned." It passes our wit to discover wherein the amendment differs from the original motion, save in number of words. The discussion might be creditable to a debating society of sucking barristers and special pleaders, but hardly to men of great reputation and experience met together for real work. The original motion was at last carried.

The second recommendation, moved by Dr. Storrar, was—"That the time of commencing Professional studies shall be understood to be the time of commencing studies at a Medical School; and that no qualifying body be held to have complied with the recommendation of the Council which will allow the examination in general education to be passed after the commencement of Professional study;" and it was ingeniously postponed and neutral-tinted by Mr. Arnott, who moved—"That 'the time of commencing Professional studies shall be understood to be the time of commencing studies at a Medical School,' be transferred to the recommendations on Professional education;" and "That the concluding paragraph of the second recommendation—viz., 'That no qualifying body be held to have complied with the recommendation of the Council which shall allow the examination in general education to be passed after the commencement of Professional study,' be omitted." His amendments were carried.

A list of the national educational bodies whose testimonials of proficiency may be admitted was agreed upon; and after a vast amount of discussion as to whether a minimum standard of preliminary examination should be fixed by the Council, and as to the expediency of positively requiring a knowledge of Greek as well as Latin, it was determined "that the examination in general education be eventually left entirely to the examining boards of the national educational bodies recognised by the Medical Council," but that a knowledge of Latin be absolutely required.

A simple and, we think, very good system of registration of Medical students was adopted; and late on Friday the committee had arrived at the consideration of the recommendation, "that the age of twenty-one be the earliest age at which any Professional licence shall be obtained;" to this Mr. Syme moved the amendment—"That the committee proceed to consider the subjects and course of study requisite for a Medical Professional education," and the amendment being carried, he then moved "that the Council proceed to frame a course of study for Medical education, which may be recommended to the licensing bodies." The discussion on this motion, and the amendment proposed to it, occupied the Committee the whole of Saturday and Monday, and ended in "*vox et preterea nihil*." The original motion and the amendment, for the latter of which we must refer our readers to the Minutes, were both negatived, and on Tuesday, instead of the Council resolving into a General Committee on Education, it did what had in effect been proposed and negatived on the Thursday previous, namely, appointed a Special Committee to

draw up a scheme of Medical education. We have not space for more this week, but intend in our next number to give our readers the most important speeches of the debate. So far, we fear they must think that the Council has presented them with bread and sack in most intolerably Falstaffian proportions; the whole proceedings irresistibly remind one of a review-day, when, after the public has been regaled with numerous complicated and unintelligible evolutions, and with a vast amount of noise and smoke, the affair ends in the general order of—"As you were."

THE "BRITISH MEDICAL JOURNAL" ON SCIENCE.

It is a distinguishing mark of civilised people that they avoid personalities. For this end all sorts of courteous contrivances are in use in the common intercourse of life. In many languages they speak, not of persons, but of attributes, as "your excellency," "your lordship," "your holiness," "your worship," and the like. Usually we speak in the plural when we mean the singular; and the "you" is employed as a courtesy, whilst "thou" would be a sign either of reproach, or of the extremest familiarity, or of great vulgarity. More particularly is this usage adapted to the conductors of periodicals. The editor says not "I," but "we;" so as not only to avoid the *ego*, but to intimate that it is not a "person" who is in question, but an abstraction; the "Journal," the sentiment of the proprietary, or of a committee of management, or of those professional friends by whose counsel the editor is assisted. And, in attacking anything contained in a journal, ordinary courtesy demands that we attack, not the editor, nor Mr. A., or Dr. B., supposing we know the editor's name, but "the journal," the "management," the set of opinions, or the party of which it is the "organ."

Now, the *British Medical Journal* accuses the editor of the *Medical Times and Gazette* of personality, because of our strong condemnation of the tradesmanlike tone which that journal has of late exhibited. We can only say that when anything personal is pointed out we shall be but too ready to retract and apologise for it. But whilst avoiding all attacks upon persons, we do not see why we should desist from pointing out the strange confusion of thought, the abominable taste, and the low, mercenary tone of the journal which is published by the British Medical Association.

If a man wants a trade in which he can make money fast, we are afraid that we must recommend him to turn speculator, or stock-jobber, or distiller; or, if he is not too nice, let him be a publican or perfumer, let him deal in gin or in bear's grease, but certainly let him not attempt physic. Yet, poor as the Doctor may be, there is a prestige about him which the richer shopkeeper sees with envy, and there is a satisfaction in his work—laborious and repulsive as it may be—which makes some amends for the emptiness of his purse. He feels that he is a professional man, that he is doing good to his fellow creatures, and enlarging the bounds of science.

And these are the two pearls which the "organ" of the British Medical Association, like a certain beast, would trample under foot. We have lately shown how it deals with the notion of humanity; and now for its treatment of science.

A discussion had arisen in that journal about the quantity of scientific instruction to be imparted to Medical students, on which point three things are clear to us. One is, that although no man can be a good *practitioner* without *practice*, yet that, of any number of men, those who are prepared for practice by a course of scientific instruction will be better in the end than others who begin without such a discipline. Secondly, we do not affirm that all men require, or ought to have, the same amount of scientific preparation; but we do affirm that a Medical *school*, to be worthy of the name, should be capable, not merely of providing the a b c which shall enable the πολλοι to squeeze through Hall and College, but of showing the very fullest and most advanced stage of science. Thirdly, it is clear that this can be done, not by mere books,

or apparatus, or anatomical preparations, but by living Professors. As in a living language there always are new terms and niceties of phrase which cannot be got from books, however classical, so in an advancing science the latest and furthest and fullest knowledge can only be obtained from the teacher who is himself engaged in making the science. The best books can only give last year's knowledge. Whoever wants to know the whole of ophthalmology must visit Donders, Graefe, Bowman, or Wilde, and see what they do and hear what they say. And nothing is so potent in setting the student to work as to witness the self-denial and enthusiasm with which the best teachers in all schools work for the love of science herself.

Such seems to have been also the sentiments of the Professor of Physiology at King's College, a man who excites the wonder of the Profession by the extent and multiplicity of his original research. In a letter to the *British* last week, he pleaded the great importance of the scientific part of Medical education, and showed conclusively enough that it was inconsistent to pooh-pooh science, and in the same page to rail at a man for lauding "the Germans." Taking ophthalmology for an example, Dr. Beale showed that if we did not encourage the teaching of it in the best and most perfect manner in our schools, our pupils must go to Germany to learn it, and, if they do, must form a high estimate of the foreign schools in which they study.

Through that spell which seems to have come over the *British Medical Journal*, it criticised Dr. Beale's letter, and ventured to assert that "in this country, and especially in London, *men give lectures in order to get* (indirectly, of course) *private practice, not to advance the study of science. Lecturers here keep an eye ever on the main chance.* Can three Medical lecturers in London be named who are not lecturing with the view of private practice in their eye?" !!

Now, if the "organ" had said that men give lectures to get practice and to advance the study of science, it might have justly been considered true, in a sense, though not very refined, nor elevated, nor complimentary to the London lecturers. But when it is asserted that men lecture to get practice, and *not* to advance science, we are made to stare at the audacity which dictated anything so uncourteous and offensive, and so contrary to what men see and know to be true who enjoy the friendship of half-a-dozen of Hospital Physicians or Surgeons in London.

The organ of the British Medical Association actually, when addressed ably and dispassionately on questions of great interest, not only to lecturers and teachers, but to the whole body of British Medicine and Surgery, tells the London lecturers that they keep an eye ever on the main chance!—tells Dr. Beale he seems to think there is no limit to the voracity and capacity of students! Does the British Medical Association think it decent that a scientific discussion should be treated in this low and discourteous spirit?

THE WEEK.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XIV.—MARCH 3.

Anatomy of the Chimpanzee continued.—In the adult male the penis is very small, of a long and slender form, and terminating in a small, narrow glans, of very different form from that of man. On the other hand, the testes are extremely large. The communication between the tunica vaginalis and the abdominal cavity is shut off as in man. The reproductive organs of the adult female have not been described, but in a young example of that sex, the clitoris was very large, the vagina proper narrow, but dilated at the posterior part, the uterus simple having the same general form as that of a child of corresponding age, but differing in being more flattened from before backwards and quite straight.

We have at present no definite knowledge of the changes which take place in the embryo before birth, but the sub-

sequent laws of growth can be readily studied on the collection of skeletons in the College Museum, and give results in some respects very different from those observed in the human subject. The total height of the whole body when full grown is about three times its height at birth. There is the same comparatively small increase in the head as in man, the vertical height of the adult skull not exceeding twice that of the new-born animal. In man we saw a great difference in the relative growth of the legs and arms as compared with each other, and with the trunk, but in the chimpanzee the same proportion is approximatively preserved throughout; hence the young chimpanzee and the human child are more alike in form and proportions than are the adults of both species. As regards special segments of the limbs, a different law of growth prevails from that observed in man; the hand and foot are proportionately longer in the young, and as growth advances the other segments increase at their expense. Among other changes which take place in the process of development may be noticed the obliteration of the suture between the maxilla and the premaxilla before the milk teeth are all in place; in this respect the chimpanzee approaches man and differs from all other apes. With growth also comes an immense increase of macrogathism and prognathism, and a great development of the frontal sinus and supra-orbital ridges, which greatly alter the external appearance of the skull.

In the adult state, certain differences are observed between the sexes, independently of those directly connected with the generative function. In the first place, it is to be noted that there is no very marked difference of size between the male and female. In the dentition a striking sexual character is seen in the greater size of the canine teeth in the male. The pelvis presents characters in the two sexes quite parallel to those observed in the human subject. Although of precisely the same vertical height, every other dimension of the female chimpanzee's pelvis is strikingly greater than that of the male, particularly the breadth of the inferior outlet.

Although the number of chimpanzees' skeletons and skulls in our collection is not yet very numerous, it is sufficient to show that there is a considerable range of variation between different individuals. A cast of a skull of a variety called by M. Du Chaillu "Kooloo-Kamba" was exhibited, differing from the ordinary form in the comparatively small size and excavation of contour of the face, great size of cranial cavity, and depth of ramus of lower jaw. It might have been thought to belong to a distinct species from another skull exhibited, if the collection did not furnish several examples directly intermediate in all their characters. Professor Huxley remarked that if the tendency to vary was so strong in this anthropoid ape, that amongst individuals having a very limited geographical area, and subject to the same climatic and other external conditions, we could find skulls differing from each other as widely as those of the European and Australian among men, we should not be surprised to find that man, spread over every part of the globe, should present the range of variation we have seen in his physical characters; nor should we find it necessary, in accounting for such variation, to go back to diversity of origin or difference of species.

The Gorilla (*Troglodytes gorilla*) inhabits the same tract of country as the chimpanzee, but is perhaps not so widely spread. It lives more in the hilly inland parts than the chimpanzee; when on the ground it readily assumes the erect posture; its stentorian howl can be heard at a great distance, and the old males are very ferocious. Little more than this is known of its habits. The stature of an adult male, when placed upright, is about five feet, perhaps never exceeding five feet six inches. The colour of its hair is blackish-dun; in old specimens grey. The integument of the exposed parts of the face, etc., is not pale, as in the chimpanzee, but black. The manner in which the hair is distributed is much as in the chimpanzee. The general proportions of the body are also very like those of that animal, the length of the arms being about two-thirds of the height, the legs two-thirds of the

arms, and the height two-thirds of the span from tip to tip of the extended fingers. In minor respects there are differences of proportion from those of the chimpanzee. Thus, the humerus is longer than the radius, instead of being nearly equal, and the hand is much shorter in proportion to the forearm and humerus. The dimensions in the male gorilla's skeleton in the College museum are—Humerus, 17 inches; radius, 13; hand, $9\frac{1}{2}$. The foot is very distinctly longer than the hand; the great toe is proportionally stouter than in the chimpanzee: the sole of the foot and palm of the hand are extremely broad, and there is a very marked syndactyly of the toes and fingers, extending as far as the end of the first phalanx. The nose is somewhat more projecting than in the chimpanzee, the external ear differs in being very much smaller.

The number of the vertebræ of the different regions of the spine are the same as in the chimpanzee, viz., cervical 7, dorsal 13, lumbar 4, sacral 5, coccygeal not satisfactorily determined. The cervical vertebræ are remarkable for the great elongation of their spinous processes, for the attachment of muscles to support the great weight of the head and jaws. The last lumbar vertebra has its lateral processes expanded and united with the sacrum. The thorax is of great size, the sternum broad and flat; the space between the last rib and the crest of the ilium is very small.

In no part of the organisation of the gorilla is its difference from man so apparent as in the skull. This, however, is more apparent than real, as the true characters of the brain case are completely hidden by the prodigious development of the lambdoidal and sagittal crests and the supra-orbital ridges. The capacity of the largest cranium of a gorilla yet measured is nearly thirty-five cubic inches. In this respect, and the greater development of the mastoid process, the gorilla's skull approximates more than the chimpanzee to the human subject. In all other characters it approaches more to the lower apes, especially the baboons. One of the peculiarities belonging to the latter division is the union of the frontal bone across the base of the skull, covering the junction of the presphenoid and ethmoid, and causing the olfactory fossa to become narrower and more funnel-shaped.

PARLIAMENTARY.

In the House of Lords on Thursday, April 28, a conversation took place relative to the proposed removal of the seat of Government from Calcutta, and also on the recent Government interference with the native mode of disposing of their dead. (a) From what Lord Wodehouse said, it appears that the question of the removal of the seat of Government is now under the consideration of the authorities. Lord Ellenborough supported the claims of Calcutta on the authority of the late Duke of Wellington, who considered it to be unattackable by sea and land, and held that a maritime position which enabled the Government to maintain a free communication with its naval force was of the utmost importance. Of course, whilst India is held as a conquered country, such reasons must be allowed their full weight; but even they do not prove that it is necessary to make the most unhealthy spot in India the great seat of our commerce and the centre of civilisation. It may be questioned whether all the benefits this country has derived from her Indian possessions have not been too dearly purchased by the valuable lives that have been sacrificed to the pestilential miasms of the delta of the Ganges.

The bill for the punishment of rape by whipping was read

(a) The improvement of Calcutta has been often enough talked of to be, at least, begun in good earnest. The Marquis of Wellesley ordered a commission to examine and report on the subject; but he soon after left India, and the commission was scattered by sickness and death. Sir J. R. Martin laboured hard at the work under the Marquis of Hastings, and drew up an elaborate memoir on the Medical Topography of Calcutta more than twenty years ago. Lord Metcalfe, Lord Auckland, and Sir John Grant seconded Sir Ranald's efforts. He also desired to set on foot a complete system of social and sanitary statistics, military and civil. The fault of the present state of Calcutta lies not with the Medical Profession, but with the Government.

a third time. Lord Wodhouse moved an amendment, that the infliction of that punishment should be left to the discretion of the judge. The Lord Chancellor supported the amendment, and quoted the opinion of the judges of the Common Pleas, Exchequer, and Queen's Bench, to the effect that if the punishment were made compulsory, juries would show a greater disinclination to convict than at present. The House divided on the amendment, which was adopted by a majority of 35. The bill was then passed.

In the House of Commons on Friday, April 29, Mr. D. Seymour called attention to the extensive employment of boys in sweeping chimneys, and the systematic violation of the Act for the Regulation of Chimneysweepers and Chimneys. He read from printed reports numerous instances of children of tender age, some only seven years old, including female children, employed to climb chimneys, and described the cruelties practised upon them. The witnesses whose evidence he referred to attributed the non-enforcement of the law to the apathy of the magistrates and their indisposition to convict.

Sir G. Grey said there was reason to believe that there was a very extensive violation of the law, and that the attention of the Government had been directed to the subject.

Mr. Dillwyn called attention to the insufficiency and inconvenience of the temporary Museum for Inventions at South Kensington, and the Patent Library in Southampton-buildings, and to the expediency of uniting the Museum for Inventions and the Patent Library under one building, and at a convenient distance from the law courts.

Mr. Cowper admitted the importance of the subject, which, he said, was under the consideration of the Government, and he explained the arrangements they contemplated, the bringing the Museum in contiguity with the Patent Office and Library being, however, no part of them.

On Monday, May 2, in the House of Commons, Mr. J. B. Smith moved to limit the continuance of the sugar duties to one year. In urging this amendment he entered into the whole question, arguing strongly against the policy of the system of classification, as well as against *ad valorem* duties generally, and in favour of a fixed duty, observing that one rate of duty upon sugar would have the same effect, as regarded the producers, as if there were no duty at all, while consumers, whose interest should be paramount, would have a better article at a cheaper rate. He proposed that the duties should continue in force for one year only, in order to afford an opportunity for reconsidering the question next Session.

The amendment was seconded by Mr. Leatham.

After a long debate, the House divided, and the amendment was negatived by 97 to 14.

The Penal Servitude Acts Amendment Bill was read a third time and passed.

On Tuesday, May 3, in the House of Commons, Mr. W. Ewart moved for the appointment of a Select Committee to inquire into the expediency of maintaining the punishment of death. He repeated the arguments he had urged upon former occasions, citing authorities and statistics, insisting upon the uncertainty of the law, numbers of persons whose guilt was certain escaping capital punishment for murder through the reluctance of juries to convict, the feeling of the times, the modern theories of Medical science as to insanity, and other causes. He noticed certain modifications of the law which had been suggested and the objections to which they were open, and stated the propositions he meant to submit to the committee if his motion should be acceded to—a course he deemed preferable to asking the House to pledge itself by a resolution in favour of abolishing the punishment of death.

The motion was seconded by Mr. Denman, who, confining himself to the crime of murder, said if it could be proved that by capital punishment murders had decreased, he should be ready to vote for its retention; but he had good ground for thinking that the effect of capital punishment was not to diminish, but to increase crime. He showed that the number of acquittals in cases of prosecution for murder was enormously in excess of acquittals in other cases; and upon these chances of escape, he observed, criminals calculated, and were even incited by them to repeat the crime. He mentioned instances within his own knowledge in confirmation of his argument as to the inefficiency of capital punishment, which was further strengthened by showing the effects resulting from its abolition in other countries.

Lord H. Lennox moved as an amendment, "that a Select Committee be appointed to inquire into the operation of the

laws relating to capital punishments." He thought the time had arrived for an inquiry into the whole question—into the justice of inflicting the same punishment, and that the greatest of all punishments, for a crime varying so much in its character as murder, and into the present mode of commuting the penalty.

The amendment was seconded by Mr. Mitford.

Alderman Rose was opposed to the abolition of the punishment of death in cases of premeditated murder, which would be to remove one of the safeguards of society.

Mr. Neate suggested what, in his opinion, should be the subjects of inquiry, which he thought might be better conducted by a commission.

Sir G. Grey observed that since Mr. Ewart last brought forward this question (in 1856) considerable changes had taken place in the administration of the law, and capital punishment had been practically limited to the crime of murder. Under these circumstances Mr. Ewart asked the House to refer the question, whether capital punishment should be maintained or abolished, to a committee, and the Government were of opinion that it was not a fit question to refer to a committee of fifteen gentlemen upstairs, whose report would not be binding upon the House. He retained the opinion he had before expressed, that it would not be expedient or safe to abolish capital punishment altogether for grave cases of murder. He believed, in spite of statistics, that this punishment had a deterring effect, and was much dreaded. He could not, therefore, consent to the original motion; but the amendment of Lord H. Lennox proposed that the inquiry should be into the operation of the laws relating to capital punishments; and Mr. Neate had given notice of another amendment (which he was precluded from moving), that the inquiry should be made by a commission into the provisions and operation of those laws, and to report whether it was desirable to make any alteration therein. He pointed out various points which he thought might very well be made subjects of inquiry, and which he thought should be by a commission, as the result would have more weight. If, therefore, the motion and the amendment were both withdrawn, the Government would be prepared to appoint a commission for the purpose.

Mr. Bright observed that the main question raised by Mr. Ewart's motion was, if an inquiry should be instituted, whether capital punishment should be maintained or abolished, and he thought a Committee of that House could take evidence upon this subject as well as a commission. He was still of opinion that capital punishments were of no avail in deterring from crime. Seeing what had been done by the amelioration of our criminal code, could any man believe that human life was rendered more secure by capital punishment? He read replies to inquiries he had made as to the results of the abolition of the death penalty in some of the States of America, which showed that cases of murder or violence had not increased; that convictions were far more certain, and that the change had been upheld by public opinion. Would a change, he asked, which had proved successful in other countries be less successful here, and render life less secure? He hoped, he said, that the Government would put upon the commission men in whom the House and the country, and those whose opinions were adverse to capital punishments, had confidence, and who would give a fair opinion.

Mr. Newdegate, after replying at some length to Mr. Bright, observed that it was unfortunate, after discovering our secondary punishments to be inadequate, and when we were obliged to retain among us our worst criminals, that we should be raising doubts whether the capital penalty against murder should be retained.

Mr. Gilpin said there was no ground for accusing the opponents of capital punishment of any sympathy with crime; they were actuated by a sincere desire to advocate that punishment most deterrent from crime. He drew the attention of the House to cases which had not been alluded to, of innocent persons who had suffered death, and by man's weak judgment had been condemned to a punishment they did not deserve, but which was irrevocable and irreversible.

Mr. Roebuck remarked that the cases referred to by Mr. Gilpin had no application to the present time, when there was so great a regard for human life.

Sir F. Crossley said he was opposed to capital punishment because it did not agree with the merciful character of Christian dispensation.

Sir J. Walsh thought it better that the proposed inquiry should be by a commission than by a committee. He believed

it was necessary for the protection of life that we should maintain capital punishment, which had a deterrent effect upon the criminal and dangerous classes, and for which it was impossible to devise an adequate substitute.

After some observations by Mr. Hibbert and Mr. Maguire, the amendment and the motion were both withdrawn.

Mr. Neate then moved an address to Her Majesty, praying that she will be pleased to issue a Royal Commission to inquire into the provisions and operation of the laws under which the punishment of death is now inflicted in the United Kingdom, and the manner in which it is inflicted, and to report whether it is desirable to make any alteration therein.

The motion was agreed to.

We believe that the determination to appoint a Royal Commission to consider the whole question of capital punishment will be received by all classes of thinkers, and especially by the Medical Profession, with entire satisfaction. Without expressing any opinion as to the propriety of capital punishment in cases of wilful murder, we hold that it will be a public deliverance if an end be put to the present state of things—the unsatisfactory acquittals, and the still more unsatisfactory commutations of sentence, which are a scandal to English justice, and a premium to crime.

On Wednesday, May 4, in the House of Commons, on the order for going into Committee upon the Weights and Measures (Metric System) Bill,

Mr. Humberston was opposed to the further progress of the Bill, which was repugnant, he said, to the common sense of the people of this country, who were not prepared to give up their ancient system.

Mr. Adderley observed that the principle of the measure had been already discussed, and had been affirmed by the House.

After a few words from Mr. Griffith, the House went into Committee upon the Bill; but many questions having arisen in the discussion of the details, upon Mr. M. Gibson undertaking, on the part of the Government, to introduce certain clauses, to be embodied in the Bill, Mr. W. Ewart, who had charge of it, consented to put off the Committee, and the Chairman was ordered to report progress.

QUARTERLY JOURNALS.

THE *Quarterly Journal of Science* has a good article "On Milk and Dairy Arrangements," by Dr. Voelcker, in the course of which are some very practical remarks upon the subject of adulteration. He says that his own experience leads him to conclude "that a specimen of milk is rich when it contains 12 per cent. of solid matter and about 3 per cent. of pure fat; anything above this is of extra rich quality. Good average milk contains 10 to 11 per cent. of dry matter and about 2½ per cent. of pure fat. It yields 9 to 10 per cent. of cream. Poor milk, whether naturally or artificially diluted, contains 90 per cent. of water and less than 2 per cent. of pure fat, and yields only 4 to 8 per cent. of cream." Speaking of the *lactometer*, he says "it was never intended to indicate the relative richness of good samples of milk, but to point out whether samples of a fair or doubtful appearance had been watered or were of a naturally defective composition; and this purpose it satisfactorily fulfils." From his investigations it appears—"1. That good new milk has a specific gravity of about 1030. 2. That skim milk is a little more dense, being about 1034. 3. That milk which has a specific gravity of 1025 or less is mixed with water or naturally very poor. 4. That when milk is deprived of about 10 per cent. of cream and the original volume is made up by 10 per cent. of water the specific gravity of such skimmed and watered milk is about the same as that of good new milk. This circumstance, however, does not constitute any serious objection to the hydrometer, as milk skimmed to that extent cannot be mixed with water without becoming so blue and transparent that no instrument would be required to detect the adulteration. 5. That when unskimmed milk is mixed with only 20 per cent. of water the admixture is indicated at once by the specific gravity of about 1025. 6. That for these reasons the hydrometer or lactometer is well adapted for detecting the

admixture of water or to show an unusually poor quality of the unadulterated milk."

In the *Quarterly Journal of Microscopical Science* for April Dr. Beale promulgates some "new views with regard to exudations." Differing from those pathologists who believe that a clear transparent plasma may give rise to the formation of living cells, as well as from those who dogmatically lay it down that every cell comes from a pre-existing cell, Dr. Beale holds that there are living bodies which are not cells, and yet which grow and multiply, and that many of the clear fluids which are considered as "*exudations*" from the blood really contain a multitude of extremely minute particles of living matter, which are intimately related to the white blood corpuscles, and that these grow and become one source of the small granular cells or corpuscles which are so familiar to all who have studied morbid changes in the tissues. Some of these may be so small as to be invisible by a power magnifying 5000 diameters. Such living or germinal matter, he holds, may retain its vitality even when detached from the body, germinating again when placed under favourable conditions. In this way he explains the propagation of purulent ophthalmia, and suggests that small masses of germinal matter are really the agents which are directly concerned in the introduction and distribution of the so-called animal poisons. He adduces the analogy of living vegetable organisms which are only just visible by a power of 5000 linear. "Pus corpuscles and ordinary lymph corpuscles are too large to be carried through the air, but minute particles may be detached from any of these bodies not larger than the germs of fungi which we know to exist in the atmosphere, and are thus transferred from one place to another. No doubt the great majority of such minute particles of living matter in a peculiarly active state of vitality would die long before they reached a new locality favourable to their propagation, but a few might escape, and meeting with a favourable surface would germinate. Warmth, moist air, little change in the atmosphere, are conditions under which the life of such minute particles of living matter would probably be preserved, and which are the conditions favourable to the propagation and spread of many of those contagious diseases which have long been attributed to the transference of matter which acts like ferments."

FROM ABROAD—THE PNEUMONOSCOPE—UNSUSPECTED TRICHINIASIS.

A NEW *scope* is among the latest inventions which have appeared at Paris, under the designation of a "Pneumonoscope." It is a mannikin, having for its object to teach the mysteries of auscultation, independently of the uncertainties and inconveniences of clinical observation, the various sounds in all their grades being producible by this apparatus at will. Twelve openings are practised in a bust, ten at its anterior and two at its posterior surfaces, each ticketed with the name of the sound to be heard. At the base a number of caoutchouc tubes pass out, and to the extremity of these a hand-bellows is attached. By alternate compression and relaxation of the bellows we are enabled to produce, according to the tube employed, on listening at the corresponding aperture, every variety of respiratory sound, whether normal, feeble, exaggerated, cavernous, amphoric, metallic, etc. For the production of the various *râles* it is necessary to affix to the bellows prepared mouth-pieces, moistened by saliva or albuminous water, when we get every variety of *râle*, whether crepitating, cavernous, soufflant, or what not. Fluctuation or friction movements within the thorax are imitated also by means of other simple adjuncts. At first sight this might seem but an ingenious toy or scientific curiosity; but it is said that Practitioners so well versed in auscultation as MM. Bouillaud, Barth, Trousseau, Blache, and Bécларd have testified in favour of its practical utility as a means of instruction.

Enlightened by the recent revelations on trichina-disease, it becomes instructive to look back to instances of reputed wholesale poisoning, which at the time of their occurrence were

inexplicable. Dr. E. Wagner, of Leipzig, whose communication on a trichina epidemic in that city we noticed recently, refers to the narration of such an event contained in Wald's translation of Taylor's "Medical Jurisprudence," which occurred near Oschatz, near Leipzig, in 1848. A considerable number of guests attended a festivity consisting of a dinner and supper, and it was found that twenty-eight of the number who had partaken of both meals became seriously ill, while those of them who had left before supper-time remained perfectly well. Among the dishes served up at the supper were raw and cooked ham and Russian salad, this last containing among other things raw ham and brain sausage. The twenty-eight patients resided at various places, and were attended by eleven Medical men, some of whom believed the symptoms due to poisoning by copper, or arsenic, but most considered them as the result of indigestion. Two deaths occurred, and nothing explanatory was elicited by the autopsies; and the legal investigation led to no result. The details of this occurrence, related by Dr. Ströfer in the *Deutsch Zeitsch für Staatsarz*, 1850, p. 71, exhibit several circumstances which are now recognised as characteristic of trichiniasis. We believe that several obscure cases of supposed poisoning occurring in our own country would admit of a similar explanation.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, MONDAY, APRIL 25, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the chair.

Present—

- | | | |
|---------------------|------------------|-----------------|
| Dr. Alderson. | Dr. Andrew Wood. | Dr. Corrigan. |
| Mr. Arnott. | Dr. Fleming. | Dr. Sharpey. |
| Mr. Cooper. | Mr. Syme. | Dr. Parkes. |
| Dr. Acland. | Dr. Thomson. | Dr. Quain. |
| Dr. Paget. | Dr. A. Smith. | Mr. Rumsey. |
| Dr. Embleton. | Mr. Hargrave. | Dr. Christison. |
| Dr. Storrar. | Dr. Leet. | Dr. Stokes. |
| Dr. Alexander Wood. | Dr. Apjohn. | |

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

The following Committees were appointed:—

Business Committee.

- | | |
|----------------------------|---------------|
| Dr. Andrew Wood, Chairman. | Dr. Corrigan. |
| Dr. Embleton. | Mr. Rumsey. |

Finance Committee.

- | | |
|------------------------|--------------------|
| Dr. Sharpey, Chairman. | Dr. Aquilla Smith. |
| Mr. Arnott. | Dr. Quain. |
| Dr. Fleming. | |

Committee on Returns received from the Bodies in Schedule (A).

- | | |
|-------------------------|-------------|
| Dr. Embleton, Chairman. | Dr. Leet. |
| Mr. Cooper. | Dr. Apjohn. |
| Dr. Thomson. | Dr. Stokes. |

1. Moved by Dr. ANDREW WOOD, seconded by Dr. ALEXANDER WOOD—"That reporters be admitted to the meetings of the General Medical Council."

(*First Amendment.*)

Moved by Dr. ACLAND, seconded by Dr. CHRISTISON—"That a Committee be appointed to consider, and to report to the present meeting, the advantages and the disadvantages to the business of the Council which may arise from the admission of reporters; and to suggest the various ways in which (should the Council resolve to introduce them) they might be admitted to the Council, Branch Councils, or Committees."

(*Second Amendment.*)

Moved by Dr. THOMSON, seconded by Mr. COOPER—"That the Council deem it expedient and desirable that their proceedings should be published, and that a Committee be forthwith appointed to consider and report upon the best means of accomplishing this object."

The Second Amendment was put to the vote, and the numbers were found to be equal for and against it.

The PRESIDENT then gave his casting vote in favour of the amendment. Dr. ANDREW WOOD required that the names for and against the amendment should be taken down.

For the Amendment.

- The President.
- Mr. Arnott.
- Mr. Cooper.
- Dr. Acland.
- Dr. Paget.
- Dr. Storrar.
- Dr. Thomson.
- Dr. Sharpey.
- Dr. Quain.
- Mr. Rumsey.
- Dr. Christison.
- Dr. Stokes.

Against the Amendment.

- Dr. Alderson.
- Dr. Embleton.
- Dr. Alexander Wood.
- Dr. Andrew Wood.
- Dr. Fleming.
- Mr. Syme.
- Dr. Smith.
- Mr. Hargrave.
- Dr. Leet.
- Dr. Apjohn.
- Dr. Corrigan.
- Dr. Parkes.

The following Members of Council were appointed a Committee to con-

sider and report as to the best mode of publishing the proceedings of the Council:—

- | | |
|------------------------|---------------|
| Dr. Thomson, Chairman. | Dr. Apjohn. |
| Mr. Cooper. | Dr. Corrigan. |
| Dr. Storrar. | Mr. Rumsey. |
| Dr. Alexander Wood. | Dr. Stokes. |

Moved by Dr. ALEXANDER WOOD, seconded by Dr. STOKES—"That the Committee appointed to consider the best means of publishing the proceedings of the Council be requested to report to-morrow, and that the consideration of that report take precedence of all other business."—Agreed to.

2. Moved by Dr. QUAIN, seconded by Dr. ANDREW WOOD—"That a Committee be appointed to revise the standing orders."—Agreed to.

The Committee to consist of—

- | | |
|---------------------------|---------------|
| Dr. Christison, Chairman. | Dr. Corrigan. |
| Dr. Storrar. | Dr. Quain. |
| Dr. Alexander Wood. | |

Confirmed—GEORGE BURROWS, *President*.

MINUTES OF MEETING, TUESDAY, APRIL 26, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the chair.

Present—As before.

The Minutes of the last meeting were read and confirmed.

1. Dr. THOMSON presented the following Report from the Committee appointed to consider the best means of publishing the proceedings of the Council.

Report.

The Committee on publication of the Proceedings of the Council, met this day, and having considered the matter remitted to them by the Council, agreed by a majority to adopt the following resolutions, and directed the chairman to lay these resolutions before the Council as the report of the committee.

1. That reporters be admitted to the meetings of the Council.
2. That a special reporter be engaged by the Council to prepare a report of the proceedings.
3. That the Council reserve the power of withholding the privilege of admission to reporters, whenever the Council may think fit.

ALLEN THOMSON, *Chairman*.

Moved by Dr. THOMSON, seconded by Mr. HARGRAVE—"That the report be received."—Agreed to.

Moved by Dr. THOMSON, and seconded by Dr. STOKES—"That the report be adopted."

Amendment moved by Mr. SYME, and seconded by Dr. ANDREW WOOD—"That the Council proceed to consider the resolutions contained in the Report separately."—The amendment was carried.

Moved by Mr. SYME, seconded by Dr. ANDREW WOOD—"That the first resolution of the Report be adopted."

Amendment moved by Dr. ALDERSON, seconded by Dr. QUAIN—"That the second resolution of the report be first considered."

The amendment was negatived.

The motion was then put to the vote, and carried.

Moved by Dr. A. SMITH, seconded by Mr. ARNOTT—"That the second resolution of the Report be adopted."—Agreed to.

Moved by Dr. A. SMITH, seconded by Mr. ARNOTT—"That the third resolution of the Report be adopted."—Agreed to.

Moved by Dr. PARKES, seconded by Dr. FLEMING—"That the Business Committee, with the President and the Registrar, be appointed to carry into effect the foregoing resolutions."

2. Dr. CHRISTISON presented the following Report of the Committee appointed to revise the Standing Orders:—

Report.

The Standing Orders Committee appointed on the 25th instant to revise the Standing Orders of the Council, report that they have for the present confined their attention to Articles 7, 8, 9, and 10 of Section III., "Order of Business." They recommend that these articles be repealed, and that the following be substituted:—

1. That the seconder of a motion may, if he pleases, reserve his speech.
2. That, if an amendment be proposed on a motion, the amendment shall be disposed of before any other amendment shall be moved.
3. That such amendment shall first be put to the vote; that if it be negatived, a second amendment may be moved, and shall be disposed of in the same way as the first amendment; and so on until no further amendment shall be proposed.
4. That, should every amendment be negatived, the original motion shall then be put to the vote.
5. That, if any amendment be carried, it shall then be put as a substantive motion, and treated, as to further amendments, and the right of speaking on it, in all respects as an original motion.

Moved by Dr. CHRISTISON, seconded by Dr. STORRAR—"That the Report be received."—Agreed to.

Moved by Dr. ALEXANDER WOOD, seconded by Dr. PARKES—"That the resolutions of the Report of the Committee on Standing Orders be considered *seriatim*."—Agreed to.

Moved by Dr. ALEXANDER WOOD, seconded by Mr. ARNOTT—"That the first resolution of the Report of the Committee on Standing Orders be adopted."—Agreed to.

Moved by Mr. ARNOTT, seconded by Dr. STORRAR—"That the second resolution of the Report be adopted."

Amendment moved by Dr. ALEXANDER WOOD, seconded by Mr. SYME—"That the present standing orders, in regard to the number of amendments that may be moved on any motion, be not altered."

The amendment was negatived.

The motion was then put to the vote and carried.

Moved by Dr. STORRAR, seconded by Mr. ARNOTT—"That the third resolution be adopted."—Agreed to.

Moved by Dr. STORRAR, seconded by Mr. HARGRAVE—"That the fourth resolution be adopted."—Agreed to.

Moved by Mr. HARGRAVE, seconded by Mr. ARNOTT—"That the fifth resolution be adopted."—Agreed to.

3. Moved by Mr. ARNOTT, seconded by Dr. PAGET—"That the number of members of the Executive Committee be confined to four, exclusive of the President."—Agreed to.

Moved by Mr. ARNOTT, seconded by Mr. SYME—"That the members of

the Executive Committee shall be elected by ballot, by means of marked lists."—Agreed to.

4. Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON—"That the claims of Messrs. Spottiswoode, referred to the General Council by the Executive Committee, be now referred to the Finance Committee, to be reported on by them."—Agreed to.

Confirmed—GEORGE BURROWS, President.

MINUTES OF MEETING, WEDNESDAY, APRIL 27, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the chair.

Present—As before.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. QUAIN, seconded by Mr. HARGRAVE—"That a Committee be appointed to consider and report on the arrangements to be made for producing the next edition of the British Pharmacopœia."—Agreed to.

The Committee to consist of—

Dr. Christison, Chairman.	Dr. Apjohn.
Dr. Acland.	Dr. Quain.
Dr. Alderson.	Dr. A. Smith.

2. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the Council do now resolve itself into a Committee on Education."—Agreed to.

3. Moved by Dr. STORRAR, seconded by Dr. ALEXANDER WOOD—"That the President be requested to take the chair and preside over the Committee."—Agreed to.

1. Moved by Dr. STORRAR, seconded by Mr. HARGRAVE—"That the Committee proceed to consider, one by one, the recommendations of the Council relating to general and professional education and examination."

Amendment moved by Mr. SYME, seconded by Dr. ANDREW WOOD—"That the Committee do now proceed to consider the whole subject of Medical education and examination, with the view of preparing a report for the guidance of licensing bodies."

The Amendment was negatived.

The Motion was then put to the vote, and carried.

2. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the first Recommendation, viz., 'That all students pass an examination in general education before they commence their Professional studies,' be adopted."

Amendment moved by Dr. ACLAND, seconded by Dr. PAGET—"That the first resolution stand as follows:—'That all students pass an examination on subjects to be included under the head of general education prior to the date from which the commencement of their Professional studies is to be reckoned.'"

The Amendment was negatived.

The Motion was then put to the vote, and carried.

3. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the second recommendation be adopted, viz., 'That the time of commencing Professional studies shall be understood to be the time of commencing studies at a Medical school; and that no qualifying body be held to have complied with the recommendation of the Council which shall allow the examination in general education to be passed after the commencement of Professional study.'"

Amendment moved by Mr. ARNOTT, seconded by Dr. A. SMITH—"That 'the time of commencing Professional studies shall be understood to be the time of commencing studies at a Medical school,' be transferred to the Recommendations on Professional education."

The Amendment was carried.

Amendment moved by Mr. ARNOTT, seconded by Dr. ACLAND—"That the concluding paragraph of the second recommendation, viz., 'That no qualifying body be held to have complied with the recommendation of the Council which shall allow the examination in general education to be passed after the commencement of Professional study,' be omitted."

The Amendment was carried.

Moved by Dr. PARKES, seconded by Mr. HARGRAVE—"That testimonials of proficiency granted by the national educational bodies, according to the subjoined list, may be accepted, the Council reserving the right to add to, or take from, the list."

1. A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council.
2. Oxford Responsions or Moderations.
3. Cambridge Previous Examinations.
4. Matriculation Examination of the University of London.
5. Oxford Middle Class Examinations (Senior).
6. Cambridge Middle Class Examinations (Senior).
7. Durham Middle Class Examinations (Senior).
8. Durham Examinations for Students in Arts, in their second and first years.
9. Durham Registration Examination for Medical Students.
10. Dublin University Entrance Examination.
11. Queen's University, Ireland, Two Years' Arts Course for the Diploma of Licentiate in Arts.
12. Preliminary Examinations at the end of A.B. Course.
13. Middle Class Examinations.
14. Matriculation Examinations.
15. First Class Certificate of the College of Preceptors.
16. "Testamur" granted by Codrington College, Barbadoes.
17. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a Certificate that the Student has been examined in Latin and Mathematics.

Amendment moved by Dr. CORRIGAN, seconded by Mr. RUMSEY—"That Testimonials of Proficiency granted by the National Educational Bodies according to the List contained in the Third Recommendation, be accepted, provided that the Examinations conducted by those Bodies comprise at least the following subjects:—English, Greek, Latin, Mathematics, Arithmetic to the end of Decimal Fractions, One Modern Language."

The amendment was negatived.

Amendment moved by Dr. ALEXANDER WOOD, seconded by Dr. ANDREW WOOD—"That a Minimum Standard of Preliminary Education and Examination shall be fixed by the Council; that Testimonials of Proficiency granted by the National Educational Bodies may be admitted, provided the Council deem the Education required by them to be sufficient; and that a Sub-Committee be appointed to prepare a Minimum Standard to be submitted to the Council for its consideration."

At six o'clock the Meeting of the General Committee was adjourned.

Confirmed—GEORGE BURROWS, President.

MINUTES OF MEETING, THURSDAY, APRIL 28, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Present—As before.

Dr. BURROWS, *President*, in the Chair.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. STORRAR, seconded by Mr. HARGRAVE—"That the Council do now resolve itself into a Committee on Education."—Agreed to.

2. Moved by Dr. ALEXANDER WOOD, seconded by Dr. STORRAR—"That the President be requested to take the chair, and preside over the Committee."—Agreed to.

1. The Committee resumed the consideration of the amendment moved, at the last meeting, by Dr. ALEXANDER WOOD, seconded by Dr. ANDREW WOOD, viz.—"That a minimum standard of preliminary examination shall be fixed by the Council; that testimonials of proficiency granted by the National Educational Bodies may be admitted, provided the Council deem the education required by them to be sufficient; and that a sub-Committee be appointed to prepare a minimum standard to be submitted to the Council for its consideration."

The amendment was negatived.

The original motion, moved, at the last meeting, by Dr. PARKES, seconded by Mr. HARGRAVE, was then put to the vote, viz.—"That testimonials of proficiency granted by the National Educational Bodies according to the subjoined list may be accepted, the Council reserving the right to add to, or take from, the list."—Carried.

1. A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council.
2. Oxford Responsions or Moderations.
3. Cambridge Previous Examinations.
4. Matriculation Examination of the University of London.
5. Oxford Middle Class Examinations (Senior).
6. Cambridge Middle Class Examinations (Senior).
7. Durham Middle Class Examinations (Senior).
8. Durham Examinations for Students in Arts, in their second and first years.
9. Durham Registration Examination for Medical Students.
10. Dublin University Entrance Examination.
11. Queen's University, Ireland, Two Years' Arts Course for the Diploma of Licentiate in Arts.
12. Preliminary Examinations at the end of A.B. Course.
13. Middle Class Examinations.
14. Matriculation Examinations.
15. First Class Certificate of the College of Preceptors.
16. "Testamur" granted by Codrington College, Barbadoes.
17. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a Certificate that the Student has been examined in Latin and Mathematics.

2. Moved by Dr. STORRAR, seconded by Mr. ARNOTT—"That the fourth recommendation of the Council be adopted, viz., 'That the Examination in General Education be eventually left entirely to the Examining Boards of the National Educational Bodies recognised by the Medical Council.'"

Amendment moved by Dr. STOKES, seconded by Mr. SYME—"That with the view of saving time, a sub-Committee be appointed, for the purpose of preparing a report on the subject of Medical Education, which may form a definite basis for the discussions of the question in the General Council."

The Amendment was negatived.

The Motion was then put to the vote, and carried.

3. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the fifth recommendation of the Council be adopted, viz., 'That no Certificate of Proficiency in General Education, which does not affirm the proficiency of the Candidate in Latin, be deemed a sufficient proof of Preliminary Education previous to the commencement of Professional Studies.'"

Amendment moved by Dr. CORRIGAN, seconded by Dr. APJOHN—"That no Certificate of Proficiency in General Education, which does not affirm an acquaintance with Greek and Latin, be deemed a sufficient proof of Preliminary Education previous to the commencement of Professional Studies."

The Amendment was negatived.

The Motion was then put to the vote, and carried.

4. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the sixth recommendation be adopted, viz., 'That Students who cannot produce any of the Testimonials referred to in the Third Resolution, be required to pass an Examination in Arts, established by any of the Bodies named in Schedule (A) of the Medical Act, and approved by the General Council, provided that such an Examination be in every case conducted by a Special Board of Examiners in Arts.'"

Amendment moved by Dr. CORRIGAN, seconded by Mr. HARGRAVE—"That the words after 'General Council' in the fifth line of the sixth recommendation be omitted; and that the recommendation be adopted as thus amended."

The amendment was carried.

5. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the seventh recommendation be adopted—viz., 'That, without professing to lay down any complete scheme of general education for persons intending to become members of the Medical Profession, the Committee recommend that the scheme of examination in arts of the licensing bodies be, as nearly as practicable, similar to that of any of the national educational bodies above specified.'"

The motion was put to the vote, and negatived.

6. Moved by Dr. STORRAR, seconded by Dr. EMBLETON—"That the eighth recommendation be adopted as follows:—'That all Medical students be required to be registered.'"—Agreed to.

7. Moved by Dr. STORRAR, seconded by Dr. A. SMITH—"That the ninth recommendation be adopted—viz., 'That the lists of students registered be closed within fifteen days after the commencement of each session or term.'"—Agreed to.

8. Moved by Dr. STORRAR, seconded by Dr. A. SMITH—"That the tenth recommendation be adopted—viz., 'That no student beginning Professional study after September, 1861, be registered who has not passed an arts examination in conformity with Resolutions 3 or 6.'"

Amendment, moved by Dr. ALEXANDER WOOD, seconded by Dr. ACLAND—"That a Sub-Committee be appointed to consider the best scheme of registering Medical students."

The amendment was carried, and the following Committee appointed:—

Dr. Alexander Wood, Chairman.	Dr. Fleming.
Mr. Arnott.	Dr. Apjohn.
Dr. Embleton.	Dr. Stokes.

Confirmed—GEORGE BURROWS, President.

MINUTES OF MEETING, FRIDAY, APRIL 29, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the chair.

Present—As before.

The Minutes of the last meeting were read and confirmed.

1. Read the following letter and correspondence:—

“Catholic University of Ireland, 86, Stephen’s-green, Dublin, April 18, 1864.

“Sir,—I have the honour to enclose, for the information of the General Medical Council, a copy of a correspondence between our institution and the Registrar of the Branch Council, Ireland.

“By this it will be seen that we have been recommended by the Branch Council to make application to the General Medical Council in order to obtain recognition of our entrance examination.

“I have also done myself the honour to forward two copies of our calendar for the present year, by which it will be seen that our University gives as complete an education as institutions which are recognised by your Council (pp. 48 to 52).

“May I beg that you will do us the favour to submit to the Council our application to have our entrance examination recognised by them, and may I hope that the Council will favourably entertain our request?

“I am, Sir, your obedient servant,
(Signed) THOMAS SCRATTON, Sec. Cath. Univ.

“Dr. Hawkins, Registrar, 32, Soho-square, London, W.”

Copy.

“Branch Medical Council, Ireland, 35, Dawson-street, Dublin, March 9, 1864.

“Sir,—I am directed by this Branch Council to request that you will have the goodness to inform me whether any students are pursuing their Professional studies in your Medical school who had not previously passed an examination in general education recognised by the General Medical Council; and if so, that you will be so good as to state their number.

“I am, Sir, your obedient servant,
(Signed) WM. EDW. STEELE, M.D., Registrar.

“Secretary, Catholic University, Stephen’s-green South.”

Copy.

“86, Stephen’s-green, S., March 18th, 1864.

“Sir,—In reply to your letter of the 9th inst., I beg to say that I have learned from the Honorary Secretary of our Medical Faculty that the information you ask has already been supplied through the Registrar of the Royal College of Surgeons of Ireland.

“However, in order to guard against some mistakes into which your Council may be led by these formal returns, I am directed further to state, that several of our Medical students have attained considerable proficiency in general education, although we have no official mode of knowing whether they have passed an examination recognised by your Central Council. The authorities of this University are most anxious to advance the general education of our Medical students, and will be happy to carry out, as far as possible, the wishes of the General Medical Council, and the regulations it may make for that purpose. By offering Exhibitions and other advantages, the Rector and University Council have endeavoured to induce the students in Medicine to matriculate in Arts also, and to attend lectures in philosophy and letters, and in Science.

“A large number are now availing themselves of these advantages, and have passed our Entrance Examination; and of that number eleven have passed the Scholarship (as it is called in this University), or *Responsions*, at the end of their second year of general studies, while two have passed the B.A. Examination, and several are preparing to pass that Examination in the course of this year.

“As it appears from the recent Census returns, that in 1861, of 954 Medical students in Ireland, 329, or more than one-third, were Catholics, over whom, without doubt, the Catholic prelates at the head of this institution have considerable influence, the Rector and Council of this University think they may safely say, that a much larger number would enter for general education could we offer them the inducement of a Degree in Arts or Science recognised by law.

“In conclusion, I am directed to send, for the information of your Branch Council, and of the General Medical Council, two copies of our University Calendar for this year, inviting your attention to our Regulations regarding Matriculation and Degrees (pp. 48 to 52). You will there see that even for entrance into this University we require a knowledge of one Greek and one Latin book from the following list; and also of Arithmetic, Algebra (as far as simple Equations inclusively), Euclid, etc.

“ENTRANCE OR MATRICULATION EXAMINATION.

“Each candidate for entrance must be recommended by the person who last had the care of his education, and by his Bishop, or by one of the clergymen of his parish. He presents himself, in the first place, to the Dean of the House which he wishes to join, or to the Vice-Rector, if he wishes to be an Extern.

“Candidates for Entrance will be examined:—

1. In the Christian Doctrine.
2. In any one Greek and any one Latin Book, of their own selection, from the following Entrance Lists:—

GREEK.

Herodotus, Book i.
Xenophon’s Anabasis.
Plato, Apologia Socratis.
Lucian, Walker’s Selections.
Homer’s Iliad, Books i. ii. iii.
Sophocles, any play.
Euripides, any play.

LATIN.

Virgil, Georgics, any two books.
“ Aeneid, any four books.
“ Bucolics, with one book of Georgics, or two of Aeneid.
Horace, Odes, any three books.
“ Satires or Epistles.
Cicero, Select Orations, viz., in Catilinam, i.—iv., pro Milone, pro Lege Manilia, and pro Archia.
Livy, Books i., ii., iii., or iv., v.

“3. They will further be examined in—

Arithmetic. The Elements of Ancient and Modern
Algebra, as far as Simple Equations, History,
inclusively. The Elements of Modern Geo-
graphy.
Euclid, Books i. ii. Latin Prose Composition.
English Composition.
The Rudiments of French

“The Degree Examination which we prescribe is as high as that required by other Universities.

“We respectfully submit that even the former of these Examinations indicates a state of education fully equal to that recognised by you, and we therefore respectfully request the General Medical Council to recognise the examinations presented by this University.

“I am, Sir, your obedient servant,

“(Signed) THOMAS SCRATTON, Sec. Cath. Univ.

“Wm. Edw. Steele, Esq., Registrar, 35, Dawson-street.”

Copy.

“Branch Medical Council, Ireland, 35, Dawson-street, Dublin, March 21, 1864.

“Sir,—I beg to acknowledge the receipt of your letter of the 18th inst., together with two copies of the Calendar of your University, for which latter permit me to offer my thanks.

“Referring to the latter part of your letter, in which you apply for the recognition by the Council of the entrance examination of the University, I take the liberty of suggesting your applying to the General Medical Council, 32, Soho-square, London, W., the registrar of which is Dr. Hawkins, on the subject, it being very unlikely that the Branch Council will meet previously to the assembling of the former in London.

“I am, Sir, your obedient servant,

“(Signed) WM. EDW. STEELE, M.D., Registrar.

“Thomas Scratton, Esq., Secretary, Catholic University, Stephen’s-green.”

Moved by Dr. CHRISTISON, seconded by Dr. STORRAR:—“That the following answer be returned by the registrar, to the communication now before the Council:—

“Sir,—I have laid before the General Medical Council your letter of the 18th inst, requesting that the entrance examination of ‘The Catholic University of Ireland’ should be recognised among the examinations in preliminary education received from the various chartered or incorporated educational bodies; and in reply I am directed to request you will have the kindness to transmit to the General Medical Council a copy of the Charter or Act of Incorporation of ‘the Catholic University.’—Agreed to.

2. Dr. CHRISTISON presented the following Report of the Committee appointed on April 28, 1864, relative to the Pharmacopœia:—

Report.

The Committee report—

1. That it is desirable to make further arrangements during the present session of Council for preparing the next edition of the British Pharmacopœia.

2. That a Committee of the Council be appointed to superintend the preparing for the press, and the editing of the work, and to submit the same to the Council for approval in proof.

3. That the gentlemen already nominated in London, Edinburgh, and Dublin, for the purpose of reporting from time to time on the improvements in Pharmacy, be requested to continue their services, and that their reports be communicated to the Pharmacopœia Committee of the Council.

4. That an editor or editors shall be appointed by the Pharmacopœia Committee, who shall prepare the work, in all its details, under their control.

Moved by Dr. STORRAR, seconded by Dr. CHRISTISON:—“That the Report of the Committee relative to the Pharmacopœia be received and entered on the minutes.”—Agreed to.

3. Moved by Dr. ANDREW WOOD, seconded by Mr. HARGRAVE:—“That the Council resolve itself into a Committee, and that the President be requested to take the chair.”—Agreed to.

1. Dr. ALEXANDER WOOD presented the following report from the Sub-Committee on the best scheme of Registering Medical Students:—

REPORT OF THE SUB-COMMITTEE ON REGISTRATION OF MEDICAL STUDENTS.
Your Sub-Committee is of opinion that the registration of Medical Students, if properly conducted, is a matter of primary importance, as giving security to the Council and the Profession.

1. That every student has passed an examination in arts before commencing his Professional studies.

2. That the exact date at which a student has commenced his Professional studies has been ascertained and registered, so as to show how far the recommendations of the Council in these respects have been complied with.

The chief difficulties which past experience has shown to exist appear to your Committee to be—

1. The want of a sufficient distinction between students commencing their studies and those who may be commencing their second, third, or fourth sessions.

2. The fact that many students enter at several different schools at the same time.

Having regard to these difficulties, your Sub-Committee begs to recommend the following regulations, as at once simple and practical:—

1. That the registration be placed under the charge of the branch registrars.

2. That each student be only once registered, and that when he first enrolls himself as a Medical student.

3. That the registrar of each School of Medicine, or other authorised person, keep a list of all students entering for the first time at that school, agreeably to the subjoined form.

4. That the register at each school be closed within fifteen days after the commencement of each session or term.

5. That these lists, as soon as possible thereafter, be transmitted, along with the certificates of each student having passed an arts examination, to the branch registrar of that division of the kingdom where the school is situated, and that he from them frame an accurate register of Medical students of that division of the kingdom where he has charge.

6. That the register of Medical students so prepared by the registrars, after examination by the several Branch Councils, be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, print the same in alphabetical order, and supply a copy of this authorised list to each of the bodies in Schedule (A) to the Medical Act.

7. That the several licensing bodies be requested, after October, 1868, to abstain from examining any candidate for license or degree whose name does not appear on the authorised list of Medical students.

8. That the Branch Councils be desired to take means to make these regulations known to the Medical Students at the various Medical Schools.

ALEXANDER WOOD, *Chairman*.

Form of Register of Medical Students.

Name.	Age last Birthday.	Prelim. Examin. and Date.	Date of Registration.	Place of Study.

Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON—"That the report of the Sub-Committee on registration of Medical students be received and entered on the Minutes."—Agreed to.

Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON—"That the consideration of the report on the registration of Medical students be deferred till after the discussion of the question of Professional education."—Agreed to.

2. Moved by Dr. STORRAR, seconded by Dr. PAGET—"That the seventeenth recommendation of the Council be adopted, viz., 'That the age of twenty-one be the earliest age at which any Professional licence shall be obtained.'"

Amendment moved by Mr. SYME, seconded by Dr. ANDREW WOOD—"That the Committee proceed to consider the subjects and course of study requisite for a Medical Professional education."

The Amendment was carried.

3. Moved by Mr. SYME, seconded by Dr. ANDREW WOOD—"That the Council proceed to frame a course of study for Medical education, which may be recommended to the licensing bodies."

The debate on this subject not being concluded at six o'clock, it was moved by Dr. THOMSON, seconded by Dr. PARKES—"That the Committee do now adjourn."—Agreed to.

Confirmed—GEORGE BURROWS, *President*.

MINUTES OF MEETING, SATURDAY, APRIL 30, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the chair.

Present—As before.

The Minutes of the last Meeting were read and confirmed.

Moved by Dr. THOMSON, seconded by Dr. PARKES—"That the Council resolve itself into a Committee on Education, and that the President be requested to take the chair."—Agreed to.

The debate was resumed on the motion, which was moved at the last meeting by Mr. SYME, and seconded by Dr. ANDREW WOOD—viz., "That the Council proceed to frame a course of study for Medical education which may be recommended to the licensing bodies."

Amendment moved by Dr. THOMSON, seconded by Dr. SHARPEY—"That, instead of proceeding to frame a course of study for Medical education, etc., the Council adopt the following resolution:—

"That, viewing with general approval the conditions required by the different bodies enumerated in Schedule (A) of the Medical Act of candidates for a qualification, the Council do not think it expedient, for the present, to proceed to frame a complete or formal scheme of Professional education and examination. But, in order to indicate the general nature of their views upon this subject, they resolve to communicate the following recommendations for the guidance of the various licensing boards:—

"1. That twenty-one years be the earliest age at which a Professional licence can be obtained.

"2. That no licence be obtained at an earlier period than four years after the registration of the candidate as a Medical student.

"3. That the course of study required for a licence shall comprehend not less than four winter sessions, or three winter and two summer sessions at a recognised Medical School; and that evidence shall be produced that the remaining period of the four years has been passed in the acquisition of Professional knowledge.

"4. That the Professional examination be divided into at least two parts; that the first of these, embracing the preparatory branches of study, be not undergone before the conclusion of the second sessional year of nine months; and that the final examination be not undergone till the completion of the whole prescribed course of study, nor at an earlier period than three years and nine months after the commencement of Professional study.

"5. That the Professional examinations be conducted partly in writing and partly *viva voce*; and in all parts which admit of it, also practically and by demonstrations.

"6. That the Council recommend to the several Licensing Bodies that the courses of instruction required by them severally should be framed in such a manner as to secure a due share of attention, both to the preparatory and to the final, or more strictly practical, branches, and by class examinations, and all other means which may be deemed proper, to promote, as far as possible, the self-culture and useful practical education of those who seek to obtain a licence. The Council would accordingly suggest to these bodies that it is desirable to avoid enforcing attendance upon a large number of courses of instruction during the same term of study, and to arrange the subjects of examination in such a manner as will guide the student in the most approved order of study.

"7. That the regulation of the extent and duration of courses of lectures and instruction be left to the authorities of the several Medical schools; and that in the case of branches of scientific study, not purely Professional, which are included in the curriculum, the scope and extent of attainment required of the candidates be indicated by means of a published conspectus of the subjects of examination to be issued by the several Examining Boards.

"8. That with a view to secure fairness and efficiency in examinations, the Council resolve to institute a system of supervision or inspection, to be conducted in the meantime for each division of the country, under the direction of its Branch Council; the results of which supervision are to be reported annually to the General Council."

At a quarter before six o'clock the debate was adjourned.

2. Moved by Dr. ACLAND, seconded by Dr. EMBLETON—"That the Council resume."—Agreed to

1. Moved by Dr. QUAIN, seconded by Mr. RUMSEY—"That the report of the Committee on the Pharmacopœia be adopted."—Agreed to. (See Minutes, No. 62, p. 6.)

Confirmed—GEORGE BURROWS, *President*.

MINUTES OF MEETING, MONDAY, MAY 2, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the Chair.

Present—As before.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. QUAIN, seconded by Mr. SYME—"That the Pharmacopœia Committee consist of four members:

"Dr. Christison, *Chairman*.

"Dr. Apjohn.

"Dr. Sharpey.

"Dr. Quain."

—Agreed to.

2. Moved by Dr. ACLAND, seconded by Dr. ANDREW WOOD—"That the Council resolve itself into a Committee on Education, and that the President be requested to take the chair."—Agreed to.

1. The Debate was resumed on the Motion, which was moved by Mr. SYME at the meeting on the 29th of April (see Minutes, No. 62, p. 10), and seconded by Dr. ANDREW WOOD, viz.:—"That the Council proceed to frame a Course of Study for Medical Education, which may be recommended to the Licensing Bodies;"

And on the amendment, moved by Dr. THOMSON, seconded by Dr. SHARPEY, viz.:—"That, instead of proceeding to frame a Course of Study for Medical Education, etc., the Council adopt the following resolution:—

"That, viewing with general approval the conditions required by the different Bodies enumerated in Schedule (A) of the Medical Act, of Candidates for a Qualification, the Council do not think it expedient, for the present, to proceed to frame a complete or formal Scheme of Professional education and examination. But, in order to indicate the general nature of their views upon this subject, they resolve to communicate the following recommendations for the guidance of the various Licensing Boards:—

"1. That Twenty-one years be the earliest age at which a Professional Licence can be obtained.

"2. That no Licence be obtained at an earlier period than four years after the registration of the candidate as a Medical Student.

"3. That the course of study required for a Licence shall comprehend not less than four winter sessions, or three winter and two summer sessions at a recognised Medical school; and that evidence shall be produced that the remaining period of the four years has been passed in the acquisition of Professional knowledge.

"4. That the Professional examination be divided into at least two parts; that these, embracing the preparatory branches of study, be not undergone before the conclusion of the second sessional year of nine months; and that the final examination be not undergone till the completion of the whole prescribed course of study, nor at an earlier period than three years and nine months after the commencement of Professional study.

"5. That the Professional examinations be conducted partly in writing and partly *viva voce*; and, in all parts which admit of it, also practically and by demonstrations.

"6. That the Council recommend to the several licensing bodies that the courses of instruction required by them severally should be framed in such a manner as to secure a due share of attention, both to the preparatory and to the final, or more strictly practical, branches, and by class examinations, and all other means which may be deemed proper, to promote, as far as possible, the self-culture and useful practical education of those who seek to obtain a licence. The Council would accordingly suggest to these bodies that it is desirable to avoid enforcing attendance upon a large number of courses of instruction during the same term of study, and to arrange the subjects of examination in such a manner as will guide the student in the most approved order of study.

"7. That the regulation of the extent and duration of courses of lectures and instruction be left to the authorities of the several Medical Schools; and that in the case of branches of scientific study, not purely Professional, which are included in the curriculum, the scope and extent of attainment required of the candidates be indicated by means of a published conspectus of the subjects of examination to be issued by the several examining boards.

"8. That with a view to secure fairness and efficiency in examinations, the Council resolve to institute a system of supervision or inspection, to be conducted in the meantime for each division of the country under the direction of its Branch Council; the results of which supervision are to be reported annually to the General Council.

The Amendment was put to the vote, and negatived.

The original Motion was also negatived.

2. Moved by Dr. STORRAR, seconded by Dr. CHRISTISON—"That the seventeenth Recommendation of the Council be adopted."

Confirmed—GEORGE BURROWS, *President*.

MINUTES OF MEETING, TUESDAY, MAY 3, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. BURROWS, *President*, in the chair.

Present—

Dr. Alderson.

Mr. Arnott.

Mr. Cooper.

Dr. Paget.

Dr. Embleton.

Dr. Storrar.

Dr. Alexander Wood.

Dr. Andrew Wood.

Dr. Fleming.

Mr. Syme.

Dr. Thomson.

Dr. A. Smith.

Mr. Hargrave.

Dr. Leet.

Dr. Apjohn.

Dr. Corrigan.

Dr. Sharpey.

Dr. Parkes.

Dr. Quain.

Mr. Rumsey.

Dr. Christison.

Dr. Stokes.

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

1. Moved by Mr. HARGRAVE, seconded by Mr. COOPER—"That the Council resolve itself into a Committee on Education, and that the President be requested to take the chair."

Amendment moved by Dr. CHRISTISON, seconded by Dr. STORRAR—

"That the Council do not resolve itself into a General Committee of Education, but that a Select Committee be now appointed for the purpose of considering the recommendations of the Council on Professional education, and the various motions and notices of motions as to education which have been submitted to the Council, with the view of preparing such a report on Medical education as may be presented, and, if approved, passed during the present Session."

The amendment was carried.

Moved by Dr. CHRISTISON, seconded by Mr. SYME—"That the following be the Select Committee on Education:

"Dr. Christison, Chairman.	Dr. Thomson.
Mr. Arnott.	Mr. Apjohn.
Dr. Paget.	Dr. Parkes.
Dr. Storrar.	Dr. Stokes."
Dr. Alexander Wood.	

—Agreed to.

2. Read the following reference to the Branch Councils made by the General Council on June 3, 1863 (see Minutes, vol. ii. p. 244):—"That the report of the Medical Acts Amendment Committee be forwarded to the Branch Councils for their observations thereon."

The observations of the Branch Councils, in pursuance of the foregoing reference, having been read, it was moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That the observations of the Branch Councils be entered on the Minutes."—Agreed to.

BRANCH COUNCIL FOR ENGLAND, MARCH 4, 1864.

(See Minutes Branch Council for England, No. 20, p. 7.)

Moved by Dr. STORRAR, seconded by Mr. ARNOTT—"That the Branch Council, having given their attention to the Report of the Medical Acts Amendment Committee, forwarded by the General Council to the Branch Councils for their observations thereon, are of opinion that it is not expedient at the present time to engage in fresh legislation."—Agreed to.

SCOTTISH BRANCH OF GENERAL COUNCIL, APRIL 2, 1864.

(See Minutes Branch Council for Scotland, No. 29, p. 89.)

On the motion of Dr. ANDREW WOOD, it was resolved:—

I. That the Branch Council have considered the proposed Amendments on the Medical Act, remitted to them by the Medical Council for their observations thereon.

II. That the Branch Council believe that much of the dissatisfaction of the Medical Profession, with reference to the working of the Medical Act, has arisen from the faulty construction of some parts of that Act.

III. That, in an especial manner, this has been the case regarding two points, viz., 1st, The failure of Clause XL. to carry out its objects of protecting the registered Practitioner, and of enabling the public to distinguish between qualified and unqualified Practitioners; and, 2nd, The insufficiency of Clause XX. as regards provision for the enforcement of the regulations issued by the Medical Council in reference to Medical education.

IV. That the Branch Council, without expressing a definitive approval of any of the subjoined Clauses which have been proposed to be substituted for Clause XL, consider the subject well worthy of the mature consideration of the Medical Council. (a)

V. That the Branch Council approve of the Clause proposed to be substituted for Clause XX, viz. —

"It shall be lawful for the General Council to lay down such regulations respecting the education and examination of Practitioners in Medicine, Surgery, and Pharmacy, as may appear to them fitted to insure adequate knowledge and skill in the several departments of the Profession; and the said General Council shall then submit said regulations to her Majesty's most Honourable Privy Council. And the said regulations, if sanctioned by the said Privy Council, shall then be obligatory upon all Universities, Colleges, and other bodies enumerated in Schedule (A) to this Act."

VI. That, in regard to the proposed clauses for the regulation of Pharmacy, the Branch Council, whilst they consider it very desirable that there should be certain legal regulations as to the sale of drugs in this country, with a view to the safety of the public, think that that object would be best carried out by means of special statute.

VII. That the Branch Council consider that the Medical Council, at their approaching meeting, should take the subject of the amendment of their Medical Acts into early consideration, with a view to their submitting the result of their deliberations regarding it (should they resolve that legislation is called for) to the Secretary of the Home Department, during the Session of the Council.

(a) Draft I.—"Any person not legally possessing any of the qualifications under Schedule (A) to this Act, who shall profess the practice of Medicine or Surgery, taking or using the name or title of a Physician, Doctor of Medicine, Doctor, Licentiate in Medicine or Surgery, Bachelor of Medicine, Surgeon, General Practitioner or Apothecary, or any name implying that he is a legally-qualified Practitioner, shall," etc., etc.

Draft II.—"Any person professing to undertake the treatment or cure of diseases, who shall wilfully and falsely pretend to be, or take or use the name of a Physician, Doctor, Bachelor of Medicine, Surgeon, General Practitioner, or Practitioner in Medicine or Surgery, Apothecary, or any name, title, prefix, addition, or description contained in Schedule (A) to this Act, or any other name, title, prefix, addition, or description implying that he is a legally qualified Medical Practitioner, not being possessed of a legal Medical qualification which would entitle him to registration, shall, upon a summary conviction for any such offence, pay a sum not exceeding £20."

Draft III.—Clause taken from the New Medical Act for Victoria:—

"On and after the day of , 186 , it shall not be lawful for any person, unless registered under this Act, to pretend to be, or take or use the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical or General Practitioner, or Surgeon, Apothecary, or Accoucheur, or Licentiate or Practitioner in Midwifery, or any other Medical or Surgical name or title; and every unregistered person so offending shall forfeit and pay a sum not exceeding £50, to be recovered in a summary way before any two Justices of the Peace, by any person suing for the same in any Court of Petty Sessions."

IRISH BRANCH OF GENERAL COUNCIL, MARCH 14, 1864.

(See Minutes Branch Council for Ireland, No. 50, p. 2.)

The Council resumed the consideration of the proposed amendments of the Medical Act, and altered certain of the Sections as follows:—

PREAMBLE—Omitting the first sentence, to the word "Practitioners," and the words "And" and "moreover," in the following lines. Thus:—

"Whereas it is necessary for the safety and protection of the public, towards securing adequately educated Practitioners in the several Departments of Medicine Surgery, and Pharmacy: Be it therefore enacted, etc., etc."

SECT. XXIX.—Introducing the words, "Registrar of each Branch," after the word "The" in the first line. Thus:—

"The Registrar of each Branch Council may refuse to register any person who may have been convicted, in England or Ireland, of any felony or misdemeanour, or in Scotland of any crime and or offence; and if any registered person shall be so convicted, or shall, after due inquiry, be judged by the General Council to have been guilty of infamous conduct in a Professional respect, whether before or after registration, the General Council may, if they see fit, direct the Registrar to erase the name of such person from the Register."

SECT. XL.—Omitting the words, "or Surgeon," between the words, "Practitioner" and "Apothecary." Thus:—

"On and after the day of , 186 , it shall not be lawful for any person, unless registered under this Act, to pretend to be, or take or use the name or title of Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical or General Practitioner, Apothecary or Accoucheur, or Licentiate or Practitioner in Midwifery, or any other Medical or Surgical name or title; and every unregistered person so offending shall forfeit and pay a sum not exceeding £20, to be recovered in a summary way before the Justices of the Peace."

Resolved.—That the bill as now amended be adopted and communicated to the Registrar of the General Council, in accordance with the resolution of the said Council.

Moved by Dr. CORRIGAN, seconded by Dr. APJOHN—

"That the proposed Medical Bill, as amended by the Medical Acts Amendment Committee of last year, be forwarded to our solicitor, with directions to have it drafted, as soon as possible, and returned to the Executive Committee;

"That the Executive Committee take means to have the Bill so drafted laid on the table of the House of Commons, at the commencement of next Session of Parliament;

"That a copy of the Bill so drafted be forwarded without delay by the Executive Committee to the Branch Councils, to the several bodies enumerated in Schedule (A) of the Medical Act, to the Pharmaceutical Society, and the Press; so that all parties concerned may have ample opportunity, in the interval between publication of the Draft Bill and next meeting of Parliament, of considering the Bill, and of suggesting such amendments as they may desire.

"That the General Medical Council meet at as early a period as may be necessary next year, to consider the various Amendments that may be suggested in the interval, in order to insert in the bill such amendments as may meet their approbation."

Amendment, moved by Dr. STORRAR, and seconded by Mr. ARNOTT — "That looking to the great diversity of opinion which exists in Great Britain, in regard to the objects which it is desirable to obtain by an amendment of the Medical Acts, it is not at present expedient that the Council should engage in fresh legislation."

Moved by Dr. ALEXANDER WOOD, seconded by Mr. HARGRAVE:—"That the debate on the amendment of the Medical Acts be adjourned until Wednesday, the 4th of May."—Agreed to.

3. Dr. SHARPEY having presented the Report of the Finance Committee, it was moved by Dr. SHARPEY, seconded by Dr. PAGET—"That the Report be received and entered on the Minutes."

REPORT OF THE FINANCE COMMITTEE.

The Finance Committee beg leave to present, in the table subjoined, a statement of the estimated and actual income and expenditure of the year 1863; also an estimate of the income from ordinary sources, and of the expenditure, as far as the Committee are able to judge, for the year 1864. Appended is a statement of the Pharmacopœia account, exhibiting the expense incurred in the preparation and publication of the British Pharmacopœia, from the commencement of the undertaking up to April 19, 1864, except some incidental charges, estimated not to exceed £10; also the number of copies printed, and the present state of the sale of the work, with the proceeds of the sale up to the same date.

The sums advanced in former years on account of the Pharmacopœia have been included in the annual accounts laid before Parliament, and defrayed, along with the ordinary expenses of those years, by a percentage rate on the income of the three Branch Councils, as directed by the Medical Act. The Committee recommend that, when all the expenses of the publication shall have been defrayed out of the proceeds of the sale of the work, the surplus be reserved for investment as a Special Fund, available for the purposes of the Pharmacopœia.

The Committee further recommend that £50 be presented to Dr. Garrod in acknowledgment of special services rendered in the publication of the Pharmacopœia, which were undertaken by him at the request of the Executive Committee; also that gratuities be given of £30 to Mr. Bell, and £20 to Mr. Rope, the clerks, for extra trouble and efficient service in conducting the sale, by which the charge for publishers' commission is saved to the Council.

The Committee have examined into Messrs. Spottiswoode's account referred to them by the Council. It appears that in February, 1862, Messrs. Spottiswoode laid in a stock of new type and the requisite supply of paper for the work, by direction of the Pharmacopœia Committee, on the understanding that the printing would be immediately proceeded with, but that in consequence of the delay which subsequently took place these materials lay long unemployed. Messrs. Spottiswoode estimate at £75 their loss occasioned thereby, and also from the printing being deferred to the busy season of 1863, instead of being done in the summer, as expected. They do not press this charge as a claim, but submit it for equitable consideration; and the Committee recommend that it should be paid. With regard to an extra claim for binding, submitted by Messrs. Spottiswoode, the Committee regret that, after giving it their careful consideration, they do not feel themselves justified in recommending that it should be allowed.

In conclusion, the Committee recommend that two members of the Executive Committee be annually appointed to audit the accounts of the General Council.

W SHARPEY, Chairman.

1. That the chemists and druggists now assembled recognise the desirability of giving all possible encouragement to scientific and educational qualification for the trade of a chemist and druggist, but they consider themselves, in common with their brethren, quite competent to accomplish all needful reform in their own body, and repudiate the 56th and 57th Clauses of the proposed Act of the Medical Council as being unjust in principle and an unwarrantable attempt to interfere with their rights as independent citizens.

2. That an Act of Incorporation, based upon a recognition of existing rights, and subjecting every future candidate for the trade to an educational test, as suggested by the United Society of Chemists and Druggists, is most desirable, and this meeting would urge upon the trade the necessity of a combined and determined effort for its attainment.

3. That the proceedings of this meeting be made known to the Medical Council, with the intimation that the Chemists and Druggists of this country require to be consulted upon any measure affecting their own interests, and that they will accept of no proposal which does not acknowledge the necessity of an incorporation of the entire trade, giving them the right of self-government.

4. That a copy of these resolutions, together with copies of the objectionable clauses in the proposed Medical Act, and the suggestions of the United Society of Chemists and Druggists for an incorporation of the trade, be forwarded to the Members of Parliament for the City of London and the Metropolitan Boroughs, requesting them to withhold their support from any measure affecting the interests of Chemists and Druggists which has not been submitted to the judgment of the trade.

Correct copy of resolutions certified by Mr. Alderman Dakin,
Chairman of the Meeting, and President of the United
Society of Chemists and Druggists.

C. F. BUOTT,

Secretary of the United Society of Chemists and Druggists.

20, New Ormond-street, February 6, 1864.

5. Moved by Dr. SMITH, seconded by Mr. HARGRAVE—"That a copy of the two volumes of the Minutes of the Medical Council be presented to each of the Universities and Corporations in Schedule (A) of the Medical Act."—Agreed to.

6. Moved by Mr. ARNOTT, seconded by Dr. STOKES—"That a copy of the letters from the Bodies mentioned in Schedule (A) to the Medical Act, explanatory of their regulations, be presented to each of the Universities and Corporations in Schedule (A)."—Agreed to.

Confirmed—GEORGE BURROWS, *President*.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF THE POTTERIES, STAFFORDSHIRE.

THE traveller who would obtain the best idea of what may be strictly called the Potteries of Staffordshire should go to Newcastle-under-Lyme, and from thence a little distance out in an easterly direction, to what is called Basford Bank. A little way down this descent, or small hill, he will take in, in a bird's-eye view, nearly the whole of the district in which the manufacture of earthenware is carried on in this part of England. A century ago Basford Bank must have afforded one of the most beautiful outstretches of rural scenery that could be presented to the eye. And even now, despite the presence of smoking furnaces, bottle-shaped kilns, closely-packed houses, and almost entire annihilation of rich, flowery land, deep and dense forest, and bright river, there is beauty. Standing with the face to the east, we can here take in all, or nearly all, the pottery towns. To the right, that is to say, in the south, is the large town of Stoke-on-Trent; a little above it, and in the south-east, is Shelton, and rather more to the east and spreading out in a long line, is Hanley. Immediately in front is modern Etruria, like a straight street detached from village or township. To the north-east is Burslem, and to the north Tunstall. A little to the left of Etruria Earl Granville's iron works stand prominently forward in the picture; and on an elevation hard by the North Staffordshire Infirmary presents a commanding position. In these we have included all the pottery towns of this part, except Longton and Wolstanton; for Newcastle-under-Lyme, although it contains amongst its inhabitants many men who work in the potteries, is not, strictly speaking, a pottery town, Stoke-upon-Trent being the centre borough town of the Pottery district.

REGISTRATION DISTRICTS.

The Registrar-General divides the district into two main divisions, with subdivisions. These main divisions are Wolstanton and Stoke-upon-Trent. Under the head Wolstanton he includes the district of Wolstanton, containing in the year 1861 a population of 9563; the sub-district of Tunstall, containing a population of 22,466, and having, with Wolstanton, an area in statute acres of 10,739; and the sub-district of Burslem, having a population of 22,327, and an area of 2940 statute acres. Under the head Stoke-upon-Trent he includes the sub-district of Hanley, with a population of 16,848; of Shelton, with a population of 18,331; of Stoke-upon-Trent, with a population of 11,390; Fenton, with a population of 7882; and of Longton, with a population of 16,857. The whole of the

Stoke-on-Trent district is included in an area of 10,490 statute acres.

STOKE AND SHELTON.

Stoke-upon-Trent, the nominal centre of the Pottery district, is one of the old towns of Staffordshire, probably having a date as ancient as that of Stafford itself. The town, almost within the present century an inconsiderable place, now stretches out into wide dimensions, with fine streets, regularly built, commodious houses, extensive manufactories, and every evidence of an active, and even over-active, life. The neighbourhood around is exceedingly picturesque. Shelton is a smaller town, very similar, and also of antiquity.

HANLEY.

Hanley is a modern place, containing several collieries and potteries in its vicinity. It seems to have been of little importance at the beginning of this century, but once started it rapidly underwent increase, and in 1811 it had a population of 4481, with 911 houses. The town of Hanley now spreads over an immense tract of ground, is crowded with a manufacturing population, and withal presents a picturesque character.

ETRURIA.

At a distance from Hanley, scarcely looking like a town, but rather like a series of small hamlets, spread out on irregular and rising ground, is Etruria, a modern place, founded by the famous Josiah Wedgwood, in the last century. It was evidently originally built in one straight line or street, as a small village, in fact, for housing the persons employed in Mr. Wedgwood's works. The name was given to it from the Italian Etruria. In this place the great Wedgwood made those wonderful discoveries which have added so marvellously to the industrial art and the wealth of this country. Here he made the name for the Wedgwood manufacture; and the young members of our Profession who are commencing their careers in the surgeries of our provincial brethren may learn with interest, as they turn from beating up the *Pil. saponis c. opio* in their Wedgwood mortars to the pages of the *Medical Times and Gazette*, that this remarkable Englishman was the son of a potter in no very affluent circumstances; that he possessed nothing but his own industry, talent, and perseverance to carry him on; that he was simple and unassuming in manner, and childlike almost in the way in which he experimented and asked questions of nature; free from all pride and bigotry; and great because of his very simplicity. Wedgwood may be said to have made the Pottery district, for although truly it existed before him, it was comparatively in a small way and rude; he made it large—one of the most important industries in England, in fact—and, above all, artistic. It is this latter fact, the infusion of something new into the art of pottery, that has made modern Etruria so formidable a rival of the Etruria of the past; and one could have wished almost that, in the building of the little town, its founder had also again considered the beautiful as well as the useful; for, in plain truth, Etruria as a place disappoints the expectation. There is about the word a classical sound, which makes one think of an open plain, with fine buildings and half-ruined structures, with vestiges of past art peeping out everywhere; but that which, in fact, is a plain English street, or large village, unadorned, unrelieved, and unpretending. Nevertheless, the art is there, and a wonderful art indeed, hidden though it is; but it has to be sought in the rooms and warehouses of the manufactory that skirts the canal that winds by: in them, the schoolrooms of the best potters in England, and the centres from whence come those articles with which our tables may be so chastely decorated in transformed clay, there is art unsurpassed.

BURBLEM.

Burslem is called by Pitt,—who, I believe, in turn borrows the name,—“the mother of the Staffordshire potteries.” It is a place of very ancient time, and in the reign of Henry III. was evidently of great importance. It was here that the earthenware manufacture was introduced into Staffordshire; and the historians have busied themselves very greatly to ascertain why this should have been the case. Pitt, who is very careful in his descriptions, answers the question by attributing the introduction to the abundant and almost inexhaustible supply of clay and coal upon the spot, and the inland situation of the district which contributed to render labour cheap. The favourable circumstances to the manufacture are thus summed up:—“The measures or strata by which the beds of coal are divided consist most commonly of clays of different kinds, some of which make excellent fire-bricks for building.

the potters' kilns, and *saggars* (a corruption of the German *Schrager*, which signifies cases or supporters), in which the ware is burnt. Finer clays, of various colours and textures, are likewise plentiful in many places, most of them near the surface of the earth; and of these the bodies of the wares themselves were formerly manufactured. The coals being then also got near the surface were plentiful and cheap."

The town of Burslem, although thus of ancient date, is comparatively modern in appearance. Old-fashioned houses certainly are rare, and the streets assume a regularity which shows that what is now Burslem is mainly Burslem of the latter half of the last and of the present century.

TUNSTALL.

Tunstall is a smaller place, which has existed for many centuries; for in the reign of Kyng Harrye ye Syxh after ye conquest of England, one Phythyon of Tunstall leaves a document which shows that he "dyd purchys a garden place yt llythe in Tunstal of Hary of Tunstall his broders."

DIVISIONS OF OCCUPATION.

The population of these towns are mainly engaged in earthenware manufacture and mining, but not exclusively.

In the district of Wolstanton, including the towns of Tunstall and Burslem, there are 3859 males and 1493 females engaged in pottery work, or 5352 in all. In the same district there are 563 males engaged in iron mining, and 2306 males in coal mining. In the district of Stoke-on-Trent, including Hanley, Shelton, and Longton, there are 5813 males and 3338 females occupied in pottery work; and in the same district there are 2436 males engaged in coal mining.

The youths and children employed in pottery work in the Staffordshire potteries are very numerous, amounting, according to an estimate by Mr. Longe, to about 11,000, all under 18 years of age. Of those between 13 and 14, there are 6500; and of those between 8 and 13, 4500. I should observe, however, that Mr. Longe includes the small districts of Colridge and Dutchall in his calculations.

NEWCASTLE-UNDER-LYME.

The town and district of Newcastle-under-Lyme includes Whitmore and Audley. The population of Whitmore in 1861 was 1302, and the area in statute acres 6680. The population of Audley was 7625, and the area in statute acres 11,171. The population of Newcastle-under-Lyme was 15,640, and the area in statute acres 8,867.

Newcastle existed in the reign of King John as the town or castle of "Chesterton-under-Lyme." The castle in process of decay, in the reign of Henry III. was rebuilt by the Earl of Lancashire, and called the New Castle; hence probably the present name. On this latter point, however, there are endless speculations. The town was incorporated by Henry III., on September 18, 1285. No remnants of the castle now remain. The town is a borough, returning two members to Parliament. The streets of the town are not very regular, but are wide and spacious; the ground is hilly in parts, and several streets are built in the lines of the descents. The houses in the worst parts of the town are low, heavy, and dark.

Newcastle suffers from the same disadvantages as Stafford in regard to cattle fairs. On days when cattle are brought in large numbers for sale they are simply turned into the public streets, and are there bought and sold, so that the whole town is, in short, a market. The streets afterwards are left in the most filthy condition; the surface drains are choked; on the sideways it is most uncomfortable for all persons, and especially for females, to walk; and, in spite of partial cleansing, the air is rendered noisome for several hours. It is astounding that in an English town in this half of the boasted nineteenth century such an intolerable, disgusting, and unnecessary nuisance should be permitted. After I had described the cattle market of Stafford in a previous number of this series of papers, I received "a cutting" from some local newspaper in which either the editor of the paper or a contributor treated the matter as an impossible fact,—as something that told amusingly, but could not be. I really am hardly surprised at the incredulity thus displayed, for it is a veritable barbarism to make a town even for a day a wide-spread manure-heap. But, strange as it may appear, it is strictly true—true in regard to Stafford, and equally true in respect to Newcastle-under-Lyme.

There are many points of historical interest about Newcastle upon which I dare not dwell at length; I am bound, however to note that it was the birthplace of two of the most remarkable men, of the men of mark, of the Commonwealth. The first of these celebrities was Major-General Thomas

Harrison—a soldier who fought bravely, and who adhered to his principles with a fanaticism that knew no abatement. When, in 1653, Cromwell, having dissolved the Parliament, and for a time had held supreme power, selected 139 members of assembly, Harrison was one of five invited by the assembly to sit with them. When the assembly, on December 12, 1653, was broken up, Harrison was one of thirty members who insisted on keeping their seats; and it is of Harrison on this occasion the story is told, that when Major White, coming from the Protector with a file of musket men in his rear, entered the House he said (addressing Harrison), "What do you here?" To which Harrison replied, "We are seeking the Lord," and White returned, "Then you had better go elsewhere, for to my certain knowledge he has not been here these twelve years." A strange man this Harrison, but honest, and consistent to a fault; not a man to be remembered with affection, but yet one of whom any town may be proud. Anabaptist Harrison! (a)

The second celebrity of Newcastle, Goodwin, was for a time Chaplain to the Protector. He was a stern man, and full of hard thoughts, but he was honest, too. He enjoyed a joke, and, I believe, he rather liked sack and—for shame!—Hollands. He played a more important part in the reign of Cromwell than I dare venture to describe here. The reader will remember him as the officiating preacher when poor Jerry White, caught at the feet of Frances Cromwell, told the Protector a white lie, to wit, that he loved *not* Lady Frances, but her maid; and who therewith was married to the maid by order of his Highness, before another word of explanation could be offered or received.

(To be continued.)

SECOND THOUGHTS ON THE BRITISH PHARMACOPŒIA.

By A CHEMIST.

No. IV.

It was impossible to proceed far into an examination of the new Pharmacopœia without forming some conjectures—or a theory, if so grave a word is in place—to account for its origin and character. It appeared to us that the book was hopelessly delayed. The committees met time after time. Faction fights were frequent. The Scottish and Irish members fought with desperate tenacity for the most trivial peculiarities of their respective nations. The best men in the committees became wearied and disgusted. At last, after an enormous expense had been incurred, the Council ordered the book to be published *somehow*—no further delay was allowed. The adoption into, or rejection from, the list of *Materia Medica*; the ingredients, proportions, and processes of the formulæ, after having been hopelessly debated, were determined by the voice of the most tenacious members. As to researches in botany, natural history, or chemistry, nothing of the kind need be attributed to them.

This supposition seems to be fully justified by the defence of Dr. Frederick Farre, one of the ostensible editors, against the strictures of the President of the London College. "It must be borne in mind," he says, "that in order to amalgamate the Pharmacopœias of the three kingdoms it was necessary to make concessions on all sides, and that the representatives of the London College could not always have their own way." If a mere amalgamation of the old books were the task the Medical Council set themselves, we need not wonder at the result. That it makes no pretensions to represent the information of the Profession respecting remedial agents cannot be too distinctly and unequivocally proclaimed. The reading public perceive and take more interest in questions of this kind than the Profession are apt to imagine. They should be told that very few, if any, regular and qualified Practitioners confine themselves in their choice of remedial agents to the Pharmacopœia. Their handbooks are and will continue to be dispensatories and systems, the range of which is incomparably greater; while "Prescribers' Manuals" and receipt-books, etc., supply further and most useful information.

Dr. Nevins has enumerated upwards of thirty medicines in general use in the metropolis not to be found in the British Pharmacopœia. Probably, for the empire, three hundred

(a) It is commonly stated that Harrison was one of the first nominated Major-Generals of the Protector, but the statement is not true. He was just the man whom Cromwell would not have selected at once to the post.

would be nearer the mark. So far from many of the omitted drugs being locally or rarely used, we have heard a West-end pharmacist assert that he sells in his establishment a larger quantity of tincture of sumbul than of any tincture in the Pharmacopœia.

What is the meaning of the revolt of the London College of Physicians from the authority of the Medical Council, as indicated by the speech of the President? If the Fellows and Licentiates of that body follow his advice, to ignore the British and adhere to the old London Pharmacopœia, what becomes of the injunction to the druggists to destroy or alter all their preparations?

Dr. Farre's apology for the errors in the chemical processes is very rich. He admits that chemicals are not made by the persons for whom the book was professedly compiled, but by manufacturers; but, says he, "the introduction of chemical processes into the Pharmacopœia, if it did no good, at all events did no harm." No harm to excite the ridicule of all persons concerned, to expose any one simple enough to attempt the processes to failure, to fill up a book with errors and fallacious statements, and then to employ the prestige of a learned and ruling body to enforce a sale of such a work! The compilers pride themselves on a new feature in the work, namely, the solutions and substances used for volumetric analysis. Allowing these to be useful to the chemist, what has it to do in a Pharmacopœia?

A misapprehension of the purposes and aims of a Pharmacopœia is manifest throughout the entire work. Surely it is not to teach chemistry. If it were, the book is not of much value for the purpose. The Council ought to have been above the vulgar affectation of appearing scientific beyond the occasion. But all, or nearly all, their science is behind the age, whilst both in the proper sphere of a Pharmacopœia, therapeutics and pharmacy, they seem to be unacquainted with recent progress. It is scarcely too much to say that nearly all the chemistry of the book is faulty. The British Pharmacopœia recognises in a very few instances comparatively new forms for preparing medicines,—the pseudo-crystalline scales of the citrates of iron, the granulated sulphate of iron, and some concentrated solutions under the title of fluid extracts. It is impossible to understand why others are omitted which are extensively in use by all grades of the Profession:—1. Granulated citrates and other salts. 2. Concentrated groups of principles representing the active portions of vegetables, separated from the bulky and inert matter, woody fibre, starch, gum, etc., with which they are associated in nature. There is great affectation of scientific refinement in some directions, whilst this, one of the most recent improvements of science as applicable to therapeutics, is ignored. The absolute isolation of the vegetable alkaloids is all very well in a chemical point of view, but the best Practitioners have always held that quinia, morphia, etc., do not fully represent the curative properties of the plants whence they are derived. No better illustration of this can be found than one of their new preparations, namely, resin of podophyllum. The formula given for making this resin aims at making it perfectly pure, but it is well known that pure resin of podophyllum is not the desired remedy derived from that plant. In the powder now in extensive use under the name of podophyllin there are several cognate resins, the difference between which is clearly marked by their being soluble in different menstrua. Chemists have not yet succeeded in separating and classing these severally, inasmuch as they are not crystalline bodies. But it is the group in combination that is valuable as a remedy, not the resin which predominates in quantity. Every Practitioner who has carefully studied this medicine will bear out these remarks. We may illustrate the subject by the case of the new and beautiful dyes derived from the products of the decomposition of coal. For some time the variety of dyeing matters termed magenta dyes were supposed to be the result of the reaction of certain substances on *aniline*, but on examining more accurately the aniline of commerce it was found that it was invariably associated with another basic hydrocarbon, namely, *toluidine*. When the latter, which was deemed an impurity, was separated, and pure aniline obtained, it was found that it produced, with the same agents, no colours. The separated toluidine was equally valueless as a source of colours. But when aniline is mixed with a minute portion of toluidine, the compound or mixture yields all the desired dyes. It is just so with the resin of podophyllum, and the same is certainly the case with a great number of the new remedies which have recently come into use, and are now found in all druggists' shops. It is not irrelevant to remark that podophyllin,

which was until quite recently imported from America, is now prepared in enormous quantities in this country. We hear of one maker who prepares as much as twenty pounds of it at a time. It is perhaps needless to add that his process is not that of the new Pharmacopœia.

The recognition of the concentrated preparation alluded to was the more incumbent on the compilers of the Pharmacopœia, inasmuch as no simple preparation, such as tincture, infusion, or decoction of podophyllum, could possibly be used internally. In the root itself a most offensive and acrid matter, soluble in water and spirit, is contained, unbearable by the human stomach.

We cannot in these strictures on the therapeutics of the Pharmacopœia enter further into the subject, but it is one well deserving the attention of the Profession. Allied to it, however, there is one point to which we would briefly advert—it is that of Mr. Graham's great discovery of *dialysis*. Why is all notice of this omitted from the Pharmacopœia? We have a large space devoted to volumetrical analysis—quite (in our opinion) out of place, although interesting to those engaged in chemical researches. But the application of dialysis in the preparation of efficient remedies from vegetable bodies promises results of the highest interest and importance. It would appear that, by the agency of this method, we might have all the crystalline principles of the barks for instance, or of opium grouped precisely as they are in nature, and separated from all extraneous and inert matter. On the other hand, it may be found that the colloid materials of some plants are possessed of the properties we need to effect our purposes in therapeutics. If ever the art of healing takes on a scientific form dialysis will be its most useful instrument. It is of the highest interest and importance in chemistry to isolate all the proximate principles of plants, but not for therapeutics. This holds good in some instances with inorganic bodies; for example, iodine and the iodides are the agents most used by the Profession, but is pure iodine or the iodide a perfect substitute for the burnt sponge which they have superseded? The consumption of lozenges of burnt sponge by the public in districts where goitre prevails is enormous.

In connexion with this subject, it is curious and worthy of note how deeply rooted in Medical practice certain empirical formulæ are, and have been for ages, so that in the year 1864 they are retained side by side with the latest discoveries and improvements. Modified and improved, as some think, generally simplified, we have many of them in the British Pharmacopœia. In several instances a comparison with the original forms will show that the alterations can scarcely be regarded as improvements. Some have been rejected, but, nevertheless, they continue in use and retain their popular estimation:—

Old Names.	Modern Names.
Friar's Balsam.	Tinct. benzoin co.
Paregoric elixir.	Tinct. camph. c opio.
Turlington's drops.	Tinct. lavend. co.
Huxham's tincture of bark.	Tinct. cinch co.
Elixir salutis.	Tinct. sennæ co.
Ward's paste.	Conf. pip co.
„ powders	Pulv. jalap. co.
Lenitive electuary.	Conf. senna co.
Lisbon diet drink.	Decoct. sarzee co.
Venice treacle.	Conf. opii.
Hiera picra.	Pulv. aloes c. cannella.
Elixir vitæ.	Tinct. aloes co.
Elixir of vitriol.	Acid sulph. arom.
Rufus' pill.	Pil aloes c. myrrhæ.
Plummer's pill.	Pil cal. co.
Matthew's pill.	Pil sapon c. opii.
Pil cocciæ minores	Pil coloc. co.
Pil ex duobus.	Pil aloes c. scamon.
Dover's powder.	Pulv. ipecac. c. opii.
Diachylon.	Emp. plumb.

It would be useful to go back to the oldest forms of many of these, and examine them in the light of modern science, to discover how far the many changes they have undergone have been warranted. Of such as we find in the British Pharmacopœia, as compared with its immediate predecessors, few are improvements, some are manifestly the contrary, whilst many formulæ in popular use and estimation ought, if any are admitted into a Pharmacopœia, to be of the number.

We have now run over this pretentious work, and pointed out errors and imperfections enough to warrant the conclusion that it is a palpable failure. Whether the Medical Council or any other body of Medical men should take upon them-

selves the task of preparing a Pharmacopœia worthy of the Profession, is, we think, an important question not lightly to be answered or put aside. We purpose in a future paper to venture on a sketch of such a work, and to offer a few suggestions as to the mode of its preparation and publication.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 26.

Dr. BASHAM, Vice-President, in the Chair.

A paper, by Dr. MORELL MACKENZIE, was read, entitled

A DESCRIPTION OF THE FIRST LARYNGOSCOPE, AS INVENTED AND EMPLOYED BY DR. B. G. BABINGTON, F.R.S., IN THE YEAR 1829.

The author stated that in this communication it was not intended to trace the successive steps which finally led to the more general use of the laryngoscope in practical medicine. This had already been done in an able article by Mr. Windsor, in the *British and Foreign Medico-Chirurgical Review*. The object of the present paper was to fix distinctly the epoch of the first employment of the laryngoscope in the investigation of laryngeal disease. In considering this question it was necessary to bear in mind the essential conditions under which laryngoscopy is practised. These were—1st. The visual ray from the observer's eye has to be directed to a part which, when the mouth is open, is hidden from direct view by the projecting angle formed by the base of the tongue and the epiglottis. 2nd. The part to which the visual ray is directed—that is to say, the larynx—is not penetrated by light. To overcome these obstacles to laryngoscopy there are required, then (1), a small mirror placed at the back of the throat at such an angle that the visual ray can be directed into the larynx; and (2) an apparatus for concentrating the luminous rays, and projecting them upon the small mirror, so that they can be reflected into the larynx. For this latter purpose modern laryngoscopists generally use a second mirror (the ophthalmoscopic mirror of Rüete). The essential requisites of a laryngoscope were clearly perceived by Dr. Babington as early as the year 1829. At that period his inventive genius was directed to the subject, and he contrived a laryngoscope very similar to the one now in use. It consisted of a small laryngeal mirror, and a hand-mirror for concentrating the light. The patient sat with his back to the sun, and while the illuminating mirror (a common back-hair glass) was held with the left hand, the laryngeal mirror was introduced with the right. Dr. Babington's labours did not end here. By a very simple mechanism, a tongue-depressor was united with the laryngeal mirror, and thereby one of the most serious obstacles to laryngoscopy was attempted to be overcome. This ingenious laryngoscope [instrument shown] was exhibited at the Hunterian Society on March 18, 1829; and a report of the meeting was published in the *London Medical Gazette* of March 28, 1829. It was made by an optician named Elsworth, and the invoice [shown] was dated June 23, 1829. In this laryngoscope a spring between the shanks of the laryngeal mirror and the spatula was fixed in such a way that by pressing the two handles together the tongue was depressed. Afterwards (between the years 1830 and 1835) Dr. Babington gave up the tongue-depressor, and had two instruments made very similar to those now in use, except that instead of being of glass they were of steel. The maker's name (Laundy) is stamped on one of the mirrors. In rendering justice to a distinguished Physician, the author did not wish to detract from the credit fairly due to others who, at different times and independently of one another, had contrived an apparatus for inspecting the larynx. Dr. Czermak's great merit consisted in his having so simplified the instrument that it could be used by the many; and his talent and enthusiastic teaching had so prominently associated his name with the laryngoscope that his reputation would not suffer from a due recognition of Dr. Babington's claims. The author said it could not be denied that as early as 1827 Dr. Senn, of Geneva, tried to make use of a small mirror to examine the larynx of a child on whom he was about to perform tracheotomy. Dr. Senn was unsuccessful because he only employed one of the

factors in laryngoscopy; and whilst he attributed his failure to "the small size of the mirror," it really depended on the non-illumination of the larynx. Dr. Senn's case, moreover, was not published in the *Journal de Progrès* till the year 1829, a short time after Dr. Babington's description had appeared in the *London Medical Gazette*.

Dr. GIBB said he was glad that the subject of the author's paper had been brought before such a tribunal as this Society, for the discovery of the laryngoscope would now be recorded in such a manner that the claims of the original inventor would not be overlooked. This was important not only to Dr. Babington himself, but also for the history of the instrument. He could not sufficiently express himself in terms of praise towards Dr. Babington for his own most ingenious invention, one that is already proving of immense value in the diagnosis and treatment of laryngeal affections. When Czermak visited London in 1860, the belief was then entertained from his writings and conversation that Liston was the inventor of the laryngoscope, and that idea was entertained until quite lately. When he (Dr. Gibb) brought the subject of the laryngoscope before another Society in 1862, he was informed by Mr. Streeter, of Harpur-street, that Dr. Babington had to his knowledge used the instrument for many years, but he could not refer him to any published notice of it. Last year, however, this was rectified, and the original notice of the invention, as recorded in the *Medical Gazette* for 1829, appeared in another journal, and indisputably settled the question as to Dr. Babington's claims in the matter; and in his (Dr. Gibb's) work, recently published, he had taken care to rectify what was, on his part, an unintentional act of injustice to Dr. Babington. He would observe, however, that Bozzini, of Frankfort, in 1807, conceived the idea of illuminating many of the cavities of the body; but so far as he (Dr. Gibb) could investigate the evidence, he had examined the nostrils only, and, therefore, was the first to practise rhinoscopy. Dr. Babington's great discovery occurred in 1829. He was followed by Selligie about 1833, an ingenious mechanic, mentioned by Trousseau and Belloc in their work on Consumption of the Larynx. Beaumes, of Lyons, came next in 1838, and he practised rhinoscopy as well. Liston followed in 1840, Warden in 1844, and Avery in 1846. The last-named showed him (Dr. Gibb) his instruments in 1848, with some cases of cleft palate, although no observations were published. And, lastly, Garcia's researches were printed in 1855. There could be no doubt that most of these intuitively conceived the idea of inspecting the larynx; but as the priority of the invention now stands, Dr. Babington was the discoverer of the laryngoscope, and the first to apply it either with the direct or reflected rays of the sun; Bozzini first practised rhinoscopy; and Garcia autolaryngoscopy. To revert, however, to the instruments of Dr. Babington, the simplicity of their construction and their utility were unequalled, and not surpassed by many of the instruments of more modern invention; the combination of laryngeal mirror and tongue depressor in the same instrument was most ingenious. From what had been stated in the author's paper, and from a letter he had lately received from Dr. Babington himself, it was quite clear that the merit of using reflected light was wholly Dr. Babington's, who employed a small hand-glass to receive the rays of the sun, the patient's back being turned to the light. This merit has been claimed for others, but cannot be so for the future; and although the author has stated that Dr. Senne attempted to use a laryngeal mirror in 1827 upon a child, he (Dr. Gibb) did not see that it in any way affected the credit of Dr. Babington as the discoverer of the laryngoscope; and he once more tendered to him his grateful acknowledgments for what he had done for mankind by his simple, yet remarkable and highly-important invention.

Dr. COPLAND agreed with Dr. Gibb in the encomium he had passed on Dr. Babington. He felt sure that the Society would be glad to see Dr. Mackenzie's paper in its annals, and he (Dr. Copland) was proud of having introduced Dr. Mackenzie to the Society.

Dr. BABINGTON said that perhaps he ought to have been silent, but he wished to say a few words. At the time the instruments were invented a great deal was being said about infiltration of the glottis, and it occurred to him that it was desirable to seek means of examining the glottis more narrowly. With this instrument he had seen ulceration on the epiglottis, but he confessed that he did not contemplate looking through the glottis. He felt exceedingly obliged to Dr. Mackenzie and to Dr. Gibb, although he considered that he had been praised far too highly.

Mr. THOMAS BRYANT read a paper on

TWO CASES OF STONE IN THE BLADDER OF THE FEMALE TREATED BY RAPID URETHRAL DILATATION, WITH REMARKS ON THE OPERATION.

The author commenced by giving the history of two cases, of which the following are brief notes:—*Case 1.*—H. C., aged 52, admitted October 13, 1862. She had had symptoms of urinary irritation for eight months, and for three had been quite unable to retain her urine. On November 19 the stone was removed by rapid urethral dilatation, and it measured $1\frac{1}{4}$ inch by 1 inch in diameter. The operation was followed by immediate relief. On the day following the patient could hold her urine for twenty minutes, and in a week for many hours, and in three weeks she left well. *Case 2.*—Ann C., aged 35, was admitted on February 17, 1864. Urinary symptoms had existed for seven months, and were very severe; the urine was full of pus, mucus, and was intensely fetid. The least examination caused her great pain. After rest in bed for several weeks these symptoms had improved, and on March 5 the operation was performed. Chloroform was given, and the urethra rapidly dilated by Weiss's dilator. The stone was then removed, but little difficulty being experienced in its removal. The calculus measured 2 inches by $1\frac{1}{2}$ inch in diameter, and $5\frac{1}{4}$ inches by $4\frac{1}{2}$ inches in circumference, weighing 2 oz. 2 dr. The next day the patient could hold her urine for fifteen minutes, on the second for forty, on the third for two hours and a half, and on the fifth day for five hours. A small slough separated on the sixth day from the urethra, and during an examination the finger was introduced again into the bladder, which caused some little incontinence; but this gradually disappeared, and on April 5 she was able to retain her urine for five hours. She is now convalescent, having good power over her bladder for three or four hours. The author then passed on to the consideration of the dilatability of the female urethra, and quoted many interesting cases, which were tabulated, in which a calculus had been expelled by natural efforts, and in which *no* incontinence of urine was the result. He then proceeded to consider the operation of urethral dilatation as a means of removing a calculus or foreign body; and gave an analysis of twenty-eight cases, which he had tabulated, in which he proved that incontinence of urine resulted in only four out of the twenty-eight examples, and that in these four the dilatation had been *slowly* performed. He then considered in detail many of the cases, and enlarged upon the best mode of performing the operation. The subject of urethral lithotomy next obtained a notice; and it was proved that an incontinence of urine was a common result of the operation—nine subjects out of twenty being left in such a condition. Removal of a calculus by lithotomy was then touched on, and the subject of vaginal lithotomy introduced, the author indicating the exceptional cases in which either operation may be required. The following conclusions were then drawn up:—1. That the female urethra may be dilated to a considerable extent with facility, and without danger. 2. That *slow* and tedious dilatation of the urethra, by sponge tents or other means, appears to be injurious. 3. That *rapid* urethral dilatation, with the patient under the influence of chloroform, is the safest and most expeditious method of removing all average-sized calculi and foreign bodies from the female bladder; for calculi one inch in diameter in children, and even two inches in adults, have been safely extracted by this practice. 4. That the operation of incising the neck of the bladder and urethra is one of danger, and should be laid aside. 5. That lithotomy is a valuable operation in cases in which a stone cannot be safely removed by rapid urethral dilatation—that is, when the stone is very large, and when the bladder is healthy; and that it is the best practice to remove the broken fragments by the forceps as speedily as possible. 6. That vaginal lithotomy is an operation of value when the other modes of operation are inapplicable; but that, as a general practice, it is not required.

Mr. URE said the Society must feel indebted to Mr. Bryant for his valuable paper. He (Mr. Ure) believed that there were cases in which lithotomy was advisable. He then related a case in which the sub-pubic operation of lithotomy had been performed with good results, no incontinence remaining.

Mr. WALTER COULSON congratulated Mr. Bryant on his paper. For his own part, he (Mr. Coulson) much preferred the operation advocated for the removal of the stone from the female bladder to vaginal lithotomy for two reasons—first, because there was risk of a vesico-vaginal fistula following as a consequence of the latter operation; and secondly, because

the operation itself was much more tedious, and involved a long confinement to bed. Still, in the hands of Mr. Baker Brown and Mr. James Lane, the results had been very satisfactory. He doubted, however, whether other Surgeons, who had not the same experience in the operation for vesico-vaginal fistula, would be equally successful. Mr. Coulson alluded to a case in which he had removed a phosphate calculus the size of a large walnut. He had used Weiss's instrument, and was surprised to find how readily the urethra could be dilated. The patient did very well, was able to sit up three days after the operation, and could hold her water for two hours. No incontinence followed. He mentioned another case, at which he had assisted, when a much larger stone had been removed by urethral dilatation, and where no incontinence resulted a fortnight after the operation. Referring to what had fallen from the last speaker, he did not think it was ever necessary to incise the urethra, as the tissues were capable of very considerable dilatation. There was one passage in Mr. Bryant's paper in which he could not concur. He stated that vaginal lithotomy might be advisable where the calculus was large. Should the size of the stone be such as to render its removal entire through the urethra after dilatation impossible, he should be disposed, first, to dilate the urethra, and then to crush the calculus, not with the lithotrite but with a forceps, as used in lithotomy, in the male when the stone is too large to come away. He considered this proceeding preferable to vaginal lithotomy, for should the stone be so large as to render impossible its removal through the urethra, it would be necessary to make an incision that would involve pretty nearly the whole length of the original wall of the bladder. This was a serious objection. Therefore, where the calculus was very large, Mr. Colson preferred rapid urethral dilatation, and crushing, when necessary, to either vaginal lithotomy or to urethral dilatation with incision of the urethra.

Dr. WYNN WILLIAMS said that a specimen had been shown him by Mr. Clements, of Shrewsbury, of a crochet needle removed by the Messrs. Weiss's dilator from the female bladder. It was encrusted by a deposit as large as a pigeon's egg, and had been in two years. The patient did well, and had no incontinence.

Mr. SPENCER WELLS said that there could be no doubt of the difficulty of dealing by lithotomy with such a case as that described by Mr. Henry Thompson. A large stone and small irritable bladder clearly indicated that if dilatation were inadmissible, some form of lithotomy—vaginal, urethro-vaginal, or the lateral operation so successfully practised by Dr. Buchanan, of Glasgow—was called for. But in a case where the stone was of moderate size—say, from half an ounce to an ounce—and the bladder of moderate capacity—say, from four to six ounces—it was a serious question whether lithotomy or dilatation should be preferred. Mr. Bryant's proofs against slow dilatation were conclusive; but those in favour of rapid dilatation did not appear sufficient to induce us to reject lithotomy in cases to which it is applicable. Lithotomy is a very easy operation in women. It may be performed without uncovering them, and by injections through a large catheter the whole of the fragments may be removed at one sitting. There is no fear of any incontinence of urine. But dilatation is very uncertain. In a very important case which had come under his (Mr. Wells') care some years ago, he had asked several of the most experienced London and provincial Surgeons what their experience of dilatation was, and all had agreed that it was extremely uncertain, and that incontinence might follow a very moderate degree of dilatation. He treated this case most successfully by lithotomy. One Surgeon said that he had dilated in nine cases, and seven were "dribblers" for the rest of their lives. Mr. Bryant's facts were strongly in favour of rapid dilatation; but were not strong enough to prove its superiority to lithotomy in cases where lithotomy was applicable.

Mr. HENRY THOMPSON regarded the paper as a valuable contribution to practical Surgery, because it was impossible for any one Surgeon to come to logical conclusions respecting the best mode of treating these cases from his own experience alone, stone in the female being, comparatively speaking, a rare affection. Mr. Bryant had contrasted the method of rapidly dilating the urethra by means of Weiss's instrument with that of slowly dilating it by sponge tents. It might be regarded, perhaps, as generally agreed that the latter method was not a desirable one. This left for consideration the treatment by lithotomy, by incisions, and by rapid dilatation, as well as that in which the two latter were combined. With regard to lithotomy, although he approved of it for stones of

moderate size, he was quite sure that all who had attempted to remove a large stone at one sitting by this means encountered difficulties and risks of no ordinary kind. The bladder soon became empty, and the manipulation and removal of large, sharp, and angular fragments in that condition he considered a very hazardous proceeding, and one which probably involved more damage to the urethra, to say nothing of the bladder, than the removal of a good-sized stone entire. He was not quite sure whether the combination of incision with some dilatation had received all the attention it merited. For large stones he could speak in high terms of its value. This might be illustrated by briefly referring to a case which had occurred in his own practice two months ago. He had been called by Dr. Ashurst, in Kent, to see a lady, aged 77 years, who had suffered very severely from the presence of a large calculus. She was placed under chloroform. Mr. Thompson then dilated the urethra so as to admit the left finger easily; and having thus examined the stone, and found that it was too large to pass by any dilatation he thought proper to employ, he made an incision downwards in the median line, using the index finger as a director, and divided mainly the floor of the urethra and soft parts beneath, after the manner recommended by Mr. Ferguson, incising only very slightly the neck of the bladder. Having done this he extracted, slowly and carefully, a stone $2\frac{1}{4}$ inches long by $1\frac{3}{4}$ inches wide, and weighing nearly $2\frac{1}{2}$ ounces. He then introduced Marion Sims' vaginal speculum, and closed the incision by metallic suture, as when operating for vesico-vaginal fistula. The result was perfect. The patient, notwithstanding her age, was now perfectly well, walking about, and retaining her urine for three hours with ease. For very large calculi he should prefer again to adopt this method to that of trusting solely to the large amount of unaided dilatation which would be required.

The AUTHOR, in his reply, expressed his pleasure at having elicited the details of several interesting cases from Mr. Ure, Mr. Thompson, and Mr. Birkett. The success of Mr. Ure's case was very good, but it was open to a doubt whether the calculus might not have been removed more readily and with equal safety by rapid urethral dilatation than by the operation which had been performed. He would remind Mr. Wells that he (the author) had not disputed the possibility of removing a calculus from the female bladder by lithotripsy; for in certain cases this operation was of great value; but his aim had been to show that the same end might be secured in the majority of cases by a simpler and more expeditious practice. The expression of the Surgeon which Mr. Wells had quoted was very singular; it would be of great interest to have the details of the several cases to which he had alluded. Mr. Thompson's case was one of great practical interest; the operation he had performed for the removal of the stone was probably the best. He (the author) thanked the Society for the kind way in which they had received his communication.

Mr. BIRKETT showed some

CALCULI REMOVED FROM A WOMAN WHO HAD PROLAPSUS UTERI.

She was a patient of Mr. Roper, of Shoreditch. She had had prolapsus of the uteri and bladder for seven years. Three months ago she expelled fourteen stones. When Mr. Birkett saw her it was easy to take hold of the bladder and rattle the stones in it. A good many were extracted by dressing forceps. Dr. Odling had analysed them, and found them to consist of seventy-five parts of phosphate of lime, twenty parts of carbonate of lime, a trace of triple phosphates, alkaline salts, and organic matter. Mr. Birkett said that having shown them to a Medical man from Boulogne, he was asked if the patient had not had prolapsus of the uterus and bladder. Mr. Birkett wished to know if any of the members present had observed such calculi in prolapsus of the uterus and bladder.

Dr. BASHAM said the calculi were very curious in a chemical point of view. They were composed in the same proportions of phosphate and carbonate of lime as bone.

Dr. BABINGTON thought that phosphatic calculi were rather prostatic than vesical, and were generally found with deteriorated health.

MEDICAL PRACTITIONERS OF PARIS.—According to the Medical Almanack for 1864 published by the *Union Médicale*, there are 1600 Doctors of Medicine practising in the Department of the Seine; and if to these be added 270 *officiers de santé*, we have 1870 Medical Practitioners, or (taking the population of the Department at 1,500,000) 1 Practitioner for 875 inhabitants.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 28th ult., viz. :—

Messrs. Frederick William Richards, Winchester; William Frederick Knapp, Headington; George Huntsman Shaw, Attercliffe, near Sheffield; William Soltan Eccles, Plymouth; Frederic Charles Bailey, L.S.A., Woolwich; Thomas Francis Raven, Cambridge, and Henry Maturin, Lymington, Hants, Students of St. Bartholomew's Hospital. Arthur Bayley Adams, Lymington, Hants; Edmund Woods Hawkins, Commercial-road; Charles Meymott Tidy, Cambridge-heath; John Dawson, Great Yarmouth, and George Welland Mackenzie, Tiverton, Devon, of the London Hospital. Thomas Henry Knott, Bath, and Henry Octavius Steele, Harsley, Yorkshire, of Guy's Hospital. Walter Hardin, Woolwich, and Henry Rayner, Hythe, Kent, of St. Thomas's Hospital. Edward Norton, Birmingham, and Charles Humphrey Weld, Tenterden, Kent, of the Middlesex Hospital. William Akerman, St. Just, of University College. Ernest Arthur Hudson, Queen Anne-street, of St. Mary's Hospital. James Taylor Smith, Newcastle, and Joseph Birt, Leamington.

Admitted Members on the 29th ult. :—

Messrs. William Nicholas Heygate, Hanslapes, Bucks; Francis Snaith, Boston, Lincolnshire; Danielles, L.S.A., Fairford, Gloucestershire; Frederick Chabet, Camberwell-road; William Warwick Wagstaffe, Lambeth, and George Fredrick Sankey, Maidstone, Students of St. Thomas's Hospital. Charles Bradley, Nottingham; Joseph Needham Scrope Shrapnel, L.S.A., Isle of Wight; James Whitworth, Port Talbot, Glamorganshire, and Herbert Davies, Llanybyther, Carmarthen, of University College. Frederick John Cropp, Clapham; Vincent Frederick Eck, Cleveland-square, and Henry Hope, Richmond, of St. Bartholomew's Hospital. Edward Dyer, Canonbury, and David Martin Williams, Calcutta, of the Charing-cross Hospital. Ralph Burnham, Preston, Yorkshire, of the Westminster Hospital; Robert Wrentmore Thomas, Bristol, St. George's Hospital. Algernon William Winn, Scarborough, King's College; Robert Winter, Hampstead, St. Mary's Hospital. Samuel Duckering, L.S.A., Grantham, and William Robert Coward, South Shields.

The following Gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 21st ult., and when eligible will be admitted to the Pass Examination :—

H. D. Reynolds, F. M. Rickard, T. G. Simpson, Alfred Harwood, and E. A. Trimmell, of Guy's Hospital; T. H. Wilkin, R. D. Broughton, and W. L. Shepard, of St. Bartholomew's Hospital; J. H. Wathen, Joseph Thompson, and Marcus Beck, of University College; O. T. Williams, H. P. Gordon, and E. Mc. C. McCready, of Dublin; E. M. Little and Osman Vincent, King's College; H. T. Nettleton and Richard Bugden, Westminster Hospital; G. W. Wiggin, Leeds; C. T. Aveling, St. Thomas's Hospital; J. A. Richardson, Hull; Arthur Richardson, Charing-cross; Edward Bousfield, Birmingham; John Soane, London Hospital; Laurence Corban, Cork; and H. T. Ryder, Middlesex Hospital.

The following gentlemen passed their Primary Examinations on the 3rd inst., viz. :—

Messrs. J. P. Hughes, Josiah Leale, T. M. Joseph, A. M. Roberts, George Crowe, Frederick Barton, J. D'A. Harvey, and F. T. Coates, Students of University College. J. T. Ransford, H. A. R. Thomson, J. W. G. Farwell, G. C. Sanders, W. B. Holderness, William Keen, and C. L. Ridout, of St. George's Hospital. P. L. Karkeek, Joseph Fall, Thomas Cole, Thomas Cuddeford, J. C. Galton, and H. D. Dodd, of St. Bartholomew's Hospital. William Nuttall, G. S. Madeley, Joseph McWilliams, W. H. Carruthers, and Robert Lephton, of Manchester; Robert Hullah, St. Thomas's Hospital; S. H. Woodgates, Westminster Hospital; S. T. Taylor, St. Mary's Hospital; T. H. Burdett, Birmingham; Joseph Westmoreland, Leeds; Frederick Turner, Sheffield, and J. M. Moore, Edinburgh.

The following passed their Primary Examinations on the 4th inst., viz. :—

Messrs. G. J. Muriel, A. B. Fry, J. H. Croft, George Birch, A. E. Fludery and Francis Lett, Students of Guy's Hospital; T. S. Gell, Robert Aldren, J. M. Gordon, G. F. Fulcher, and D. W. Robertson, of Edinburgh; W. R. Rule, G. H. Dodsworth, and A. J. Leggatt, of St. George's Hospital; H. B. Forward and Horatio Wood, of Birmingham; Joseph Kirk and T. H. Broeklehurst, of Manchester; C. E. Proctor and G. H. P. Evans, of St. Bartholomew's Hospital; C. F. Lethbridge, University College; J. K. Hyland, Dublin; Robert Barker, Newcastle; W. O. Withers, King's College; and A. A. McClure, New York.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, April 28, 1864 :—

Thomas Edward Blick, Islip, near Oxford; William Henry Sutcliffe, Manchester.

The following gentleman, also on the same day, passed his First Examination :—

David Howell Thomas, St. Bartholomew's Hospital.

The following gentlemen passed their Preliminary Examinations in Arts, and received Certificates of Proficiency in General Education, on April 29 and 30, 1864 :—

Dacre Fox and James Tudor Phillips, certificates of special proficiency. A. J. Baker, Whiteheads-grove, S.W.; Thomas Budd, Brockham, Surrey; Alfred Cuff, Camden-road Villas; H. W. Polwell, 55, Gloucester-street; Dacre Fox, Stowmarket, Suffolk; Thomas W. Gower, Rochford, Kent; John George Hurford, 17, Nelson-square; Albert Ellis, Fairford, Gloucester; William A. Kibler, Hackney; Edward Rodolph Luard, Rathbone-place;

Albert M'Cann, Parliament-street; Richard Alfred Morrish, Ledbury; H. R. Moullin, Guernsey; Robert A. Painter, Shoreditch; Michael Perry, St. Bartholomew's Hospital; James Tudor Phillips, Newcastle, Emlyn; Robert Sheffield, Swallows-gardens; Charles B. Sweeting, Nassau, Bahamas; Thomas Charles Thorniercraft, Faversham; Frank Sextus Tuck, Seaford; Richard L. Wilson, Uppingham; Thomas Wilson, Manchester; John Skilbeck Wood, Wakefield; Edward Young, Hawkhurst.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- ADAMS, M. A., M.R.C.S. Eng., has been elected Honorary Surgeon to the Kent County Ophthalmic Hospital, Maidstone.
- ATKINSON, HARRY LEIGH, M.D., Melbourne (formerly Resident Surgeon), has been elected Honorary Surgeon to the Bendigo Hospital, Sandhurst, Victoria, Australia.
- HAINES, RICHARD WHEELER, M.R.C.S. Eng., has been elected House-Physician to King's College Hospital.
- HEAD, HENRY H., M.D. Edin., has been elected Physician to the Adelaide Hospital, Dublin.
- KEMPTHORNE, HENRY LAW, L.R.C.P. Lond., has been elected Resident Accoucheur to King's College Hospital.
- PHELAN, WILLIAM B., L.R.C.P. Edin., has been appointed Medical Officer to the Kilmoganny Police and Military.
- RICHMOND, SYLVESTER, M.R.C.S. Eng., has been elected House-Surgeon to King's College Hospital.
- TAGGART, JOHN, M.D. Edin., has been elected Medical Officer to the Antrim Union Workhouse, Antrim.

DEATHS.

- BOLLAND, JOHN, L.R.C.P. Edin., at Gardiner's-place, Dublin, of Daventry, Northamptonshire, on April 25, aged 26.
- COOKE, CHARLES TURNER, M.R.C.S. Eng., at 26, Cambray, Cheltenham, on May 1, aged 70.
- COOPER, HENRY RALPH, M.R.C.S. Eng., at Ixworth, Suffolk, on May 2, aged 49.
- CURTIS, JOHN WRIGHT, M.D. Edin., at Alton, Hants, on April 27, aged 50.
- KELLY, JAMES, M.D. Edin., at 4, Pembroke-street, Liverpool, on April 1, aged 70.
- KELLY, JOHN, M.D., at Notting-hill, on April 30.
- PARETT, JAMES, M.R.C.S. Eng., at Bartholomew-terrace, Dover, on March 13.

LAVAL UNIVERSITY, QUEBEC.—The honorary degree of Doctor of Laws has been conferred upon Dr. Gibb, of Portman-street, by the Council of this University.

ST. ANDREW'S UNIVERSITY GRADUATES' DINNER.—The St. Andrew's University Graduates' dinner was held at the London Tavern on Tuesday, and was a marked success. Nearly one hundred graduates were present, and amongst the guests were Lord Campbell, Dr. Brady, M.P., Alderman Sydney, M.P., Dr. Allen Thomson, Mr. Robert Chambers, Mr. Mandy, Colonel Ogilvie, Mr. Glaisher, F.R.S., Mr. Erasmus Wilson, F.R.S., Professor Gamgee, Mr. Knight, Mr. G. Clarkson Stanfield, Mr. Winwood Reade, Dr. Gardiner Hill, Mr. Clarke, etc. Dr. Richardson occupied the chair. There were also present many eminent provincial graduates, amongst whom we noticed Dr. Day, of Stafford; Dr. West, of Alford; Dr. Ogden Fletcher and Dr. J. Shepherd Fletcher, of Manchester; Dr. Skinner, of Liverpool; and Dr. Davies, of Stafford. The chairman, in proposing the toast of the evening, "Success to the University of St. Andrew's," described in rapid review the lives of the eminent men who had adorned the University—viz., Cardinal Beatson, Arthur Melville, John Knox, Thomas Chalmers, Lord Chancellor Campbell, J. Napier, inventor of the system of logarithms, Adam Fergusson, Lord Elgin, introducer of the Elgin marbles, Lord Erskine, and, amongst Medical men, Arbuthnot and the immortal Jenner, to whom the chairman paid an earnest tribute. The toast was received with great enthusiasm. After the toast, a presentation was made to Dr. Day, of St. Mary Church, Torquay, the late eminent Chandos Professor in the University. The testimonial, which was extremely handsome, bore a suitable inscription, intimating that it was presented to him by 158 graduates, in token of their admiration of his labours in literature, science, and Medicine, and in special recognition of the services he had rendered to the University during his fourteen years of office. The Chairman expressed his deep regret that Dr. Day, owing to the impaired condition of his health, was unable to attend, and expressed a hope that the offering now made to him would be a constant source of happiness and usefulness. He would find in the richly-carved cabinet before the meeting the illustrated edition of the "Règne Animal" of the illustrious Cuvier—a work which would bring the whole of the animal kingdom within his reach, and would grow more

valuable with age. He concluded by proposing health and long life to Dr. Day—a sentiment that was most heartily received. Dr. Day, of Stafford, in a speech marked by much good feeling, taste, and eloquence, received the testimonial on behalf of Professor Day. In addition to the above-named toasts, the usual loyal toasts were proposed, as well as "The Army, Navy, and Volunteers," responded to by Colonel Ogilvie; "The Houses of Lords and Commons," responded to respectively by Lord Campbell and Dr. Brady, M.P.; the "Chairman" by Dr. Day, "The Medical Council of Education" by Dr. Dobell, responded to by Dr. Allen Thomson; "Success to Literature," responded to by Mr. Robert Chambers; "The Fine Arts," proposed by Mr. Chambers, and responded to by Mr. G. Clarkson Stanfield; "Science and the Learned Societies," proposed by Dr. Semple, and responded to by Mr. Glaisher; "The Bar," proposed by Dr. Edwards, and responded to by Mr. Knight; "The Vice-Chairman and Committee," proposed by Mr. Erasmus Wilson, and responded to by Dr. Paul; and "The Ladies," proposed by Dr. Sedgewick, and responded to by Mr. Winwood Reade. Taking it altogether, the first dinner of the University of St. Andrew's will not soon be forgotten. The music, under the direction of Mr. Land, was admirably sustained by Mr. Kennedy, the Scottish vocalist, and Miss Eyles, and all the arrangements were in excellent and classical taste.

FOOD FOR DIABETES.—Mr. Blatchley has sent us some biscuits of almond, and of almond and bran, as food for the diabetic in place of wheaten bread. They were introduced by Dr. Pavy, and composed chiefly of sweet almonds and eggs, with a small portion of very fine washed bran. The small quantity of sugar in the almond is removed by water. They look nice, smell nice, and taste nice, and if there are any amongst our readers who do not object to a fattening food, they will find them a good accompaniment to a bottle of dry sherry.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

- Medicus.*—We believe them to be legally qualified.
- B. Anxious.*—Apply for information to the Secretary of the Pharmaceutical Society.
- E. B.*—We know nothing of the statement said to have been drawn up by Dr. Stenhouse, nor by whom it was signed.
- Q., Greenwich.*—One friend selected by each disputant, with a third as umpire, would be a far better court than twenty or thirty summoned to a quasi-public meeting.
- The Seaside Convalescent Institution.*—When Dr. Finkel next makes up his catalogue of Poet Physicians, he must include the name of Dr. Henry G. Wright, whose song, "The Breeze that Blows over the Sea," set to music by Frank Mori, was received with great applause at a concert given on behalf of the Seaside Convalescent Institution.
- Mr. Tyler, the Professor of Gymnastics, has lately given a course gratuitously to the boys of the Curzon Schools, Mayfair, and now, we believe, intends to form a class for children of the higher orders at the same place. The system seems easy to learn and agreeable to practise; it involves no heavy weights nor straining efforts, and we believe deserves the encomiums passed on it by the Association of Medical Officers of Health.
- Sir William R. Wilde's lecture on Ireland, Past and Present, is one of the ablest and most eloquent productions of its distinguished author. The sketch it gives of the early ethnology of Europe in general, and of the early population of Ireland in particular, and of the circumstances which affect the food of the people, and of their prospects, is truly admirable. There is all the enthusiasm of the Irishman and the antiquarian, mingled with the utmost good sense, prudence, and political foresight. We hope to see it published in a separate form.
- A Correspondent* directs our attention to the *St. James's Medley*, a monthly shilling magazine of the superior class. It may interest our readers to learn that it contains a capital paper on the geological formation, the scenery, and natural history of the Sussex coast, under the title of "A South Coast Ramble," signed with the initials of a well-known and accomplished Practitioner at Brighton—W. E. C. N.; also a very good scientific summary, and one of a series of papers purporting to be the Professional Reminiscences of Dr. Peregrine, although it is doubtful if a well-known and popular member of our Profession be the author. In this paper he gives us a chapter on Knots; all the puzzles, and complications, and problems of life are compared to knots. "To disentangle hard knots there must be three requisites—good eyes, good sense, and good temper. For the nature of the minutest knot that ever was made in this life is to have two sides to it, and if you can get hold of these you can pull them apart. But to get hold of them you must see them." "Next,

there must be good sense to determine how to undo it; and lastly, there must be good temper to undo it gently." So says a pattern monthly nurse.

BINIODIDE OF MERCURY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In Dr. Sadler's communication last week upon the external use of biniodide of mercury, he states that "he has not seen any reference to its power in reducing glandular and other tumours in the human subject." I take the liberty of directing his attention to an article published in the *British and Foreign Medical Review*, by Dr. Forbes, in the April number of 1845, p. 518. It is too long to be transcribed here, and too good to be curtailed, but if he will refer to the original it will repay him for his research. I would not thus have taken the liberty, but seeing that Dr. Sadler is interested, and with good reason, in the subject, and as the gratification both of receiving and imparting information upon professional subjects is reciprocal, I feel sure that he will impute to me none other than the right motive.

Gringley, April 29.

H. RAYNES.

BINIODIDE OF MERCURY IN BRONCHOCELE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In a recent number of the *Medical Times and Gazette* Dr. Sadler, writing of the value of the external use of the biniodide of mercury in glandular swellings, recommends sixty, or at the least thirty, grains of the salt to the ounce of simple ointment.

I have found the biniodide of great value in the treatment of bronchocele, but I trouble you with this note not so much to say so as to warn those who have not tried it against using so large a proportion of mineral. It will be found that, if genuine, ten grains of the biniodide to the ounce is as much as the skin of female necks will bear.

HENRY CASTLE, M.D.

Newport, I.W., May 2.

THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I hope for the honour of the Medical Profession that the advertisement of the Director-General in *Lancet*, April 30, will receive but few replies. That advertisement is a great injustice to the present Army Medical officers, as, in the first place, they will of course be sent abroad, whether their turn of foreign service has come or not. In the second place, the admission of men without examination to enjoy the same rank and pay is a downright insult, and will tend to degrade the commissioned Medical officers in the eyes of their combatant brethren. So the result will be that numbers of the present Assistant-Surgeons will resign, rather than go abroad or be put on the same footing with those youths of 40 holding no commissions, who are neither civilians nor soldiers. They will be permitted to wear the uniform, which will cost them a trifle, and buy furniture for their quarters, and perhaps after a few months will receive notice to quit, and again be thrown on the world with their forty years' experience.

I am, &c.

F.R.C.S.

MORTALITY OF SCARLET FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your review of Mr. Chavasse's work, appearing in your Number for April 16, occurs the astounding statement, being a quotation from the above-named gentleman's work, "that he had not lost more than one case of scarlet fever during the last fourteen years."

This, indeed, could we accept the statement as being the whole truth, is an amount of success very much to be envied. I have not by any means an extensive practice, yet, on looking over my books for half the period Mr. Chavasse speaks of, I find I have given certificates of death for fifteen cases of scarlet fever. I have tried the ammonia treatment, and the acid treatment, cold affusion, and, I suppose, nearly every other treatment that has been suggested in this disease, and all I have seen of it tends but the more to convince me that, in spite of every means that may be adopted, a large proportion of the bad cases will die. And I think I am not wrong in saying that this will accord with the experience of your readers in every part of the kingdom.

I hope Mr. Chavasse will favour the Profession with the number of cases he has seen of this disease, or even with an approximation to it, and say whether, in recording his unparalleled success, he omits scarlatinal dropsy and the other sequela which are found so frequently fatal in the hands of the best Practitioners.

Newcastle-on-Tyne.

A NEW METHOD OF TREATING FRACTURE OF THE CLAVICLE.

By THOS. DOWNIE, M.D., etc.

When the clavicle is fractured, the fracture generally takes place at the centre of the bone, especially when caused by indirect violence, such as a fall on the shoulder or arm, or pressure from opposing forces coming in contact with the shoulders. In 1852, I had under my care an example of fracture of the clavicle from the latter cause in a boy, 12 years of age, who had both clavicles fractured by a cart, his shoulders being squeezed between the wheel and a wall. The clavicle may also be fractured by direct violence, such as a kick from a horse, or even a blow from a man. When fracture is the result of direct violence, the fracture may, of course, take place at any part of the bone.

In March, 1861, I had a young man under my care for a fractured clavicle got in a brawl, another man having dealt my patient a severe blow on the left clavicle; the blow knocked my patient down, and, as he is of opinion, fractured the clavicle at the same time. Be this as it may, the fracture being situated near to the acromial extremity of the bone proved extremely troublesome, on account of my not being able to get the fractured ends of the bone to remain in contact by any of the ordinary appliances. Do what I liked, the acromial portion of the fractured bone would continually tilt away from the sternal portion, till I hit upon the following plan:—I put a large strengthening plaster on the chest and another on the back, directly opposite each other, placing them lengthwise from the clavicle downwards. Above these I placed a bandage ten inches in breadth, and made it as tight as the patient could bear. A piece of strong bandage cloth three inches in breadth was then stitched to the upper ends of the plasters and bandage, and was left so loose that a pad could easily be got under it. A pad was then placed in the axilla, and the shoulders strapped back by a figure of eight bandage in the usual way; the fractured ends of the bone were then accurately brought together; a firm pad placed over them, and kept in its place by the left hand. A small wooden peg three inches in length was then slipped under the cross bandage, right above the centre of the pad, and twisted till the bandage exerted such an amount of pressure on the pad as kept the frac-

tured ends of the bone *in situ*. The pad used was a piece of wood three inches in length by one in thickness; the ends of the upper surface were bevelled off to within an inch of the centre, the centre of the under surface was hollowed out; the piece of wood was then enveloped in calico, and the under surface padded with cotton wool. Every second day the wooden peg got a twist or two, in order to keep the pad firm. By these means the fractured ends of the bone were kept accurately together, and although eight days had elapsed before they were brought into operation, an excellent cura was effected.

I would suggest that this form might be tried in cases of dislocation of the acromial extremity of the bone; it is possible that it might take the opportunity off our heads of not being able to do anything for this dislocation.

Blantyre, April 26.

APPOINTMENTS FOR THE WEEK.

May 7. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Frankland, "On the Metallic Elements."

9. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

UNIVERSITY COLLEGE, LONDON, 3 p.m. Distribution of Prizes.

10. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. John Crawford, Esq., F.R.S., "On the Supposed Stone, Bronze, and Iron Ages of Society." Dr. Donovan, "On Empirical and Scientific Physiognomy as Applied to Study of Races of Man and Individuals."

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Life."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. G. B. Brodie, "Statistics of Queen Charlotte's Lying-in Hospital." Mr. Berkeley Hill, "On the Occurrence of an Additional Muscle to the Subclavius."

11. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.

12. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

ROYAL INSTITUTION, 3 p.m. John Hullah, Esq., "On Music (1600-1750)."

13. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. J. Scott Russell, Esq., "On the Mechanical Use of Gun-cotton."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at two o'clock:—

By Mr. Fergusson—For Amputation of Leg; for Amputation of Foot (Pirigoff); for Secondary Amputation of Leg Below Knee; Lithotritry; for Removal of Warts from Labia.

By Mr. Henry Smith—For Ligature of External Iliac Artery; Lithotritry.

ORIGINAL LECTURES.

LECTURES
ON THE CONSERVATION OF ENERGY.

By Professor HELMHOLTZ.

DELIVERED AT
The Royal Institution
ON APRIL 21, 1864.

LECTURE VI.

LADIES AND GENTLEMEN,—In my last lecture I began to speak on the chemical processes going on in the interior of the living bodies of men and animals. It is one of the greatest advantages in the application of the law of the conservation of force, that we have not to inquire into the intermediate states between the commencement of a process and its final result. The quantity of energy given out during any natural process, for instance, during a chemical process, such as goes on in the bodies of animals, is quite independent of the intermediate states; and we have only to look to the final results, and compare them with the state at the beginning to determine the quantity of energy. During my last lecture I explained what substances are introduced into the body; and we have seen that these substances are taken from the vegetable kingdom and introduced into the animal body nearly in the same state as they are contained in animals themselves, so that no great alteration of the food which is taken in is necessary. Some of the substances of food undergo a process of fermentation, by which they become soluble, but their nature is not much altered. Then we have seen that the oxygen of the air and various combustible substances are taken into the body, and received into the blood, which carries them through the whole organisation by the fine capillary vessels which penetrate to all parts of the body, so that every organ of our body, as far as blood-vessels penetrate, receives its share of combustible food and of oxygen. In the same way, by means of the blood, those substances which are the result of the decomposition going on in the organs of the body are removed. They are in the first instance absorbed by the blood, and by the blood carried to those places where substances can be excreted or removed from the body. Leaving out small quantities of other matters excreted in other ways which are unimportant—their quantity being so small, and excluding those substances which pass through the organism without being received into the blood, the principal places of excretion are the lungs, the skin, and the kidneys.

The lungs remove gaseous substances from the body, and their principal product is carbonic acid, which by respiration is removed from the body. Carbonic acid is already contained in the blood, principally in the venous blood. The arterial blood contains more oxygen than carbonic acid; the venous blood contains more carbonic acid than oxygen. The blood passing through the lungs does not lose its whole quantity of carbonic acid, but always retains a small quantity; and instead of that part which is given off, it receives oxygen from the air. In the last lecture we saw that blood taken out of the body, and shaken with oxygen or carbonic acid, takes in these gases, and gives off those gases which it contained before. By far the greater part, more than nine-tenths, of all the carbon which is used in our organisation is carried out by the lungs. It can be shown very easily that a great quantity of carbonic acid is carried out through the lungs. If I blow the air which I expire into this solution of hydrate of baryta, which, as you see, is quite a clear fluid, you will see how swiftly this solution becomes opaque by the deposit of carbonate of baryta. [Experiment.] By far the greater part of the carbon, therefore, is exhaled by the lungs, although we do not see anything of this exhalation; indeed, the greatest loss of solid substance which our body produces continually goes on through the lungs in the form of invisible gases. The quantity of carbon exhaled by the lungs in the course of twenty-four hours is half a pound, if the man is in a state of complete repose. If great bodily exercise takes place, this quantity can be increased to more than a pound or a pound and a quarter during the twenty-four hours. We lose a small quantity of carbonic acid by the skin, also water, and some solid substances. The nitrogen which is taken in into the body is removed by the kidneys in the form of urea. The chemical composition of this substance is $2C, 2N, 4H$, and $2O$.

It contains a very great quantity of nitrogen—the same equivalent as of carbon. It is the substance of our body which is the richest in nitrogen. The presence of urea in the blood can be proved, although its quantity is very small; and we may infer from this that it is produced in the organs of our body, absorbed by the blood, and carried out afterwards by the kidneys. The minimum quantity of nitrogen necessary to sustain life is one-twentieth the quantity of carbon. 240 grammes is the minimum of carbon which must be exhaled by the lungs, and 10.5 grammes the minimum of nitrogen which must be given out from the body in twenty-four hours if life is to be sustained in a healthy state. You see, therefore, that the quantity of carbon exhaled is more than twenty times that of the nitrogen. Therefore, you see that our body takes in combustible substances and oxygen. When we look only to those substances which are carried out in great quantities, it loses carbon in the form of carbonic acid, hydrogen in the form of water, and nitrogen in the form of urea. Urea is a substance very soluble in water, as I said before, and the watery solution of it is very soon decomposed into carbonate of ammonia; so that those watery excretions of our body which contain urea are decomposed afterwards, and the urea converted into carbonate of ammonia. Now you see that from the life of animals those combinations are produced which plants want to receive as food. Plants live on carbonic acid, water, and ammonia. In place of ammonia nitric acid may be substituted, or combinations of nitric acid, which are easily produced from ammonia. So you see that while animals take in these combustible substances of complicated composition which are produced by plants, they, on the contrary, give out those simpler combinations which are the food of plants; therefore, the final result of the chemical processes going on in the animal body is that, instead of free oxygen and combustible substances which are taken in, carbonic acid, water, and ammonia are given out.

Now we must ask what quantities of energy are produced by the body. We have to look, in this case, only to those quantities of energy which are given out by the body, not to those which are used in the interior of the body without having any effect in the external world; because, if motions are going on in the interior of the body, like the motion of blood, and if these motions are destroyed also in the interior of the body so that they cannot have any external effect, then the destruction of their mechanical power must necessarily produce heat, and the quantity of energy which they produce can come to the external world only in the form of heat; therefore we have only to look to those quantities of energy which the living bodies of men and animals give out into the external world. Now we have first heat as the effect of animal life; at least, the bodies of men, of mammalia, and birds are always of a higher temperature, as everybody knows, than the surrounding parts of nature. It can be shown that this is the case also with cold-blooded animals; though their temperature is very low, it is not much different from the temperature which a body wetted in the same way as the surface of these animals would have, under the same temperature of the surrounding air or water.

All living animals give out continually greater or smaller quantities of heat; besides, they produce mechanical effects. Let me speak at first of the mechanical effects which they produce, and afterwards of the heat. All the mechanical effects which the higher classes of animals produce, are caused by the contraction of muscles. Muscles are those parts which we call flesh in common life. The muscles are elastic ligaments of a red colour. You all know that flesh is composed of fibres; these fibres are muscular fibres fixed with their ends to the bones with the aid of tendons, and the whole muscle can be considered as an elastic ligament. Indeed, the degree of elasticity is very similar to the elasticity which an India-rubber ligament would have under the same circumstances. But the elasticity of the living muscles has one important peculiarity, namely, its intensity can be augmented or diminished. Now we have seen already that there are several such cases in which the elasticity of an elastic body can be augmented or diminished; and we have seen that the law of conservation of force can be consistent with these cases only when the diminution of elasticity is produced by some other natural process, by which a quantity of energy is destroyed or applied to the elastic body. I have spoken, in the first lecture, of the elasticity of air and of steam, and we have seen that the addition of heat to air or steam increases the elastic force, and that, in such a way, we can vary the intensity of the elastic force, and by this varia-

tion of the elastic force we produce a great amount of work ; indeed, the steam-engine works by the force of such elasticity. Now you can observe the change of the intensity of the elastic force of our muscles very easily. If you put your hand on the muscles of your arm, as long as the arm is in repose they are quite soft and yielding ; but if you make an exertion with the arm, raising a weight perhaps, you will feel that the muscles which raise the arm become tense and hard. We must ask if this change of elasticity of the muscles is connected with any other natural processes going on in the muscles, processes of such a kind that energy can be given to the muscles. We know that such processes exist. We can prove that a constant development of electricity takes place in the muscles, and that electricity undergoes a peculiar alteration when the elasticity of the muscles is altered. Then we can show that chemical processes are going on in the muscles while they are contracted, and that heat, at last, is developed. I will show you first the electrical effects of the muscles, which subject has been principally investigated by Professor Du Bois Reymond, of Berlin, who has lectured in the Royal Institution. I will show you some of his principal experiments, because they have not been often made in England, and probably the greater number of you have not seen them. I have here two platinum plates, dipped into two vessels filled with salt water. I can connect the platinum ends with a multiplier. The plates are separated, and between them are two wetted pieces of paper, on which is a little cotton pad also wetted with the salt water. The whole circuit is sufficiently free from motive forces, so that if a muscle laid upon these plates produces a current, we shall be sure that the electro-motive forces which produce the current are resident in the interior of the muscle. I have some pieces of muscles taken from a frog which I have killed before the beginning of the lecture. I take a piece of the muscle of the leg, lay it across the cotton, and you see the needle of the multiplier is moving. [Experiment.] The muscle is cut with the fibres separated in a transverse direction, and if I turn the muscle in the opposite direction you see the needle moves in the contrary direction. (Experiment.) You see, therefore, that we have here an electrical effect produced by a piece of muscle which has been separated from the animal more than half an hour. This electrical effect, the so-called muscular current, is produced by living muscles, and by muscles of dead animals as long as they retain their irritability,—as long as they can contract. Now, I take another muscle with a tendon connected with it, and I will put it upon these pieces of cotton. This muscle has no transverse section, but ends where the tendon is attached, and so the current is not quite so strong as it was before. [Experiment.] The frogs are very small, and the muscles do not produce the same effect as they would do if they were larger. To show you the irritating effects of electricity, and to show that the elasticity of the muscle is altered in this way, I will connect another muscle with this lever, and you will see that if I connect the muscle with the induction apparatus, and set it to work, the muscle will contract and raise the lever. [Experiment.] Every electrical discharge brings forth a contraction of the muscle ; and if I bring the apparatus into continuous effect, the muscle remains contracted. I will put another piece of nerve upon two pieces of platinum connected with the induction coil, and the muscle upon the electrodes of the galvanometer. As soon as I irritate the nerve by the currents of the induction coil, the muscle contracts, and you have a new electrical current which deflects the needle. [Experiment.] You saw the muscular current at first deflected the needle, and then it returned to its position of equilibrium under the influence of the galvanic polarisation of the platinum plates ; and when I irritated the nerve of the muscle, the needle went in the other direction, showing that an alteration of the current was produced. It is not only a constant current going in an opposite direction, but it can be shown that a great number of electrical discharges take place during this state of the muscle, and that the muscular current is in a continuous state of oscillation, so that it acts upon other nerves which are brought under the influence of the muscular current, quite like the electric organ of an electrical fish. Therefore we see that the contraction of muscles is accompanied by electrical currents, and Dubois has proved that every contraction of the muscle and every irritation of the nerve is connected with peculiar alterations of their electrical effects.

Secondly, I told you that heat is produced during the contraction of muscles. It was proved by Messrs. Becquerel and

Breschet, by means of the thermo-electrical apparatus, that the temperature of the muscles is raised. They made a little apparatus, a peculiar form of thermo-electric pile, the points of which could be introduced into the living muscle. Breschet found that if the muscle was contracted it became warmer ; he found a rise of temperature of one degree. Now, it was doubtful if this increase of temperature in the muscle of a man was produced by an effect of the muscle itself, or whether it was produced by a greater velocity of the flow of blood through the muscle ; and therefore I repeated these experiments on the muscles of frogs which were dead, and in which the circulation of the blood had stopped. I found the same effect there. The muscles of a dead frog even, as long as they retain their irritability, become warmer when they are made to contract. Messrs. Billroth and Fick, in Zurich, have made very important observations on the heating of muscles. It was observed that the temperature of such human bodies as died from tetanus was peculiarly high. The common temperature of the blood of the interior of our body is 38° Centigrade. In feverish states it rises sometimes to 40° to 41°, but if it gets to that height, the death of the patient is probably not far off. Now, in such cases of tetanus the temperature rises even to 44°. We can produce tetanus, as you have seen here, on frogs and also on the bodies of recently killed warm-blooded animals ; and Fick found that this heat was produced by the muscles alone, that the muscles were hotter than the remainder of the body. So that the great heating power of the muscles was demonstrated by these experiments, and proved to be much higher than it had been known hitherto.

Then I told you that chemical processes are going on in the interior of the muscles. I had an idea at first that it must be so, and I tried to find the decompositions when I was a student. Physiological chemistry was not very far advanced at that time, and I could only find that the quantity of those substances which are soluble in alcohol is increased during the contraction of the muscles ; and, on the contrary, those peculiar substances of the flesh which gives the peculiar taste and the peculiar power to beef-tea,—those substances soluble in water were diminished by the contraction. Afterwards my friend, Du Bois Reymond, found that, during the contraction of muscles, the watery fluid with which they are wetted becomes acid, and that lactic acid was formed during the contraction of muscles. This agreed with my former experiments, in so far as the combinations of lactic acid are all soluble in alcohol. But a far greater amount of decomposition becomes perceptible when we look to the quantity of oxygen contained in the muscles themselves, and in the blood which is carried through the muscles. Some new investigations of Professor Ludwig in Vienna, and several of his pupils', show that the arterial blood which is carried through a muscle in the state of contraction is almost completely deprived of its oxygen. When this blood is carried through a muscle which is not in contraction, so that it becomes venous blood, the quantity of oxygen remaining is commonly $7\frac{1}{2}$ per cent., a little more or a little less ; but if the muscle through which the blood is carried is thrown into contraction, then the quantity of oxygen is diminished sometimes to $1\frac{3}{10}$ per cent. ; therefore nearly the whole quantity of oxygen which is contained in the blood is lost when the muscle is contracted, and remains in the muscle, being chemically combined with the substance of the muscle. These are the results of physiological experiments relating immediately to the muscles themselves. But we find the consequences of this very swift decomposition going on in the muscles during their contraction in the air which is expired ; for when the muscles require to have so much more oxygen during their contraction, of course we must take in that oxygen by our lungs, and a corresponding, or nearly corresponding, quantity of carbonic acid is exhaled during that time. Very important researches on the change of respiration, and the chief products of respiration produced by exercise of the muscles, have been carried out during the last few years by your countryman, Dr. Edward Smith, of London. He has constructed an apparatus for measuring the quantity of air inhaled, and the quantity of carbonic acid exhaled, by the lungs of men. It is one which can be easily carried about, and he was able to take it with him in travelling, and going up mountains. He has also used it while working in the treadmill. The treadmill has lately become a physiological instrument of great importance, because it is the most convenient place for producing great exercise of muscle, while the person always remains at the same spot, so that one can very easily connect the mouth or nose with apparatus for ascertaining the amount of inhalation. I have here a little portable gas-meter, constructed after the plans

of Dr. Edward Smith, which is for measuring the quantity of air inhaled. It contains nothing but a little leather bag, which moves up and down, and you see how this moves when I inhale through the apparatus. [Experiment.] There is a system of little wheels, which show the quantity of air inspired. The whole instrument is so light that one can carry it in going up mountains and so on, and here is an apparatus for condensing the whole quantity of carbonic acid which is exhaled during some hours by the lungs of a man. It has in its interior a quantity of little cellules connected one with the other, so that the air which goes into one of these apparatus is obliged to go through the whole length of these cellules, which are partially filled with a solution of hydrate of potash. The oxygen of the air is by that means taken away, and the fluid in which the carbonic acid is contained, combined with potash, may be investigated chemically, and the quantity of carbonic acid ascertained. This apparatus is very small, so that it can be carried to all places, and is capable of receiving the whole quantity of carbonic acid which is expired during several hours. By these researches we have ascertained the actual qualities of carbonic acid which are exhaled during a long period. All the former experiments were made on too small a scale, and the quantities of the products of respiration were too minute to give any correct calculation for any long period. Dr. Edward Smith has sometimes continued his investigations on the amount of carbonic acid during twenty-four hours, both waking and sleeping, for at last, by practice, he was enabled to breathe through this apparatus while he slept. Now, the great change which goes on in the rate of respiration during muscular exertion is evident to observation without any apparatus. You know that when you go up a mountain where you must raise the great weight of your own body, you get into an intense state of respiration, and the circulation of the blood is made swifter than it was before. I have tried such experiments myself. I found that when awake, and in a state of repose during the day, I inspired nineteen times in a minute. Going up a mountain as fast as I could, I increased the rate of respiration to fifty times in a minute. The number of pulsations of my heart was seventy in the minute in a state of repose, and they were increased to nearly 200 when I was in a state of bodily exertion. The results of Dr. Smith's investigations show even a still greater increase of respiration; so that during great exertion the quantity of carbonic acid exhaled by the lungs becomes five times as much as it is during a state of repose during the day, and ten times as much as it is during the night when you are sleeping. There is, therefore, an immense increase of respiration; and the increase of the chemical processes is, indeed, far greater than the external signs of this increased respiration given by the pulsation of the heart, and the number of inhalations. You see, therefore, that no mechanical power can be developed by our muscles without a great increase of chemical processes. A very important question connected with this fact is, How much of the chemical intensity of the chemical energy of the decomposition of our body is converted into mechanical power? When the body is in complete repose, and it is fed in such a way that its weight and its composition remain unaltered, there is neither increase nor diminution of weight; in such a case the whole work given out by the body is only heat—no other form of energy, if the body is reposing; and the quantity of heat which can be given out by the body must be equivalent to the quantity of chemical energy which is destroyed by the conversion of the combustible substances of our food. We cannot directly determine the quantity of heat which could be produced by the change of food and oxygen into carbonic acid, urea, water, and some other substances which the body loses, as the hairs which fall out, and so on; but we could burn these other substances, so that they also are converted into carbonic acid, water, and ammonia. Now, let the quantity of food and the quantity of oxygen taken by a man or by an animal be combined in the living body, and suppose that those substances which are given from the body, and which are not completely burnt, may afterwards be burnt by heat in an open fire, then you will have all the food converted into carbonic acid, water, and ammonia. You can take the same quantity of food and the same quantity of oxygen, and burn it directly in an open fire, and then you will get the same quantity of carbonic acid, of water, and of ammonia, as before; and therefore the whole quantity of energy produced by these two processes must be the same, according to the law of conservation of force. We can conclude from this that in a state of repose the quantity of heat developed by

the human body must be like the difference between the heat of combustion of the food introduced and the heat of combustion of the excretions. Experiments on the amount of heat produced in the living bodies of animals have been performed by two French physicists—Messrs. Dulong and Despretz—who have found that the quantity of heat developed in the living body is equal to the heat of the combustion of the food. They have proved it, as far as it was possible to calculate the heat of combustion at that time. They themselves say, indeed, that the heat of combustion was not completely as great as the heat given out by the living body; but they have used for the calculation a theoretical rule which is nearly, but not completely true. I cannot go into the details of this calculation, I have explained this in a paper written on animal heat. It may be concluded from these experiments that, as far as the accuracy of the calculation of the heat of combustion allows us to judge, the quantity of heat developed in the interior of the body is the same as the heat of combustion. When work is being done by the human body, then this work must be done at the expense of a part, at least, of the heat given out by the body. We have no cooling of the body, because, during the contraction of the muscles, the intensity of the chemical processes is so very much increased that even more heat is produced than during the state of repose; and, according to the investigations of Dr. Smith, it is increased to five times as much as it is in the state of repose. We can calculate, from the experiments of Dulong and Despretz, who found how much heat was developed during a certain state of respiration in some animals, how much the human body would be heated during one hour by the chemical processes going on in its interior. I found that this quantity during one hour is about $1\frac{2}{10}^{\circ}$ Centigrade. This heat of the body would be equivalent to an elevation of its weight through 1760 feet, according to the mechanical equivalent of work done. If we exercise ourselves very much we can attain that result within an hour, but the exercise is rather severe. We find, therefore, that the work done in a state of great exertion is equivalent to the heat developed during a state of repose; and, therefore, of the whole work done by chemical actions, which is, as we have said, five times as great as during the state of repose, one one-fifth of the heat is equivalent to the work which can be done, and four-fifths are really converted into heat, and give the greater quantity of heat which is produced in the body. We find that the amount of energy produced by burning the fuel of a steam-engine which can be converted into heat, is only one-tenth part of the whole, and that nine-tenths are the least proportion which is converted into heat and is destroyed and lost. Therefore, the muscles of our body do not waste so much energy as our best artificial machinery. In fact, it can be shown theoretically that it is not possible to construct steam-engines which can convert a greater quantity of heat into mechanical power. This relation becomes still more astonishing when we consider one of the organs of our body—the heart—which is peculiarly adapted to long-continued exertion. The heart contracts continuously during our life, and presses blood into the arteries. In the arteries the blood has to resist great pressure, and the work which is done by the heart can be calculated. We will suppose that, instead of pressing blood into the arteries, this mechanical energy of the heart should be converted into such a form that the weight of the heart should be raised to a certain elevation; we should find that the human heart raises its own weight during one hour 20,250 feet. Steam-engines, which are able to raise weights to a great height, are used on those railways where the gradients are very steep, and also for going over mountains. When the railway was constructed from Trieste to Vienna, the constructors of steam-engines were asked to build engines the best adapted to raise the weight of a train up a great height. The prize engine was the Bavaria. This machine has power to raise its own weight during one hour 2700 feet. You see, therefore, that the mechanical power of the human heart when compared with its own weight is more than eight times as great as the mechanical power given by the best constructed steam-engines peculiarly adapted to raise the weight of trains. In this way, the mechanism of our muscles surpasses in its effect all our artificial machines which have been constructed hitherto; and the power of flying, which birds and insects possess, is really only possible by the great power which these very light organs, the muscles, develop by their contraction, so that we shall be able to construct flying engines only when we can produce as much power from as small a weight as the living muscles do.

Now I must conclude these lectures. I have been able only

to give a very short survey of the whole matter, but I hope you will have seen how extended the bearings of this law are for all the processes of inorganic and organic nature, and how intimately it is connected with the most important questions which natural science can bring forward,—and there I must leave it. You will have opportunities of hearing lectures and of reading books, by which you will get better and more especial instruction about these things than I have been able to give you.

CLINICAL LECTURE ON FLEXIONS AND VERSIONS OF THE UNIMPREGNATED UTERUS.

By W. O. PRIESTLEY, M.D.,

Professor of Obstetric Medicine in King's College.

(Continued from page 503.)

The *treatment* of these affections is surrounded by difficulties, and often very unsatisfactory in its results. There is, unfortunately, in any case but little tendency to spontaneous cure, and yet injudicious and inappropriate interference is very likely to be followed by aggravation of the symptoms. In some instances we can scarcely hope to do more than palliate the symptoms as they arise, as, for instance, in those where the displacement is produced by the presence of a fibroid uterine tumour, or by the pressure of an ovarian tumour from above. In speaking of the management of other cases, in which we have more hope of doing good, it is convenient to divide them into two classes—1st, those in which the displacement is associated with some removable morbid condition of the uterus or ovaries; and, 2ndly, those in which version or flexion exists without such complication. The first class comprises the largest number of cases, inasmuch as in a large proportion of instances the displacement results from the upper part of the womb becoming too heavy to be kept upright by its usual supports, and the falling backward or forward is therefore secondary to some morbid change active or passive in its operation which has preceded the alteration in position. The first rule, therefore, for guidance in all instances of displacement where there is uterine enlargement with pain and tenderness is that we should first treat the disease of the uterus, and leave the displacement, as Dr. West expresses it, to take care of itself.

It is true that in some rare cases where congestion and hypertrophy of the uterus co-exist with displacement, we may, by pushing up the fundus with the finger, restore it to its usual position, and it will remain there, the recovery from the other ailments being thus much facilitated. But in most patients so suffering, even if we succeed in rectifying the position of the uterus, the fundus gravitates back again immediately the finger is withdrawn; and the case now under treatment in the Hospital is but a type of others very frequently met with, the uterus being so sensitive that the slightest pressure produces severe pain, and any attempt to lift it up either by the finger or with the uterine sound would be likely to do more harm than good.

The indications, therefore, are to endeavour to relieve the local pain, palliate any distressing sympathetic symptoms, and where it is practicable, to promote the return of the uterus to its normal size and weight, as we do in ordinary cases where no displacement is present. To further these objects in the case I have alluded to, four leeches were applied to the cervix uteri, and ʒj. doses of liq. hydrarg. bichlorid. were given, after the plan recommended by Dr. Oldham some years ago. At the same time the bowels were carefully regulated, and moderate diet allowed, and she was recommended to observe strictly the horizontal posture, a most important part of the treatment in all uterine disease. Notable relief was very soon experienced, and improvement has since gone on steadily. Diarrhœa threatened in ten days after her admission, and the bromide of potassium in ʒ-grain doses was substituted for the bichloride of mercury. I may state that although mercury given in the way I have mentioned is less likely to produce ptyalism than some other modes of administration, and is really most useful, yet it is generally desirable after a time to omit it altogether, and prescribe suitable doses of bromide or iodide of potassium, or of both combined. Another point needing special attention is the management of the menstrual periods. Greater care even than in the interval should be exercised to avert undue congestion, and if any relaxation of

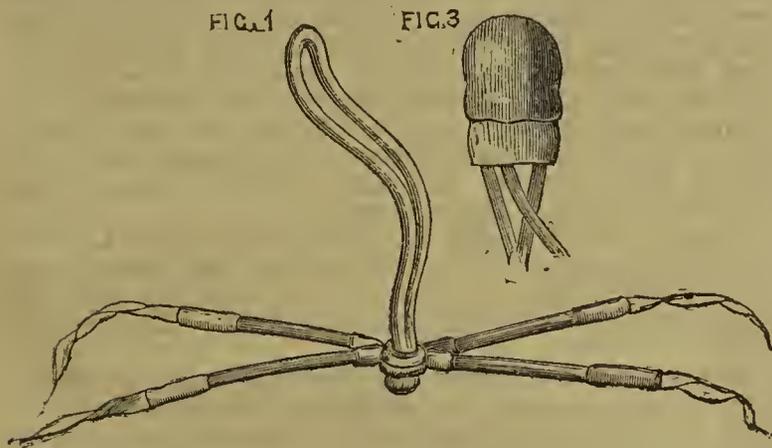

the rules as to getting up has been permitted, the patient should now sedulously keep her bed. If much pain is experienced it may be relieved by a pill containing three or four grains of camphor and a third of a grain of extract of belladonna every three hours, or by an appropriate dose of some opiate preparation. The progress of recovery in such cases is at best tedious, often imperfect, and, so long as the uterus lies in its abnormal position, a rekindling of the more severe symptoms is readily produced by an apparently slight cause. If we succeed in reducing the size of the uterus, and the pain and tenderness disappear, while the displacement yet remains, the case may now be ranged with those of the second class; and this brings me to the question,—How shall we treat instances of uterine displacement without uterine disease? In reply to this, I may state that some patients so circumstanced need no treatment whatever. From time to time instances are met with, perhaps accidentally, where the displacement is so slight as to give rise to little or no inconvenience; or, if the displacement be greater in degree, either the womb itself or the system of the patient is so tolerant of the change of position, that it exists months or years without producing discomfort. The experienced Medical Practitioner cannot, nevertheless, lose sight of the fact that, so long as displacement is present, the womb is much more likely than under the ordinary circumstances to take on any of those morbid changes which are favoured by its circulation being impeded and its functions deranged. In all patients, therefore, where flexion or version is known to exist, he would gladly remove the proclivity to more severe attendant symptoms, which may supervene at any time, and, it may be, at the same time remove the cause of sterility or abortion, by rectifying and retaining the uterus in its proper place, if this could readily be achieved.

Unfortunately, any method of treatment with which we are yet acquainted, and which promises any degree of success, entails penalties and inconveniences on the patient, which we are scarcely justified in subjecting her to, on the mere chance of prospective evils which may never arise. Some of the plans proposed oblige her to relinquish for the time all active occupations and duties, and may thus possibly deteriorate the general health. The use of mechanical expedients necessarily entails frequent vaginal examinations; and with some a risk is incurred of stirring up those very morbid processes which we are anxious to avoid. While, therefore, it is better not to interfere locally where displacement produces no special inconvenience—and this applies more particularly when the patients are unmarried women—the Practitioner cannot be absolved from making no endeavour to relieve those patients who are less fortunate, and in whom uterine deviation without obvious uterine disease entails evil consequences. Wherever flexion or version predisposes to repeated attacks of uterine and ovarian congestion, or inflammation, or gives rise to serious discomfort, and sympathetic constitutional disturbance, whenever in married women, it seems unhappily to be the cause of sterility or abortion, he is, I think, bound to attempt something by way of palliation and cure.

Proceeding on the principle that the least possible local interference which will answer the purpose required is best, we may, in a suitable case of retroversion or retroflexion, begin by restoring the womb to its natural position either by the finger pushed up behind the cervix in the vagina, or introduced into the rectum, or, where the finger is not sufficient, by the sound passed into the uterine cavity. The patient should at the same time be directed to keep the prone posture, or to lie on the side, with the pelvis inclined forwards. In this way we get the force of gravity to aid in keeping the uterus in its replaced position; and if in the movements of the patient it again relapses, we may lift it up from time to time, and gradually accustom the organ to keep *in situ*. Throughout, great attention should be given to improve the general health, to regulate the condition of the bowels, and to remove any undue congestion of the pelvic organs which may arise from an inactive state of the liver. We may employ likewise the cold hip bath, the cold douche into the vagina, or some astringent injection, with the object of giving tonicity to the parts and improving the relaxed condition of the uterine ligaments. The observance of these simple rules will occasionally be quite sufficient to remedy the displacement, and restore the patient to health and comfort, particularly if the displacement be recent or be the result of accident. It must, however, be confessed that the instances in which cure is effected by these means are not numerous. In the majority of cases, the fundus uteri falls back to its abnormal position as soon as

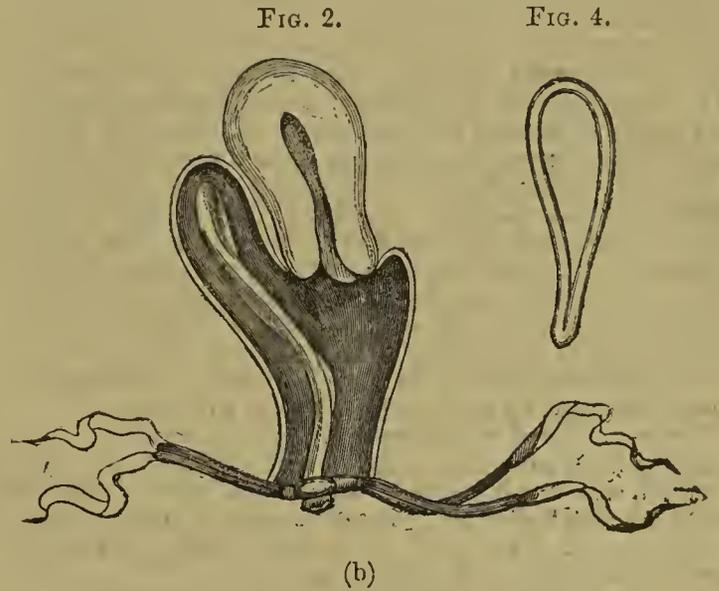

the force which raised it is withdrawn, and a more prolonged and constant use of the prone couch, as recommended by some authorities, while it does not remedy the malposition, injuriously affects the general health. Under these circumstances one naturally turns to the idea of some mechanical contrivance which imitates the finger or sound used in replacing the womb, but which, instead of being a temporary force, may be a permanent support, and at the same time permit, if possible, the patient to move about. With this object various instruments have been invented by Drs. Simpson, Valleix, Detschy, Graily Hewitt, and Routh. Those known as Dr. Simpson's, and described by him in an able memoir in the year 1848, have received the largest share of attention. Dr. Simpson's pessaries consist essentially of a stem to be passed into the uterine cavity, and retained there, either by a base sufficiently large to be grasped by the vagina, or by the union of a wire framework which lies externally on the symphysis pubis, with the base of the stem worn in the interior of the womb. I have seen pessaries constructed on this principle extensively employed both by Dr. Simpson himself and by the late M. Valleix in Paris, and in many cases I have seen notable benefit, result. Much opposition has, however, been raised both in this country and on the Continent to their general adoption; and in a discussion before the French Academy of Medicine ten years ago, the most disastrous consequences were stated occasionally to have occurred. It has not fallen to my lot to witness any results so serious as those mentioned during the discussion alluded to, yet I have sometimes seen much irritation, pain, and hæmorrhage follow the introduction of an intra-uterine pessary, and necessitate its withdrawal. The interior of the uterus in some women is so sensitive that it may be compared with the conjunctiva of the eye,—the slightest touch giving pain; the introduction of the uterine sound being followed by severe suffering, and the retention of an intra-uterine pessary being altogether intolerable. Besides this, the introduction of these supports is not a very easy matter, and their adjustment requires both skill and experience. While, therefore, I should not hesitate to have recourse to an intra-uterine pessary in a suitable case, where other means had been unsuccessfully employed, I prefer commonly to use some support which does not require to enter the uterine cavity, and is therefore less likely to be followed by unpleasant consequences, and to call for a suspension of treatment.

I have found best to answer this purpose a pessary made of gutta-percha, which may have a wire framework, thus rendering it amenable to any alteration of curve which the case requires. The form (Fig. 1) is that of a loop, ending

below in a stem, which projects slightly beyond the vulva, and to this stem elastic straps are attached, which are fastened behind and before to a waistband. The figure is somewhat like the letter S, from which the upper limb has been cut off, the lower limb sweeping over the edge of the perineum. The upper extremity is passed into the vagina and pushed up behind the cervix uteri (Fig. 2), thus raising the fundus and keeping it upright, the elastic thigh-straps retaining it in position without exerting undue pressure. Ordinarily, it is desirable to raise the uterus, and then introduce the support to keep it in position; but this is not always possible, and is not essentially necessary, as the pressure of the pessary will gradually lift up the fundus. My friend Dr. G. de Mussy has suggested that if the upper end were covered by an air cushion, it would not only give more equable support to the uterus, but by filling the space occupied by the reflexed fundus, more effectually counteract its backward tendency. I have, consequently, had a small india-rubber pouch attached to the

top, which can be inflated by an elastic bottle after introduction, and thus fulfil the indications mentioned (Fig. 3). (a) If

rectocele exists as well as retroflexion, or retroversion, the loop of the pessary may be entirely covered over with india-rubber, and it thus answers the double purpose of supporting the uterus and the rectocele. In ordinary cases of retroflexion it is best to dispense with caoutchouc additions, as they are not necessary, and, besides being undurable, provoke more profuse discharges, and produce a greater distension of the vagina. The advantages of this form of pessary are, that it generally produces little discomfort, it distends and relaxes the vagina in the least degree possible, and it permits the patient to take exercise. In most cases, it not only efficiently supports the uterus, but it counteracts also the tendency to prolapse of the ovary, which has been mentioned as one of the troublesome complications and causes of suffering in retroflexion and retroversion. It is probably in those cases, where one or both ovaries are prolapsed and tender, or where the uterus, notwithstanding suitable treatment, remains large and yet sensitive, that the addition of the india-rubber cushion is most desirable. In other instances, as before mentioned, it is best to dispense with it.

Another excellent form of pessary is that invented by Dr. Hodge, of Philadelphia, and called by him the lever-pessary. It is made of vulcanite or gutta-percha, and is somewhat like a horse-shoe in shape, with a curve somewhat like the letter S. There are two principal forms of this pessary. It is passed up behind the cervix uteri, and is altogether contained in the vagina, doing away with the necessity for straps and bandages. This latter is an important advantage, which is, however, counterbalanced, in some degree, by the instrument not reaching quite high enough to keep the uterus erect, and by the tendency it has in some patients to slip out of the vagina during defæcation. All forms of vaginal pessary, even if they do not fulfil entirely the purpose of keeping the uterus in its normal position, may act beneficially by steadying the organ and warding off the effects of concussion. In this way the ordinary round, inflated, ball pessary, introduced into the vagina, by raising and supporting the entire womb, often gives marked relief in any of the varieties of uterine deviation. Pessaries of the kind I have described may be worn for two, three, or more months, care being taken to remove them occasionally for the sake of cleanliness; and it is generally desirable to withdraw them during the menstrual periods. My friend Dr. Moir, of Edinburgh, has recently proposed that, in the more obstinate cases of retroflexion without enlargement, we should dilate the uterus with a graduated series of sponge-tents, thus bringing the womb artificially into the condition observed after early miscarriage, and then allow it to contract gradually upon a properly-adapted series of intra-uterine pessaries. I have not yet attempted this procedure, but Dr. Moir speaks well of it, and he is a careful and trustworthy observer.

When the uterus is anteflexed or anteverted, the same kind of intra-uterine pessaries as those employed in retroflexion and retroversion have been recommended by Dr. Simpson and M. Valleix as equally applicable for keeping the womb erect.

(a) The cap or pouch represented in Fig. 3 is somewhat too large, and is apt to bend over.
(b) Made by Coxeter and by Russell, George-street, Portman-square.

Various pessaries which do not enter the cavity of the womb are not so readily adapted to support the fundus when it inclines to fall forwards as when it inclines to fall backwards. The attachment of the bladder to the anterior wall directly interferes with the efficient adjustment of the support I have spoken of as useful in cases of retroflexion and retroversion; and the pressure on the bladder during its distension would be a source of serious inconvenience. If, therefore, we relinquish intra-uterine pessaries, we have to content ourselves either with introducing a simple round, inflated ball into the vagina for the purpose of raising and giving a general support to the uterus, or we may employ some of the varieties of pessary which have been devised with the object of keeping the cervix uteri forward towards the symphysis pubis, and in this way using the lower segment of the womb as a sort of lever to elevate the fundus. A disc or ring of ivory or wood, so adjusted across the pelvis that the cervix is retained in its centre, was used by the late Dr. Dewees and others.

I have employed advantageously with the same view a pear-shaped gutta-percha loop (Fig. 4), first showed to me by Dr. Simpson, and which passes up behind the cervix, supporting it and drawing it forward, the narrowed and lower extremity which lies over the edge of the perineum being free and unattached to bandages or thigh straps.

The pessaries of Dr. Hodge would no doubt fulfil very well the same indication. The simple loop (Fig. 4) I have also used advantageously in some of the less obstinate cases of retroflexion.

In conclusion, I may add that, in all the forms of uterine displacement, great care should be taken that treatment interferes the least possible with the general health; and that in all cases where there are evidences of feebleness, anæmia, and mental depression, these should be counteracted by appropriate means.

ORIGINAL COMMUNICATIONS.

CASES OF SOFTENING OF THE BRAIN AND SPINAL CORD.

By JOHN W. OGLE, M.D., F.R.C.P.,

Assistant-Physician to, and Lecturer on Clinical Pathology at, St. George's Hospital.

(Continued from page 479.)

Case 8.—E. M., aged 25, was admitted June 27, 1846. Ill ten days with constant pain in head and sickness; began with rigors, pain in head, and vomiting. Three days before admission, headache became worse, and leeches were applied to temples, with relief; pain recurred, and he was then cupped. Bowels open with medicine.

On Admission.—Face flushed and anxious; skin warm; eyes injected, with great intolerance of light; pupils dilated, especially the right one, which scarcely acted at all; slight ptosis of left upper eyelid; vision imperfect, and said to be sometimes double and “treble;” sometimes sight was clear when only one eye was used. No paralysis of limbs; no convulsive movements. Memory imperfect, and could “not answer for what she said.” Constant pain in head. Tongue white, moist; pulse 90, weak. No petechiæ observed on skin. Abdomen soft and tympanitic. Slight tenderness of the epigastrium. Ordered calomel and senna, with saline draughts and cold lotion to head.

Somewhat delirious at night. Morphia at bedtime, and wine given. Headache became worse, and more delirious. Pupils more dilated; ptosis of eyelid worse; pulse 120. Evacuations passed unconsciously, and twitchings of lower limbs came on, with partial loss of motion. Epistaxis and hæmoptysis supervened. Head turned away from light. Twitchings of legs. Tongue pushed to the left, and became worse. Counter-irritation behind ear, and aperients resorted to. She gradually sank without any convulsive movements, and died July 2.

Post-mortem Examination.—Cranium: Bones of head thick and heavy; diploë quite obliterated. A bony projection from the inner surface of the frontal bones on left of the great longitudinal sinus was found. Veins and sinuses of cranium and choroid plexus and brain gorged with blood. Arachnoid white and opaque about Pineal gland only. Lateral ventricles full and dilated. Fornix softened and creamy. Thorax.—Patches of ecchymosed blood existed in the lungs. Heart

natural. Abdomen: Kidneys congested. Blood-coagula, one of the size of an egg, in the broad ligament of uterus. Other organs natural.

Case 9.—Susan W., aged 47, was admitted into the Hospital December 30, 1847. Had had an apoplectic fit two years before, which had left partial hemiplegia on the right side. Remained the same until nine months ago, when another fit occurred; again been bedridden, but sensible until two weeks before admission (but right side paralysed), when a succession of fits came on, and paralysis of the right side more complete. Evacuations then and since passed unconsciously. Admitted stertorous and insensible; no strabismus or facial paralysis; pupils sluggish and dilated; urine, by catheter, albuminous; sloughing of the back came on. Gradually sank, and died on January 3, in spite of stimulating enemata and stimulants, with counter-irritation.

Post-mortem Examination.—Cranium: Much arachnoid serous fluid found. Half of the middle of the left cerebral hemisphere very softened, and left corpus striatum broken down. Remains of old clot at under part of left corpus striatum and optic thalamus. At under surface of left cerebral hemisphere (middle of anterior lobe), spots of ecchymosed blood found, and in substance of brain corresponding, many bloody puncta. Great atheroma of vessels at base of brain, in some cases almost obliterating the calibre of the vessels. Much fluid in lateral ventricles. Thorax.—Lungs congested. Heart hypertrophied and dilated. Valves healthy. Slight atheroma of aorta. Blood fluid generally. Abdomen: Kidneys granular, dwindled, and contracted.

Case 10.—Wm. R., shoemaker, aged 32, admitted into the Hospital December 5, 1849, with loss of power in arms and legs, but chiefly of the left side. Loss of power appeared greater in upper than lower limbs; could limp about, but could not feed himself. Illness had come on quite gradually, and without any “fit.” Pain affecting left side of head and face. Great indistinctness of articulation; indolence and apathy; pallid face; pulse quiet; tongue coated; gums tender, owing to the use of mercury. Ordered aperients and alum gargle, and blister to nape of neck. The loss of motion in the arm became greater. Occasionally severe headache. Ordered decoction of aloes, ʒss., ter. die. Vomiting supervened, and also greater apathy and tendency to sleep.

The mind began to wander. Pulse became more feeble. The face became expressionless, and rather drawn to the right side. Mercurials were given. Gradual stupor preceded death, which occurred December 20.

Post-mortem Examination.—Cranium: Cerebral membranes healthy. Surface of upper and outer of right hemisphere depressed (size of shilling), and here the grey and white matter was softened, containing as it were a small cavity with irregular walls, and eaten away like the edge of an ulcer. The pia mater here and around more vascular. Another softened part of the same size existed at the under surface of the middle lobe of right hemisphere. Ventricles dilated with serous fluid. Septum and fornix firm. Thorax: Lungs congested posteriorly; heart natural. Abdomen: Kidneys diseased and granular, etc.; other organs natural.

Case 11.—W. W., aged 57, admitted December 4, 1850, greatly exhausted; much pain in head and limbs; face dusky; skin coolish; pulse feeble. Ordered the iodide of potassium thrice a-day, and opium at bedtime. Blisters behind ears.

The pain became very severe. Breathing oppressed, with a little cough and frothy expectoration. Chest resonant, but with rather deficient respiratory movements, and full of sonorous and moist râles. No cardiac bruit. Urine free from albumen, scanty. Bowels not open. Ordered calomel and senna. He became low and depressed, and the cough and dyspnoea increased. Stimulants were freely given, but he gradually sank, and died January 8.

Post-mortem Examination.—Cranium: On inner side of the right middle cerebral lobe, half an inch above corpus callosum, a portion of medullary substance (size of small nut) was softened, and of a yellowish colour, and easily separated from medullary portion; otherwise, the brain was healthy. Thorax: Lungs emphysematous and containing crude tubercles; seropurulent fluid and lymph existed in the peritoneal cavity.

Case 12.—Thomas T., aged 54, admitted June 6, 1852; a dissipated man. Injured himself on the elbow by a wound which bled freely, dividing some superficial veins. Tinct. opii, ℥x., ordered at once. Inf. rosæ, tinct. opii, ℥x., 6 times horis. He became delirious, and passed a restless night. Hands very tremulous; skin dry; tongue moist. Porter and

rum (4 oz.) ordered. He afterwards slept better, but still was delirious, and fancied he saw objects of all kinds about him. Ordered inf. rosæ, c., tinct. cinch., and tinct. opii., 4 tis horis, and under this improved and became rational, but still was tremulous in movements. He became again delirious, and vomiting set in. Egg-flip given. Skin became hot and dry, and pulse flickering and weak. Ordered pulv. opii., gr. j., 4 tis horis, in addition to egg-flip. Muttering delirium came on; he became violently excited. Coma preceded death, which occurred June 19.

Post-mortem Examination.—The open mouth of divided veins seen in the wound, like those of arteries, having been glued by inflammation to surrounding parts. Some of these veins were traced, and found filled with pus-like fluid. Cranium: Much sub-arachnoid fluid found. Patch of old lymph on the arachnoid cavity anterior part of right hemisphere; pia-mater congested. On the upper part of the left cerebral hemisphere was a small circumscribed patch, where the cerebral matter looked as if bruised, and was diffuent. Whole of brain wet and pale. Thorax: Lungs emphysematous. Small mass of tubercle in one lung and an old cicatrix. Abdomen: Kidneys granular; other organs natural.

Case 13.—Maria B., aged 33, admitted August 21, 1854, with scirrhous of left breast, which was amputated. Went on well for some days, but phagedæna set in. Ordered tinct. opii., ʒss., 2 tis horis. Subsequently seized with apoplectic fit, after which the whole of the right side of body and left of face was paralysed and power of articulation destroyed. She was also unconscious. A turpentine injection administered. She remained unconscious for a length of time, and was placed under the influence of mercury. She gradually recovered power of speech, but imperfectly; pulse remained quiet; the distortion of face continued, though diminished. She partially recovered power in arm. Anasarca of legs set in. Subsequently a bed-sore came on. She became attacked with bronchitis, and died apparently from bed-sores, December 1.

Post-mortem Examination.—No abscess or sinus about the breast existed. Thorax: Lungs congested. Coronary arteries of the heart very atheromatous. Cranium: Much sub-arachnoid fluid existed. Brain generally diminished in consistency, but fornix and septum lucidum more so. Lateral ventricles distended with clear fluid. Posterior and upper parts of left optic thalamus to the extent of a threepenny piece, of a light ochrey colour, and very softened. Greater part of the posterior portion of the left corpus striatum and neighbouring part to three-quarters of an inch outwards, and also downwards so far as to involve the anterior part of the middle and a portion of the anterior lobe of left side, even to surface of the convolutions, was very softened. Extremity of middle lobe was quite broken down. On *microscopical examination* of the softened part of brain, it was found to clear considerably by hydrochloric acid. It contained numbers of granular cells, which were cleared also by acetic acid and also by sulphuric ether, also numbers of fat globules, and of dark yellow round and angular bodies in and around the minute blood-vessels, not affected by hydrochloric acid, and many cholesterine plates. The Basilar artery and branches natural, and also the circle of Willis, *except the left middle cerebral artery, which shortly after its origin was opaque and firm, retaining its cylindrical character (its consistence being that of cartilage);* but as it became less by subdivision, both it and its branches outside the brain were entire and natural. Abdomen: Fœtid liquid green pus was found behind the cæcum in the areolar tissue, and in the midst of this the appendix cæci was found thick and vascular, and pierced by an ulcerated perforation. Cyst of ovary adherent to cæcum. Kidneys light yellow, with flakes of fibrine in their substance. Abdominal aorta atheromatous.

Case 14.—Mark B., aged 44, admitted May 24, 1854. Had had a stricture of urethra and a "false passage." Rigors came on in connection with the necessary catheterisms. On one day (August 31) he suddenly experienced faintness, with lividity and blueness of face and body, and the pulse became imperceptible. There was no coma and no spasm of the glottis. He died one hour after the seizure. He had previously never had any fits.

Post-mortem Examination.—Cranium: Dura mater very adherent to skull. Brain softer and more vascular than natural. Fornix and septum softened decidedly. Cerebral ventricles very large. Thorax: Organs natural. Abdomen: Kidneys congested. Double stricture and abscess of the prostate were found also.

Case 15.—Fred. F., aged 25, an intemperate man, admitted

into the Hospital June 25, 1855, in fairly good health until ten days previously, when, after lying in damp grass, he suddenly felt great pain in the head on rising, and also numbness all down the right side of body, which continued for a week. He then had a "fit."

On admission the left arm and hand, and the left side of the face were found to be much paralysed as to motor power, but he managed to walk into the ward; sensibility of skin everywhere natural; left arm was rigid and clenched against the breast; pupils of eyes equal, sluggish, and slight convergent squint of the left eye existed. Sphincter of rectum paralysed, and the urine only passed after a length of time, and with difficulty (sometimes an hour, the neighbouring patient said he was, in voiding it); sounds of the heart natural; his manner was wild, and he laughed strangely; his nights were restless, and in a day or two much pain at the forehead came on and vomiting; peculiar flickering movement of the muscles of the left side of the face, eyelids, etc., and also of the left arm came on.

Subsequently on one day he had three or four convulsive "fits." In the first one he became "black" in the face; in the others the right arm worked very much, and there was much snoring noise, but no screaming, and both arms remained fixed. The eyeballs rolled much, and the left one chiefly turned upwards and inwards and the right one upwards and outwards; mouth slightly drawn to the left; tickling of either sole of the foot produced much general movement of the body. Treated by purgatives, blisters to neck, cupping to temples, and calomel every few hours. Subsequently he fell into a semi-comatose state, with stertorous breathing and dyspnoea. After one of these convulsive attacks he gradually sank, and died July 1.

Post-mortem Examination.—All the limbs were rigid; the left eye three-quarters open; the other closed. Cranium: Intracranial veins and sinuses very full of blood and in the superior longitudinal sinus a small, oldish, discoloured clot; arachnoid in places opaque, and much fluid existed beneath this membrane and in the ventricles; inner surface of ventricles, corpus callosum, septum, and fornix all much softened. Slight yellow lymph under arachnoid covering upper parts of the cerebellum; other parts of brain natural. *Microscopical examination* of the turbid fluid in the ventricles showed the presence of numerous large and small, round, oval, delicate cells containing from one to three nuclei; some very large free nuclear bodies; some large club-shaped cells rather hooked in form and containing single nuclei, and of these some appeared double as it were, one nucleus being common to two. Moreover, some of these large cells had three projections from their walls (triply caudate). In addition many loose nerve tubes were found in the fluid; no compound or granular corpuscles existed, and nothing like blood-vessels. No glomeruli (but only fatty matters) was met with in the softened surface of the ventricles. Other organs of the body natural.

(To be continued.)

CLINICAL NOTES AND OBSERVATIONS.

By F. A. BULLEY, F.R.C.S.,

Senior Surgeon to the Royal Berkshire Hospital, Reading.

INFLAMMATION AND GANGRENE OF THE THIGH.

WILLIAM T., a farm labourer, aged 52, was admitted into the Hospital February 22, 1864, apparently in a dying state. His lips, gums, and tongue were covered with a brown, typhoid fur, his pulse was scarcely perceptible at the wrists, his breathing short and frequent, and his skin generally dry and somewhat hot, with constant thirst, and low, muttering delirium. On examination I found the right thigh greatly increased in size, with a dark-coloured slough of the integument on the inner side, extending from within two inches of Poupert's ligament, about two-thirds down the thigh. The surrounding skin, nearly as far as the knee-joint on the inner side, was of a dusky red colour for some distance beyond the slough, and here and there in this reddened border were spots of darker colour—little ecchymoses, as of commencing gangrene of the cellular structure underneath. The destruction of the skin had been preceded by the formation of some large vesicles, containing a serous fluid mixed with blood. The fascia exposed by the destroyed integument was in a highly putrefied state, with a feeling as if matter in some quantity was contained beneath it. He had always been a very temperate man, and had latterly lived very poorly, and, indeed, insufficiently, from the largeness of his family. The parts of

the limb below the gangrene were of the natural temperature and appearance, and entirely free from any gangrenous discoloration of the integument. The foot was warm, and properly supplied with blood through the tibial arteries, which were apparently quite pervious.

His wife gave me the following account of the commencement and progress of his disease:—He had for some time past, when at his work, been subject to sudden attacks of severe pain at the pit of the stomach, attended with most distressing flatulence and palpitation of the heart. He said he sometimes felt as if his heart would burst, and on some occasions had the greatest difficulty in getting home. On the morning of his last seizure, five days before his admission into the Hospital, he went to his work, seeming better than usual; it was an intensely cold frosty day, with a cold easterly wind blowing. Quite suddenly, while working in the farm-yard, he was seized with a shivering fit, and immediately afterwards he said he felt a sudden severe pain, and a sensation like cramp in the inside of the affected thigh. Being taken home, the thigh was observed to be very much swelled and red, and in the evening some black marks, like bruises, appeared upon different parts of its inner and posterior aspect. The next morning the black marks had become larger, and upon those which had appeared earliest vesications were beginning to form. This was attended with a great amount of fever of a low type, as indicated by his brown tongue and sordes on the gums, which had continued until the time I saw him. There had been no moisture on the skin during the progress of the fever, and his motions, generally of a relaxed nature, had been all along particularly unhealthy and offensive.

For treatment, he was ordered to take twelve ounces of port wine daily; an oatmeal poultice to be constantly applied over the sloughing parts; to be constantly supplied with strong beef-tea; and to take a mixture containing quinine in the decoction of oak bark every four hours.

23rd.—Next day. Has passed a feverish, delirious night. The gangrene of the skin has extended, and become more generally detached by the poultice, leaving a large surface of gangrenous fascia exposed beneath. There has been a great discharge of matter through some openings in the sphacelated fascia. He is very low, apparently sinking.

24th.—Seems somewhat better; his breathing is not so short as it was last evening, and he is more sensible. The foot and leg continue warm, and free from any appearance of gangrene. There has been a great discharge with the poultice.

25th.—Very restless during the night, with increasing delirium. Pulse almost imperceptible this morning; mouth literally filled with sordes; every appearance of approaching death. Towards evening his breathing became obstructed by accumulating mucus in the lungs, his pulse gradually became weaker and weaker, and he shortly afterwards expired.

The friends of the patient obstinately refused a post-mortem examination of the body, and even of the affected extremity; but it was evident that the gangrene was confined to that portion of the limb supplied by the profunda and its branches, the parts immediately adjoining being comparatively free from change.

It is difficult, of course, in the absence of direct proof, to assign an exact cause for the sudden and destructive inflammation observed in this case; but from the circumstance of the patient having obviously exhibited symptoms of diseased heart prior to the fatal attack, it is not improbable that it may have been the result of embolism, or, as the term implies, a separation or displacement either of some morbid vegetation previously adherent to the mitral or aortic valves, which had accidentally made its way into the profunda artery, and there become impacted, or by a coagulum of blood formed in the heart during the protracted cold stage of the attack, which had been washed out by the rush of blood on reaction, and become similarly fixed in this vessel, instead of passing, as might be more easily supposed, and, I believe, more usually happens along the straightforward current of the femoral, and becoming ultimately arrested in its course only by having arrived at a portion of the artery in the same straight line, of too small a calibre to allow of its further progress. In the case which I have related, it is possible that, at the moment of the occurrence of the embolism, or at least in the passage of the embolus down the femoral artery, the limb of the patient might have been in such a position as to cause the muscular compression of that vessel in some part of its course, and thus occasion the foreign body to pass out of its more natural course into the profunda.

Medical Times and Gazette.

SATURDAY, MAY 14.

THE MEDICAL COUNCIL.

THE Minutes which we published in our last week's number contained the Report of the Finance Committee, and the "statement" of the British Pharmacopœia account. We doubt not that these have been examined with very considerable interest; they show that the income of the Medical Council was for the year 1863 £5467, of which as much as £4386 15s. was derived from fees paid during the year—a very handsome annual tax for the Profession to pay—a little fact the knowledge of which must considerably increase the interest with which they watch the proceedings of their Parliament. The British Pharmacopœia cost altogether the pretty sum of £6329. The sale of it has already produced £5022—nearly all of it money actually received; and as Her Majesty's Government is the only purchaser who has not yet paid up, we may, we suppose, fairly congratulate the Council on having made no bad debts on their Pharmacopœia account. We are eager to compliment them whenever we can; and, looked at purely from an £ s. d. point of view, their Pharmacopœia seems to have been quite a brilliant success. It was not intended to be a profitable investment (we suppose); but five-sixths of its cost have been already repaid, and the value of the stock on hand gives a handsome surplus. Even the—dodge, shall we say?—well, the politic expedient, or the happy accident—of publishing the more expensive edition some weeks before the cheaper one has brought its full reward. Of the 13,000 copies published of the 8vo edition, 12,115 have been sold; while of the 15,000 copies of the 32mo edition, only 2730 have as yet gone off. It may, indeed, be objected, on the other hand, that the British Pharmacopœia is full of faults and errors, of commission and omission; that for all the purposes of a Pharmacopœia it is nearly useless; that a revised and amended edition will be required before the Profession can accept it as a working implement; that this necessity has been so far recognised that arrangements have already been made for the production of such an edition, &c. But grant all this, and what then? The British nation is spending every year vast sums on what some consider as nothing but failures in the way of new means of offence and defence; and shall we grumble at a costly failure or two in the reconstruction of our own Professional artillery? What are a few thousands, more or less, to such a wealthy Profession as ours?

We were in error in stating last week that a new system of registration of Medical students had been approved and adopted by the Council. The Report of the Sub-Committee on Registration was "received and ordered to be entered on the Minutes," but the consideration of it was "deferred till after the discussion of the question of Professional education." The Select Committee on Education have since reported on this subject, with the others referred to them, and their re-

commendations, which were, in fact, those of the Registration Sub-Committee, have with slight modifications been adopted by the Council. They advise that students be registered only once, viz., at the commencement of Professional study; the register is to note the name and age of the student, the preliminary examination and its date, the date of registration, and the place of study; the Registrar of the General Council is to prepare an authorised list of all registered students, and to supply copies of the list to all the Licensing Bodies, who are to be requested not to examine, after October, 1868, "any candidate for licence or degree whose name does not appear on the authorised list of Medical students." We are inclined to think that this system will be found highly useful; it is very simple, and can be easily worked through the Licensing Bodies and the Branch Registrars.

We publish this week two of the most important speeches on professional education and examination. We hope that it will not for a moment be thought that there were not many other very important speeches delivered; we would not suggest even any invidious comparison, but the speeches we publish appeared to us the fullest and most weighty on the subjects treated of, and we particularly recommend Dr. Parkes' speech to the attention of our readers. He has had, as it were, to examine the examiners of the various licensing boards, for all the men who come before him for examination have been already passed into the Profession; most, if not all, of them possess a double qualification, and it must excite the gravest astonishment and reprehension that men so grossly ignorant of their Profession as some of these diplomaed candidates proved to be could have found it possible to obtain any qualification from any licensing body whatever. How can we wonder that Medical men should but too often make such a pitiable figure in practice, in the witness-box, and before the educated public in general, when we read such confessions of gross incapacity, and "dulness all over," as Dr. Parkes has given us from the army examination-papers? We should much like to know how long ago or how lately the answers especially quoted by Dr. Parkes were given, for the Horse Guards authorities have of late years been most consistently and untiringly endeavouring to make the Army Medical Service so unpopular that few really able or "good" men will think of it, and they have succeeded at last in converting it into a Refuge for the Destitute;—a Workhouse, to which only the very weakest and most incapable of the products of our schools will resort, as the only mode of escaping starvation. Is it not true also that the service has of late been recruited almost exclusively from one part of the kingdom? Has not the Medical press of that part rather boasted of this as a kind of triumph?

Still, console ourselves as we may with the reflection that the Army Examining Board has now to deal chiefly with the very dregs of our schools, the fact remains that these men do come before that Board as qualified Practitioners, and the question recurs—How is it that such men can possibly obtain any qualification at all?

The divided responsibility of the Licensing Boards has probably much to do with it. One cares only for Surgery and Surgical Anatomy; a second for Medicine, Medical Anatomy, and Midwifery; and so on; and so between the various stools candidates who would disgrace any body of educated men slip into the Profession. In this way only can it be explained how such men have appeared before Dr. Parkes as legal Practitioners, or how men possessing a qualification shall, by a second Examining Board, be proved to be utterly ignorant of the composition of water, of the atmosphere, or of the commonest medicines, and incapable of reading an ordinary prescription.

The select committee suggest that the Licensing Bodies, etc., should consider, before the next session of the Council, "Whether it be advisable and practicable to establish in England, Scotland, and Ireland severally, a conjoint Examining Board, before whom candidates may be subjected to a single

series of examinations for the double qualification of Physician and Surgeon." It is a valuable suggestion, but we should prefer that there should be, for each division of the kingdom, a central Examining Board through which all men should enter the Profession, and upon whose qualification men may embroider special and higher degrees or diplomas in Medicine, Surgery, or Midwifery, obtained by examinations instituted by the several Universities, Colleges, and Halls. It is only by some such means as this, we think, that we can be sure that no man shall be able to enter the Profession without being really fitted to practise. We agree with the declaration made by an eminent Physician at a dinner of a Hospital School, that "he despised the man who was incapable of practising his Profession from the administration of a glyster upwards."

The whole debate on Professional Education was valuable, as amply showing the hopelessness of our looking for any definite scheme of education or examination at present from such a Board as the Medical Council. Though no one will doubt the ability and honesty of intention of all its members, their speeches irresistibly force upon us the impression that each man thinks more of the particular college or corporation he represents than of the public good—he gives to his own party what is due to mankind. We are sure that all the alleged "difficulties" and "impossibilities" in the way of making students work, of obliging them to attend lectures, class examinations, etc.; of giving real clinical teaching, of making examinations for a license practical, and so on, would all disappear if men were only thinking of making thoroughly efficient Practitioners, and not at all caring whether such changes might not make St. Boniface's School unpopular, or the examinations at Celsus College and St. Gregory's University shunned; and we further believe that a school which should have the courage to adopt a good collegiate discipline, and "send away," or rusticate, men who only wasted their time in idleness or vice, would eventually and quickly become a highly popular school. At the same time, we do not ask for a rigid, detailed scheme of education; a bed of Procrustes for Medical Students; nor do we greatly care how or in what exact order of succession a man gets the required knowledge, so long as we can be satisfied that he does get it before he gets his license to practise.

As to the Preliminary Education, we regret that the Council have not had the courage yet to fix a minimum standard; such a guide would have been of great value, and we cannot understand why it should not have been given. The precise number of subjects we do not think of primary importance; but we confess that we do not think it would be going very far to require that a boy of 17 who desires to enter one of the learned professions should have some knowledge of Greek as well as of Latin (we would *not* require Sanskrit); nor can we agree with the President of the Council when he argues against transferring the subjects of chemistry and botany to general education, because this would be "incompatible with the present system of education of the majority of English schoolboys. If it were done, it would exclude from the Profession most of those brought up at the larger schools, such as Eton, Harrow, Rugby, etc." Whatever was required, that a boy would be taught somehow; one instructor's difficulty or impossibility would become another's opportunity, and the supply in instruction would undoubtedly meet the demand and the necessity; examinations and qualifications should surely guide and foster education, not wait upon it.

But whatever subjects may be demanded in the Preliminary Examination, the chief point looked to should be *thoroughness* of knowledge, so that when students begin their Professional studies they may have already learnt how to learn, instead of coming, as they too often do, to a Medical school without the least conception of what really *knowing* any subject means.

We believe that the Council finally rose on Saturday, but as we have not been able yet to obtain the minutes of the last meeting, we cannot finish the subject this week.

THE DEBATE ON THE PRESENT STATE OF THE ARMY MEDICAL DEPARTMENT.

It is with a feeling of gladness that we direct attention to that part of our journal which contains the debate in the House of Commons on the 5th instant. Colonel North and General Peel deserve infinite credit for bringing the lamentable condition of the Army Medical Department into prominence. Upon the whole, the question was fairly met, and there was as much candour in the reply by the Marquis of Hartington as we can reasonably anticipate from official lips. No doubt there is some force in his observation that we must look to the numerous openings for Medical men offering much greater advantages than Her Majesty's army as one of the causes of the present dearth of candidates. It is notorious, however, that the authorities were sowing the wind when they abrogated the Royal Warrant of 1858, and they have themselves to thank if they are now reaping the whirlwind. When they cancelled a single term of that Warrant they were breaking faith with all those who had entered the service under its provisions and its promises. No subsequent restorations wrung from them by sheer necessity could stay the current of discontent which had set in. The Warrant of 1861 and the Queen's Regulations of 1859 are sufficient proofs that the Royal Warrant of 1858 was not acted upon. Medical officers found themselves burdened every year with more work and fresh duties; they discovered that they must be moved from one foreign station to another or submit to half-pay; they saw, or thought they saw, many of their accustomed privileges passing away, and they felt that a spirit of miserable parsimony and a petty interference with them in the discharge of their duties were in rapid development. Men began to ask themselves what material advantages the service offered, and they were not slow in discovering how small these were. The younger men found they might live, die, or retire Assistant-Surgeons as far as promotion was concerned. No wonder they contrasted their position and prospects with those afforded in other walks of life, and that the result was very adverse to the Army Medical Department.

It was not so much a question between combatants and non-combatants as an equitable and, above all, a clear definition of the functions and rights of each that was required. The question of relative rank was only mooted when the authorities had withdrawn from the Surgeons the rank assigned to them by the warrant; and it was elevated to a prominent position by the discussions which took place in the military journals. This was not the seeking of the Medical officers, but it was fomented by the intemperate and invidious letters from combatant officers in the military organs. The better class of men deprecated the discussion in this way as likely to promote a spirit of antagonism between them and their executive brethren. Unfortunately very much of the present discontent and unpopularity of the Department has arisen from circumstances which need never have occurred had the Department been true to itself—had there been the same conviction that Whitehall-yard was to the Medical officer what the Horse Guards is to the combatant. We do not pretend to explain—we are content to state the fact—that when Mr. Alexander was at the head of the Department, there was none of this grumbling among his subordinates, although some of the causes of complaint were in existence.

The members of the Department viewed with dismay the imposition upon them of derogatory and unprofessional duties, such as are involved in the present regulations for branding soldiers, and they asked themselves whether it were just or logical that "a system of imposing fines on Medical officers for passing recruits"—as it was fitly characterised by Earl de Grey and Ripon—should ever have been put in force.

With the older and better class of Medical officers—those who have the interests of their Profession and the science at heart—the introduction and threatened swamping of the department with an inferior class of men were matters of

genuine regret. The Director-General might hold that Marlboroughs and Wellingtons were common characters among military officers, but the competitive examinations must have taught him that Brodies, Coopers, and Jenners were not plentiful among the candidates presenting themselves for examination. We glow with shame and indignation as we peruse Dr. Parkes' masterly speech in defence of competitive examinations for the public service. It is truly awful to dwell upon what might have been the case but for the protection which these examinations have thrown over the soldier. By every principle of humanity and common sense the nation is bound to protect itself and its servants against such gross ignorance as Dr. Parkes has found among the Medical candidates for the army. The existence of such illustrious ignorance is so discreditable to us as a Profession, that we would fain hope that the very worst specimens of the Profession had been tempted to try their chances with the army, in the bare hope that they might gain an access under the pressure of that necessitous law which was driving the authorities to obtain Medical men anywhere and anyhow. It may, we think, be accepted that the more highly educated and better born the Medical officer, the better will it be for those with whom he mixes and for whom his services are exercised. Now, one thing appears certain, that if the Medical ranks have to be filled up in the way they have been lately, there will be a wide chasm between the Medical and the executive branches. A certain standard of scientific attainments is happily guaranteed by the army examinations; but this is not everything. Courteous bearing and urbanity in small things flow out of a due admixture of self-respect and educated tolerance. These are the fruits of a social kind of influence, obtained in a sphere very different from that of a Medical University. All the world over, the less self-respect, the greater the desire to obtain the outward semblances of dignity, under the guise of what is reflected, say, from military dress, manners, and authority.

We desire to see the day when the Medical Department is recruited from the rank of the most gentlemanly and best educated men of our Universities. Medical officers are called upon to mix with gentlemen; they represent our Profession in the most diverse and opposite parts of the globe; they have opportunities for studying epidemic and other diseases which are surpassed by none; and they have equal advantages for furthering the progress of knowledge and the advance of science. What we want, then, is, that our army brethren should not only occupy a high place in our Medical and other literature, but that they should raise us as a Profession in the estimation of the public by their learning, their courtesy, forbearance, and the exercise of good works to all. There is no more honourable calling in life than that of an Army Surgeon. We have watched the gradual dissolution of the Medical Department with sorrowful interest, and the time is coming when we may anticipate that something shall arise, Phoenix-like, out of its ashes.

THE WEEK.

THE APPROACHING ANNUAL MEETING OF THE "ROYAL MEDICAL BENEVOLENT COLLEGE" AND THE SCHOOL.

As the day draws near for the annual meeting of the Governors of the Royal Medical Benevolent College, the question of the school recurs to our mind. Nor are we alone in this. It is the very topic which the Council of the College will introduce for discussion. The point for us to settle, and for each governor to settle in his own mind before he goes to the meeting, is, whether the mode in which the Council suggests that it shall be dealt with is that which ought to be adopted, or which the interests of the Profession demand shall be condemned. The proposition of the Council may be learned from our advertising columns. Briefly, it is this:—To receive into the school the sons of persons who are *not* Medical men, charging them £65 per annum; while the sons of Medical men, who may remain as "exhibitioners," shall continue to

pay the obnoxious £40 per annum. But this is not all. For every lay scholar thus admitted, a Medical man's son is to be excluded, inasmuch as the total number of scholars is not to be increased, but, on the contrary, absolutely to be reduced from 200 to 180. In other words, not only does the Council propose to continue breaking faith with its original supporters by charging £40 in place of £25, thus no longer making the education at the College a boon to the less wealthy amongst us, but they positively go the length of proposing to oust the son of a Medical man whenever they can get an extra £25 a-year by *substituting for him the son of a layman*. Their proposal can mean nothing short of this. Did it mean less, some limit would have been placed upon the power which they ask the governors to confer upon them. Once let the resolution be passed, and the College might displace half their Medical scholars for whose benefit the school was established, in order to substitute for them as many boys who have no connection with our Profession at all—any boys, in short, who might be lucky enough to find a friend amongst those members of the Council who would make Epsom a second Eton. Will the governors permit their Council thus to wipe out the word "Medical" from the scholastic department of the Council, and shall it be no longer "benevolent" in any other sense than being "charitable?" Will no member of the Council itself stand up on the 18th inst. and protest against the scheme? Is there not one among them with the courage to express before the governors his dissent from so monstrous a proposal? We know that the Council is divided. Let those in the minority declare themselves, that each governor may learn who they are that are the friends and who the enemies of their order; who it is that would divert the stream of benevolence from its proper channel; who it is that, not content with robbing the poor, seeks further to aggrandise the rich. We entreat the governors who really have the interests of their poorer brethren at heart, although they may talk and protest about it less than the Treasurer does, to attend the meeting. It will be the most important annual meeting yet held. The very principle on which the College is founded will be undermined if the proposition of the Council is carried. Let them keep this in mind. Altogether a different motion is advertised to be proposed by Mr. Cattlin, which will give the governors an opportunity of expressing by their votes their desires upon the subject.

THE PARISIAN POISONING CASE.

THE trial which is now going on at the Court of Assizes of the Seine, before M. Le Conseiller de Boissieu, presents so many points of Medico-legal interest that we propose hereafter to notice it at greater length. The accused Count La Pommerais is not a Physician, as has been stated in most of the journals, but a homœopathic Practitioner. He is charged with having, on November 17 last, poisoned his paramour, a widow named Pauw, for the purpose of obtaining £22,000, for which sum he had induced her to insure her life. Although an homœopathic Practitioner, he was found to be possessed of large quantities of the most potent poisons. The poison which he is believed to have used was digitaline. On June 11 and 19 the accused bought three grammes of digitaline. Of this fifteen centigrammes only were found in his possession. This great diminution in the quantity of digitaline cannot be accounted for by homœopathic practice, for homœopathy fairly carried out repudiates the use of concentrated medicines, especially in appreciable doses. But then are homœopaths honest? The present, moreover, is not the only case in which grave suspicion attaches to the prisoner. It is said that on October 4, 1861, the accused bought fifty centimes of digitaline. Not long after, his mother-in-law, Madame Dubizy, dined in his company in excellent health, but was soon afterwards seized with violent vomitings. He alleged that she was attacked with cholera; nevertheless, on the night preceding Madame Dubizy's decease, he prescribed ten cen-

tigrammes of digitaline and twenty-five of hydrochlorate of morphia. In this case, as in that of widow Pauw, a person in excellent health died suddenly of vomitings and purgings, under the eye and care of the accused, who had bought and used a considerable quantity of digitaline, which he could not account for; in each case the accused either neglected to obtain or to follow the advice of other Medical men, and in each there was the absence of any cause which could account for death.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XV.—MARCH 5.

Anatomy of the Gorilla continued.—The facial portion of the skull is slightly more prognathous and macrognathous than that of the chimpanzee. The jugal arch is considerably stronger and more curved. The palate is longer and narrower. An interesting character (not being an adaptive modification, but a mark of serial degradation) is the late disappearance of the suture between the premaxilla and the maxilla, which remains open up to adult age. In the lower jaw the great depth and massiveness of the rami and the entire absence of any mental prominence may be noted. The body of the hyoid bone forms a more considerable cup-shaped cavity than in the chimpanzee; its greater cornua are well developed, the lesser cornua rudimentary.

The scapula of the gorilla is markedly more like that of the human subject than is the chimpanzee's. The coracoid process is strong and curved. The humerus is longer than the radius; the radius itself has a strong curve. The hand in its fundamental construction resembles that of man and the chimpanzee; where it differs from the latter it is generally in the direction of the human type. The thumb is longer and stronger in proportion to the hand than in the chimpanzee, and the form of the trapezium is more like that of man. The pelvis has the great depth, the obliquity of the upper aperture, the great length of the antero-posterior, as compared with the transverse diameter, the long symphysis pubis, and the eversion of the ischia characteristic of the ape. It approaches the human type somewhat, however, in the great width of the ilia. The femur is somewhat more like that of man than the chimpanzee's. The articulation of the astragalus with the tibia has the same obliquity as in the chimpanzee, but the bone itself is stronger and broader. The calcaneum projects rather further backwards, but retains its narrowness and the single tubercle. The entocuneiform bone has the characteristic ape form. In the proportion of the different regions of the foot there is a slight approximation to man, which is lost, however, in the proportionately shorter hallux. On the whole, though with certain exceptions here and there, where the gorilla departs from the chimpanzee in the character of its limbs it approaches man, while in the skull it comes nearer to the lower apes, so that it is by no means an easy question to decide which of the two animals forms the nearest approximation to man in its osteology. Perhaps the greater relative size of the cranial cavity inclines the balance in favour of the gorilla.

The dentition is essentially the same as in man and the chimpanzee, but deviating further from the former in the immense development of the upper canines, and in the greater relative size of the posterior inferior molars. The milk teeth closely correspond with those of the chimpanzee, as does the order in which the teeth succeed each other, the permanent canine being the last in place.

Our knowledge of the myology of the gorilla is at present very defective, being derived chiefly from Duvernoy's dissection of one individual, supplemented by some original observations of Professor Huxley on the muscles of the hand and foot. Taking them in the same order as was done in the case of the chimpanzee, first, may be considered those muscles of the limbs not commonly found in man and stated to be present in the gorilla. These are the dorso-epitrochlear and the levator

claviculæ; the *scansorius* is not mentioned by Duvernoy. 2. Those muscles existing in man, but which have not been hitherto found in the gorilla. The *subclavius* was only represented by a ligament. The *plantaris*, *extensor primi internodii pollicis*, and the *peroneus tertius* were all absent. The two last appear to be constantly wanting in the apes. 3. Muscles commonly said to be absent in the apes, but which are found in the gorilla. The *transversus pedis* is powerfully developed, arising by three bundles from the heads of the second, third, and fourth metatarsal bones. The *extensor indicis* is perfectly distinct, giving no division to the other digits. The *extensor minimi digiti* goes altogether to the little finger. 4. Muscles which differ from those of man in their origin. The most important of these is the *flexor brevis digitorum*; the portion which arises from the *os calcis* gives the perforated tendons to the second and third toes; the remainder arises by two fleshy bellies from the surface of the long flexor tendon. The tendon for the fifth toe is not perforated, but runs to the outer side of the deep tendon. The *soleus* arises by a single head from the fibula. 5. Muscles which differ from those of man in their insertion. Duvernoy found the *flexor pollicis longus* represented by a small tendon from the *flexor profundus digitorum* going to the thumb as in the chimpanzee. Prof. Huxley found the tendon on the palmar surface of the thumb, but on tracing it upwards, it did not appear to join the other flexor, but ended by spreading out in the fascia of the palm, and was partly inserted into the trapezium and first metacarpal bone, so that, functionally, the muscle may be said in this instance to have been absent. In the foot the long flexors have essentially the same arrangement as in the chimpanzee, the *flexor digitorum* goes to the second and fifth digits, and the *flexor hallucis* to the first, third, and fourth, with only a slight intermingling of their fibres. The *flexor accessorius* is well developed, with its ordinary connections. 6. Muscles which are single in man, but divided in the apes. The division of the tendons of the *tibialis anticus* and *extensor ossis metacarpi pollicis*, so marked in the chimpanzee, was found in the gorilla not to extend higher than in man.

The gorilla's hand and foot afford through their great size very fine illustrations of the arrangement and action of the *interossei* and *lumbricales*. The latter are four in number in the hand, and are inserted into the *extensor* sheaths as usual; in the foot there are but two. The *interossei* of the hand agree in the main features of their arrangement with those of the human hand, being double on each side of every finger, the more dorsally placed muscles are inserted into the side of the base of the first phalanx, and the others send their tendons into the *extensor* sheath, and form the chief *extensor* of the last phalanx. The *interossei* of the foot agree on the whole with what has been observed in man and the chimpanzee, though there is a tendency to a division of the muscles, a slight approximation to the arrangement in the hand. The dorsal *interosseous* muscle of the second and fourth spaces presents the great peculiarity of being divided in the middle line into two distinct muscles, each having a tendon inserted into the opposed sides of the fingers bounding the space. There is also a distinct "*interosseus volaris primus*," as in the hand of man. On the whole, the muscular arrangements of the limb leave us much in the same uncertainty as the osteology, in reference to the nearer approach to man, presented by the gorilla or chimpanzee.

The larynx in its general characters resembles that of man and the chimpanzee. Connected with it in the adult gorilla is a system of great cavities, developments of the two laryngeal *sacculi*, each of which is equally dilated, and produced into large *cæcal* *sacculated* pouches, extending all over the sides of the neck in the interspaces between the muscles, from the rami of the lower jaw to the *axillæ*. As age advances the sacs of the two sides coalesce in the middle line over the trachea, and form an elongated bag, the upper end of which fits into the hollow of the body of the *hyoid* bone. The use of this immense and complex apparatus is not known.

PARLIAMENTARY.

ON Thursday, May 5, the House of Commons went into Committee of Supply on the Army Estimates, commencing at vote 7, £262,216 for Medical services, being a reduction on the original vote of £2000 on account of diets and Medical comforts.

Colonel North called attention to the position of the Medical department of the army, showing that, in accordance with the statements of the Commander-in-Chief, Sir R. Airey, and Sir G. Wetherall, it was undermined in time of peace. In support of these statements he added that, notwithstanding there were 200 vacancies in the department, and that the age of admission had recently been extended from twenty-five to thirty years, there were only six applicants, the number just previously, when the age was fixed at twenty-five having been only fourteen. He should like to know whether the House and the country desired that such a state of things should continue to exist. Had the Medical officers of the army shown themselves to be unworthy of the service? Such was not the opinion of Lord De Ros, who when examined on a committee which sat to inquire into the subject, stated that nothing could be more creditable than the conduct of those officers; nor of Sir R. Airey, who said, specially in reference to the Crimean war, that he did not think it possible to have a more energetic class of men. That being so, and it being the fact that the condition of the Medical department of the army was such that no men of ability in their Profession would join it, he thought it was time that the attention of the House should be directed to the subject.

General Peel said that if it were true that there were 200 vacancies and only a few applicants, as had been stated, the matter became one of serious importance. When he was Secretary for War, the Medical Warrant of 1858 had been issued, founded on the recommendations of the Sanitary Committee, and carrying every one of these recommendations into effect. Such, he might add, was the satisfaction given to the Medical Profession by that Warrant, that some of the best students became candidates for the service, as he had been informed by Sir B. Brodie and Sir James Clarke. Subsequently there were great complaints that the Warrant had been broken through, and that the question of relative rank had been set aside. He hoped the noble lord the Under-Secretary for War would be able to explain how that had happened, and how it came to pass that the Medical examination for the army, which was intended to be competitive, was now reduced to such a level that it was impossible to get ordinary students to undergo a mere qualifying examination. He had himself accompanied a deputation of Medical officers to his late lamented friend Sir G. Lewis, and he quite admitted that some of the complaints which they advanced might be frivolous; but, then, the committee which had been appointed by the War Office had reported entirely in favour of the Medical officers, and he should like to know why their recommendation had not been carried out.

Mr. O'Reilly expressed his satisfaction at hearing the observations which had fallen from the last speaker, adding that he could bear testimony from experience to the favourable light in which the Warrant of 1858 was regarded by Medical officers, and to the fact that the changes which had been made in it were most injurious to the efficiency of the service.

Sir J. Trelawny asked the noble marquis whether he was disposed to grant a commission to investigate particular evils existing in and near large garrison towns. Infectious diseases might often be prevented as well as cured, and he believed that great social as well as physical benefits might be looked for from such an inquiry.

Colonel Sykes said that on comparing the cost of Medical men, medicines, Hospital corps, and other necessary appliances for maintaining the health of the army, he found that in England it was at the rate of £1 11s. 7d., while in France it was £1 10s. 8d. He believed that to contrast the total numbers with the total cost was the only method of arriving at a sound and just result.

Captain Jervis, referring to the question raised by the hon. baronet the member for Tavistock, said it was one of vital importance. Nobody who had read the reports of the army and navy, or those which had been published respecting our Mediterranean and Indian stations, could fail to be struck with the number of men invalided during their term of service, or prematurely thrown as pensioners upon the country. It was the bounden duty of the Government to institute measures of a remedial character, and if, in addition to the reports in their possession, they wished to strengthen themselves by the

opinions of a committee or commission, the House, he thought, would gladly afford the requisite facilities.

Colonel Dunne expressed his approval of the good sense shown by the hon. baronet the member for Tavistock in introducing the subject. The matter was one which it was impossible to debate in the house, and yet every man knowing anything of the military and naval services was aware that it lay at the root of their health and efficiency. He was anxious to obtain some information with regard to the purveyor's department, the vote for which seemed to be much larger than was necessary, and the duties of which he was informed could be divided between the Medical staff, the storekeeper, and the barrack-masters.

The Marquis of Hartington said the hon. and gallant member for Oxfordshire had called the attention of the Committee to the deficiency in the supply of Surgeons for the military service, but had attributed that circumstance to the wrong cause.

Colonel North observed that he had not assigned any reasons, not knowing what the reasons were.

The Marquis of Hartington replied that either the hon. and gallant member or the hon. and gallant general sitting below him had connected the deficiency of Surgeons with the failure to carry out in their integrity the recommendations of the commission on which the Warrant was founded. In all essential particulars those recommendations had been complied with, and the Medical officers had obtained every substantial advantage contemplated by those recommendations. In one or two points these had been departed from, but they were hardly of a character to deter any Medical man otherwise desirous of doing so from entering the service. It was perfectly true that in consequence of objections raised by the regimental officers, acquiesced in by the Horse Guards, and sanctioned by the late Lord Herbert, Medical officers, although enjoying the relative rank laid down for them in the Warrant, were not to act as presidents of boards of survey or other boards when one of their number happened to be the senior officer present; but he could not imagine that trifles such as these would make any Medical man hold back who intended to connect himself professionally with the army. The difficulty of obtaining Medical officers might in part be accounted for by the fact that, in spite of the increase of population in the United Kingdom, there was, if anything, for the last few years a diminution in the number of men educated for the Medical Profession. The great steamboat companies, railways, mining and other private undertakings likewise entered into competition with the Government, and offered to Medical men more immediate advantages, as well as the prospect of a more speedy rise in the world, than could be hoped for in the army. He was afraid that if, within the next few years, the demand which had sprung up in this country for members of the Medical Profession should not be met by an increased supply, Her Majesty's Government would have to consider the expediency of offering increased advantages, not in the way of additional rank, but of increased pay. He assured the House that the subject had by no means escaped attention. Within the last few days Earl de Grey had consulted, not only the Director-General and others, but likewise Medical men unconnected with the army. He was not in a position to state the nature of their recommendations, but he could assure the Committee that the subject had not escaped attention, and that measures would be promptly taken to keep up the necessary supply of Medical men. The subject adverted to by his hon. friend (Sir J. Trelawny) was one of great importance, but it affected the navy as well as the army, and ought not to be partially dealt with. It had received the consideration both of his noble friend (Lord C. Paget) and himself, and later in the Session it was his noble friend's intention to propose the appointment either of a committee or commission to inquire into the question. In reply to the hon. and gallant member (Colonel Dunne), he would state that he was not aware of any extravagance in the vote for the purveying service. That service used to be performed partly by the purveyors and partly by the commissariat, but the system was not found to answer during the Crimean war, and the present service was adopted on the recommendation of the Sanitary Commission. If the hon. Member would look at the Estimates he would see that a reduction had taken place in that portion of the vote which was susceptible of reduction. The Medical items were in excess of last year, but that was on account of the New Zealand war.

Colonel North said that officers in the Medical service did not so much complain of the question of rank. What they wanted was the permission to retire after twenty years' ser-

vice, so as to be able to obtain private practice. The country had a right to expect that when its troops were prostrated by wounds or unhealthy climates they would have the best possible Medical advice. At present there was no less than 200 vacancies in the Medical department. During the Crimean war there was scarcely a family in the country, from the peer to the peasant, that did not mourn the loss of some relative. A committee was appointed in 1856, which reported that the Medical officers had been deficient during the war. Eight years had elapsed and the same state of things existed. If war broke out to-morrow what would the troops do for Surgeons? The authorities were obliged to send Assistant-Surgeons out to India who had only just returned from Canada, New Zealand, or the West Indies. A class of acting Assistant-Surgeons had been appointed who had never before been heard of in this country, and some of the regiments had no Assistant-Surgeons. The country had a right to expect that the Medical department of the army should be placed in the best possible position.

The vote was agreed to.

In the House of Lords on Friday, May 6, the Lord Chancellor brought in a bill for the limitation of actions and process for small debts, to amend the Acts relating to County Courts, and give them a limited jurisdiction in Equity. He described the present state of the law as to the recovery of small debts, pointing out the severity with which the proceedings in the county courts pressed on the poorer classes. The power of these courts to imprison small debtors had been found very injurious in its operation. He proved from the returns laid before Parliament that up to the year 1863 more than 17,000 persons had been imprisoned by the order of the county courts. In many of these cases the sums claimed were incredibly small, 4s., 3s., or 2s., and in one case a man was sent to prison in default of paying the sum of 9d. This power of imprisonment had no limitation but the discretion or clemency of the judge. A man might be confined several times for the same debt. The advantages the present law gave the creditor were so great that, practically, the whole value of the debtor's labour was mortgaged for the creditor's benefit. As a remedy for these evils, he proposed by the present bill to limit the power of imprisonment by a clause requiring the judge to take into consideration all the circumstances of the case. Imprisonment would be ordered only in cases of debt contracted by fraud and false pretences. But that imprisonment would be made a real punishment, instead of a nominal infliction, as it was in some districts. The bill would attempt to assimilate the case of the small debtor to that of the insolvent with greater liabilities by giving the judge power to call all the creditors of a working man together to prove their debts. An order would then be made for the amount to be set apart by the debtor for their payment, the money to be paid into court and distributed by it. A debt contracted with the keeper of an alehouse for intoxicating liquors consumed on the premises would not be recoverable by process under this Act. The second part of the bill invested the county courts with a limited equitable jurisdiction in cases involving sums too small to bear the expense of an application to the Court of Chancery.

Lord Cranworth reserved his opinion of the bill as a whole, but admitted it was most desirable to get rid of the system of imprisonment for debt by these courts. The difficulty was that imprisonment was often the only means of compelling the payment. To abolish the power entirely they might have to make debts of very small amount debts of honour, not recoverable by legal process at all.

The bill was read a first time.

We do not think the Lord Chancellor's bill if it become law will injuriously affect the Profession of Medicine; we are happy to believe that there are very few Medical men who would not far rather lose a debt than imprison the debtor. Should the bill pass it will deal a blow at the small credit system in all businesses and professions, and in this respect it will probably prove a real benefit to those Medical men who practise chiefly amongst the artizan and labouring-classes. Not only will the working-man have more ready-money because he pays ready-money, but the very habit of doing so will lead him to regard debt as an incubus and a degradation.

In the House of Commons, on the order for going into a committee of supply, Mr. M'Evoy moved the following resolution:—"That Her Majesty's Government should now adopt the recommendation of the select committee of 1858, which 'recommended her Majesty's Government to take into

consideration the claims of Ireland to a grant of the half-cost of Medical officers in unions, with the view of providing for the same in future as is now the practice in England and Scotland.' "

Sir R. Peel insisted that no good ground had been assigned for the relief sought, and recommended the withdrawal of the motion.

The motion was supported by Mr. Monsell, Colonel Dunne, Mr. Bagwell, Mr. Hennessy, Sir H. Bruce, and Lord J. Browne; and opposed by Mr. Peel and Sir G. Grey.

Upon a division the resolution was negatived by seventy-three to fifty-eight.

On Monday, May 9, in the House of Commons, Lord Proby, Controller of the Household, brought up a message from the Queen, stating that in compliance with an address of the House, her Majesty would appoint a Royal Commission to inquire into the subject of capital punishment.

Mr. Dillwyn moved for a select committee to inquire as to the most suitable arrangements to be made respecting the Patent Office Library and Museum.

The motion was carried by twenty-one to sixteen.

Mr. Peel obtained leave to bring in a bill to enable her Majesty to grant a lease for 999 years of the building known as the College of Physicians, in Pall-mall East.

In the House of Lords on Tuesday, May 10, Lord Ellenborough withdrew the Sentences of Death Bill, in consequence of the inquiry pending in the other House of Parliament.

FROM ABROAD.—BAD SANITARY CONDITION OF AMERICAN CITIES
—KAROUBA AS AN ARTICLE OF DIET—PRODUCTION OF SEX.

By a stupendous effort the United States Government, or rather the public coming in aid of the Government, has effected a wonderful improvement in the sanitary condition of the army; but, according to the accounts which reach us, the great cities of the Republic still continue in a woful plight in this respect. The Medical Society of the District of Columbia has just issued a report on the sanitary condition of the cities of Washington and Georgetown, which contains the most alarming statements. We have heard much of the epidemic of small-pox, which has prevailed with much virulence in the former city; and when we peruse the statements here given of the utter neglect of all sanitary appliances, we cannot be surprised at any disease assuming an epidemic and virulent form. Great overcrowding, the want of provisions for cleansing and drainage—putrescible materials accumulating in many of the streets to the depth of twelve inches—the imperfect burial of the numerous horses that have died, and various other horrors, have hitherto, and will again, generate epidemics of typhoid fever, from which the city has not, indeed, since 1861, been free. The Committee has proposed some stringent regulations and active supervision, under the operation of which much may be hoped for. New York, though in not so bad a plight, is in an unsanitary condition which would be thought perfectly disgraceful in Europe, and political considerations are at present likely to stand in the way of its improvement. A committee has been endeavouring at Albany to get an Act passed for improving the sanitary jurisdiction of the Empire City, but it reports to its constituents that its task is a hopeless one, for it "found that the Democratic members of the Legislature regarded the proposed Act as aimed at their friends, and that the Republican members dreaded the passing of so sweeping an Act, that might be construed into unjustifiable interference with city affairs, and might injure their prospects in the next Presidential election. They were informed that the City Inspector had raised large sums from his employés to defeat the measure. They also found that in the opinion of many members of the Legislature the death of five thousand citizens was not so serious as the possibility of a Presidential defeat." At Chicago, too, described as the greatest slaughtering yard in the States, the want of sanitary provisions is felt in the prevalence of erysipelas, variola, puerperal diseases, and fever. The stench arising from the offal and refuse of the great slaughtering establishments, which also contaminate the water, is fearful.

M. Prevet has recently made some communications to the

Academies in reference to his attempts at introducing *karouba* as an important article of alimentation. A leguminous plant, which especially thrives on the shores of the Mediterranean, the *ceratonia siliqua*, produces a pod, the beans (*karouba*) of which form a common article of nutriment in Algeria, Italy, Spain, and Egypt, but which are unknown in France except to botanists and chemists. Individuals and animals fed upon it in these countries exhibit all the signs of good health, in place of those indications of defective nourishment so often met with among the poorer classes of large cities. M. Prevet, as the result of numerous experiments, has succeeded completely in the torrefaction of the bean, and has produced a substance of most agreeable odour and taste, infinitely superior to the chicory so much used by the lower classes in France, and, in some respects, to be preferred to coffee itself. It does not stimulate like this latter substance, and is thus better fitted as an article of diet for women and children; while, as its nutritive properties are very considerable, it is well suited where reparative tonics are indicated. It can be sold at a very low price.

M. Thury, of Geneva, has of late propounded the doctrine—founded, indeed, upon some practical observations—that the male sex always is produced when fecundation is operated upon ova of complete maturity, while females result when ova of a less advanced maturity are fecundated. Thus, by serving the cow with the bull at the commencement of the rut, we may always produce females, serving at the middle and terminating periods of the rut-producing males. This is so absolutely the case that the sex may be thus produced at will. M. Coste believes that this theory can be tested in the fowl, in which several eggs fecundated at the same time by a single impregnation arrive only successively, and in the order in which they are placed at maturation. He has therefore devised a series of investigations in this sense, which will be duly reported, and in the meantime mentions the results of one of the experiments. Supposing M. Thury's theory exact, all the first eggs laid should be male, all the latter ones female, the order not being inverted. Well, a fowl, separated from the cock at the commencement of her laying, laid five eggs within the space of eight days, and the sexes were produced in the following order:—Male, male, female, male, female. This interposition of a male between the two females is contradictory to the theory; but whether this constitutes a mere exception or a radical objection, further investigation must show.

M. Guérin observes (*Gaz. Med.*, May 7) that the matter cannot be so easily disposed of, inasmuch as facts have shown that fecundation of the same egg may take place on several occasions, and perhaps through several males, or that it may remain latent, so as not to induce development of the embryo until long after the fecundating principle has been deposited. A remarkable example of this came under M. Guérin's own notice. Some black turkeys had been trod during a whole season by some white turkeycocks belonging to an entirely different race. At the end of the autumn the turkeys were removed to another farm where there were no black cocks. In the spring, one of the black females, which had cohabited during all the preceding season with white cocks, laid some eggs, whence issued three white turkeys—a male and two females. Her other eggs, to the number of twelve or fifteen, produced black male and female turkeys. This fact shows that it is impossible to appreciate the degree of maturation or development by the date of fecundation; that the fecundation may go back long prior to the commencement of the development of the embryo; and that several impregnations may contribute to the fecundation of the same egg.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the General Monthly Meeting held on Monday, May 9, 1864, William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the Chair, the following gentlemen were elected Members of the Royal Institution:—The Hon. Henry Frederick Cowper, George Clive, Esq., M.P., Lieut.-Col. George Palmer Evelyn, William Dell, Esq., and William Graham, Esq.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF THE POTTERIES, STAFFORDSHIRE.

(Continued from page 520.)

At one time in its history Newcastle was famous for the manufacture of hats, but at the present moment this trade has fallen from it, and has hardly been replaced by any staple manufacture. There are now in the town 318 males and 18 females employed in pottery work; 289 males are occupied in the iron manufacture; and 996 males are miners. The divisions of the population of the various districts in reference to occupation will be best gleaned from the tables subjoined:—

Newcastle-under-Lyme District.

Total population	13,196	
Professional class	339	or 2.6 per cent.
Domestic class	5,239	„ 39.7 „
Commercial class	262	„ 2.0 „
Agricultural class	1,547	„ 11.7 „
Industrial class	5,117	„ 38.8 „
Indefinite and non-productive	692	„ 5.2 „

Wolstanton District.

Total population	27,985	
Professional class	404	or 1.4 per cent.
Domestic class	10,796	„ 38.6 „
Commercial class	738	„ 2.6 „
Agricultural class	814	„ 2.9 „
Industrial class	13,801	„ 49.4 „
Indefinite and non-productive class	1,432	„ 5.1 „

Stoke-upon-Trent District.

Total population	37,460	
Professional class	719	or 1.9 per cent.
Domestic class	13,342	„ 35.6 „
Commercial class	1,403	„ 3.7 „
Agricultural class	1,033	„ 2.8 „
Industrial class	19,367	„ 51.7 „
Indefinite and non-productive class	1,596	„ 4.3 „

SOCIAL FACTS IN THE POTTERIES.

The social and physical conditions of the lower classes in the district of the Potteries are peculiar. Provisions are not limited, and the quality of the food is good as compared with that obtainable in many other manufacturing districts. Wages are also very good. Amongst the potters a good workman will earn from thirty-three to thirty-six shillings a-week, which, when reduced by the payment say of seven or of eight shillings for boys, would leave a handsome margin; indeed, as Mr. Scriven showed some years ago, the wages of the potters are considered the best of any staple traders in the kingdom.

There are thus many advantages pertaining to the potters; but, in spite of these, no one can pass even a few days in the district, without being assured that there is something wrong. The men are unhealthy in aspect, the women cadaverous, the children small, stunted, and, though not mis-shaped, ill-shaped. Dr. Arlidge, of Newcastle, than whom there could not be a more competent judge, thus describes the potters as a class:—

“The potters as a class, both men and women, but more especially the former, represent a degenerated population, both physically and morally. They are, as a rule, stunted in growth, ill-shaped, and frequently ill-formed in the chest; they become prematurely old, and are certainly short lived; they are phlegmatic and bloodless, and exhibit their debility of constitution by obstinate attacks of dyspepsia, and disorders of the liver and kidneys, and by rheumatism. But of all diseases they are especially prone to chest disease, to pneumonia, phthisis, bronchitis, and asthma. One form would appear peculiar to them, and is known as potters’ asthma or potters’ consumption. Scrofula, attacking the glands, or bones, or other parts of the body, is a disease of two-thirds, or more, of the potters. The men are more subject to chest disease than the women. The latter, employed in ‘dipping’ and in ‘printing,’ suffer most. Those engaged in painting, burnishing, and in the ware rooms least. The most sickly men are the hollow-ware pressers, firemen, and dippers. That the ‘degenerescence’ of the population of this district is not even

greater than it is, is due to the constant recruiting from the adjacent country, and to intermarriages with more healthy races.”

Except by those who have a prejudice for supporting and sustaining all causes of disease, these painful facts are readily admitted. But the question is, why should the physical condition of the people have thus degenerated? The answer to this question seems now to be considered as in the main settled. It is assumed that the evils are traceable in great part to the occupation, and at this moment the Pottery district is attracting much attention politically, owing to the circumstance that a proposition is before the Legislature to apply the provisions of the Factory Act to the young who are employed in the earthenware manufacture.

The pottery manufacture of Staffordshire has been the subject of three inquiries under the sanction of Parliament within the last twenty-two years with reference to its effects upon persons employed in it. In 1841, Mr. Scriven made his report to the Children’s Employment Commissioners, “upon the physical and moral condition of the children labouring in that important district.” In 1860, Dr. Greenhow, by direction of the Medical Officer of the Privy Council, and continuing an inquiry of the previous year as to the “local influences which occasion in particular districts of England an habitually high rate of mortality from particular diseases,” presented his report upon “the special causes which develop pulmonary diseases, with excessive mortality in the pottery district of Staffordshire.” And, in 1862, the Assistant Commissioner of the Children’s Employment Commission, Mr. Longe, commenced an inquiry. The principal facts remained as recorded in the evidence collected by Mr. Scriven, and Mr. Longe has confined himself to exhibiting the general features of the subject, and to substantiating the facts as they exist at the present hour.

I shall refer at length, in speaking of the sanitary conditions of the Pottery district, to the details of the report of the last Children’s Employment Commission, from which the above information is taken. But I may add this much here, that the evidence collected, considered as a whole, is most conclusive in proving that overwork in childhood is the main cause of that physical degeneracy to which Dr. Arlidge has so ably, earnestly, and fearlessly directed attention. Shall we wonder, indeed, at the degeneration when we read such facts as the following, collected by Mr. Scriven:—

“The class of children whose physical condition has the strongest claims to consideration is that of the ‘jiggers’ and ‘mould-runners,’ who by the very nature of their work are rendered pale, weak, diminutive, and unhealthy. They are employed by the dish, saucer, and plate makers; their hours are from half-past 5 in the morning to 6 at night, but in numberless instances they are required to labour on till 8, 9, or 10, and this in an atmosphere varying from 100 to 120 degrees, all these extra hours being occasioned, nine times out of ten, by the selfishness or irregularities of their unworthy taskmaster. The men work by the piece; however much there may be on hand to accomplish, they seldom or ever work after Saturday noon, and often not before the following Tuesday or Wednesday morning, but spend the hard earnings of the previous days idly and unprofitably. Once gone, they again ‘buckle to,’ and work like horses. Each man employs two boys, one to turn the jigger or horizontal wheel from morning to night, the other to carry the ware just formed from the ‘whirler’ to the hot-house and the moulds back. These hot-houses are rooms within rooms, closely confined, except at the door, and without windows. In the centre stands a large cast-iron stove heated to redness, increasing the temperature often to 130 degrees. I have burst two thermometers at that point. During this inclement season I have seen these boys running to and fro on errands or to their dinners without stockings, shoes, or jackets, and with perspiration standing on their foreheads, after labouring like little slaves, with the mercury 20 degrees below freezing. The results of such transitions are soon realised, and many die of consumption, asthma, and acute inflammations. It is admitted on all hands that their work is the most arduous and fatiguing of all others. It will appear that a good workman can, and frequently does, make eight score dozen saucers a week, each dozen counting thirty-six pieces. Each piece is carried twice to and fro, and weighs (mould and bat) 2 lbs.; but as two pieces are carried at the same time, they will count but as one, and as 4 lbs. on every trip.

Let us first calculate the weight absolutely borne, then the distance run barefoot: eight times 20 is 160; 36 times

160 is 5760 pieces of 2 lbs. each, carried in six days of only 72 hours, which, multiplied by four (the weight of two moulds and bats), gives 23,040 lbs. Divided by six, the number of working days in the week, will give 3840 lbs. a day of 12 hours, without deducting the so-called one and a-half hour for meals, which, by the way, they never get.

The average distance from the whirler to the centre of the stove is an honest 7 yards; the same back will make 14; 14 times 5760 yards gives 80,640, or 45 miles 1440 yards in a week; which, divided by six, gives 7 miles 1120 yards per day. Besides this, they have to mount one, two, or three steps to place the pieces upon the shelves. But this is not enough, their master requires them, while he is taking his pipe or his pot, to wedge the clay in the yard, collect the half-dried pieces from the shelves; again, to come half an hour or more before him in the morning, to get coals in, ashes out, and sweep and make ready for him the room, or anything else that may be wanted, and probably has to walk a mile before and after his work. If the master's propensities prompt him to loiter away the earlier days of the week, he works the extra hours on middle days to make up his losses; thus the child—the almost infant child—is taxed with three or four hours' increased exertion, to the sacrifice of his health, his morals, and every domestic comfort that he would otherwise enjoy, and this, without the least remuneration, as in every case his wages are the same, whether he makes the twelve hours or sixteen.

The evil is lamented by the honest workman, by the children, by the parents, and universally by the manufacturers, who acknowledge their inability to correct it themselves without incurring the risk of exciting tumult, and thereby occasioning some delay in the execution of their orders, as the processes are so linked in with each other, that by losing one set of men the others are rendered useless.

Should a remedy be suggested, the children would have reason to hail the day of their emancipation from toil little removed from slavery."

Mr. Longe adds the following summary of the hours of work in various departments of the pottery works, and in the large and important branches in which the largest number of children are employed at the present time:—

"The usual hours of work throughout the district are similar to those stated by the employers in the tabular forms. They are generally from about 6½ a.m. to 6½ p.m. On Saturday work ceases in some manufactories at 2 p.m., in others at 4 p.m. In some manufactories work is continued to 7 p.m. on Fridays. These hours, however, are frequently exceeded in the case of pressing orders, on which occasions children as well as adults are employed to 8 or 9 p.m.; and sometimes, but I believe, very rarely, through the whole night. Some of the children are also liable to be worked beyond the usual hours through the irregular habits of the men for whom they work. . . . The above description shows the ordinary employment of these boys; they are, however, liable more than any other class of children to be worked beyond the regular hours. It is still too frequent a practice among the flat-pressers, as with other potters, to waste the first days of the week in idleness or the beerhouse, and then work themselves and their boys until 8 or 9 o'clock on Thursday and Friday in order to recover their lost time."

In my rounds through the Pottery districts I found but one opinion—an opinion in which the workmen shared—and that was that the interference of the Legislature was absolutely necessary for the purpose of effecting proper and permanent relief. Self-government as a practical method was assumed to have failed; masters could not make rules to please the men; the men could suggest no improvements that were satisfactory to the masters. Hence they all ask for a law, and probably they will soon have their desires gratified.

Two methods have been suggested for the consideration of the Legislature. The masters generally, and the Employment Commissioners are in favour of what is known as the "half-time system," by which children would be admitted to labour at 8 years, but would spend a portion of time in school and in rest. The workmen generally, on their side, wish—1. That no one should be admitted to labour until he or she shall have attained the age of 10 years. 2. That as a qualification for admission to labour, each youth should be obliged to bring a certificate of education. 3. That actual labour per day should be confined to nine hours and a-half.

I have confined myself thus far purely to a brief description of the Potteries. I hope the narrative has been sufficient to lead the reader who has not visited the locality to feel that he

knows enough of it to be interested in it. He will then move with me the more easily into the North Staffordshire Infirmary, the Hospital of the Potteries, which comes next under notice.

THE DEBATE ON EDUCATION IN THE MEDICAL COUNCIL.

* * * Owing to an unexpected failure of our reporters, we are unable to give the speeches we promised, and borrow these of Professors Parkes and Sharpey, delivered on Saturday, April 30, from the *Lancet*, in which they are reported at length:—

Dr. Parkes: I am very happy that Dr. Christison has given me the opportunity of explaining to him and the other members of the Council some of the reasons why it appears necessary that there should be an entrance examination of gentlemen about to enter the Army Medical Service; and I believe this matter will be found to be most intimately connected with Medical education, and, therefore, in explaining it I shall not be at all out of order, nor infringe on the business before the Council. I wish it to be clearly understood, that in the remarks I am about to make I am in no way referring to those gentlemen who have passed the examination for the Indian service and the army, and are now serving in various parts of the world; but I must say this, that in every examination we have had in the Indian service and the army, during the ten years I have been examiner, and during which time very nearly 800 candidates have come before the Examining Boards, there have presented themselves, on every examination, a number of men so imperfectly prepared in the practical parts of their Profession, that we found we could not conscientiously admit them into the ranks of the service. I am aware, Sir, that this may seem a strange assertion to the members of the Council, particularly when we consider that every one of those gentlemen brought forward the double qualification; but, by the permission of the Director-General, I have brought down some documentary evidence, that will be satisfactory, I believe, to every member of this Council. How, Sir, can we pass a man into the service who knows so little of anatomy as this—that he does not know the radius from the ulna, the os calcis from the astragalus—that he believes the œsophagus is in front of the arch of the aorta, and that the aorta may rise from the right ventricle? In Surgery, Sir, I do not think Mr. Syme would allow us to take a man into the army who gave an answer of this kind,—who, when asked what he would do for a partly-divided, or completely-divided, artery, replied, and in writing too, not in the hurry of oral examination, that he would immediately amputate the limb above the injury? I do not think Mr. Syme would approve of a man who, when asked how he would treat an incised wound of the knee-joint, after suggesting various remedies, replied, that if the inflammation still went on he would make large incisions into the joint. I do not think any one would wish to pass a man who, when he was asked, "what would you do if, after delivery, a woman had her breasts unpleasantly full of milk?" would answer, "I would pass a trocar into the breast." Then, in examination upon Medicine, I cannot pass a man who cannot diagnose a single case of phthisis, or who, when he is taken to the bedside, and there is a board at the head of the bed with the name of the disease upon it, "aneurism of the aorta," with bulging pulsation, shrill and loud murmur, who knows it is a case of aneurism of the aorta, who takes twenty minutes to examine the case, and half an hour to write down what he can tell about it, and cannot put down a single symptom or sign of aneurism of the aorta; nor can I pass a man conscientiously, as a man well up in the practice of Medicine—a man who has been two years at a London School of Medicine and one year at a Scotch School—who tells me that all that time he has never once heard that the term "scabies" is applied to a disease called the itch. Then, Sir, to cite some few more instances in what we call natural history: (and here I should have liked to have passed these papers to Dr. Christison. I will not do so; but I know that on these points he will feel particularly interested, for I know that for years Dr. Christison has in his lectures most properly called attention to the subject; and I must say the Edinburgh men have always given correct answers on these points, and in consequence have directed particular attention to the article of diet. And I am sure there can be no more important subject for the study of the Medical student than digestion and diet, in these days when

every man in the country is talking about diet and knows a great deal upon the subject :)—here is an answer given by an Englishman, not a Scotchman; a man at a first-rate London school; a man who had passed his examinations as a Surgeon and Apothecary. The question is this: "Mention the principal heads under which alimentary substances may be arranged, and give one or two instances of each." Nothing can be more simple: it is a question that is put in class examination. I will read the answer of this gentleman, who, I need not say, did not pass into the army:—"The division is into the nitrogenous and the non-nitrogenous aliments: these may be subdivided into albuminous, fibrous, caseous, and gaseous. An example of the nitrogenous is, all vegetables; of the non-nitrogenous, all meats, including carnivora"—carnivora being wrongly spelt. "Of the subdivision albuminous, perhaps the most common example is the hen's egg; of the fibrous, the meat of the ox or sheep. Veal and pork, I believe, do not contain so much fibrin. Of the caseous, milk and cheese; of the gaseous, soda water." I will not pursue these examples, but I have plenty of them here; and I can assure you that if we had kept all the documents—which we have not done—I could cover half the table with extraordinary answers. And I beg the Council to believe that I am not exaggerating; I am really only citing instances which occur at every examination. Dr. Stokes said very justly yesterday, that the object of examination is to determine what a man knows, and what he does not know. Now I have found not the least difficulty in ascertaining what he does not know, but it surpasses the skill of Dr. Stokes and myself to discover sometimes what he does know; and the only words in which I can sum up the whole subject are the emphatic words of my colleague, Mr. Paget, in one of these memoranda on oral examination, when, after endeavouring for a long time—and an extremely weary work it is—to get something out of a man, to ascertain whether he knows anything at all about his profession, he was obliged to sum up the whole result of his examination in these emphatic words: "Dull all over." And that, Sir, is the character of this class of men. I wish again to repeat, that I am not referring to the men who have passed into the service,—many of whom have passed most creditable examinations,—but men whom I hope we never shall see admitted into the public service. But I come to this point,—and I hope the Council will trust me when I affirm it as a matter of most perfect truth, and if I were permitted to show these papers, I could convince every one sitting at this table,—that the Medical corporations are admitting a number of men into the Profession who cannot practise their calling with safety to their patients. Dr. Stokes also remarked yesterday, and very justly, that the object of the examination is, not to determine whether a student shall be on a level with the examiner, but to determine whether a man can be safely let out into the world. That object of the examination is not fulfilled; and I mean to say there is hardly any of the great Medical corporations that has not sinned in this matter. And now, Sir, I bring the point to this issue. As long as the Medical corporations allow men to pass into the Profession who cannot be allowed, without danger to the lives of the patients, to treat the persons who come to them for advice, so long must the Army Medical Department institute an examination for itself. It must protect itself. And I do entreat this Council not to urge upon the Government, by suppressing that examination, a course which the Government cannot attend to, or, if it does attend to, can do so only upon the chance of lessening the welfare, diminishing the health, and even imperilling the life of the soldier. And here I may allude to an argument brought forward by my colleague, Dr. Maclean. In the Civil Service, when a man goes into practice, there is a great check upon him. The civilian can employ whom he likes. A Practitioner has to pass through a dreary time of waiting, which perhaps improves his knowledge, or tests his capacity. He is subjected also to the supervision of his Professional brethren. But in the army it is quite otherwise. You select a set of men, and give them absolute control over the health of soldiers. Soldiers are compelled to go to a particular Medical officer. Will you, then, run the risk of diminishing in any way for the soldier the guarantee that the Medical officer who is put in charge of him is a competent person? I believe, Sir, it is impossible that this Council can come to any other conclusion than that the Army Medical Department must enforce its Medical examination. But let me pass on to another point. I can conceive that Dr. Christison will say this—"However much it may be desirable to institute an entrance examination for men who have already passed examinations at Colleges, still this examination must be

in practical subjects. It must be in subjects which will test their powers as Practitioners." And on this point I may say that I in a great measure agree with Dr. Christison. But then, you understand, this is an objection to the details of the examination for entrance into the service, not the principle of the examination itself; and I am quite certain that if Dr. Christison or Mr. Syme, or any member of this Council, could make any suggestions as to the details of the examination for entrance into the army, I can answer for it that the Director-General and the Secretary of State would give the greatest possible attention to them. But let me refer to the kind of examination we have instituted, and in doing so I must diverge for a moment to bring before you some points connected with the Army Medical Service. Let me ask the Council this—How is the army to be officered with Medical men? There seems to be only three ways. First of all, a certain number of men may be nominated—that is to say, we may return to the old system of patronage. Now, is the Council prepared to recommend a return to that system, in which a man is brought into the Medical service of the army, perhaps, to oblige a lord, or subserve Parliamentary interest, or gratify private friendship, or it may be even to propitiate a court milliner? And I think I can refer to a member of the Council, who knows that in saying this I am not speaking beyond bounds. Are we to return to such a system as that? And even if we do return to that system, the army must still retain its entrance examination. But I do not believe for a moment that the Council will recommend a return to that system; and if it does recommend a return to that system, I do not believe the recommendation will be responded to by the Profession at large. A number of appointments may be given to various colleges and universities, and you may say, "Select your men, and send us up good men." That plan is one that has been carefully considered; it is one that requires the greatest possible supervision. In many respects it is one which it is extremely difficult to work out. Can we be sure that these colleges will do their duty? Can we be sure that, doing their duty now, they will do it ten years hence? Can you be sure that private interest will not operate? Even then an entrance examination must be required, in order to check the men that come up from the various colleges. Seeing then, that the various Licensing Bodies have passed men into the Profession that never ought to be in the Profession, can we be justified in supposing that they will always choose men who are fit for the service? Therefore, that system is not a good one. Then we come to the system at present in force—the system of open competition, in which every man, no matter what his country, no matter what his religion, no matter what his degree, so long as he has a legal qualification for the practice of Medicine and Surgery in the United Kingdom, is admitted to serve his country, if he can prove that he is a better man than those who come up also to serve their country; and I believe that is the system which is considered by the Council and the Profession at large as the proper system; and I hope no resolution will pass the Council to-day that will have the effect of diminishing the confidence of the Government in that system. But this I will say, that I hope this Council will not separate without, I will not say a recommendation, but an order to the various Licensing Bodies, to see that they do not pass men into the Profession who are not capable of practising it; and an indication that they will take immediate steps to see that the Licensing Bodies do their duty in this particular. I will now, Sir, pass on for a moment to the details of our examination. Our examination consists of these four parts, the details of which can be altered at any time. It consists of an examination in natural history, in anatomy and physiology, in Medicine, and in Surgery; and, in mentioning the details of this system, I must just advert for a moment to the time this system was commenced. It was just ten years ago, in the time of the old East India Company; and it was the fact of its being an East India Company that determined that a natural history examination should be instituted. And for this reason. There are in India a number of appointments in which a knowledge of natural history is required, such as the curatorship of gardens, the curatorship of forests, and travelling naturalist expeditions. All these were filled by Medical men. Now, however, I am sorry to say, the Medical service does not appear to be able to furnish the men who are capable of filling some of these appointments. The Indian Company said, "We will institute an examination in natural history, for these reasons—first, because the examiners will be able to point out to us the men capable of filling these posts," etc.; and it might be supposed that the Indian Company, placing into competition such admirable appointments—and,

in spite of what has been said about that service, I mean to say there is no service in the world like the Indian service—would consider that these men would be led to study natural history for the sake of getting these valuable appointments. I may mention another reason. There have been, as we know, great botanists and geologists in India; but it cannot be denied that during the century we have held India the Medical Profession at large has not communicated that amount of information to our knowledge of natural history that might have been expected from it; and the Indian Company were extremely anxious to cultivate among their Medical officers a knowledge of this subject; therefore they wished to devise means for increasing the knowledge of natural history, and they felt that, as it is a great guarantee for general professional knowledge as well as general intelligence that a man should be acquainted with some other sciences besides those which strictly belong to his profession, it would be a good thing to see, if possible, that the men entering their service made the study of natural history form part of their general training. These are the reasons why the examinations were instituted; and when the army Medical officers were ordered to be placed under separate examiners, it seemed to Lord Herbert desirable that the plan should be continued. For some years, however, there has been really no examination in natural history. Dr. Hooker, after trying to work this examination as well as possible, and for the first few years sending out men who were perfectly capable of fulfilling some of the duties to which I have referred, found gradually, and especially during the last few years, when such constant attacks were made on this part of the examination, that it was absolutely necessary to drop the special examination in natural history; and if the members of the Council will take the trouble of looking over the questions (I will tear off the answers) they will find that Dr. Hooker's examination has been an examination in *Materia Medica* and botany, and those sciences which are not only applicable to Medicine, but which any really educated man is expected to know. But there has been really no examination in natural history for many years; and this I will say, and I wish to be clearly understood by the members of the Council, that no man has been rejected for natural history in that examination; that in no single instance has a good Physician and Surgeon, provided there are vacancies, not passed into the service. It is very common, I know, for the men to say, "I was rejected for natural history," just as in the University of London, when a man is rejected for his education, he says he was rejected for logic and moral philosophy; but I do not know a single case in which a man has not passed merely on his pure Professional merits. Examinations were ordered in anatomy and physiology. You will find it is the anatomy of the Surgeon and Physician, not the anatomy of the schools, in which the candidates should be prepared to pass an examination. The questions in anatomy are such that Mr. Syme would find no difficulty in at once passing upon, because he is dealing with them constantly. I assure you that if you look through the questions in anatomy and physiology, you will find that they deal entirely with those departments of anatomy which refer especially to Medical and Surgical practice. So again, with the physiological branch. You will find that the questions have an immediate bearing on Medical and surgical practice. I do not deny that a question of high physiology may not be introduced, in order to give the best men an opportunity of showing themselves. If we did not put in some questions which are necessary in order to distinguish between the best men, how should we find them out? With regard to medicine and Surgery, therefore, I will only say this: we were directed in the first instance by the authorities to make the examinations as practical as possible, and we have done so. In our written examinations we have made the questions, as far as possible, practical; and in looking over Mr. Paget's questions and mine, I think you will see that this has always been borne in mind. Never in Surgery has Mr. Paget asked a question which can be said to pass into the transcendentalism of education. Then, Sir, we instituted practical examinations, in accordance with the wishes of the authorities, and very high encomiums indeed have been passed on the practical examinations. I have thought much over the subject since it has been under the consideration of certain members of the Council, and I do not, after considering the subject in all its bearings, see how we can improve, in practical points, the examination in Medicine and Surgery. At the same time I would remark that I am sure I can answer for the examiners in Medicine and Surgery that they will pay the greatest attention to any suggestions that can be made. So much, then, for the details of the

examinations, and so much, generally, for the subject of the Army Medical Department, in which I hope I have shown—first, that there must be an entrance examination; secondly, that the present system of competitive examination is the best, and possibly the only one that can be adopted. Having said thus much, Sir, allow me to say a few words upon the larger question of Medical education—a question which I view by the light of very considerable experience in Medical examination, and very considerable experience in tuition, both in the case of students in the course of their studies and in the case of gentlemen when they have passed through their course of studies; and I cannot say that I agree with what has been said here, that the present system of Medical education is satisfactory. In chemistry, for example, only to cite an instance, I cannot think the present system satisfactory when I find that in India there is a constant failure of justice because within hundreds of miles there is no man to be found who can make a simple chemical examination in a case of poisoning; when I find that for years in that country the army at various stations have been drinking impure water, because no man could be found who could apply a simple chemical test to ascertain that impurity. I cannot think the examination in anatomy is satisfactory when I find that many men come up for our examination who are extremely deficient in some of the rudimentary points, such as the knowledge of the formation of a skeleton—that very important point without which no man can be a good Physician or Surgeon. I can appeal to my colleague, Mr. Busk, that there is a remarkable ignorance on the part of men who present themselves—men who in many respects are very well educated. I cannot conceive the teaching in Medicine and Surgery satisfactory when I see such results as these—that men not only cannot very frequently, as I know is the case, write an intelligible report of a case, but cannot put up a fractured limb, and cannot perform such an operation as passing a catheter without danger to the person operated upon, and this even in the case of men who are well educated, and who will be eventually extremely useful practitioners. I cannot conceive, then, that the state of Medical education is satisfactory. And the question is—not to occupy the Council too long—how this Council may deal with what I consider a very unsatisfactory state of things. And I believe the Council can deal with it in this way, and in this way only. They must deal first with the examinations. They must see that these are such as they should be. I do not demand a high standard of examination. I do not demand anything more than that in the examinations it shall be seen that a man is not dangerous; if possible, that he should be gifted with such knowledge that will enable him to do good to the patients he is called upon to treat. And then, Sir, when the examinations have been dealt with, I think the next business of the Council should be to indicate in general terms those things to the licensing bodies and great Medical Schools which, in the opinion of the Council, require consideration, and possibly reformation; leaving it for the great licensing bodies and Medical schools to debate the question, and see how the improvement may be best carried out. But on the question of examinations, Sir, I will say this: that I am convinced that no good will be done until the Council devise a scheme by which there can be a complete supervision of them. And that is what we should do at this meeting. We should not separate before this is done; or, if we cannot now devise a scheme for complete supervision, we should commence a process that will lead eventually next year to complete supervision. Therefore, Sir, I am prepared to move, when the proper time comes, the following amendment, which will embody the points to which I have just referred:—

"That the Registrar be directed to write to the several licensing bodies requiring them to forward to the Council an exact statement of the nature and extent of the examination or examinations (written, oral, or practical,) to which candidates for their licences or diplomas are subjected, and of the rules and standards of knowledge which are followed in the granting of licences. That the Registrar be also directed to write to the several licensing bodies, informing them that the Council does not at present intend to suggest any alteration in the Medical curriculum, or in the general arrangements of Medical teaching, but that the Council directs attention to, and requests the opinions of the Medical corporations on, the following points:—

"a. The desirability of increasing the amount, and rendering more definite the kind of practical instruction in chemistry, Anatomy, Medicine, and Surgery, and of making the final examinations a better test of such practical knowledge than they now are.

"*b.* The desirability of representing to the Medical schools the importance of directing the studies of the future general Practitioner entirely in the manner best suited for the requirements of general practice, by teaching him thoroughly the groundwork of his Profession, instead of requiring him to obtain an imperfect knowledge of many things which are less useful to him, and, whenever practicable, by making the student work for himself, instead of obliging him to attend a large number of lectures, which are often imperfectly understood and dimly remembered.

"*c.* The question whether, by a re-arrangement of the courses of lectures, by omitting second courses, and by making the yearly Medical session consist of two four months' courses, with one and three months' interval between them, the several parts of Medical education would not be better taught than by the present division into courses of unequal length.

"*d.* The desirability of the Medical schools enforcing good class examinations, not as a substitute for the final examinations, but as a means of testing whether the student has mastered the subject before him, without which he should not be permitted to pass on to the next subject laid down in the curriculum."

Dr. SHARPEY could confirm what Dr. Parkes had said as to the extreme insufficiency in point of practical skill of some of the candidates who present themselves for examination for the Army Medical Service. Upon the general question of Medical education, he gathered from the course of the debate that the best plan to pursue would be to endeavour to arrive at some general resolutions which should embody the collective opinion of the Council, and then issue recommendations, leaving the details to be settled by those who are charged more immediately with the conduct of Medical education. Different modes of conducting Medical education prevailed in different parts of the kingdom, and some persons had urged the Council to establish uniformity. He would advise the Council to look to results rather than to uniformity, and not to support it at the expense of freedom of action, lest in endeavouring to secure uniformity they should bring the whole system to the dead level of mediocrity. With these few words on the general question, Dr. Sharpey next addressed himself to the particular points which had been brought before the meeting. With regard to the age at which candidates should be admitted, there was no difference of opinion; nor was there with respect to the recommendation that a term of four years' Professional study should be adhered to. Upon the great question, as to the subjects prescribed by the curriculum—speaking of the subjects only, and not of the mode of studying them—he did not think they could propose any revision, especially as there did not appear to be any uniformity of opinion in the Council on the question. He also believed it would be found unadvisable to introduce a prescribed order of study. The capacities, opportunities, and abilities of students are so different that it would only perplex and embarrass to subject them to the same order of study. It appeared to him that it would be equally hopeless to induce the Council to agree upon the order of study, as it was upon the subjects which should constitute the curriculum. In his opinion it should be left to the examinations, which would sufficiently regulate the order in which the different subjects should be prescribed. Upon the all-important subject of examinations, it was known that the University of Edinburgh had for a long time held a preliminary examination and a final examination. By this arrangement, the student, after he has passed his first examination, is disengaged of much minute detail not absolutely necessary for his future progress, yet of much value in enabling him to prepare for his final examination. It was in contemplation at Edinburgh to introduce a still earlier examination in scientific subjects, not purely professional, such as natural history, chemistry, botany, geology. In the University of London for several years there has been a preliminary scientific examination in chemistry, natural philosophy, botany, and zoology. He did not recommend licensing bodies to introduce zoology and natural history as a necessary part of the examination for a general Practitioner; but they might offer some inducements to students to pass an examination in chemistry before commencing their regular professional studies. At first it might be optional, afterwards it might be conditional. With regard to the system of examination in classes in preparatory subjects adopted in Edinburgh, Dr. Sharpey expressed his approval of the plan, and was of opinion that an examination conducted in this way could be more full and searching than at a later period. The student has timely warning of his defects, and there is time for him to remedy

them, and his mind is relieved of details in preparing for his final examination, the essentials of the subject remaining in his memory. There would, however, be great difficulty in introducing this system into the London schools; the nearest approach to it would be to allow students at the end of each year to present themselves for examination upon the subjects in which they have been engaged during the session. With regard to practical examinations, his own experience induced him to say that they should be introduced wherever it is possible. In the University of London there is scarcely an examination in which a part of the exercise is not by demonstration of specimens or other practical means. He differed from Mr. Syme upon the subject of clinical examinations. The student should be subjected to examinations at the bedside, in order to test his practical proficiency, and it would be a strong inducement to students to give more attention to clinical study, and thus to qualify themselves for taking charge of patients after they have passed their examinations. He was also of opinion that steps should be taken for the supervision of examination, and he appealed to the Council to take that question seriously into consideration. In the meantime, a partial supervision might be carried out by the Branch Councils, by having the examination-papers submitted to their inspection, and by some of the members of the Branch Council being present at the examinations. Something had been said about the excess of lectures, on the ground that they took up time which might be devoted to the study of practical subjects. The best men did not think there was too great a demand upon their time in attending lectures; and if more time were wanted for practical study, the proper mode would be to dispense with a second attendance upon any course of lectures, and to make each course as complete as possible. (Hear.) It would then be in the power of the students to attend the second time if they found it convenient; but if a course of lectures be divided there is no remedy. As Dr. Thomson stated, it would be better to leave something to be regulated by the schools and teachers; for, with the competition that existed, the Council might be assured that the schools would take care to educate the men up to their examinations. With respect to class examinations, he would recommend, as long as the examinations were oral, that the students should listen to their companions, and take down a note of any part that was valuable to be retained. The class examinations could be improved by the introduction of written papers; and independently of their serving as a criterion of fitness for obtaining a licence, they were of such value that he would have them made compulsory. It would relieve the lecturer of a great difficulty, and would enable him to grant a certificate of attendance upon appearance at the examination, and in this respect the plan would have a most salutary effect in ensuring attendance. With reference to the proposal to divide the year into two sessions of four months each, commencing at November and April, he should have no objection to it if the arrangement should be thought advantageous in the country; but he did not think it would be advisable in the London schools. It would take away two of the best months of the session, October and March. It was the duty of the Council to encourage attention being given to practical studies, in which the student is himself engaged; and of all practical studies, excepting the study of diseases, there is none so important as practical anatomy. It would place that study at a disadvantage if they were to cut off the whole of the month of October, and in the middle of the session to cut out the month of March. The division of the session would do more harm by dislocating their present arrangements than it could possibly do good.

LETTER FROM NAPOLEON TO TISSOT.—In his biography of the celebrated Swiss Physician Tissot, who died at Lausanne in 1797, Dr. Eynard publishes a letter addressed to him by Napoleon while the writer was an artillery officer. It relates to the Archdeacon of Ajaccio, Napoleon's great uncle, then a sufferer from the gout. After detailing his uncle's symptoms at length, Napoleon terminates his letter with the expression of his high consideration for his correspondent, derived from a perusal of his works, and an anticipation of the debt of gratitude which he should owe to him. The letter was dated Ajaccio, April 1, 1787, and was endorsed in Tissot's handwriting, "Unanswered letter, of little interest." It may be doubted whether, had Tissot lived to the end of the century, this commentary would have appeared on the letter.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, WEDNESDAY, MAY 4, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

DR. BURROWS, *President*, in the chair.

Present—

Dr. Alderson.	Dr. Andrew Wood.	Dr. Corrigan.
Mr. Arnott.	Dr. Fleming.	Dr. Sharpey.
Mr. Cooper.	Mr. Syme.	Dr. Parkes.
Dr. Acland.	Dr. Thomson.	Dr. Quain.
Dr. Paget.	Dr. A. Smith.	Mr. Rumsey.
Dr. Embleton.	Mr. Hargrave.	Dr. Christison.
Dr. Storrar.	Dr. Leet.	Dr. Stokes.
Dr. Alexander Wood.	Dr. Apjohn.	

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

1. Read the following memorial, addressed to the General Council of Medical Registration and Education:—

"We the undersigned registered Medical Practitioners of Banbury beg respectfully to call your attention to a consideration of the 40th Section of the Act, which imposes a penalty for 'falsely pretending to be a registered person,' and which has recently received a practical interpretation in one of the Metropolitan Police Courts; with the view that the different Registrars under the Act should be instructed by the Medical Council to take proceedings against offenders, rather than allowing the law to be vindicated by private individuals.

"The attention of your memorialists has been drawn to this by a most flagrant case of an unregistered person, without a diploma, or even Medical education, being allowed to assume the title of 'Dr.' and to practise in this town in defiance of the Act.

"ARTHUR B. RYE, F.R.C.S., L.S.A.
R. STANTON WISE, M.D., M.R.C.S., &c.
JOHN GRIFFIN, M.D., M.R.C.S.L.
THOMAS CLARKE, M.R.C.S.L.
RICHARD GRIMBLY, M.R.C.S., L.S.A.
C. L. H. PEMBERTON, M.R.C.S. Eng., L.S.A.
WILLIAM T. DOUGLAS, M.R.C.S., L.S.A."

Moved by Dr. ANDREW WOOD, seconded by Dr. ACLAND—"That the memorial from the Practitioners of Banbury be received and entered on the Minutes; and that the Registrar be directed to write in reply that it has been received, and to transmit to the memorialists a copy of so much of a report adopted by the Council on the 4th of August, 1859, as refers to the subject in question." (See Minutes, vol. i., p. 35).—Agreed to.

2. Read the following letter:—

"King and Queen's College of Physicians in Ireland,
Dublin, April 29, 1864.

"SIR,—I am directed to inform you that on the 2nd May, 1863, the following resolution was passed by this College:

"That the appointment of Inspectors of Apothecaries' Shops by the College of Physicians be discontinued after the publication of the *British Pharmacopœia*; and the College desire to convey to the General Medical Council their conviction that some legislative measure is necessary for the inspection of compounding establishments, and for ensuring the competency of the persons who conduct them."

"I am, Sir, your obedient servant,
L. ARTHILL, Fellow and Registrar.

"To the Registrar, General Medical Council, London."

Moved by Dr. A. SMITH, seconded by Dr. LEET—"That the letter be received and entered on the Minutes."—Agreed to.

3. The adjourned Debate was resumed on the motion, moved at the last meeting by Dr. CORRIGAN, and seconded by Dr. APJOHN, viz:—

"That the proposed Medical Bill, as amended by the Medical Acts Amendment Committee of last year, be forwarded to our solicitor, with directions to have it drafted as soon as possible, and returned to the Executive Committee;

"That the Executive Committee take means to have the Bill so drafted laid on the table of the House of Commons at the commencement of next Session of Parliament;

"That a copy of the Bill so drafted be forwarded without delay by the Executive Committee to the Branch Councils, to the several Bodies enumerated in Schedule (A) of the Medical Act, to the Pharmaceutical Society and the Press; so that all parties concerned may have ample opportunity, in the interval between publication of the Draft Bill and next meeting of Parliament, of considering the Bill, and of suggesting such amendments as they may desire;

"That the General Medical Council meet at as early a period as may be necessary next year, to consider the various amendments that may be suggested in the interval, in order to insert in the Bill such amendments as may meet their approbation."

And on the amendment moved by Dr. STORRAR, and seconded by Mr. ARNOTT, viz:—"That, looking to the great diversity of opinion which exists in Great Britain, in regard to the objects which it is desirable to obtain by an amendment of the Medical Acts, it is not at present expedient that the Council should engage in fresh legislation."

The amendment was negatived.

Second amendment, moved by Dr. ALEXANDER WOOD, seconded by Dr. SHARPEY:

"That the Council, while appreciating the labour and care bestowed by the Medical Acts Amendment Committee on the heads of a Medical Bill proposed in their Report, regret that it is impossible at this late period of the Session, to enter on the full consideration of so wide and important a subject;

"That the Council request the Branch Councils, in the interval between this Session and the succeeding one, to consider how Clauses XX., XXXI., and XL. of the Medical Act could be best amended;

"That the Council resolve to appoint an early day, at their meeting next Session, for the consideration of the whole subject."

The second amendment was carried.

Dr. CORRIGAN required that the names of the majority and minority should be taken down.

<i>Majority.</i>	<i>Minority.</i>
Dr. Alderson.	Mr. Arnott.
Dr. Paget.	Dr. Andrew Wood.
Dr. Embleton.	Dr. Fleming.
Dr. Storrar.	Dr. A. Smith.
Dr. Alexander Wood.	Mr. Hargrave.
Mr. Syme.	Dr. Apjohn.
Dr. Leet.	Dr. Corrigan.
Dr. Sharpey.	Dr. Parkes.
Mr. Rumsey.	Dr. Stokes.
Dr. Christison.	

The amendment was then put as a substantive motion.

Amendment, moved by Dr. ANDREW WOOD, seconded by Mr. HARGRAVE—"That it be remitted to the Executive Committee to have drafted by a Parliamentary solicitor a bill, having regard chiefly to Clauses XX., XXXI., and XL. of the Medical Act; that the bill so drafted be transmitted confidentially to the Branch Councils for their opinion; that thereafter the bill be re-drafted, so as to be in a condition to be submitted to the General Medical Council at its next meeting."

The amendment was negatived.

The substantive motion was then put, and carried.

3. A letter having been read from Mr. Thomas Edis, of Barton-street, Gloucester, requesting that his name might be restored to the Medical Register, as it had been omitted through change of residence, it was moved by Dr. STORRAR, seconded by Dr. ANDREW WOOD—"That the name of Thomas Edis be replaced on the Register."—Agreed to.

4. Read, the following letter:—

"Royal College of Physicians, Edinburgh, 5th Nov., 1863.

"Dr. Hawkins, Registrar,
General Council of Medical Education and Registration.

"Sir,—By direction of the Royal College of Physicians of Edinburgh, beg to intimate to you, on behalf of the General Council of Medical Education and Registration of the United Kingdom, that, at a meeting of the Royal College of Physicians of Edinburgh, duly called and held here on 3rd inst., the following motion was submitted to the College, and carried:

"It having been proved to the satisfaction of the College, that Robert Jacob Jordan, a Licentiate of this College, has been guilty of conduct unbecoming the character of a Physician, in publishing, or causing to be published, an indecent work, entitled, 'The Illustrated and Descriptive Catalogue of the Subjects contained in the London Anatomical Museum; to which is annexed the Guide to Masculine Vigour—by a Physician;'" that the said Robert Jacob Jordan be deprived of his Licence from the College;

"That the College thereon declared that the said Robert Jacob Jordan was deprived of his licence from this College, and of the diploma as a Licentiate of this College, conferred on him on the 14th June, 1859, and of all the rights and privileges which, as a Licentiate of this College, he does enjoy."

"In intimating this deprivation of Mr. Robert Jacob Jordan's licence from this College to you as Registrar of the General Council of Medical Education and Registration of the United Kingdom, the College directed me to request of you 'that any qualifications derived from this College and entered in the Medical Register, as pertaining to Mr. Jordan, may be expunged.'

"I am, Sir, your most obedient servant,

"CHRISTOPHER DOUGLAS,
Clerk to the Royal College of Physicians
of Edinburgh."

Moved by Dr. ALEXANDER WOOD, seconded by Dr. ANDREW WOOD—"That the name and qualification, as Licentiate of the Royal College of Physicians of Edinburgh, of Mr. Robert Jacob Jordan, be removed from the Register."—Agreed to.

5. A letter having been read from the Secretary of a reading society at Croydon, respecting an indecent publication, it was moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That, as advised by their Solicitor, there does not appear to the Medical Council to be any evidence to connect the publication with any registered Practitioner, and that the publication referred to does not, therefore, come within the province of the Council."—Agreed to.

*Confirmed—*GEORGE BURROWS, *President*.

MINUTES OF MEETING, THURSDAY, MAY 5, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

DR. BURROWS, *President*, in the chair.

*Present—*As before.

The Minutes of the last meeting were read and confirmed.

1. Read—The following letter:—

"Cawood, Selby, Yorkshire, April 25, 1864.

"To the General Medical Council of Education and Registration.

"Gentlemen,—Will you kindly permit me to appear before you to plead my cause for permission to present myself at one of the examining boards?"

"I have suffered much from my former misconduct, and have, since my name was erased from the Medical Register, striven all in my power to redeem the past, by attending the lectures and Hospital practice required by candidates for examination (having not done so prior to that time, which caused the Medical men in this district to be so bitter against me. This feeling, I am happy to say, has subsided).

"I have held for some years (and continue) the appointments of Medical officer to several clubs and townships, besides having a large midwifery practice; I therefore trust, as I am truly penitent for my former imprudence, you will take my case into your kind consideration, and not compel me to continue in practice unqualified as I undoubtedly must without your help, and my gratitude for your kindness shall be evinced by my future life.

"Anxiously waiting your reply,

"I am, Gentlemen, your obedient Servant,

"RICHARD ORGAN."

Moved by Dr. ALEXANDER WOOD, seconded by Mr. SYME:—"That the Council decline to accede to the request of Mr. Organ."—Agreed to.

The Report of the Select Committee on Education was presented by Dr. Christison.

Report.

The Committee appointed on May 3, relative to Professional education,

have to Report that they have carefully considered all the points referred to them by the Council.

They understand the object of the Council to be, that this report should comprise a statement of all recommendations as to Professional education, arising from the late discussion in Committee of Council, as to which there appears to be a general agreement in the Council, and which may be sent forth this session as recommendations to the several licensing bodies of the Kingdom, or suggestions to them for information. The Committee trust that they have kept this object steadily in view in the following recommendations:—

I.—REGISTRATION.

The Committee recommend under this head that the regulations proposed in the Report of the Sub-Committee on Registration (Minutes No. 62, pp. 7 and 8) be adopted, with a slight change in No. 3 of these regulations, which will then stand as follows:—

1. That the registration of Medical students be placed under the charge of the branch registrars.
2. That each student be only once registered—viz., when he first enrolls himself as a Medical student.
3. That each licensing body request from each School of Medicine under its jurisdiction a list of all students entering on the study of Medicine for the first time at that school, agreeably to the subjoined form.

Form of Register of Medical Students.

Name.	Age last Birthday.	Prelim. Examn. and Date.	Date of Registration.	Place of Study.

4. That the register at each school be closed within fifteen days after the commencement of each session or term.

5. That these lists, as soon as possible thereafter, be transmitted, along with the certificates of each student having passed an arts examination, to the branch registrar of that division of the Kingdom where the school is situated, and that he from them frame an accurate register of Medical students of that division of the Kingdom of which he is registrar.

6. That the registers of Medical students so prepared by the registrars, after examination by the several Branch Councils, be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, print the same in alphabetical order, and supply a copy of this authorised list to each of the bodies in Schedule (A) to the Medical Act.

7. That the several licensing bodies be requested, after October, 1868, to abstain from examining any candidate for licence or degree whose name does not appear on the authorised list of Medical students.

8. That the Branch Councils be desired to take means to make these regulations known to the Medical students at the various Medical schools.

9. That exceptions allowed by the Licensing Bodies to any of the preceding regulations as to registration, together with the reasons for such exceptions, be transmitted to the Branch Council of the part of the United Kingdom in which they have been granted.

II.—AGE FOR LICENCE TO PRACTISE.

The Committee, after having taken into consideration Mr. Rumsey's notice of motion, that the earliest age for obtaining any licence to practise Medicine or Surgery should be twenty-two, recommend that the Resolution 17 of the Recommendations of Council in 1863, p. 7, be adhered to in the following shape:—

1. That the age of twenty-one be the earliest age at which any Professional licence shall be obtained, and that the age shall in all instances be duly certified.

III.—PROFESSIONAL STUDY.

The Committee have taken into consideration the notices of motion as to Professional study given by Dr. Thomson, Dr. Parkes, and Dr. Storrar, and have come to the following recommendations, in which not only these gentlemen, but likewise every other member of Committee present have concurred:—

1. That no licence be obtained at an earlier period than after the close of the last Winter Session of four years of study after the registration of the candidate as a Medical student.

2. That the course of study required for a licence shall comprehend attendance during not less than four Winter Sessions, or three Winter and two Summer Sessions, at a recognised Medical school, and that evidence shall be produced that the remaining period of the four years has been passed in the acquisition of Professional knowledge.

3. That, in reference specially to Dr. Parkes' notice of motion as to duration of Sessions and of courses of lectures, the regulation of the duration of Sessions and the extent and duration of courses of lectures and instruction be left for the present to the several Licensing Bodies.

4. That it be recommended to the several Licensing Bodies that the courses of instruction required by them should be framed in such a manner as to secure a due share of attention both to preparatory branches and to those more strictly connected with the practice of Medicine and Surgery; and that it be suggested accordingly to these Bodies that their regulations should be such as to prevent attendance upon lectures from interfering with Hospital and clinical study.

5. That, while avoiding for the present all other details by which this object may be attained, it be recommended that no subject of lectures be enforced by regulation to be attended oftener than once.

6. That the Council intimate that they will view with approbation any encouragement held out by the Licensing Bodies to students to prosecute the study of the natural sciences before they engage in studies of a strictly Professional character.

7. That the several Licensing Bodies be requested to furnish a short statement of the mode in which their examinations are now conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each or all of these ways.

IV.—EXAMINATIONS.

The Committee have considered the subject of examinations with

peculiar care, which was rendered imperative by the proofs brought before the Council in the late discussion on education that the examinations of the Licensing Boards, however conscientiously carried on under the present system, are not always sufficient for their purpose. The subject is one confessedly of much difficulty. The Committee have resolved to recommend:—

1. That the Licensing Boards be advised to encourage the periodical examination of students at their several classes.

2. That the final examination of the Licensing Boards be so carried on as to be an efficient test of the practical acquaintance of candidates with the several branches of Medical knowledge, and especially with the practice of Medicine and Surgery.

3. That the Professional examination for any licence be divided into two parts—the first embracing the primary or fundamental branches of Medicine; and the second the branches directly connected with the practice of Medicine and Surgery; that the former be not undergone till after the close of the winter session of the second year of Professional study; and the latter, or final examination, not till after the close of the winter session of the fourth year of such study.

4. That the examination in chemistry, botany, and natural history may be undergone at an earlier period.

5. That the Professional examinations be conducted both in writing and orally, and that they be practical in all branches in which they admit of being made so.

6. That the Professional examinations be held by the several Licensing Bodies, except in special cases, at stated periods, to be publicly notified.

7. That returns from the Licensing Bodies in Schedule (A) be made annually on the 1st of January, and in the subjoined form, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second examinations, and the number of those who have been rejected at the first and second examinations respectively; and that the Registrar forward a sufficient number of forms, with a notice for their being returned, in due time.

FORM OF RETURN OF EXAMINATIONS, AND THEIR RESULTS.

Passed.				Rejected.	
1st Examination.		2nd Examination.		1st Examination.	2nd Examination.
No.	Name.	No.	Name.	No.	No.

V.—SUPERVISION OF EXAMINATIONS.

So much has been truly said in the late discussions in the Council, as to the duty which lies with the Council to carry out the enactments of the Medical Act relative to the supervision of the examinations of the Licensing Boards, that the Committee have felt a great desire to recommend some definite course which the Council might at once pursue for establishing such supervision.

They fear, however, that the Medical Act is defective in this respect, inasmuch as it has not contemplated either the great amount of time and labour required to carry on a really effective supervision of the very numerous examinations of the Licensing Boards of the Kingdom, some of which do not meet for examination at the seats of the Branch Councils, or the amount of qualifications and Professional position necessary to constitute a staff of efficient visitors of examinations; and, consequently, has omitted to provide the means of remunerating them for their important services. But, notwithstanding this obstacle, the Committee recommend that a trial of visitation be immediately made on such a scale as may be a guide to the Council for further regulations on the subject at a future meeting. For this end they recommend that the Branch Councils be instructed severally to organise a set of trial visitations on a scale which may enable them to report upon their success, the conditions for efficiency, and the requisite means for rendering them adequately extensive.

VI.—SUGGESTIONS FOR OBTAINING INFORMATION.

To these recommendations, which it seems to them advisable that the Council resolve now to adopt, the Committee think it right to add others, as to which the opinions of the Licensing Bodies, and of the Medical schools connected with them, should be requested in time for the consideration of the Council at its next Session, viz.:—

1. Whether, in the opinion of the Licensing Bodies, the commencement of Professional study, by which the duration of it must be regulated, should be held to be only entrance on such study at a recognised Medical school?

2. Whether a "Medical school" may be better or otherwise defined than as one where there is an opportunity of studying at a general Hospital, containing at least eighty beds for patients, and also a teacher of practical anatomy recognised by a Licensing Body?

3. Whether entrance on apprenticeship should be held as another way of constituting the commencement of Professional study?

4. Whether the same privilege be extended to pupilage under a registered Practitioner, who has charge of a Union Workhouse, a Dispensary, or an Hospital, though destitute of Medical or Surgical teachers?

5. Whether any other mode of study may be similarly recognised as the commencement of Professional study?

6. Whether, looking to the great extension of the primary or fundamental sciences of Medicine during the last forty years, the subjects embraced in courses of lectures on these sciences may not be better arranged and treated than now; so that they may be made more applicable than they are at present to the practical instruction of Medical students, as distinguished from general students?

7. Whether it be advisable or not, and if advisable, whether, and how, it may be practicable to adopt, in part at least, the principle of *ad eundem* examinations: so that a candidate who has been satisfactorily examined, in part or completely, for any Professional title conveying the right of practice, shall not be subject to re-examination on precisely the same branches by another Examining Body, before whom he may appear as candidate for the same, or a different, qualifying Professional title?

8. Whether it be advisable and practicable for the relief of candidates for licences from superfluous examinations, to establish in England, Scotland, and Ireland severally, a conjunct Examining Board, before whom candidates may be subjected to a single series of examinations for the "double qualification" of Physician and Surgeon.

9. Whether it be desirable that the oral and practical parts of the Professional examinations should be so conducted as to be open to registered Medical Practitioners and registered Medical Students.

Lastly, In conformity with the notices of motions by Dr. Acland, the Committee recommend the Council to appoint a Select Committee to consider and report at the next session of the Council what are the subjects of examination which should be required of all students prior to commencing the prescribed course of Professional education, and what are the Professional subjects of examination which should be required of all candidates before they receive the license to practise Medicine, or Surgery, or Medicine and Surgery.

R. CHRISTISON, *Chairman.*

Moved by Dr. CHRISTISON, seconded by Dr. ANDREW WOOD—"That the Report be received and entered on the Minutes."—Agreed to.

2. Moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That the standing order, paragraph 12, Section III., 'Order of Business,' be amended so as to read as follows:—"That, in cases when a division takes place, any member of the Council may require that the names or numbers of the majority and minority be entered on the Minutes."

Amendment, moved by Dr. ALEXANDER WOOD, seconded by Mr. HARGRAVE—"That standing order, paragraph 12, Section III., be altered to the following effect:—"That, in all cases when a division has taken place, any member of the Council may require that the names or numbers of the majority and minority, and of those declining to vote, be entered on the Minutes."

The amendment was carried; and, having been then put as a substantive motion, was agreed to.

3. Moved by Dr. A. SMITH, seconded by Dr. CORRIGAN—"That the names of persons which have been removed from the register by order of the General Medical Council, or by the Executive Committee, in accordance with the standing orders, be printed annually as an appendix to the register."

The motion was negatived.

4. Moved by Dr. A. SMITH, seconded by Dr. ALEXANDER WOOD—"That the Executive Committee be authorised to remove from the register the qualification of any person who has been deprived of his Diploma or Licence by any of the bodies in Schedule (A) of the Medical Act."—Agreed to.

"That the Executive Committee be authorised to remove from the register the name of any person who has been expelled, or deprived of his Diploma or Licence by any of the bodies in Schedule (A) of the Medical Act, provided the said person has not registered any other qualification."

5. Moved by Dr. A. SMITH, seconded by Dr. ALEXANDER WOOD:—"That the standing order, chap. viii., paragraph 6, be amended as follows:—"That, should the Council remove the name of any person from the Register, under section xxviii. or xxix. of the Medical Act, due intimation of the same be made to all the Bodies enumerated in Schedule (A) to the Act."—Agreed to.

6. Moved by Mr. SYME, seconded by Mr. RUMSEY:—"That no Member of the Medical Council shall speak upon any subject for more than a quarter of an hour, without permission of the Council."

The motion was negatived.

Mr. SYME required that the numbers of the majority and minority, and of those who declined to vote, be entered on the Minutes.

Majority	11
Minority	6
Declined to vote	5

7. Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON:—"That the various standing orders which have been agreed upon during this session be referred to the Committee on Standing Orders, in order that they may be incorporated with the Standing Orders of the Council, and with instructions to that Committee to number the orders."—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. ANDREW WOOD:—"That Dr. Embleton be appointed Chairman of the Committee on the Standing Orders, in the room of Dr. Christison, resigned."—Agreed to.

8. Moved by Dr. ALEXANDER WOOD, seconded by Dr. ANDREW WOOD—"That the Council take into consideration the Report of the Committee on the requirements of the Commissioners for administering the Laws for Relief of the Poor in Ireland, deferred from last session."—No. 54, Sect. 26, vol. ii., pp. 231, 232, and 233.—Agreed to.

Moved by Dr. ALEXANDER WOOD, seconded by Dr. ANDREW WOOD—"That, whereas the Commissioners for administering the Laws for the Relief of the Poor in Ireland require a Licence in Midwifery from Candidates for employment under them, the Medical Council requests the President to communicate with the Home Secretary, for the purpose of inducing him to request the Commissioners to receive the Certificates of all the Bodies in Schedule (A) to the Medical Act, examining in Midwifery, thereby carrying out the reciprocity in practice which it was one object of the Medical Act to secure."

The motion was carried.

Dr. ALEXANDER WOOD required that the names of the majority and minority be entered on the Minutes:

<i>Majority.</i>	<i>Minority.</i>
The President.	Dr. Smith.
Dr. Alderson.	Mr. Hargrave.
Mr. Cooper.	Dr. Apjohn.
Dr. Acland.	Dr. Corrigan.
Dr. Paget.	
Dr. Embleton.	
Dr. Storrar.	
Dr. Alexander Wood.	
Dr. Andrew Wood.	
Dr. Fleming.	
Mr. Syme.	
Dr. Sharpey.	
Dr. Parkes.	
Dr. Rumsey.	
Dr. Christison.	
Dr. Stokes.	

Moved by Dr. ALEXANDER WOOD, and seconded by Mr. SYME:—"That the Registrar be instructed not to enter on the register the licences in midwifery of the King and Queen's College of Physicians in Ireland, or of the College of Surgeons of Ireland, inasmuch as these qualifications do not appear on Schedule (A) to the Medical Act."

Amendment, moved by Dr. ARJOHN, and seconded by Dr. CORRIGAN:—"That before undertaking to give directions to the Executive Committee to depart from the regulations under which the Register has hitherto been published, the opinion of Sir Hugh Cairns and Mr. Hobhouse, referred to in the Report of the Committee on the requirement of the Poor-law Commissioners, &c. (see Minutes, vol. ii., p. 232), be read by the Registrar."

The amendment was negatived.

Second amendment, moved by Dr. PARKES, and seconded by Mr. ARNOTT:—"That both as regards future registration, and also the registrations already effected, a case be drawn out, without delay, by the Executive Committee and the solicitor to the Council, and be submitted to the law officers of the Crown, as to the legality of registering licenses in midwifery which do not appear in Schedule (A) to the Medical Act, and that the Executive Committee be authorised to act on the legal opinions thus obtained."

The second amendment was carried, and, having been put as a substantive motion, was agreed to.

9. Moved by Dr. QUAIN, and seconded by Dr. EMBLETON:—"That at future meetings of the Council, the first hour after the chair has been taken each day be appropriated to the consideration of such matters of business of the Council as are not likely to call for lengthened debate."

The motion was negatived.

Confirmed—GEORGE BURROWS, *President.*

MINUTES OF MEETING, FRIDAY, MAY 6, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Present—As before.

Dr. BURROWS, *President*, in the chair.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. CHRISTISON, seconded by Dr. STORRAR—"That the standing orders, in regard to order of business, be suspended, and that the Council proceed to consider the report of the Select Committee on Professional education."

The motion was negatived.

2. A correspondence having been read, which had taken place between the Poor-law Board, the Guiltcross Union, the Faculty of Physicians and Surgeons of Glasgow, and the Registrar of the General Medical Council, in reference to the question, whether the Licence of the Faculty of Glasgow confers a qualification both in Medicine and in Surgery.

Moved by Dr. FLEMING, seconded by Dr. ALEXANDER WOOD—"That in reply to the inquiry made by the Secretary of the Poor-law Board, in regard to the powers conferred by the licence of the Faculty of Physicians and Surgeons of Glasgow, the Registrar be instructed to intimate that the question involving the legal interpretation of a charter is one which the Council is not competent to answer."—Agreed to.

3. Read, the following letter from the Director-General of the Army Medical Department:—

"Army Medical Department, April 9, 1864.

"Sir,—The President and Fellows of the King and Queen's College of Physicians in Ireland having applied to the Secretary of State for War to have the letters 'Phys.' inserted in the Army List, after the names of such Medical officers as may possess the qualification of that body, and Lord De Grey having determined to have the subject referred to the General Medical Council, with a view of eliciting their opinion as to the expediency of recognising such a title as a means of distinguishing such Licentiates from other legally qualified Medical Practitioners, I shall feel obliged by your having the matter so submitted to the General Medical Council at their next meeting.

"I have the honour to be, Sir,

"Your most obedient humble servant,

(Signed)

"J. B. GIBSON, *Director-General.*

"The Secretary, General Council of Medical Education, "32, Soho-square, W."

Moved by Dr. CORRIGAN, seconded by Dr. SMITH—"That it is the opinion of the General Medical Council that it would not be advisable to insert the letters 'Phys.' but that it is the opinion of the General Medical Council that the several Medical qualifications which army Surgeons possess, as inserted in the *Medical Register*, might be entered after their names in the *Army List*."—Agreed to.

4. Moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That a letter from the King and Queen's College of Physicians respecting the licence granted by the Apothecaries' Hall of Ireland be read."

The previous question was moved by Dr. PAGET, seconded by Dr. ACLAND.—Agreed to.

5. Moved by Dr. ALEXANDER WOOD, seconded by Mr. SYME—"That the standing order, Sect. III., No. 5, be suspended, and that the Council do now proceed to consider the Report of the Select Committee on Education."—Agreed to.

Moved by Dr. FLEMING, seconded by Dr. STORRAR—"That the Report of the Select Committee on Education be held as read."—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 1, Sect. I, of the Report of the Select Committee be adopted, viz.: "That the registration of Medical students be placed under the charge of the Branch Registrars."—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 2, Sect. I, be adopted as thus amended, viz.: "That every student be registered at the commencement of Professional study."—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 3, Sect. I, be adopted, as thus amended, viz.: "That the several Licensing Bodies be requested to furnish to the Branch Registrars, at the beginning of January annually, a list of students who have been registered for the first time during the preceding year, according to the subjoined form:"

Form of Register of Medical Students.

Name.	Age last Birthday.	Prelim. Examin. and Date.	Date of Registration.	Place of Study.

—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 4, Sect. I., be adopted as thus amended, viz., 'That the Register of each Licensing Body be closed within fifteen days after the commencement of each Session or Term; 'And that Regulations 4 and 5 be transposed.'"—Agreed to.

Moved by Dr. CHRISTISON, seconded by Mr. ARNOTT—"That Regulation No. 5, Sect. I., be adopted as thus amended, viz., 'That from the lists of the Licensing Bodies each Branch Registrar shall frame an accurate Register of Medical students of the division of the United Kingdom of which he is Registrar.'"—Agreed to.

Moved by Dr. CHRISTISON, seconded by Mr. ARNOTT—"That Regulation No. 6, Sect. I., be adopted as thus amended, viz.:—"That the register of Medical students so prepared by the Registrars, after examination by the several Branch Councils, be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, prepare and print an alphabetical list of all registered students, and supply a copy of this authorised list to each of the bodies in Schedule (A) of the Medical Act.'"—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 7, Sect. I., be adopted as thus amended, viz.:—"That the several Licensing Bodies be requested, after October, 1868, to abstain from examining any candidate for licence or degree whose name does not appear on the authorised list of Medical students as having passed the preliminary examination in arts, or whose name is not already on the Medical Register.'"—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 8, Sect. I., be adopted, viz., 'That the Branch Councils be desired to take means to make these Regulations known to the Medical students at the various Medical schools.'"—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 9, Sect. I., be adopted as thus amended, viz., 'That exceptions allowed to the Licensing Bodies to any of the preceding Regulations as to registration, together with the reasons for such exceptions, be transmitted in a separate list, to the Branch Council of the part of the United Kingdom in which they have been granted.'"—Agreed to.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That Regulation No. 1, Sect. II., be adopted, viz.:—"That the age of 21 be the earliest age at which any Professional licence shall be obtained; and that the age shall in all instances be duly certified.'"—

Amendment moved by Mr. RUMSEY, seconded by Mr. HARGRAVE—"That Regulation No. 1, Sect. II., be adopted with the addition—"That, after the year 1868, the earliest age at which any Professional licence shall be obtained be 22.'"—

The amendment was negatived.

Mr. RUMSEY required that the numbers be entered on the Minutes:—

Majority	11
Minority	7
Declined to vote	5

The motion was then put and carried.

Moved by Dr. CHRISTISON, seconded by Dr. STOKES—"That the further consideration of the report of the Select Committee be now adjourned."—Agreed to.

6. Moved by Dr. A. SMITH, seconded by Dr. ANDREW WOOD—"That the Standing Orders be suspended, and that the Council meet to-morrow at twelve, instead of two o'clock."—Agreed to.

7. Moved by Dr. CHRISTISON, seconded by Dr. ANDREW WOOD—"That the Standing Orders be suspended, and that the Council now proceed to ballot for the members of the Executive Committee."—Agreed to.

A ballot having been taken, Mr. Arnott, Dr. Acland, Dr. Sharpey, and Dr. Quain were found to be elected.

Confirmed—J. M. ARNOTT, Chairman.

REVIEWS.

Die Pathologie und Therapie der Rachitis. Von Dr. G. RITTER.

The Pathology and Therapeutics of Rickets. By Dr. GOTTFRIED RITTER, of Rittershain, Director of the Medical Poliklinik at Prague. Berlin, 1863.

DR. RITTER'S work is carefully and scientifically written, and appears to be based upon a large clinical experience. For the most part his views confirm those put forth by Dr. Jenner in the lectures published in the *Medical Times and Gazette* in the year 1860. On some points, however, to which we shall allude, he is opposed to him. Rickets would appear to be extremely common in Prague. On instituting a searching examination, Dr. Ritter found that more than 31 per cent. of all the children attending the institution to which he is attached showed more or less decided tokens of the past or present existence of that disease. This, of course, was among the poor; but he is of opinion that of all morbid diatheses among children rickets is the most prevalent, and furnishes the greatest number of victims. Its existence often escapes notice, in his opinion, owing to superficial methods of examination. Among the causes of the disease he places first, hereditary descent, in this respect ranking it on a par with tuberculosis; phthisis, especially on the father's side, and, although less frequently, syphilis, predispose to rickets in the children, as also do general debility and bad nutrition of the mother. Dr. Ritter does not recognise a greater predisposition on the part of the later-born children. Next to hereditary tendency come overcrowding of dwellings and contamination of the air.

The first part of Dr. Ritter's volume is occupied with the description of the morbid processes in the bony structures, which constitute the most obvious, though not the most essential, characters of the disease. The idea, advanced

especially by some French writers, that the rachitic condition of the bones is due simply to non-assimilation or excessive excretion of the earthy elements, is shown to be entirely inapplicable, and the character of rickets as a special form of dyscrasy is maintained. The chemical differences of rachitic from healthy bones in the early years of life are thus summed up, chiefly from Friedleben's analyses:—There is a diminished quantity of earthy salts, especially at the height of the disease, nearer the normal amount in the older portions of the bone, and much below it in the newly-formed portions; in the latter an increased quantity of carbonic acid; in all, little difference in respect to fatty matters, with the exception of the long bones, in which it is increased, owing to apparent infiltration of the bony substance with marrow; the specific gravity of the bones is diminished. Their organic basis is not essentially altered, but the unossified cartilage contains an excess of water.

The most usual period of the development of the disease is about the middle of the first year of life, but traces of it are frequently visible at birth. The deformities often commence in the trunk, and extend later to the extremities. The progress of the disease seems sometimes to be checked by tuberculosis, to which it greatly predisposes. The size of the head is generally increased, the forehead prominent; it is for the most part asymmetrical, the right oblique diameter being the shorter. The "soft hind head" first described by Elsasser, in which some portions of the posterior part of the skull are thinned and yield to slight pressure, Dr. Ritter denies to be of a rachitic character; it is connected rather with hydrocephalus. The case is the same with the head-sweats, which Dr. Ritter ascribes to the same tendency to effusion that exists within the skull. The blowing sound heard on auscultating the head in some cases has no special relation to rickets; its cause is arterial.

Dr. Ritter takes some pains to point out the differences between the distortion of the pelvis which arises from rickets in early life, and that which is due to the later access of osteomalacia. The former is to be ascribed to two distinct factors—first, the direct effects of the rachitic disease; and secondly, alteration of form from pressure on the yielding bones when the child begins to walk before the disease has ceased. The direct rachitic changes arise from the abnormal and unequal growth of the periosteum and cartilage, especially on the edges of the bones, and from the checked and irregular ossification and the retarded growth arising from this cause. From the weight of the body ensue a pressing forwards and downwards of the promontory and sacrum, while the arch of the pubis is carried upwards and becomes flattened. Thus the pelvis becomes narrowed from before backwards—the transversely oval or the simple flattened rachitic pelvis. In osteomalacia, on the other hand, the three points which sustain the weight of the body, the promontory and the two acetabula, are pressed together, and the pelvis has a triangular form, the symphysis pubis often projecting into a beak-shaped process. The two forms, however, are often mingled and mutually obscured. Asymmetry of the pelvis arises from spinal curvatures.

In respect to the condition of the internal organs, Dr. Ritter disputes altogether Dr. Jenner's view of albuminoid infiltration of the liver, spleen, and other glands as an especial characteristic of the disease, and as the cause of the emaciation. He affirms such infiltration to be rare in rickets, and when present to bear no constant relation to the general nutrition. The projection of the abdomen is due mainly to gaseous distension of the intestines; spinal curvature, depression of the diaphragm, and enlargement of the glandular organs contributing to it more or less. Dr. Ritter holds that the almost constant patches of solidified lung tissue are due, as the rule, to the mechanical pressure of the enlarged articulations of the ribs. Emphysema is almost always present, and the bronchi contain frothy or slimy mucus. In some cases of slowly progressing tuberculosis of the lungs the distorted rachitic thorax tends to resume its normal form. At least, Dr. Ritter feels sure he has witnessed this result, and thinks it might aid the diagnosis of tubercle in rachitic patients. Diarrhœa is almost invariably present at some stage of the disease; in the great majority of cases it attends its commencement. Cough and dyspnœa, frequently of a paroxysmal character, are seldom absent, and often these first attract the notice of the friends. There is no proof of pain or increased tenderness in the bones or skin. The restlessness and shrinking of the child are accounted for by the severity of the other symptoms.

For treatment Dr. Ritter recommends, in addition to hygiene, in which plenty of good air holds the first place, and natural

and nutritious food the second, the milder preparations of iron. He distrusts altogether cod liver oil. The mother's health should be sedulously attended to during pregnancy, the child suckled entirely during the first few months, and too soft pillows avoided; this latter recommendation doubtless having an especial value where German customs prevail. For the diarrhoea he uses chalk with astringents; for the pulmonary symptoms, ipecacuanha and morphia; and for the fever, quinine, and in some cases digitalis. Cold applications to the head are of the chief service in the cerebral complications. For the remaining distortions in those who recover, gymnastic exercises and Surgical treatment are the remedies.

Guida Teorico-Pratica del Medico Militare in Campagna.
Dal Cavaliere FRANCESCO CORTESE, Ispettore Sanitario nell'Esercito Italiano, etc., etc. Torino, 1862-63. Pp. 357 and 339.

Theoretical-Practical Guide for the Army Surgeon in the Field.
By Cavalier FRANCESCO CORTESE, Inspector-General of the Italian Army, etc., etc.

DR. CORTESE, formerly Professor of Anatomy at the University of Padua, and well known by earlier contributions to anatomy and physiology, is one of the oldest Italian Army Surgeons. He served in most of the Italian wars, and during the late campaign had charge of the 4th division under General Cialdini, took part in the principal engagements, and had the opportunity of gathering such experience as few Army Surgeons of the present day have had. A work, therefore, on military Surgery from his hand *à priori* deserves notice.

The work is divided into two parts. In the introduction to the first the author speaks about the preliminary arrangements at the commencement of a war, the construction of Hospitals and ventilation, overcrowding being particularly warned against. In the late discussion at the French Academy of Medicine on the reasons of the lower rate of mortality in the English Hospitals compared to the French, the importance of this question has been sufficiently argued and settled. The author recommends all sick officers to be admitted into Hospital instead of private houses, such an arrangement greatly simplifying supervision and the labour of the Medical officers. He speaks of the construction of huts and tents—the latter particularly to be used for itch and syphilitic patients, in order not to overcrowd the Hospitals. In this we do not agree with the author, and would prefer, climate permitting, to place the typhoid patients and the severely wounded in tents.

The mode of removing the wounded from the field, and the sick from one Hospital to another, is next considered, the caçolets being highly recommended for this purpose. During the late Italian war the voluntary supplies from the inhabitants were very numerous, but such are not to be relied upon; and great stress is laid on the necessity, in supplying the wants of an army, of duly considering the difference between fighting in a *friendly* country or that of the *enemy*.

The utmost simplicity in bandages and appliances is recommended, and a separation of the Medical from the Surgical cases, as well as a proper division of Professional labour amongst the Medical officers—a subject well worthy of attention in the army of every country. The first part of the work is devoted to the treatment of the wounded on the field, and in the *ambulances*. The first chapter treats of gunshot wounds in general by different projectiles, — 1st, according to their size and material; 2nd, the tissues affected by them; 3rd, their direction. The immediate treatment of gunshot wounds, the extraction of the ball, according to the parts where it is lodged, and immediate amputations, are next considered. The second chapter diffusely treats of contused wounds; the third, of wounds by burning; the fourth, of cut wounds,—all according to the parts affected. The fifth chapter speaks of the assistance to be rendered *on the field*, in cases of hæmorrhage, of amputation, and in the treatment of stumps.

The introduction of the second part of the work relates to the remedies and appliances used in military Hospitals, the various bandages, the application of ice and cold water, irrigation and immersion, poultices and the dressing of wounds, blood-letting, diet, and anæsthetics. As an Italian Surgeon, it is worthy of note that the author disapproves of too much bleeding of the wounded, warning against pyæmia as a frequent consequence, the absorption of septic material being thereby promoted. The articles in the first chapter on Hospital gangrene (against which the author strongly recommends the

early use of the actual cautery), on pyæmia, and tetanus, are eminently worthy of notice. The remainder of this part of the work contains the treatment of the different wounds, and their consequences. Resection of the different articulations is also well discussed.

Such is an outline of this very excellent work, which certainly furnishes the Army Surgeon with most valuable information, such as will enable him to meet the contingencies of the field; for, as the author very properly remarks, "the ulterior treatment of soldiers does not differ from that of other patients. To the soldier in Hospital the general principles of Surgery are applicable."

We would have liked to see a chapter added on *feigned diseases*, without which no treatise on Military Surgery can be said to be complete.

The author evinces a good knowledge of ancient and modern contributions to French, English, and German Military Surgery, to which he adds a great amount of personal experience. He is at present engaged on a work "On a Scale of Compensation (pensions) to be allowed to Soldiers according to the extent of Injuries received," which, to judge from his present book, will, doubtlessly, be of great value to the military authorities; and in it the author may perhaps be able to introduce a chapter on "*feigned diseases*."

An Essay, Historical and Critical, on the Mechanism of Parturition. By WILLIAM LEISHMAN, M.D., etc., Physician to the University Lying-in Hospital, and to the Royal Infirmary; Lecturer on Medical Jurisprudence in Anderson's University, Glasgow. Svo. London: Churchill and Sons. 1864. Pp. 129.

On the Diseases of Women. By FLEETWOOD CHURCHILL, M.D., etc., Professor of Midwifery and Diseases of Women and Children to the King and Queen's College of Physicians, Ireland, etc. Fifth Edition, carefully revised and enlarged. Dublin: Fannin and Co. 1864. Pp. 938.

Three Hundred Consultations in Midwifery. By ROBERT LEE, M.D., F.R.S. London: John Churchill and Sons. 1864. 12mo, pp. 217.

THESE three works may be fairly held to represent respectively the theory and physiological basis of obstetrical science; the various morbid processes incident to parturition and other cognate functions of the female; and the actual practical way in which both branches of information are brought under the notice of the Medical man in his ordinary avocations. Although they exhibit great differences in character, size, and scope, all alike serve to complete the circle of useful knowledge, and deserve the serious attention both of students and Practitioners.

Dr. Leishman introduces his subject by asserting that it is still too much of a theory, in spite of the elaboration with which modern teachers have expounded it. "Hence, as an almost inevitable result, new views have been propounded which, as inevitably have conducted in later years to perplexity and doubt in regard to what was previously comparatively clear. My main object," he says, "in the following memoir is to place before my readers, as clearly as the difficulty of the subject and my powers of description will permit, the great mechanical laws which guide us in the practice of the obstetric art. But I may state at the same time that it is my intention, both in reference to the history of the subject and otherwise, to give to the expression 'mechanism of parturition' a somewhat more extended signification than it usually bears."

He then at once proceeds to an interesting review of obstetrics in their historical aspect, from the most ancient down to modern times. This occupies about half the essay; and while it passes rapidly over earlier and cruder notions, examines in some detail the views of Naegelé, West, Rigby, and other distinguished accoucheurs.

In a third chapter cranial presentations are considered, and their varieties illustrated by some good woodcuts. Naegelé's views on "Biparietal Obliquity" are controverted relatively to the brim of the pelvis, but admitted and confirmed as regards a lower position of the presenting head. The position of the head at the outlet forms a fourth chapter; its obliquity is accurately measured by a cord held perpendicularly from pubes to perinaeum when it first emerges from the vulva; and then the practical question of supporting the perinaeum is entered upon. This measure is stated to have originated with Giffard in 1734, and to have been first inculcated as a duty of the Accoucheur by Professor Hamilton, of Edinburgh. The

conflicting views of modern authorities are adverted to, and the writer speaks strongly as to the uselessness of the practice; indeed, he holds the opinion that "the more assiduously the perinæum is supported in natural labour, the greater is its danger of rupture." The accident, when it actually occurs, he refers rather to pelvic deformities, malpresentations, rigidity, great rapidity of labour, injudicious use of instruments, persistence of the hymen, or, last, but not least, to mechanical support. Other cranial positions, their comparative frequency, and the discrepant statistics of various writers occupy the next place, followed by the question of artificial rectification to be brought about where such a proceeding might be advantageous. With this the essay concludes, the writer regretting that the length to which his observations on the ordinary cranial positions have extended precludes a consideration of breech, footling, and face presentations.

Of the second work on our list it is hardly necessary to speak in detail. Its appearance in a fifth edition, as well as its acknowledged reputation, testify sufficiently to its value. The author expresses, in a preface, his anxiety to afford all possible accuracy by repeated correction; alludes to the considerable additions which the work has received, mainly the result of increased experience; and acknowledges his obligations, among others, to Dr. M'Clintock, for his liberality in allowing the plates from his work to be at Dr. Churchill's disposal in augmentation of the illustrations to the book. It will be seen from the title that the bulk of this standard work now nearly reaches 1000 pages.

Dr. Robert Lee dedicates to the pupils of St. George's Hospital 300 observations from his practice. They are rather fragmentary in character, and no statement of general results is appended beyond a short paragraph on the last page, saying that they are supplementary to the "histories of 545 cases of difficult, preternatural, and complicated labour," comprised in the second edition of the author's "Clinical Midwifery." Whatever may be our opinion of Dr. Lee's practice as here detailed (and on former occasions it has been our duty to express disapprobation of it in some respects), there can be no doubt that he deserves the thanks of the Profession for frankly laying open to criticism the simple facts of his more remarkable cases. The little book affords a fair sample of the problems propounded to an obstetric Practitioner in high repute, and the way in which they come before him. We can entertain no doubt of their accuracy as to observation and record; nor is it un instructive to use them, like their mathematical correlatives, as theorems for our own private solution.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 5 AND 19.

Mr. PRESCOTT HEWETT, President.

Dr. WALE HICKS read a report on a

SPECIMEN OF LUNG AND SPLEEN OF A HORSE

obtained at the Veterinary College, and mentioned in our last report. The spleen was seen to be almost filled with nodules of tolerably firm yellowish-white tissue, the larger nodules being about two inches in diameter, and the smaller about a quarter of an inch. The lung was affected much in the same way, but the masses were greyish-white, less firm, and more juicy, and many of them were very minute. Portions, both of the lung and spleen, were removed for microscopic examination. On making thin sections of the lung tissue, and washing and pressing them, portions of the infiltrated substance were removed, and many of the air-cells could be distinctly seen, empty and healthy looking, which were before entirely blocked up. The matter contained in the air cavities, however, was not so easily or so completely removeable as in the specimen of horse's lung before examined. The cell-growth somewhat resembled that in the previous specimen, but was more varied. Most of the corpuscles had a finely granular appearance, and some of them contained a number of distinct minute globules resembling oil globules. A considerable number of the corpuscles were small and rounded, about the size of a blood corpuscle; a smaller number were much larger, double or treble the diameter of the former, also spherical, and containing a distinct nucleus. Besides these,

there were many other corpuscles intermediate in size, varying greatly in shape, some oval or rounded, others fusiform or canteate; most of these were also nucleated. Some of the juice from the cancerous nodules of the spleen was also examined, and found to resemble greatly that from the lung, the chief difference being that the cells were somewhat less distinct and well formed, and were mingled with some of the elongated fusiform fibre-cells of the spleen, and with a greater quantity of granular matter than was observed in the lung.

Dr. GIBB read a report on Dr. Murchison's case of

NECROSIS OF THE HYOID BONE.

The specimens submitted to him, after the most careful examination and comparison with a number of healthy bones, were made out to be component parts of a necrosed hyoid bone. The larger specimen consisted of the right half of the body of the bone, being much thicker than natural, the result of the morbid process, which most probably was in the first instance periosteal, and extending to the true osseous structure. The anterior projecting angles for the origin of muscles corresponded pretty accurately with those of the healthy bone. The smaller specimen was a portion of one of the greater cornua, probably the right, as the general disease would seem to have been mainly confined to that side. Dr. Gibb thought that, allowing for the alterations produced by inflammation, the diagnosis of the bone involved was most satisfactorily established.

Dr. SCHULHOF showed several

FIBRINOUS CASTS OF THE UTERUS.

A woman, 62 years of age, who had had good health until recently, began to suffer from a sanguinous discharge, and subsequently passed two substances analogous to the amenorrhœal membrane of younger women.

The specimens were referred to Dr. Graily Hewett for further examination.

Mr. SQUIRE then showed the

OVA OF THE PEDICULUS CORPORIS.

They had been taken from a man, 60 years of age, who had suffered from prurigo two years. He said that the body louse was a frequent cause of the disease called prurigo senilis. It was not often found, as it was not looked for in the right place, viz., in the clothes. Mr. Squire had examined sixteen cases, and had found the lice in each.

Dr. BRISTOWE could confirm Mr. Squire's statements as to the lice being a frequent cause of prurigo senilis.

Dr. HARLEY showed a specimen of

CONGENITAL MALFORMATION OF THE KIDNEY.

A child died at the age of 10 months of croup, having had no symptom of renal disease. Her only peculiarity was that she would never lie on the right side. There was no kidney stricture to be seen, the ureter was quite occluded, and a mass of cysts occupied the site of the kidney.

Dr. GIBB exhibited some

WORMS EXIELLED FROM THE NOSE AND FRONTAL SINUSES

of a girl, aged 11 years. For three months she complained of pains in her head and over the frontal sinuses, and also in the chest. The face, forehead, and nose then became swollen and erysipelatous, with a discharge from the nose and the passage of several worms, which were believed to come from the frontal sinuses. They were exceedingly small, about an inch long, and when coiled up were not larger than pins' heads. The girl is still under treatment in the Westminster Hospital.

Mr. MASON inquired if Dr. Gibb had seen any of the worms passed.

Dr. GIBB had seen them come from the right nostril.

Dr. OGLE exhibited

A CHILD HAVING THE GREATER PART OF THE STOMACH, DUODENUM, AND ALL THE INTESTINES EXTERNALLY LYING ON THE OUTER SURFACE OF THE ABDOMEN—ILLUSTRATED BY PHOTOGRAPHIC REPRESENTATIONS.

For the opportunity of exhibiting this specimen Dr. Ogle was indebted to Mr. James Eaton, of Grantham, formerly a student at St. George's Hospital. The child (a male) was apparently an eight months' child, and was born alive. The mother, in good health, aged 23, had a natural and very easy labour, and the liquor amnii had escaped before Medical aid could be obtained. The child breathed easily at first, but after a few hours began to breathe heavily. The exposed stomach and bowels became inflated and inflamed, after two evacuations of meconium. On the following day the breathing had become laborious, and the viscera more distended. There was also

much crying, as if pain was suffered. The child died twenty-nine hours after birth. The viscera, situated externally, were quite devoid of any peritoneal investment, and communicated with the abdominal cavity by means of an opening of the size of a shilling in the abdominal parietes, about an inch from the umbilicus. When the intestines, etc., were drawn on one side, the liver within the abdomen could be seen through the above-mentioned opening. The peritonium lining the abdominal walls was found to be directly continuous with the outer skin at the forementioned opening in the abdominal parietes. No other maldisposition of parts was found in the body.

Dr. OGLE also exhibited a specimen of

COLLOID OR ALVEOLAR CANCER OF THE PERITONEUM OF VERY RAPID GROWTH.

The patient, a woman aged 47, was admitted into St. George's Hospital, under Dr. Ogle's care, in September in last year. She had only been ill between seven and eight weeks, suffering at first from anasarca of the legs; frequent vomiting and constipation followed (but never jaundice), and she was admitted with constant vomiting of a greenish fluid, and pain chiefly at the right side of the epigastric region. The urine was free from albumen. Much pain came on over the belly, which had become distended with fluid, and irregular, hard masses became felt in the abdomen, especially in the right cæcal region. The pulse was mostly very quick (about 112 in a minute). She sank and died two weeks after admission, and about ten weeks after the first symptoms set in (her mind remaining entire to the last). After death the entire peritoneum was found studded with numbers of colloid carcinomatous growths, forming a continuous layer, and the great omentum formed a large mass of the same growth. Moreover, the pylorus of the stomach was thickened by a growth of a distinctly *scirrhus* nature.

(To be continued.)

MEDICAL NEWS.

UNIVERSITY OF ST. ANDREWS.—List of Candidates who obtained the degree of M.D. on April 29, 1864:—

William Sankey, M.R.C.S.E., L.S.A., Sutton Valence, Kent; William Parker, L.F.P.S., L.S.A., Bermondsey; James Walsh, M.R.C.S.E., M.R.C.P.E., L.M.I., Staff-Surgeon, Limerick; John Alfred Lush, M.R.C.S.E., L.S.A., Salisbury; John Fenton, L.R.C.P.E., F.R.C.S., L.S.A., Liverpool; W. P. Charsley, M.R.C.S.L., Principal Civil Medical Officer, Ceylon; William Nassau Irwin, L.R.C.S.I., L.R.C.P.L., diploma Midwifery, Monaghan, Ireland; Walter Mc. D. Kelly, L.R.C.S. Edin., L.S.A., Crook, Durham; Thomas Wilson, M.R.C.S.E., L.S.A., Hull; J. Sydney Smith, M.R.C.S.E., L.M., L.S.A., Tiverton.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 10th inst., viz.:—

Messrs. Herbert Branwhite Spurgin, Thrapston, Northamptonshire; Thomas Edward Darley Hayes, Liverpool; Edwin Burrell, Westly, near Bury St. Edmunds; Robert Charles Earle, Totness, Devon; George Paddon, Hitchin, Herts; Henry Richard Smith, Newark, Notts, and Henry Todd, Broughton, Bradford, Yorkshire, Students of Guy's Hospital. Charles Clairidge Brewer, Newport, Monmouthshire; George Alexander Augustus Coates, Sirhawy, Monmouthshire, and Jesse Wheelock Thibon, Antigua, West Indies, of St. Bartholomew's Hospital. William Richard Goodfellow, Commercial-road, of the London Hospital; Henri Victor Bertin, L.R.C.P. Lond., St. John's-wood, of St. Mary's Hospital; Charles St. Aubyn Hawken, Redruth, of the Westminster Hospital; George Grewcock, Folkingham, Lincolnshire, University College; Martindale Cowslade Ward, Markham-square, Chelsea, of St. George's Hospital; Frederick Henry Hume, Angell-terrace, Islington, of St. Thomas's Hospital; John Drust, Gainsborough, of the Middlesex Hospital; Charles Frederick Knight, L.S.A., Brill, Bucks, of the Charing-cross Hospital; Hubert Charles Pickard Masser, Longford Coventry; William Slingsley Mann, Birmingham; James Saltus Conyers, Demerara, West Indies; Joseph Morris, L.R.C.P. Lond. and L.S.A., Studley, Warwickshire, and Henry Gilbert Jackson, Leeds.

Admitted Members on the 11th inst.:—

Messrs. Ralph Alexander Busby, Leamington; James Hamilton Martin, Tregony, Cornwall; Peter Harding, Shrewsbury, and Walter Smith, Bognor, Sussex, Students of University College; Andrew Miller, Highbury, and James Buntles Colthurst, Bristol, of King's College. Joseph William Barrett, Eton, and Samuel Henry Woodgates, M.D. Univ. Glasgow, Herford, of Guy's Hospital; Albert Louis Peacock, L.S.A., Huntingdon, and Eugene Francis Cronin, M.D. St. And., Clapham, of the Westminster Hospital; Frederick Le Fevre, Milburn, Leiston, Saxmundham, of Charing-cross Hospital; William Augustus Sparring, Norwich, of the London Hospital; Charles Fox Oxley, Pontefract, Yorkshire, of St. George's Hospital; Charles William Ellis Foster, Aldershot; John Williams, Anglesey; John Thomas Caldwell, L.S.A., Knutsford, Cheshire; William Askwith Rudd, Hull; William Astly Sherratt Dykes, L.S.A. Hull; John Albert Eatock, Rivington, near Bolton; William Henry Flint, Buxton, Derbyshire, and Robert Francis Allen, Clough-jordan, County Tipperary.

At the same meeting of the Court Mr. William Anderson (a) of the Royal Marine Artillery, Portsmouth, passed his examination for Naval Surgeon; this gentleman had previously been admitted a Member of the Edinburgh College of Surgeons, his diploma bearing date July 17, 1855.

The following Gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 5th inst., and when eligible will be admitted to the Pass Examination:—

Messrs. E. T. Willoughby, Polyxén Vandagne, M. H. Cantrel, E. L. de Morgan, and T. G. P. Hallett, Students of University College; A. C. Wakefield, David Thomas, A. M. Watson, J. M. MacFarlane, and R. W. Goldie, of Edinburgh; James Taylor, Glasgow; Osmer King, and F. B. Lardner, of Guy's Hospital; J. R. Dunn, Middlesex Hospital; Vaughan Carnley, Hull; W. K. Treves, St. Thomas's Hospital; W. H. Plaister, Bristol; G. A. Kenyon, St. George's Hospital; J. T. Hughes, Aberdeen; Augustin le Rossignol, London Hospital, and F. L. Attwood, St. Mary's Hospital.

THE FELLOWSHIP.—The following gentlemen have just passed the Preliminary Examination in Classics, Mathematics and French for the Fellowship of the Royal College of Surgeons of England, and when eligible will be admitted to the Final Examination, viz.:—

Messrs. George William Smith, Aytoun-street, Manchester, diploma of membership dated January 26, 1855; John Sebastian Wilkinson, Davies-street, May 15, 1857, and Samuel Edwin Solly, Savill-row, a Student of St. Thomas's Hospital.

APOTHECARIES' HALL.—Name of gentleman who passed his Examination in the Science and Practice of Medicine, and received a certificate to Practise on Thursday, May 5, 1864:—

Thomas Henry Knott, Guy's Hospital.

As an Assistant:—

John Evans, Cardiff.

The following gentleman, also on the same day, passed his First Examination:—

James Taylor, Anderson's University, Glasgow.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

COMFSON, J. C., M.R.C.S. Eng., has been elected House-Surgeon to the Leith Hospital, and to the Edinburgh and Leith Humane Society and Dispensary.

DEBUS, H., Ph.D., has been elected one of the Examiners in Chemistry in the University of London.

ELLIS, GEORGE VINER, F.R.C.S. Eng., has been elected one of the Examiners in Anatomy in the University of London.

FAIRBANK, F. ROYSTON, L.R.C.P. Lond., has been elected one of the Surgeons to the Ardwick and Ancoats Dispensary, Manchester.

FARBE, FREDERICK J., M.D., has been elected one of the Examiners in Materia Medica and Pharmaceutical Chemistry in the University of London.

GARROD, ALFRED B., M.D. Lond., has been elected one of the Examiners in Materia Medica and Pharmaceutical Chemistry in the University of London.

GUY, WILLIAM R., M.B., Cantab., has been elected one of the Examiners in Forensic Medicine in the University of London.

HEYGATE, WILLIAM NICHOLAS, M.R.C.S. Eng., has been elected Resident Accoucheur to St. Thomas's Hospital.

HOOKE, JOSEPH D., M.D., Glasg., has been elected one of the Examiners in Botany and Vegetable Physiology in the University of London.

HUMBLE, The Rev. Dr., M.D., M.R.C.P. Lond., has been appointed Medical Missionary at El Carmen, South America.

LIVETT, HENRY W., M.D., has been appointed Hon. Assistant-Surgeon to the 10th (or Wells) Somerset R.V.C.

MILLER, W. A., M.D., has been elected one of the Examiners in Chemistry in the University of London.

ODLING, WILLIAM, M.B. Lond., has been elected one of the Examiners in Forensic Medicine in the University of London.

PARKES, EDMUND A., M.D. Lond., has been elected one of the Examiners in the Practice of Medicine in the University of London.

REDFERN, Professor, has been elected one of the Examiners in Anatomy in the University of London.

RICKARDS, WALTER, M.R.C.S. Eng., has been appointed Resident Medical Officer to University College Hospital.

SIBSON, FRANCIS, M.D. Lond., has been elected one of the Examiners in the Practice of Medicine in the University of London.

SMITH, WILLIAM T., M.D. Lond., has been elected one of the Examiners in Midwifery in the University of London.

STAINTHORPE, THOMAS, M.D., L.R.C.P. Ed., has been elected Medical Officer and Public Vaccinator for the Shotley High District of the Hexham Union, Northumberland.

THOMSON, T., M.D., has been elected one of the Examiners in Botany and Vegetable Physiology in the University of London.

WEST, CHARLES, M.D., has been elected one of the Examiners in Midwifery in the University of London.

WILLIAMS, CALEB, M.D., Aberd., has been elected Consulting-Physician to the York County Lunatic Asylum.

DEATHS.

- COCKE, THOMAS GOLDING, L.S.A., at Chapel-Halstead, Essex, on May 9, aged 57.
 COOPER, GEORGE FRANCIS, M.D. St. And., at New Brentford, Middlesex, on May 8, aged 37.
 DAWSON, WILLIAM, M.R.C.S. Eng., at Southgate, Wakefield, on April 26, aged 65.
 HOWELL, THOMAS, M.R.C.S. Eng., at New Kent-road, London, on May 8, aged 49.
 NORMANDY, DR., at Odin Lodge, Clapham, on May 10, aged 55.
 ORTON, RICHARD, M.R.C.S. Eng., at Beeston, Notts, on April 25, aged 24.

UNIVERSITY OF CAMBRIDGE. — The Examinations for Medical and Surgical Degrees will commence on Monday, May 30, at 9 a.m., in the Arts' Schools. Candidates are required to signify the same to the Regius Professor of Physic on or before May 16, specifying whether they offer themselves for the first or second Examination, and to send at the same time their certificates.

THE COLLEGE LECTURES.—Professor Fergusson, F.R.S., will deliver a Course of Lectures in the Theatre of the Royal College of Surgeons "On the Progress of Surgery during the Present Century." These Lectures will be delivered on Mondays, Wednesdays, and Fridays, at four o'clock, instead of Tuesdays, Thursdays, and Saturdays, as heretofore, and commencing on Monday, the 6th proximo.

F.R.S.—Out of forty-seven candidates for the Fellowship of the Royal Society the Council recommend the following fifteen for election at the meeting on June 2:—Sir H. Barkly, Dr. W. Brinton, Dr. T. S. Cobbold, Mr. A. J. Ellis, Mr. J. Evans, Mr. W. H. Flower, Mr. T. Grubb, Sir J. C. D. Hay, Dr. W. Jenner, Sir C. Looock, Mr. W. Sanders, Colonel W. J. Smythe, R.A., Lieutenant-Colonel A. Strange, Mr. R. Warrington, and Mr. N. Wood.

THE LEVEE.—At the levee which was held on Saturday, May 7, the following members of the Profession were presented to H.R.H. the Prince of Wales:—Bennett, Dr. W. R., R.N., Greenwich Hospital, by the Duke of Somerset. Broughton, Surgeon-Major F., Bombay Army, by the Secretary of State for India. Clayton, Mr. Oscar, by Sir Frederick Pollock. Croft, Dr. J. M'Grigor, by Sir Charles R. M'Grigor, Bart. Dalziel, Dr. William F. B., Bengal Army, by the Secretary of State for India. Fogo, Surgeon-Major J. M. S., Royal Horse Artillery, by Dr. J. B. Gibson, C.B., Director-General of the Army Medical Department. Gallagher, Dr. John, R.N., Deputy Inspector-General, on promotion and appointment, by the Duke of Somerset. Miles, Assistant-Surgeon H. C., on appointment to Royal Horse Artillery, by Dr. J. B. Gibson, C.B., Director-General of the Army Medical Department. Ross, Surgeon A. C., M.D., on return from China and appointment to the 92nd Highlanders, by Dr. J. B. Gibson, C.B., Director-General of the Army Medical Department. Ramsey, Mr. Henry, on his appointment by her Majesty to be a member of the Medical Council, by the Earl Granville. Sands, Dr. John Lee, R.N., Greenwich Hospital, by the Duke of Somerset. Toynbee, Mr. Joseph, F.R.S., by the Duke of Argyll. The following gentlemen attended the levee:—Drs. Granville, Alexander Marsden, J. B. Gibson, C.B., and Baines; Mr. John Lovell, etc., etc.

UNIVERSITY COLLEGE, LONDON.—The presentation of prizes to the students of the Faculty of Medicine who stood the best in the class examinations at the close of the Winter Term took place on Monday in the Botanical Theatre of the College. Lord Wodehouse presided. The following were the principal prizes distributed:—Anatomy and Physiology (Professor Sharpey, M.D., F.R.S., Dean).—Gold medal and first certificate, J. Pearson Irvine, B.A., of Galgate, Lancaster; first silver medal and second certificate, James S. Cluff, of Kildare, Ireland; second silver medal and third certificate, Thomas Bailey, of London. Anatomy (Professor Ellis).—Senior Class—Gold medal and first certificate, George O. Spencer; first silver medal and second certificate, Frederick B. Nunnerly; second silver medal and third certificate, Henry Clothier. Junior Class.—Silver medal and first certificate, Gysbert H. Maasdorp, of the Cape of Good Hope. Chemistry (Professor Williamson).—Gold medal and first certificate, Mr. James S. Cluff; first silver medal and second certificate, Russell Forbest Carpenter, of London; second silver medal and third certificate, Charles Graham, of Berwick-upon-Tweed. Practical Physiology and Histology (Professor Harley, M.D.).—Silver medal and first certificate, W. Andrew Stuart. Comparative Anatomy (Professor Grant, M.D.).—Gold medal

and first certificate, James S. Cluff. The Principles and Practice of Medicine (Professor Jenner, M.D.).—Gold medal and first certificate, William Snow, of Barnstaple; first silver medal and second certificate, Bryan Holme Allen, of London; second silver medal and third certificate, Marcus Beck. The Principles and Practice of Surgery (Professor Erichsen).—Gold medal and first certificate, Charles Bradlley, of Nottingham; first silver medal and second certificate, George Grewcock, of Folkingham. Dr. Fellowe's Clinical Medals.—Gold medal and first certificate, Bryan Holme Allen; silver medal and second certificate, Alexander Bruce, of London. Special Class of Clinical Medicine (Professor Reynolds, M.D.).—First prize (microscope), William Snow; second prize ("Guide du Medicien Practicien," par M. Valleix), Mr. John M. Whitwell, of Kendal; third prize ("Todd's Clinical Lectures"), Bryan Holme Allen.

ROYAL INSTITUTION OF GREAT BRITAIN. — The annual meeting was held on Monday, May 2, William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the Chair. The Annual Report of the Committee of Visitors for the year 1863 was read and adopted. The amount of contributions from members and subscribers in 1863 amounted to £3423; the receipts for subscriptions to lectures were £716 12s. 6d.; the total income for the year amounted to £5532 10s. 7d. On December 31, 1863, the funded property was £30,107 14s. 11d.; and the balance at the bankers', £1056 14s. 9d., with six Exchequer bills of £100 each. Fifty-five new members were elected in 1863. A list of books presented, amounting in number to 121 volumes, accompanies the report, making, with those purchased by the managers and patrons, a total of 561 volumes (including periodicals) added to the library in the year. Sixty-three Lectures and nineteen Evening Discourses were delivered during the year 1863. Thanks were voted to the President, Treasurer, and Secretary, to the Committees of Managers and Visitors, and to Professor Faraday and the other Professors, for their services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—*President*—The Duke of Northumberland, K.G., F.R.S. *Treasurer*—William Pole, Esq., M.A., F.R.S. *Secretary*—Henry Bence Jones, M.A., M.D., F.R.S. *Managers*—George Busk, Esq., F.R.C.S., F.R.S.; Warren De la Rue, Esq., Ph.D., F.R.S.; Sir George Everest, C.B., F.R.S.; John Peter Gassiot, Esq., F.R.S.; John Hall Gladstone, Esq., Ph.D., F.R.S.; William Robert Grove, Esq., M.A., Q.C., F.R.S.; Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.; John Lubbock, Esq., F.R.S.; John Carrick Moore, Esq., M.A., F.R.S.; William Frederick Pollock, Esq., M.A.; Robert P. Roupell, Esq., M.A., Q.C.; Major-General Sabine, R.A., D.C.L., Pres. R.S.; the Right Hon. Lord Stanley, M.P., F.R.S.; Joseph William Thrupp, Esq.; Colonel Philip James Yorke, F.R.S. *Visitors*—John Derby Allcroft, Esq.; the Hon. and Rev. Samuel Best; John Charles Burgoyne, Esq.; George Frederick Chambers, Esq.; John George Dodson, Esq., M.P.; Christopher Darby Griffith, Esq., M.P.; Henry Harwood Harwood, Esq.; Thomas Henry, Esq.; Thomas Hyde Hills, Esq.; Harry Mackenzie, Esq.; John North, Esq., the Lord Overstone, M.A., F.G.S.; Edmund Packe, Esq.; the Earl Stanhope, D.C.L., F.R.S., Pres. Soc. Antiq.; George Tomline, Esq., M.P.

POISONING BY PHOSPHORUS.—A case of suspected child murder by phosphorus has lately been brought before a coroner's jury at Llangadock, in Wales. The investigation resulted in a verdict of wilful murder against the child's mother. The symptoms were those of irritant poisoning. It was proved in evidence that the evacuations from the stomach and bowels smelt like brimstone, and appeared to shine in the dark. The post-mortem appearances were characteristic of acute gastritis, with softening and partial destruction of the mucous and muscular coats of the stomach. As the chemical examination for phosphorus is a matter of great scientific interest, we subjoin in full the evidence given by Dr. Herapath before the coroner's court. Dr. Herapath deposed: Dr. Prothero, of Llandilo, brought and delivered into my own hands—first, a small bottle, well secured by bladder, etc., containing two teaspoonfuls of thick gruelly fluid, which were all the contents of the child's stomach; second, a large stone jar, containing the liver, heart, lungs, and kidneys of the same infant; third, a smaller stone jar, containing the stomach, which had been opened, and the large and small intestines; fourth, the history of the case and symptoms exhibited led to the suspicion of phosphorus poisoning, the body having been buried

since March 6, and the death occurred on the 4th—a period of twenty days. I examined the stomach, and this organ had been opened along the lesser curvature. The œsophagus was still attached to it. Numerous linear ulcerations were upon the mucous surface of the œsophagus, with redder edges, more numerous at the cardiac end. The greater cul de sac of the stomach and its cardiac extremity had numerous bright red inflamed spots and patches, the mucous membrane softened and destroyed by ulceration or erosion, the viscus distinctly thinner at those spots than at other places. This appearance denoted acute inflammation of the stomach of recent date, very like the effects of arsenical poison. The whole viscera were very fresh and well preserved, which rather favoured the same idea. The duodenum, the large and small intestines, had other reddened spots and patches, but of less severity, whilst Peyer's patches were somewhat enlarged. The rectum was more reddened than any other portion of the intestinal mucous membrane. The chemical examination of the viscera, etc., is as follows:—First, they were *seriatim* removed with great care on clean porcelain vessels to the interior of a photographic camera, and examined in the dark for evidence of luminosity. None presented itself, however, and the contents of the viscera were equally devoid of any such appearances. Second, the contents of the stomach were treated with pure ether. The ethereal fluid decanted and filtered reduced the salts of gold and silver in such manner as a very minute trace of free or inflammable phosphorus would produce. Secondly, the residual acid fluid was next tested by Mitcherlich's plan, by distillation with sulphuric acid, but without any corroborative evidence of the presence of phosphorus. Thirdly, the same acid fluid was now tested by Scherer's distillation with zinc, and the evolved gas, chiefly hydrogen, passed through ammoniacal nitrate of silver; a black precipitate resulted, too minute in quantity to further test for phosphorus. This gave doubtful evidence of phosphorus existing as phosphorous acid in the contents of the stomach. 4th. The examination of the stomach's contents gave indications of phosphorus in the free state by the ether test, and probable evidence of phosphorous acid by Scherer's mode of testing for phosphuretted hydrogen. 5th. The whole intestines having been slit up for examination, the contents of the large intestine were carefully collected, amounting to two drachms of yellow pasty fecal matter. This was first tested by Mitcherlich's process, but no evidence of phosphorus in the free condition resulted. The acid fluid produced was then tested by Scherer's process as before for phosphorus in the oxidised form of phosphorous acid; and the resulting black precipitate oxidised by nitric acid, and tested by a magnesian salt and ammonia. The characteristic crystals of phosphate, ammonia, and magnesia were obtained, which proved the existence of phosphide of silver in the black precipitate, which probably arose from the presence of phosphorous acid in the contents of the rectum, cœcum, and colon, in small quantity. 6th. The contents of the small intestines were also removed carefully, and tested in the same way. Similar results were obtained, viz., the absence of free or combustible phosphorus, but the presence of phosphorous acid. 7th. One portion of the contents of the duodenum was tested by the tincture of iodine, for the presence of starch, but no blue reaction exhibited itself; whereas a reddish port wine colour was exhibited, which appeared to be due to the presence of dextrine, a substance into which starch is converted by digestion. 8th. In another portion of the contents of the small intestines, I endeavoured to destroy the organic matter of the feces by nitric acid, and expected to find the Prussian blue colouring matter, but failed in obtaining any. 9th.—The whole of the stomach, small and large intestines, were dissolved in the dark by means of hydrochloric acid, absolutely pure, but no luminous appearances were exhibited. These phenomena would have been observed if a certain proportion of inflammable phosphorus had been present; it is a test nearly as good as Mitcherlich's. 10th.—The acid solution, filtered from undissolved matters, were tested in a gas evolution bottle and with certain apparatus attached, which enabled me to test at one operation for arseniuretted hydrogen, antimoniuuretted hydrogen, sulphuretted and phosphuretted hydrogen. There was negative evidence of the three former gases, but the black precipitate resulting was proved to be phosphide of silver, and therefore demonstrated the existence of an appreciable quantity of oxidised phosphorus existing in the tissues of the viscera as phosphorous acid—the same product as exists after the phosphorus paste has been exposed to the air. 11th.—A large portion of the liver was dissolved and treated in a similar manner, by which a further quantity of phosphide of

silver was obtained, from which crystals of phosphate, ammonia, and magnesia were obtained and examined by the microscope. Results:—Evidence of the presence of free phosphorus in minute quantity was obtained from the contents of the stomach; whilst evidence of phosphorous acid, the lower oxide of phosphorus, was obtained by Scherer's test, as modified by myself from the contents of the stomach, and of the large and small intestines; whilst a still larger quantity of the same phosphorous acid was shown to have been absorbed or imbibed by the tissues of the stomach and intestines and to be present in the liver; whilst the presence of dextrine in the intestinal canal shows that starch had been present there during life. I infer that phosphorus was probably the cause of the acute inflammation of the mucous surface of the stomach and intestines, of which the infant died.

THE ordinary monthly meeting of the Odontological Society was held on the 2nd inst. at Soho-square, Edward Saunders, Esq. (President), in the chair. Models of remarkable cases were presented by Messrs. Ibbeston, Cartwright, Hulme, Fox, and Brunell. An improved "bite" was sent by Mr. Balkwill, of Plymouth, and Mr. Catlin said he would test it, and report upon it at a future meeting. Mr. Kirby said he had used a somewhat similar instrument for two or three years, and had found it to answer perfectly. A paper was read by Mr. Cartwright, entitled "Reflections on the Cause and Treatment of some Forms of Irregularity," he defined irregularity to depend on the want of space in the bone of the jaw, and not so much on the teeth. At the close of a very elaborate paper, he said his object was to draw the attention of the Society to the notion that it was next to heresy to extract teeth for the cure of irregularity, and to urge them not to accept that proposition without due consideration, above all, not to assist in propagating a questionable theory by assenting to the idea that the temporary teeth had to do with the eventual size and shape of the jaw, and that their removal was a source of contraction, or that it was bad practice to sacrifice permanent teeth in order to make room for the regular placement of the rest. The science of dental Surgery had suffered by the ill-judged way in which the term "contraction" was freely paraded, and an old, correct, and honest practice had been unjustly questioned by the introduction of an idea which was in its working not successful when weighed in the scale of experience. Mr. Cartwright illustrated his paper by a large number of models and drawings, and at the close was greeted with a hearty round of applause. Mr. Ballard said he attributed a great deal of the deformity existing in the upper and under jaws of children to the early acquired habit of thumb-sucking, and also tongue-sucking, the jaws being pushed outwards by the continued pressure. He said the habit not only caused the irregularities in the jaws, but also seriously affected the health of the patient, in one instance that had come under his notice causing death. It was to this habit that he attributed many of the diseases of children, the origin of which was imperfectly understood. The further discussion of the paper was adjourned until the next meeting.

A CASE was tried on Wednesday, May 11, at the Central Criminal Court, which illustrates the hopelessness of getting juries to convict illegal practitioners, even upon strong evidence. A man of the name of Stevens, who was formerly a grocer, and is now a "Medical botanist," of High-street, Whitechapel, was charged with the manslaughter of a lad named William Probee. The lad was suffering from inflammation of the hip-joint, for which Stevens prescribed large doses of cayenne pepper. Dr. Letheby and Mr. Gant proved that the patient died of exhaustion following inflammatory fever and gastritis. The stomach was reddened and inflamed, and considerable quantities of cayenne pepper were found in the stomach and in the medicine the boy was taking. Nevertheless, the jury acquitted the prisoner.

THAT the General Prison for Scotland is conspicuous for its exemption from epidemics, and the city of Perth is subject to an excessive mortality from epidemics. . . . We are driven to the conclusion that cleanliness, good dietary, regimen, —perhaps, more than all, the adequate drainage and ventilation introduced by those who had the superintendence of the prison at its construction,—in fine, excellent hygienic and sanitary police have placed the prisoners of the General Prison in a condition of body and circumstances which are prophylactic, and act as preventives to the visitations of zymotics. In regard to the city, the very opposite is the case. Its *locale* is evidently bad; it is surrounded on all sides by

heights, among which it is shut out from free ventilation; it is frequently enveloped in fogs and dense vapour; the drainage is almost wholly defective; its streets are filthy; instead of having underground drains—except in one principal street—the site of the Fair City is generally honeycombed with sinks and cesspools, so that at all times the air is loaded with impurity. We know that filth and epidemic fevers attend upon each other as cause and effect, and the insanitary condition of the citizens is such as at any time to predispose to the ravages of epidemics.—*J. Bruce Thomson, in the Edinburgh Medical Journal.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Coghlan's paper shall appear as soon as possible.

Portsmouth.—We received a letter, but no newspapers. We are always glad to advocate the claims of the Irish Dispensary officers.

We are assured that small-pox does exist amongst the garrison at Portsmouth, spite of any official denial of the same.

We regret to learn that a paragraph copied into our last number from the *News*, which announced that Dr. Farr was likely to possess a new office with salary of £2500, is not well founded.

Hospital Salubrity.—The small-pox has appeared in the Parisian Hospitals, —131 cases during the month of March; 25 per cent. at the Lariboisiere; 8 of the whole fatal. M. Hérard says:—"One or two small-pox patients came into my two wards, and a petty epidemic immediately appeared, and attacked five or six men and as many women in succession, all vaccinated." The wards are crowded, those for the men containing eight, and those for the women four, supplementary beds. See the Report of the Société Médicale des Hôpitaux de Paris, in *L'Union Médicale* of May 10.

"*Epsom College.*"—The *Guardian* newspaper contains the following intelligence:—"Ascension Day was observed as usual at *Epsom College*. The rain prevented the hymn, 'Christe Rex Altissime,' being sung from the tower, but the afternoon was favourable to the athletic sports. Prizes were awarded for flat and hurdle races, gymnastics, jumping, rackets, quoits, bowling, and throwing the cricket ball, the most remarkable being a silver cup to Little, for a mile race completed in 5 minutes 20 seconds, a telescope to Tait and Pritchett for a fine display of gymnastics, and a silver pencilcase to Woodhouse for a long jump of 16 feet 4 inches. Full choral service was performed in the chapel at eleven and half-past five, the head master preaching in the morning. The prizes were distributed by Mrs. Thornton in the evening before a number of visitors, and the day ended with the performance of several glee by the choir." We congratulate the Council upon the healthy, religious, and gentlemanly tone of these proceedings. But it is not every one who would know that the Institution so commended is the Royal Medical Benevolent College. Doubtless "*Epsom College*" is a shorter and a better name; and there is a good deal in a name, spite of what "the divine Williams" may say to the contrary. When Tom Smith rises in the world, nobody objects to his becoming Thomas De Smythe, Esq., and visiting all the county, but then Tom must not cut his poor relations. It is a very good thing to provide a gratuitous education for the orphan and destitute children of deceased brethren, but a much better thing to ease the burdens of living men, and to enable the man who is toiling along with a large family and small income to get a thorough "*Harrow or Eton*" education for his sons on easy terms. All political science shows that the best charity is that which helps those who help themselves. Supposing that an education costs £40, it is greater charity to supplement with £15 the means of those who can pay £25 only, than to give the £40 outright to a small number. There are a good many things to be done on the level ground before we ought to sing a hymn on the top of a tower.

CHLOROFORM AND EAU DE COLOGNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your correspondent, "C. R.," will oblige one of your readers by specifying the proportion of Eau de Cologne and chloroform which he uses in midwifery practice, and the periods of the labour at which it is given.

I am, &c.

A. B.

SUGGESTIONS TO OVIOTOMISTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Any suggestion for relieving symptoms frequently present during the operation of ovariectomy, and facilitating the after-treatment of the patient, is worth attention at the present time.

The syncope, collapse, vomiting, etc., etc., during the tapping for ascites, and more especially in ovariectomy, are due to a well-recognised cause, namely, the quick removal of pressure upon, and the consequent dilatation of, the large abdominal vessels. In the former operation the gradually-tightened bandage gives support to those vessels; in the latter, the hands of the assistants, pressing upon the epigastrium and flanks of the abdomen. These last are uncertain and variable in strength, and often in the progress of the operation only partial.

I have to suggest the steady uniform pressure of diffused weight, as of that of a half-filled bag of shot, confined equally in interocular spaces throughout the bag. This to be placed upon the epigastrium as soon as the trochar is passed into the cyst, and moved lower down upon the abdo-

men as the fluid or wall of the cyst is withdrawn, other bags being at hand, if necessary, to proportion the pressure.

I question whether any system of after-bandaging is adequate to produce so much direct pressure upon the abdominal vessels as that which may in this way be obtained,—a pressure which, both during and after the operation, should be correspondent to that of the cyst the operator is unloading or has removed.

The number of deaths after ovariectomy, recorded as due to hæmorrhage into the peritoneum, is large. Persistent pressure upon the abdominal aorta in controlling that cause may be worth considering, as also the repressing of peristaltic action.

The present system of bandaging the abdomen after the operation is insecure as to uniform pressure; it takes time, necessitates some movement of the patient, entails additional exhaustion, and, if padding has to be used, often proves cumbersome inconvenient body clothing. Diffused pressure upon the abdomen may be applied through the bed-clothes, provided the patient's body be kept supine.

I beg to make these suggestions for the consideration of ovariectomists.

I am, &c.

Northampton, May 2.

Pulvis Jacobi ver, Newbery's,

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

THE ORIGINAL CHLORODYNE.

INVENTED AND MANUFACTURED, IN 1844, BY RICHARD FREEMAN.

*By the decision of Vice-Chancellor Sir W. Page Wood, R. Freeman is entitled to the SOLE right to use the word
 Original as a prefix to the word Chlorodyne.*

The large and still-increasing demand which the Inventor has for this therapeutic is evidence of the high estimation in which its properties are held by the Profession generally; and on a recent occasion a number of eminent London Physicians and Surgeons of long standing in the Profession, and who hold public appointments, made affidavits to the fact that Freeman's Original Chlorodyne is a more certain and reliable, a more valuable and a preferable, preparation to that of any other maker's. It is offered to the Profession as the best preparation of the kind, and at a price which allows the poorest sufferer to enjoy its extraordinary beneficial effects.

MANUFACTURED BY THE INVENTOR,

RICHARD FREEMAN, PHARMACEUTIST, KENNINGTON-ROAD, LONDON, S.;

And Sold by all Wholesale Druggists, in Actinic Glass Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d. each.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warrington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury,
 London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

ORIGINAL LECTURES.

COURSE OF LECTURES ON THE URINE AND DISEASES OF THE URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

LECTURE IV.

URIC ACID $C_{10}H_4N_4O_6$; atomic equivalent, 168.

CHEMISTRY.

Uric acid is a white crystalline, feebly-acid, (b) tasteless, organic substance; insoluble either in alcohol, or in ether, and only sparingly soluble in water. 2000 parts of hot, and 11,000 parts of cold water are required to dissolve one part of uric acid. It is readily soluble in strong sulphuric acid, without undergoing decomposition, as may be proved by its speedy re-precipitation on the simple addition of water.

By dry distillation uric acid is transformed into urea, cyanuric acid, hydrocyanic acid, carbonate of ammonia, aloxan, and an oily coal. Uric acid unites with bases, such as soda, potash, and ammonia, and forms with them crystalline urates.

Both uric acid and its salts are easily recognised by yielding the beautiful purpurate of ammonia (murexide of Liebig) when treated with nitric acid, and ammonia. The best way of applying the test is as follows:—Place a little of the suspected substance on a platinum spatula or piece of white porcelain, moisten it slightly with strong nitric acid and heat the mixture gently over a spirit lamp, till the excess of acid is driven off. If uric acid or any of its salts be present the dry mass assumes, on the addition of a few drops of liquor ammoniæ, a brilliant crimson colour, and on the addition of caustic potash a purplish blue tint.

In employing this test the only substances likely to be mistaken for uric acid are tyrosine, hypoxanthine, and xanthoglobuline, which, according to Scherer, gave a similar reaction. With these substances, however, the colour is more of a yellow than a red, and after incineration there is left a black glistening stain on the platinum whereby they are distinguished from uric acid. Caffeine is said to give the murexide reaction, but it is a substance not likely to be confounded with uric acid.

Seeing that the murexide test is not always to be relied on in the presence of tyrosine, hypoxanthine, and xanthoglobuline, Schiff recommends freshly precipitated carbonate of silver to be employed. Nitrate of silver precipitated by carbonate of soda, one c.c. of which gives a grey colour with $\frac{1}{47500}$ th gramme of uric acid. As chlorides and phosphates disturb the reaction, a few drops of nitrate of silver are to be added to the suspected liquid, quickly filtered, and then the carbonate of soda solution added; the quantity of carbonate of silver precipitate ought not to be too great.

The reaction can be easily shown on filter paper in the following manner:—Dissolve a little uric acid in carbonate of soda or potash, put a drop or two on paper, and add nitrate of silver, a distinct grey stain instantly appears, thereby indicating the presence of uric acid. Tannic acid is the only other substance which gives the grey colour with carbonate of silver, and it can be distinguished from uric acid by the chloride of iron turning it black.

Quantitative Analysis.—To two hundred cubic centimetres (6.45 oz.) of urine add twenty c.c. of strong hydrochloric or nitric acid(c). Stir the mixture, and set it aside in a cold place for twenty-four or thirty-six hours. By the end of this time the uric acid will have crystallised at the bottom, on the sides, and at the surface of the liquid, which will have assumed a dark colour in consequence of the liberation of the urohematine by the acid. Collect the crystals on a small filter, wash them slightly with alcohol, acidulated with a few drops of hydrochloric or nitric acid, dry and weigh them.

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

(b) It is so feebly acid that it is unable to redden litmus.

(c) Thudichum prefers the nitric, as uric acid is even less soluble in it than in hydrochloric acid.

The amount found is the quantity of uric acid contained in 200 c.c. of urine. In order, therefore, to find how much has been passed in the twenty-four hours, we say if 200 c.c. of urine contain x grammes of uric acid, what will 1000 c.c. of urine (or the amount passed in the twenty-four hours) contain?

$$\frac{x \times 1000}{200} = \text{to the quantity of uric acid passed in 24 hours.}$$

We have next to consider the physiological and pathological relations of uric acid.

PHYSIOLOGY.

Uric acid is found in the liquid urines of the omnivora and carnivora, as well as in the solid urines of serpents, birds, and insects. Almost the only urine in which uric acid does not occur is that of the herbivora. It exists in urine, combined with soda, potash, and ammonia. Its quantity varies greatly in the urines of different species of animals. For example, while that of serpents is almost entirely composed of it, that of the carnivora contains but a very small proportion(d). Human urine stands between the two; but even in it the quantity of uric acid seldom exceeds one part per 1000 (Lehmann). Its relative proportion to that of urea is generally put down as 1 to 30.

During health uric acid is never absent from human urine, though the quantity varies very much according to the kind of food. In disease there is occasionally none to be detected.

Quantity of Uric Acid passed during Twenty-four Hours by Healthy Adults.

Diet.	Name of observers.			
	Lehmann.		The Author.	
	grammes.	grains.	grammes.	grains.
Animal . . .	1.478	= 22.9	1.250	= 19.3
Mixed . . .	1.183	= 18.3	0.755	= 11.7
Vegetable . . .	1.021	= 15.8	0.500	= 7.7
Non-nitrogenised	0.735	= 11.3	0.340	= 5.27

The above tables show that the quantity of uric acid daily excreted is greatly influenced by our food. It further appears that the amount depends on conditions analogous to those influencing the quantity of urea.

It will be observed that, although the relative proportion of uric acid passed by Lehmann and myself on different diets is tolerably uniform, yet the absolute amount is quite different. The same law seems to be applicable to uric acid as is applicable to urea, namely, that the daily excretion is much influenced by national peculiarity.

The following table illustrates this:—

On mixed diet.	grammes.	grains.	Name of observers.
Germans . . .	0.939	= 14.554	Kerner.
Englishmen . . .	0.755	= 11.702	The Author.(e)
Frenchmen . . .	0.510	= 7.905	Becquerel.

While the influence of the kind of diet on uric acid and urea is much the same, that of the kind of drink is very different. Thus, port wine and beer increase the elimination of uric acid, whereas tea and coffee diminish it, which is the reverse of what happens with urea.

It is curious that the urine of human infants while at the breast is devoid of uric acid (Bird), while that of sucking calves possesses it (Wöhler). It seems, indeed, as if the natural order of things was reversed, for infants' urine is said to contain an excess of hippuric acid, and calf's urine none. Some may doubt the fact regarding the absence of uric acid from the urine of the human infant on account of the circumstance that uric acid calculi are not at all uncommon in very early life. This, however, arises from pathological conditions of the system, while the other is supposed to be due to physiological states. I have twice tested infants' urine—one aged ten days, the other eight weeks—for uric acid, and found none.

Climate has a most striking effect on the quantity of uric acid passed in the twenty-four hours. Nearly double the quantity is excreted in winter as in summer. Dr. G. Pringle, while working in my private laboratory, found that he passed, during summer, 0.734 grammes (11.37 grains) of uric acid in the twenty-four hours; and during winter, 1.39 grammes (21.54 grains).

(d) I have frequently found it absent from dog's urine, when the animals were entirely flesh fed. In these cases the urea was always very abundant.

(e) Parkes puts the mean of uric acid passed by adults during the twenty-four hours at 0.555 grammes = 8.50 grains, and the proportion as 6.959 for every pound of bodily weight.

The seat of origin of the uric acid in the animal economy is still a question *sub judice*. One thing is, however, certain, namely, that it is not formed by the kidneys; in fact, I don't believe that the kidneys form any of the substances they excrete.

Uric acid, like urea, can be detected in the blood, but whether or not it is formed in the circulation or in the tissues it is exceedingly difficult to say. It has been detected in the brain, liver, lungs, and spleen, and, as it occurs in the spleen in the greatest quantity, many regard that organ as the chief seat of its formation. I may add that, like urea, its source appears to be twofold; first, the disintegration of the nitrogenised tissues; and, secondly, the transformation of the excess of albuminous food.

Urea appears to stand in relation to uric acid as a substance belonging to a higher grade of metamorphosis; for whatever accelerates oxidation increases the amount of the eliminated urea, and diminishes that of the eliminated uric acid; while whatever interferes with oxidation decreases the urea, and increases the uric acid in the urine. It has already been shown that urea can be artificially formed from uric acid out of the body, (f) as well as that uric acid is convertible into urea in the body of the rabbit. It may be here added that Stockris has found that the same thing occurs in the human body (g).

Although, as before said, uric acid is always present in normal human urine, it is never spontaneously deposited from it in a free state. And this arises from the circumstance that all the uric acid in healthy urine is combined with alkaline bases in the form of soluble salts, urate of soda, urate of potash, and urate of ammonia.

In normal urine these salts are all in a state of solution. But whenever from any cause they chance to be in excess, or the water of the urine to be in diminished quantity, they are deposited in an amorphous state, and as such commonly receive the name of urates or lithates. Bird, Bowman, and mostly all the writers of their time, thought that urates consisted in general of the urate of ammonia. Liebig, Heintz, and Lehmann have, however, shown that they most frequently consist of the urate of soda, which is readily distinguished from the urate of ammonia by its much greater solubility. If, for example, a small quantity of urine containing the deposit be put into a test tube, and a gentle heat applied, as soon as the temperature of the liquid gets up to, or a little beyond that of the human frame (100° F.), the sediment, if consisting of the urate of soda, is redissolved, and the urine becomes quite clear. If, on the other hand, the deposit be composed of the urate of ammonia, the liquid requires to be heated to near the boiling point before the sediment entirely disappears. On rising in the morning, if I find a deposit in my urine, I can in general readily tell whether or not it is composed of the urate of soda by observing if it disappears on the addition of the warm, freshly-passed urine.

ORIGINAL COMMUNICATIONS.

CASES OF SOFTENING OF THE BRAIN AND SPINAL CORD.

By JOHN W. OGLE, M.D., F.R.C.P.,

Assistant-Physician to, and Lecturer on Clinical Pathology at, St. George's Hospital.

(Continued from page 533.)

Case 16.—Richard W., aged 65, admitted February 6, 1856, old sailor and gin drinker, affected by acute dementia, admitted on account of eczema and sores on the leg. Erysipelas came on, and he died February 17.

Post-mortem Examination.—Cranium: Viscid, sub-arachnoid fluid existed; cerebral membranes natural; arteries of brain very atheromatous; brain generally very softened. Other organs not examined.

Case 17.—Sarah H., aged 47, admitted May 6, 1856. Was an out-patient for palpitation some time. On the 5th had a fit,

(f) Ranke obtained urea from uric acid by simply acting upon it at a high temperature with alkali in presence of a ferment.

(g) In order to ascertain whether uric acid becomes transformed into urea in the human body, Stockris, whilst maintaining a uniform diet, took several doses of urates, carefully determining, before and after the experiments, the amounts of uric acid and urea in the urine. He concludes from the results obtained, that uric acid becomes metamorphosed into urea within the organism, and the seat of the metamorphosis he believes (from experiments on the liver of animals) to be the liver.—Archiv. v. Donders, u. Berlin, vol. ii., part iii., p. 260.

and on 6th had three more. In the last seizure mouth said to be drawn to one side; was quite unconscious for a long time, and afterwards the speech became much affected.

On admission, was almost quite comatose; occasionally articulating a few words. Breathing stertorous; left cheek flapping loosely at each expiration. Heart's action very irregular. Pulse weak and intermittent. Mouth slightly drawn to the *right*. Motor power in *left* hand much diminished.

Ordered leeches to temples: blister to neck, and mercury every few hours.

On the night of the 7th she was delirious, requiring restraint. More comfortable next day, and able to swallow easily. The bowels very open. She, however, relapsed into coma, and died on the 9th.

Post-mortem Examination.—Cranium: Cranial bones thicker than usual. Cerebral convolutions flattened. Only slight ventricular fluid. Upper parts of both hemispheres natural, but the remainder of the *right* hemisphere, and especially the middle lobe, was soft and diffuent. In the middle lobe on *right* side small (four) circumscribed patches of the size of filberts existed, formed of punctiform extravasations of blood, and one also existed in corpus striatum. Thorax: Heart rather hypertrophied. Left auricle dilated. Abdomen: Kidneys rather granular. Other organs natural.

Case 18.—Wm. T., aged 53, admitted September 11, 1856. Of drunken habits. Had a fall producing compound fracture of right leg. Became very excited after admission, and on the fourth day decidedly delirious, though not exactly as if from drink, as he slept a little, and no tremors or sweating existed. Tongue clean. Pulse rapid and small. Skin very yellow. No rigors. Much abdominal flatus. Excitement like that of madness came on, and the fracture much disturbed. Became very noisy and talkative. Put on good diet and brandy, with tinct. opii, \mathfrak{mxx} ., 3 tis horis.

No rigors came on at any time, but he gradually sank and died September 27.

Post-mortem Examination.—Clotted blood and fibrinous coagulum decomposing in the femoral vein. Abdomen: Kidneys were cysted. Thorax: Lower parts of lungs breaking up by slight pressure. Cranium: Much sub-arachnoid and ventricular fluid. Anterior of the *right* corpus striatum was very softened, and of a reddish colour, strongly contrasting with neighbouring parts in colour and consistency. Great rigidity, with much atheromatous deposit in vessels at base of brain, but vessels connected with softened part of brain not apparently affected.

Case 19.—Eliza B., aged 19, admitted July 1, 1859. Servant-of-all-work. Had had rheumatic wandering pains, and uneasiness at epigastrium. Right ankle swollen and painful. Systolic bruit at apex of the heart. Pulse quiet. Tongue clean. Bowels open. Catamenia absent about three months. Got better under colchicum and alkalies.

Became suddenly seized with oppression of breathing, and a very weak intermitting pulse. Loud bruit heard at the base of the heart with the first sound, as well as at the apex. Pupils very contracted.

Ordered calomel and opium 6 horis, and empl. lyttæ to the neck.

A second fit of the same kind occurred, and for the next four days she was only partially conscious. Calomel continued, empl. lytt. rg. cordis.

Pulse intermittent every sixth beat, and the murmurs very loud. Much headache complained of. Exocardial friction sound became audible, but quickly departed. Loss of power gradually came on in the *left* side, and afterwards complete hemiplegia. Delirium came on, and involuntary evacuations; also bed sores. Subsequently the pain became great at back of neck, and she screamed when raised.

In great agony until death, which occurred July 31.

Post-mortem Examination.—Petechial spots found over abdomen, and in the mucous membrane of larynx and trachea. Cranium: Brain wet. Blood extravasated in pia-mater between convolutions. Corpus striatum on *right* side very much softened, down to base of brain. Termination of the right carotid and the posterior communicating arteries surrounded by much fibrinous deposit, and these arteries filled with clot, discoloured in parts. In the arteries at the base of the brain near the softened parts the coagula contained pus and "exudation" corpuscles. Thorax: Old pericardial adhesions. Small abscess in the wall of the left ventricle of heart, in connection with partial softening of fibrinous deposit. Mitral valve with much fibrinous deposit attached, as also the lining of left auricle and aortic valve. Lungs congested, partly

sinking in water. Abdomen: Fibrinous masses found in the spleen and kidneys. Other organs natural.

Case 20.—Elizabeth J., aged 43, admitted February 11, 1857, was walking two weeks previously and became giddy, and saved from falling by passers-by. Recovered in a few minutes, but could not say where she lived. Found her way home, and next day could not rise from her bed, and was unable to move the *right* leg or arm.

Admitted in this state; quite rational, but speech rather hesitating. Tongue coated; pupils equal, acted freely; bowels costive. Ordered cal. and senna, also salines and tincture of bark every four hours; afterwards iodide of potassium (gr. iij.) was added. Subsequently severe pain in the head came on, and severe dyspnoea, which was relieved by ether.

March 3.—Seized with an epileptic fit lasting five minutes, and she lay quiet for half-an-hour. Was able to talk, and whilst doing so became convulsed and shortly afterwards died.

Post-mortem Examination.—Slight œdema of legs existed. Thorax: *Tough fibrinous granulations were attached to the auricular surface of the mitral valve of heart and lining of left auricle.* In right auricle was a large mass of firm, blood-stained fibrin, chiefly in appendix. Abdomen: Kidney mottled with yellow material amidst the urinary tubes. Cranium: Brain rather softened throughout; in *left* optic thalamus was a small patch of softening of a slight yellow tinge, and presenting numerous "exudation-corpuseles." The blood-vessels examined microscopically contained dark streaks (fatty) along their walls. In other parts of the thalamus which were not softened similar exudation-corpuseles also existed.

Case 21.—The patient, aged 34, was admitted into the Hospital on December 21, 1859. In the previous July he had had a blow over the left eye, since which time it had remained partially closed. Six weeks before admission he complained of acute pain in the lower part of the dorsal region, and two weeks afterwards he had numbness of the lower limbs, but he followed his work until two days before admission, when he walked very awkwardly, and had a sense of numbness in, but no very marked want of sensibility of, the legs. There was pain in the lower part of the dorsal region of the spine, and some difficulty in passing and in "holding" the urine. Under the use of large doses of potass. iod. and tincture of cantharides and bark, he regained power so as to walk much better; but on January 9 he was suddenly attacked with giddiness, and on the 12th became delirious. The speech became indistinct, and vomiting followed, the pupils remaining natural. He became violent, and passed the evacuations in bed, and afterwards was quite insensible. Ptosis of the right eye then showed itself, and the left eye, which was closed when he was admitted, became quite open. Before his death, which occurred on February 12, the ptosis on the right side disappeared.

Post-mortem Examination.—Cranium: There was extensive softening of the cortical part of the cerebral hemisphere. The part affected was at the base near the fissure of Sylvius. The fornix was also much softened. *This was in connection with obstruction, by fibrinous plug, of the middle cerebral artery in the fissure of Sylvius, near the "locus perforatus anticus" on the left side.* There was much old thickening in the sub-arachnoid tissue and adhesion of the arachnoid and pia-mater, and the arteries at the base of the brain generally were atheromatous. In this case, unfortunately, the cerebral organs only could be examined. (b)

Case 22.—Wm. P., aged 42, admitted May 25, 1859. Had had severe sore-throat; and on admission it was found very red. Slow and muddled in manner; hesitated, with a vacant look; left pupil smaller than the right one. Tongue tremulous; pulse 112, feeble. Ordered ammonia, salines, and brandy; subsequently iron and columba. Lost his memory, and became subject to delusions. Left pupil became much smaller than its fellow. Morphia was administered. Subsequently coma came on, and both pupils became contracted, the left mostly so; limbs constantly twitching. Pulse became rapid, and death occurred June 4.

Post-mortem Examination.—Cranium: Brain-vessels congested; sinuses full of blood; slight softening of corpus callosum and septum of ventricles. Thorax: Pleural adhesions existed, and also red hepatisation of the lower part of the right lung. Abdomen: Kidneys congested; other organs natural.

(b) See St. George's Hospital "Museum Catalogue," Series viii., No. 52.

Case 23.—Archibald B., a carpenter, of middle age, was admitted into the Hospital November 30, 1859, having enjoyed good health until two weeks before admission, when the *right* foot became numb and powerless. The paralysis slowly, as it were, crept up the limb in the course of three days, and then the right shoulder became similarly affected; shortly after, the whole of the *right* arm was affected by the paralysis. He had no giddiness or pain in the head. On admission, there was complete loss of power and deficient sensibility of the skin of the right arm, which was not in any way rigid. There was no facial paralysis, and the pupils were unaffected. The tongue, however, was protruded somewhat towards the right side. The mind was unaffected, and the articulation natural. On the day after admission, the urine had to be drawn off, and was found to be free from albumen. After a time the evacuations were passed unconsciously, and there was a little slowness of speech. The pulse remained of good strength, and about 80 to 84 per minute. Bed sores came on; the articulation became very indistinct, and at last impossible; the pupils widely dilated; the pulse very feeble. He appeared quite sensible to the last, gradually sank, and died Jan. 17, 1860.

Post-mortem Examination.—Cranium: The cranial bones and membranes were natural. The convolutions of the cerebral hemispheres were flattened, and the lateral ventricles were distended by clear fluid. The greater part of the *left* hemisphere (the middle and posterior lobes), also the left optic thalamus were much softened, and a portion of the *right* cerebral hemisphere was in a similar state. *Microscopical examination* showed the presence in the softened parts of a large number of "granular corpuseles." Thorax: The lungs showed one or two patches of so-called "cellular pneumonia," much resembling "secondary deposits;" heart weak and flabby; other organs of body natural. (c)

Case 24.—Wm. S., aged 60, admitted March 10, 1860; a clerk; was well until two days before admission, when he became unable to walk without difficulty. On the next day the face drawn to one side, and hemiplegia of the *right* side as to motion became complete. No fit or loss of consciousness. The pupils of the eyes were natural. Sensibility of affected limbs impaired to some extent only. Right arm became rather contracted, and he was unable to find words to answer with, but understood when addressed; articulation clear. Pulse 100; tongue furred; no albumen in urine. Ordered turpentine injections, also cal. and colocynth, and empl. lyttæ nuchæ, followed by diuretics. Went on in the same until one day when he was found comatose and stertorous, with dysphagia. Cupped on neck to ten ounces. An epileptic seizure occurred that day, and he died one hour afterwards, April 2.

Post-mortem Examination.—Cranium: Right cerebral hemisphere natural; all of upper part of the *left* hemisphere very softened, nearly to level of the ventricle, and the superficial parts of optic thalamus and corpus striatum in the same state. No granular masses found under microscope. Arteries of the brain very atheromatous, especially the left carotid, which was thickened and dilated irregularly. Thorax: Heart hypertrophied; coronary arteries very atheromatous; pericardium very adherent.

Case 25.—Cath. G., aged 38, July 5, 1860. Mother of eight children; has had good general health; had had miscarriage two months before admission, attended with much hæmorrhage. Went on well until two days before admission, when she became delirious. No convulsions or rigors. Admitted with symptoms not unlike fever, but had not quite the languor of fever; muttering; left pupil larger than right, and less active; no facial distortion; limbs natural; pulse 90 to 94; did not protrude tongue, which was moist; evacuations involuntary. Wine and stimulants given. She became lower, and bark was given, and subsequently became comatose and stertorous. Skin not moist. Pulse 90. Turpentine injection given. Pulse became rapid and feeble. Respiration quick, and râles in chest came on. Coma became worse, and she died July 16.

Post-mortem Examination.—Cranium: Cerebral membranes and sinuses congested. Slight amount of recent lymph on parietal arachnoid, covering the falx cerebri. In right lobe of brain (centrum ovale minus) patch of ecchymosis, large as a cherry, with yellow softened tissue around; the surrounding part soft and yellow. In left lobe was larger patch of ecchymosis, towards the middle of the external circumference, in which was a yellow mass size of pea, like secondary deposit; brain diffuent around the clot; whole hemisphere softened

(c) See "Hospital Museum Catalogue," Series viii., No. 51.

and yellowish. Ventricles very distended with serum. Thorax: Heart fatty; lungs healthy. Abdomen: Kidneys cysted. Uterus with ulcerated lining and fibrinous deposit in one part of muscular walls; one of the large veins in broad ligament blocked up by large oval discoloured coagulum. Other organs natural.

(To be continued.)

SUCCESSFUL CASE OF OVARIOTOMY IN A PERSON SIXTY-SEVEN YEARS OF AGE.

By EDWARD DEWES, M.D.,

Physician to the Coventry and Warwickshire Hospital.

Mrs. N., aged 67, of spare habit, the mother of three children, of whom the youngest is 37 years of age, called upon me in August, 1863, relative to an enlargement of the abdomen. She states that she has always enjoyed excellent health, and has not had occasion to consult a Medical man during the last twelve years. The abdomen is filled by an ovarian cyst extending from the symphysis pubis to the ensiform cartilage. Fluctuation is very distinct, percussion dull over the front of the abdomen, clear in both loins, most so in the right. On examination per vaginam the uterus is found to be *in situ*, free, and moveable. She has noticed the abdomen getting larger for the last fifteen months, and thinks that the swelling commenced on the left side.

As she had not experienced any inflammatory symptoms, and her health was in a very satisfactory condition, I considered the case, notwithstanding her advanced age, a favourable one for extirpation, and proposed a consultation with Mr. John Clay, of Birmingham, who, after a careful examination, concurred in the opinion.

As, however, the patient experienced very little inconvenience, except from her increased size, and was able to get about with some degree of comfort, she would not at that time consent to any operation.

In February, 1864, however, the abdomen having increased considerably in size, and the breathing having become somewhat embarrassed, she consented to the performance of the operation. On examining the state of the lungs, sub-crepitant râles were found in their bases, partly the result of cold, but in some degree due to the pressure of the cyst upon these organs. The more urgent of these symptoms having yielded to the application of a blister and the administration of tonic remedies, the operation was performed on March 15 by Mr. Clay, with the assistance of the following Professional friends and myself:—Dr. Laxon, Dr. M'Veagh, Mr. Ebbage, and Mr. White, of Kempsey.

The patient was quickly placed under the influence of chloroform, an incision two inches and a-half long was made below the umbilicus, the cyst, which was perfectly free from adhesions, was tapped and gradually drawn forwards as it emptied itself. The contents measured twenty pints. The peritoneum was in a normal condition.

On the extraction of the tumour, it was found to be without a pedicle. It was absolutely sessile upon the broad ligament, which latter presented a thick fleshy appearance, was extremely vascular, and contained many large tortuous vessels. Dreading any interference with this structure lest inflammation should be excited in it, Mr. Clay adopted the proceeding of forming an artificial pedicle out of the base of the tumour by placing around it (having previously destroyed the secreting surface of the cyst) a calliper clamp, and cutting through the sac so as to leave a portion of it to form the pedicle. This was brought outside the wound, and secured at its lower end. The wound was then closed by a hair-lip pin, one deep silver wire suture transfixing the peritoneum and one superficial suture.

Shortly after the operation the patient complained of severe dragging pains in the back. In the evening the pain had become so urgent and the abdominal wall was so depressed by the pull of the uterus on the clamp that the latter was removed, and the pedicle secured by a strong hempen ligature, the stump being allowed to sink within the abdomen. It did not, however, recede so far as might have been expected, the bulk of the pedicle remaining external to the abdominal parietes.

The tumour proved to be connected with the left ovary, and consisted of one large cyst containing numerous secondary cysts, varying from the size of a pea to that of an orange, several of them containing thick dark-coloured gelatinous matter.

The after-treatment consisted in strict abstinence from food for several days, a little champagne or brandy and water only being allowed; the frequent use of injections of beef-tea, brandy, and laudanum; and the use of the catheter at regular intervals.

The sutures were removed on the fourth and sixth days; the artificially-formed pedicle gradually sloughed away; the pulse was never higher than 90; and the patient made a rapid recovery without the occurrence of a single unfavourable symptom.

This person is, I believe, the oldest upon whom the operation of ovariectomy has been performed in England. Dr. Atler, of America, mentions one about the same age who also recovered.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

A CASE OF DISEASE OF THE HIP-JOINT, WITH DISLOCATION FORWARDS—DEATH FROM ABDOMINAL DISEASE—POST-MORTEM EXAMINATION OF THE JOINT.

(Under the care of Mr. PARTRIDGE and Mr. WATSON.)

L. A., aged 26, a carpenter at Beaconsfield, in Buckinghamshire, was admitted, under the care of Mr. Watson, in September, 1862, and was subsequently under the care of Mr. Partridge. His aspect is decidedly scrofulous, and he comes of a very scrofulous family. Mr. Rees, of Beaconsfield, under whose care he has been, gives the following account of the case:—"He first came under my care in May, 1860. He was then suffering from severe pain in the hip, with all the symptoms of sciatica. I administered the usual remedies, with counter irritation, with very little relief. Occasionally the pain was so intense that large doses of opium failed to give him any relief. He attributed this pain to cold caught when out at work by sitting upon damp timber. I attended him up to October, 1860, when he became a patient of the Windsor Infirmary, and subsequently of the Westminster Hospital. He returned home about April 20, 1861. In addition to the other symptoms, he was now complaining of violent pain in the groin, attended with considerable swelling, which he attributed to the needles which had been introduced there at the Westminster Hospital. On May 11 following I opened a large abscess, which continued to discharge up to the time of his death, various abscesses having formed in different parts. His brother about ten years ago suffered from inflammation in the knee-joint, and was sent home from a London Hospital as incurable. In that case no matter formed. Happily, country air and patience quite restored him, and he is now an active and healthy young man, and married."

On admission into King's College Hospital his condition was as follows:—The left leg and foot were rotated outwards, the limb much shortened, the gluteal region flattened, and an unusual prominence occupied the inguinal region and the upper part of the thigh. This swelling was in the greater part of its extent of a firm elastic nature, and marked on the surface by a network of several large veins. At the upper part, however, and about opposite the centre of Poupert's ligament, there was a bony induration, and below this the movements of the head of the bone could be felt immediately under the skin when the limb was rotated. Several sinuses opened at various points in the neighbourhood of the joint, from which there was a constant thin sero-purulent discharge, but on probing which no bare bone could be felt. He had little or no pain, except on moving the joint or making pressure in front of it; but he complained of pain in the knee and down the inside of the leg. His general health had only suffered so far that he lost flesh.

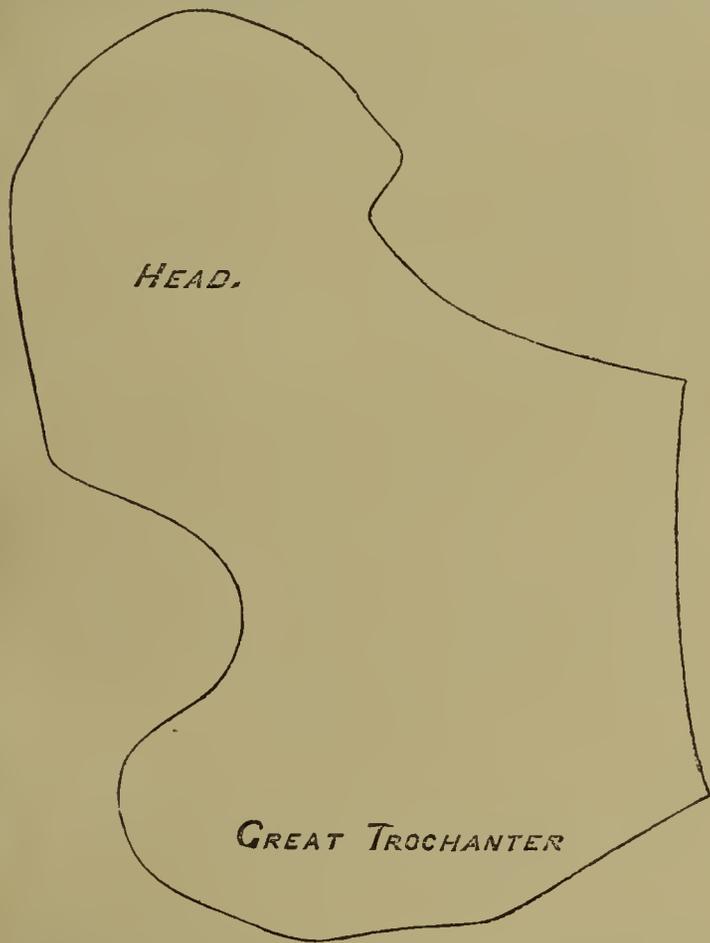

Various forms of splints were applied, with a view of keeping the joint at perfect rest, but he was unable to bear any of them, and he left the Hospital at the end of two or three months very little benefited.

At the early part of the present year he began to suffer much from severe abdominal pain and to waste rapidly, and these symptoms, notwithstanding Mr. Rees' judicious treatment, became much aggravated in the beginning of February.

He died on February 10, after several days and nights of intense agony, as if from the presence of some abdominal abscess.

Autopsy.—On cutting down upon the point at which the head of the bone was felt, the knife at once entered the newly-formed articulation, which was covered only by thickened cicatricial tissue, and lay at about a quarter of an inch from the surface. The joint appeared to be surrounded by a capsular ligament, and did not communicate with any of the numerous sinuses surrounding it. The head of the femur was very much worn down on the upper and posterior aspects, and covered in the greater part of its extent by loosely attached fungoid granulations of a deep black colour, and the same material lined the newly-formed socket. At the under and back part of the head these granulations were deficient, leaving the bone rough and bare. The new socket, which was very shallow and broad, was situated in front of the horizontal ramus of the os pubis, and had evidently been formed by the gradual yielding of the anterior lip of the acetabulum and the subsequent formation of new bone, for no traces of the original cavity could be discovered. At several places along the crest of the ilium the bone was quite bare, and easily broken down by the slightest pressure.

The accompanying outline of a vertical section through the head of the bone shows the alteration of shape which it has undergone. The cancellated tissue, to the depth of half an

inch from its surface, was occupied by what was proved by the microscope to be yellow firm adipose tissue, but which gave the appearance of an interstitial thickening of the cancelli to the naked eye. At one or two points of the cut surface, the bone was so soft as to break down easily, and this was particularly the case in the great trochanter. The material occupying the softened part of the great trochanter presented under the microscope a quantity of finely-granular fatty matter and *débris* of the different tissues. This material lay in the interstices of the bone, which appeared to be much wasted, and in many parts so thin and membranous as to allow of easy examination with a $\frac{2}{3}$ " object glass without any preparation, consisting, in fact, of a single layer of bone cells placed in juxtaposition.

GUY'S HOSPITAL.

PERITONITIS (INFLAMMATION OF RIGHT OVARY).

(Under the care of Dr. BARLOW.)

This case is interesting as showing the connection between peritonitis and disease of the ovary, as pointed out in Dr.

Barlow's "Manual of the Practice of Medicine." There is, according to many Hospital Physicians, no such disease as idiopathic peritonitis.

Ann Elizabeth M., aged 33, a seamstress, living in Shadwell, was admitted into No. 20 Miriam, October 3, 1863.

She is a well-formed woman, unmarried, and has had no previous illness. On Monday last, five days ago, she felt pains down the spine and about her shoulders, which were of sufficient severity to confine her to bed. On Thursday she was attacked with acute pain in the right iliac region, and on Friday took some jalap, which operated twice; she also vomited once or twice on that day, and the pain extended over the abdomen.

On admission, Saturday, October 3.—Complains of acute pain in the right iliac region, and of less severe pain over the whole of the abdomen, the surface of which is hot and tender. Breathing quick, and entirely thoracic; skin moist; tongue considerably furred; pulse small and quick, 110; urine natural colour, slightly cloudy, but contains no albumen; no cough; vomits a quantity of greenish fluid; bowels have been relieved; the catamenia had just appeared. She was ordered by Mr. Stocker half a grain of opium every four hours.

4th.—Abdomen very painful and tense. Complains of much thirst. \mathcal{R} . Pulv. opii., gr. j.; hydrarg. chlor. g. ss., ft. pil. 6tis horis. s.

5th.—Pulse small and weak, 110; tongue dry and furred; state of abdomen much the same. Enema saponis.

6th.—Bowels moved once by the enema. Sickness and pain continue much the same, the right iliac region being still chiefly painful. \mathcal{R} . pil. Haust. efferves., 4tis horis. The pain returned more severely in the evening. Pulse 120. To have a linseed-meal poultice.

7th.—The poultice gave considerable relief. Tongue cleaner; urine normal, and passed freely; vomiting of a clear brownish fluid recurs two or three times daily; bowels not moved this morning. \mathcal{R} . enema saponis. Pil. saponis, io. gr. v., 3tis horis. Repeat haust. eff.; brandy, \mathfrak{z} iv.; milk and lime-water.

8th.—Abdomen tympanitic; pulse small and feeble, 120. The enema brought away a small quantity of hardened fœces. Has been sick once this morning. Passed rather a restless night, but dozed comfortably towards morning. Tongue coated with brown fur.

9th.—Much the same. Pulse more feeble, 120. Was very ill during the night, so much so that the nurse thought she was dying. Respiration 40. Has slight bronchitis; has not yet been at all affected by the opium. \mathcal{R} . Hyd. chlor., gr. j.; opii., gr. j., 4tis horis. \mathcal{R} . Strychniæ, gr. $\frac{1}{4}$; acid phosph. dil., \mathfrak{z} j.; aq. ad \mathfrak{z} iv.; M. capt., \mathfrak{z} ss., 4tis horis.

10th.—Tongue cleaner round the edges. Pulse more full. Sickness less. Abdomen not quite so tender. Has slept comfortably for several hours.

11th.—Seems a little affected by the opium. Not so well as yesterday.

12th.—Weaker. Has had no sickness since last evening, but takes scarcely any nourishment. Slight bronchial cough. Pulse 132; respiration 30. Does not now complain of pain in right iliac region on pressure, but says she feels pain about the right hypochondrium, increased on pressure. Beef-tea enema. \mathcal{R} . pil. 6tis. vel. 8tis. horis.

13th.—Enema administered at 9 p.m. and retained till 2 a.m. No sickness and very little pain, but very weak. Bowels freely opened. \mathcal{R} . enema noct maneque. Sodæ bicarb., gr. x.; acid hydrocyan. dil., \mathfrak{m} ij.; æther chloric, \mathfrak{m} xv.; sp. ammon. arom., \mathfrak{m} xv.; mist. acaciæ, \mathfrak{z} j.; ex aqua, 4tis horis.

14th.—Abdomen more tympanitic. Pulse 125; respiration 30. Urine passed freely. Bowels rather relaxed.

15th.—Much troubled with bronchitis. Weaker. Pulse 142. Much tympanitis, but no dulness. Sickness has returned since last evening. Died exhausted about 6.30 p.m.

On *Post-Mortem Examination*, the intestines were found all matted together. In the interstices was a quantity of purulent matter, in some parts pure pus, in others dirty-coloured fluid. There was found also a collection of purulent matter between the diaphragm and the right lobe of the liver. On separating the intestines from one another, the seat of the disease seemed to be in the right iliac region, in consequence of there being a larger collection of pus and the parts around being soft and sloughy. On removing the cæcum and appendix, although their exterior was sloughing, the interior was healthy. Close in contact with the cæcum was the distended Fallopian tube and ovary. The latter was rather larger than usual, and in its interior was an abscess communicating with the external surface, which was soft and

sloughy. There was follicular ulceration about the os uteri and the vagina. All the other organs were healthy.

For the report of this case we are indebted to Mr. Herbert Spurgin.

SATURDAY, MAY 21.

THE MEDICAL COUNCIL.

ON Saturday, the twelfth and last day of the Session, the Council determined to have a long day's work; eager to deserve well of the Profession, they burnt the candle at both ends; suspending their standing orders, they met at twelve instead of two o'clock; and they sat after the sacred hour of six. In presence of such noble devotion to duty, we ought, perhaps, to bow in mute admiration, yet we cannot help asking—"Cui bono?" what did they actually *do* in those six long hours?

Well, it is much easier to say what they did *not* do than what they did. They did not continue the discussion of the report on Professional education. The previous evening they determined to recommend "That the age of 21 be the earliest age at which any Professional licence shall be obtained; and that the age shall in all instances be duly certified." Mr. Rumsey moved as an amendment, "That after 1868 the earliest age at which any Professional licence shall be obtained be 22," but this was negatived by 11 to 7; five members of the Council not having any opinion on the subject, or fearing to state their opinion, declined to vote at all. We regret the fate of Mr. Rumsey's amendment, as we think it would help to raise the Profession in public estimation, and if, as has been said, it had any tendency to diminish the number of Medical men below the demand for them, such a state of things would be quickly rectified by the public being thereby forced to treat Medical men better, and to pay them better. However, the passing their novel "recommendation" so completely exhausted the Council that they felt quite unequal to continuing the discussion of the Report on Saturday; and what were they to do? "Consideration like an angel came" to the rescue, and they directed that the Report of the Select Committee should be forwarded to the various bodies in schedule (A), with the dreary information that it is "under the consideration of the Council," and asking their observations on the suggestions contained in it.

The Council did not do various things they were asked to do. They refused to give the "National Life-boat Institution any opinion" on the relative merits of the plans of Dr. Marshall Hall and Dr. H. R. Sylvester for the restoration of the apparently dead from drowning; the question "did not come within the sphere of their duties."

They refused to give the Vestry of Bermondsey any advice as to the best method "of preventing the registration of uncertified deaths," or on the means "of protecting the public against unqualified Practitioners." Such matters "do not lie within the province of the Council."

They refused to take into consideration the proposal of Mr. Gason (of Rome) "That they should take into consideration the advisability of calling the attention of Her Majesty's Government to the justice of placing those Medical men residing abroad, who conform to the laws of their country, on the same footing as Medical men residing in the United Kingdom;" and "That registers be supplied to Her Majesty's ministers and consuls for the furtherance of that object." "The Medical Council have no power to comply with such proposals."

They refused any help, or assistance, or consolation, even, to Dr. Henry Scott, who is tormented by a quack of the name of Hamilton, who has established himself in London, and under the name of "Henry Scott," issues a vile pamphlet, addressed to the female sex, on female irregularities and obstructions. We regret that we cannot give our readers the exact terms in which the Council couched their refusal and confession of impotency, for the instances quoted above show a charming variety of phrase, and it is heartbreaking to lose any opportunity of getting instruction in return for the thousands our Council costs us.

In the art of "how not to do it" our Great Moral Persuader shines. It is evidently delighted when anything comes before it to which it can give at once a positive, decided, and unanimous negative; but if real action be proposed, and on a matter that unhappily comes undeniably "within the sphere of its duties," then it takes refuge in moral suasion; or if there is no other way of avoiding an affirmative resolution, some of its members "decline to vote,"—a degree of liberty which, however, the Council are not disposed to allow their President or Chairman. They would reverse in the Medical Council the doctrine that "that in the Captain's but a choleric word which in the soldier is flat blasphemy;" and they are to take counsel's opinion "whether the President or Chairman for the time being is not bound to give his casting vote in the case of an equality of votes on a division." It does not seem to have even occurred to the Council that the instances we have quoted of their powerlessness to do anything are, if true, so many reasons for trying to amend the Medical Act. Dr. Corrigan, who had been "Chairman of the Medical Acts Amendment Committee" since 1860, thought it was time that the Council should cease "to consider" whether any, and if any, what, amendments were needed, and that they ought to take action in the matter; but that was going a great deal too fast for the Council; they are horribly afraid of going to Parliament; they must be unanimous first as to what they ask for; Parliament will say, "Is this demanded only by a majority, or are you unanimous?" and if the former, they will be turned back, like naughty boys, to get their lesson more perfectly. So the Branch Councils are again to "consider" how certain clauses of the Act may be best amended; and the General Council are to "consider the whole subject" again next Session. What utterly dreary, heart-sickenning work this is! Since when, we would ask, have we in England governed by unanimity of opinion? When did we give up the rule by majorities? But who will believe that it is the truth, or any part even of the truth, that a necessity of previous unanimity is the reason that the Council delay going to Parliament for enlarged and more accurately defined powers? Who does not more than suspect that, in fact, the Council are haunted and paralysed by a dread lest an account of their five years' stewardship should be demanded of them, and then that, instead of gaining enlarged power, even that which they have might be taken from them.

When we come to business done—that is to say, to affirmative resolutions passed, on Saturday—we find that almost the whole consisted of votes of thanks, or votes of money. Few bodies, singular or composite, find any difficulty in passing the latter, so long as the banker is responsively sympathetic, so that the Medical Council can hardly claim much credit on that score. They also passed a resolution that the attention of the Secretary of the Home

Department be drawn "to the present defective state of the law regarding the practice of pharmacy, under which any person, however ignorant, may undertake it; and expressing the opinion of the General Medical Council that some legislative enactment is urgently called for to ensure competency in persons keeping open shops for dispensing medicines and for the compounding of Physicians' and Surgeons' prescriptions." We congratulate the Council on the cautious manner in which they have dealt with this subject. We hold that it would have been a most grave error to have tacked a pharmacy clause on to the Medical Act. Pharmacy, which is a trade, would then have claimed equality with the science and art of Medicine; chemists and druggists would have claimed to be registered under the Medical Act; it would have been increasingly difficult for the public to distinguish between them and the registered Medical man, and "counter practice" would have been fostered and rendered more flourishing. But while we maintain that pharmacy is a trade, and, according to the present prevailing views, ought therefore to be free, and while we admit that to prevent any Briton from getting poisoned if he likes would be an interference with the liberty of the subject, it does, nevertheless, seem desirable that some means should exist whereby he may know who is or is not likely to poison him, who has or has not been educated in the trade he chooses to adopt. The matter is therefore a somewhat difficult one to handle, and is best left to the Legislature to deal with separately from the Medical Profession.

With this expression of our qualified concurrence in one of the resolutions of the Council, we must close our notices of their proceedings. We cannot devote any more space to them. While we assure them that we fully appreciate the difficulties they have to contend with, we heartily wish that we could honestly congratulate them on showing more earnestness and singleness of mind in their endeavours to overcome those difficulties. We commend to their serious consideration the following words of one of their own body:—"If, then, the Licensing Bodies had failed in their duty, what had the Medical Council been about? This is the sixth session in which they had met, and they had never once expressed to the Medical Profession what they thought necessary for the purpose. . . . In this state of things he would advise the Council not to trust too much to the patience of the public. He was only surprised that their patience had lasted so long."

THE WEEK.

PARLIAMENTARY.

In the House of Commons, on Friday, May 13, Colonel French asked the Home Secretary whether it was the fact that the Archbishop of Canterbury had the power to confer the title of Doctor of Medicine on persons who had not undergone an examination before the College of Physicians.

Sir G. Grey said he had not been able, upon short notice, to ascertain all the facts of the case, but there was an old statute under which the Archbishop of Canterbury had the power of conferring the degree of Doctor of Medicine. (Laughter.) He believed this power was not recognised by the last Medical Act, and he might add that the present Archbishop of Canterbury had never exercised the power. (Laughter.)

The House adjourned until Thursday, the 19th inst.

The House of Lords adjourned until Monday, the 23rd inst.

THE ARMY MEDICAL DEPARTMENT.

It is a matter of some congratulation that the moribund state of the Army Medical Department is beginning to attract notice outside the Profession. The cool manner in which, in the recent debate, the Marquis of Hartington dismissed the complaints of the Medical officers as "trifles," scarcely worthy of official notice, has produced the following remonstrance from a writer in the *Times* of Monday. If next year should witness the breaking out of the general conflagration which has been so long prophesied, Government will find that the

bad faith they have kept with the Medical officers has had anything but a "trifling" effect on the efficiency of the service:—

"Army Medical Department.

"(To the Editor of the 'Times.')

"Sir,—In the *Times* of the 6th inst. we read that the Under-Secretary of State for War had stated in the House of Commons, in reply to the remarks made by Colonel North and General Peel, that the deficiency of army Surgeons might be attributed to the decrease in the number of individuals educated for the Medical Profession, but not to the 'failure to carry out in their integrity the recommendations of the commission on which the warrant was founded.' The noble Lord 'could not imagine that trifles such as these would make any Medical man hold back who intended to connect himself professionally with the army.' It is to be regretted that the noble Lord should entertain such an erroneous idea. It is well known in the Profession that the dearth of candidates for the commission of Assistant-Surgeon in the army is entirely attributable to the failure to carry out in their integrity the provisions of the warrant of October, 1858; and the knowledge that advantages and privileges conferred one day are either withdrawn the next or else evaded by the military authorities. In fact, there is a feeling of insecurity, justified by the conduct of the authorities since 1858.

"Questions which appear trifling probably to the noble Lord and other persons not intimately concerned are, nevertheless, of considerable importance to those directly affected by them, and questions of 'position' have a greater influence with the higher classes of Professional men than the mere consideration of pay.

"The authorities have thought it right to yield in this matter to the inordinate jealousy of the (so-called) combatant officers, and they are now reaping the results.

"So far as I can learn—and I have taken much pains to ascertain the opinions of the Profession in the matter—the desire is to enjoy in all things, except military command, the advantages and precedence attaching to the ranks with which theirs relatively correspond.

"I am, Sir, your obedient servant,

"A CONSTANT READER."

CORONER LANKESTER'S FIRST ANNUAL REPORT.

DOCTOR-CORONER LANKESTER has lately read before the Social Science Association a most weighty and instructive paper on the inquests which he presided over during the first year of his office. As he well observes, such a report "may supply the statesman, the jurist, and the philanthropist with the facts that demonstrate the vast importance of the coroner's court to the safety of life in the only country in Europe in which it exists in all its integrity. It is not alone in the investigation of cases to which criminality is attached that the coroner's court is of importance. It ought to be made the great safeguard of society against the prevalence of any preventible cause of death, whilst its importance can hardly be exaggerated in its investigations of the cause of death in our prisons, lunatic asylums, and workhouses." He complains justly of the "uncertain way in which the coroner's court is called into action. One of the most common sources of information to the coroner is the refusal of the district registrar to register a death upon an irregular or unusual Medical certificate of death. Where an intelligent registrar refers an irregular certificate to the summoning officer of the coroner, or to the coroner himself, or refuses to register without a Medical certificate, or a notice from the coroner, there the coroner's inquest is called into action, and life receives its greatest protection. The registrar is, however, not legally required to give any information to the coroner, and a registration of death may take place without Medical certificate. The registration of death and the burial of the body without any Medical certificate is of very common occurrence in London. Not only are unsatisfactory certificates accepted, but Medical certificates are registered in which the Medical men have not seen the person alive, and in some cases where they have neither seen them alive nor dead. It has come to my knowledge that the registration of death has taken place in cases of violent

death and sudden death without any appeal to the coroner of the district. It is very evident that such a system is fraught with danger to the public, and that it ought not to be left to the judgment of the registrar as to whether the coroner shall be informed of the entire absence or irregularity of a Medical certificate. It would at least be a thing easy of accomplishment in the London districts to require that incomplete or irregular certificates be sent to the coroner before registration." Even in cases where the inquest ends in a verdict of natural death it is of great use. "The progress of pestilence may not unfrequently be stayed. In many cases the law requires the removal of nuisances injurious to health, and where notice is served for the removal of these nuisances, and they have not been removed and are the cause of death, there can be little doubt that parties so offending expose themselves to verdicts of manslaughter in coroners' courts. It sometimes happens in Hospitals that erysipelas and pyæmia become epidemic, and the investigation before the coroner's court is most efficacious in drawing the attention of all concerned to the causes of these diseases and their removal. In cases also of small-pox where children die, and their parents have neglected vaccination after due notice of its requirement by the law, it is a question as to whether they do not expose themselves to a verdict of manslaughter." Inquests are often held where death has arisen from unsuspected inflammation of the lungs. This may give a hint to some of us when called to treat cases of "debility." Out of 346 accidental deaths, 90 were those of infants smothered whilst in bed with their mothers. The coroner concludes with a caution to his Medical brethren. "The importance of accurate post-mortem examinations at coroners' inquests can hardly be overrated. When the jury finds simply a verdict of 'found dead,' the whole question of the cause of death is left open to a variety of surmises, and the object of the coroner's court is defeated. At the same time, unless the post-mortem examination is complete it may mislead the jury. It is a frequent practice amongst Medical men to carry their examination only so far as they think necessary to discover the cause of death, and then to leave important organs unexamined. In this way the brain is sometimes not looked at when violence has been done to other parts of the body, thus leaving the question of whether a person may not have received the injuries by falling down in a fit unanswered. It is sometimes the case that an effusion of blood on the brain takes place as the consequence of vomiting from poisoning. In such cases, if the head only is examined the effusion is supposed to be the cause of death, and the poisoning is undiscovered."

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XVI.—MARCH 8.

Anatomy of the Gorilla continued.—Of the structure of the internal organs of the gorilla, very little is known. Duvernoy has described the larynx and male organs of generation; Gratiolet the brain, from an exceedingly imperfect specimen; and Professor Huxley has himself been able to add some observations upon the thoracic and abdominal viscera. The heart is very human in form, and the great arteries spring from the arch of the aorta in precisely the same manner as in man,—that is, the right carotid and subclavian arise from a common innominate vessel, and the left carotid and left subclavian separately from the aorta,—an arrangement which is soon lost in descending the series of apes. The lungs are divided into the same number of lobes as in man. The stomach is of the same form, and the cæcum very large, and provided with a long vermiform appendix. The liver in the only specimen examined departs remarkably from the human type, inasmuch as both right and left lobes are subdivided by deep fissures. The state of the brain examined by Gratiolet only sufficed to show that the principal sulci and gyri agreed with those of the chimpanzee. The form of the organ is, however, well seen in a cast of the interior of the cranium. It is longer and more

depressed than in the chimpanzee, and the olfactory lobes are more prominent. When the tentorial plane is horizontal, the posterior lobes of the cerebrum project to a marked extent beyond the cerebellum. The glans penis is more developed than in the chimpanzee, having a button-shaped dilatation at the extremity.

The female gorilla is much smaller than the male. Her skull wants the great crests or ridges, and her teeth, especially the canines, are smaller. The pelvis of the female presents a considerable approximation to the form of the human pelvis. It is much shorter than in the male, somewhat narrower from spine to spine of the ilium, and while the transverse diameter of the brim is nearly equal in the two sexes, the antero-posterior diameter is very much less in the female. In the outlet of the pelvis the distinction between the sexes is not so marked. As far as could be learned from measurements of two young gorillas, the law of growth is the same as in the chimpanzee.

Professor Huxley here took occasion to revert to the chimpanzee, for the purpose of describing the placenta and fœtus of one of these animals preserved in the College museum. The placenta was a circular mass, three inches and a-half in diameter, and half an inch thick, not divided into lobes. In its structure, as well as in the cord and membranes, it generally resembled the human placenta. The fœtus was eleven inches and a-half long, and would probably correspond to a human fœtus of the eighth month. As might be expected, the head was considerably larger in proportion to the rest of the body than in the adult or young after birth; the arms were notably shorter, which might at first be supposed to indicate an approximation to the human type, but the legs were also shorter to a proportionate amount. This shortening of the limbs is, then, a fœtal character, and as it had taken place to a corresponding extent in both limbs, it shows, in an interesting manner, the *ape* character of the chimpanzee strongly and definitely marked at this period of intra-uterine life.

The next animal taken under consideration was the orang-outang. It is only known to exist at present in the great islands of Borneo and Sumatra, where it is comparatively rare, and confines itself to the wooded, hilly, inland parts. There is no trustworthy evidence that it ever exceeds four feet four inches in height. The span is nearly twice that extent, being to the height as 18 or 19 to 10. The legs are proportionately shorter than in the chimpanzee and gorilla. The foot is longer than the hand, and both are singularly narrow. The forearm is nearly of equal length with the upper arm, and the thigh is very little longer than the leg. In most of these proportions it deviates further from man than do the chimpanzee and the gorilla. The hair is of a reddish brown; on the arms it is disposed as before described in the other anthropoid apes and man. On the chin it grows in especial abundance, forming a large beard, but the greater part of the face is naked. A peculiar appearance is given to the physiognomy of the adult male by a remarkable development of fibro-cellular lobes, containing much fat, projecting outwards from either cheek; these are not found in any other apes.

The habits of the orang have been observed and described by S. Muller, Sir J. Brooke, Mr. Wallace, and others. It very unwillingly assumes the erect posture, perhaps never in its native haunts. When it walks upon the ground it swings itself along by its very long arms as with crutches, not resting exactly on the knuckles as the great African apes, but with the inner edge of the index finger on the ground, and the thumb spread out. The hind foot does not come flat on the ground, but rests on its outer edge, with the toes close together and curved. Even when passing from bough to bough of the trees among which its life is chiefly spent, it observes a remarkable slowness and caution in its movements. It builds itself a kind of nest of leaves and twigs, and has an exceedingly loud voice, during the lower notes of which the great laryngeal pouch is seen to swell.

The vertebral column possesses even less of the human sigmoid curve than the chimpanzee and gorilla, but the sacro-lumbar angle is distinctly marked, and the coccyx continues the curve of the sacrum. There are seven cervical vertebræ, twelve dorsal (with twelve pairs of ribs), generally four lumbar, and five sacral. The large specimen in the College museum has five lumbar, giving the same vertebral formula as in man. The spinous processes of the cervical vertebræ are very long. The sternum exhibits an interesting modification (seen only exceptionally in man), being formed from a double series of ossifications, placed side by side. The scapula, on the whole, bears a greater resemblance to that of man than it does in either the chimpanzee or the gorilla. The clavicle, on the other hand, departs further, being very straight and long. The articular head of the humerus is large, and the shaft comparatively slender. The bones of the forearm present the widely-curved radius, and the short olecranon characteristic of the ape. The hand deviates from the human type much more than in the other anthropoid apes; it is very long and narrow, and the phalanges are greatly curved. The thumb only reaches to the end of the second metacarpal bone. As in most of the lower apes, there are nine bones in the carpus, the additional one being situated between the scaphoid, os magnum, and trapezoid, and is probably a dismemberment of the former. This is a significant difference from the hand of the chimpanzee and gorilla, because it is one which does not appear to be in any way adaptive. The ilium does not extend so high as in the chimpanzee or the gorilla; it is broader than in the former, but less so than in the latter. The ischia have the characteristic eversion of the ape. A remarkable circumstance connected with the femur is the entire absence of the round ligament. The foot deviates very greatly from that of man. The tarsus is the shortest segment, the metatarsus next, and the digits the longest. The calcaneal process is narrow from side to side. The mobility between the distal and proximal divisions of the tarsus is exceedingly great, and is the chief cause of the habitual turning inwards of the sole of the foot. The entocuneiform bone has the simian character remarkably well shown. There is a considerable space between the articular surface for the first and second metatarsal bones, in consequence of which the hallux takes a position at right angles to the foot, with the greatest ease. The scansorial curvature of the phalanges is even more definitely marked than in the hand. The hallux is remarkably short, and its distal phalanx, with the nail, is not unfrequently absent; even when it is present, the end of this digit does not reach the extremity of the second metatarsal bone.

THE FRENCH POISONING CASE.

THE trial of La Pommerais for murdering the widow De Pauw has at length come to a close. The prisoner was found guilty; and, as the jury made no mention in their verdict of extenuating circumstances, he has been condemned to death. A large body of Medical evidence was taken during the trial. MM. Nélaton, Velpeau, and Desormeme were examined respecting the pretended illness of Madame de Pauw. It will be remembered that the prosecution alleged that she had simulated illness by the advice of the prisoner in order to impose on the insurance companies and induce them to grant her a life annuity in lieu of her policy. The three Medical witnesses hardly remembered her, but on their prescriptions being placed before them they said that they could not have considered her seriously ill. They had prescribed simply for slight nervous excitement. MM. Tardieu and Roussin conducted the post-mortem examination; and, although they did not detect poison in the viscera of the deceased, yet from the absence of disease in the internal organs, from the symptoms exhibited before death, and from experiments made on animals with the vomited matters scraped from the floor of the room which deceased had occupied, and with the contents of the stomach, they concluded that she had died from some powerful

poison—probably digitaline. This opinion was combated by M. Hebert, of the Hospital La Clinique. He maintained that the experiments with the matter scraped from the floor were perfectly valueless, as it was impossible to say that organic matter in a state of putrefaction might not have been sufficiently poisonous to cause the death of the animals experimented on. Claude Bernard, Vulpiau, and Raynal were also examined on the action of digitaline, and detailed the result of their experiments with that substance. The trial was conducted *more Gallico*, the judge condescending to rate the prisoner, and to damage his witnesses in the eyes of the jury in a manner which to Englishmen appears utterly irreconcilable with the even-handed justice of a judicial proceeding. During his imprisonment La Pommerais attempted on three occasions to commit suicide. The judge stated that he considered this strong evidence of his guilt.

FROM ABROAD — THE PROFESSION IN RELATION TO LIFE ASSURANCE—THE CIVIL PRACTITIONERS OF FOGGIA—STATISTICS OF SUICIDE.

M. GUÉRIN adverts in the *Gazette Médicale* to one or two points of purely Professional interest in relation to the late trial of the poisoner La Pommerais. First, Medical men are regarded quite in an exceptional light in France as regards life assurance. It was one of the charges against the accused that when he made these assurances he concealed from the offices that he was a Medical man; and this special fact became the occasion of a general declaration of incompatibility between this title and the right of contracting assurance for life. This exception, which may be regarded almost as an injury to the Profession, is based upon two assumptions—the possibility of the Medical man being aware of information which he may employ injuriously to the interest of the companies, and the fact that he is in a position to criminally abridge the life of a relative which he may have assured. There can be no doubt that both these circumstances have been sometimes realised. A Medical man may have it in his power to conceal from the knowledge of the office disease which must shorten life; and that in some instances he has availed himself of his knowledge of drugs to perpetrate murder is well known. In face of this double ground of suspicion, which M. Guérin declares to be inseparable from Practitioners who are desirous of insuring the lives of their relatives, he gives him the extraordinary advice to entirely abstain from assuring their own or relatives' lives. This is the only way, he declares, to raise themselves in consideration, and to place themselves beyond the range of all injurious suspicions. So that, because some individuals may exhibit a lax morality in replying to the questions proposed, and others, in however an infinitesimal proportion, may become guilty of positive crime, the entire character and consideration of a noble profession is to be blasted, and to be pronounced, even by itself, as incapable of participating in the advantages of one of the greatest of modern social improvements. To admit the general applicability of the assumption by abstention, so far from "raising the Profession in consideration," would be to call down upon its head well-merited contempt.

Another point noticed by M. Guérin is, that the accused prescribed poisonous doses of digitaline and hydrochlorate of morphia, and he asks, was the *pharmacien* justified in dispensing these? The judge ruled that he was bound to prepare the prescription, retaining it in order to cover his own responsibility with respect to it. Yet it is obvious that silence and inaction may favour mistakes or crimes. In fact, *pharmaciens* have often called the attention of Practitioners to what seemed to them dangerous amounts prescribed, and many have been the calamities thus averted; and M. Guérin is of opinion that in all cases in which medicinal substances are prescribed in poisonous doses, the *pharmacien*, though not obliged by law to do so, nor possessed of any power to control the amount prescribed, should always

seek for a confirmation of the wishes of the Practitioner from his own lips.

Some time since (*Med. Times and Gazette*, April 2) we noticed what appeared to be a grave dereliction of duty and humanity on the part of the Medical Practitioners of Foggia, near Naples, who were said to have refused their attendance on soldiers in the Military Hospitals suffering during an epidemic of typhus. Grave censures were passed upon them in the Italian Parliament, and the expulsion of those of them who belonged to the Italian Medical Association was decreed. It turns out, however, that matters have been carried on too hastily, as, upon further investigation, much exaggeration and misrepresentation would seem to have prevailed. The affair, in fact, arose, in the first instance, from the local authorities having refused to institute the necessary hygienic preventives indicated by the Sanitary Council and the local Medical Committee, and then, when the danger, which had been sought to be avoided, really arrived, throwing all the responsibility of providing the necessary attendance upon those whose councils they had set at nought. Moreover, no request for the attendance of the civil Practitioners in the Military Hospitals was made by competent authorities, but all soldiers sent to the civil Hospitals were carefully attended to—one of the Physicians in attendance, indeed, meeting his death from the contagion. Notwithstanding the absence of the proper formal request, Dr. Nigri went to attend the soldiers in the Military Hospitals, and the other Practitioners soon followed his example. The Medical Association, having carefully gone into all these facts, has revoked its former condemnatory resolution, somewhat hastily formed, and completely exonerated its fellow associates.

M. Legoyt, the director of one of the Statistical Departments of the French Government, a candidate for membership in the Academy of Medicine, read to that body a paper on the statistics of suicide, which terminates with the following conclusions:—1. In Bavaria, Denmark, France, Hanover, Mecklenberg, Prussia, Saxony, and Sweden, suicide increases more rapidly than the population and the general mortality. 2. Suicide especially prevails in the Northern States of Germany and different parts of Denmark. Norway and Sweden, though inhabited by the same race, are placed at a considerable distance from Denmark. England, contrary to a generally-received opinion, occupies the lowest rank in the scale of frequency. Suicide is also of infrequent occurrence in the three Catholic countries—Austria, Spain, and Belgium; and France would occupy about the same rank were it not for the great number of suicides which take place in Paris, being one-seventh of the whole number which occur in France. 3. As a general rule, there are 29 or 30 female to the 100 male suicides. 4. They regularly increase in number with age to between 60 and 70 years. 5. In January there are fewest, in July most suicides. 6. Putting aside mental diseases and physical sufferings, which affect both sexes much alike, women yield chiefly to moral influences, while men are powerfully affected by material circumstances. Drunkenness and debauchery figure only to an insignificant amount among the indirect causes of female suicides. 7. In Denmark, Saxony, and Spain, in which countries the inquiry has been entered into, married persons have been those who have yielded least to the propensity, and widowers have done so most. Persons who have been divorced or separated are, however, those who are proportionally more liable to suicide. 8. In Prussia, during two years, Protestants furnished 153 suicides per million; Jews, 51; and Catholics, 47. 9. Suicides are far more frequent in towns than in rural districts. To sum up: the most remarkable fact which comes out of the inquiry is the general and rapid increase of suicide.

UNIVERSITY OF CAMBRIDGE.—The examination for the degree of Master in Surgery will take place on the 24th of this month, instead of on the 30th as before announced.

THE NORTH STAFFORDSHIRE INFIRMARY.

ADMINISTRATION.

Like to the South Staffordshire General Hospital, at Wolverhampton, the North Staffordshire Infirmary, as the Hospital of the Potteries is designated, was originally a Dispensary and house of recovery. It is situated in Etruria, and is distant two miles from Newcastle, a mile and a-half from Stoke, and three-quarters of a mile from Hanley; it may be considered as nearly in the centre of the Potteries. It was transformed from a Dispensary into an Infirmary in the year 1815, and in 1819 the present building was opened with accommodation for forty in-patients. The institution was founded on the faith of receiving subscriptions from the workmen of the establishments in the Potteries as well as from the masters. The building stands on copyhold land, situated in the Duchy of Lancaster. The property, consisting of real property, funded, and accumulating property, is vested in trustees. The accumulating fund, which now amounts to £1269 4s. 2d. at Three per Cent. Consols, is held in trust to accumulate until it shall produce a clear income of £1000 a-year.

NUMBER OF PATIENTS TREATED.

At the present time the institution contains 130 beds. In the winter months an average of 106 beds are occupied daily, and 90 at other periods.

The average number of patients admitted into the Infirmary runs from 940 to 1030. The number of out-patients averages 4000 annually. The duration of each patient in Hospital is nominally two months; the duration under treatment of out-patients is three months. The number of wards in the Infirmary is seventeen; the maximum number of beds in each ward is thirteen, and the maximum number of patients is thirteen.

RULES FOR ADMISSION OF PATIENTS.

The rules for the admission of patients into the Infirmary differ considerably from those of other similar institutions. The Infirmary is, in fact, to an extent self-supporting, an "establishment subscription" being allowed, by which a number of persons in the district can subscribe, and be entitled to the privilege of giving admission tickets to the sick amongst them. As this plan works well, I subjoin an outline of the rules of the Infirmary, in so far as they relate to the mixed plan of honorary and self-supporting subscriptions.

For honorary subscribers there is a scale of privileges of recommendation. An annual subscription of £1 1s. may admit one out-patient at one time; a subscription of £2 2s. may admit one in and one out-patient. The scale progresses in this manner according to a fixed rule, and a subscriber of £10 10s. a-year may have five out-patients at one time, and five in-patients in the course of the year.

No subscriber of less than twenty guineas a-year is entitled to more than three in-patients at a time; but subscribers of ten guineas a-year are allowed one more in-patient at a time for every additional ten guineas subscription.

A donation of ten guineas paid by an individual entitles the donor, during his life, to the privileges of an annual subscriber of one guinea; a donation of twenty guineas, to the privileges of a subscriber of two guineas; and so in proportion for every additional ten guineas.

A subscription or donation from a partnership is considered as from an individual, and entitles the firm to one vote, and to all other privileges enjoyed by an individual.

The "establishment subscription" is managed as follows:—The establishment subscription is considered a joint subscription of the persons contributing the same, in the manufactory or other establishment from which it is paid, and entitles them as a body to privileges on the scale already described as for subscribers.

The establishment subscribers contribute during every working week, according to the following scale:—Each person who earns upwards of eighteen shillings per week contributes not less than one penny weekly; each person who earns upwards of seven shillings per week contributes not less than one halfpenny weekly; and each person who earns not more than seven shillings per week contributes not less than one farthing weekly.

Persons who are subscribers, their children and step-children

under 14 years of age, and wives (not employed in manufactories or collieries), alone are recommended as patients by virtue of an establishment subscription.

The master of an establishment which subscribes can also either himself vote and recommend patients in his name, or address to the Secretary a certificate containing the name of the person who is alone to exercise those privileges; the fact is registered by the Secretary; only one vote is allowed on behalf of each establishment.

Overseers of parishes, the chairman or other specially-authorized members of boards of guardians, and the stewards of friendly societies, may also subscribe, but they alone can vote and recommend patients in virtue of those subscriptions, the first confining their recommendations to their own parishioners, the last to the members of their respective societies; only one vote is allowed on behalf of each union, parish, or friendly society.

Donations from parishes, unions, friendly societies, or other bodies, entitle the proper officers for the time being, during ten years, to the same privileges which the same donation would confer on individuals for life.

Any Physician or Surgeon of the institution who has discharged the duties of his office for twenty years and upwards, is eligible on his retirement to the appointment of Physician or Surgeon extraordinary for life by a general meeting of governors, and every Physician or Surgeon extraordinary enjoys all the privileges of a governor subscribing two guineas per annum.

Ministers who obtain and pay to the institution congregational collections, amounting in each case to four guineas and upwards, are governors for the year in which such payment is made, and are entitled to vote and act as such for one year from date of payment; for every four guineas they have the privilege of recommending one in-patient for the year, but their recommendations are confined to residents in the respective parishes where the congregational collections have been made.

I have noted these regulations at length, because the balance-sheets of the Infirmary show that the rules work well and easily.

INCOME OF HOSPITAL AND COST OF PATIENTS.

The sources of income of the Infirmary have already been described. The income varies from £3500 to £3750 a year. In 1861, an average year, the receipts in full were £3685 0s. 6d. Of this sum, £1747 14s. 5d. was derived from "establishment subscriptions" alone; £1170 was derived from other subscriptions, the rest were donations and from miscellaneous sources. The expenditure of the Hospital is usually kept within the receipts, and a balance in the treasurer's hands is not unfrequent. We may attribute this, I think, justly to the permanency of the establishment subscriptions.

The cost of patients per head has been gradually rising during the past twelve years. In the year 1851-2 the cost per head of in-patients was £1 9s. 5 $\frac{1}{4}$ d., while in 1860-61 the cost was £1 19s. 8 $\frac{1}{4}$ d. Amongst out-patients in the first-named year, the cost was 1s. 2 $\frac{1}{2}$ d. per head, and in the second, 1s. 4 $\frac{3}{4}$ d.; taking the total, the cost of patients all round in 1851-2 was £2 6s. 7 $\frac{3}{4}$ d., while in 1860-61, it was £3 0s. 7 $\frac{3}{4}$ d.; the expenses, in fact, seem to have risen almost equally in every department—in house expenses, dispensary, and miscellaneous. Still, the average cost of patients is much less than at Wolverhampton, and is nearly the same as at Stafford.

Subscribers to the Hospital are specially desired never to give a recommendation to a patient who may request it, when he who makes the request is able to subscribe himself. The fever patients are considered as in-patients, and as such are charged against the privileges of the governor who recommends them. But any subscriber, in addition to the privileges arising from his subscription, may have one fever patient constantly on the books, provided he send one guinea with each patient.

MEDICAL STAFF.

The Medical staff of the North Staffordshire Infirmary consists of two Physicians—Dr. J. T. Arlidge, M.D., and Dr. A. F. Gooday, M.D.; three Surgeons Extraordinary—J. Spark, Esq., D. Ball, Esq., and S. M. Turner, Esq.; three Surgeons—R. Garner, Esq., J. Walker, Esq., and W. H. Folker, Esq.; and one House-Surgeon and Apothecary—W. D. Spanton, Esq.

In addition to these officers there is a dispenser and two resident pupils. The Physicians and Surgeons consider the present resident staff miserably deficient. They are of opinion that an assistant House-Surgeon and six pupils are absolutely

necessary, in order that patients may be efficiently examined prior to admission, and that correct records may be kept of the practice of the institution.

SANITARY ARRANGEMENTS.

The site selected by the worthy founders of the Infirmary was unquestionably as good as could be wished at the foundation. It was in the centre of the district, and it was on a spot elevated and pleasantly situated. The potters were for many years proud of their Medical institutions, and the Medical staff were alike satisfied. Mr. Hugh Davies, now of this city, but who some years ago was House-Surgeon to the Infirmary, tells me that in his time the place was most beautiful. The air was pure and clear, the scenery open and varied, and all around was like a garden. Unfortunately, these beauties and satisfactory conditions remain now only in the recollection, and even in the recollection of but a few individuals. In the lapse of time the district, becoming rapidly more and more industrial, has changed so thoroughly in character that the Infirmary must needs be removed. In the course of various mining operations its foundations have been shaken, and the deep clefts in its walls, strong girders, and imperfectly-fitting windows and doors—which latter seem as though they were under a continual course of carpentry—tell how rudely the building has been shaken. Again, the air around is no longer transparent and pure; for a great part of the year the atmosphere is charged with smoke or sulphurous vapour from the furnaces, and the landscape is hidden. At the time of my visits the wind lay well for carrying off the suspended particles of carbon, and in consequence the air was very clear, and one could appreciate the excellence of the site at the time when there was nothing from day to day, except the clouds of heaven, to obscure the prospect; but this was an exceptional occasion, it seemed; for the wind ordinarily is perverse, and will bear the carbon and the sulphurous gas to the doors and windows of this sick man's house.

Little indeed thought the founders of this house of the days that were to come, when the artizan should thrust forth his hand, and all-powerful labour should wring the wealth out of the earth of North Staffordshire around their refuge for the wearied. Little thought they that in the year 1864 there would rise within four hundred yards of the Infirmary four blast furnaces, and that on three sides of it numerous other smoking shafts of mines, and iron works, and bone works would charge the air with unwholesome vapours; still less thought they of the constant thunderstorms of steam hammers playing day and night within two hundred yards of that house, or of the lightning glare of the furnaces flickering through the windows in the dead of night. Least of all would they dream that patients coming from afar, from the open quiet villages of districts where the landowner and engineer have as yet played no shrewd tricks with nature, would ever have to ask for health at a home where hardy flowers, nerveless and unimpressionable, die from poisoned air.

But now all these unseen objections have reached realisation; and a site, once the best, perhaps, in England for a country Hospital, has become the worst. A site on which the disabled man must find every sense injuriously influenced, and where that element of cure for which he instinctively craves more than for any other—*absolute rest*—is forbidden to enter.

Again, owing to the increase of population, the building itself is not in any sense fitted for present requirements. It was not built in the first instance on scientific principles, and at best was meant for a limited number of patients and attendants. In this day, when the demands upon it are so great, every kind of difficulty besets the management. The difficulty of avoiding overcrowding has constantly to be met; the cooking possibilities are narrowed to the finest point; the lodgment of nurses is indifferent, and in short, as we shall see in speaking of details, every condition that can make the carrying out of sanitary rules easy and agreeable is removed as far off as it can be. And so it is now universally agreed that the Infirmary must come down; and a few years will, I doubt not, see in its successor on a new site a building with every necessary accommodation and all appliances of art to boot.

Respecting the old Infirmary, nevertheless, much good may be said, and from it various useful lessons may be learned. Its situation for many years saved it from dangers to which other Hospitals in crowded localities are exposed; for into it for a long time, despite the badness of the construction, good air would find its way. Then came the period when the air lost its freshness; and so surely as that occurred the evils of over-

crowded wards showed themselves. Once, and more than once, as a result, wards have had to be closed and Surgical operations suspended because of the presence of the plagues of Hospitals. Then, by rigid adherence to sanitary measures, the destructive disorders have been exorcised; and lately, owing to the determinate zeal and care of a Medical staff, that for enlightenment and practical learning is second to none in this kingdom, the most important operations have been performed with results rarely achieved under circumstances infinitely happier and fairer. But the cost, in labour, in anxiety, in watchfulness—who shall count it up? It is not to be counted, indeed, but it indicates what can be done under conditions that are as indifferent as may be, when more than one idea is developed in the Medical and Surgical mind; when the thought and ambition of curing the sick is devoted to treatment in its wholeness:—When with the questions—what shall be done by the hand, and what medicines shall be prescribed, it is also asked, where shall the sick man be placed, and what shall he eat, and drink, and breathe?

It is obvious on a mere inspection of the Infirmary, as it now is, that it is unfit for the objects it is intended to carry out. Externally it has a broken-down, patched appearance; and internally all its parts are defective. The central staircase is so placed as to act as a shaft from the basement; the corridors are narrow, being, in fact, mere passages; the windows are small, and the inconveniences for moving patients from one part of the house to another are not only many, but apparently insurmountable.

CLASSIFICATION AND CONDITION OF WARDS.

The wards, which are seventeen in number, are divided into Medical and Surgical. The Surgical wards include one which is set apart for accidents, and which serves for general cases. Two wards were built originally, as an additional wing, for cases of burns, and are still used primarily, but not exclusively for this purpose; two wards are set apart for eye cases, one for males and one for females. In the basement is a wretched room, called the outer ward, for females syphilitic cases.

Cubic Space.—The cubic space allowed has been very irregular and limited. I find from an inquiry that has lately been made for the information of the Board of Management, that until lately there were only 675 cubic feet per patient in some wards, and 575 in others. In one ward the space was still less.

The cubic contents of the wards show that—

57 beds (<i>i.e.</i> , nearly half) have less than 600 cubic feet.	
24 „ „ „	700 „
30 „ „ „	800 „
18 „ „ „	860 „

Taking the average of patients, however, during the last five months as numbering 106, the cubic space to each has been 818 feet.

The accident ward, containing nine beds, is always full: the cubic space per bed is only 784 feet, half of what it should be. The beds are only two feet six inches apart from side to side, and three feet from end to end. The women's fever ward has four beds (cubic space, only 531 feet to each bed): it measures 10 feet by 16 feet, and ventilates on one side into a nearly dark passage, with an open and offensive sink, belonging to the adjacent accident ward and closet, and, on the other side, into the fever ward beyond.

Ventilation.—There is no systematic ventilation, but in some of the wards there is a grating in the floor, and in others there are openings in the wall at the upper part, near the ceiling, which openings pass into the air directly, and give rise to currents producing downward draughts which are always objectionable, and are dangerous to those who happen to lie in bed immediately beneath them. I understand that in one patient fatal symptoms were produced by this exposure to a blast of cold air.

The air of the wards is exceedingly impure; it smells foully everywhere, and in the committee-room, where I sat for a time, the atmosphere was sickening; I learned that lady visitors have often been unable to perform their duties owing to the stench.

The windows and doors are drawn out of the perpendicular as the result of mining operations near; so that both windows and doors are opened and shut with difficulty, and demand the constant care of the joiner, who, with all his skill, can neither prevent draughts through crevices and ill-fitting joints, nor make a sash move for any length of time smoothly and correctly.

Warming.—The warming is imperfect, being dependent on fires in old fashioned fire-stoves, in the use of which there is no consideration of the economy of fuel, nor of the distribu-

tion of heat. In the new wing there are some small hot water pipes which throw out heat, but are very imperfect as a system.

Sunlight is much excluded from the Hospital; in some cases so effectually that no gleam of it falls directly on any bed. In the northern aspect, where there is the greatest deficiency of light, and where the air from the blast furnaces sweeps along most determinately, the flowers placed in the windows invariably dwindle and die. The reporters on the condition of the Infirmary to whom I have referred, dwell specially on the defective state of the windows. They remark, that in all the wards, except the new wing, and one end of the men's fever ward, the beds are arranged on one side, along dead walls; and in the new wing, the arrangement of the windows is so defective, that some beds are, from necessity, placed immediately under the windows. Also, in all the wards, with the exception of the new wing, the windows are on one side and at one end only. The wards are entered from interior corridors, of from three feet six inches to four feet wide, dark, and unventilated, except from the main staircase, or great funnel, as it may be called, whence all the steaming and cooking smells of the offices ascend.

The water-closets are, I think I may say, in every case abominably placed. In numerous instances they open partly into the wards. The number of closets is also deficient. The smell from one water-closet diffused itself recently so steadily through the ward to which it was annexed, that the following placard had to be placed in a prominent position:—“Put down the closet lid, and shut the door, when you come out of the closet.”

The lavatories and sinks are open to the same objection. I found in almost every case that these communicated with the wards, and, what is worse, there were no windows in them that admitted any sufficiency of light. Hence, these close corners became loaded with organic impurities, which in process of decomposition charged the air with odours little less objectionable than those arising from the closets themselves.

The water supply is derived from the water company, and the water is intended to rise to the upper floor: but the supply occasionally fails altogether, and often fails in the upper floor. The water is not inferior in quality, but, as in seasons of frost it is sometimes unattainable for many weeks, great and serious inconveniences necessarily result.

The baths are scarcely worthy of mention. In all the house there are two baths, one for males and one for females. Both are placed on the first floor, out of reach of the patients above and below. These baths themselves are rendered less useful than they might be by the irregular supplies of hot and cold water. Of course there is no hot-air bath in the building.

The floors are cleansed by simple washing with soap and water. It is very difficult to keep them clean, and almost dangerous to clean them, for as they consist of deal which is much worn, and is soft and porous, they allow dirt rapidly to accumulate on them, and in the process of cleaning they absorb so much water that the period for drying is greatly prolonged. At this moment, as a temporary remedy, all the floors are being painted with oxide of zinc paint.

The decorations of the wards,—save the mark!—are of stone paint shoulder high, with whitewashed wall above. The walls are very uneven and cracked and rough. There is, to use a plain term, a squalid appearance at every point that scarcely admits of any description that might not seem to be exaggerated.

The drainage has of late been improved, but it is imperfect. It consists of a main drain or sewer that runs from east to west, and receives the contents of all the minor drains. The main drain is now constructed of iron; the iron answers well. In former times emanations from the main sewer were a cause of constant annoyance and danger.

The bedsteads are of iron, and curtains are not patronised. The bedding consists of an under straw mattress with a hair mattress above.

CLASSIFICATION OF PATIENTS.

The Surgical cases are separated from the Medical, and in the Medical cases each Physician has his own ward. The cases attended to by the Surgeons are mixed, *i.e.*, no Surgeon has a ward distinctly to himself. Fever cases are admitted, and at one time two wards were set apart for such cases; but they were considered amongst the worst wards in the house, and were soon given up to general cases. At this time the fever cases are distributed as widely as they can be amongst the other Medical cases. The experience of this admixture of cases demonstrates forcibly the soundness of the objection to such admixture put forward by Dr. Murchison. It was found at once that fever patients admitted in the manner named caused

the spread of contagion amongst other patients and amongst the nurses. Last autumn, a case of typhus having been introduced into the Infirmary, the disease spread quickly; two of the nurses were attacked, and one died; several of the general patients were also attacked, and, to add to the disaster, certain patients left the Institution from sheer terror, and conveyed the poison and the disorder into families residing in the neighbourhood.

It would appear also that in some instances typhoid fever has arisen "spontaneously" in the Infirmary. Mr. Orton, the late House-Surgeon, in a letter written and published during the present year, states, from his own observation, that in two cases fine, healthy young women were admitted into the so-called outer ward within a few weeks of each other. They both took typhoid fever, neither of them having been previously exposed to the contagion, and they both died. Mr. Orton attributes their deaths to the defective drainage in the ward.

THE NURSING SYSTEM.

The nursing system is most inefficient, and will, it is to be hoped, be remedied in a new Hospital as surely as the other evils, to which attention has been drawn. The nurses, one and all, appear to be obliging, kind women, but overworked and depressed. This is not to be wondered at. In seventeen wards, containing an average of 106 beds, there are four day nurses and two night nurses. To help them they have two *seourers*, and in the accident ward the house porter, who has many other important duties (including attendance in the "burnt ward"), takes the main charge. But is it possible to imagine the attention that can be paid to the patients, on thirty-seven of whom one nurse must alone attend? The reason of this deficiency is want of accommodation. In a Hospital where, as it sometimes happens, two patients have to be put into one bed, where is there room for nurses and attendants?

DIET OF THE HOSPITAL.

Objection has been made to the diet of the Infirmary, and with little less justice than in the case of the other complaints that have been raised. The table subjoined gives all the facts. It shows at best that, whatever may be said of quantity, quality of food is not an element in the calculation and in the practical argument as to the best means of feeding 106 sick people.

	Milk Diet.	Low Diet.	Middle Diet.	Full Diet.
Breakfast	1 pt. milk. 4 oz. bread.	1 pt. tea. 2 oz. bread and butter.	1 pt. tea or cocoa. 6 oz. bread and butter.	1 pt. tea or cocoa. 6 oz. bread and butter.
Dinner	1 pt. milk. 4 oz. bread. 8 oz. pud- ding.	1 pt. gruel. 4 oz. bread.	1 pt. broth. 2 oz. bread. 10 oz. rice pud- ding.	FOR MEN: Cooked meat, without bone, 4 oz. Potatoes, 8 oz. Rice pudding, 8 oz. Bread, 2 oz. Beer, ½ pt. FOR WOMEN: Cooked meat, without bone, 3 oz. Potatoes, 6 oz. Rice pudding, 8 oz. Bread, 2 oz. Beer, ½ pt.
Tea	1 pt. milk. 4 oz. bread.	1 pt. tea. 2 oz. bread and butter.	1 pt. tea. 6 oz. bread and butter.	1 pt. tea. 6 oz. bread and butter.
Supper	½ pt. gruel and sago al- ternately.	½ pt. gruel and sago alternately.	½ pt. gruel and sago alternately.	½ pt. gruel and sago alternately.
Daily al- lowance to each patient.	3 pt. milk. 12 oz. bread. 8 oz. rice pudding. ½ pt. gruel or sago.	3 pt. tea. 4 oz. bread. 4 oz. bread and butter. 1 pt. gruel. ½ pt. gruel or sago.	1 pt. tea or cocoa. 1 pt. tea. 1 pt. broth. 12 oz. bread and butter. 2 oz. bread. 10 oz. rice pud- ding. ½ pt. gruel or sago.	1 pt. tea or cocoa. 1 pt. tea. 12 oz. bread and butter. 2 oz. bread. 4 oz. meat for men. 8 oz. potatoes, ditto. 3 oz. meat for women. 6 oz. potatoes, ditto. ½ pt. beer. 8 oz. rice pud- ding. ½ pt. gruel or sago.

Extras to be specially ordered:—Chops, beef-tea, fish, poultry, sago, arrowroot, eggs, ale, porter, wine, or spirits.

In reference to this dietary, the Medical officers report that it is very imperfect; but, although they are thoroughly impressed with the necessity of change, the kitchen is so exceedingly small and inconvenient that they can only arrange to let each patient have mutton once a week, and that only by serving one or two wards each day. This, though an improvement upon the former daily rations of boiled beef, is but a scant variety, not nearly sufficient for sick persons.

USE OF ALCOHOLICS.

Alcohol is moderately used in the Infirmary. The amount of wine allowed can scarcely exceed one ounce per day for each patient, and brandy scarcely a quarter ounce. Ale, beer, and porter are rather freely given, probably at an average amount of one and a quarter to one and a half pint per patient per day.

PRACTICE OF THE HOSPITAL.

The Medical practice of the Hospital presents an extraordinary number of cases of chest affection. Pulmonary consumption stands very high in the list—first, perhaps, of all in respect to *fatality*. In addition to the acute and sub-acute inflammatory disorders of the chest, "potters' asthma" and chronic bronchitis are common maladies. Potters' asthma is a disorder that may be considered peculiar to the district and to the occupation. It is analagous to the consumption of coal miners and of knife grinders. It is due evidently to the inhalation of the dust, consisting of particles of fine dry clay, which are thrown into the air in the various processes of earthenware manufacture. The lungs in potters' asthma become firm and hepatised in parts.

Rheumatism in the sub-acute and chronic forms is also common. It prevails amongst the firemen of the pottery kilns, being due to exposure to constant changes of heat and cold. The same disorder is also frequent amongst miners. Heart disease, as a sequence of rheumatism, is, of course, prevalent. Lead colic and various degrees of paralysis from lead are prominent objects of clinical observation. These affections are peculiar to those who are engaged in the process of "dipping" in glazing the earthenware.

Taking the Medical diseases as presented by the number of cases rather than by the mortality, we may place the more prominent disorders in the following order, and may obtain a fair percentage average showing the relationship which the disorders bear, relatively, the one to the other:—

Bronchitis (including potters' asthma)	23.40 per cent.
Rheumatism, acute and chronic	23.00 "
Phthisis	16.00 "
Dyspepsia	7.00 "
Heart disease	6.00 "
Typhoid fever	4.90 "
Pneumonia	4.30 "
Pleuritis	3.00 "
Chorea	3.00 "
Paralysis (Hemiplegia)	3.00 "
Epilepsy	2.00 "

The above short table is deduced from the official report of cases treated in the year 1861—the year on which Dr. Farr bases his average of the mortality of the large Hospitals of the kingdom. It represents only the in-door cases, and does not include the diathetic conditions of disease, and certain maladies which are common in the out-patient department. Respecting these, Dr. Arlidge informs me that scrofula, affecting chiefly the glands and joints, is the prevailing diathesis, and that goitre is frequently met with.

On the Surgical side the most common diseases are venereal affections, diseases of the bones and of joints, diseases of the eye (mostly acute), and cancerous disorders. The Surgical operations are very numerous. The capital operations average from 55 to 70 a year, the minor from 40 to 50; the tooth extractions run from 800 to 900, and the treatment of fractures and dislocations make up 100. In the out-patient department there are no fewer than from 400 to 450 cases of accident annually.

The following table exhibits the average of the more important Surgical cases calculated on their percentages, for 1861:—

Fractures, simple and compound	16.25 per cent.
Diseases of bones and joints	15.50 "
Syphilis and gonorrhœa	13.00 "
Contusions	11.75 "
Ulcers	7.50 "
Burns	6.25 "
Abscess	5.75 "
Erysipelas	3.75 "

Sprains	3.75 per cent.
Ophthalmia	3.50 ,,
Corneitis	3.25 ,,
Orchitis	3.00 ,,
Cataract	2.50 ,,
Calculus	1.00 ,,

The same observations as were made in respect to the Infirmary at Wolverhampton apply here, but not to so great an extent; the cases of accidents that are brought in are usually excessively severe, and the shock prolonged.

MORTALITY.

The general rate of mortality of the North Staffordshire Infirmary in the year 1861 was 50.51 per cent. on Dr. Farr's method of computation. This is almost 6 per cent. higher

than the mortality of the Hospital at Wolverhampton, and 14 per cent. above that of Norwich and Stafford.

The Surgical Mortality is high by comparison with the other Hospitals we have had under notice. During the past ten years the mortality after operations has been in the proportion of one death after 8.80 operations, or at the rate of 11.31 per cent. Considering the bad condition of the Hospital, and severity of the Surgery, the wonder is that this mortality should not have been greater. Fortunately, the facts bearing on the mortality after operations, during the last ten years, have been kept, and the Medical staff were most ready to place them entirely at my disposal. They have been very carefully condensed by the House-Surgeon, Mr. Spanton, and are now for the first time laid before the Profession. A more valuable series of operative experiences could scarcely be presented.

Table of the Principal Operations performed at the North Staffordshire Infirmary during the Last Ten Years.

CHLOROFORM.

Chloroform is administered in the North Staffordshire Infirmary for every kind of operation, except the most trivial, and no accident whatever has occurred from its administration. At first, the inhaler invented by Dr. Snow was exclusively used, but in time this inhaler was thought to be inconvenient, and so here, as in many other similar institutions, it was thrown aside. For many years past the narcotic has been simply poured on to a silk handkerchief or a piece of lint, and held over the mouth and nostrils with room for the admission of air. The symptoms produced are watched with the utmost possible care, and one Practitioner, usually one of the Physicians, takes sole charge of the administration. The number of administrations amounts now to more than three thousand.

POINTS OF PRACTICE.

I cannot allow this opportunity to pass without saying that any inquiring stranger will find in the North Staffordshire Hospital as united and as energetic a Medical staff as could be met with anywhere. Possessing a magnificent field for observation and research, the members of the staff compete only in striving to gather together all the new facts of the day, and in subjecting proposed and reasonable methods of novel treatment to immediate and rigid trial. An annual report of all their proceedings would be one of the most valuable records of the day, and it is really to be hoped that such a record will soon be a part of the work of these gentlemen, whose only failing is that, either from an undervaluation of their own labours or too severe an exclusion, they keep their vast experience bottled up

like a specimen in a museum, to be shown to all who may call, but not to go forth to those who cannot call. The late Dr. Addison, after visiting the Infirmary and seeing the richness of the practice, expressed, I am told, that he could wish to end his days no better than in becoming a retired student with the clinical experience of this Hospital for his field of clinical observation. Whoever visits the same place, anxious for the advancement of our wonderful science, will readily appreciate the feeling of the eminent "Guy's man" who said the wish that I have written.

One disadvantage is felt by the Medical officers of the Infirmary, and that is that they have few post-mortem experiences. Such is the extreme prejudice of the people against the examination of the dead, that an autopsy is of rare occurrence. Until a more enlightened sentiment prevails pathology as deduced from morbid anatomy will have a poor chance of original development in North Staffordshire.

In the Medical department of the practice of the Infirmary I find Dr. Arlidge treating acute rheumatism entirely by alkalis in full doses, and he informs me that in no case where the patient, on being brought in, has been free from cardiac complication, has that complication arisen. On comparing, also, the treatment of cases so treated with cases treated previously on other and less definite plans, Dr. Arlidge deduces that under the alkaline plan the period of treatment has been reduced one-third at least.

The reader who has done me the kindness to peruse, during the last ten or twelve years, the views I have proposed respect-

ing the treatment of *every disorder* marked by hyperinosis, and terminating, in their worst form, in death from fibrinous deposition in the heart, will remember that on no subject have I pushed any point more determinately than in respect to the rational treatment of these disorders by the alkalies, and especially by ammonia. To my great satisfaction I find that Dr. Arlidge has undertaken to treat the leading disease of the type named, I mean pneumonia, with alkalies, and that, too, with complete success. Since the full application of alkaline treatment together with fluid nourishment, and a little wine when that is demanded, not a case has been lost.

As no case of pneumonia ever ended fatally during the first or second stages from any other cause than from fibrinous deposit on the right side of the heart, and as it is impossible for such deposit to occur if the blood is early and thoroughly rendered super-alkaline, the results obtained by Dr. Arlidge are as rational and accountable as they are satisfactory and commendable.

Dr. Arlidge has treated several cases of epilepsy with bromide of potassium, and with considerable success.

On the Surgical side I found various points of practice of great interest. I was so fortunate as to be present on operating day, and to see the operation for ovariectomy performed by Mr. Walker. In manipulative dexterity and coolness nothing more could be wished than was evidenced by the Surgeons in all their proceedings.

Regarding special points of Surgical practice, I may first note the fact, that three cases of ovariectomy have been performed in this Infirmary. The cases have in every instance been extreme, and the condition of the Infirmary has certainly not been very conducive to their recovery. To avoid risks, the cases have been isolated, and attention to the minutest details in after treatment has been rigorously pursued. The result is that all the patients have recovered.

Through the courtesy of Mr. Spanton, I am enabled to subjoin the particulars of these operations:—

THREE CASES OF OVARIAN DISEASE — OPERATION IN EACH CASE—RECOVERY.

Case 1.—S. B., 33, married, was admitted under Mr. Folker with a large ovarian tumour, on October 16, 1863: the tumour had been noticed about twelve months before. She had been previously three times tapped with temporary relief. On admission, the circumference of the abdomen was forty-five inches. The operation was performed on October 18, chloroform being administered. The tumour was firmly adherent, and three and a-half gallons of fluid were drawn off. The pedicle, which was large, was secured with an iron clamp, and the wound was closed with deep and superficial wire sutures. The tumour was multilocular, weighing nine pounds. The operation lasted about an hour. The patient was for some time in a very low condition, and chloroform sickness was very obstinate. The bowels acted on the 21st, sickness was still troublesome. On the 28th the clamp was removed, the pedicle having sloughed nearly off. On November 1 the patient got up for the first time. The wound continued to discharge for a long time, but on December 21 she was discharged well.

Case 2.—M. S., aged 47, married, was admitted under Mr. Folker on March 22, 1864, with an ovarian tumour of about seven years' duration. The patient had never been tapped; the circumference of the abdomen was forty-two inches.

The operation was performed on March 26 under chloroform; the incision was about four inches in length; the adhesions were slight, and the pedicle, which was long and narrow, was tied with whipcord—a harelip pin being first passed through it. The wound was secured with wire sutures. About twenty-two pints of fluid were drawn off, and the tumour altogether weighed 33 lbs. The patient made most satisfactory progress, never having sickness or other untoward symptom. A suppository of opium was given a few times, but no other medicines.

On April 3 the ligature came away, and on April 24 the patient could walk out of doors. She was discharged on May the 2nd well.

Case 3.—M. S., aged 37, married, was admitted under the care of Mr. Walker, on March 14, 1864, with ovarian tumour. The patient first noticed the tumour two years before, and of late it had rendered her life miserable. The circumference of the abdomen was thirty-nine and a-half inches. The operation was performed on April 2, under the influence of chloroform. The incision was about five inches in length; the omentum

was firmly adherent to the surface of the tumour, and the tumour contained thirty pints of fluid. It was unilocular. The pedicle was secured with whipcord and a harelip pin, being very slender and long. The patient was exceedingly low after the operation, and was sick a few times; but after the second day she progressed very favourably, having not a bad symptom. The ligature came away on April 11. It is worthy of note that the patient menstruated a little three days after the operation.

On April 23 she was allowed to get up, and on April 30 was discharged quite well. No medicine was given besides an opiate suppository a few times, and a castor-oil enema.

In the last two cases the wound was dressed with a weak solution of iodine. This was done on the suggestion of Dr. Richardson, and it appeared to answer well in destroying the unpleasant smell. In both cases, the pedicle became attached to the edges of the wound.

Various cases of recto-vaginal fistula and of prolapsus uteri have been treated successfully by operation. Of the former class of cases the following is an excellent illustration:—

CASE OF VAGINAL FISTULA—OPERATION—RECOVERY.

(Under the care of Mr. WALKER.)

Ann Proudlove, a paintress, aged 22, single, was admitted an in-patient on January 19, 1864. She is of stunted growth, but has always had good health. In August last, after a labour of four days' duration, she was confined. The child was at maturity, and about the ordinary size, but stillborn. A Surgeon attended her at the confinement; but no instruments were used. On the following day she first perceived the urine dribbling from her, and it has continued to escape involuntarily up to the present time; she does not perceive that it is any worse now than it was at the commencement. On admission her under linen was thoroughly saturated with urine. She was in a state of the greatest discomfort from the continual contact of the wet clothes with the surrounding parts; she had a very forlorn aspect, and her thighs, as well as the external organs of generation, were much excoriated from the constant dribbling of urine. A speculum was passed into the vagina, and, with the assistance of a probe in the urethra, a fistula was detected about three inches up the vagina between the uterus and vagina. She had no power of retaining the smallest quantity of water in the bladder, and never passed any by the urethra. She was ordered potas. bicarb., gr. xx.; potas. nit., gr. v.; tr. hyoscyami, mxx.; aq., ℥j., ter die, and to have full diet, with four ounces of wine. She was quite willing to submit to an operation, and on January 30, being first under the influence of chloroform, was placed in the lithotomy position. Owing to a contraction of the upper part of the vagina by a fibrous band, which appeared to be the result of old sloughing, only one edge of the fistulous opening could be made visible; this was well pared, and the other edge, which was not *in situ*, thoroughly scarified with a small knife. Three sutures of silver wire, fastened with three metallic clamps, were applied. A catheter was frequently passed for a week succeeding the operation, an opiate administered each night, and the bowels kept confined for five days. The clamps and one of the sutures were taken away nine days after the operation. Two of the sutures could not be found, but one came away in a few days, and the other was removed, with a collection of phosphates which had formed around it, a month afterwards. There was no sloughing; the patient very soon expressed herself as "being more comfortable than she had been for many months before;" she could retain her urine in the bladder to the amount of four to six ounces at one time.

On February 23 she was allowed to sit up; and on March 24, feeling quite well, and not a drop of water having escaped through the opening since the operation, she was discharged cured.

Several tumours of a glandular and fibrous nature have been lately successfully treated by passing a needle or fine tenotomy knife into them, so as to break down and disorganise the interior to a small extent. They afterwards become absorbed, and so gradually disappear.

The common carotid artery was ligatured some time ago in a child who had a large naevus below the ear. Convulsions came on after the operation, but the child made a perfect recovery.

Mr. Folker had a case of ligature of the external iliac for femoral aneurism a few months ago. The sac of the aneurism afterwards suppurated, but the patient is now quite well.

Mr. Folker never uses now any dressing in his cases of amputation, but puts in a number of sutures, and leaves the wound exposed, after the method suggested by Mr. Teale.

Mr. Walker has recently introduced into practice an ingenious pessary, made of earthenware. The pessary is hollow and highly glazed: it is either circular or oval in shape, and is made of three sizes. There is a hole in the centre large enough to admit the end of a finger, by which means the pessary can be withdrawn by the patient with the greatest ease, and replaced when required, without the assistance of a Surgeon. The pessary is perfectly smooth, and is not liable to abrasion from contact with the vaginal or other fluids; it is, therefore, cleanly in the highest degree. This, combined with the facility of removal, is, in fact, its chief advantage as an instrument, but it also has the merit of cheapness, which is no small recommendation, when it is required for Hospital practice. These pessaries are manufactured for Mr. Walker by Messrs. Pinder, Bourne, and Co., of Burslem.

Lastly, Mr. Spanton, the House-Surgeon to the Infirmary, reports to me that carbolic acid is found to be extremely useful in the treatment of scabies, and that it promises to replace sulphur ointment and the other common remedies.

THE LIBRARY.

Three years since a grant of £50 was allowed for the library and the museum, and since then a grant of £10 a-year has been continued. The *Library* is in the board-room, and consists of a few hundred volumes, including many old works, a few new ones, and the Medical periodicals.

THE MUSEUM.

The *Museum* is small, but contains some very curious specimens. There is a specimen of a case which occurred in the year 1853, where a man, aged 45, who was admitted with dropsy died twelve days after admission. The left kidney, the specimen of which is now referred to, weighs five pounds four ounces avoirdupois. The enlargement is in the medullary structure, and is chiefly at the upper part of the kidney, the lower cones and the pelvis being natural. The renal vein is enormously enlarged. The opposite kidney was healthy, and weighed seven ounces and a-half. There is also a singular specimen of fracture of the skull. A tailor was brought to the Infirmary on June 25, 1854, for injuries received from falling into a marl pit. He showed on arrival a severe bruise on the right side of his forehead with laceration. Under treatment he recovered, but a month later he was seized with pain in the head which passed away, and returned again in a fortnight. On August 30, the pain in his head was intolerable; towards evening he became insensible. In the course of the following day he died. On examining the head an extensive fracture was found, extending from the cavernous sinus of the left side, and somewhat obliquely, through the tella turcica, to the orbital surface of the frontal bone on the right side. The bone was literally smashed in, to the depth of three-quarters of an inch, encroaching into the back part of the orbit and roof of the nose; the crista galli was pushed to the left side, and the cavity formed contained about half an ounce of pus; the brain was pulpy. The frontal bone, externally, is broken into ten irregular segments, two of the fractures extending through the inner table. Some of the broken fragments had been quite detached, but were reunited by a firm callus. Purulent matter was found in the spinal canal as low down as the dorsal region. The great peculiarities of this case were, that the frontal bone gave no external evidence of fracture, that strabismus was never present, and that no head symptoms were developed until a month after the accident. The symptoms evidently followed on the formation of pus.

There is a model of a tumour that was removed from the tongue of a woman aged thirty-eight years. The tumour, which was fibrous, was situated on the dorsum of the tongue, and a little on the left side. It was nearly globular, and measured eight inches and a-half round in the horizontal, and seven and a-half in the perpendicular direction. It weighed exactly a quarter of a pound avoirdupois, after removal. It had caused partial absorption of the lower jaw and displacement of several teeth, with loss of some others. The case made a good recovery. Mr. Folker was the operator.

There is a cabinet, presented by the late Mr. Turner, containing some valuable specimens of diseased bones and resections. No history attaches to the specimens.

The present Medical staff are most anxious to make the museum worthier of the Hospital: they are much impeded by the difficulty, already referred to, of obtaining permission to conduct post-mortem inquiries.

In these observations I have condensed into the limited

space necessarily at my disposal the leading facts connected with the history of the North Staffordshire Infirmary. If I have been severe on the defects of the Institution, I have also been perfectly candid as to its influences for good; and I hope the members of the Medical staff will correct me if a word has been said that, even by accident, may be thought hypercritical.

It is for the sake of every one connected with the Infirmary, indeed, that the exact facts be stated, because it is an Institution having but one object, that of saving life. That in its day it has performed its part right well is true; that its management has had no share in the production of those causes by which, in more senses than one, it is undermined, is equally true; but, admitting these facts, it is also true that under existing circumstances its power for good is now crippled and narrowed. As regards construction, it is out of all character—a blot on the map of sanitary science; as regards position, it is equally faulty: and if its supporters would really see a Hospital in the Potteries that shall continue to do them honour; if for their benevolence they would like to read off a reduction in the rate of mortality—that sound proof that money spent on Hospitals is money not lost—they will allow no tradition, no idea of expense, no temporary agitation to prevent them razing the old building to the ground, and erecting a pavilion Hospital in some new and more favoured spot, where the air is unpolluted, where there is rest for the sick, and where a surrounding healthy vegetation tells the story that life is there respected and held at its prime worth.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, SATURDAY, MAY 7, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Present—

Dr. Alderson.	Dr. Andrew Wood.	Dr. Corrigan.
Mr. Arnott.	Dr. Thomson.	Dr. Sharpey.
Mr. Cooper.	Dr. A. Smith.	Dr. Quain.
Dr. Acland.	Dr. Leet.	Mr. Rumsey.
Dr. Embleton.	Dr. Apjohn.	Dr. Stokes.
Dr. Storrar.		

Dr. FRANCIS HAWKINS, Registrar.

The Minutes of the last Meeting were read and confirmed.

1. Moved by Dr. ACLAND, seconded by Mr. COOPER—"That, in the absence of the President, Mr. Arnott be requested to take the chair."—Agreed to.

2. A letter having been read from the King and Queen's College of Physicians in Ireland, and also two letters referred to in that letter, moved by Dr. A. SMITH, seconded by Dr. CORRIGAN—"That the letter from the King and Queen's College of Physicians, respecting the licence granted by the Apothecaries' Hall of Ireland, along with the letters Nos. 2 and 3, referred to in that letter, be entered on the Minutes."

The Motion having been put to the vote, the Chairman declared that the Motion was not carried, the numbers for and against it being equal.

The CHAIRMAN being called upon to give a casting vote declined to do so; whereupon Dr. ANDREW WOOD stated that he intended to raise the question at a future time, whether the President or Chairman for the time be not bound to give a casting vote, "in case of an equality of votes."

Dr. STORRAR required that the names of those who voted for and against the Motion, and of those who did not vote, be entered on the Minutes.

For	6
Against	6
Declined to vote	1

The President took the chair at Two o'clock.

Moved by Dr. A. SMITH, seconded by Dr. CORRIGAN—"That when the General Medical Council expressed its opinion, in the resolution of June 2nd, 1863, 'that registered Licentiates of the Apothecaries' Company of Dublin are, as Apothecaries, entitled to practise Medicine in Great Britain and Ireland,' it did not intend to convey that the licence of the Apothecaries' Company of Ireland should be considered for the public service as a Medical qualification to be recognised as equivalent to a degree in Medicine, or to a licence from a College of Physicians; or to express an opinion on the claim of the Apothecaries' Hall of Ireland to give a licence in Medicine, the question being one involving the legal interpretation of an Act of Parliament, which the Council is not competent to decide."

Dr. STORRAR moved, and Dr. ACLAND seconded, the previous question, which was carried.

Dr. CORRIGAN required that the numbers of the majority and minority, and of those who did not vote, be entered on the Minutes.

Majority	8
Minority	6
Declined to vote	1

3. Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON—"That the Executive Committee be directed to take the opinion of counsel on the question, whether or not, in the case of an equality of votes upon a division, the President or Chairman of the Council for the time being is bound to decide the matter in hand by giving his casting vote."—Agreed to.

4. Read the following letter from the Catholic University of Ireland:—

"Catholic University of Ireland, 86, Stephen's-green,
"Dublin, May 2, 1864.

"SIR,—In reply to your letter of April 29 ult., I am directed by the Rector and Council of this University to say that they were not aware that the

Moved by Mr. ARNOTT, seconded by Mr. COOPER—"That the report be received and entered on the Minutes."—Agreed to.

14. Dr. EMBLETON presented the Report of the Committee appointed to revise the standing orders.

Report.

The Committee on the Standing Orders and Regulations having arranged and numbered them, beg to lay them before the Council, and recommend that they be printed.

An alteration has been made in the "Scale of Travelling Expenses," substituting for

Leeds	£ s. d.
	4 4 0
and	
Worcester	4 4 0

the following:—

Cheltenham	£ s. d.
	4 4 0
Southampton	2 2 0

D. EMBLETON, *Chairman.*

Moved by Dr. EMBLETON, seconded by Dr. APJOHN:—"That the Report of the Committee on the Standing Orders be received and adopted."—Agreed to.

15. Moved by Dr. A. SMITH, and seconded by Dr. CORRIGAN:—"That the decision on the resolution moved by Dr. Smith, and seconded by Dr. Corrigan, in the early part of this day, was informal; inasmuch as 'the previous question' was put without the amendments on such resolution being permitted to be considered."

The motion was negatived.

16. Moved by Dr. SHARPEY, seconded by Dr. AQUILLA SMITH:—"That the Pharmacopœia Committee be authorised to draw on the treasurers, to an extent not exceeding £100, for expenses which may be incurred in carrying out the objects of its appointment."—Agreed to.

17. Moved by Dr. SHARPEY, seconded by Dr. STORRAR:—"That the cordial thanks of the Council be tendered to Dr. Hawkins, for the unremitting care and attention he has bestowed on the business of the Council for the five years he has discharged the duties of Secretary; and that £105 be now presented to him in acknowledgment of the sense which the Council entertains of his valuable services."—Agreed to.

18. Moved by Dr. ACLAND, seconded by Dr. ANDREW WOOD:—"That the Report of the Select Committee on Education be forwarded to the various bodies in Schedule (A), with a letter from the Registrar, to the effect that the Report is under the consideration of the Council, and calling their attention to the suggestions of the Report, and soliciting their observations thereon; also, distinguishing the resolutions which have been adopted by the Council from those which have not yet been considered; and that it be referred to the Executive Committee to carry this resolution into effect."—Agreed to.

19. Moved by Dr. SMITH, seconded by Dr. ANDREW WOOD:—"That the standing order as to the hour of adjournment be suspended."—Agreed to.

20. Moved by Dr. ANDREW WOOD, and seconded by Dr. A. SMITH:—"That the powers and duties delegated to the Executive Committee, in accordance with Sect. IX. of the Medical Act, shall be vested in the Committee until the next Meeting of the General Medical Council."

21. Moved by Dr. ANDREW WOOD, seconded by Dr. AQUILLA SMITH:—"That the thanks of the Council are due, and are hereby tendered, to the Treasurers, Dr. Sharpey and Dr. Quain, for their important services."—Agreed to.

22. Moved by Dr. ANDREW WOOD, seconded by Dr. AQUILLA SMITH:—"That the thanks of this Council are eminently due, and are hereby offered, to the Royal College of Physicians, London, for their obliging and courteous accommodation during the present session of the Medical Council."—Agreed to.

23. Moved by Dr. ANDREW WOOD, seconded by Dr. AQUILLA SMITH:—"That a gratuity of fifteen guineas be given to the resident officials of the College of Physicians for services rendered to the Council."—Agreed to.

* By the Regulations of the University of London (see Calendar, 1864, page 106), the first examination for the degree of M.B. includes four subjects, viz., Anatomy, Physiology, Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry; but candidates for this examination are permitted to defer the subject of Physiology to a following year.

The list headed "Entire" contains the names of those undergraduates who elected to pass the examination in all four subjects at once in 1863.

That headed "Excluding Physiology" contains the names of those who elected to be examined in three subjects in 1863, and to defer the fourth, viz., Physiology, to a future year.

That headed "Physiology only" contains the names of those who, having elected to pass in a former year in three subjects, passed in 1863 in Physiology.

24. Moved by Dr. A. SMITH, seconded by Dr. ANDREW WOOD—"That a gratuity of ten guineas be given to Mr. Bell, and the same to Mr. Roope, the clerks, in consideration of their extra services during the present lengthened session of the General Medical Council."—Agreed to.

25. Moved by Dr. ANDREW WOOD, seconded by Mr. ARNOTT—"That the thanks of the Council are cordially tendered to the President for his kind, courteous, and efficient services during the present session of the General Medical Council."—Agreed to.

REVIEWS.

Lectures on the Diseases of Women. By CHARLES WEST, M.D., F.R.C.P., Examiner in Midwifery in the University of London, etc. Third Edition. London: Churchill. 1864. Pp. 637.

ANY one familiar with the character of the leading Practitioners in London will recognise in the author of this book a man well versed in Professional literature, a good pathologist, and one well fortified with all the experience and authority derivable from the offices of Professor and Physician to one of the largest Hospitals. His opinions, too, if they have any bias, are considered to incline to the side of conservatism, and anything clap-trap or sensational would be sure to meet with his reprobation. We look, therefore, with curiosity to the volume before us, as we should to the contents of a crucible in which something of mixed base and true metal have been submitted to a severe ordeal.

In the second edition of this work, Dr. West gives three reasons for rejecting the operation of ovariectomy.

"1st. The high mortality, which experience and dexterity have failed to lessen.

"2nd. The special hazard attendant on those cases where the operation is specially indicated, such as in the young, and where the tumour is multilocular, and contains more or less of solid matter.

"3rdly. The uncertainty as to the prognosis even in the most favourable cases."

We turn, therefore, with interest to see what the last six years have done in confirming or altering his conclusion. The fatality of the operation in completed cases is very little, if at all, lessened. Dr. Atlee's tables down to the year 1850 give a mortality of 32.27 per cent. The operations of Mr. Baker Brown, Mr. Hutchinson, Dr. Tyler Smith, and Mr. Spencer Wells, all performed since that period, show a death-rate of 30.3 per cent. While the statistics of Dr. Clay, in the appendix to the translation of Kiwisch on "Diseases of the Ovaries," display an increase in the deaths from 43 to 46 per cent. in the cases before and after 1855.

The increased experience of Mr. Spencer Wells shows no diminution of the dangers of ovariectomy, of his first 50 cases 17 died; of his last 43, 15 died.

The duration of life after the operation has not been much prolonged; in 68 fatal cases six years ago, Dr. West found that 37 cases or 54.4 per cent. died within 72 hours; while Dr. Clay's table shows 50.6 per cent. of deaths within a similar period.

To what, then, are we to attribute the change of opinion thus expressed by the author?

"I think, then, that we are now bound to admit ovariectomy as one of the legitimate operations of Surgery; as holding out a prospect, and a daily-brightening prospect, of escape from a painful and inevitable death, which at last, indeed, becomes welcome, only because the road that leads to it conducts the patient through such utter misery."

First, the diagnosis has very greatly improved, and the number of cases in which the operation has had to be partially or entirely abandoned has very much decreased. Dr. Clay gives 107 cases before 1855 to 6 after that year. This is doubtless to be received with caution, as other similar cases may not have been published. Mr. Spencer Wells mentions six cases and Dr. West one more.

2ndly. Youth is not an objection to the operation. Mr. Spencer Wells had eight successful cases between the ages of 17 and 25; in fact, he had no fatal case before 26.

3rdly. A compound cyst, with more or less solid matter, is not an obstacle to its successful performance. In thirty-three successful cases of the above Surgeon only two were simple cysts.

And, lastly. The reduction of the risk of hæmorrhage, the return of the pedicle into the abdomen, and the more judicious after treatment, have all tended to bring about the change which we see in Dr. West's opinion.

The views of Dr. H. Bennet are controverted in this as in former editions. The liability to ulceration of the os and hypertrophy of the cervix, said by this author to depend, to a great extent, upon the greater vascularity of the cervix, compared with the fundus, is denied by Dr. West, who shows that the contrary is the fact—that ulceration may exist to a considerable extent without producing the symptoms attributed to it, and without being followed by hypertrophy; as also, on the other hand, that hypertrophy may be present without any ulceration. He considers that the good which is supposed to result from the use of caustics may fairly be attributed to the rest and other hygienic measures so strictly enforced.

Sub-acute ovaritis forms another subject for comment in this as in the second edition. The difficulty of determining when the process of ovulation has passed from the physiological to the pathological state has led Dr. Tilt to assume that the pain which we frequently have in the region of the ovaries, attended with some slight enlargement of these organs, is due to a sub-acute form of inflammation. In common with Dr. Churchill, our author considers the pain to be neuralgic in character, and refers to the rarity with which we meet with pathological changes compared with the frequency of this form of pain.

Organic stricture of the neck of the womb Dr. West considers to be of rare occurrence, depending generally, when it exists, upon imperfect development of the generative organs as a whole. It may exist as the result of inflammation; and he mentions a case in which he was unable to pass even the finest bougie, resulting from a previous confinement. Holding these views, hysterotomes and cervical dilators meet with no favour in his eyes—on the contrary, he considers them to be injurious, and has seen pelvic abscesses follow their employment.

Anatomy, Descriptive and Surgical. By HENRY GRAY, F.R.S. etc. Third Edition. By T. HOLMES, M.A. Cantab., Assistant-Surgeon and Lecturer on Anatomy at St. George's Hospital. Longmans. 1864.

It is unnecessary to repeat once more the deserved commendation which this work of Mr. Gray has met with. In many respects we consider it the best treatise of the kind which has been published. In the first place, it is free from the extreme dryness, verging on pedantry, which disfigures some rival publications; and anatomy is a subject of such necessary detail and complexity that hardly any device can be objectionable which facilitates its mastering and retention by the student. Moreover, the large size of the volume contrasts favourably with other contemporaries. Erasmus Wilson's little manual, though deservedly a favourite with students, from its lucid arrangement, is occasionally incorrect in detail, and offers too confined a space for illustration. The woodcuts in this work are abundant and admirable, especially those which show the results of fracture, dislocation, and the like. These might prove of the greatest service, not only to students, but also to Practitioners who wish to refresh their memory on some particular point with a view to diagnosis or treatment.

Mr. Holmes, who assisted the author in the first edition, now edits the third without change on the original scheme or any modification in its execution. His task "has been restricted to an attempt to give greater precision to the language, and to supply the necessary references to anatomical works of merit which had been published since the date of the last edition."

We heartily recommend the book to all ranks of the Profession.

Evening Thoughts. By a PHYSICIAN. Third Edition. London: Van Voorst. 1864. Pp. 143.

WE have been a good deal gratified with the reading of this little book. It is the work of a Christian philosopher who puts his Christianity as a practical religion first and his philosophy second, but who maintains everywhere that reason and revealed religion are so far from being in opposition that both teach the same moral lessons. It is none the worse, too, for being fragmentary—perhaps the better, because the writer can stop in his deductions when he pleases, or where he feels that he is getting out of his depth. The reader will mostly be able to accompany him as far as he goes, and sometimes will be disposed to try a step or two in advance. This is again an advantage, inasmuch as the train of thought followed is always a healthy one, and if pursued in the author's spirit is

calculated to charm while it benefits. The subjects of the "Evening Thoughts" are such as these:—"Head and Heart," "Imagination," "Conscience," "Philosophy and Christianity," "Discourses," "Contemplation and Action," "Sundays," "Systematising Divines," "Fixed Ideas," "Demonology," &c. Altogether some fifty topics are more or less lightly touched upon.

The Seven Sources of Health. By W. STRANGE, M.D. Henry Renshaw, 356, Strand. 2s. 6d.

THIS is a popular Medical book, and one marked by good sense and freedom from quackery. The Seven Sources of Health are—Air, Light, Heat and Climate, Food and Drink, Exercise, Bathing, and Sleep; to each of these a chapter is devoted, besides one in the beginning on Physiology, and one in the end on Health of Mind. The author writes like an earnest, conscientious man with a thorough knowledge of his Profession and of the allied sciences, and a keen desire of imparting his knowledge; we might even venture to say that at times he even falls into a kind of *preaching* tone. But to counterbalance this defect (if it be one), we must admit that he has a keen eye to the points of a pretty woman, and dilates upon them with a sincerity with which we fully sympathise. He does not dabble in matters purely Medical, nor make his book an advertisement for "peculiar views" of his own as to the treatment of any pet disease; therefore, his Professional brethren may fairly recommend it to readers who desire to know how they may best avail themselves of the Seven Sources of Health.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 5 AND 19.

Mr. PRESCOTT HEWETT, President.

(Continued from page 552.)

Dr. OGLE showed a

FIBRINOUS PLUG OBLITERATING A PART OF THE MIDDLE CEREBRAL ARTERY, AND CAUSING A SOFTENING OF THE BRAIN IN THE NEIGHBOURHOOD.

The fibrinous plug was adherent to the arterial walls, and decolourised, and the softened brain below the surface was of a very soft consistence, extending as far inwards as the right corpus striatum. The heart and its valves were healthy, but adherent to the inner surface of the ascending aorta, at about one inch above the aortic valve, very large fibrinous deposits, the so-called "vegetation," were met with. Masses or wedges of fibrinous deposit were also found in the spleen and one kidney. The patient (an intemperate man, aged 34), who had been subject to epileptic seizures, was admitted into St. George's Hospital with pain in the right side of the head and right temple, and having a peculiar "heaviness" of manner; the left arm was very cold, and weaker than the right one; the muscles of the left side of the face were wanting in power and expression; the left pupil was dilated; and shortly after admission he had an epileptic attack, in which the muscles of the left side of the body were much convulsed, and the mouth drawn to the right. Eventually, gangrene of the great toe, and afterwards of the dorsum of one foot, came on; and he sank and died one month after admission.

SECONDARY ABSCESS OF THE BRAIN FOLLOWING AMPUTATION.

The purulent accumulation was of about the size of a filbert, and situated on the lowest part of the middle lobe of the left cerebral hemisphere. The other parts of the brain were healthy. The patient, a man aged 35, had left the Hospital after an amputation of the forearm. Having been frequently drunk, he was again admitted, owing to shivering, sweating, and vomiting. The rigors recurred daily, at almost the same hour, reminding one of ague. An abscess formed in one of the buttocks, the general surface became very yellow, and he sank and died twenty-seven days after admission. After death, in addition to the cerebral abscess, a small part of the ulna was found necrosed, and a large abscess was found within one of the deltoid muscles.

EXTRAVASATION OF BLOOD INTO THE PONS VAROLII, AND ALSO, BUT TO A SLIGHTER DEGREE, INTO THE LEFT OPTIC THALAMUS AND RIGHT CORPUS STRIATUM.

The pons Varolii was much broken down, and the extravasa-

tion extended into the right crus cerebelli, and had broken into the fourth ventricle. Much bloody fluid existed in the lateral ventricles, whose septum was broken down. The patient, a man, aged 49, was admitted into St. George's Hospital quite sensible and coherent in conversation. He had staggered on walking home after having drunk two glasses of beer, and complained of being unable to see properly. When examined, there was loss of power to move the legs, the skin of which was without sensation, and there was incontinence of urine. He vomited a quantity of stuff smelling strongly of beer. He became comatose, and died on the day after admission.

EXTRAVASATION OF BLOOD INTO THE CENTRAL PART OF THE PONS VAROLII, EXTENDING INTO BOTH CRUSA CEREBELLI.

The patient was a drunken woman, aged 33, who for some time had suffered from headaches and giddiness. She had been "hemiplegic" on the left side since a fit which occurred two weeks previously, and had never regained consciousness. When admitted, the speech was inarticulate, and there was no sensation or power of moving the muscles on the left side of the body. Difficulty in breathing and swallowing came on; she became comatose, and died three days after admission. The heart, lungs, kidneys, etc., were found healthy after death.

PARAPLEGIA FROM SOFTENING OF THE SPINAL CORD ASSOCIATED WITH A LARGE CALCULUS IN THE BLADDER; PROBABLY, IN THE ONSET, AN INSTANCE OF "REFLEX PARAPLEGIA."

The case was that of a gentleman, about 58 years old, who had in early life suffered much from gravel and irritation of the kidneys. Twelve years before death he had begun to pass blood in the urine after a slight fall or slip down a bank. Subsequently, pus was passed by the bladder, with and without blood, in large quantities. About five years after the first symptoms, difficulty in walking and numbness of the legs came on, and gradually almost complete loss of power in the legs was established. A calculus was detected in the bladder by Mr. Adams, of Harrington-square, but as it was surmised that disease of the kidneys existed also, any operation with a view to remove the calculus was not considered advisable. Eventually, and a few days before death, loss of sensibility of the skin of the legs and face was experienced, and hyperæsthesia of the arms came on. The patient died, owing to accumulation of mucus in the bronchial tubes. After death, the bladder, containing the calculus, weighing $2\frac{3}{4}$ oz. and 40 grains, was found very inflamed, and a large abscess in the left kidney was met with; there were also indications in the left ureter that a calculus had at some time been impacted therein. There was extensive softening of the lower part of the lumbar region of the spinal cord, and also of the lower part of the cervical region. Dr. Ogle thought that, in connexion with this case, the question as to the interference which the existence of paraplegia might be supposed to produce with operative measures for the relief of stone in the bladder, might fairly be raised, and it was mainly with a view to that general question that he had exhibited the specimen. In reference to this subject Dr. Brown Sequard had told Dr. Ogle that, judging from his experiments upon certain of the lower animals, he should consider the presence of paraplegia rather an advantage than detrimental, in case that lithotomy had to be performed.

The PRESIDENT said that if, in a case of paraplegia with stone in the bladder, there was kidney disease, he should not operate; but that the fact that there was paraplegia would not deter him.

RUPTURE OF THE HEART.

This was presented to the Society for Mr. Roper, of Shore-ditch; and the principal point of interest was, how far the Surgeon and the public were justified in attributing the patient's death to starvation. The latter was a woman, about 60 years of age, and was endeavouring to subsist on a few pence a-week in a lodging containing no fire, and having no clothes to cover her. She died suddenly, and there was found a laceration through the left ventricle. The coronary artery was discased, and the muscular tissue was pale and soft. There were sufficient morbid conditions found in the organ to account for the rupture; but at the same time Dr. Wilks thought that an impoverished condition of the blood might have aggravated the tendency to muscular degeneration, and that the remarks of Mr. Roper before the coroner were quite reasonable—"That the deceased died immediately from rupture of the heart; but that privations, want of nourishment, proper clothing, and of warmth would undoubtedly have accelerated

the rupture of the heart. There was no trace of fat in the interior of the body."

LARDACEOUS DISEASE OF THE VISCERA.

The liver, spleen, and kidneys of a young man were shown who had long suffered from this form of disease. The point of interest was in the fact that, on the surface of the liver, where it was adherent to the diaphragm, there was a layer of pure lardaceous material almost an inch thick. In this no trace of hepatic structure was visible; and it thus seemed as if a free deposition of the adventitious material had taken place on the outside of the organ.

Mr. SPENCER WELLS exhibited three specimens of
CANCER OF THE OVARIES.

In the first case both ovaries were affected. The patient was married, 44 years old, childless, and the disease had been of three years' duration, but had only caused much inconvenience during the last year of life. Six months before her death ten pints of fluid were removed by tapping. Mr. Wells only saw her six weeks before her death, and made the diagnosis of two ovarian tumours surrounded by ascitic fluid, and from the cadaverous aspect suspected malignancy. Fifteen pints of ascitic fluid were removed by tapping, and hard masses were then felt more distinctly in the abdomen and pelvis. She lived about five weeks after the tapping, and died exhausted. The tumours were distinctly cancerous, and the peritoneum was studded with cancerous tubercles. The second patient was also childless, though she had been married twice; she was 59 years old. Only the left ovary was affected. The tumour had been surrounded by ascitic fluid, which had been removed several times by tapping. The disease was only about twelve months from its commencement to its termination. After death the tumour was found to be inseparable from the bladder, uterus, and rectum. Portions of it were distinctly cancerous. The third was a case of encephaloid in a girl between 13 and 14 years old. The growth had been extremely rapid, only having been noticed about two months before death. Microscopic sections, prepared by Dr. Wilson Fox, were exhibited to show that the stroma of the right ovary was infiltrated with cancer. But whether the mass of soft cancer which had filled the pelvis had originated in the ovary or had extended to it, Mr. Wells was doubtful. The question of ovariectomy had been considered in all these cases, but had been negatived by the visible cachexia indicative of malignant disease.

Mr. SPENCER WELLS also exhibited a specimen of
TUBERCLE OF THE OVARY.

The deposit was observed beneath the peritoneal coat of a large cyst which Mr. Wells had removed from a single lady, 23 years of age, who died five days after the operation from diffuse peritonitis of a low form, probably tubercular.

Dr. WILSON FOX described this cyst as single, with the exception of a few scattered thin-walled cysts on the inner surface. On the outer surface, beneath the peritoneal coat, and firmly blended with the surrounding stroma of the cyst-wall, there were numerous nodules about the size of peppercorns, of a cartilaginous hardness, appearing on section glistening and semi-transparent at the circumference, and opaque and cheesy at the centre, which was slightly softened. The nodules themselves were without any trace of vessels, but the tissue around each nodule was very highly injected, and in the injected area there were delicate false membranes studded with the finest granulations of miliary tubercle. False membranes were also seen on other parts of the tumour containing fine granulations of miliary tubercle; and similar grey granulations, not larger than a pin-point or a poppy-seed, were seen on other parts of the outer wall of the cyst. Under the microscope, the outer part of the larger masses and small grey granulations were seen to have the same structure, and to consist of slightly elongated cells containing large, round, very clear, highly-refracting nuclei, each nucleus containing a nucleolus. The nuclei were in some parts free. In some parts of the field, cells with two nuclei could be seen; these were embedded in a clear, separating, finely striated, and very firm intercellular substance. The cells averaged $\frac{1}{2500}$ th in diameter, the nuclei $\frac{1}{4500}$ th. The cheesy yellow matter in the centre of the nodules consisted of oil globules, granular debris, and shrivelled cells. From these characters Dr. Fox had no doubt that the nodules and grey granulations were of tubercular nature.

In reply to Dr. BRISTOWE, Mr. WELLS said that no post-mortem examination had been allowed, so that he could give no information as to the state of other organs; but the lungs had been examined during life, and were believed to be healthy.

Mr. SPENCER WELLS then exhibited the uterus, left ovary, and pedicle left after removal of a tumour of the right ovary, the patient having died three days after

RETURN OF THE LIGATURE INTO THE ABDOMEN.

About two pints of dark red serum had been effused into the peritoneal cavity, which contained neither blood nor ovarian fluid. The recent lymph was confined entirely to the lower and back part of the abdomen and pelvis, the peritonitis radiating from the pedicle, not from the wound in the abdominal wall, which was completely united, nor from a surface where the cyst had been adherent. There was no such attempt to capsulate the pedicle and ligature as there probably would have been had the patient been in better health. She was a married, childless woman, 50 years of age. Mr. Wells thought her chances of recovery would have been greater had it been possible to keep the end of the pedicle outside the abdomen, and he stated that the trials which he had made of returning the pedicle seemed to teach that in young or healthy subjects where circumscribed peritonitis and effusion of plastic lymph might be expected the practice was a good one; but in debilitated or cachectic patients, in whom diffuse peritonitis and effusion of serum, or of aplastic lymph might be feared, it would be safer (when the clamp could not be used) to leave the ends of the ligatures hanging out through the wound, and thus secure an opening for the escape of effused serum, and for the ligature itself with the tissues enclosed in it after their separation.

THE PAST QUARTER.

The following extracts from the Registrar-General's Quarterly Return of Births, Deaths, and Marriages are of more than ordinary interest:—

“The Return exhibits important, and even striking, results in its threefold variety of subject. Rising with an increasing population the number of marriages was greater than it had ever been before in any quarter. The marriage-rate (*i.e.*, proportion of persons married to population) was high, though in some previous instances it had been higher. The registration of births may be described as ‘extraordinary,’ for not only were the births more numerous than they had been at any previous period, but relatively to population they were also numerous beyond example within the last ten years. And in respect to the deaths, a remarkably high rate of mortality attests the severity with which the inclemency of the winter pressed on the public health.

“DEATHS; AND THE STATE OF THE PUBLIC HEALTH.

“The deaths greatly exceed the average number. Seldom has a winter been more fatal; for 143,030 deaths, 1572 a day, were registered in ninety-one days, including the additional day of leap year, for which due correction is made. The mortality was at the rate of 2·773 per cent.; whereas the average of the season in the preceding ten years was 2·490 per cent.; thus the rate was nearly 28 instead of 25 in 1000.

“14,698 persons died in excess of the average number.

“Since 1842 it is only in the two winters (1847-48) after the potato failure, and in the winter of the Crimean war (1855), that the country has experienced any higher rates of mortality. The winter death-rate per 1000 was 2·850 and 2·794 in the former years, 2·910 in 1855, and 2·773 in 1864.

“In unhealthy places, and in England formerly, when the land was undrained, and when zymotic matter soiled the air and waters more abundantly than it does in these days, the mortality was highest in the hot months of the year; but in the last quarter of a century the summer diseases have to some extent subsided, and left the mortality highest in winter, when the cold weather, in some proportion to its intensity, cuts off the weakly and the aged.

“Upon dividing the population into two portions, the one living in the districts comprising the chief towns is found to have experienced the highest rate of mortality, or 2·974 per cent., while the mortality was at the rate of 2·508 in the small towns and in the country districts. The town rate was ·296, the country rate ·228, above their respective averages; thus the increase of the rate was greater in the town than in the country districts.

“London suffered to an extraordinary extent, and is accountable for a large share of the increase. The average annual rate of the winter quarter in London is 2·577 per cent., but in the last winter quarter the rate becomes 3·088, or ·511 above

the average. The funerals increased in the proportion of five to six.

“The annexed table shows the rate of mortality during the winter quarters in each division. It will be observed that the mortality of Lancashire and Cheshire is slightly above that of London, but is not so much above its average as the mortality of London.

“Average Annual Rate of Mortality in the Eleven Divisions of England in the Ten Years 1851-60, and in the Winter Quarter of 1864.

Divisions.	Average annual rate of mortality per 1000 in 10 years, 1851-60.	Annual rate of mortality per 1000 in the winter quarter 1864.
1. London	23·63	30·88
2. South Eastern Counties	19·55	24·18
3. South Midland Counties	20·44	26·53
4. Eastern Counties	20·58	24·51
5. South Western Counties	20·01	25·97
6. West Midland Counties	22·35	27·57
7. North Midland Counties	21·10	25·84
8. North Western Counties	25·51	30·97
9. Yorkshire	23·09	28·31
10. Northern Counties	21·99	25·18
11. Monmouthshire and Wales	21·28	26·28

“When the thermometer falls to the freezing point of water, the mortality is raised all over the country; and the population of London is excessively sensitive to cold; thus the corrected average deaths for the second week of January are 1550, but the actual number of registered deaths this year was 2427. The mean temperature of the preceding week, instead of 37°·8, had fallen to 26°·7; and the temperature of one chill night (Thursday, January 7) had descended to 14°·3, or to 17°·7 below the freezing point of Fahrenheit; and 877 lives were extinguished by ‘the cold wave of the atmosphere.’

“The excess of the rate of mortality per cent. during the last winter quarter was ·228 in the country districts and small towns, ·284 in the large town districts, exclusive of London, and ·511 in London, above the average of the quarter.

“Fire is a necessary of life in this climate; and a warm hearth mitigates the severity of winter. Fire is as much required by the poor as by the rich; and a tax on coals, like a tax on salt, presses with undue severity on people of small means. Coal at the pit's mouth costs about 5s. a ton; and anything that facilitates its carriage and distribution in cities, by the abolition of duties and monopolies, or by laying down railways, if it lead to a diminution of cost, will preserve many lives that come to an untimely end in such severe weather as has reigned during the last winter months.

“The rate of mortality in the South Eastern Division was 18 per cent. higher than it was in the two preceding March quarters; in the Northern Division, where the coal is cheap, the rise in the mortality was only 4 per cent.

“Inflammation or congestion of the lungs and the air tubes are the common results of severe cold; and they carried off the aged in great numbers. Scarlatina, measles, small-pox, were prevalent and fatal; diphtheria and whooping-cough are also mentioned among the prevalent diseases of some districts. Where these diseases were epidemic the mortality of districts was high, as the inhabitants suffered from the zymotic poison and from cold.

“Mr. Rawlinson, in his intelligent report, justly says:— ‘The high death-rate prevailing in Lancashire towns has its main cause in the foul cottage cesspit. An inspection of any town in the district will show this.’(a) The works on which the people are employed at the instance of the local authorities are nearly all of a hygienic character, and cannot fail to be salutary through all future times.”

(a) Report of Robert Rawlinson, Esq., C.E., to the President of the Poor Law Board, April, 1864.

EXTRAORDINARY LONGEVITY.—The obituary of the *Times* of the 17th inst. contained some rare instances of prolonged life in the case of six persons, four gentlemen and two ladies, whose united ages amounted to 537 years, giving on an average 90 years and 6 months to each. The ladies, as usual, took the precedence, the eldest having reached the great age of 103 years, and the youngest 83. Of the gentlemen, the eldest was 90, and the youngest 85 years of age.

MEDICAL NEWS.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH. — DOUBLE QUALIFICATION.—The following Gentlemen passed their first Professional Examinations during the May sittings of the Examiners:—

William H. Arrowsmith, Dublin; William T. Crabbe, Kirriemuir; Henry Allyn Nicholson, Penrith; Arthur Strickland, Tarbolton, Leeds; Alexander Clarke, Campsie; Thorburn Paterson, Bonnyrigg; Alexander S. Esson, Edinburgh; Frank Kennedy Dickson, Edinburgh; James Milward, Bristol, and George W. Robertson Hay, Roxburghshire.

The following Gentlemen passed their Final Examinations and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh:—

Theobald Andrew Purcell, Dublin; Evan Jenkins, Llandyssul, Cardigan; John Alexander Campbell, Co. Londonderry; Stephen Coll Mackenzie, Calcutta; John Thomson, Fifeshire; Matthew Mulvany, Co. Meath; John Francis Madigan, Co. Limerick; James Callaghan, Cork; William Sinclair, Stirling; George Macdonald, Perthshire; Arthur William Shedden, Madras; Smith Houston Davson, Berbee, British Guiana; Richard Cranke, Lancashire; Francis M'Bean Stewart, Dundee; John Allen, Malta, and Patrick O'Neill, Co. Kildare.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College, at a meeting of the Court of Examiners, on the 12th inst.:—

Joseph Fall, York; John Tasker Evans, Hertford; Edward Ingram Bostock, Horsham, Sussex; and Charles John Grellet, Lloyd-square, Students of St. Bartholomew's Hospital; Henry William Alexander MacKinnon, Somerset-street; Thomas Clave Shawe, L.S.A., Stockport; and William Watmough, L.S.A., Poeklington, Yorkshire, of King's College; Timothy Tudge, Yeovil; John Ablewhite Smith, Louth, Lincolnshire; and Charles Wightwick Pitt, Malmesbury, of the Middlesex Hospital; Robert Edward Owen, Beaumaris, and Joseph Johnson, Hogsthorpe, Lincolnshire, of Guy's Hospital; Griffith Griffiths, Alltwen, Glamorgans., of University College; Philip Cowen, Kennington, of St. Thomas's Hospital; Thomas Edward Blich, Islip, Oxon, of St. Mary's Hospital; William Westbrook Squires, Liverpool; Charles Perks, L.R.C.P. and L.S.A., Lichfield; James McCully, Belfast; and Joseph Wilkinson Warburton, Liverpool.

The following were admitted Members on the 13th inst.:—

John Talfourd Jones, M.B. Lond. and L.S.A., Brecon, South Wales; Thomas Griffith Evans, L.S.A., Lawrence-lane; and Francis Rawle, L.S.A., Lambeth, Students of University College; George Edward Shuttleworth, Russell-square, Fitzroy-square, and John Richard Peel, London, of King's College; William Liddard, Mildmay-road, Islington, of the Middlesex Hospital; Frederick Manser, Chatham, of Guy's Hospital; Alfred Orlando Jones, Bamsbury, of St. Thomas's Hospital; Thomas Nimmo, Kirkaldy, Fifeshire; Henry Wade Battersby, Dublin; and Henry Commins, Bray, County Wicklow.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 17th inst., and when eligible will be admitted to the Pass Examination:—

C. J. S. Digges, George Massy, George Stokes, and George Percy, Students of the Dublin School; William Smith, R. C. Goddard, and Herbert Wood, of the Manchester School; George Cooper and H. W. Pullan, of the Leeds School; G. B. Millett and Robert Robertson, of St. Mary's Hospital; F. J. Grose and T. C. Murphy, of University College; Frederick Reynolds and H. H. Braye, of Guy's Hospital; J. H. Tarleton, of St. Bartholomew's Hospital; and W. H. Ansell, of Charing-cross Hospital.

The following passed on the 18th inst.:—

Joseph Burne, R. H. Williams, J. N. Stone, R. C. Parkinson, Edward Boragh, and F. F. Dickinson, Students of the Dublin School; John Brady, David Wilson, and William Burrows, of Belfast; F. T. Prince, O. G. Langdon, and W. A. Daniel, of St. Bartholomew's Hospital; J. E. Tilton, Bristol; W. R. G. Hinds, Galway; John Cremonini, of Birmingham; J. H. Rumsey, of St. George's Hospital; R. T. le Sueur, of Edinburgh; and Richard Talbot, of Guy's Hospital.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Mr. George Haliburton Hume passed his first Professional Examinations during the May sittings of the examiners; and the following gentlemen passed their Final Examinations and were admitted Licentiates of the College:—

Henry Cook, Newport, Monmouth; William John Wilson, Co. Armagh; Parker Arthur Smith, Canada; James Hill, Northumberland; John Wyber, Glasgow; John Winspeare McCarty, Cork; James George Lyon, Forfar; James Smith, Dumfries; John Knox, Tyrone; Thomas Raleigh Phayre, Co. Limerick; Alexander Donald Neil Munro, Edinburgh; George Augustus Christie, New Brunswick; Angus Macdonald, Aberdeen; Adam Orr, Clonmel; James Johnstone Hyslop Hope, Lanarkshire; Archibald Barr Telford, Lanarkshire; William Dobie, Langholm; Robert Skimming, Wigtown; Thomas Morris, Fifeshire; James Provan, Haddingtonshire.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of

Medicine, and received certificates to Practise on Thursday, May 12, 1864:—

John Henry Ashton, 10, Upper Bamsbury-street; William Coleridge Kiernander, 2, Brunswick-square; William Norris Marshall, Upper North-gate-street, Chester; William Jones, Trewalter, Brecon; Robert Chapman Gibson, Fyfield, Ongar, Essex.

The following gentlemen, also on the same day, passed their First Examination:—

Henry Hargreaves Birtwell, St. Thomas's Hospital; Edward Monroe Spooner, London Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BARKLY, WILLIAM, L.D.S.R.C.S. Eng., has been appointed Assistant-Dental Surgeon to the National Dental Hospital, Great Portland-st., W.

BEVVIS, CHARLES, M.D. St. And., has been appointed Resident Medical Officer to the Leeds Fever Hospital.

CAIRNS, THOMAS, M.D. Edin., has been elected one of the Medical Officers of the Royal Dispensary and Vaccine Institution, Edinburgh.

COWIE, JOHN, M.D. St. And., has been appointed Admiralty Surgeon and Agent at Lerwick.

HAWKES, J., M.D., has been appointed Assistant Medical Officer to the Female Department of the Middlesex County Lunatic Asylum at Hanwell.

LINDSAY, JAMES M., M.D. St. And., has been appointed Resident Medical Superintendent of the Female Department of the Middlesex County Lunatic Asylum at Hanwell.

MURRAY, JOHN, L.F.P.S. Glasg., has been appointed Surgeon to Cardowan and Heathfield Fire-Clay Works.

SHEEN, ALFRED, M.D. St. And., has been elected House-Surgeon and Secretary to the Glamorganshire and Monmouthshire Infirmary and Dispensary, Cardiff.

DEATHS.

ARMSTRONG, WILLIAM, L.R.C.S. Edin., at Wark, Hexham, Northumberland, on March 3.

BROWNE, ROBERT, L.R.C.S.I., Surgeon-Major H.M. 25th Regt., 2nd Battalion, at Barranderry House, Kiltigan, Baltinglass, Ireland, on May 9.

EMANUEL, LEONARD, M.D. St. And., Assistant-Surgeon H.M. Bengal Army, at 21, Inverness-road, Bayswater, aged 29.

JOHNS, ROBERT, L.K.Q.C.P.I., at Westland-row, Merrion-square, Dublin, recently, aged 49.

LEWER, JOHN RICHARD, M.R.C.S. Eng., at Whampo, China, March 7, aged 43.

MEWBURN, J., M.D., at Danby House, Stamford, Canada West, on April 12, formerly of Whitby, Yorks.

RIACH, JOHN, M.D., formerly Surgeon H.M. 67th Foot, at Allanbank, near Perth, N.B., on May 14, aged 73.

TRIMBLE, JOHN, M.D. Edin., at Castlebellingham, Co. Louth, on May 6.

THE ROYAL COLLEGE OF PHYSICIANS AND MISS GARRETT.—The legal advisers of the College of Physicians—the Attorney-General and Mr. Cleasby—have advised the College that they have no legal power to confer on female candidates their license. They have, therefore, "courteously declined" Miss Garrett's application to be admitted for examination.

SCHOOL OF PHYSIC IN IRELAND.—At a meeting held on Saturday, the 14th inst., in the Provost's house, Trinity College, Dr. Aquilla Smith was unanimously elected King's Professor of Materia Medica in the room of the late Dr. Osborne. The electors were the Rev. the Provost of Trinity College; the Regius Professor of Physic in the University, Dr. Stokes; and three electors chosen by the King and Queen's College of Physicians in Ireland.

INTERESTING COINCIDENCE.—The *Times* informs us that "the Ladies' National Convocation of New York" delayed the adjournment of the meeting till the members had been photographed; and one of our Medical contemporaries tells us that during the last days of the late prorogued session of the Medical Council a photographer attended, and took the portraits of the members.

A UNIVERSITY FOR WALES.—The committee formed with the view of promoting the establishment of a University for Wales have issued a circular in further explanation of the object in view and of the plan proposed to be followed. The committee already consists of a number of peers, members of the House of Commons, and other gentlemen of property and official position in the principality. The model proposed to be followed is that of the London University and of the Queen's Colleges in Ireland, and the institution will be purely non-sectarian, all theological teaching being entirely eschewed. A national fund will be raised, and Parliament is to be appealed to for assistance, and there is every prospect that an arrangement will be made to merge the Lampeter College into the proposed University.

THE GREAT NORTHERN HOSPITAL.—We are glad to observe that the Corporation of London have made a grant of fifty guineas to this Hospital, which has been lately removed to the Caledonian-road.

MEDICAL CHARITIES.—The Profession will be glad to see the following extraordinary illustrations of princely munificence on the part of Mr. G. Wheelhouse, formerly of Deptford, who has made bequests to the amount of £13,000, and in doing so has not forgotten the charities of our Profession, which benefit to the amount of £5500, distributed in the following manner, viz. :—To the Westminster Hospital, £500; the Royal Free Hospital, £500; the Middlesex Hospital, £500; the Charing-cross Hospital, £500; the North London Hospital, £500; the Great Northern Hospital, £300; St. Mary's Hospital, £500; the Metropolitan Free Hospital, £500; the Seaman's Hospital, £500; the Royal Hospital for Incurables, £500; the Royal Infirmary for Children and Women, £500; and to the Scarborough Dispensary, to be expended in annual sums of £10 until the amount is exhausted, £200.

THE PHARMACEUTICAL SOCIETY.—On Tuesday evening the annual *soirée* of this Society was held at 17, Bloomsbury-square. A number of the newest inventions were exhibited, including the photo-sculptures, by Claudet, resulting from a number of photographs taken of individuals and then reduced to plaster, producing the most life-like reality; the electric signal, which intimates when the signal-light is out, and indicating caution to the signalman; the application of electricity to the distance-signals in place of mechanical power, thus making the semaphore subject to electricity, securing rapidity and accuracy without the clumsiness of mechanical operation. Specimens of iodine, produced from sea-weed, by the British Sea-weed Company, were also exhibited, and attracted marked attention. There were subsequent experiments on gun-cotton, optical subjects, etc., accompanied by brief explanatory lectures.

CAUTION TO EDITORS.—Acting Assistant-Surgeon B. B. Miles, U.S.A., is accused by a correspondent of the *American Medical Times* of something like plagiarism. He is said to have passed off an article on Erysipelas, by the late Dr. Todd, as his own; and now to have paid Professor Longmore a similar compliment by adopting much of his article on Gun-shot Fractures of the Knee in Holmes's Surgery.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.—The twelfth anniversary of this important charity was celebrated on Saturday evening by a public dinner, in Willis's-rooms, St. James's, at which Sir Charles Locock, M.D., presided. The Chairman was supported by Archdeacon Robinson, Master of the Temple, the Rev. Dr. Mortimer, Sir John Fisher, Sir Walter Stirling, Mr. Du Pré, M.P., Mr. G. Lyall, M.P., Mr. Angerstein, M.P., Colonel Palmer, Mr. Fergusson, Dr. Babington, Dr. Randall, Dr. Billing, Dr. Ray, Dr. Shaw, etc. Grace was said by the Rev. Dr. Thornton. In giving the health of "The Queen," the Chairman expressed a hope that her Majesty, returning from Scotland with re-invigorated health, would soon be enabled to resume the personal discharge of those public duties to which her loving people so anxiously look forward. In proposing "The Health of the Prince and Princess of Wales," Sir Charles mentioned the gratifying fact that the infant Duke of Cornwall "is a very healthy and thriving child, and gives every promise of turning out a robust, manly prince." "The Army, the Navy, and the Volunteers" was proposed by Sir Walter Stirling, and acknowledged by Colonel Walker. "The Church" was given by Mr. William Gilpin, and eloquently responded to by the Ven. Master of the Temple. The Chairman prefaced the toast of the evening by briefly stating the objects and urging the claims of the Royal Medical Benevolent College. It is founded by the Medical Profession as an asylum for such of their brethren as from ill-health, want of Professional success, or other adverse influences, have sunk into poverty, and for the widows of Medical men in reduced circumstances. The College is situated at Epsom, and provides three furnished apartments to each of its pensioners, of whom there are 100, with such additional assistance and accommodation as the funds permit. There is also a school, in which a liberal education is given to 200 boys, the sons of duly qualified Medical men; 40 foundation scholars being clothed, boarded, and educated entirely at the expense of the institution. Occasional assistance and annuities are also provided for Medical men and their families in distressed circumstances. A chapel for divine service according to the ritual of the Church of England also forms part of the foundation.

The treasurer congratulated those present on the prosperity of the institution, and announced a subscription list of upwards of £1100. Mr. Du Pré, M.P., proposed the health of the Chairman, which was received with much cordiality.

THE LATE MR. WILLIAM HORSELL.—In our last number we mentioned that this gentleman, who had left England last summer for Lagos and Abeokuta, accompanied by Mr. and Miss Bischopp, to aid, by their personal efforts, and at their own cost, in the cause of civilisation in Africa, had been delivering a lecture in Anamaboc. It is now our painful duty to announce the death of this gentleman, who died on board the schooner *Just*, outside the bar of Lagos, on Thursday, December 24 last. Having known him during the past two years as an ardent inquirer into the wants of the uncivilised African, and the mode of treatment required for bringing him within the pale of civilisation, we feel deeply grieved at his thus sudden death, before even arriving at his proposed field of labour. Mr. Horsell seems to have died of fever. He felt confident when here that, as a vegetarian, and a total abstinence man, he should not be subject to that African disease. He would not credit that the system requires good support against that malady. We understand that Miss Bischopp, not at all discouraged by this sad event, was about to leave Lagos for Abeokuta at the time the last mail was quitting that part of the coast.—*African Times*.

UNIVERSITY COLLEGE, LONDON.—The distribution of Prizes in the Medical Faculty took place at the College on Monday, the 9th inst., Lord Wodehouse presiding. The most interesting portion of the Dean's report of the proceedings of the Faculty during the year was that in which he referred to an extension of the means afforded to students for clinical study in the Hospital of the College. Since the foundation of the Medical School of the College, he stated, every opportunity had been taken of establishing practical courses of study, in which the learner himself might take an active part in the work. Thus, a course of practical chemistry, involving work in the laboratory, had been established by the late Professor of Chemistry, Mr. Graham, now Master of the Mint, and had been continued by Professor Williamson. So, also, a physiological laboratory had been opened for practical study of physiology, structural anatomy, and physiological chemistry, and a class for practical instruction in these subjects had been carried on by Dr. Harley since 1856. Above all, in the Hospital, attention had all along been paid to means for making the students practically familiar with the work of their Profession. Instruction in operative Surgery on the dead body was given by Mr. Marshall, by whom, also, instruction was given in the art of bandaging. Over and above the clinical instruction afforded by the Physicians of the Hospital, there had long been instruction in Clinical Surgery and Clinical Medicine by special Professors of these subjects. During the past year, however, Dr. Russell Reynolds, the Professor of Clinical Medicine, had instituted a new course of clinical teaching, which had produced good results. A certain number of the students had gone through this special course, the object of which was to bring each individual in direct contact with patients, so that he should, for himself, hear their complaints, examine them, make his own diagnosis, and suggest the treatment which he thought advisable. This was done by requiring from each student a written report, in each case according to a particular form, and by making that report the subject of subsequent examinations and comment. Altogether, the plan was so promising of good that the Council had conferred special prizes and certificates on the students recommended by Dr. Reynolds for the merit of their clinical reports. *Winter Term, 1863-64.*—Anatomy and Physiology (Professor Sharpey, M.D.).—Gold medal, J. Pearson Irvine, of Galgate, Launceston; first silver medal, James S. Cluff, of Kildress, Ireland; second silver medal, Thomas Bailey, of London. Anatomy (Professor Ellis).—Senior Class: Gold medal, George O. Spencer, of Notting-hill; first silver medal, Frederick B. Nunnerley, of Burton-on-Trent; second silver medal, Henry Clothier, of Haselmere, Surrey. Junior Class: Silver medal, G. H. Maasdorp, of Cape of Good Hope. Chemistry (Professor Williamson, F.R.S.).—Gold medal, James S. Cluff, of Kildress, Ireland; first silver medal, Russell Forbes Carpenter, of London; second silver medal, Charles Graham, of Berwick-on-Tweed. Practical Physiology and Histology (Professor Harley, M.D.).—Silver medal, William Andrew Stuart, of Barbados. Comparative Anatomy (Professor Grant, M.D.).—Gold medal, James S. Cluff, of Kildress, Ireland. Medicine (Professor Jenner, M.D.).—

Gold medal, William Snow, of Barnstaple; first silver medal, Bryan Holme Allen, of London; second silver medal, Marcus Beck, of Isleworth. Surgery (Professor Erichsen).—Gold medal, Charles Bradley, of Nottingham; first silver medal, George Grewcock, of Folkinham; second silver medal, William Spooner, of Eling, Southampton. Fellowes' Clinical Medals.—Gold medal, Bryan Holme Allen, of London; silver medal Alexander Bruce, of London. Special Class of Clinical Medicines.—First prize (microscope), William Snow, of Barnstaple; second prize (book), John M. Whitwell, of Kendal; third prize (book), Benjamin Holme Allen, of London.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—DISTRIBUTION OF PRIZES.—On Thursday, the 12th inst., the prizes in the several classes of the Westminster Hospital Medical School were distributed to the successful competitors by the Very Rev. the Dean of Westminster, who was supported on the occasion by the Rev. Canon Nepeau, Mr. Anderdon, one of the Vice-Presidents of the Hospital, Mr. Bedford, Mr. Furnivall, and the Medical Staff and Lecturers, besides numerous friends of the pupils. Mr. Power, the Dean of the School, opened the proceedings by reading his annual report of the Medical School, in which he gave a most favourable account of its condition, and of the diligence and conduct of the students, and particularly adverted to the success with which all the pupils had passed their several examinations during the past season. The following prizes were then distributed by the Very Rev. the Dean of Westminster:—*Summer Session, 1863.*—Practical Chemistry: Mr. G. P. Bate, prize, Surgical instruments. *Materia Medica:* Mr. G. P. Bate, prize, Surgical instruments; Mr. R. Bugden, certificate. *Botany:* Mr. R. Bugden, certificate. *Forensic Medicine:* Mr. G. E. L. Pearse, certificate. *Midwifery:* Mr. G. P. Bate, prize, Surgical instruments; Mr. G. E. L. Pearse, certificate; Mr. Ralph Burnham, certificate. *Winter Session, 1863-64.*—Anatomy: Mr. G. P. Bate, prize, Surgical instruments; Mr. R. Bugden, certificate; Mr. Brooks, deserving of honourable mention; Mr. W. Moore, deserving of honourable mention. *Chemistry:* Mr. J. C. F. McDonald, prize, Scott's poems, Tennyson's poems; Mr. W. Moore, certificate; Mr. W. C. Watson, certificate. *Physiology:* Mr. G. P. Bate, prize, Surgical instruments; Mr. J. C. F. McDonald, certificate. *Medicine:* Mr. W. Yates and Mr. G. E. L. Pearse (equal), prize, Bible, ditto, Scott's poems. *Surgery:* Mr. Ralph Burnham, prize, Staunton's Shakespeare, Longfellow's poems; Mr. G. R. L. Pearse, certificate; Mr. C. St. Aubyn Hawken, honourable mention. *Clinical Medicine:* Mr. G. E. L. Pearse, certificate. *Clinical Surgery:* Mr. C. St. Aubyn Hawken, certificate. *Dental Surgery:* Mr. G. P. Bate, prize, dental instruments; Mr. Oakman, certificate. *Chadwick prize:* Mr. G. E. L. Pearse, Lowe's Ferns, Tennyson's poems, Surgical instruments. *Prosector's prizes:* Mr. C. St. Aubyn Hawken, Mr. Ralph Burnham. Dr. Basham made some remarks upon the Chadwick prize, which he said had been founded in perpetuity by a lady who had been a most munificent benefactor to the Westminster Hospital, in memory of her husband. He also spoke in the highest terms of the gentleman who had gained the prize this year (Mr. Pearse), who, he said, might be considered in all senses a Westminster student, since he was the son of an old Westminster Hospital pupil and had received his general education at the Westminster School, which preliminary education Dr. Basham thought had had considerable influence upon his subsequent success. Mr. Barnard Holt proposed a vote of thanks to the Dean of Westminster for his kindness in presiding on the occasion. The Dean, in returning thanks, said that it had given him great pleasure to preside, and that there were only two drawbacks to his efficiency on such an occasion, namely, that he did not profess either a knowledge of science or great readiness of speech. He had always taken great interest in education and in the rising generation, and it was, therefore, a sincere pleasure to him to see so many gentlemen making such satisfactory progress in their studies. He had lately been speaking respecting Hospitals to a distinguished man of letters, who had said that what struck him most with regard to modern Hospitals was that a Hospital for the sick and a school of instruction for students could be satisfactorily united, seeing the great difficulty there always was in uniting any two interests. He thought that the Medical Profession was the only one in which it was impossible to rise but by hard work and personal qualities, for in diplomacy, in the Law, and even in the Church, a man might be pushed on by interest and personal connection. Hippocrates had said, "Art is long, and life short." Life was still short, but art,

and Medical art particularly, had become enormously extended by the discovery and addition of new sciences; and he, therefore, exhorted the student not to cease in his efforts to obtain knowledge when his actual days of studentship were passed. (Cheers.)

SEUTIN'S STARCH BANDAGE.—The Brussels *Presse Medicale* relates a notable example of the great utility of the starch bandage. The Director of the Brussels Mint, while visiting the Escorial at Madrid, met with a fall which dislocated his patella and tore a portion of the triceps. His presence being at the same time urgently required in Brussels, a Belgian Surgeon was sent to fetch him, and he having applied Seutin's starch bandage was enabled to bring home his patient by the ordinary means of conveyance, not the slightest pain or other ill effect being produced during so long a journey.

DR. BARCLAY ON THE LEICESTER INFIRMARY.—Now, I am very desirous of being amiable to-night, and when money is spent and paid, and a building finished, after having been deliberately ordered by a vote of the governors, it is perhaps an additional waste to throw after it vain regrets; but I must ask of you to remember that I have a right to do it in this instance, because I stood up alone—alone, I had not a seconder—to vote for an entirely new building. For the thousandth time people have now been convinced that the cheapest alteration of an old building is to pull it down. In this instance it was particularly desirable; for the retaining of one old wall, the front one, involved the adoption of the same style of building throughout. A very fine opportunity has now been lost for ever of showing what an Infirmary might be. We have served one good end, we fill one round of the ladder by which men mount to perfection. There are two or three lessons have been taught to Hospital builders by us that could have been taught by no other method than dearly-bought experience. Now to judge the Infirmary by the rules I have followed throughout. First, its adaptation to its end: large wards, lofty wards, cross ventilation and heating by radiation, (that is, by old-fashioned simple open fires), rooms for boards, for resident officers, for pupils, Surgery and Dispensary accommodation. These are the wants of an Infirmary, and so far as the wards themselves are concerned, I believe the new ones to be the finest in England or out of it. Miss Nightingale deserves the credit of having first impressed on builders the truth that the only real ventilation is to be obtained by cross ventilation by windows. "The wind goeth where it listeth," and we have only to give it free scope—free entrance, and free exit. Air will not be controlled, and enter by ventilating holes and escape by others, or go up ventilating shafts to order. Such an attempt was made in addition to the simple cross ventilation, and in the cold weather in January last, we had to have all the apertures pasted up with brown paper. I am concerned and constrained to state that the ventilation of wards re-constructed in the old part of the building is in some cases defective. In the new part the convalescent wards are constructed so as to render a proper circulation of air almost an impossibility; if the style had admitted of dormer windows in the roof the problem would have been solved on the spot. The faults of the Infirmary are almost all due to the style imposed upon us. It left no freedom of action. Windows have to be placed where they ought to come in regular course, not where they are wanted. There is a handsome centre entrance, hardly ever used by anybody, and to which a carriage cannot drive up. Patients—bad accidents and fever cases, have to be landed in the open street, usually among a crowd of idle spectators, and carried in before the public, whereby the feelings of both public and patients are shocked. Then the difference of levels involved by altering instead of rebuilding is a most serious fault. By the hoist, or lift, heavy articles, such as coals, are carried up one, two, three stories, but when they are wheeled along to the wards, we meet two, three, ten steps up or down. Everything has to be transhipped; and the ward, which from its proximity to the entrance, should have been the accident ward, was rejected unanimously by the Surgeons, from the dangerous descent of half a dozen steps. Further, the style adopted rendered impossible the proper construction of latrines and sculleries. We had, in most instances, to put them at the ends of the wards, but even there independent cross ventilation was not to be obtained. Without that, air will be sucked into the wards, and as I have proved with a candle, the air does so enter them—of course, contaminated and impure. They are going to build a very large new Infirmary at Leeds, and one of the Physicians came over here to see what he could learn from

our experience. He at once detected the fault I refer to, and has since informed me how well they hope to overcome the difficulty by adopting the flexible and useful Gothic style, by which they attain the end window—a great element in cheerfulness—and have the ward conveniences in little square or round turrets at the corners, entirely shut off from the ward, ventilated each for itself by cross windows, and thus entirely avoiding the draughts of impure air into the wards. I do not desire to say more, indeed, the less said about the outside appearance of the building the better; the new wards are of themselves very fine wards, and it is a very fine and noble institution. There is another fault that could hardly have been foreseen—a fault that would probably have been equally committed in an entirely new building, Gothic or other. The kitchens are on the sunk floor, directly under the main centre. The consequence is, that at cooking times the whole house is filled to the roof with the most objectionable odour of cooking, which penetrates through floors, through plaster, up the staircases, up the hoist, impregnating the whole centre, from the ground to the attic. I believe the remedy for this would be to have the kitchen, as it is to be in some of the large new London hotels, on the roof, and to let the dinners down instead of sending them up. The lessons taught, then, by the erection of this Infirmary are these:—Have every floor on the same level from end to end; adopt the Gothic style, which enables you to put windows and doors, big or little, just where they are wanted; trust entirely to Nature's ventilation by windows on both sides of the wards; put your kitchens either in a separate building, or on the roof; and above all, never attempt to alter an old building, but have it entirely new.—*Reprinted from the Leicester Advertiser.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Anxious Inquirer.—Become M.R.C.P. Lond.

The author of a paper on the Ferruginous Treatment of Syphilis has forgotten to send us the last page of his communication.

John—of St. Albans—Fair Play.—May I ask your constant readers (myself being one of the many) which parties ought to be prosecuted by the Medical Council—poor Jenkins, at Worship-street Court, who was mulcted in the penalty of £5, or the bare-faced H—s, whose filthy productions are a disgrace to the age we live in, and who withal assert that they are duly registered Practitioners? Such lies were far beyond poor Jenkins. Surely the Medical Council will interfere?

The Ashantee War.—On a former occasion we felt ourselves bound to remonstrate against the loss of English life entailed by the Oxford and Cambridge mission to Central Africa. We count ourselves second to none in appreciation of the motives which prompted that effort, but we maintained that more care should have been taken in selecting the field of labour, and that neither religion nor humanity permitted the condemnation of civilised English men and women to certain death by fever and starvation. Now, however, the Army authorities appear to have thrown all other African blunderers into the shade. The following extracts from letters which have been published in the *Times* give a pleasant picture of campaigning in the "bush." We do not profess to be well acquainted with the grounds of the Ashantee war—we dare say it is as defensible as the war in New Zealand or the bombardment of Kagosima—but we maintain that no victory over a savage horde is worth one tithe of the misery and suffering into which we are recklessly plunging the troops we have sentenced to the Gold Coast:—

“Cape Coast Castle, Africa, April 15.

“As it is, here I am, and must make the best of it, but unless you were on the spot and could see the result of a few weeks' residence in the bush—as shown in the unhappy persons who have just returned from it—you will hardly realise the amount of philosophy it requires to come to this sensible resolution. It simply means dying (as many have already), or, what is fifty times worse, coming out of it with a constitution ruined for ever. No less than six officers leave by this mail; two or three will never reach England, and the rest can never be what they were before. To call the tragedy now being enacted here a farce may appear an anomaly, but so it is, for a war it can hardly be when they have been in what they call 'the field' (the swamp would be a more appropriate term) for the last three months and never seen so much as a single Ashanteeman. The amount of human life and money being expended is something awful to contemplate, nor can the end—taking Commassie, the capital of Ashantee—ever be attained—no, not if ten times the number of troops now here were sent, and well the king knows this; hence his taking no notice, and his wise remark, 'that though the white men have sent plenty of guns into the bush, he knows the bush will prove stronger than the guns.' One has only to be here a day or two to perfectly coincide with his sable Majesty. The rains have set in, and nothing can be done until November, when they will be over; but as a large quantity of stores have been collected at the camp—a collection of mud huts eighty miles in the interior—situated in a dense forest now under water—it will be necessary to keep a force there to protect them. The officers and two companies of my regiment have been selected for this service, and we start next week. If

I ever return I shall be very much surprised and pleased, but I am free to confess I do not in the least anticipate it, for to send us at this season of the year into the bush with no shelter but what a mud hut affords, and no food but salt pork and biscuit, is well known to all acquainted with this climate to be simply death. I go, my friend, as I am bound to do, and will meet my fate as a gentleman should, but if I were offered this minute to choose between allowing my company to pop at me at 300 yards for half an hour, I should readily accept the alternative.”

“God help us! Here we all are at last! I fancied I had seen some of the worst places there are, but imagination never pictured such a reality as this. We had been expected for two months, and yet no preparation was made for the reception of 200 men and 29 officers. Most of the men could go into the Castle; none of the officers could do so. Some of them are under tents with some of their men; the rest of us were quietly told to go and shift for ourselves, neither quarters nor lodging-money being given. The town and country are one mass of filth, and the stench is almost unendurable. We are allowed a gallon of water a day for washing, cooking, and drinking. When we landed, out of the nineteen officers we found here there were only three who were able to crawl about. Five go home—if they live long enough—by this mail; some went by last, and I don't know how many have died before they could be got off. This is from bush work during the dry season; and what are they going to do now? Why, keep two camps eighty miles up in the bush, in the middle of a swamp, where it will rain perpetually for six months. And what are they going to do it for? To eat up some stores which have been taken up and are in excess there, and which they do not wish to carry down again. And, to complete the whole matter, it is not certain that one Ashantee has been seen during the whole time that such humbug has been going on, which is now for nearly eighteen months, at a cost of upwards of £1000 a day to you at home.”

NELSON'S INJURY AT CALVI.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—At the siege of Calvi in 1794, as every one knows, Nelson lost one of his eyes from sand and small gravel driven into it from a shot which struck the ground near him. Some years ago I read in one of the Medical journals an account of this case, with (I think) extracts from the report to the Admiralty from the Medical officer who attended Nelson. Can any one of your readers refer me to the Medical journal in which this appeared? Perhaps it was in the *Medical Times and Gazette*. I regret I did not take a note of it at the time. I am, &c. W. M.

THE CHEAPEST DISINFECTANT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I ask permission to recommend to the readers of the *Medical Times and Gazette* a strong solution of iodine in methylated spirit, as a safe, cheap, and efficient disinfectant. Iodine is 8d. per ounce wholesale, and methylated spirit 4s. per gallon; therefore, supposing 4 oz. of iodine dissolved in a gallon of spirit cost 6s. 8d., allow a like sum for bottles, corks, and profit, and we ought to get for 6d. about 6 oz. of the tincture.

The advantages of iodine are (I believe it was first proposed as a disinfectant by Dr. Richardson) that it purifies solid surfaces as well as Condy's and Burnett's liquids; and that it is also volatile and acts on the air like chloride of lime, without its abominably nauseous odour.

In every house where there are sinks, closets, &c., internally, it is a good plan to disinfect them thoroughly from time to time in hot weather. Dust-bins should be treated with something to neutralise the emanations of the decaying vegetable rubbish thrown into them. When there is sickness in a house, and a *chaise percée* has to be used, it is very disgusting to have the contents taken without any precaution and allowed to waft a perfume all over the house. For all these purposes, for which a liquid disinfectant is convenient, I believe my Professional brethren will find the tincture of iodine the most handy and effectual.

I am, &c.

Mayfair, May 17.

R. DRUITT.

THE EMPLOYMENT OF SPONGES IN HOSPITALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In replying to my paper read before the Medico-Chirurgical Society at its last meeting, I am afraid I did not express myself very clearly with regard to the employment of sponges. What I meant to convey was this,—that sponges are never used in the Hospital; for all purposes of ablution pieces of flannel are employed, which are either burnt when the patient leaves the Hospital, or thoroughly cleansed in a solution of chloride of lime. It is of importance that this should be clearly understood.

I am, &c.

Queen Charlotte's Hospital, May 14.

GEORGE BRODIE.

POOR-LAW MEDICAL REFORM ASSOCIATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged for space to inform the Poor-law Medical officers that in "Knight's Official Advertiser" of the 16th inst. is the following:—"It is understood that the Committee (Select Committee on Poor Relief, England) have agreed to resolutions on several subjects on which they have taken evidence, viz., the distress in the metropolis in 1861, the continuance of the central authority, the power possessed by the Poor-law Board of issuing general orders, Medical relief, pauper education, religious rights of workhouse inmates, district auditors, power of Poor-law Board to dismiss officers, equalisation of rating, casual and houseless poor, classification in workhouses, and superannuation of paid officers. It now only remains for the committee to settle the terms of their report to the House. Mr. Villiers, the chairman of the committee, stated on the 5th instant, in reply to a question of Mr. Göschen, that he was led to believe that the report would be presented before long, and in time for legislation this session."

Since April 14 I have received the following subscriptions towards the funds of the Association:—E. Hall, Ulverstone, 10s.; C. Heaton, Leek, 3s. 6d.; R. Cooper, Leek, 3s. 6d.; R. Turnock, Leek, 3s. 6d.; T. Robinson, Cheadle, 5s.; E. C. Buckoll, Radford, 5s.; J. Westell, Cookham, 10s.; S. A. Plumb, Cookham, 10s.; T. Hewlett, Hendon, £1 1s.; H. Horsfall, Wakefield, 10s.; B. Kemp, Wakefield, 10s.; E. Walker, Wakefield, 10s.; T. Walker, Wakefield, 10s.; F. G. Wills, Chard, 5s.; R. Ransome, Cambridge, 10s.; R. F. Thompson, South Shields, 7s. 6d.; J. D. Hulme, Blaby, 5s.; R. W. P. Kerswill, St. Germans, 5s.; E. J. Worth, St. Germans, 5s.; J. Yeoman, Whitby, 10s.; and W. N. Clarkson, Whitby 5s.

I am, &c.

12, Royal-terrace, Weymouth, May 17.

RICHARD GRIFFIN.

NAVAL ASSISTANT-SURGEONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Parks' address to the Medical Council on the scarcity of competent candidates to fill up the ranks of the Army Medical Department is extremely interesting. I read a report of that address in your paper of the 14th instant, and as I have not heard any complaint made of a want of candidates for the navy, the question suggests itself to my mind—can it be possible that the navy fills up its ranks with the waifs and strays from the army competitive examinations?

The question is one of very great moment, as it concerns the efficiency of a very important branch of the public service, and from whatever quarter the candidates come, I am afraid I should be inclined to account for the anomaly by saying that the navy accepts a lower standard of qualification than the army.

The correctness of this conclusion may be denied by the naval authorities, and they may take credit for offering some greater inducements to account for their success. They may possibly allege that young Surgeons have an aversion to roomy quarters on shore, and prefer a hammock in the cock-pit of a line-of-battle ship, or at the best, a dark, unventilated room in the shape of a cabin, 6 feet by 4; or, that tired of the freedom of movement they have hitherto enjoyed, they prefer being shut up in a floating prison for the best part of their natural lives.

My reply would be—put them to the test—abolish your private board of examiners as the army and all other public bodies have done, and have one common examining board for the two services. Allow the successful candidates to choose the army or the navy, as the Woolwich cadets are allowed to select the engineers or the artillery, and you will then see which service is really popular with competent men.

In asking you to publish these few remarks I am not sanguine enough to expect that the navy board will readily adopt my suggestion. But the startling disclosures of incompetency made by Dr. Parks renders it desirable that measures should be adopted to prevent our sailors being given over, bound hand and foot, to the tender mercies of men who would treat a wounded artery by the amputation of a limb, and a wounded knee-joint by free incisions. I am, &c.

May 16.

M.D., R.N.

HARRIS P. TWISS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We beg to call your attention to a brief *resumé* of the above case, which has occupied a large share of the attention, not only of the Profession, but of the public.

The plaintiff in the case was Dr. Pitt Harris, Medical officer of the Newport Dispensary, Nenagh Union, a gentleman who accepted the appointment with the knowledge that more than one of his predecessors had been driven from Newport by the most determined persecution; and one of his predecessors lately asserted publicly in the Petty Sessions Court that "he never would have resigned the appointments but for the persecution which he suffered from Mr. Twiss" (the defendant).

For the last eighteen months Mr. Twiss, a Poor-law Guardian and a member of the Committee of Management of the Newport Dispensary, possessing property to the amount of between three and four thousand a-year, put in force all those means of annoying Dr. Harris with the existence of which every Medical officer must be well acquainted; but finding that nothing could disturb the equanimity of the Doctor, and that he showed a quiet determination not to be driven out of Newport as his predecessors had been, Mr. Twiss at length proceeded to open slander, and at a public meeting of the Board of Guardians, held in Nenagh, where he knew that reporters from every newspaper in the county attended, accused the Medical officer of incapacity and neglect, in "failing to discover that the bones of a boy's arm were broken and refusing to set them, and that the father of the boy (his own bailiff) had to send for a bone setter, who set the bones."

The position and capacity of this bone setter may be imagined from his own evidence at a subsequent investigation before the Committee of Management. He said that "he was a bone setter since before he was born, and his generation before him."

Dr. Harris immediately directed his solicitor to take proceedings against Mr. Twiss for oral slander, and accordingly he was served with a writ, damages laid at £1000. Mr. Twiss filed three pleas in defence—viz., 1st, a denial of the words; 2nd, a denial of the words in the defamatory sense attributed to them; and 3rd, privilege.

The plaintiff was advised by counsel that he would get a verdict on the first two pleas, but would be defeated on the plea of privilege, and, nevertheless, resolved to go to a jury, hoping that, should a jury endorse this opinion as law, it might possibly lead to a revision of a law which is a violation of all justice, a law which gives a Guardian the "privilege" of blasting the Professional reputation of a Medical man without fear of punishment. The judge (as was predicted by the plaintiff's counsel) directed the jury to find a verdict for the plaintiff on the two first pleas, and for the defendant on the third, "privilege," with costs. Taking into consideration these facts, and that in reality the plaintiff, Dr. Harris, fearlessly fought the battle of the Profession against wealth and power, a Committee has been formed of Professional and non-professional gentlemen with the object of calling on his brother Practitioners not alone to indemnify him, but by doing so to protest publicly against a state of the law under which each in his turn may suffer.

Subscriptions will be received by the following gentlemen:—

GEORGE W. BASSETT, Proprietor of the <i>Southern Chronicle</i> , Limerick,	} Hon. Secs.
THOMAS GLOVER, Francis-street, Limerick,	
EDWARD HAMILTON, M.D., F.R.C.S.I., Surgeon of Stevens' Hospital, 123, Stephens'-green West, Ireland.	} Treasurer for Ireland.
GEORGE WOODS, M.D., Surgeon of the General Hospital, Southport,	
	} Treasurer for England.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON
EPILEPSY,

DELIVERED AT

The Hospital for Epilepsy and Paralysis.

By J. S. RAMSKILL, M.D., etc.,

Assistant-Physician to the London Hospital; Physician to the Hospital for Epilepsy and Paralysis.

LECTURE IV.

GENTLEMAN,—Belladonna has active manifestations expressed elsewhere than on the iris, the throat, and skin. It has a well-known action on the bladder in cases of incontinence of urine in children, in spasm of bladder, and we find it exerted on the intestines in epileptics. Its influence in this latter respect is occasionally very inconvenient, inasmuch as a proper influence of the drug cannot be kept up, owing to the diarrhoea which ensues, whilst it very commonly happens that the accustomed use of purgatives becomes unnecessary during its administration. We account for these phenomena, also, by the supposition of a special tonic action on the sympathetic—a nerve abundantly distributed to the intestines and the viscera in the abdomen. It has been suggested that belladonna reduces constipation in epilepsy by lessening or removing clonic spasm which may exist in the muscular coat of an intestine; and in a great many instances, no doubt, this spasm is the true cause of the constipation, and its removal is the effect of the belladonna treatment; but we have no evidence that such spasm exists in a great many cases where obstinate constipation occurs, and especially in those improving cases where there is not the faintest sign of a clonic spasm in any other part of the body. In support of the theory of spasm, the evidence of Van der Kolk may be cited. He found, post mortem, on several occasions, decided contractions in different parts of the intestines. But, on the other hand, a great many post-mortems of epileptics have been performed where no such strictures were discovered, yet the pre-existing constipation was marked. I have myself seen three cases of this kind. It is true, a spasm of intestine may occur here and there, subside, reappear more or less frequently, and after death leave no trace behind it; but I think some commotion, flatulence, or abnormal sensation would be felt by the patient, and elicited by the cross-examination of the Physician. I think the constipation in these cases is due to atony of the muscular coat of the entire tract, to a deficiency of susceptibility to impressions which marks the muscular condition of most chronic epileptics. Powerful stimulant purgatives are very much more permanently useful in these latter cases than in the former, where a temporary benefit is the most we obtain.

With respect to the bladder, we meet with two common forms of spasm associated with epilepsy. A patient micturates at normal periods, usually freely and well; occasionally, however, when two-thirds of the contents of the bladder are discharged, the stream sinks to a mere dribble, and the act is finished by great expulsive efforts, attended by a decided feeling of obstruction to be overcome. This may be due to failure of power of the detrusor muscle, but as we have no analogous phenomenon occurring in the rectum, for I know of no failure of defæcation when a strong desire existed, and as the occurrence of a partial spasm of the sphincter, which the detrusor tends to overpower, seems to be the more natural explanation, and in accordance with the natural history of the disease, I shall take this to be the true explanation of the feeble micturition.

The second form is, perhaps, the more common. A patient will micturate easily and with a full stream until the bladder is again nearly empty, when a complete stoppage, accompanied by a decided crampy feeling referred to the neck of the bladder and parts adjoining, occurs. In a few seconds the feeling passes away, and the power of micturition returns in its full capacity. I would here warn you not to consent to any exploration of the urethra in these cases, if done merely to satisfy the wish of an excitable nervous patient. The following case illustrates the danger of this:—H. H., aged 25, suffered from attacks of grand mal once in five weeks, with interparoxysmal phenomena, "jerks and starts," in fact, clonic convulsions of most of the voluntary muscles. His other symptoms do not bear on the point I wish to illustrate

except this one, that he had an occasional spasm of the neck of the bladder, or of the muscular portion of the urethra, or both, recurring not oftener than twice a-week, and then apparently as a sequel to great fatigue or prolonged anxiety. The flow of urine was not checked more than two or three seconds. Now, it occurred to him that he had stricture of the urethra, and he resolved to have the passage explored. He did so; no stricture was found, but as a result of that exploration he had daily, for nearly a fortnight, more or less spasm occurring on all efforts at micturition, and sometimes accompanied by very considerable pain, and cramp, involving all the hypogastric region. In bad paroxysms the symptoms would cease, and recur three or four times in four or five minutes, stopping the flow of urine, the passage of which was the exciting cause. The suffering this patient sometimes experienced was sufficient to produce an anxious, distorted countenance, covered with profuse perspiration.

In fact, he had decided epilepsy of the bladder. There was occasionally a trace of sugar to be found, and latterly a little mucus, but beyond this, the urine was perfectly healthy. The case is the only one of the kind I have met with, but the great local suffering this patient experienced certainly justifies me in advising you not to meddle with the urethra or bladder merely to satisfy the curiosity of the patient. General treatment availed little for the relief of the local suffering, and injections into the bladder seemed neutralised in their effect by the passage of the instrument employed to introduce them. These injections were on several occasions twenty drops of Battley's laudanum; twenty of laudanum and four grains of hyoscyamus. Again the same ingredients, combined with half a grain of belladonna, in warm barley water as a vehicle. Although there was no disposition on any occasion to expel the injection, yet it produced little effect on the coming attack. The patient was most benefited by belladonna suppositories, small injections of carbonic acid into the bladder, and, finally, by cod-liver oil, and by removal to the sea side. He is now in his old condition. He has a slight spasm, as a result of over mental fatigue, or too much exercise. I do not know any reason why we should not have a spasm of the bladder, body, or neck, or of the urethra without the association of clonic convulsions or startings in any other muscles of the body, but I have never seen such a case, except in accidental complication with real stricture. In this case the stricture predisposes to muscular cramp, and under such circumstances, guided by the local aspect of affairs, you may call in the help of the Surgeon. I may observe that I have seen spasm of bladder act as an aura to the general convulsions. As belladonna removes constipation, so it removes likewise the ordinary cases of spasm of bladder of either kind. So also it improves the power of expelling urine, which, in some cases of epilepsy, is very feeble, independently of any spasm. It does so by its tonic action on the sympathetic, thus indirectly improving nutrition and removing muscular debility. Clonic spasms always co-exist with imperfect nutrition, and hence the best way to annihilate the spasm is to improve nutrition. Theory and practice in this respect point in the same direction.

Amongst the out-patients to-day was one (J. H.) whom you have seen; and we suppose him cured. His history is as follows:—

J. H., aged 19, apprentice to carpenter; had fits five years. Had no fits in childhood; has five brothers. All the family healthy; no history of syphilis. First fit occurred after a hard day's work, having gone without dinner; it lasted half an hour, was followed by stupor of two hours' duration. A second fit happened in ten days, after a feeling of exhaustion produced by lifting timber. Afterwards, the attacks came at variable intervals, the longest being three weeks apart. They never happen in bed; usually in the after part of the day; convulsion equal; no scream; does not bite his tongue. Has no petit mal. Memory defective, especially latterly; attention good; answers questions with some anxiety and effort. Well nourished as to bulk; fair and tall; says he is physically strong. Pupils large. Has always cold feet and hands. He denies the practice of masturbation. Says he knows when a fit is about him by a sinking feeling in the belly, and his back feels weak; is always more or less flatulent, but most so before a fit; he feels a great want and a desire to eat, but cannot eat much. He shivers once or twice, then falls without further warning. A spoonful of brandy without water will often prevent the fit, then he has always loud eructation of wind. Bowels not relieved for three days together, and often not then without the aid of medicine.

July 3.—Ordered extract of belladonna, gr. $\frac{1}{4}$; cod-liver

oil, ʒj., with four drops of phosphorised oil of the Prussian Pharmacopœia three times daily. To have a hot pediluvium every night; and a hot shower-bath, followed immediately by a free sprinkling of cold water, every morning. To apply a strong liniment of turpentine to the epigastric region about the time of the fits.

10th.—The report is:—One fit of slighter character; all other symptoms better. To continue the same treatment, but increase the belladonna to $\frac{1}{3}$ rd of a grain.

23rd.—No fit. Flatulence very troublesome at times; it is not so confined to the upper part of the abdomen. Better after meals. Bowels relaxed. To continue the same treatment.

On January 7 he reported having had another fit; he had been well until that time, and he attributes this attack to having left off medicine for three weeks, and to excessive eating and drinking at Christmas time. We continued the same treatment, and from that period to the present (July 10) he has remained well. The flatulence, sinking, and all other symptoms have entirely disappeared, and he looks in perfect health.

This case is a fair, but not a very good, type of a very common class of epileptics. They have for an aura some disturbance of sensation, accompanied, or not, by abnormal feeling of motion in the abdomen. Patients describe these feelings variously, as turning upside down, sinking, fainting, a sense of great coldness, or a rush upwards from the epigastric region, of heat, trembling, borborygmi, shivering, or a feeling of complete collapse, and emptiness of stomach, sometimes with nausea.

More or less of these feelings may be always present, and exaggerated only just before a fit. I call this class of cases Ganglionic Epilepsy, and I believe the symptoms complained of arise from a disturbed condition of the solar plexus and the ganglionic system of the abdomen generally. It may be from a failure of action, or from a disturbed or intermittent action of the solar plexus, and its dependent neighbouring ganglia. I believe the morbid action starting in the ganglion system propagates itself, by way of the splanchnic nerves, to the cerebro-spinal centre, and a fit follows. But what I wish most particularly to enforce just now is that this disorder of the ganglionic system is a disease *per se*, often existing alone, and antecedent to any epileptic attack; in fact, that the epilepsy is an accident which issues from, and follows, it, and so is fundamentally different from epilepsy arising from disease in the cerebro-spinal centre, or from a distinct cause of irritation situate in any other part of the body. This ganglionic affection is as much related to hysteria, tetanus, catalepsy, and, perhaps, intermittent fever and cholera, as to epilepsy; and when I meet with such a case I think it wise to ignore the convulsive attacks for a time, if they be infrequent, or look upon them only as an index of our progress in restoring power to the great centre. I should ignore the attacks altogether were it not for the fact, that each attack may, by causing congested blood-vessels, by effusions, by mechanically weakening delicate brain-structure, predispose to other attacks, or by dilating the minute and weakened vessels on the medulla oblongata, cause permanent mischief.

On interrogating such patients, you will generally find a history of overwork, of underfeeding, of mental anxiety, of grief; amongst the female sex of exhausting discharges, as menorrhagia, of many miscarriages, of numerous children, of prolonged lactation. Indeed, many cases arising from the last cause which we meet with in general Hospitals, possess every symptom that epileptics exhibit, even to the clonic convulsive action of the muscles, minus only the general convulsion and loss of consciousness.

The ganglionic system, we have shown, presides over the circulation in the brain; it enters largely into the composition of its substance, and is abundantly distributed to all the viscera in the body. But its great centre is in the abdomen, and failure of power in the central ganglion here, must be followed by failure in some degree, everywhere. What particular nosological disease follows must depend on predisposition, hereditary influence, or special debility of particular centres or parts of body.

Conversely, too, disease of the cerebro-spinal centre, or of brain proper, must influence the ganglionic system, although in a very much smaller degree, and in a more limited area; for, in the one case we have an affection of the great ganglionic plexuses in the abdomen, in the other only a local mischief, since a large amount of cerebral disease is hardly consistent with life.

I look upon the solar and neighbouring plexuses, and the

ganglia down the spine, as not only generators, but reservoirs of power. A blow on the epigastrium kills by paralysing the solar plexus; prolonged and unaccustomed exertion takes away all appetite, by exhausting the centre, as many of you must have experienced after walking all day on a first of September. Violent emotion causes fainting, acting in the same way by paralysing the great centre; fright gives rise to a very large percentage of our epileptics; but the fright does not act so immediately, causing the fit; the ganglia are only disordered functionally at first; sometimes days or weeks of uneasiness in the epigastrium, sinking, and mental uneasiness precede the convulsion. Chorea, also, acknowledges fright as its chief cause. Neither is the effect of fear shown in at once producing chorea. A disturbance of nutrition precedes it, and the regulation of nutrition is the great function of the ganglionic system. Given, then, a case of ganglionic epilepsy, our chief and first business is to restore power to the great nervous centre. How this was accomplished in the patient J. H., is mentioned in the short history of his case.

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

LECTURE IV.

Continued from page 558.)

PATHOLOGY.

Deposits of Urates are of a yellow or pink colour, according to the amount and kind of urohæmatin present in the liquid. The higher the colour the more febrile the state of the body. At one time their presence in the urine was regarded as a sign of the crisis of disease, and hence they received the name of critical discharges. Modern investigation has, however, proved that they cannot always be looked upon in this light, as they may also appear under a variety of conditions, which, although abnormal in themselves, are not truly diseased states, according to the usual meaning of the word. Thus, for example, urates may be deposited in the urine after a slight attack of indigestion, the result of over eating or drinking. Great exertion, especially if accompanied by profuse sweating, will also cause them to appear. Hence we find them present in the urine after a fatiguing walk, a long day's hunting, or even after a ball, or other such occasional amusement, especially if it has been associated with much mental excitement. Hard study, and even a fright will in some persons be followed by a deposit of urate of soda. A sudden change in the mode of life is a very common cause of their appearance, as, for example, confinement in town to country people, or a few days' residence in France to an Englishman unaccustomed to French dishes. Under none of these circumstances can the deposit be said to indicate a state of disease. It does nothing more than denote a temporary abnormal condition of system which may soon disappear without treatment. If, however, the deposit, instead of being merely temporary, lasts for some days, that of itself would denote that something more than a mere ephemeral derangement of the system is present, and may deserve immediate attention. A deposit in the urine is always a sign of something being wrong, and although, as we have seen, it may occur from very trivial causes, whenever it takes place without appreciable cause, in the otherwise apparently healthy, it is a sign not to be disregarded, as, under such circumstances, it is not unfrequently either the forerunner or associate of gravel or stone. Uric acid in some form or other is the commonest ingredient of all calculi, and there is no period of life exempt from them.

Urates are a very common deposit in the course of acute disease, and they even seldom fail to recur at some period or other in the course of chronic affections. It is, however, only in diseases of an acute febrile or inflammatory type that their sudden appearance can be regarded as indicative of a crisis. Their sudden appearance is due to an important change

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

having occurred in the condition of the patient, and in general, though not always, it is a change for the better. Such, for example, is observed to occur in cases of gout and rheumatism where the climax has been reached. So also in pneumonia and pleurisy when re-solution and absorption commence.

Should a patient, not labouring under any febrile or inflammatory affection, be every now and then troubled with a pink deposit in the urine without any assignable cause, it will be found, in almost nine cases out of ten, that he is suffering from some chronic affection of the heart, liver, or spleen, with which is associated a tendency to gravel. In all such cases, therefore, steps should immediately be taken to counteract this disposition by the administration of alkaline tonics. Should there, however, be any counter-indication to the direct alkaline treatment, those acid salts are to be employed which, during their passage through the body, are converted into alkaline carbonates—such, for example, as citrates, tartrates, lactates, and acetates. Every now and then an exceptional case may arise, where a mineral acid tonic is demanded, under such circumstances the above rule may be departed from, and the case treated according to its special requirements.

It not unfrequently happens that there are crystals of free uric acid scattered among an amorphous deposit of urates. This is more frequently the case in the course of chronic than of acute affections, and generally arises from there being an excess of acid in the urine which has combined with some of the alkaline base and set a portion of the uric acid free.

The crystals of uric acid form on the bottom and sides of the vessel as the urine cools, and, if large, they may be readily detected by the naked eye, in consequence of their yellow, red, or brown colour. Uric acid, like urea, when crystallised in urine always takes up a part of the urohæmatine or any other colouring matter that may chance to be present. So that, the paler the urine, the less coloured are the crystals; the darker the urine the more coloured the crystals. In abnormal urines containing blue, black, or saffron-coloured pigment, the uric acid crystals are blue, black, or yellow; as in these variously-coloured specimens now before you. The crystals are easily recognised by the naked eye if the urine be put into a wine-glass and the deposit allowed to fall to the bottom.

Uric acid is not necessarily in excess when it crystallises spontaneously—though that is the general rule. It has just been said that an excess of free acid induces its crystallisation. I may now add that it is also deposited when from any cause the proportion of alkaline base is abnormally diminished. This arises from the circumstance that uric acid is much less soluble than any of its salts, even the urate of ammonia included.

The daily amount of uric acid excreted varies very considerably in disease. It is generally in excess during the course of all fevers (yellow fever excepted), exanthematous affections, and inflammatory diseases. It has been found doubled in typhus (Parkes), greatly increased in small-pox, as well as considerably augmented in pneumonia. In certain diseases crystals of free uric acid are spontaneously deposited in the urine. This is more particularly the case in hepatic, cardiac, and splenic diseases.

In liver affections there is frequently a spontaneous deposit of free uric acid among the amorphous urates, which, as already said, are so common in those affections. This is more particularly observable in cancer of that organ, in which case, too, the uric acid is generally in excess;—a fact frequently made use of in diagnosis, for in non-malignant hepatic disease, especially towards its latter stages, the uric acid is found to be remarkably diminished. I had once an admirable opportunity of verifying this statement in a fatal case of jaundice, about which there was some difference of opinion as to its cause, some of the Medical attendants thinking it a case of cancer; others of non-malignant obstruction,—the latter view being greatly supported by the fact of there being no excess of uric acid in the urine. This case I had the opportunity of carefully watching to its termination, and, gradually, as the liver ceased to perform its normal functions, the uric acid diminished, until it at length totally disappeared from the urine.(h)

In leucocythemia a great excess of uric acid is said to occur.

(h) A full report of this case is given in the author's work on Jaundice, and Diseases of the Liver and Pancreas, p. 71.

It even occasionally happens that a spontaneous deposit of free uric acid occurs in the course of chronic bronchitis, emphysema, and phthisis. This is supposed to be in consequence of the uric acid in the blood being imperfectly oxidised into urea.

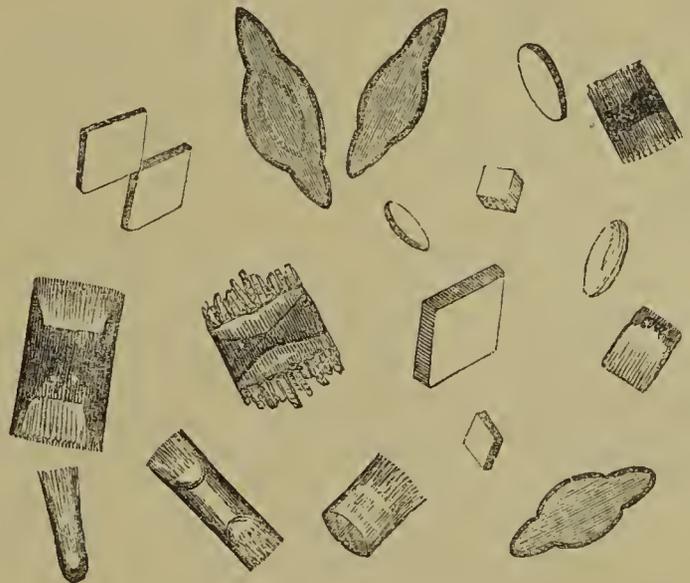

It will be remembered that it was already said that urea to some extent comes from the direct oxidation of uric acid in the circulation, and therefore, whatever retards oxidation tends to diminish the quantity of urea and increase that of uric acid. Hence it is that in all cases of disease attended with imperfect arterialisation of the blood the urea is diminished, and the uric acid increased. There are, of course, exceptions to this rule; in December, 1859, Mr. Murray sent me some urine from a case of acute phthisis in which there was both an excess of urea and of uric acid.

In certain pathological states of the system the quantity of uric acid excreted is occasionally so great that the simple addition of nitric acid to the urine causes an instantaneous deposit to occur; a deposit which, as Beale justly remarks, is apt to be mistaken for albumen. On one occasion I obtained a copious deposit of amorphous uric acid from the urine of a young man aged 19, suffering from pneumonia of the right side. It was on the eighth day of the disease, and the first of the reappearance of the chlorides. I have observed the same thing in phthisis, Rees has noticed it in typhoid, Parkes in typhus, and Beale has also obtained these uric acid precipitates in a case of hydatid tumour of the liver, and in one of a man suffering from rheumatic fever.

Free uric acid is in general very readily recognised with the microscope, for although the crystals assume a multitude of forms, each form is well defined.

Fig. 9 shows the forms of uric acid most frequently met with.

FIG. 9.

Common forms of Uric Acid.

The crystals may be well-marked diamond-shaped plates, rounded lozenges, ovals, squares, or rods. They may be perfectly solid or composed of condensed bundles of needle-shaped crystals, which are occasionally free at the ends and cause the crystals to resemble, in some degree, a small-toothed comb or a scrubbing brush.

All uric acid crystals polarise, but the play of colours is best seen in the thin flat plates. Indeed, it is sometimes necessary to place a piece of selenite beneath the slide containing the crystals in order to get the polarised colours distinctly.

When a difficulty arises regarding the chemical nature of a crystal, in consequence of it having assumed an unusual form, add a drop of caustic potash, and after the crystal has become dissolved, neutralise the solution with a little hydrochloric acid, and most probably the uric acid will re-crystallise in one of the more common forms. I find the colour always a great aid to the diagnosis, for no crystals are so prone to take up the colouring matter of the urine as those of uric acid. Indeed, by far the majority of crystalline substances met with in human urine are perfectly colourless, even when crystallised in highly coloured urine.

The subjoined woodcut (Fig. 10) contains all the rare forms of uric acid crystals I have ever met with, and I think I may even venture to affirm that the types of all the various forms of uric acid are represented in these two woodcuts (Figs. 9 and 10).

a and *b* in Fig. 10 are not very uncommon. They are often to be met with in the urine of patients labouring under hepatic disease, more especially those in which there is a tendency to gravel or stone. *c* are rare. They look like old-fashioned arrow-heads. Those represented were sketched from a spontaneous deposit in the urine of a gentleman labouring under diphtheria. On one occasion they had a blueish-purple tint. *d* is the rarest of all the forms of uric acid; I have

FIG. 10.

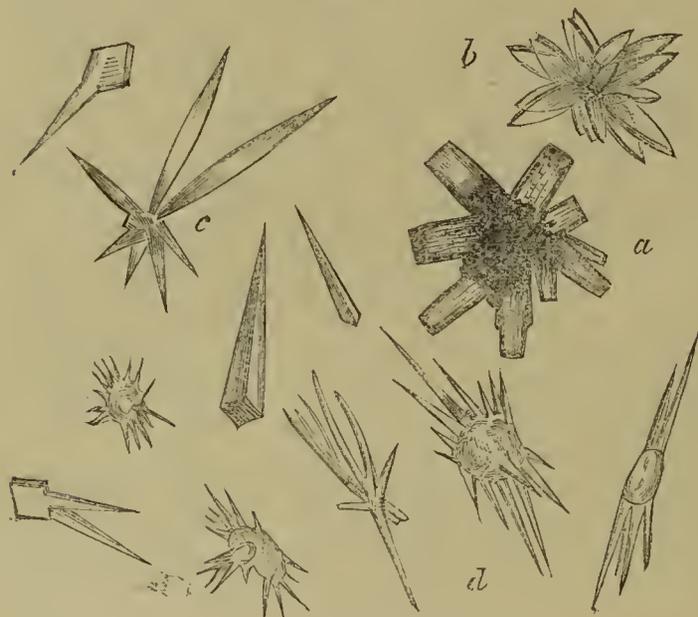

FIG. 10.—Rare forms of uric acid.

only once or twice met with it. Those given were sketched for me by Mr. Alexander Bruce, and are most faithful representations of the crystals, the true nature of which was ascertained by chemical analysis. These crystals were spontaneously deposited in the urine of a boy aged 7 years (Hospital case) suffering from albumenoid disease of the liver, spleen, and kidneys.

Both liver and spleen were excessively enlarged, and the urine was highly albuminous. This leads me to remark that the presence of albumen influences to a certain extent the form of crystalline urinary deposits, especially those of uric acid. Crystals of uric acid are frequently deposited round tube casts and masses of epithelium. Sometimes they appear in the form of rows, as if they had been deposited in one of the tubuli uriniferi, and afterwards floated out with the urine. This is not at all improbable, for be it remembered that, under certain pathological conditions which in this country are, unfortunately, far from rare, deposits of uric acid, either free or combined, take place in all parts of the urinary passages—in the urethra, in the bladder, in the uterus, or in the kidneys. The deposit may occur in the form of sand (as seen in this beautiful wax model), as gravel (as represented in this drawing), or as calculi (as seen in this preparation).

ORIGINAL COMMUNICATIONS.

THE ACTION OF WATER ON LEAD. DETECTION OF FREE HYDROCHLORIC ACID IN ANOTHER WELL OF SPRING WATER.

By HENRY OSBORN, M.R.C.P. Lond.,
Consulting Physician to the Southampton Dispensary.

A PERIOD of more than twenty years has now elapsed since I first discovered the presence of an uncombined mineral acid in spring water, which acid I found to possess the property of corroding lead to such an extent as to render the water highly poisonous, having nearly caused the death of the father of the family who drank the water. The fact of chlorine or hydrochloric acid being a corroding agent of lead induced me to bring the important discovery before the British Association, which was held in this town in September, 1846. Notwithstanding the numerous examinations which I had made of water for the presence of lead and its solvents, I failed to detect the free acid, except in a single instance, until a year or two subsequent to the above date, when I again met with its presence. The first was found in a closed or covered well (to which a pump was attached) in the New Forest, about ten

or fifteen miles from Southampton; but the second was discovered in a closed well at Portswood, about two miles from the town.

The circumstance which led me to detect the existence of free hydrochloric acid in another locality was as follows:—At a meeting of the Southampton Microscopical Society last March Mr. Tovey, an excellent microscopist and a member of the society, informed me that he suspected the water which a relation of his was using for domestic purposes contained an acid; and calling to his recollection that I read a paper (a) before the British Association “On the Action of Water on Lead,” he thought the discovery of an acid in water had some foundation, though it was doubted at the time, it being the opinion that an uncombined mineral acid could not exist in a soil where earthy carbonates are always present. Mr. Tovey stated that his relation had been living in London before he went to reside at Bitterne, and all the kettles were encrusted with fur, but the water which was now used, drawn from an open well, had dissolved the fur and made the kettles quite clean and bright. I expressed my wish to examine the water, and on being furnished with a wine bottle of it proceeded to evaporate the water most carefully below 212°. The water being reduced to one-half its bulk reddened litmus paper slightly, and when it was evaporated to one ounce gave a strong reaction to litmus. I then requested Mr. Tovey to procure me two gallons of the water for further examination. One quart was carefully reduced as before to about twelve drachms, and found to possess the same acid reaction. I tested this concentrated water for lime, magnesia, and iron, all of which were found in solution; a per-salt of iron existing. The acids indicated by the usual tests were sulphuric and hydrochloric, but I omitted to test for nitric and nitrous acids in this stage of the investigation.

Three quarts of water were next evaporated to two ounces, or rather less, and introduced into a glass retort in order to separate the free acid by distillation. When about two drachms of water had collected in the receiver, it was removed from time to time, and tested with litmus and nitrate of silver; but no acid was indicated until the last two drachms, or thereabouts, came over. The acid thus obtained was strongly acid to litmus, and, when two or three drops were placed on the tongue, it was acid to the taste, and possessed a peculiar odour which I could not recognise; but hydrochloric acid was readily detected by the usual tests. The saline matter left in the retort presented a yellow colour, and not appearing to be quite dry, the heat of the sand bath was increased to about 300°, when fumes of a reddish yellow colour appeared in the retort, having the odour of nitrous acid. A little distilled water being placed in the receiver, the nitrous fumes became absorbed, and, on examination, nitrous acid, with a little hydrochloric, were present. The first acid which came over was evidently impregnated with nitrous, though so slightly that I could not recognise the odour at first.

I have not proved that the nitrous acid existed in a free state, but in all probability a nitrite (perhaps nitrite of iron) suffered decomposition by increasing the temperature, but this point I have not yet determined. I recollect, about fifteen years since, procuring some water from an open spring (not a well), and evaporating a certain quantity of it to dryness at 212°, when the residue appeared to contain a large quantity of organic matter, being very dark in colour; but on elevating the temperature with a view to get rid of the organic matter by ignition, a sudden burst of nitrous fumes took place, showing the presence of nitrites; the water, however, gave no reaction to litmus in any stage of the evaporation.

In conclusion, I wish it to be understood that I bring this subject forward again, not so much with the view to establish a chemical question, but more particularly as an important Medical and sanitary question, as I have hitherto done. The existence of a solvent of lead, in addition to carbonic acid, capable of acting upon almost any metal, and occurring in three different localities, must show that the greatest caution is requisite in the selection of some safe material for the transmission of water. Enamelled iron and gutta-percha are, perhaps, the safest, though the durability of the latter is not always to be depended upon, besides imparting, as it does, a disagreeable taste to water for some time after being in use. Galvanised iron, *i.e.*, iron coated with zinc, is often substituted for lead; and I regret to state that I have met with cases of dyspepsia and other symptoms resulting from zinc in water.

CASE OF PARALYSIS RELIEVED BY ICE.

By F. BROUGHTON, F.R.C.S.,

Surgeon-Major Bombay Army.

Case of J. D., Fairlight, Sussex, 1864.—In the month of October, 1863, I was requested by a friend to visit a poor, bed-ridden girl in whom she took some interest, from the circumstance of her having been her housemaid.

I found the girl (aged 21) had been confined to her bed for upwards of a year. There was entire loss of sensation and motion in both inferior extremities. She could not turn in bed, nor assist herself in any way, but was treated by her mother and sister in every respect as an infant. The loss of motion and sensation extended to a little above the knees. There was neither wasting nor rigidity in the muscles of the legs, but the feet were both stiff and attenuated. She could bear pricking and cutting the skin of both legs without any effect or twitching. Upon examination of the spine, I found no curvature in either cervical or dorsal region; but there was an actual shortening of the left leg of an inch by measurement, and this was connected with an obscure thickening in the sacral region, although I failed to detect any curve in that portion of the spine. There was extreme tenderness on pressure in the lower cervical and dorsal region.

Her general health was good; menstruation natural; had never suffered from any symptoms of hysteria, nor had any accident or injury in childhood. I found upon inquiry that from an infant she had never played like other children; and this was caused by weakness in her back, so that she was accustomed to limp upon one leg.

As she grew older this limp somewhat decreased, and although she never was capable of joining in the sports of her companions, she was still able to go into service, and had for some time performed her duties to the satisfaction of her mistress.

The pain in the back, however, increased, and although much and varied treatment had been resorted to, up to the period when I first saw her both she and her father and mother had given up all hope of recovery.

About this period my attention had been directed to the agency of ice in such cases, by the perusal of Dr. Chapman's paper in your Journal, and, I confess, with no very sanguine hope of success, I directed two pounds of ice, in oiled silk bags, to be applied to the spine every morning for two hours, followed by hand friction down the spine to the extremities for two hours following, the whole body being subsequently eased in flannel.

At first, great pain and distress was the effect produced. The skin in the region subjected to the ice became purple and congested. Her appetite was impaired, and the bowels irregular. I had some difficulty in persuading her to submit to a continuance of the treatment, but at the end of ten days she became reconciled to her suffering, as a little sensation commenced in her feet. This was soon followed by slight motion, and by the middle of November she could turn herself in bed. I continued the ice and frictions, and by December 1 she was able to stand and move about the room. She improved to such an extent that on Christmas-day I had the satisfaction of meeting her walking in the streets of the village in which she resides.

I saw her on February 29, as I was then leaving the neighbourhood, and found her quite able to conduct the ordinary duties of a cottage household.

I employed no medicines in this case, treating the constipation alluded to by a wet compress, and I am disposed to think that this short history may be held as a proof that there is considerable power in the local application of cold in this class of cases, and that a careful investigation of its effects is worthy of the attention of the Profession.

PRESERVATION OF CHLOROFORM.—It requires but a short time for chloroform which is exposed to the sun's rays to undergo decomposition, hydrochloric acid being developed, and a strong odour of chlorine being present. This is prevented if the chloroform is kept in the dark; and when it has undergone decomposition by exposure, M. Boettger finds that it may be easily purified by shaking it up with a few fragments of caustic soda. As long, indeed, as it is in contact with the caustic soda it may be preserved for an indefinite period in diffused light.—*Bull. de Thérap.*, May 15.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

SIX CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

At pages 560 and 586 of our last volume, reports may be found of eight cases in which Mr. Spencer Wells had performed ovariectomy at the Samaritan Hospital. We now give six other cases in which he has operated since our previous report, making the total number of his operations in this Hospital 52, with a result of 36 recoveries and 16 deaths, or a mortality of 30 per cent. There was an error of one case in our former summary, page 560.

Case 1.—*Ovarian Tumour—Ascites—Umbilical Hernia—Prolapse of Uterus and Vagina—Ovariectomy—Death on the Eighth Day.*

A widow, 33 years old, mother of three children, the youngest 7 years old, came from Dudley, and was admitted November 5, 1863, with an ovarian tumour surrounded by ascitic fluid, the integuments at the umbilicus much distended by the fluid and covering protruding omentum, the uterus prolapsed several inches beyond the valva, inverting the vagina, and causing both cystocele and rectocele, the cavity of the uterus measuring six inches. The disease was of about four years' duration, and the patient had been tapped fifteen times since the first tapping two years before admission, the quantity varying from twenty to thirty quarts. She was kept in Hospital till the cessation of an expected menstrual period, and well fed. On November 30, 1863, the day fixed for operation, the measurements were,—girth at umbilical level, 52 inches; from ensiform cartilage to umbilicus, 17 inches; from umbilicus to symphysis pubis, 10 inches; from ilium to ilium across the front of abdomen, 34 inches. Dr. Parson administered chloroform. Mr. Archer, Dr. Eastlake, Dr. Ritchie, etc., were present. An incision was made from the lower border of the umbilical hernia downwards for five inches, and a very thick, dense sac was exposed, which was at first taken to be the cyst, as thick ovarian fluid escaped as soon as it was opened. Forty-three pints of this fluid escaped, and then an attempt was made to separate a portion of omentum which was adhering around the umbilical ring. This led to the discovery that the ovarian fluid had been free in the peritoneal cavity, and that the only attachments of the ovarian tumour, which was of the size of an adult head, were to the piece of omentum which was protruded at the umbilicus. On separating this, the tumour was easily removed, and a long, slender pedicle, after being temporarily secured by a clamp, was transfixed, tied by a double silk ligature, cut off short, and returned. The only bleeding was from four vessels in the separated omentum. One was stopped by torsion; three ligatures were used to the others, cut off short, and returned. The wound was closed by five deep and several superficial silk sutures.

For the first twenty-four hours after operation the voice and aspect were good, but the pulse varied from 112 to 140. There was a good deal of abdominal pain and some vomiting, with scanty secretion of urine and pungently hot skin, varied by occasional free perspiration. On the second day a dark sanguineous discharge came on from the uterus (which had been replaced) and continued all day. On the third day diarrhoea set in, and was relieved by hot linseed poultices; all the stitches were removed, and some dead epidermis was removed from the umbilicus. She said that this desquamation had always followed her tappings. On the fourth and fifth days she was much better, although the diarrhoea continued, and there was a dark fetid discharge from the umbilicus with a further separation of cuticle. On the sixth day the vomiting and diarrhoea seemed to be ceasing, but on the seventh morning the pulse became more rapid and feeble; she continued to sink all day, and died at night.

A post-mortem examination was made by Dr. Ritchie. Part of the skin which had been distended at the umbilicus had been separated by sloughing, and portions of subcutaneous cellular tissue were also in a sloughy state between the edges of the skin which had been divided at the incision. There was some subcutaneous emphysema between the um-

bilious and sternum. On dividing and raising the abdominal wall, the parietal peritoneum was seen to be accurately united beneath the whole length of the wound, and the slough at the umbilicus was perfectly excluded from the peritoneal cavity. The fundus uteri lay on a level between the symphysis pubis and promontory of sacrum. A layer of recent gelatinous lymph formed a sort of arched roof from the sacrum and rectum over the uterus to the bladder and pubes, enclosing about a pint of turbid serum in the pouch of peritoneum between the uterus and rectum, and to the right side of the uterus. This pouch was lined by a layer of lymph. There was a good deal of serum in the loose cellular tissue of the pelvis. The right Fallopian tube and part of the broad ligament were surrounded by silk ligatures which had not included the elongated round ligament. The small slough enclosed in the ligatures had been surrounded by two coils of small intestine, which were adherent to each other and to the end of the pedicle. The omentum seemed quite healthy, but at its lower end there were two ligatures which were very close to the spot where the pedicle and intestine were adhering together.

Mr. Wells remarked to the gentlemen who were present at the examination that it was a matter of doubt whether the fluid in Douglas's space was the remnant of some ovarian fluid which he had not thoroughly sponged out at the operation. He thought this probable, as he had not pushed up the uterus from its prolapsed position until the end of the operation. But it was possibly due to the effusion of serum from a localised peritonitis around the pedicle, which serum had gravitated to the most depending part of the peritoneal sac. It was much less likely to be the serum of pelvic cellulitis escaped into the peritoneal sac. If he had made a puncture by the vagina and let off the fluid, as he had done in three other cases, he thought the patient would have had a much greater chance of recovery; but nothing had led him to suspect the presence of the fluid or to make the examination by which it would have been detected. The case showed the importance of making vaginal examinations when bad symptoms came on after ovariectomy, and, in his opinion, it told against the practice of leaving the pedicle within the abdomen when it could be kept outside, and very strongly in favour of the practice of uniting the peritoneal edges of the incision. It also taught us not to conclude at the operation from the escape of ovarian fluid that the sac had been opened, because this fluid might be free in the peritoneal cavity, one or more cysts having given way long before.

Case 2.—Multilocular Ovarian Tumour—Prolapsus of Uterus and Vagina—Ovariectomy—Recovery.

A married woman, 41 years of age, was sent to Mr. Wells by Dr. Whitehead, of Manchester, and Mr. Melland, of Rusholme; and was admitted February 2, 1864, with a large ovarian tumour, and prolapse of uterus and vagina, irritable bladder, and some œdema of legs. The prolapsed surface of uterus and vagina was much ulcerated. She had been tapped once in January, a few days before admission. She was kept for more than three weeks on good diet, and to allow the menstrual period to pass over, and ovariectomy was performed on the 29th of February. Dr. Keith, of Edinburgh, was among the visitors. Dr. Parson administered chloroform. An incision nine inches long was made from just below the umbilicus to two inches above the pubis. The tumour was surrounded by viscid fluid. One long firm band of adhesion was secured by a clamp and divided. (The clamp was removed towards the close of the operation, one vessel tied, and the ligature cut off short.) A pedicle of the thickness of two fingers was secured by a small clamp, between two and three inches from the side of the uterus, and the ovarian tumour was removed entire. The prolapsed uterus was pushed up, all fluid was carefully sponged out of the peritoneal cavity, the pedicle and clamp fixed outside, and the wound united by deep and superficial silk sutures in the usual manner.

The recovery was almost uninterrupted, the only trouble arising from cough, which led to repeated prolapse of uterus, notwithstanding the pressure of sponges and bandages. The clamp came off on March 8, and she was discharged on the 24th. She called on the 31st, and has been heard of since her return to Manchester in excellent health, cured not only of the ovarian tumour, but of the uterine and vaginal prolapse.

Case 3.—Multilocular Ovarian Cyst—Ovariectomy—Recovery.

An unmarried dressmaker, from Yarmouth, 23 years of age, was sent to Mr. S. Wells by Dr. King, of Savill-row, as a

favourable case for ovariectomy. The growth of a multilocular ovarian cyst had been rapid, and she had not been tapped. Ovariectomy was performed on March 14. Dr. Koepl, of Brussels, Dr. Hazenfeld, of Pesth, Dr. Druitt, etc., were present. An incision four inches long, made downwards from one inch below the umbilicus, exposed a non-adherent cyst, which was tapped, emptied, and withdrawn. The pedicle was of the thickness of three fingers, and a long expansion of the right broad ligament ran up between the Fallopian tube and the cyst wall, greatly increasing the difficulty of surrounding the pedicle. But after transfixing the broad ligament, and then tying and dividing it, the pedicle was secured by a small clamp close to the cyst, and the ligatures were tied to the clamp, the whole of the strangulated parts being fixed outside. The left ovary was found to be healthy, and the wound was closed in the usual manner. Nine pints and a-half of fluid were collected, and the mass of small cysts weighed about 3 lb.

She went on remarkably well. The clamp was allowed to remain till it came away spontaneously on the fourteenth day, and the patient was discharged well on April 4, exactly three weeks after operation.

(To be continued.)

MIDDLESEX HOSPITAL.

CASES OF TYPHOID AND TYPHUS FEVER, ESPECIALLY WITH REFERENCE TO THE CONDITION OF THE URINE.

(Communicated by WM. DUNNETT SPANTON, late Resident Obstetric Assistant to the Middlesex Hospital; House-Surgeon to the North Staffordshire Infirmary.)

(Continued from page 506.)

Case 3.—Susan C., aged 11 years, admitted, under the care of Dr. Goodfellow, on January 1, 1862. Had been a healthy child previously. Had scarlatina and small-pox when young. At the house where the patient has worked as servant three children have had typhoid fever, and at her own home four of the family in succession have been attacked. Her illness began on December 10, with the usual symptoms. A week before admission diarrhœa came on, and soon after delirium. Headache and deafness were severe; there was no epistaxis. Urine had been high coloured and scanty.

On admission there was great prostration; the countenance distressed; lips very dry and incrustated. Skin pungently hot and dry; over the abdomen a few "typhoid" spots. No other eruption. Much meteorism. No gurgling. Abdomen tender everywhere on slight pressure. Tongue cannot be protruded; dry, incrustated, and fissured. Thirst urgent. Complete anorexia. Respiration 30. Frequent "rattling" cough. Breath sounds healthy. Pulse 136, excessively small and weak. Headache severe from brow to occiput. Frequent muttering delirium. Considerable deafness in both ears. Speech almost unintelligible. Ordered to have 6 ozs. wine daily, simple diet with arrowroot, and strong beef-tea. Also a draught of nitric acid and compound tincture of cardamoms, and a pill of camphor, quinine, each one grain, and Dover's powder, a grain and a-half, every six hours. The head to be shaved.

January 2.—Restless and delirious during the night. No fresh spots. Bowels open twice; motions dark ochre-coloured, loose; respiration, 30; pulse, 150. Urine, during twenty-four hours after admission, 10 ozs., very high-coloured, clear, acid, sp. gr. 1025; phosphates copious; albumen about $\frac{1}{10}$ th; solids, 58.25 grains in 1000, 279.60 grains in the whole; urea, 33.55 grains in 1000, 161.05 grains in the whole. To continue medicine. To have a powder of chalk and opium if there be diarrhœa.

3rd.—Very restless. Skin less hot; one or two fresh spots; abdomen very tender; bowels open twice yesterday and once in night involuntarily; tongue dry, almost black, deeply fissured; pulse, 132. Takes food fairly. To have a linseed poultice, with mustard and laudanum, to the abdomen. To have added to the pill a-sixth of a grain of sulphate of copper.

4th.—Less delirium. Two fresh spots; others remain distinct. Abdomen less tender; respiration, 34; pulse, 144; passes urine involuntarily.

6th.—Much improved. Replies rationally to questions. Skin less hot and dry. One loose involuntary motion on night of 4th inst.; none since. Tongue can be protruded a little. Takes food fairly. Respiration, 60; cough slight; bronchitic sounds all over chest; pulse, 136; deafness continues; no headache; pupils large and sluggish. To take a pill every

eight hours. To have added to the draught some oxymel of squill. The wine reduced to 4 ozs. daily.

8th.—Slept well; little delirium; very irritable; no pain in abdomen; no spots visible; had one natural motion yesterday; tongue less dry and fissured; thirst slight; takes food well; respiration, 44; pulse, 132, regular. To take the pill twice daily, and to take a teaspoonful of castor-oil occasionally.

9th.—Urine passed voluntarily about 20 ozs. since last night, high-coloured, clear, acid, sp. gr. 1026; no phosphatic cloud with heat; no albumen; solids, 60·58 grs. in 1000; urica, 22·30 grs. in 1000.

13th.—Sleeps well; no delirium; skin still hot and rather dry; abdomen flaccid, painless; bowels confined; tongue becoming coated with new epithelium; respiration easy; pulse, 126, very small; some headache; deafness as before. To omit the medicine. To have beef-tea and an egg daily, and a draught of quinine and sulphuric acid twice a-day.

14th.—Owing to vomiting of food since yesterday, she had a draught of magnesia and aromatic spirit of ammonia every six hours instead of the quinine.

16th.—Improved; no sickness; bowels confined; little appetite; respiration calm; no cough; pulse, 116; some headache still; less deafness. There has been a discharge of pus from the left ear. Urine, 13 ozs. in twenty-four hours, acid, high-coloured, turbid with urates; no phosphatic cloud nor albumen; sp. gr., 1020; solids, 46·60 grs. in 1000, 290·78 grs. in whole; urea, 16·80 grs. in 1000, 104·85 grs. in whole.

18th.—Countenance much more natural; tongue moist, white along dorsum. One motion to-day, dark, rather loose; respiration, 26; pulse, 116, of better power. No headache; deafness slight; urine acid, turbid, sp. gr. 1021, free from albumen. To take the quinine draught twice a-day, and to have meat diet, with four ounces of wine.

20th.—To take, instead of the draught, a pill containing a grain of quinine and a grain and a-half of pil. ipecac. co. twice or thrice daily.

27th.—Convalescent; has not yet been up, but is anxious for it. Appetite fair; tongue clean, moist; bowels confined, unless she takes the castor-oil; respiration easy; pulse 100, firmer; no headache nor deafness. Urine, in twenty-four hours, sixteen ounces, clear, amber-coloured, sp. gr. 1020, free from albumen; solids 46·60 grains in 1000, 357·88 grains in whole; urea, 13·76 grains in 1000, 105·67 grains in whole.

On February 7 the patient was allowed to leave her bed. From this time she gradually improved without any untoward symptom, and on the 25th was discharged well.

Case 4.—Harriet P., aged 29 years, admitted under the care of Dr. Thompson, on November 6, 1861. Has generally been healthy, and lived well. On October 22 she went to Northampton to see her father, who died of typhoid fever on the 25th. On the 31st the patient left, not feeling so well as usual. The symptoms of typhoid began from that day to be manifest.

On admission the countenance was deeply flushed, the lips parched and florid; skin pungently hot, free from eruption; bowels relaxed; tenderness on pressure over the whole abdomen, most marked in the right iliac region, where there was also slight gurgling; tongue dry, brown, fissured; much thirst and anorexia; respiration 36, short. At posterior part of each lung sonorous and sibilant rhonchi were heard; slight cough; pulse, 124, weak; heart sounds healthy; very severe vertical headache; slight deafness and tinnitus aurium; intelligence confused. Ordered to have simple diet, beef-tea, and four ounces of wine daily. To take a draught containing bicarbonate of soda, chloric æther, and syrup of poppies, with camphor mixture every six hours. The head to be shaved, and ice applied to it, and turpentine fomentations applied over the abdomen.

November 8, ninth day.—Delirium during the night; decubitus dorsal; countenance very dull; several "rose spots" over abdomen; no petechiæ; several motions since admission, pultaceous, of a dark green colour; thirst extreme; respiration, 44, short; pulse, 140, small, weak; headache very severe; sometimes delirious, but not constantly. Ordered to take the pilula cupri comp. twice a-day.

9th.—Violently delirious during the night, and continues so. Lips and teeth incrustated; skin less pungently hot; tongue deeply fissured, dry; last night passed four loose motions and urine involuntarily; respiration, 40; no friction sound audible; pulse, 140, very weak and small. Ordered to have three ounces of brandy immediately and ten ounces of wine daily; to continue the pills every six hours; to have applied over the abdomen a poultice of linseed with laudanum.

11th.—Delirium continues, but is not constant; face flushed; spots disappearing—no fresh ones; bowels continue loose; respiration, 32; bronchial breathing at both apices, most marked on the right side, where is dulness on percussion; pulse, 130, small and weak; headache very severe. To have an enema of starch, with twenty minims of tincture of opium, directly; wine reduced to six ounces.

13th.—Restless; no delirium; replies readily to questions; bowels open once since injection; tongue moist, fissured, florid; very little abdominal tenderness; respiration, 26; pulse, 112, small; headache relieved by the ice—very severe when this is not applied.

14th.—Better night; respiration, 30; pulse, 124; numerous pemphigenous spots on the back. To have eight ounces of wine daily; arrowroot, milk, and beef-tea as before.

15th.—No delirium; perspired freely last night; no fresh spots—a few are still visible; abdomen tender on pressure; much gurgling; two dark loose motions to-day; respiration, 32; frequent cough; pulse, 116, very small, firmer. To have turpentine fomentations to the abdomen, and tinct. of iodine painted over the chest.

17th.—Much improved; skin hot, moist; spots all gone; tongue clean, mammillated; bowels confined; less thirst; no pain in abdomen, unless it is pressed; respiration, 28; breathing good at the bases of lungs; bronchial at right apex as before; pulse, 98, small, soft; headache slight.

21st.—Convalescent; aspect cheerful; bowels quiet; abdomen quite free from tenderness; appetite returning; respiration, 24; cough troublesome in the night; pulse 92, fuller, soft; no headache; occasional deafness and tinnitus aurium. To have an egg daily.

23rd.—Awoke in the night with sharp pain in the abdomen, which passed off. Bowels rather loose. Respiration 24, pulse 76. To take one of the pills each night, and a draught of carbonate of soda and tincture of orange thrice daily. To have two eggs daily.

28th.—Except a slight return of abdominal pain on the 25th inst., which was relieved by turpentine fomentations and a small dose of castor oil, the patient has steadily improved; she is now able to be up during part of the day. Ordered to have fish diet.

On December 21 she was discharged well.

Case 5.—Thomas R., aged 23 years, admitted under the care of Dr. Goodfellow on February 13, 1862. About five days before admission, after living badly for some time, began to suffer from anorexia, thirst, headache, tinnitus aurium, cough with some dyspnoea and general malaise; had also epistaxis several times. The bowels were confined.

On admission his face was deeply flushed, the lips dry; skin hot and dry, almost covered with a measly eruption, the spots ill-defined and irregular, of a dusky colour, not disappearing on pressure; bowels rather relaxed; slight tenderness in hepatic region, none elsewhere; tongue dry, brown in centre, grey and moist at edges; much thirst and anorexia; respiration 30, short; subcrepitan rhonchi at base of lungs; some cough; pulse 112, moderately full; heart sounds distant. Complains of vertigo and constant tinnitus aurium; no deafness or headache; slight strabismus of both eyes; somnolent, but mind coherent; urine amber coloured, clear, acid, sp. gr. 1022, giving slight phosphatic cloud with heat, about $\frac{1}{2}$ th albumen. Solids 51·26 grs. in 1000; urea 36·95 grs. in 1000. The head was ordered to be shaved, and spirit lotion applied to it. Simple diet and beef-tea with a drink of two drachms of chlorine water in a pint of water were ordered, and a draught containing five minims of nitro-hydrochloric acid every second hour.

February 14.—Slept fairly; no delirium; eruption more dusky; bowels open once during the night; motion loose, free from blood; respiration 26, short; pulse 128, small, compressible; urine sp. gr. 10·18, acid, amber coloured, albumen about $\frac{1}{2}$ th.

15th.—Muttering delirium during the night. Spots marked yesterday are less distinct; no true petechiæ. One feculent motion free from blood. Respiration 40. Sputa rust coloured. Pulse 120. Urine: Sp. gr. 1019, acid, amber coloured, 16 ozs. during twenty-four hours; a trace of albumen; solids 44·25 grs. in 1000, 339·84 grs. in the whole; urea 28·50 grs. in 1000, 218·88 grs. in the whole. To have a pill containing a grain of Dover's powder and two grains of hyd. c. cretâ night and morning. To continue the draught. To have as much wine as he likes.

16th.—Rather restless during the night. Several true "rose spots" are visible among the dusky patches. Bowels

open twice. Respiration 52. Pulse 124. Tinnitus continues. No headache. Urine in twenty-four hours, 18 ozs., sp. gr. 1015, acid, amber coloured; albumen a trace; solids 301.96 grs. in whole, 34.95 grs. in 1000; urea 241.22 grs. in whole, 27.92 grs. in 1000.

17th.—Much the same. Respiration 44. Pulse 124. Urine in twenty-four hours 17 ozs., acid, amber coloured, with deposit of urates: sp. gr. 1017; trace of albumen; solids 39.61 grs. in 1000, 323.20 grs. in whole; urea 25.32 grs. in 1000, 206.62 grs. in whole.

18th.—Slept well. Skin less hot and dry. Numerous petechiæ are now visible. Tongue moist, cleaning. Bowels confined. Respiration 36. Cough almost gone. Pulse 128. No headache, no deafness, nor tinnitus. Urine in twenty-four hours, 33 ozs., dark amber coloured, turbid with urates, acid, sp. gr. 1018; no albumen; solids 41.94 grs. in 1000, 664.32 grs. in whole; urea 14.975 grs. in 1000, 237.20 grs. in whole. To omit the pills; continue the draught and 6 ozs. sherry.

19th.—Urine passed chiefly at stool, amber coloured, clear, acid, sp. gr. 1020; no albumen; solids 46.60 grs. in 1000; urea 17.52 grs. in 1000.

20th.—Sleeps quietly. No fresh spots. Bowels relaxed. Tongue cleaning. Respiration 36. Pulse 96. Low spirited, and complains of headache. Urine acid, clear, pale amber coloured, sp. gr. 1017; no albumen; solids, 39.61 grs. in 1000; urea 18.08 grs. in 1000.

22nd.—Much improved. Rash nearly gone. Bowels quiet. Tongue almost clean. Cough troublesome. Respiration 32. Pulse 96. No headache. Deafness continues. Urine in twenty-four hours, 30 ozs., acid, light amber coloured, sp. gr. 1018; no albumen; solids 41.94 grs. in 1000, 559.53 grs. in whole; urea 32.30 grs. in 1000, 565.12 grs. in whole. To have a draught of acetate of ammonia every six hours.

24th.—Urine in the twenty-four hours 32 ozs., acid, pale amber coloured, sp. gr. 1018; no albumen; solids, 41.94 grs. in 1000, 644.19 grs. in whole. Urea 30.00 grs. in 1000, 460.08 grs. in whole.

March 2.—Is able to be up a little. Perspired very freely last night. Bowels open once daily. Appetite good. Resp. 23. Pulse 72. Senses all perfect. Urine in twenty-four hours, 60 ozs., acid, clear, straw coloured, sp. gr. 1010; no albumen; solids, 23.30 grs. in 1000, 671.04 grs. in whole. Urea, 9.30 grs. in 1000, 267.85 grs. in whole. To omit the medicine, to have good diet and continue the wine.

11th.—The patient continued to improve rapidly, with the exception of a rash appearing over the body like that of scabies. This was relieved by the use of sulphur. Discharged to-day.

Case 6.—Thomas S., aged 61 years, a laundryman, was admitted under the care of Dr. Goodfellow on February 13, 1862. This patient had a very low form of typhus. The rash was very well marked, with constant and long-continued low delirium and extreme prostration. He remained in a very precarious state until February 23, when some degree of improvement was manifest, and from that time he became slowly convalescent, and left the Hospital at the end of March. The treatment consisted of quinine, acids, and bark, with abundance of wine, beef tea, etc.

(To be continued.)

MUNIFICENCE.—The Right Hon. Lord Stanley, M.P., has just transferred to trustees the sum of £1000 for the benefit of the West Norfolk and Lynn Hospital, and the friends of the undermentioned Medical charities will be glad to learn that their respective funds have been increased by the following liberal bequests under the will of Mrs. Elizabeth Veal, of Bellevue, Hampstead, which has just been sworn under £10,000. This lady has directed that £500, free of duty, be given to University College Hospital, £500 to King's College Hospital, and £500 to the Cancer Hospital. The late Sir William Brown, Bart., of Richmond-hill, has bequeathed to the Northern Hospital, Liverpool, £1000; the Southern Hospital, £500; the Royal Infirmary, £500; Deaf and Dumb School, £500; Blind School, £500; and to the Eye and Ear Infirmary, £100. Thus we have the magnificent sum of £5600 distributed to Medical charities in one week.

CASTOR-OIL IN THE FORM OF PILLS.—M. Stanislas Martin recommends the following as an easy mode of administering castor-oil. Rub up together oil 15, powdered gum acacia 8, and water 15 parts, and then gradually add 15 parts of wheat flour. Mix well together, and divide into boluses or pills, which, left exposed to the air, soon become dry. The purgative action may be increased by substituting an equal quantity of magnesia for the flour.—*Bull. de Thérap.*, May 15.

SATURDAY, MAY 28.

THE LA POMMERAIS TRIAL.

THE trial for poisoning which has lately been concluded in Paris demands a more than passing notice. It may be said to mark an era in the history of toxicology. Hitherto, the great means by which science has aided justice have been the test-tube and the balance, whilst physiological experiments, if offered as evidence at all, have been received as of doubtful, or, at least, of inferior, value. We do not call to mind any previous instance of alleged poisoning where experiments made on animals with the vomited matters and extracts derived from the viscera have been considered sufficiently trustworthy scientific evidence to support a conviction. It will be remembered that this kind of proof was recently offered in this country by a distinguished toxicologist, but the jury did not consider it so free from doubt as to warrant the condemnation of the accused. We may at once say that we entirely agree with the verdict in the Parisian case. The amount of moral evidence against La Pommerais was enormous, and, taken together with the symptoms and mode of death of the murdered woman, and the absence of all previous disease, as proved by the post-mortem examination, constituted an overwhelming weight of proof. We also freely admit that the results of the experiments made by MM. Tardieu and Roussin were perfectly in accordance with, and intensified the force of, the other evidence. But even in this instance we are not prepared to regard the physiological as the main proof against the prisoner; neither are we disposed to accept evidence of this kind as of equal value with chemical—at least, until the action of all toxic substances, organic and inorganic, upon the lower animals has been more systematically and carefully investigated and compared with their known effects upon the human subject. It is quite true that there are certain organic vegetable poisons, of which digitaline is one, which cannot, in the existing state of chemical science, be isolated and satisfactorily demonstrated. Where poisoning by these is suspected, physiological experiment may be accepted as an ancillary mode of investigation; but we hold that it would be dangerous at present to exalt such proof into the rank of a certain and crucial test.

The enormous amount of evidence taken in the late trial obliges us to confine our attention solely to the Medical and toxicological details. Of these we shall endeavour to acquaint our readers with the most important. We may notice, however, that La Pommerais was tried for two murders—that of his mother-in-law, Madame Dubizy, of which he was acquitted, and that of his mistress, Madame de Pauw. It is to the facts of the latter case that we shall alone refer.

In order to give the following account the form of a connected history, we may remind our readers that the prisoner is a homœopathic Practitioner; that he had induced his victim to insure her life for the sum of £22,000 in eight different insurance offices; that he had also persuaded her to assign

the insurances to himself. A short time before her death, she had, by his advice, feigned illness in order to deceive the insurance offices, and obtain from them a life annuity in place of an insurance. Although a homœopathic Practitioner, La Pommerais was found to be possessed of a large quantity of the most potent poisons. In the month of June last, he had purchased three grammes of digitaline, of which only fifteen centigrammes remained in his possession. At eight o'clock in the evening before the death of Madame de Pauw, La Pommerais visited her. Directly after he left she was taken ill, vomited violently through the night, and died at five o'clock in the afternoon of the next day.

It was on the 17th of November last that M. Paul Blachez was called to attend Madame de Pauw. On his arrival, he found her in a dying state. She was apparently unconscious, at least it was impossible to elicit any sign from her; her body was covered with an abundant cold sweat; there was great disturbance of the circulation, the pulse being irregular and intermitting. She cried out continually, in a weak voice, "Oh, my head! oh, my head!" She retched several times, but whilst he was with her did not vomit freely. She then fainted so completely that her pulse entirely disappeared, a whitish froth escaped from her mouth, and she died. He at the time attributed her death to the rupture of an aneurism. She had, however, in the September previously, consulted, amongst other Medical men, a M. Gaudinot, on account of a fall which she asserted she had had, and he had attended her at intervals up to the day of her death. M. Gaudinot was applied to for a certificate of the cause of death, and he gave one to the effect that it was the result of gastro-enteritis, produced by the fall, and terminating in perforation of the stomach. Our readers will remember that the whole story of the fall and of her subsequent illness was fabricated for the purpose of deceiving the insurance companies. The evidence proved that she had been in excellent health up to the time of her death, and that just before she was taken ill she had dined heartily on vegetables.

Thirteen days after her death the body was exhumed under the superintendence of M. Tardieu, Professor of Legal Medicine and Dean of the Faculty of Medicine in Paris. The body and external organs were in a state of perfect preservation—so perfect that had any lesions, the result of previous disease, been present, they would have been at once recognised. The results of the autopsy were entirely negative. The heart was unaltered in size, and its valves acted perfectly. The blood was semi-coagulated, but there was an absence of clots. The lining membrane of the stomach was perfectly healthy, that of the intestines presented some sanguineous infiltrations, but they were few in number. The deceased was advanced seven or eight weeks in pregnancy. The chemical analysis, which was conducted by M. Roussin, was made by obtaining alcoholic and watery extracts of a portion of the stomach and intestines. The solid residue exhibited no trace of mineral poison, neither was any organic poison which could be isolated obtained from the extracts.

Shavings of the floor of the apartment on which the deceased had vomited were also procured, and for the purpose of comparison shavings from the floor of a different part of the room. From the former sixteen grammes and a-half of alcoholic extract were obtained. This had a brown colour, a peculiar rancid and oily odour, and a very bitter taste. On incineration it left no metallic residue; it was precipitated abundantly by tannic acid; the addition of sulphuric acid turned it of a reddish purple colour, and hydrochloric acid produced a green tint. The extract of the shavings which were unsoiled by the vomited matters had an aspect and odour closely resembling the preceding, but it had no bitter taste, it was not precipitated by tannic acid, and only slightly coloured by sulphuric and hydrochloric acids; the tints struck by these acids were entirely different to those produced in the former extract.

It was clear that this result proved nothing as to the

existence of poison. The change in colour produced by sulphuric acid, and the precipitation by tannic acid, are reactions common to many organic matters, and, as was observed by M. Hébert, the green colour which followed the addition of hydrochloric acid would have been a more important indication had the chlorophyll of the vegetables (cauliflower and sorrel) which she had eaten, and the green colouring matter of the bile, been previously removed. In the failure of their chemical investigation, therefore, the experts had recourse to physiological experiment.

The first trial was made with the extract obtained from the shavings of the floor on which deceased had vomited. At five minutes past one a dog was inoculated with five grammes of this extract, introduced by two incisions on the inner surface of the thighs. At half-past three, the animal vomited thrice. The vomited matters were glairy and bilious. The pulse, which at the commencement of the experiment was 110, had fallen to 94; it was irregular and intermittent. The beat of the heart was irregular and intermittent, at times appearing to cease suddenly, and then becoming rapid. The respirations were slightly intermittent. At half-past four the heart-beats fell to 76, and the animal again vomited. At eight in the evening it could stand with difficulty. The slightest movement appeared painful, and provoked vomiting. The heart beats were still irregular, and 68 in the minute. At eight the following morning the animal was cold, but sensible. The heart-beats were less strong, and had fallen to 40. Their irregularity and intermittence were very remarkable. Respiration was jerking and intermitting. The animal died at eleven o'clock, apparently without pain. There was no coma. The examination of the body was made two hours after death. The ventricles of the heart were markedly contracted, although the auricles were dilated. All the cavities of the heart were filled with black, thick, and partly coagulated blood. On removing the pericardium some elevations of a vivid red colour were observed on the surface of the heart near the apex.

2nd Experiment.—Two grammes of the same extract were administered by the mouth to a rabbit. Great irregularity of the heart's action ensued. The beats fell to 41 in a minute. The animal died in two hours and three-quarters from the administration of the extract. The eardiae auricles were found dilated, the ventricles contracted, the latter strongly contrasted by their blackish colour with the rest of the organ. The interventricular space was remarkably depressed. The apex of the heart was of a vivid red colour, and the walls presented several red elevated spots.

The third experiment was one made for the sake of comparison with the extract obtained from the shavings of the floor, on which the vomited matters had not fallen. Four grammes of this extract were administered to a rabbit. It did not vomit nor was it in the least incommoded, and two days afterwards it continued in perfect health.

The fourth experiment was made with the alcoholic and aqueous extracts obtained from the stomach and intestines of the deceased. Five grammes of a mixture composed of equal parts of these extracts were introduced into an incision made on the inner surface of the thigh of an adult vigorous dog. At three o'clock the animal's pulse beat 102 in a minute. At half-past four it seemed depressed, anxious, it respired with difficulty, and its pulse had fallen to 86, and the heart's action was irregular and intermittent, but less so than in the case of the dog experimented on with the vomited matters. The animal vomited twice. At eight in the evening the pulse had fallen to 55, and was manifestly irregular and intermittent. Respiration seemed difficult. The animal frequently changed its position and uttered half stifled cries; it retained its intelligence. The following day, at half-past eight in the morning, the beat of the heart had risen to 70 pulsations in the minute; the general condition of the animal was improved, and it ultimately recovered.

The fifth experiment was also made with the extracts of the

viscera. Four grammes were administered to a rabbit, which died in a few minutes. The experimenters thought that its rapid death was owing to some accidental complication—perhaps syncope—having hastened the action of the poison.

The sixth experiment was performed on three frogs. After having laid the heart bare in each, and observed that the pulsations in the three were perfectly equal, the experiment proceeded as follows:—

1. The first frog was left in the normal condition, care only being taken to preserve the humidity of the heart.

2. The second frog. Six drops of a solution containing one centigramme of digitaline in six grammes of water were injected under the skin of the belly.

3. The third frog. Fifty centigrammes of the extract made from the shavings of the floor on which the vomited matters had been spilt were injected under the skin of the belly.

The following variations in the number and beats of the heart were observed in the three animals:—

Minutes.	No. 1. Pulsations.	No. 2. Pulsations.	No. 3. Pulsations.
After 6	. 42	20	26
„ 10	. 40	16 irregular	24 irregular.
„ 20	. 40	15 id.	20 id.
„ 28	. 38	0	12 very irregular.
„ 31	. 36	0	0

This experiment was repeated several times with the same result.

The experts relied on the first experiment as proof of the fact that the vomited matters contained poison. The third demonstrated that the poison did not previously exist in the floor of the room. The fourth was held to prove that the stomach and intestines of the deceased contained the same poison, but in less quantity than the vomited matter, the dog having recovered from its effects. The sixth experiment on the frogs was instituted to demonstrate the nature of the poison used. The experimenters did not consider it of the highest importance, but it corroborated the former ones. It pointed to that group of organic poisons which are known especially to affect the heart's action, and heightened the probability that death had been caused by digitaline. The report of M. Tardieu drew a comparison between the symptoms exhibited by the first dog and those noticed in the last illness of the deceased. In both there were repeated and violent vomitings, and rapid loss of power. In both the pulse was irregular and intermitting; in both the heart's action was tumultuous and irregular, apparently ceasing at times, until it was finally suppressed. The following were the conclusions of the report:—

1. Madame de Pauw died from the effects of poison.

2. The poison which killed her was one of those vegetable poisons which do not leave characteristic traces in the organs of the body, nor can they be isolated by chemical analysis. They reveal their presence by their effects, and are detected by their deadly action on living beings.

3. We obtained from the vomited matters and the organs of deceased submitted to analysis a very energetic poisonous principle which, when administered to animals, produced analogous effects to those observed in Madame de Pauw, and killed them in the same manner.

4. These effects and this action have a strong resemblance to those of digitaline, and without asserting it as a fact, there is a strong presumption that Madame de Pauw was killed by that agent.

5. That deceased was not really ill before the day which preceded her death.

6. The post-mortem examination proved that death was not caused by the effect of a fall, nor by an internal hæmorrhage, nor by an acute or chronic gastro-enteritis, nor by a perforation of the stomach, nor by any natural cause.

We will only add that M. Tardieu's report is drawn up with marvellous clearness, minuteness, and perspicuity, and is a model in way of arrangement and execution for similar documents.

We have now to examine the criticisms on the report of MM. Tardieu and Roussin, offered by M. Hébert, the expert employed for the defence. The first point noticed by M. Hébert was, that the unusual preservation of the body, as poisoning by any mineral substance was out of the question, did not favour the idea of poisoning. He next asserted that neither the chemical nor the physiological experiments made with the shavings of the floor on which the vomited matters had been spilt, were of any force. The reason for assigning no weight to the chemical experiments we have already noticed. The objections to the physiological experiments were the following:—The extract of the vomited matter contained organic matter in a state of decomposition, sufficient of itself to produce toxic effects. The dog in the first experiment exhibited a gradual and progressive retardation of the heart's action, and after death that organ was found in a state of contraction. There are two reasons for believing that death did not result from digitaline—the first, because MM. Bouley, Reynal, Delafond, Dupuy, and Stannius, have found that digitaline in small doses retards the heart's action, but accelerates it if given in considerable doses. Secondly, that in poisoning by digitaline the heart, instead of being contracted, is dilated and gorged with blood.

With regard to the state of the heart, the same objection applies to the rabbit used in the second experiment. The rabbit also being an herbivorous animal was one of the worst which could be selected for an experiment with digitaline, for MM. Homolle and Quevenne have demonstrated that herbivora, and rabbits especially, are refractory to the action of digitaline. The dog submitted to the fourth experiment was only indisposed; it did not die, much to M. Hébert's surprise, for there had been injected into its subcutaneous cellular tissue alcoholic and watery extracts of the viscera of a person who had been dead a fortnight. Although the parts were in a remarkable state of preservation, it could not be alleged that no process of decomposition had taken place in that time, and the known facts of poisoning by decomposing animal matters completely account for the phenomena observed. With regard to the frogs, M. Hébert observed that these animals were worse chosen than the rabbits, because, according to Stannius, they are exceedingly refractory to the action of digitaline. M. Hébert was astonished at the statement that the number of cardiac pulsations was perfectly equal in the three animals, because in experiments made by him he had found notable differences. The preliminary operation to which they had been submitted, consisting of raising the skin, the abdominal muscles, and sternum, in order to bare the heart, would suffice by the hæmorrhage and shock produced to sensibly alter the action of the heart and to diminish the number of its pulsations. In the first frog experimented on by the experts the pulsations had fallen from forty-two to thirty-six, whilst in one experimented on by M. Hébert they had fallen in thirty-one minutes from fifty-seven to forty-three. M. Hébert expressed himself surprised at the result of the experiment on the second frog, because he had made similar experiments with a solution of exactly the same strength. One frog had received thirty-six drops in six injections without any inconvenience; a second received fifty drops in one injection, and was but slightly indisposed, and soon recovered.

Two other objections were especially urged by M. Hébert. One was that the experts had not for comparison poisoned a dog with digitaline in the same manner that the dog was poisoned with the extract of the vomited matters. The other was that they had not repeated the experiment on the dog which recovered by administering a stronger dose of the extract derived from the stomach and intestines. M. Hébert concluded by insisting on the following points:—1. That there was no chemical evidence of poisoning. 2. That the experiments made on animals not only were insufficient to demonstrate the presence of digitaline in the vomited matters, but, on the contrary, proved positively that the vomited matters did not contain it. 3. That no animal was poisoned by the

extract of the organs of the deceased, and that the symptoms observed in the dog inoculated with it were attributable to the action of putrified organic matter. He concluded that the existence of poisonous matter supposed to be digitaline had not been demonstrated, and that the facts alleged in the report of the experts did not prove that the deceased had been poisoned.

It will be observed that M. Hébert limited his attack on the evidence given by the experts to what we believe to have been the most vulnerable point in their report—the physiological experiments. He left entirely unnoticed the symptoms which had been observed before death, and the entire absence of natural disease revealed by the autopsy of the deceased. The objection to the report, founded on the state of preservation of the internal organs of the body, was answered by the statement that the experts did not rely upon that condition as any proof of poisoning, but simply as enabling them to pronounce definitely as to the non-existence of previous disease. The assertion that the extract obtained from the viscera really contained organic matter in a state of putrefaction was met by the statement that the matter with which the dog was inoculated was not the mere *débris* of the organs themselves, but was the product of the treatment of the organs with alcohol at 95°, and with boiling water, and subsequent filtration and evaporation. The objection that a second dog had not been poisoned by digitaline was answered by the assertion that the experimenters had not thought it necessary: their conviction was complete. Moreover, that the readiness with which a dog vomits was a reason for not administering to that animal digitaline by the mouth. The only way to obviate immediate vomiting was by tying the gullet—an operation which was now allowed to have thrown doubts on the results of all Orfila's experiments. We may observe, however, that this was no answer to the objection that digitaline had not been introduced into the subcutaneous cellular tissue. Another objection, that a larger quantity of the extract of the stomach and intestines had not been given to the dog which recovered, was met by the assertion that the dog was poisoned, although it did not die. Its pulse fell from 100 to 50. It was clear that the poison existed in less quantity in the viscera than in the vomited matters. In answering the objections derived from the action of putrefying substances, M. Tardieu referred to a paper by M. Reveil, now before the Academy, which the writer supposes to have established the fact, that, contrary to the observations of Orfila and other authors, no poisonous substance, such as the cyanide of ammonium, separable by solvents or distillation, is formed during putrefaction. It need scarcely be observed that such an unsupported assertion, derived from a document not in court, would not have been received as evidence in England.

After a long discussion between the experts for the prosecution and M. Hébert in reference to the extract from the soiled shavings, the latter limited his position to the following assertion:—"That the product had caused the death of the dog inoculated with it, but that the death was not such as digitaline would have produced; and that, instead of concluding digitaline was present in it, we ought logically to conclude that it was not."

An objection was also made to the evidence derived from the shavings of the floor on the ground that the apartment had been previously occupied by a photographer, and that some of the chemicals used in his business might have fallen and remained on the floor. The matters, examined, however, were found to have been recently spilt. The photographer had not occupied the apartment for three months previously. Analysis gave no evidence of a salt of silver or of any mineral substance, whilst such substances as the cyanide of potassium, which are used in photography, would have become long before decomposed.

The evidence of MM. Claude Bernard, Vulpian, Bouley, and Reynal was taken on the question raised by M. Hébert,

whether, after poisoning by digitaline, the heart was contracted as asserted by the experts, or dilated as stated by M. Hébert. M. Claude Bernard stated, as the result of his experiments, that in the higher animals, when poisoned with digitaline, there is at first agitation, then, after some hours, death takes place suddenly, as if from syncope. A particular characteristic of poisoning by this substance is that immediately after death red arterialised blood continues to be poured into the left cavities of the heart, because respiration continues after the complete arrest of the cardiac pulsations. Death, therefore, occurs from the cessation of the heart's action, and at first the organ is dilated by the blood which continues to flow into its cavities. But cadaveric rigidity follows much more rapidly in the muscular structure of the heart than in the other muscles of the organism. Contraction of the ventricles, therefore, rapidly replaces the dilatation, and in the course of a very few minutes they empty themselves of the blood which has been poured into them. A quarter of an hour after death the state of contraction is clearly manifest, and the rigidity continues. In answer to questions put by M. Hébert, M. Claude Bernard said that there was nothing in the condition of the dog poisoned in the first experiment which appeared to him to contra-indicate the idea of poisoning by digitaline. But the experiment would have been more convincing had the autopsy been made a few minutes instead of two hours after death. In his experience there is often in poisoning by digitaline at first an acceleration of the heart's movements, but that finally retardation sets in, and continues to increase until complete arrest terminates life.

M. Vulpian's evidence referred to the effect of digitaline on frogs. He dissented from the statement of Stannius that digitaline did not affect batrachian reptiles. On the contrary, he found that the action of digitaline was most powerful on frogs. When injected under the skin it produced in a few minutes manifest changes in the movements of the heart; the auricles begin to contract somewhat irregularly, but the movements of the ventricle are especially affected, they contract with great irregularity, certain points of the ventricle appearing to escape the general movement; at the same time the pulsations become slower and slower, and after some minutes the heart becomes motionless. The ventricle stops first and remains empty, pale, and contracted, the auricles continue for a short time to act, but too feebly to force the blood into the ventricle; they remain fully dilated after the contraction of the ventricle. There is also this peculiarity observed, that even after the arrest of the heart's action the frog will continue to leap about with but little less vivacity than in the normal condition. There are several other poisons which act in the same way as digitaline when introduced under the skin of the frog; these are, the poison of the toad and of the aquatic salamander, *Upas antiar*, alcoholic extract of *Tanghinia venenifera*, and watery and alcoholic extracts of the *Veratrum viride*. M. Vulpian concluded by stating that he had tried other vegetable poisons and tannin, and had never observed analogous phenomena.

The experiments of MM. Bouley and Reynal had been made with digitaline on horses. They had never observed the cardiac ventricles contracted. On the contrary, the heart had always appeared flabby; but as the examinations were made five or six hours after death this might have been due to the commencement of putrefaction, which takes place much more quickly in herbivora than in carnivora, especially after death by the vegetable poisons.

The only other point to be noticed is that La Pommerais had endeavoured to explain the great diminution in the quantity of digitaline found in his possession by saying that he prescribed it externally as well as internally, and that besides furnishing it to his patients, he had distributed it to students who were his pupils. He said he had also sent a quantity to his brother-in-law, a chemist, in the country, who had the packet still in his possession. The packet was subsequently produced, and submitted to analysis by M. Roussin.

Analysis showed that if digitaline was present at all it was in infinitesimal proportions. The contents of the packet consisted of sugar of milk.

In concluding an article, the length of which is only justified by the scientific importance of the trial, we shall offer but few comments. As we have said, we believe the guilt of the prisoner was entirely proved, but we regard the evidence of the experts (we refer to their experiments) although confirmatory, and, on the whole, satisfactory of its kind, as the least portion of the proof against him. We should be sorry, in the present state of science, to see a conviction for murder on such evidence alone.

A writer in a French journal has criticised the report of MM. Tardieu and Roussin on the ground that it descended too deeply into minutiae, and as, for instance, in noticing the contracted condition of the heart, invalidated their conclusions by raising points on which a critical defence could seize. We do not sympathise with the objection. If a man's life depend on a physiological experiment, for Heaven's sake let the minutest particulars be observed and noted, whether they weigh in the scale of guilt or innocence. A more valid criticism appears to us to have been that it would have been better to avoid experiments on animals so remote in the zoological scale from Man as rabbits and frogs. We are, however, most ready to confess that, considering the great difficulties under which the investigation was conducted, it was performed with surpassing skill and sagacity. We only wish that all the great Medico-legal inquiries which have taken place in this country were as creditable to British science. But whilst thus expressing our appreciation of the performances of the experts, we are bound to add that never were we more impressed with the superiority of English judicial proceedings than when reading the reports of this trial. The debates—we had almost said altercations—between the experts for the prosecution and defence would have been scarcely tolerated in an English Medical Society, much less in a court of justice; whilst the frequent interruptions, the loose reception of evidence, the attacks of the judge on the prisoner, and his mode of detracting from the value of the evidence offered by the defence, contrast most strongly with the order, the careful sifting of evidence, and the even-handed fairness which are the characteristic features of our own legal tribunals.

THE WEEK.

APPOINTMENT OF EXAMINER AT THE ARMY MEDICAL BOARD.

MR. PAGET, after holding the post of Examiner in Surgery to the East India Company, and then to the Army Medical Department for ten years, has been compelled by the increasing claims of private practice to resign the appointment. It has been with difficulty, indeed, that for two or three years he has found time to go through the serious labour entailed by the examination. The Secretary of State, at the suggestion of the Director-General, has appointed Mr. Prescott Hewett, of St. George's, who will prove a worthy successor to Mr. Paget. Mr. Hewett has declined some appointments of a similar kind, but we congratulate the Medical Department of the Army that he has consented to accept this important post.

PARLIAMENTARY.

ON Thursday, May 19, the House of Commons reassembled after the Whitsuntide recess.

On Friday, May 20, Sir J. Pakington asked what causes had led to the war with the King of Ashantee; and whether there was any prospect of Her Majesty's troops being relieved from the destructive effects of that climate by a peaceful solution of that question. He wanted to know, he said, not only what were the causes, but what were the objects of the war. He described the destructive effects of the climate upon the negro as well as the European troops, and expressed a hope that the policy in which the war originated would be put a stop to.

Mr. Cardwell explained very fully the origin of the war, the

preparations made for it, and the precautions taken for securing the health of the troops, the views of the Government in engaging in it, and the state of affairs up to the date of the last mail. He said that in conjunction with the War Office and the Horse Guards, he had taken measures for withdrawing our troops from the interior of the country, and placing the defence of the Prah in the hands of those native chiefs whose duty and interest it is to protect their own territories from hostile incursions. He added, "We also propose, as far as possible, to provide for the safety, health, and well-being of our troops on the Gold Coast; and though it is impossible to speak with any certainty as to unknown and unforeseen occurrences, I entirely sympathise with the feeling that it is not our duty to make expeditions into the interior of such a climate as that of Africa. We have no desire whatever for any extension of territory; we have no wish to make wars of conquest or of vengeance; and as the rains have put an end to the late warlike preparations, so it is not our intention to renew them for the purpose of invading the territory of the King of Ashantee."

In the House of Lords on Monday, May 23, the Lord Chancellor moved the second reading of the County Courts Acts Amendment Bill.

Lord Brougham was of opinion that the Bill required amendment in Committee.

Lord St. Leonards said that this was a question of great social importance. By the existing law a debt was recoverable for a period of six years from the time of its contract, acknowledgment, or part payment, but the present Bill declared that no debt under £20 should be recoverable after the expiration of a year from the time of its being due. He saw no reason for this reduction of the term of six years to one year, and he was certainly of opinion that the period within which small debts might be recoverable ought not to be less than three years. In his opinion, the Bill was one which would have as wide an operation as it was possible to conceive, and, if passed into law, it might fairly be called a Bill for stopping the credit of the labouring classes. He strongly objected to county courts being turned into courts of equity.

Lord Chelmsford looked upon the Bill as involving a social question of the highest importance; it was a question which required the most cautious deliberation. He should not offer any opposition to the second reading of the Bill, but its future progress required to be watched very narrowly.

Lord Lyveden supported the Bill.

Lord Cranworth approved the material features of the Bill, and gave his cordial assent to the second reading.

The Bill was read a second time.

THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH ON THE STATE OF THE ARMY MEDICAL DEPARTMENT.

We publish with great pleasure the following memorial on the subject of the present condition of the Army Medical Department, addressed by the Royal College of Physicians of Edinburgh to Lord Palmerston. We hope that the other licensing and examining bodies will join with the Edinburgh College in pressing this matter on the attention of Government. The state of the Army Medical service is not only disgraceful to the authorities, but now absolutely injurious to the interests of the public:—

"To the Right Honourable Viscount Palmerston, First Lord of Her Majesty's Treasury,

"The Memorial of the Royal College of Physicians of Edinburgh, Humbly Sheweth,—

"That the Royal College of Physicians are charged with the licensing of Medical Practitioners, and are therefore bound to watch over the interests of the Medical Profession and of the public.

"That the attention of the College has been frequently drawn to the very unsatisfactory condition of the Medical Department of the Army; and that the evils often complained of have now become so aggravated that they consider themselves called upon, in the public interest, to bring the subject directly under your lordship's notice. Your memorialists would, therefore, beg respectfully to lay before your lordship the following statement of facts:—

"Previous to 1854 public attention had not been specially directed to the Medical Department of the Army; and though the officers of that Department considered that they laboured under various hardships, a sufficient supply of Medical men

for the wants of the Service could always be obtained. On the outbreak of the Crimean war, it was soon discovered that there was a great deficiency of Medical officers; and this deficiency was subsequently the cause of a great amount of suffering among the troops. As it was found impossible to obtain a sufficient supply of regular Assistant-Surgeons, passed according to the requirements of the Army Medical Board, a number of civilians were engaged as Acting Assistant-Surgeons, to perform the duties of Commissioned Assistant-Surgeons. Notwithstanding, the Medical Department of the Army confessedly broke down, in consequence, not of the inefficiency of the officers, but of the smallness of their number.

"In 1856 a Select Committee of the House of Commons considered the whole subject, and recommended in their report that the pay of Assistant-Surgeons should be increased, and that means should be taken to make it unnecessary in future to have recourse to Civil Assistants.

"In 1857 a Royal Warrant was issued, which raised the pay of Assistant-Surgeons to ten shillings per day.

"In 1858 a new Royal Warrant for the Medical Department of the Army appeared, which was justly regarded as a great boon by the officers of that service. Among other important concessions, it was ordered that Medical officers should have a certain rank relative to combatant officers, and that this rank should carry with it all precedence and advantages, with the single exception that the presidency of courts-martial should always be held by combatant officers. The result of these concessions was, that an abundant supply of eligible candidates presented themselves, so that the authorities were enabled to raise the standard of examination and of qualification.

"Complaints, however, were soon made that the Warrant of 1858 was not fully carried out, and especially that the regulation with regard to relative rank was systematically violated.

"On the 28th of March, 1861, a new Warrant was issued, ordering that Assistant-Surgeons, promoted after that date, should rank with majors, but junior of that rank; this order being in direct contravention of the Warrant of 1858, which directed that Medical and combatant officers should rank according to the date of their commissions. At the same time, a reduction in the number of Assistant-Surgeons was made, whereby additional duties were thrown upon the rest, and it became very difficult for them to obtain leave of absence.

"In 1862, an order was issued, that Staff and Regimental Surgeons should, in their annual reports, answer a variety of questions with respect to the Assistant-Surgeons who had served under them during any part of the preceding year. Some of these questions were of such a nature that one Gentleman should not be called upon to answer them in regard to another. Thus, the Surgeon was required to state the character of his Assistant-Surgeon as to sobriety, correctness of general conduct, temper, and similar points. This was felt degrading to the character of Staff and Regimental Surgeons, as constituting them spies upon their juniors, whereby suspicion and distrust were necessarily engendered.

"In March, 1863, a new Warrant was issued, which restored, though not in its full integrity, the relative rank conceded by the Warrant of 1858.

"The effect of the changes which have been introduced since 1858 has been deplorable. Many Medical officers have resigned, and it has been found impossible to supply their place. For some time past the number of candidates at the competitive examinations has been much below the number of vacancies; and of these candidates a large proportion have been found grossly ignorant, and have been rejected, which clearly indicates that the Army is unpopular among that class of Medical men whose services it would be for the interest of the Department to secure. So difficult has it been to procure candidates, that the limit of age of entrance has been raised from twenty-five to thirty; and that lately the Director-General has advertised for acting Assistant-Surgeons, who are eligible up to the age of forty years, and who are to take the place on home service of Commissioned Assistant-Surgeons.

"Your memorialists, viewing with great anxiety this very unsatisfactory state of an important branch of her Majesty's service, would beg respectfully to urge upon your lordship the necessity for a reform of the following grievances, to which military Medical officers are subject:—

"First, in consequence of vacancies not having been filled up, promotion has become so slow that no Assistant-Surgeon now entering the service can expect to become a Surgeon in less than fifteen years.

"Second, in consequence of the deficient number of Medical

officers in the army, it is with great difficulty that leave of absence can be obtained.

"Third, in consequence of the appointment for home service of Acting Assistant-Surgeons, the commissioned Assistant-Surgeons will be almost exclusively employed on foreign service, and will be deprived of their proper turn of serving in this country.

"Fourth, the system of confidential reports, of an inquisitorial character, is felt as a degradation, both by those who are required to draw them up, and by those to whose conduct they refer.

"Fifth, Medical officers are required to superintend the branding of deserters, and are thereby placed in a position which no Professional gentleman should be called upon to occupy.

"In name and by authority of

"The Royal College of Physicians,

"JOHN GRAHAM MACDONALD BURT,
"President.

"Edinburgh, 12th May, 1864."

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XVII.—MARCH 10.

The anatomy of the Orang-utang continued.—The skull of the orang presents a less marked prominence of the supra-orbital ridge than that of the gorilla, and the bony crests are less developed, although in this respect there are considerable individual differences. As a general rule, though by no means without exception, the parietal bones unite with the great alæ of the sphenoid, as they do in man, but not in the gorilla and chimpanzee. The mastoid process, as in the other anthropoid apes, has scarcely any prominence downwards, though it is much developed laterally. The styloid process is more conspicuous than in the gorilla or the chimpanzee. A vertical section of the skull shows that the cranial cavity is higher, in proportion to its length than in the other great apes; but this approximation towards the human type is more than balanced by other characters of degradation. The olfactory fossa is narrow, and produced downwards and forwards, so that the cerebral hemispheres hardly cover the olfactory lobes in front. The junction of the presphenoid and the ethmoid are not covered by a process of the frontal, but the first-named bone has a different form from that of the human subject. There is a mere trace of the fossa in the petrosal bone, which, in the lower apes, lodges a process of the cerebellum. As in the other great apes, the condyles are situated further back than in man, in the fourth fifth of the base of the skull. The general contour of the face is more excavated than in the gorilla and chimpanzee, the nasal bones are flatter, the macrognathism and prognathism are carried to about the same extent. The sides of the palate are straight, and somewhat approximated posteriorly. The pre-maxillary suture persists to adult age, as in the gorilla. In the lower jaw there is an entire absence of any mental prominence. To sum up the cranial characters, though in a few points the orang approaches nearer to man than do the chimpanzee and gorilla, in the great majority it either remains on the same level with these animals, or departs further than they do from the human type. On the other hand, the hyoid bone presents a decidedly greater resemblance to that of man.

The dentition offers no very striking characters of difference from that of the other great apes. It has the human peculiarities of the proportionate size of the different incisors, and of the patterns on the upper and lower molars. In other respects it exhibits the ape characters, especially in the great size of the canines, the multiplication of the fangs of the premolars, and the slope of the anterior edge of the first inferior premolar. As to the order of succession, the second permanent molar, both above and below, appears always to be in use before the canine and before the outer incisor. There is one specimen in the College museum which shows the canine fully developed before the third molar, but whether this is an individual peculiarity or the rule, there is not sufficient evidence to show,

The muscles of the orang have been dissected and described by Sandifort, Owen, Duvernoy, Church, and Professor Huxley. The account now given of them was confined to the anterior and posterior extremities, and they were grouped in the same way as had been done in the case of the chimpanzee and gorilla. 1. The muscles of the orang not commonly found in man are the levator claviculæ, dorso-epitrochlear, and scensorius. A most remarkable muscle belonging to this group was present in the specimen dissected by Professor Huxley, viz., an opponens hallucis, inserted into the middle third of the metatarsal bone of this hallux; this has not been described by other authors, nor, indeed, is there any trustworthy evidence of the existence of such a muscle in any of the Mammalia. 2. The muscles usually present in man, but not found in the orang, are the extensor primi internodii pollicis, and the peroneus tertius. 3. Muscles which differ essentially in their origin. The pectoralis major arises by two large slips leaving a considerable triangular interval between them. The soleus arises from the fibula alone. The flexor longus hallucis arises from the fibula, and from the outer condyle of the femur. This is a very remarkable circumstance, as the foot muscles scarcely ever arise from the upper bone of the limb, though an analogous arrangement is common in the upper extremity. The flexor brevis digitorum pedis has also a very singular origin by four heads, one from the calcaneum, giving the perforated tendon to the third digit, another from the sheath covering the long flexor tendons in the back of the leg, giving the tendon to the second digit, and the two others, furnishing the tendons of the fourth and fifth digits, arise from the tendon of the flexor communis in the sole of the foot. The dorsal interossei of the foot occupying the second space, change their origin so as to resemble the corresponding muscle in the hand. 4. Muscles which differ in their insertion. The extensor minimi digiti sends tendons to the fourth and fifth, and the extensor indicis to the second and third digits, so that every digit has a superficial and a deep extensor; this being the normal arrangement in many of the lower mammalia, is a mark of degradation in the orang's hand. It also shows that the extensor indicis and extensor minimi digiti, instead of being especially developed, as is sometimes stated, in the hand of man, are but fragments of a more extensive system of deep muscles found in the lower animals. The peroneus longus gives a slip to the fifth metatarsal bone, but the main part of the tendon has its usual insertion. In the hand the muscle corresponding to the flexor longus pollicis goes only to the index finger, and there is not even a rudiment of a tendon to the pollex; this arrangement appears to be peculiar to the orang among the apes. The great flexors of the toes are distributed as follows:—The flexor digitorum gives tendons to the second and fifth digits, and the flexor hallucis to the third and fourth; there is no connexion between them, except such as arises from the intervening loose cellular tissue and the origin of the lumbricalis muscles. There is no long flexor tendon to the hallux, and there is usually no flexor accessorius. 5. Muscles which differ from that of man by their subdivision. The biceps of the thigh is altogether divided into two muscles. The division of the extensor ossis metacarpi pollicis and the tibialis anticus is not carried so far as in the chimpanzee. The interossei of the hands are double muscles, as distinctly as in the other anthropoid apes, while those in the foot are single. The abductor hallucis is very complex in its origin. The transversus pedis is distinctly represented, arising from the heads of the second and third metatarsal bones. It is thus seen that in its myology generally the orang recedes farther than the previously-described great apes from man, for it possesses all the characters by which they deviated from him, and many others special to itself, or found also among the lower mammals. It is, indeed, hardly too much to say that in the arrangement of its muscles the orang differs as much from the chimpanzee as the latter does from man.

The larynx of the orang possesses all the cartilages, liga-

ments, and muscles found in the same organ in man, but with certain differences of detail. The enormous development of the laryngeal sacculus in the adult animal has been carefully described by Sandifort. It is larger even than in the gorilla, and consists of a great median bag, covered by a strong layer of muscular fibres from the platysma, and sending cœcal prolongations backwards beneath the trapezius muscle as far as the occiput, beneath the scapula, and into the axilla. The walls of the sac are abundantly supplied with blood-vessels, and have numerous branches of the superior laryngeal nerve ramifying upon them. Its cavity communicates by two distinct canals with both ventricles of the larynx. In the young orang there are two small distinct sacs, which coalesce in the middle line as growth advances. The suggestion of Sandifort that this large reservoir of air assists to prolong the loud roar of the animal is not consistent with the fact of its opening into the air passages being above the situation of the vocal cords.

FROM ABROAD—INSANE COLONIES IN FRANCE—PROLONGATION OF ANÆSTHESIA BY MORPHIA—EXCISION OF THE KNEE FOR GUNSHOT WOUND.

WE have heard much of the advantages and disadvantages of the insane colonies so long established at Gheel; and it seems that the French Government has resolved to introduce the system. The Council-General of the Rhone has recently, with the approval of the Minister of the Interior, voted the funds necessary for placing out among families one hundred indigent insane persons whose mental condition does not necessitate their sequestration in an asylum. Upon the recommendation of the chief Physician, the indigent insane, recognised as incurable and inoffensive, are to be removed from the Antiquaille Asylum, at present overcrowded with patients, and placed out. "Without doubt," observes M. Garnier, in the *Union Médicale*, "this example will become promptly contagious; and this will be much to be commended, providing that there be constituted a Medical and administrative inspection of these patients as in the case of foundlings. Unable to restore their moral health to these poor creatures, we can at least provide for their physical well-being by this family regimen, life in the open air and varied labours, which are more likely to conduce to it than the residence in an asylum. For the safety of the families concerned and the success of the experiment, care must be taken that the persons selected are both incurable and harmless."

The Versailles Medical Society has been continuing its interesting researches (*Med. Times and Gaz.*, March 5) upon the subcutaneous injection of morphia during anæsthesia produced by chloroform. The animals submitted to the simultaneous action of the two agents have always exhibited a duration of insensibility proportionate to the quantity of morphia injected. In the last experiment performed, five centigrammes of morphia being employed, complete insensibility continued during three hours. The same dose injected, without chloroform having been employed, produced for a few minutes complete torpor and insensibility; but at the end of this time sensibility to pain returned completely. The conclusions from the whole series of experiments are—1. That salts of morphia, in doses of from five to ten centigrammes, injected alone produce a kind of intoxication which may go on to torpor, but do not give rise to insensibility, properly so called. The effect is not durable, and in a few minutes the animal returns to its normal condition. 2. Salts of morphia injected during anæsthesia produced by chloroform possess the singular property of prolonging the duration of the anæsthesia in proportion to the amount of morphia employed. 3. That this property may be turned to use without danger in man when the duration of an operation gives rise to fears of continuing the anæsthesia by means of chloroform.

M. Verneuil related to the Society of Surgery two successful cases of excision for gunshot wound of the knee, with the view of eliciting opinions whether this operation should not

be, as a general rule, substituted for amputation of the thigh. M. Legouest, of the Val-de-Grace, observed that, while adopting this substitution as a principle, he feels obliged to reject its application in military Surgery on the field of battle. Statistics have sufficiently proved that excision is a less fatal operation than amputation, and that generally useful limbs result. M. Verneuil explains the less fatality attending excisions by considering the shattered extremities of the bones as mere foreign bodies which are removed by this operation; but we must look further than this for the explanation. It is found in the fact that in excision the medullary canal is rarely opened, and the vessels and nerves are uninjured, whence the rarity of osteo-myelitis, phlebitis, and purulent infection, which carry off so large a number of the subjects of amputation. While admitting all the superiority of excision in civil practice, the military Surgeon still finds himself obliged to reject it, the chief ground being the far greater facility with which patients who have undergone amputation are transported. After excision a much more complicated apparatus, together with elaborate and frequent dressings, are required; and, as a much longer time is required for cure than after amputation, the patient is exposed for a longer period to all the anti-hygienic condition of military Hospitals. M. Legouest is no opponent to excision, and would be glad if it could be adopted in active military practice; but with the experience derived from the Schleswig-Holstein, Crimean, and Indian wars, he has little expectation of success following its adoption. M. Giraldes observed that the gunshot wounds received on the field of battle are very different from those which occur in civil life. The ravages which they produce are far more severe and deep-seated, while the injury sometimes extends far beyond the articular surfaces themselves. Moreover, excision of the knee performed under any circumstances, is a more serious operation than it has sometimes been stated to be; and is, in fact, as fatal as amputation of the thigh, if we do not include partial excisions, the removal of fragments, etc. M. Larrey, like M. Legouest, admits the principle of resection, but regards its application in military Surgery to be surrounded with so many difficulties as to render its performance quite exceptional. The injuries caused by modern projectiles are of so aggravated a character that amputation usually remains the sole alternative. Then there is the difficulty of transporting patients who have undergone resection, and supposing this overcome, there are numerous inconveniences and accidents attendant upon this operation which are coped with with far greater difficulty than in the case of amputation. And even supposing the patient triumphs over these, he is still exposed to ulterior accidents, which are by no means of rare occurrence after excision, such as defective consolidation, deformity, and shortening of the limb. M. Verneuil is only enabled to speak practically as regards these two cases, and he is not aware of more than ten cases of excision of the knee for gunshot wound being on record. Fortified by his own success, then, he strongly recommends the more frequent trial of the operation, and although in military Surgery there must be numerous cases in which it cannot be applicable; he believes that there are others in which, owing to the more simple nature of the wound and other circumstances, it may be advantageously performed. M. Broca protested against the abuse of statistics in comparing and estimating the various operations, the locality where they are performed being the point of greatest importance. Thus, while in Paris almost every amputation of the thigh terminates fatally, in the country a fatal result is the exception. The true test of the superiority of excision would be its performance in Paris; but, in fact, M. Verneuil's cases are no proof of this, as amputations of the thigh would also have succeeded under the same circumstances.

TOWNLEY'S case bears some analogy to that of Mrs. Real, of this city, who, in 1862, killed her alleged husband, on a breach of good faith and suspicion of inconstancy. The public, and especially its most sensitive part, was at that time much interested in the final result of the trial of that poor girl. Still a just verdict and a merciful punishment vindicated the public morals. Since her trial, the alleged insanity of Mrs. Real has vanished, and probably repentance has also purified her mind and will.—*Am. Med. Times.*

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF THE POTTERIES.

From the North Staffordshire Infirmary, the history of which was given at length in last week's *Medical Times and Gazette*, we may pass to-day to consider, in conclusion, certain general facts relating to the district, and which are of Medical and scientific interest.

MEDICAL SOCIETIES.

There is a Medical Society in the district known as the North Staffordshire Medical Society. The society is small, but very active; it has been in existence for twelve years, and increases with its life. The members meet for business purposes on the second Thursdays of every other month in Stoke-upon-Trent, and on the second Thursday in November they have a general meeting for the election of officers. At the ordinary meetings papers are read and discussed, specimens are exhibited, and cases are related. At the present time Mr. Folker is president, Mr. Yates, of Newcastle, is honorary treasurer, and Mr. R. Goodall, of Silverdale, is honorary secretary of the Society.

In addition to this society there is a Book Society, which is considered of great value as a means for disseminating new Medical works and the various Medical periodicals throughout the district.

Microscopical meetings are occasionally held at the Infirmary, and clinical lectures are sometimes delivered.

PAROCHIAL MEDICAL PRACTICE.

Parochial Medical Practice in the Potteries and Newcastle is largely divided; there are three districts, each including a union workhouse and several sub-districts. The whole may be tabulated as follows:—

Newcastle.

	Popula- tion.	Acreage.	Annual Fees.
Mr. Yates' District (Newcastle)	15,640	8,640	£40 0 0
Dr. Vernon's District (Audley)	7,625	11,102	25 0 0
Dr. Barnes' District (Whitmore)	1,302	7,572	15 0 0
Mr. Yates (Workhouse)	142	—	30 0 0

Stoke-upon-Trent.

	Popula- tion.	Acreage.	Annual Fees.
Mr. Ashwell's District (Stoke)	11,385	5,050	£25 0 0
Mr. W. H. Davis's District (Bucknall)	12,469	4,235	15 0 0
Extras			80 0 0
Mr. Folker's District (Hanley)	1,681	492	27 0 0
Extras			3 0 0
Dr. Goddard's District (Fenton)	7,993	2,193	15 0 0
Extras			51 0 0
Mr. J. B. Davis's District (Shelton)	18,331	1,034	33 0 0
Mr. Garner (Workhouse)			26 10 6

Wolstanton and Burslem.

	Popula- tion.	Acreage.	Annual Fees.
Mr. Morris's District (Burslem, N.-East).	9,203	1,875	£40 0 0
Mr. Goddard's District (Burslem, S.-West)	13,124	937	40 0 0
Mr. Davenport's District (Tunstall, with the Workhouse)	22,466	5,140	125 0 0
Mr. Alcock's District (Wolstanton)	9,563	5,240	30 0 0

It will be seen from the above that the payments to the parochial Medical officers are exceedingly small.

THE WORKHOUSE, NEWCASTLE.

The Workhouse at Newcastle-under-Lyme is situated at the south south-west part of the town, and at some distance from the town. It is a handsome building of brick, and is nominally constructed for the reception of 350 inmates. The average number is 142. The water supply of the house is from a well; the water is pumped into a cistern at the upper part of the building by hand labour, and thence it is distributed over the house and flushes all the closets. The sewage of the house is conveyed, flushed by the water, through culverts into a tank, from which it is drained off into two adjoining fields, that lie at a lower level, and there it is utilised. The greater part of the sewage is given away to the owner of the fields—all, indeed, except a small portion which is employed to fertilise a little piece of land belonging to the house.

The ventilation of the house is conducted on the natural plan, and is well secured. In some instances there are openings in or near the ceilings, but window ventilation and openings into the corridors form the principal means for the admission of air. The wards are beautifully clean and comfortable, and the contrast between this workhouse and the other workhouses of Staffordshire which I had visited was so striking, it was difficult to believe, by the comparison, that this could be a workhouse. The repulsiveness of the workhouse system was here actually relieved; the house was quite equal to any model gaol, and the excellent master, who evidently was conscious of the superiority of his establishment, was as anxious to show the various improvements and comforts as he was naturally proud of them.

The greatest fault is the limitation of cubic space. I calculate that with the present occupation the space of air for each person does not exceed three hundred cubic feet. Against this must be set off the effectiveness of the ventilation and the fact that the patients during the day are not much in the wards.

The school-rooms are commodious, large, warm, and well ventilated, and the children were exceedingly healthy in appearance. The diet of the house is modified from the regulation standard by the addition of a double quantity of rice and an increase in the quantity of soup and potatoes. The aged and infirm, at the discretion of the guardians, are allowed, in lieu of porridge, for breakfast one pint of tea daily, and five ounces of butter, and seven ounces of sugar per week. Children under nine years of age are dieted at discretion; and above five years, whether they are boys or girls, they are classed with the women.

For the sick a distinct diet table has been drawn up by the very able Medical officer, Mr. Yates. As all these Medical dietaries are of great importance now that the whole question of dietaries is under discussion, I subjoin Mr. Yates's table:—

NEWCASTLE-UNDER-LYME UNION.

Dietary for Sick Paupers.

Full Diet.

	Breakfast.			Dinner.			Supper.		
	Bread.	Butter.	Tea or Coffee.	Cooked Beef or Mutton.	Bread.	Potatoes.	Bread.	Butter.	Tea or Coffee.
Males . . .	7 oz.	5-8 oz.	1 pint.	4 oz.	7 or 2 oz.	with 1 lb.	7 oz.	5-8 oz.	1 pint.
Females . . .	7 oz.	5-8 oz.	1 pint.	4 oz.	7 or 2 oz.	with 1 lb.	7 oz.	5-8 oz.	1 pint.

Low Diet.

	Breakfast.			Dinner.			Supper.		
	Bread.	Butter.	Tea, Coffee, or Milk.	Bread.	Broth.	Pudding.	Bread.	Butter.	Tea, Coffee, or Milk.
Males . . .	4 oz.	5-8 oz.	1 pint.	2 oz.	1 1/2 pints.	16 oz.	4 oz.	5-8 oz.	1 pint.
Females . . .	4 oz.	5-8 oz.	1 pint.	2 oz.	1 1/2 pints.	16 oz.	4 oz.	5-8 oz.	1 pint.

Fever Diet.

	Breakfast.			Dinner.			Supper.		
	Bread or Dry Toast.	Tea or Coffee.		Bread or Dry Toast.	Tea or Coffee.		Bread or Dry Toast.	Tea or Coffee.	
Males . . .	4 oz.	1 pint.	—	4 oz.	1 pint.	—	4 oz.	1 pint.	—
Females . . .	4 oz.	1 pint.	—	4 oz.	1 pint.	—	4 oz.	1 pint.	—

Milk Diet.

	Breakfast.			Dinner.			Supper.		
	Milk.	Bread.		Milk.	Bread.	Pudding.	Milk.	Bread.	
Males . . .	1 pint.	4 oz.	—	1 pint.	4 oz.	12 oz.	1 pint.	4 oz.	—
Females . . .	1 pint.	4 oz.	—	1 pint.	4 oz.	12 oz.	1 pint.	4 oz.	—

N.B.—Toast-and-water, barley-water, and linseed tea, as required.

The sanitary condition of the workhouse is satisfactory, and the number of cases of epidemic disease is small. It is also

rare for any epidemic to spread in the Institution; in fact, no epidemic diseases have ever prevailed. Skin affections are almost unknown, with the exception of scabies, which is occasionally introduced from without.

CASE IN WHICH THE BRAIN IS EXPOSED.

Amongst the sick of this workhouse, Mr. Yates has under his care a well-built man, aged 36 years, who, from disease of the bones of the head, arising from syphilis (two attacks), has lost a large portion of the parietal bone on the left side. A portion of brain, of nearly one inch and three-quarters in diameter, is thus laid bare, and the membranes are also destroyed; the cerebral surface is covered only with a thin, yellow, false membrane, almost like a waxy secretion. The pulsation of the vessels of the brain is immediately under the eye. The man suffered the second time from syphilis six years ago. A few months later he had several fits of an epileptiform character. Two months after the first fit he perceived a swelling on the head, which was laid open. His friends reported that after this he "lost his senses," and did not recover them for several months. Two years since there was an open wound on the left side of the head, and a piece of bone came away, in one piece, from the upper part of the left parietal. Another piece exfoliated from the outer table of the frontal bone, and the septum of the nose and part of the roof of the mouth gave way. A little pus is daily discharged from the opening in the skull, and occasionally, but very rarely, the man has epileptic fits; he is dull, heavy, and at times much disposed to sleep. When he is excited, as by sharp walking, the pulsation in the brain is very much increased; but when he is at rest and drowsy, it is less perceptible. The brain surface appears to be entirely devoid of sensation, but if it is gently touched, with slight motion, systemic symptoms are immediately presented. The symptoms first show themselves at the stomach, the patient feels nauseated, and has a sensation of sinking and depression. The action of the pulse, too, is modified, the number of pulsations being reduced.

It has been observed in other cases where the brain has been exposed that the movements of inspiration and expiration are to be seen in the brain. This fact, which was noticed by the great Haller, was at one time thought to show, and even to prove, that the blood in passing through the lungs is impeded slightly during expiration, and that this impediment, reflected throughout all the viscera, gives rise to what has been termed the visceral respiratory pulse. In this case of Mr. Yates' I could not satisfy myself as to the existence of a respiratory pulsation, although I could readily see the pulsation that was synchronous with the beat of the heart. Perhaps I made too brief an observation in reference to the respiratory pulse; if so, and if I am in error, I hope my friend Mr. Yates, who is much interested in the progress of the case, will put me right. Physiologically, this case shows that the circulation through the brain may take place in a sufficiently active degree to sustain life, although the brain itself is directly subjected to the pressure of the atmosphere. In this sense it exhibits phenomena which are of interest in reference to the theory of Dr. Kellie that the quantity of blood in the brain must always be the same, and to the researches of Dr. Burrows, which go to show that while the quantity of blood in the brain is nearly equally the same, variations may occur. Unquestionably in this instance variations do occur in the circulation, and the question is, whether these are determined by the fact that the cranium is open, or whether they would be manifested as certainly as if the cranium were sealed up. From what I could hear of the man, I should almost infer that the atmospheric pressure on the brain did, in truth, disturb the circulation through it, but here a series of observations are required, in which the condition of the man in regard to sleepfulness, oppression, and condition of the pulse should be recorded side by side with the variations in the barometric scale.

A NEW FORM OF BEDDING.

I must not linger longer over the narrative of this Workhouse except to note a very useful form of bedding that has been introduced here by Mr. Fox, the master. Some ordinary woven cocoa-nut bedding having come into the house, Mr. Fox had some of it that had been used picked into loose fibre, and with this stuffed several ticks. The experiment succeeded excellently, the beds were soft, warm, and as cheap in the end as straw. After a time the fibre becomes matted somewhat, but it is a very slight task to take it out of the tick and pull it over again. In addition to its other properties the teased fibre bed has the advantage that the fibre may be scalded,

washed, and dried with the greatest rapidity. For the purposes of Hospitals and asylums this little practical fact is of much value, for the bed being very warm is most comfortable to the aged and weak, is clean, and always ready to be disinfected by heat and to be re-made.

A HOT-AIR BATH REQUIRED.

To make this well-conducted workhouse quite perfect, a hot-air or Turkish bath is required. The advantages of this in cleanliness, and in the treatment of various diseases I have already spoken of, in describing the workhouse at Lynn, where the bath has been a great boon. The expense of erecting this bath is so slight, as compared with its advantages, that the active Board of Guardians of the Newcastle Workhouse will not be offended with me, I am sure, for suggesting its addition to their establishment.

THE WORKHOUSE AT STOKE.

The workhouse at Stoke-on-Trent is commonly known as the "Spittals." It is built on the site of what is said to have been an old Hospital or Lazar-house, probably dedicated to a St. Loyes. The house is situated two miles and a-half from any of the towns of the district. At present it holds 380 inmates. Except for the distance, the site is good, and as the building is on high ground, with a fine, open prospect, the air is fresh and pure. The drainage of the house is complete and effective, and the water supply is pretty good. The water is derived from wells and surface springs, and is forced into all parts of the building. In its return it flushes the sewers. There are baths in the house, which are supplied with both hot and cold water. The ventilation is on the natural system, and is in good order. The schoolrooms are too crowded—a fact that is acknowledged, and is promised to be amended; indeed, it is almost settled that there shall be new schoolrooms built, so as to separate the children altogether from the adults. The children have a field for playing in, and a drum and fife band; they are also trained to work, the boys in a field, the girls in the laundry.

The clothing of the inmates is indifferent: the barracan is thin and cold after washing, and the appearance of the dress is uncomfortable, even to the looker-on. The dining-room, which answers for the purpose of a chapel, is very cheerless. The time of the adult men is also indifferently occupied, for they have little out-door labour; and indoors the unprofitable and nasty work of picking oakum is the one pursuit.

As a whole, the general sanitary appearance of the workhouse is not favourable in contrast with the workhouse at Newcastle; but Mr. Garner informs me that the result of operations in the house is extremely good, deaths being rare after any operation, however severe.

The diet consists of three scales—ordinary diet, diet for infants and for women during confinement, and diet for the sick. The aged and infirm are allowed extras, and tobacco is allowed to all over 60 if it is asked for. The diet for infants runs as follows:—

Sucking infants, in case of insufficiency of mothers' milk, are allowed—Under six months old, one pint of cow's milk per day; over six months, and under one year, one pint of milk, with 1½ oz. of sago. Infants not having the breast—Under four months, one quart of milk per day; infants over four months, and under one year, one quart of milk, with 3 oz. sago (the milk to be warmed by the addition of hot water, and sweetened, and given from the bottle). Infants over one year, and under two years, whether nursed or weaned—Morning: Half-pint of milk porridge, with 3 oz. of bread. Dinner: 6 oz. rice pudding, or 4 oz. potatoes, with half-pint of broth. Evening: Half-pint of milk, with 3 oz. of bread. In cases of sickness, to have arrowroot. Nursing mothers labouring under debility to be allowed half a pint of ale per day.

Sick Dietary.

Ordinary Diet of Paupers in the House.		
FULL DIET.		
Breakfast : 7½ oz. bread and butter 1 pint of tea or coffee.	Dinner : 4oz. cooked beef or mutton without bone 7 oz. bread, or 2 oz. bread and 1 lb. potatoes.	Supper: Same as breakfast.
LOW DIET.		
Breakfast : 6½ oz. bread and butter 1 pint of tea or coffee.	Dinner : 6 oz. bread, and 1½ pints of broth four days 1 lb. milk puddings three days.	Supper : Same as breakfast.

FEVER DIET (rarely used).

Breakfast : 4 oz. bread 1½ pint of milk porridge, or 1 pint of tea.	Dinner : 4 oz. bread 1½ pint of milk porridge.	Supper : Same as breakfast.
--	--	--------------------------------

On the 2nd of April, 1864, the number of patients in the Workhouse Infirmary was ninety-five; of these, fifty-one were allowed extras, consisting principally of spirits, wine, ale, arrowroot, milk, eggs, sago, and tobacco. The women in Staffordshire are much addicted to smoking, and are allowed tobacco like the men.

Lunatics.—About a dozen harmless imbeciles live in the Workhouse. Wards for about half a dozen who are down at the Hospital are contracted for to be enlarged and improved. The male lunatics have a spacious yard, the females have a garden for exercise.

Between sixty and seventy lunatics are in Asylums, and are paid for by the parish. Most of these are incurable or harmless, and one-half are said by the Medical director of the Stafford County Asylum, Dr. Bower, to be removable with safety to wherever they would be taken care of and treated well. It is proposed in this parish to have them, and to build a separate suite of wards for them.

For some years such cases have been forced into Asylums, till the burden on the parishes has become very great. It amounts to £1400 or £1500 per annum in Stoke. Hence the apparent great increase in pauper lunatics, and the want of Asylums.

CLUB PRACTICE.

Club Medical practice is rather extensively carried on, the payment to the Medical men being miserably low. Two shillings per head per annum is perhaps the average. The principal clubs are,—an Agricultural Club at Keele, a Ground Club at Silverdale, and in and about Newcastle various clubs of Foresters, Gardeners, and Odd Fellows.

SANITARY CONDITION OF THE POTTERIES.

The districts to which reference is made in this paper are those of Newcastle, with a population of 24,567; Wolstanton, with a population of 54,356; and Stoke-upon-Trent, with a population of 71,308.

VALUE OF LIFE.

The Registrar-General's new returns, to which attention has so often been drawn in previous papers, give us the following facts as to the value of life at different ages in the districts of Newcastle-under-Lyme and Stoke-upon-Trent. Wolstanton is not specially included, but Cheadle, a large parish in the neighbourhood, is given. I have, therefore, added Cheadle to the list:—

Average Annual Rate of Mortality in Newcastle-under-Lyme from all Causes, at Different Ages, to 100 Living, during the Ten Years 1851-60.

	Males.	Females.
All ages	2·290	2·251
Under five	8·040	6·473
Five to ten	1·021	·925
Ten to fifteen	·526	·552
Fifteen to twenty	·712	·829
Twenty to twenty-five	·787	1·048
Twenty-five to thirty-five	·807	1·078
Thirty-five to forty-five	1·018	1·381
Forty-five to fifty-five	1·490	1·568
Fifty-five to sixty-five	2·960	2·829
Sixty-five to seventy-five	6·645	6·180
Seventy-five to eighty-five	13·981	14·583
Eighty-five and upwards	30·909	36·667

Average Annual Rate of Mortality in Stoke-upon-Trent from all Causes, at Different Ages, to 100 Living, during the Ten Years 1851-60.

	Males.	Females.
All ages	2·789	2·454
Under five	9·913	8·489
Five to ten	1·084	·961
Ten to fifteen	·571	·498
Fifteen to twenty	·788	·821
Twenty to twenty-five	·931	·925
Twenty-five to thirty-five	1·014	1·028
Thirty-five to forty-five	1·523	1·375
Forty-five to fifty-five	2·724	1·694
Fifty-five to sixty-five	4·272	3·181
Sixty-five to seventy-five	8·925	7·137
Seventy-five to eighty-five	17·673	17·285
Eighty-five and upwards	30·870	31·875

Average Annual Rate of Mortality in Cheadle from all Causes, at Different Ages, to 100 Living, during the Ten Years 1851-60.

	Males.	Females.
All ages	2.134	2.020
Under five	5.853	4.632
Five to ten760	.752
Ten to fifteen486	.714
Fifteen to twenty742	.850
Twenty to twenty-five975	1.194
Twenty-five to thirty-five825	.967
Thirty-five to forty-five	1.184	1.276
Forty-five to fifty-five	1.667	1.139
Fifty-five to sixty-five	2.696	2.513
Sixty-five to seventy-five	5.683	4.757
Seventy-five to eighty-five	16.250	14.932
Eighty-five and upwards	22.857	34.118

The value of life in Newcastle, as compared with all England, is 4541 in Newcastle against 4437; for Stoke-upon-Trent it stands as 5243 against 4437, and for Cheadle 4154 against 4437. The increase of mortality is most marked in childhood, the mortality of children under five years of age being 14.513 per cent. in Newcastle against 13.517 for England; 18.402 per cent. in Stoke against 13.517 for England, and 18.402 per cent. in Cheadle against 13.517 for England altogether.

MORTALITY FROM DIFFERENT CAUSES.

The average annual rate of mortality in the Newcastle district is 23, or 2 under the average of Staffordshire as a whole; in Wolstanton it is 26, or 1 above the average; in Stoke-upon-Trent it is also 26. Taking the pottery towns altogether, they represent a fair average of the mortality of Staffordshire.

Average Annual Mortality in Newcastle-under-Lyme from Different Causes, to 100 Living, from 1851 to 1860. (a)

As regards the mortality of a portion of this district, with a special reference to that caused by pulmonary disease and consumption, some recent important inquiries have been made by Dr. Arlidge, abstracts of which he has been kind enough to place at my disposal. Dr. Arlidge calculates "that the present mortality of Stoke parish—including Henley, Shelton, Stoke, Fenton, and Longton, with a population of 71,308—is equal to an excess over that in England of 0.79—*e.i.*, nearly 8 persons die in every 1000 living, in excess, annually. Relatively to the population of the parish, this is equal to an annual loss of life of 560 individuals.

The relative mortality of males to females is as 3.15 per cent. for the former, and 2.75 for the latter sex. Of equal numbers living the ratio is 114 to 100 in Stoke, whilst in England it is 108 to 110—a fact indicating a great destruction of male life.

Below the 20th year the deaths to every 100 living equal 4.00 for males and 3.64 for females; above the 20th year they equal 2.37 for males and 1.96 for females.

A table of the mortality of different ages relatively to the whole number living at those ages shows that 25.27 per cent. die in the first year of their existence, and that the deaths under 5 years of age equal nearly one-third of the whole population under five living.

A table of the proportion of deaths to the whole number of deaths shows that *more than one-half*, viz., 52.86 per cent., of the whole number of deaths occurred among children under five years of age. The deaths under 1 year old equal 29.23 of the whole mortality; those at 1 year and under 5 equal 23.63 per cent.

Causes of Death.—Of 2107 deaths 649, or 30.79 of the whole number, were assigned to diseases of the lungs and consumption.

Of the 2107 deaths, 1194 occurred among children under 10 years old; among these lung diseases and phthisis produced 22.60 per cent. of the mortality; whereas of the 913 deaths among those 10 years old and upwards, those diseases produced 41.52 per cent. Among males singly the proportion was 42.25 per cent.

Of children under 10 years, convulsions destroyed 24.28 per cent.; marasmus, debility, etc., 15.24 per cent.; and zymotic diseases, 25.20 per cent.

Of those who died under 1 year 30.73 per cent. perished from convulsions.

Relatively to the whole population living in Stoke, 9.10 per 1000 died from lung diseases and consumption together, the average for England being 5.84 per 1000 living.

The deaths in Stoke relatively to the *whole mortality* were from lung diseases and phthisis, 307,900 per million, compared with 270,293 deaths per million in England."

WATER SUPPLY.

The water supply of the Potteries is derived mainly from wells, but in Newcastle there is a water company. Taking it altogether, the supply of water is good throughout the district, and the water generally is not hard, but the number of sources of supply are too numerous to allow of my giving any analyses that would be considered satisfactory.

DRAINAGE.

The drainage of the various Pottery towns is as yet but little attended to in a scientific point of view. Surface drainage is common, and open cesspools. Scarcely any of the towns are situated indifferently for drainage, and the flow in no case is, as far as I remember, naturally prevented. There can be no doubt that a very effective system of drainage, ensuring the collection of all the sewage, could be carried out. The sewage, up to the present time, is not utilised, except, perhaps, in a few special cases, where it is carted or barrowed from the cesspool of a house, or of a few houses, to some adjoining field.

SITE, CLIMATE, AND METEOROLOGY.

The sites of all the towns included in the Pottery districts are favourable. The climate is variable, the towns being much exposed to the influence of winds. The situation is generally considered as less damp than South Staffordshire; at the same time the air is often exceedingly humid. No meteorological station exists in the neighbourhood, and, con-

sequently, nothing accurate can be said in regard to meteorological changes themselves, or their relation to the prevailing diseases. Etruria would form an excellent station for any local meteorologist.

REVIEWS.

Scritti Medici. Editi ed in II. editi di FRANCESCO CASORATI, etc. etc. Raccolti e pubblicati per cura de' suoi figli. Volume I.—Trattato delli Febri Intermittenti, preceduto da' alcune notizie sulla vita dell' Autore. Pavia e Milano. Svo, pp. 387.

THIS work, as appears from the title, is an *in memoriam* edition of the writings of the able physiologist who was a chosen colleague of the distinguished Scarpa. His two sons, as joint-editors, explain their wish to honour a parent's memory, and also excuse possible inaccuracies by his unexpected death and their non-Medical avocations. A funeral oration by Dr. Zanini opens the book, and briefly tells the story of Casorati's life: how, at the age of six-and-twenty, he entered on the management of a large provincial general practice, and remained buried for ten years, but still "found means to register, arrange, and meditate on the results of his experience in no other way than he would have done in the tranquil practice of a Hospital." So he attained to such eminence that "he was able to pass from the modest condition of a *medico condotto* to the honours of the Professional chair, called to it by a man whose vote is of itself the greatest of eulogies—by Antonio Scarpa."

For two years he delivered courses of general pathology and materia medica in the University of Pavia, and then appears to have been displaced for political reasons by the Austrian Government. The cautious silence of the orator, and of the subsequent extracts from local newspapers, contrast strongly with the free speech of a note added by the editors since "the Austrian domination has ceased to oppress our country." Space forbids any detail as to the hold Casorati's views obtained on the Medical students who attended his instructions; it is indicated by the formation of a party among them who took a pleasure in being called "Casoratiani," and forms an amusing parallel to a similar occurrence among ourselves. A list of Casorati's written works is given by himself, as communicated to the Secretary of the Lombard Institute. The most important of them forms the substance of the volume before us—on the subject of intermittent fevers. This starts by showing how that class of disorders, under the empiric treatment, with purgatives and quinine, often turns into a severe continued type, or becomes complicated with other dangerous secondary symptoms. Etiology is then gone into; external causes, such as cold, heat, wet, miasma, and the like; internal causes, especially the transmutation of continued into intermittent fever, apparently common in Lombardy; "purulent infiltration of the blood;" and other points are adverted to. The acute and chronic complaints consequent on such disorders, and the anatomical changes left behind, are followed by a contrasted view of symptoms in intermittent and continued types. Lastly, causes and treatment bring to a close the first or "synthetic" division of the memoir.

In a second part it is shown how the ancient Physicians had recognised the true etiology of intermittents, and thus they are not "new ideas, sprung from reformers of to-day, but old knowledge forming part of the wisdom of our ancestors." Also it is indicated "that the most constant and capital symptoms of intermittent fevers which we observe now have not changed in the succession of ages," and lastly the opinion is hazarded that humoral pathology is nearer the true explanation of facts than "neoteric solidism."

A long examination of writers ancient and modern follows, and with the diagnosis and treatment of pernicious intermittents the essay terminates. From a note of the editors it appears that the later sheets of the MS. were in a rough state, and a page of heads for additional matter which is appended shows that increased Professional avocations as well as failing health brought to an end the labours of this accomplished Physician.

The work is especially valuable as forming an important link in the chain of evidence on the great and abstruse subject of fever. It is essential that we should have before us all the genera and species of a malady singularly diversified and admitting of numerous modifications, and not limit our definitions to the two or three types endemic in one special locality.

Guide Pratique du Medicin et du Malade aux Eaux Minerales, bains et aux Environs de Marienbad en Bohême. Par le Docteur EMILE KRATZMANN, etc. Paris, Bruxelles, et Leipsig: A. Lacroix and Co.

THIS is one of the numerous works, partly Medical, partly guide-books, which abound on all mineral waters of the Continent. The first part is "Historico-Topographie," and states that the Marienbad springs have been known for centuries under the name of Tepl or Auschwitz, from the neighbouring convent and village respectively. The place was first brought into notice about 1779. In 1807, says our author very quaintly, "The number of bathers and strangers attracted simply by curiosity increased annually. New buildings secured these people accommodation. Some walks were laid out, partly by the bathers themselves, and all the surrounding valley was embellished in various manners. They likewise built a chapel."

Dr. Charles Joseph Heidler, however, whose rather grim portrait decorates the work, seems to have done much for the celebrity of the springs. Under his "enlightened direction the number of affections and diseases for which the water of Marienbad offered precious resources increased considerably, and surprising results were occasionally obtained." He is, by a singular coincidence, the father-in-law of the writer, who seems to have succeeded on his retirement.

The chemical analysis of the seven springs varies considerably; almost all contain carbonic acid, and the richest in solid ingredients, termed the Ferdinand's-brunnen, holds in solution 9·5706 grammes of salts per kilogramme. More than 5 grammes of this consists of sulphate of soda, 2 of common salt, 1·29 of carbonate of soda; small quantities of carbonates of lime, magnesia, iron, and manganese, with traces of lithia, represented by 0·0090, make up the rest.

The author describes the complaints for which the various springs are advantageous with the usual minuteness of such works. Perhaps our readers will be able to anticipate them from the constituents of the water as given above.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 10.

Mr. FERGUSSON, Vice-President, in the Chair.

Mr. CHARLES HAWKINS communicated a paper, by Dr. George B. Brodie, on

STATISTICS OF QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

The author commenced his paper by observing that in consequence of a notice having appeared in one of the Medical Journals for 1862 relative to the mortality observed in the lying-in Hospitals of London, and in Queen Charlotte's Hospital in particular, the present paper was commenced to give the desired information, and to show that all the deaths which took place in the Hospital were not from puerperal causes. For the last 36 years, from 1828 to 1863 inclusive, the registers have been carefully kept, but no detailed accounts published; during this period 7736 patients (producing 7824 children), were delivered in the Hospital; of this number 3611 were single women, who are admitted if it is their first pregnancy, and of these 126 died, the remaining 4125 were married women, of whom 72 died. The great mortality existing amongst unmarried women on their passage through the puerperal state was then touched upon, and some reasons were given to account for this fact, of which the separation from friends, their living in seclusion for some months previous to their admission into the Hospital, exposure to atmospheric changes, and semi-starvation, all tending to depress the mental and bodily powers, were the principal. Some reference was also made to the married patients, who are often admitted into the Hospital in labour very shortly after they are married, and a case in illustration of this which fell under the author's notice, was given in which the patient walked from the church to the Hospital, registered her letter as a married woman, and was admitted in labour within three days from that date; the mortality amongst the married patients would, therefore, be considerably diminished if it were not for the fact that so many are exposed during the period of gestation to the same

depressing causes as the single patients. The first table (Table I.) showed the number of deliveries, and number of deaths, with the death-rate for every year since 1828. The number of women delivered at their own homes annually was also given, but of these, there being no trustworthy records, no further notice was taken. (a) A detailed investigation into the cause of death in each year was then entered into, the results of which were given in Table II.; for four years the Hospital presented a clean bill of health. Puerperal fever (under which denomination its many varieties were necessarily included) was found to have been present in 123 cases, no less than 99 of which were in primiparæ; 75 out of the 123 cases were among the single women; the death-rate from this cause was 1·57. The various periods of the year in which these cases of puerperal fever occurred was given in Table III., the result of which went to show that the healthiest months—or the months in which the least number of deaths happened—were October and August; after these the following order was observed:—November, April; January, July, September, December; May, June; February and March. For eight years the wards were free from puerperal fever. Mania was found to have been present in 16 instances, 15 of these were in primiparæ, and no fewer than 11 were single women; in 12 out of the 16 cases the age of the patient was between 20 and 24. The remaining cases referable to puerperal causes, as post-partum hæmorrhage, ruptured uterus, coma, exhaustion, etc., were 22, making, with the puerperal fever and mania, a total of 161. Of the non-puerperal causes, phthisis and diarrhœa were the principal; pneumonia and some of the eruptive fevers being also present; making altogether a total of 41, which with the 161 deaths from puerperal causes, gives the original number of 202. Another table gave the total number of cases admitted in each month during the 36 years, with the corresponding number of deaths from all causes during the same period, with a result very similar to that obtained when puerperal fever alone was observed. The death-rate of the Hospital was then entered into, which was shown to be, for the married patients, 1·84; for the single patients, 3·48; for both together, 2·6. The death-rate has varied considerably at different times; it was at its highest in 1849—the year of the cholera—and has varied from that to *nil*; in all cases but one, in which the death-rate was unusually high, the cause was found in the fact that the deaths were principally amongst the single women; for instance, in the most fatal year, 1849, the deaths of the single patients were just double the married; in 1850, there were 8 single and no married; in 1860, whereas 14 single women died, there were but 4 deaths amongst the married patients; in this lies the cause of the comparatively high mortality of Queen Charlotte's Hospital. In another table was given the death-rate observed at the "Rotunda Hospital," Dublin; it was obtained by comparing the deaths with the number of admissions during the last 36 years, and was found to be 1·45 per cent. At the "British Lying-in Hospital" the death-rate from 1849 to 1861 inclusive, was ·69, the number of admissions were very small, hardly exceeding 1550 patients. Both of these Hospitals, however, profess only to admit married women. The author went on to remark that, in his opinion, the high death-rate of the "Queen Charlotte's Hospital" was in a great measure due to the fact mentioned at the commencement of the paper, that so many of the married women are exposed during the period of gestation to many of the depressing moral agencies of a single life. A comparison was then drawn between the mortality of a lying-in Hospital with patients delivered at their own homes; the out-door midwifery department of St. George's Hospital (restricted to married women) was taken as an example; the number of patients delivered was 2800, the number of deaths 11 (one of these was a case of abortion, and happened in the Hospital); the death-rate, therefore, was ·38, very favourable when compared with 1·84 or 1·45, and this notwithstanding the filth and poverty in which they live. The author concluded this portion of the paper with a brief account of the foundation of the Hospital, and the following sketch of the ventilation and plan:—The Hospital contains two floors for the reception of patients, one for married and one for single women. On each floor are six wards, containing three beds each, in which the patients are delivered, with an average of 1000 cubic feet space to each patient; but as each ward has not always its complement of three patients, the actual quantity of cubic space to each bed

(a) The total number of patients delivered at their own habitations from 1828 to 1863 inclusive, was 10,858. The number of patients, therefore, delivered in and out of the Hospital during this period was 18,594.

is sometimes increased. On each floor also is one convalescent ward, containing six beds; the walls of the wards are made of Parian cement, painted and varnished so as to enable them to be thoroughly well washed; throughout the building runs a corridor 84 feet long by 7 feet wide, having a window at each end, and a large staircase opening at its centre, in the roof of which is a ventilating opening, protected by a cowl; the whole of the Hospital is thus completely ventilated. Each individual ward is ventilated by means of an opening in a shaft that is carried to the top of the building, an Arnott's ventilator in the chimney, and an opening (that can be closed) over the door, communicating with the corridor; the windows are on the plan adopted at St. George's and the Middlesex Hospitals, which form ventilators of themselves. In each ward there is a constant supply of hot water, and the corridors are heated by means of pipes containing hot water. The water-closets, one on each floor, are external to the building, and approached through an ante-room, so as to be entirely cut off from the rest of the building. The soil is for many feet of the best gravel, and every attention has been paid to the drainage. As soon as a patient is able to be moved from the ward in which she has been delivered, she is placed in the convalescent ward, where she remains until she leaves the Hospital. As soon as three patients have been delivered in a ward, it is not again used till it has been well cleaned, as well as the beds and bedding; by this plan each ward remains vacant for ten days or a fortnight before patients are again received into it. When a case of puerperal fever occurs, the ward is freshly whitewashed, and the walls thoroughly washed down (in some cases repainted), the bedding purified and remade, and the ward not occupied again for at least a month. Everything has been done, both in the construction of the building and in the arrangements for the management of the patient, with a view to render them as little liable to disease as possible. In Section II., facts having more direct reference to the fœtus were investigated. Of the total number of labours—7736—there were 2 cases of triplets and 84 twin births. Out of the 7650 single births, there were 235 abnormal presentations, or 1 in every 32½ cases, with a fatal result to the mother in 5 cases, or 1 in 47 cases; the head of the child, therefore, presented in 7415 instances; but of these the face presented in 15 cases, or 1 in 494½ cases, and in 103 instances the child's head passed with its face looking towards the pubis of the mother. The funis was prolapsed in 22 cases, being met with once in every 348 cases; of the 22 cases 14 of the children were stillborn; in 12 cases it was prolapsed before the head, and of the children 9 were stillborn; in 6 before the feet, and of the children 3 were stillborn; 2 were cross births, and both stillborn. The upper extremity presented in 21 cases, or 1 in 364 cases, the breech in 139 instances, being 1 in 55 labours; of the children in these 139 cases, 88, or 1 in 317, were stillborn. The lower extremity presented 49 times, or 1 in 156 labours; 18 of the children, being 1 in 210, were stillborn. Placental presentations occurred 4 times, or 1 in 1912½ cases. Twin labours were then gone into, and a table given to show the presentation in each case; in by far the greater number of instances—namely, in 39 out of the 84 cases—both children presented naturally; next to this, cases in which the head of the first child, and the nates or inferior extremities of the second child presented, were most frequently met with—namely, in 22 cases. The first child presented with the nates in but 11 cases, and the lower extremity was similarly met with in but 6 cases. This section concluded with a notice of the operations. Craniotomy was employed in 21 cases, being 1 in 361½ cases, and was followed by the death of the mother in 6 instances. Forceps were applied in 49 cases, or 1 in 158 instances, and their application was followed by the death of the mother in 10 cases, or 1 in 15½ cases.

Dr. WEBSTER, after a few remarks on the value of the paper, said that, having paid considerable attention to statistics of disease generally, he would make a few remarks on several points in the paper. The author had found that the mortality of the single women was double that of the married. Admitting the influence of distress of mind and privation to which the author had alluded, he thought it ought to be taken into consideration that the single women were always admitted for their first child, and he believed that it was admitted that there was greater danger on a first than on a future delivery. The paper was of great importance, too, as regards the question whether it is desirable or not to have lying-in Hospitals. It was a question which had been discussed throughout Europe. At one institution with which he (Dr. Webster) was connected—the St. George's and St.

James's Dispensary—there had been during the last seven years 1515 deliveries and not one death. All these women had been delivered at home. In the British Lying-in Hospital there had been 1500 deliveries in that Institution, and again no deaths. It was singular, the speaker continued, that there should be no difference when the great difference of the position of the patient was taken into consideration:—in one every possible comfort, in the other great poverty and distress. He (Dr. Webster) had found that during the last seven years 175 women had died in the lying-in Hospitals of London generally, and, as stated, during a like period, there had not been one death in the St. George's and St. James's Dispensary out of 1515 cases. This, he thought, told against the lying-in Hospitals. In Vienna the mortality had been 30 per cent. Then as to puerperal mania. There were sixteen deaths from this cause, 11 single women and 6 married, but there was no statement as to the number of patients who had had the disease and had recovered. At Bethlehem Hospital the mortality from puerperal mania was only 4½ per cent. Dr. Webster, after again remarking on the great interest of the paper, asked for information as to the deaths of the out-patients.

Mr. CHARLES HAWKINS said that, having introduced Dr. Brodie to the Society, he could not let the paper pass without some observations. He felt sure that the Society would be glad to find one of the name of Brodie again working in the Profession. It was to be hoped that the author of the paper would keep his uncle's career in view. Mr. Hawkins then said that when he first began to pay attention to the mortality of Queen Charlotte's Lying-in Hospital he was much startled by the great mortality, and he felt that it was a very serious question whether Lying-in Hospitals should be supported or not. For the construction of the present Queen Charlotte's Hospital he alone was responsible, and he was prepared to defend it. The difference in the mortality in the out-patients and the in-patients was very striking, and at one time it might have depended on the building. He wished to know from Mr. Fergusson if there was a great difference in the mortality at the King's College since rebuilding the Hospital. He believed he was right in saying that at the old Hospital everything as regards hygiene was as it ought not to have been, and the new Hospital had, no doubt, been constructed upon the most approved principles. It would now be interesting to know what difference there was in the course of disease since the new Hospital had been occupied. The answer to this question would be important, as some people put great stress on the construction of Hospitals, and seemed to think that if the Hospital was built in a proper manner death would vanish. He had understood that the patients did as well in the old as in the new Hospital. Then as to the mortality in Queen Charlotte's Hospital, he could not speak as an authority with regard to the particular disease, but he was satisfied that it was brought in, and not contracted in the Hospital. He believed that the author had stated the real causes of a great part of the mortality. It was because this Hospital admitted single women. He (Mr. Hawkins) had paid much attention to this point, and believed that nothing could be more wretched than the condition of many of these patients. Wherever they had been delivered, the result would have been the same. It might be a question whether it was wise, in a social point of view, to take married women from their homes during their confinements, but he had no doubt the mortality in single women would be greater if they were not admitted. It was often their only hope, and in a vast number of instances he felt satisfied that it prevented child murder, if not self-destruction. At Vienna at one time the mortality was 30 per cent. The beds were then divided equally between the midwives and the Medical men. The result was that on the side of the midwives the mortality fell. The reason doubtless was this, that on the Medical side the students who delivered the women made post-mortem examinations, and were engaged in attending patients in the general Hospitals. Mr. Hawkins then remarked on the admission of women for delivery into general Hospitals. He did not consider it advisable, and in Lying-in Hospitals he thought it much better that there should be several small wards than one or two large rooms, as is the case usually in the foreign Hospitals, and that Lying-in Hospitals should never be large. He concluded by saying that he considered that when the author's paper was analysed the Society would give its verdict in favour of Queen Charlotte's Lying-in Hospital.

Mr. FERGUSSON said that, not being prepared for Mr. Hawkins' question, he must not be taken as pledging himself when he stated that he was under the impression that he had

found no difference in the mortality nor in the course of diseases at King's College Hospital since the new building was erected. There was, he said, still a great difference of opinion as to the mode of carrying out the arrangements for ventilation. He could not speak exactly as to the deaths from parturition, but he believed that there had been one death a few months ago, and a short time afterwards another. Dr. Priestley had since limited the number of admissions.

Mr. CHARLES HAWKINS thought Mr. Fergusson's answer to his inquiries of the utmost importance. It went to show that in the old and new King's College Hospital there was no difference in the rate of mortality, nor had the diseases supposed to depend on badly-constructed Hospitals diminished in number in the new Hospital; indeed, Mr. Hawkins had understood that fever had been more prevalent in the new Hospital last year than it had ever been in the old one. In his opinion the new Hospital was not constructed on the best principles. At the present moment it appeared to him that the Profession as well as the public were running a little too far on the question of statistics of mortality in, as well as on the construction of, Hospitals; not that he for one moment meant it to be understood that it was not of the utmost importance that all attention should be paid to the construction and ventilation of Hospitals, but it must still be borne in mind that the rate of mortality was not simply a "brick-and-mortar" question.

Mr. FERGUSSON said that he thought there was yet much difference of opinion as to the best plan of constructing Hospitals. He would be glad, however, to take Mr. Hawkins' word that Queen Charlotte's Hospital was one of the best.

Dr. HICKS, after thanking Dr. Brodie for his valuable paper, said that the mortality of the out-door maternity patients, chiefly married, in number 15,000, was $3\frac{1}{2}$ per thousand. Dr. Hicks had not seen a genuine case of puerperal fever. All the cases of what might be included under the name puerperal fever turned out to be either one of the zymotic diseases, erysipela or pyæmia. But altogether there had been only twenty-five cases, and of these half died. Students, Dr. Hicks said, who were dissecting, were not allowed to attend women in labour. One student had a case of Surgical pyæmia amongst his midwifery patients, and though he attended twenty cases he did not carry infection to the others. There had been no deaths from puerperal mania. Dr. Hicks concluded by asking Mr. Hawkins if, when a patient at the Queen Charlotte's Hospital became ill, a single nurse was kept for that individual patient.

Dr. GRAILY HEWITT believed that in the numerous discussions which had occurred on this general question as to the utility of lying-in Hospitals, certain important circumstances had been overlooked. The great mortality occasionally witnessed in lying-in Hospitals arose from puerperal fever, disease concerning the nature and prevention of which our knowledge has been, up to within a recent period, comparatively limited; and it was, he believed, to be expected that with the aid of more extended information on the subject the disease in question might be prevented to a very much greater extent than was formerly the case. In the institution with which he was himself connected—the British Lying-in Hospital—the mortality during the thirteen years ending 1861, had been only 0.69 per cent., and during the last two years the number of deaths had been even lower than this. It must be recollected further that a certain number of cases treated in lying-in Hospitals were cases of unusual difficulty, and this was to be taken into account in estimating the rate of mortality. He attached the greatest possible importance to isolation of cases one from the other in the prevention of puerperal fever; the atmosphere of one ward should not be allowed to communicate with that of another. So, again, it was essential that the nurses exercise great care, in performing the daily ablutions, not to use sponges or flannels indiscriminately. With reference to puerperal fever, he entirely agreed with the previous speaker in considering that it was not a distinct and separate disease; it was to all intents and purposes pyæmia, and we could only hope for a successful result in its treatment by adopting measures of a sustaining and stimulating character. The mortality in lying-in Hospitals from puerperal fever would, he believed, be diminished as the knowledge which has of late years been acquired respecting the nature and treatment of this disease came to be applied.

Dr. F. W. MACKENZIE thought the opinion of the Profession would change as to the advantages of Lying-in-Hospitals. He held that the number of fever cases had nothing to do with the Hospital, but with the individuals admitted. If any one,

he continued, would study the arrangements of Queen Charlotte's Hospital, comparing it with others, and would consider the nature of the cases admitted, the conclusion arrived at would be that the real cause of the fever case was not in the Hospital, but in the patients who were admitted. Patients were admitted who were in a state of starvation, without friends, and with no home. Cases of this kind would die anywhere. Last week, Dr. Mackenzie said, a ballet dancer was admitted, who died after confinement of a dead and putrid child. She had been seduced. She had then no means of earning her livelihood; was very much exhausted, and in great distress of mind. A case of this kind could not be put down to any supposed defect in the Hospital. The fever, he said, was secondary to some general condition in the patient, and was not in itself a disease to be taken in a Hospital by a healthy woman. The whole theory of puerperal fever was wrong.

The AUTHOR, in his reply, said that the registration of the out-patients was not sufficiently accurate for statistical purposes. Those cases of mania ending in recovery were not included in his statement. In reply to Dr. Hicks' query, the Author said that when a patient was taken ill a nurse was taken on for that patient only; and in reply to Dr. Graily Hewitt, he said that the very greatest care was taken as to the sponges.

Dr. Wood said that at Bethlehem they looked on puerperal mania as the most satisfactory and most curable form of mania.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 24th inst., viz. :—

Messrs. Oliver Humphrey Fowler, Kingsclere, Hants; Edward Roberts Smith, Dudley; Francis Mears Beckett, Canterbury; Henry Nelson Edwards, Finsbury-square; Henry Melville Brewer, Newport, Monmouthshire; George Cox Douglas, Grantham, and Charles James Wills, Stockwell, Students of St. Bartholomew's Hospital. William Melvill Knipe, Leigh Linton, Worcestershire; Andrew Wise, Plumstead, Kent, and Augustin Barber Fry, Sleaford, of Guy's Hospital. Joseph Burne, Dublin; Thomas Richards Phillips, Dublin, and Frederiek Fludd Diekinson, M.D. Queen's University, Ireland, Wicklow, of the Dublin School. John Foot Churchill, Poole, Dorset, and William Burt Shorts, L.S.A., Southampton, of the Charing-cross Hospital; Philip Brookes Mason, Burton-on-Trent, and Thomas Sanders, Plymouth, University College; Joseph Gedge, Bexhill, Surrey, of King's College, and Henry Edward Armstrong, Newcastle.

At the same meeting of the Court, Mr. Charles James Devonshire passed his Examination for Naval Surgeon; this gentleman had previously been admitted a Member of the College, his Diploma bearing date April 4, 1855.

Admitted members on the 25th inst. :—

Messrs. Charles Edward Squarey, Salisbury; Matthew Henry Cantrell, Wirksworth, and Charles Read, Falmouth, students of University College; William Vaey Lyle, Harrow-road, and Daniel Webster Tomlinson, Penynant, North Wales, of St. Mary's Hospital; George Levick, Stratford, Essex, of the London Hospital; William Heath Strange, Streatley, near Reading, of St. Thomas's Hospital; John Norrish, Ceylon, of Middlesex Hospital; Nicholas Watson Fairles, South Shields, of St. Bartholomew's Hospital; Charles James Fox, L.D.S., Mortimer-street, Cavendish-square, of St. George's Hospital; William Cross, M.D., St. Andrew's, Liverpool; William Richard Gore Hinds, M.D., Queen's University, Ireland, Galway; Augustus Morton Roberts, Sheffield; William Burrows, Liverpool; and Edward Borough, Kilrush, Co. Clare.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, May 19, 1864 :—

John Arthur Ensor, 31, Carter-street, S.; John Roof Ireland, Kingswinford, Stafford; Francis Albert Davey, Bath; Henry Wilson, Glasgow; William Warwick Wagstaffe, Walcot-place, Kennington; Frederick William Richards, Winchester; Charles Durrant Pearless, East Grinstead, Essex; Evan Jenkins, Cardigan-street, S.W.; Joseph Wilkinson Warburton, Royal Infirmary, Liverpool; William Nicholas Heygate, Hanslope, Bucks; Robert Wrentmore Thomas, Cheyne-walk, Chelsea; Philip Cowen, Kennington, S.; Edwin Charles Smallman, Barnet, Herts.

The following gentleman, also on the same day, passed his First Examination :—

Richard James Andrews, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLINGHAM, JAMES H., M.R.C.S. Eng., has been appointed Dental Surgeon to the Surrey Dispensary.

ATKINSON, EDWARD, M.R.C.S. Eng., has been elected Surgeon to the Leeds Dispensary.

BALLANTINE, ROBERT, M.D. Glasg., has been appointed Surgeon to the Prison at Jedburgh.

BLAKER, NATHANIEL P., M.R.C.S. Eng., has been elected House-Surgeon to the Sussex County Hospital, Brighton.

BROWNE, JAMES C., M.D. Edin., has been appointed Assistant Medical Officer to the County Lunatic Asylum, Hatton, Warwickshire.

CARSON, THOMAS, L.R.C.S.I., has been appointed Resident Assistant Surgeon to the Dispensaries, Liverpool.

COLLIE, ALEXANDER, M.D. Aberd., has been appointed Resident Assistant to the Royal Infirmary, Dundee.

COOPER, THOMAS J., M.R.C.S. Eng., has been elected Surgeon to the Brighton and Hove Provident Dispensary.

FOX, TILBURY, M.D. Lond., has been appointed Senior Physician to the St. John's Hospital for Diseases of the Skin.

FRODSHAM, J. NIELL, M.D. Edin., has been appointed Physician to the St. John's Hospital for Diseases of the Skin.

HAUGHTON, E., L.F.P. and S., Glasg., has been appointed House-Surgeon to the General Dispensary, Rochdale.

HEWETT, PRESCOTT G., F.R.C.S. Eng., has been appointed Examiner in Surgery to the Army Medical Department.

JEFFREY, EDWARD, M.R.C.S. Eng., has been elected Surgeon to the Yeovil Infirmary and Dispensary.

LAND, ROBERT T., M.D. Edin., has been elected Surgeon to the Leeds Dispensary.

LEESON, JOSEPH F., L.R.C.P. Lond., has been appointed Medical Officer for the Workhouse of the Bradford Union, Yorkshire.

LOGAN, WILLIAM, L.F.P. and S. Glasg., has been appointed Certifying Factory Surgeon.

MARCH, HENRY C., M.B. Lond., has been appointed Medical Officer to the Rochdale Police.

NEVILL, WILLIAM, M.B., T.C.D., has been appointed Medical Officer to the Constabulary of Dungannon, Co. Tyrone.

POWELL, W. E., L.F.P. and S. Glasg., has been elected Medical Officer for the Union Workhouse of Farnham, Surrey.

POWELL, W., M.B., has been elected Resident Medical Officer to the Tower Hamlets Dispensary, Commercial-road.

ROE, W., M.D., has been appointed Resident Assistant House-Surgeon to the Dispensaries, Liverpool.

SOUTHEY, REGINALD, M.B. Oxon., has been appointed additional Assistant-Physician to the City of London Hospital for Diseases of the Chest, Victoria-park.

TAYLOR, HENRY, M.R.C.S. Eng., has been elected Resident Medical Officer to the Norwich Dispensary.

TREVOR, WILLIAM, M.R.C.S. Eng., has been elected Medical Officer to the Dulverton Union Workhouse.

WEBB, CHARLES, M.R.C.S. Eng., has been appointed Medical Officer to the Basingstoke Workhouse.

WILSON, ERASMUS, F.R.C.S. Eng., has been appointed Senior Surgeon to the St. John's Hospital for Diseases of the Skin.

WOODS, THOMAS, M.D. Glasg., has been appointed Surgeon to the Parsonstown Gaol and Constabulary.

DEATHS.

BLOOR, JOHN TABBERER, L.S.A., drowned in the River Wairiu, near Nelson, New Zealand, early in February, late of Tutbury, Staffordshire, aged 30.

JOCE, JOHN, M.R.C.S. Eng., at Colchester, Essex, on May 4, aged 58.

SKINNER, H. T., M.D., at Sandyford-place, Glasgow, on May 13.

TAYLOR, J., Surgeon R.N., at the New Passage, Gloucestershire, on May 13, aged 75.

TOMKINS, CHARLES, M.D., of Weston-super-Mare, at West Monkton, Somerset, on May 17, aged 68.

WELLS, ANTHONY, M.R.C.S. Eng., at Basingstoke, Hants, on May 15.

JACKSONIAN PRIZES.—The Council of the College of Surgeons has just announced the following as the subjects for the Jacksonian and Collegial Prizes of twenty guineas and fifty guineas respectively; for the former prize there are three subjects, each of which may have an award:—"Club-foot, its Causes, Pathology, and Treatment;" "The Diseases of the Ankle-joint, and of the Joints and Bones of the Tarsus, Requiring Surgical Treatment, and Stating the Treatment, including Operative, most suitable in each case, with the results thereof;" and "The Malformation, Diseases, and Injuries of the Fingers and Toes, with their Surgical Treatment—the Dissertation to be illustrated by Preparations and Drawings." There are also two subjects for prizes for the ensuing year, 1865, namely:—"The Diseased Conditions of the Knee-joint which require Amputation of the Limb, and of those Conditions which are favourable for Excision of the Joint, with an Explanation of the Relative Advantages of both Operations, as far as can be ascertained by Cases properly Authenticated;" and "The Relative Value of the various Modes of Treatment of Popliteal Aneurism, illustrated by Cases." The following is the subject for the Collegial Triennial Prize, the essays for which must be sent in before Christmas Day next:—"The Structural Anatomy and Physiology of the Lymphatic Vessels and Glands (the Anatomical Distribution not being required); the Communications (if any) between the Lymphatics and Blood-vessels to be Demonstrated; and the Influence (if any) which the Lymphatic Vessels or Glands Exercise on the Fluid they Transmit, to be

Elucidated—the Dissertation to be illustrated by Preparations and Drawings."

THE LA POMMERAIS CASE.—Whatever be the result of these efforts to save the life of the convict, a question will arise as to whether the large sum (£22,000) for which the life of the woman De Pauw was insured will have to be paid over to her children; and whether the transfers executed by her in favour of La Pommerais are valid. It is probable that these transfers, obtained by fraud, will be considered null and void, so that La Pommerais, or his representatives, will have no claim on the companies. But the insurances, it is contended, will be still available for the children of the murdered woman. It is established, and the companies have not, I believe, disputed the fact, that they did not sign the contracts drawn up in her name and for her behalf without having taken all the preliminary steps usual in such cases, and obtained all the information respecting the insurer when they covenanted to pay a specified sum. The conditions of the contract between Madame de Pauw and the companies were fulfilled so far. She had been visited by the companies' Medical officers, who reported that her health was excellent, and that the insurance might be safely effected; and the first premium was punctually paid. The policies of insurance specify only two cases where insurance companies may refuse payment—suicide or death in a duel; but when the party insured is murdered, his or her heirs must not suffer by the crime of a third party, nor are the companies released from their engagements. It was the woman's life that was insured, and not La Pommerais's; and in no case would the latter take anything by the transfer of her title to him, as it was shown to be obtained by fraud.—*Paris Correspondent of the Times, May 20.*

WERE our own Profession true to themselves, and if they would refuse to recommend or patronise any but graduates in pharmacy, quackery would not be enabled to ride "roughshod" over the Profession. At present, in too many instances, the apothecary's store is a mart where can be obtained almost any fancy article, stationery, cigars, and tobacco, liquor under various disguises, patent medicines for every purpose under the sun, and a few drugs. In fact, there is scarcely a druggist but is in the habit of prescribing over the counter, too frequently recommending his own wares in preference to the prescription which is brought for his compounding, and sometimes announcing a series of "cure-alls" which he calls his own, adding the title of "Doctor," without the slightest shade of a diploma, though one could be bought for a mere trifle, with all the "rights and privileges thereunto belonging."—*Philadelphia Correspondent of Am. Med. Times.*

MEDICO-CHIRURGICAL SOCIETY, ABERDEEN.—At a meeting of this Society, held on April 7, the subject of students of Medicine becoming apprentices of Medical Practitioners was brought under the notice of the Society, and it was agreed to refer the matter to a Committee to consider and report. At the meeting of May 5, the Committee's report was brought up and agreed to as follows:—On the general question of Medical apprenticeships, the Committee would remark that the system cannot be regarded as holding, in the present state of the Profession, the same important place as it did in the memory of many of our number, when in the majority of cases it was the only means of providing for the effectual study of the several branches of Medical education. In the present day, the full organisation of numerous efficient schools of Medicine, the greater facilities afforded in Hospitals for the training of students, and the system of examination now in force, as well in the ordinary courses of lectures, as preparatory to the granting of degrees and licenses, have, in the general judgment of the Profession, provided so complete a system of imparting knowledge, of stimulating the exertions of the students, and of testing their abilities, that it is now comparatively rare to find a Medical man laying himself out for taking apprentices. The Committee feel that at present the tendency of public opinion is so decidedly against the general adoption of the apprenticeship system, that it may safely be left to students themselves, and to those who have a personal interest in their education, to judge of the cogency of the arguments to recommend it in particular cases. The practical good sense of the parties most directly concerned may be held a safe guide when no undue influence is brought to bear on them; and the Committee repudiate the idea that any member of the Society would use his social or Professional influence for such a purpose. In Aberdeen, especially, as the seat of an important Medical school, in which a large proportion of those practising here are employed as examiners for degrees, both the

Profession and the public at large are naturally suspicious of any influence which might possibly be supposed to interfere with the impartial discharge of these official duties. In this very sensitiveness, however, on the part of the public, there is so ample a corrective of any unconscious bias of personal regard, that the Committee believe the credit of our Aberdeen degrees never stood higher than at present. The admitted status of the graduates of our University, and the high position many of them have taken before other examining boards, are the best indications both of the efficiency of its teaching and of the stringency of its examinations. If additional security is still required, we have it in the appointment under the late ordinances of the Universities' Commissioners of extra-Professional examiners, to be changed from time to time, and in the circumstance which the Committee think ought to be generally known, that the Medical Faculty of the University, who have long followed the rule that no Professor should examine his own son, have recently adopted the same practice with regard to apprentices and private pupils.

THE RECRUITING SURGEON.—We are not as yet at war, so that there is no extraordinary number of legs and arms in the army requiring amputation, nor do any bullets need to be extracted from the bodies of any British soldiers, except those engaged in fighting the Maories, not to mention the black-amours of Ashantee, who fight shy. What is there, then, to account for this advertisement, which has appeared in the *Times*?—

“ARMY MEDICAL DEPARTMENT, 6, WHITEHALL YARD,
“22nd April, 1864.

ACTING ASSISTANT-SURGEONS being REQUIRED for temporary service with the Army in the United Kingdom, gentlemen duly registered to practise medicine and Surgery under the Medical Act of 1858, and desirous of obtaining such appointments, may apply immediately to the Director-General for the printed form required to be filled up by every candidate previous to employment. They will receive pay at the rate of 10s. a-day, and allowances equal to those of a Staff Assistant-Surgeon. Gentlemen are not eligible for these appointments whose age exceeds forty years.

“J. B. GIBSON, M.D., Director-General.”

Whence the pressing demand for army Surgeons, manifested by the foregoing notice? Simply from the revocation at headquarters of the Royal Warrant of 1858, which assured Surgeons in the army of suitable relative rank, proper precedence, and the social position due to gentlemen. The faith thus pledged was coolly broken by certain other orders called the *Queen's Regulations*, issued in 1859, which rescinded the Queen's Warrant of 1858, with a dishonesty most derogatory to her Majesty's name, audaciously connected with them. These new arrangements, dictated at the instance of the so-called “combatant” officers, provided that the Medical officers should rank as civilians, and be treated as snobs. The consequence is what has necessitated the above advertisement. There is a Surgeon-famine in the army. Men of education refuse an office which subordinates them to a lad who is possibly a contemptible puppy. Service in the army, instead of being sought through the ordeal of a competitive examination by spirited young Surgeons, has to be unfortunately tendered to Practitioners of the mature age of forty. Their practice must be very unprofitable if they can gain anything by exchanging it for temporary employment in the army. When the gallant combatant officer, who insists that his Surgeon shall be a snob, comes to have his leg removed, or a bullet extracted from his hip-joint, he will perhaps lament that the operation has to be performed by an operator for whom Dr. Gibson, the Director-General, was reduced to advertise, in his capacity of Recruiting Medical Officer. Colonel North, in a late debate on the estimates, stated that there were two hundred vacancies for army Surgeons the other day, and that only six candidates presented themselves for examination. If war ensue, and the Duke of Cambridge, in action, should unfortunately receive any injury needing Surgical aid, it is to be hoped that the Surgeon who shall render that aid to his Royal Highness will be one of those six. In the meanwhile, perhaps, the restitution of the Royal Warrant of 1858 will relieve Dr. Gibson of the necessity of touting for Surgeons to job the army.—*Punch*.

PREGNANCY WITHOUT IMMISSIO-PENIS.—Professor Scanzoni relates the case of a woman, aged 29, in whom he detected a four-months' pregnancy, although the orifice of the vagina was closed by a firm and tense membrane, in which an aperture big enough to admit a probe was discovered with

much difficulty. In his long experience he had never met with a similar instance, although he has seen cases in which remains of the hymen existed, and one in which this membrane continued quite uninjured. The membrane only yielded slightly upwards, so that immissio-penis was completely impossible, and the question is, how did the semen reach the uterine orifice, four inches distant? After the seventh month the opening gradually widened a little, so that a quill could be easily introduced; and by the time labour set in the finger could be passed in. As the labour advanced, there was found to be also a thin circular membrane attached to the walls of the vagina at the junction of its upper and middle third; but a large opening existed in this, so that it caused no obstruction to delivery. As, however, the thickened hymen formed a dense ring, which prevented the passage of the head, a small crucial incision was performed, and the delivery easily terminated.—*Allg. Wien Med. Zeit.*, No. 4. [Dr. Mattei, in *Union Médicale*, No. 36, relates a similar case of a woman who became pregnant after having been married 11 years. The husband was aware that she was malformed, but had contented himself with incomplete connection. On examination, a cul-de-sac was found, which, probably formed through the attempts at copulation, only admitted the finger to the extent of 1½ centimetre. The most careful examination by means of the speculum could not detect the aperture by which the semen must have entered. After severe labour for three days, the tissues in front of the head gave way and admitted the finger. Delivery was completed by the forceps.]

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Mr. H. W. B.—We are obliged to limit our obituary notices strictly to members of the Medical Profession.

G. T. H.—1. A book called “Medical Guide for Emigrants,” published by the Christian Knowledge Society. Also books by Messrs. South, Smee, and Jabez Hogg. 2. Apothecaries' Hall.

B. A.—If our correspondent entertains the slightest doubt of his patient being insane, we would strongly advise him not to sign a certificate. We know of no mode in which he could be legally guaranteed against the consequences.

We are obliged, by want of space, to postpone Mr. R. O. Clark's letter on the late meeting of the Governors of the Royal Medical Benevolent College until next week.

Errata.—In the article on the French Poisoning Case in our last Number, p. 565, for “Desormemo,” read “Desormeaux;” for “Vulpiau,” read “Vulpian;” for “Raynal,” read “Reynal.”

MORTALITY OF SCARLET FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have only just this moment seen your *Medical Gazette* of the 7th inst. In reply to your correspondent “R. E.,” I beg to say that, although it is astounding, it is nevertheless true—as my certificates of death will prove—that in my own practice I had lost only one case of scarlet fever during the last fourteen years. I attribute the success to various causes—(1) to the plan of treatment, which I carry out to the very letter, and which I firmly believe prevents the cases from becoming malignant; (2) to the healthiness of Birmingham; and (3) to my practice not being among the lowest classes of the town. Be the cause what it may, the fact is as I have stated.

I have never kept a registry of the number of cases, but they must have been numerous, as my practice is much among children. I only wish my fellow workers would try my treatment, and carry it out strictly, and allow no other plan to interfere with it, and that they would publish the result in your Journal. Assured I am that, if the cases be not malignant, the plan I have recommended will be most successful. Before I adopted my present treatment I was as unfortunate as any of my Medical brethren.

I am, &c.

Birmingham, May 23.

PYE H. CHAVASSE.

HEREDITARY PALMEDACTYLISM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The fact is well-known that palmedactylism is one of those freaks of nature which are transmitted from generation to generation, but I believe it is somewhat rare to meet with a well-authenticated instance of successive generations having this deformity so largely manifested as is shown in an instance which has recently come to my knowledge. I take the liberty, therefore, of sending the particulars for publication, and should the pressure on your columns admit of it, I would be happy to see them in the *Medical Times*.

Mrs. D., the mother of four children, was born with her two middle fingers of each hand webbed. Three of her children have the same deformity, but only in one hand; the fourth, born a few weeks ago, and died three days after birth, had, in addition to the webbed fingers, a double harelip and split palate. The mother of Mrs. D., three aunts, and an uncle, had each one hand webbed; her grandmother, who only died last year, had the same fingers of same hand joined; and she informed Mrs. D. that her mother and grandmother—that is, Mrs. D.'s great, and great great grandmother—had the same peculiarity, and some generations previous which she could vouch for had the same defect.

It occurs more frequently amongst the females than the males, and some families had it only alternately; so that we have six generations in succession, with a number of instances in each well authenticated.

Alloa, May 17.

I am, &c.

JOHN DICKIE, M.D.

THE DIFFICULTIES OF THE ARMY MEDICAL DEPARTMENT.
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The call for Acting Assistant-Surgeons, while unmistakably indicating the unpopularity of the Army Medical Department, the urgent straits and miserable expedients to which the Director-General is reduced, is a procedure in many respects so objectionable as to be justifiable only by the exigencies of war.

With your permission I shall briefly advert to one or two of the most prominent and obviously injurious consequences resulting from so extraordinary a measure.

At present the period of foreign service is limited to three or five years, according as the station is considered unhealthy or otherwise, at the expiration of which time Medical Staff officers are, by regulation, entitled to return to England, and take tour of home duty until ordered abroad again in course of rotation. But if home duty is to be exclusively, or in great part, performed by Acting Assistants, it is obvious that Medical Staff officers will be almost or altogether precluded from serving in England; and, if so, the scale of pay requires to be proportionally increased, and such other alterations and arrangements intimated as must necessarily follow from the indefinite extension of foreign service.

I abstain at present from saying anything as to the efficiency with which Hospital and clerical duties are likely to be conducted by civilians not exceeding 40 years of age, who have received no special training, and being temporarily hired cannot be expected to take any interest in their work. The rank and file will be the sufferers. *Quicquid delirant reges plectuntur Aclivi.*

Instead of lowering the standard and the character of the Department by indiscriminate admission, it would have been more prudent and really more economical to have retained the high qualification; and by increasing the bounty recruits would have been readily secured, by a timely adoption of those improvements and concessions so frequently advocated in your columns. These are, briefly,—

1. Increased pay to Assistant-Surgeons if unpromoted after 10 or 12 years' service.
2. Retirement on 15s. after 20 years' service, and on 20s. or 21s. after 25 years' service.
3. Full pay retirement after 30 years' service.
4. Retirement at the age of 55 to be dependent on efficiency as determined by a Medical Board.
5. Promotion in all grades by seniority, as in the scientific corps of Artillery and Engineers, instead of emanating from Whitehall or the Horse-Guards.

Let the above come into immediate operation, and there will be no need to advertise for Acting Assistants. I am, &c. H. P.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am induced to address you for two reasons—firstly, for the purpose of thanking you for the kind interest you have taken in, and the better manner in which you have advocated the rights and privileges of the Medical officers of the army; and secondly, with the intention of pointing out what reforms are really required by the Department, and what inducements are necessary to cause an efficient class of Medical men to offer themselves for the service. Some communications have appeared in the papers, evidently from young and inexperienced writers; therefore, as a Medical officer of long experience, and one who has carefully studied the subject, I wish to point out what changes are urgently necessary.

These requirements are:—

- 1stly, strict promotion by seniority in all ranks.
- 2ndly, the scale of pay and retiring allowances recommended by your very able correspondent, "Army Surgeon," in your paper of the 19th of March last.
- 3rdly, the restoration of all the advantages conferred by the Warrant of October 1, 1858.
- 4thly, some guarantee that Medical Warrants are not to be done away or tampered with.
- 5thly, the branding of military felons not to be the duty of the Medical officer.

With regard to requirement No. 1, I may safely say that much of the ill-feeling existing amongst Medical officers of the Department is caused by the great injustice which is continually perpetrated on able and experienced officers, who have served in all quarters of the globe, by the system of selection; but it is not necessary to dilate further on this head than to quote the opinion of Dr. Mapleton, one of the Medical Board, who stated in his evidence that in promotion by selection, in nine cases out of ten, the best men are not selected; indeed, we all know that the "right man in the right place" is he who has interest and influence in the right place.

The pay and retiring allowances recommended in requirement No. 2 may appear unreasonable, but the authorities may rest assured that less will not satisfy officers now serving, nor attract well-qualified Medical men to enter a service which at once separates them from friends and relations, and dooms them to expatriation for years, if not for ever.

It is not necessary to say much in explanation of requirements Nos. 3 and 4, except to observe that in future it behoves the authorities to cause all Medical warrants to be fully and faithfully observed and carried out.

The duty of branding military offenders is, no doubt, a disagreeable one, but as it must be performed, let it be done on "company parade," the officers of the culprit's company and the Medical officer being present.

I am, &c. A STAFF SURGEON-MAJOR.

COMMUNICATIONS have been received from—

DR. HENRY BEHREND; A STAFF SURGEON-MAJOR; G. T. H.; APOTHECARIES' HALL; R. H.; MR. R. BEVEN; MESSRS. J. WEEKS AND CO.; MR. H. W. BEST; DR. W. FAIRLIE CLARKE; DR. SILVESTER; B. A.; WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON; DR. GEORGE BRODIE; MR. PYE II. CHAVASSE; DR. R. DUNDAS THOMSON; ROYAL COLLEGE OF PHYSICIANS, EDINBURGH; MR. R. OKE CLARK; OBSTETRICAL SOCIETY; ROYAL INSTITUTION; DR. A. WYNN WILLIAMS; DR. J. H. ALLINGHAM; DR. MOON.

APPOINTMENTS FOR THE WEEK.

May 28. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Alexander Herschel, Esq., "On Falling Stars."

30. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

31. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Life."

June 1. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m.
OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Dr. Greenhalgh, "On Placenta Previa." Dr. Aveling, "On Immediate Transfusion."

2. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.
ROYAL INSTITUTION, 3 p.m. John Hullah, Esq., "On Music (1600-1750)."

3. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 8 p.m. Prof. Frankland, "On Recent Chemical Researches in the Royal Institution."
WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Annual Meeting. Dr. Morel Mackenzie, "On the Laryngoscope."

International Exhibition, 1862.—The only Prize Medal
FOR

“WATER CUSHIONS and BEDS”

WAS AWARDED TO

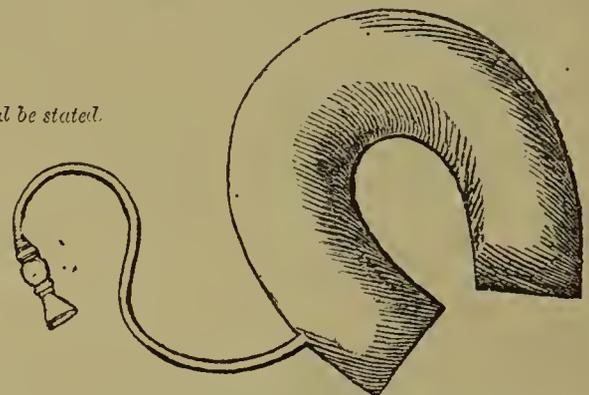

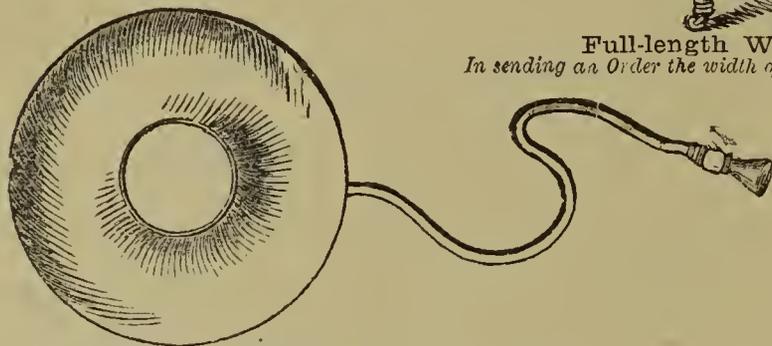

W. HOOPER, 7, Pall Mall East, and 55, Grosvenor-street, London.

USED BY
THE ROYAL FAMILY
AND ALL
CLASSES OF INVALIDS.

ALSO IN
H.M. ARMY AND NAVY,
AND THE
INDIAN PRESIDENCIES.

Full-length Water Mattress.
In sending an Order the width of the Bedstead should be stated.

Circular Water Cushion, for Sitting on.
ELASTIC BAGS, for applying dry cold or dry heat, maintaining their elasticity under all temperatures, from Zero to 212° Fahr.
Crescent Water Cushion, for the Sacrum.

WATERPROOF SHEETS, INDIA-RUBBER URINALS, ENEMAS, &c.

NEW CHEAP BINOCULAR MICROSCOPE.

H. & W. CROUCH,

(FROM SMITH, BECK, AND BECK,)

REGENT'S-CANAL DOCK, COMMERCIAL-ROAD, LONDON, E.

TESTIMONIAL.

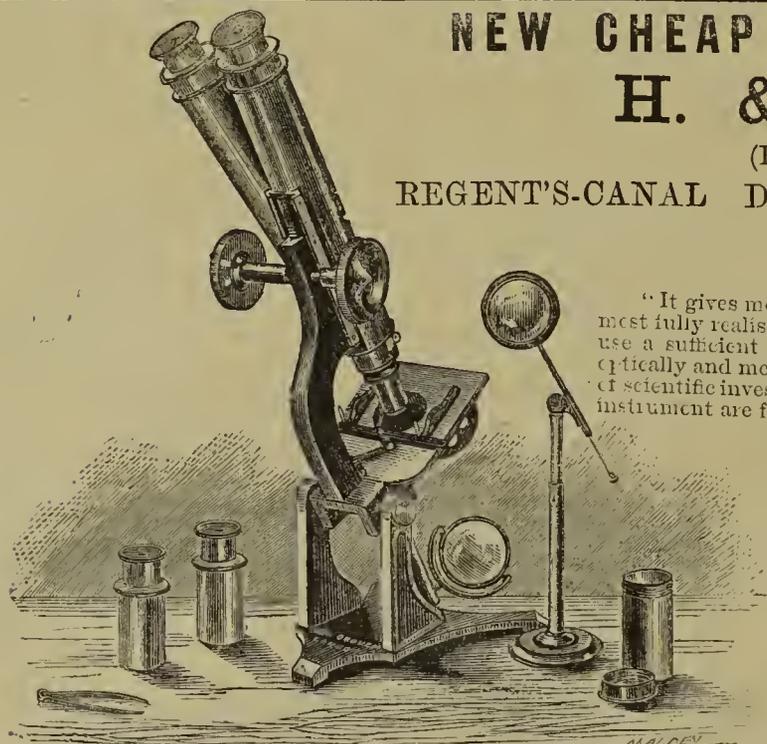

“It gives me great pleasure to be able to state that the *Cheap Binocular* of Messrs. CROUCH most fully realises my idea of what such a Microscope should be. Having had it in constant use a sufficient length of time to test its working capacity, I find it so satisfactory, both optically and mechanically, as to leave me nothing better to desire for the ordinary purposes of scientific investigation; whilst the Achromatics of the ‘Cheap Series’ supplied with this instrument are fully equal, to say the least, to any that I have seen by other makers.

“Had the ‘Cheap Binocular’ of Messrs. CROUCH been brought under my notice while the last edition of my ‘Microscope’ was passing through the press, I should certainly have given it a special notice; and I feel sure that if it had been completed in time for the International Exhibition, it would have been deemed worthy of honourable distinction by the Jury with which I was associated.

“WILLIAM B. CARPENTER, M.D., V.P.R.S.,
“Author of ‘The Microscope and its Revelations.’”

MICROSCOPE, with Condenser on Stand, Pliers, Glass Plate,
&c., packed in polished Mahogany Case, complete . . . £7 0s.
If with 2 inch of 12° and ¼ of 75°, or 1 inch of 16° and ¼ of 75° . . . £10 10s.

Particulars of Apparatus on Application.

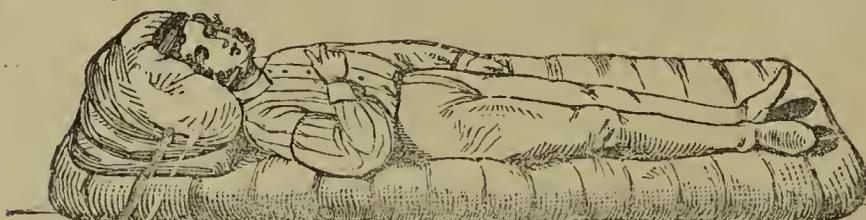

WATER BEDS.—EDMISTON & SON, 5, CHARING-CROSS (late 69, Strand),

beg to call the attention of Managers of Hospitals and Dispensaries, and the Profession generally, to the price and quality of their Hot or Cold Water Beds.

WATER BEDS, £4 14s. 6d. to £10 10s.

Water Cushions, all sizes, from 7s. 6d. to 30s.
Cotton Elastic Stockings, 3s. 6d.; Silk, 5s. 3d.
Knee Caps, Leggings, Anklets, &c. Day and Night
Urinals, from 5s. 6d. to 21s. Injection Bottles,
Bed Sheets, Accouchement Belts, &c. India-rubber
Chambers for Lunatic Asylums.

Water Beds can be had on hire. Terms, 7s. per week.

LONDON: EDMISTON & SON, THE POCKET SIPHONIA DEPOT, 5, CHARING-CROSS, W.C.

ORIGINAL LECTURES.

COURSE OF
LECTURESON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University
College Hospital.

LECTURE IV.

(Continued from page 586.)

Uric acid calculi, although most common in early life, may occur at all ages from birth upwards.

Infants have been born with stone in the bladder. Here are three well-formed calculi, as large as barleycorns, that were found by Mr. Shepherd, of Great Portland-street, in the right kidney of a child aged ten months, about the cause of whose death I was consulted by the coroner in consequence of her having died suddenly after drinking some porter.

This, on the other hand, is the kidney of a gentleman over 60 years of age, and it contains no less than fifty-nine small stones, mostly, as you see, about the size of garden peas. Curiously enough, the right kidney contained none, nor was I able to detect any in the bladder. In both this case and that of the child the calculi consist of uric acid.

Uric acid are the most common of all calculi. Of one hundred and twenty-six of the calculi in the museum of University College analysed by me a few years ago, eighty-seven consisted of uric acid either in whole or in part.

As regards the treatment of uric acid calculi, I may here say a few words.

When the calculus is in the urethra or bladder, cutting or crushing, if the condition of the patient admits of it, ought immediately to be had recourse to. But when the calculus is in the ureter or kidney, it is unfortunately beyond the reach of any instrumental interference; and in the majority of such cases, if the stone be large, incurable. Should, however, the case be seen in the early stage, it is in our power, not only to arrest any further deposit, but even, by suitable remedies, to some extent, redissolve what has already formed, more particularly if it be in the shape of sand. When, however, a large solid stone has formed, palliation, not cure, is all that can be hoped for.

The remarks now made are limited entirely to uric acid calculi; for, as you will afterwards see, there are some calculi of so soluble a nature as to admit of removal by dissolution even when in an advanced stage of formation.

Various remedies have been resorted to with the view of retaining any excess of uric acid in a soluble state until after its expulsion from the body. Carbonate of soda has been much used for this purpose, also the bicarbonate of potash, and more recently the carbonate of lithia. Each of these remedies is useful, as, indeed, all alkaline carbonates are, with the exception of that of ammonia. The carbonate of ammonia should be avoided in the uric acid diathesis on account of the salt which it forms being much less soluble than any of the others.

In treating cases of uric acid deposit, it is unnecessary to render the urine more than neutral. Indeed, there is a danger in making it alkaline from the circumstance that phosphates have a great tendency to form round uric acid calculi (as is seen in these twelve specimens of various shapes and sizes now on the table), and whenever the urine becomes artificially alkaline, although the deposition of uric acid is interrupted, a deposit of triple phosphates takes its place. The stone, therefore goes on forming as rapidly as before, the only difference being that its nature is changed.

In cases where the alkaline carbonates are counter-indicated, citrates, tartrates, or acetates may be used in their stead, for the reasons before given. Some have imagined that uric acid gravel only appears in urine of the well-fed and corpulent. This is a great error. It equally occurs in that of the poorly nourished and emaciated, the only difference being that it is more common among the former than among the latter. In this urine, you perceive, there is a copious deposit of uric

acid. The bottom of the glass looks as if it had been sprinkled over with a layer of yellow sand; yet this is the urine of a delicate, anæmic lady, with a miserable appetite. In her case the deposit appears to be hereditary—at least, her father is said to have suffered from gravel.

The most remarkable illustration, however, that I can give of the truth of the above statement is furnished by the sand and gravel in this paper, which was passed by a patient of Mr. Ramsbotham, of Amwell-street. The gentleman who passed it was not only out of condition, but was actually on what might be called starving diet. The following is the brief history of the case, kindly furnished to me by Mr. Ramsbotham:—

“An officer in the army, upwards of 60 years of age, who had seen active service in every quarter of the globe, on his return from India by the overland route, deviated from the usual track for the express purpose of restoring his shattered health in the hydropathic establishment of Prusnitz, in Silesia. He remained there some weeks; but failing to have his juvenility restored, he repaired to a rival establishment a few miles distant, in which a directly opposite mode of treatment was adopted. Instead of using water freely, both internally and externally, as in the other establishment, in the latter very little food and no water was allowed, so long as the patient's strength would permit the deprivation, and then, perhaps, only at distant periods would a wineglassful of water be given. The urine passed was scanty in quantity, and, when simply filtered, left on the paper the powder, of which this is a portion.”

On analysis, I found that the powder and small concretions consisted of uric acid, and urate of soda, with a very small quantity of urate of ammonia.

Enough has now been said regarding uric acid in excess; we shall therefore turn our attention to the equally important fact, that under certain pathological conditions its formation is diminished. We are not yet in a position to speak confidently regarding the nature of all the conditions, but we are sufficiently familiar with the fact that the elimination of uric acid by the urine is diminished in the following diseases, and that it is to some extent under the control of remedies. In yellow (Porcher) and remittent (Parkes) fevers the excretion of uric acid is much decreased. In diabetes it is likewise found to be reduced to a minimum. Lehmann, indeed, thinks that in diabetes it is replaced by hippuric acid; but although I have frequently verified the former, I have as constantly failed to confirm the latter statement of Lehmann's. In the case of saccharine urine from injury to the head (p. 446), during the first few days there was a total absence of uric acid in the man's urine. In albuminuria I have frequently found the uric acid greatly diminished, and absolutely wanting in two cases. It is said also to be deficient in the urine of cholera. In chlorosis, anæmia, and hysteria it is likewise decreased. The excretion of uric acid is diminished before the outbreak of the paroxysm of gout, but in this case it is known to accumulate in the blood. Dr. Garrod has frequently obtained crystals of uric acid from the serum of the blood of gouty patients. His method is to take from one to two fluid-drachms of the serum of blood, and put it into a flattened glass dish or capsule, about three inches in diameter, and one-third of an inch in depth; to this is added ordinary strong acetic acid, in the proportion of six minims to each fluid-drachm of serum, which usually causes the evolution of a few bubbles of gas. When the fluids are well mixed, is introduced a very fine thread, consisting of from one to three ultimate fibres, about an inch in length, from a piece of unwashed huckaback or other linen fabric, which should be depressed by means of a small rod. The glass is then put aside in a moderately warm place, until the serum is quite set and almost dry; the mantel-piece in a room of the ordinary temperature answers very well, the time varying from twenty-four to forty-eight hours, depending on the warmth and dryness of the atmosphere.

In normal blood the acid occurs in such small quantity that it is scarcely possible to detect it.

Uric acid has also been obtained from the serum of a blister placed on a gouty patient, but not when it has been placed over the goutily inflamed part—(Garrod). Both before and during the attack of gout the uric acid is diminished in the urine, but no sooner does convalescence begin than it rises even beyond the normal standard. From the twenty-four hours' urine of a convalescent patient, who was under Dr. Parkes in the University College Hospital, I obtained no less than 1.15 grammes (17.825 grains) of uric acid—double the amount the man would probably have passed under similar

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

circumstances had the uric acid not been retained in his system before and during the paroxysm.

During the last two years I have had, at intervals of about three or four months, a patient, aged 65, under treatment, who has been a martyr to very severe paroxysms of gout for, at least, twenty years. All the joints of his hands and feet are distorted from deposits, and he has no less than four well-marked concretions of the urate of soda in his right ear. This man's urine has been carefully analysed on several occasions, and the following is a sample of the results. The attack I now allude to began on November 15, 1863, was at its height on the 21st, and had disappeared on December 10.

Twenty-four Hours' Urine.

	November 18, Third Day.	November 21, Climax.	December 7, nearly Convalescent.
Quantity.	2000 c.c.	1062 c.c.	1620 c.c.
Specific gravity	1011	1010	1008
Uric acid.	0.095	0.023	0.178

On the third day of the attack he came to the Hospital, which was November 18, and was put upon the following mixture:—℞. Vini colchici, ʒss.; liq. potassæ, mvi.; Aquæ, ʒss., M., ter in die.

It would appear, then, as immediately after the gouty paroxysm has passed the uric acid increases in the urine, the increase of that ingredient in the course of the paroxysm ought to be considered as a favourable symptom.

The gouty deposits commonly called chalk stones, and which are so frequently met with in all cases of long standing, are not chalk at all, but consist of crystals of urate of soda. (Garrod.)

A deposit of urate of soda in the cartilage of the joints precedes or accompanies every attack of gout. Hence arises the necessity of freeing the system of this product. Some persons have thought, that as colchicum—the favourite remedy for gout—instead of increasing the excretion of uric acid, diminishes it, and not it alone, but even the urea, the benefits derived from this agent must, if they are not entirely imaginary, be due to some different cause than its action upon uric acid. I, however, believe that colchicum does act upon the uric acid, but not, as is usually imagined, by merely affecting its excretion. On the contrary, I believe that by some means or other it arrests its formation, and that it is on this account that an occasional dose of colchicum during the intervals is found to ward off the attack of gout.

Dr. Ranke has shown that the formation of uric acid is diminished by quinine, and Dr. G. Pringle, while working in my laboratory, made some experiments upon himself, the results of which are quite confirmatory of Dr. Ranke's views.

January, 1858. —. Age 24, healthy and well developed.

Twenty-four Hours' Urine.

Diet	Quantity of urine.	Sp. gr.	Reaction.	Quantity of uric acid.
	c.c.			grammes. grains.
Mixed; drink only water, neither tea nor coffee	656	1031	acid.	1.39 = 21.545
After taking during five days 10 grains of quinine daily; food and drink as before	665		„	0.724 = 11.222
The same after seven days of quinine treatment	602		„	0.577 = 8.945
The effect of the quinine did not pass off immediately.				
Diet as before; quinine discontinued for two days	600	1036	„	0.66 = 10.230
Do., do., do., three days	525	1033	„	0.792 = 11.276

Quinine combined with colchicum was Bequerel's favourite prescription for gout. Curiously enough, too, he used to combine it with digitalis, another substance which has the effect of diminishing the uric acid. A good formula is—℞ Ext. colchici, gr. x.; digitalini, gr. ʒ; quinae sulphatis, ʒj; conf. rosæ, q. s. Fiat massa et divide in pilulas, xij.; sumat unam ter in die.

While in Munich, a few years ago, when talking to Professor Pfeuffer regarding his treatment of gout, he told me that he found the acetate of potash a good remedy, and it so happens that this also has the effect of diminishing the amount of urea and uric acid in the urine; and, as I said with reference to colchicum, I believe it is not simply the elimination of these substances which is arrested, but their actual formation that is checked.

I have already pointed out how animal diet increases uric acid. I may mention that there are certain other remedies

besides those already spoken of, which diminish the formation of uric acid; these are atropine and cod-liver oil. Tea and coffee produce the same effect. On the other hand, there are some which, although they do not diminish its formation, yet lessen the quantity in the system by increasing its elimination from the body. Among these may be mentioned the phosphate of soda, and the liquor and bicarbonate of potash. Both in the urine of gout and of rheumatism the uric acid has been found increased after the administration of liquor potassæ, as well as after a few doses of the simple carbonate of potash, and it is not at all improbable that the beneficial action of these remedies in the above-named diseases may in a measure be due to their hastening the neutralisation and elimination of the acid. Indeed, were I asked to give an idea of the pathology of gout and rheumatism, I would say that all our knowledge as yet tends in one direction—namely, to show that both gout and rheumatism are due to the presence of an abnormal amount of acid in the system; most probably uric acid in the one case, lactic acid in the other. I have repeated Richardson's experiments of injecting lactic acid under the skin of dogs, and although not always successful, have on three or four occasions produced artificial articular rheumatism. On one occasion I even got the endocarditis he has so ably described.

Uric acid is not only eliminated by the kidneys, but by the skin, and even by the lungs; so that, by increasing the action of the skin and pulmonary exhalation, we may aid its elimination from the blood. Experience has shown that whatever interferes with cutaneous transpiration augments the quantity of uric acid in the urine. The effect of cold has been already alluded to. Skin diseases have a similar effect. In eczema and psoriasis, uric acid increases in the urine, and in the pustules of pemphigus crystals of it have been detected (Malmeston). In the urine of a severe case of pemphigus, under the care of Dr. Hughlings Jackson, which he sent to me to examine, I found 17 grains of uric acid to the 32 oz. The urine was of a dirty brown colour, with a very acid reaction, and had a specific gravity of 1023.

With regard to the influence of alcoholic drinks, beer included, it is interesting to observe how they lessen the urea and increase the uric acid in the urine; whereas, with tea and coffee, the reverse occurs: they lessen the uric acid and increase the urea. Then, again, there are substances which act similarly on both uric acid and urea. The acetate of potash, colchicum, quinine, and cod-liver oil, for example, diminish, while bicarbonate of potash and liquor potassæ increase both.

These facts furnish us with several hints which may be turned to good account in practice. Remedies we possess in abundance, if we only knew how to apply them.

When I hear men saying that the medicines they are employing are little better than useless, it often occurs to me that they are, perhaps, not far wrong, although the want of success may not be, as they "vainly" imagine, due to the impotence of remedies, but to the want of knowledge and judgment brought to bear on the employment of them. A man needs only to pay a little attention to the teachings of physiology to learn what powerful weapons nature has put into his hands. Like all weapons, however, they may be turned to good or to evil account, according to the knowledge or the inclination of their employer. I would even venture to suggest to our sceptical brethren that it would, perhaps, be wiser if, before passing judgment on any particular remedy, they first made themselves familiar with the how, when, and why to employ it.

TINCTURE OF ALOES AS AN APPLICATION TO WOUNDS.

—M. Delieux observes that, notwithstanding the great repute of aloes as an external application in former times, it is now seldom used, and that he was induced to give it a trial in consequence of its great utility in veterinary practice. After trying it in combination with other balsamic substances, he has come to use it alone, finding a saturated tincture made with one part of aloes and two of alcohol to be the best preparation. Suppurating wounds, when at all of an atonic character, are to be dressed by means of charpie dipped in the tincture, the application causing little or no pain. Old and obstinate ulcers, and ulcers from decubitus in cachectic subject are much benefited by it. It is useful also to bear in mind its great cicatrising power in wounds and ulcers occurring in our domestic animals, especially the horse. Erosures and gallings by its aid are prevented degenerating into ulcers.—*Bull. de Thérap.*, vol. 66, p. 28.

ORIGINAL COMMUNICATIONS.

THE RADICAL CURE OF INGUINAL RUPTURE.

By JOHN WOOD, F.R.C.S.,

Assistant-Surgeon to King's College Hospital.

No. VII.

ON THE CHOICE OF CASES FOR THE RADICAL CURE.

WHEN a Surgeon is consulted as to the treatment to be adopted in a case of rupture it has been a practice too commonly adopted to turn over the case entirely to the truss makers, with the idea that the province of the Surgeon has ceased with the decision that it is really a case of rupture.

The choice of the mechanical support has thus devolved upon those who, however skilful they may be in adapting contrivances, have usually so imperfect an acquaintance with the anatomy of the parts, the vital properties of the tissues, and the peculiarities of the different kinds of rupture, that the case is treated much more in the interest of a particular form of truss or a patent principle than in that of the patient. The mechanism also is often adapted for a requirement entirely suppositious, and unfitted for or detrimental to the case in question. Hence the recurring disappointments, the futile trials, and expensive failures which commonly await the hopes of the unfortunate seeking relief in the columns of the advertising newspaper. My own belief is, that the shape and size of the pad is of more importance than the means adopted for keeping it in position. All that is required of the latter is that it shall afford a sufficient and steady backward pressure upon the pad, in the right place, and *perfectly level* to the surface upon which it is applied. In most cases in which the truss does any good whatever, this is accomplished by the use of a spring of one kind or other operating from the back of the patient.

Occasionally, by a well-fitted truss of the right kind, and with great care and attention on the part of the patient or his friends, the rupture may be cured in young persons, after a year or two of constant and unremitting pressure. But when it is considered that the commencement of the cure dates from the time that the bowel was last in the sac, it will be seen that the cases in which a truss effects anything more than to keep the rupture manageable and supportable are not numerous. And there are many cases in which, from the shape and size of the hernial openings, the presence of a chronic cough or constipation, the force and advantage of the abdominal muscles, the peculiar conformation of the loins, or the general laxity of the abdominal connexions, no truss is efficacious beyond a short period, and under perfect quietude of body and limb.

All trusses are liable to fail at critical periods of position or exertion in which the patient may require all his bodily activity to extricate himself from an unpleasant or dangerous position. It is under such circumstances that strangulation, with all its attendant horrors, awaits the patient, and an operation incomparably more severe and dangerous than that for the radical cure is so frequently demanded in the attempt to save him from a painful death. All who are acquainted with Hospital statistics know how unfavourable they are in reference to the operation for strangulated hernia, how frequently it is called for, and the disadvantageous effect it usually has upon the condition of the rupture afterwards, even when its purpose of saving life has been successfully accomplished.

There are two classes of cases in which the idea of an operation for the radical cure may be entertained. In the first class are the more severe cases in which no truss pressure or retaining bandage of any kind is available to keep up the rupture and to prevent its getting larger, more painful, more inconvenient, and more disabling to the patient. These cases are usually found to be the first candidates for any method of treatment which may offer a reasonable chance of success. And for the same reasons which render them usually uncontrollable by trusses, they are the severest test of any new operation as well as the readiest subjects of it. The outcome of my experience in operating upon these aggravated cases is that a complete cure may be looked for in children and boys under 14 years, if not by one operation, by a repetition of it, and that the symptoms which ensue in them are usually so mild that the operation may be said to be quite a safe one when skilfully performed.

In adult ruptures of this severe form and large size the chances of entire success are less favourable, and the symptoms following the operation are more severe. In some, however, I have entirely succeeded, and almost all the cases have been, at any rate, so far ameliorated that a truss could be worn more effectively after the operation. In such cases the increased necessity for some means of rendering existence tolerable may fairly be considered to balance the increased risk of an operation. After 50 years of age I do not think any operation advisable as a general rule. In the earlier part of my experience a considerable proportion of these large cases was operated on, the effect being to help to reduce the proportion of successful cases, making it less than it has been in my later operations. Improvements suggested by continued experience have also, no doubt, tended to increase the per-centage of successful cases.

In the second class of cases I would place those in which a truss is more or less available in retaining the rupture. This may again be subdivided into those which easily slip down and are of considerable size, not at all times retained by the truss, and are apt to give occasionally great trouble, inconvenience, and danger by becoming strangulated; and those which are perfectly under control, easily and completely retained, and of inconsiderable size. Of the former of these it may be said that, at whatsoever age occurring, the chances of a complete closure of the hernial canal by truss pressure only are very small indeed, if not absolutely *nil*. In the latter, if occurring in early life, the chances of a cure by proper truss pressure are considerable. It is difficult to arrive at a correct conclusion with respect to the proportion of cures obtained by truss pressure, for various and evident reasons, among which an important element, viz., the dubiety of a correct diagnosis in the first instance, may fairly be reckoned. In both these kinds, however, the experience already gathered renders it indubitable that, by an operation of a perfectly safe character, and attended with little pain and personal inconvenience, the chances of a complete cure are increased 60 to 70 per cent.; that partial failure brings comparative improvement; and that the inconveniences and risks of an operation, with a choice of time and circumstance, are, to say the least, not so great as those from strangulation, obstruction, inflammation, or injury which may happen in the course of a ruptured patient's life. In the case of young children it may be put even stronger than this; the doubtful result of truss pressure, so difficult to be effectively and constantly applied, and its liability to be interrupted by illness and by an accidental descent of the viscera, may be changed almost into a certainty of success by a proceeding involving hardly any risk when skilfully applied under favourable circumstances, and attended with little pain and no deterioration of the patient's health and strength.

It will be easily gathered from the foregoing observations that while in some cases the Surgeon will be justified in recommending strongly the adoption of the operation after a trial of truss-pressure, in others it must always be left to the decision of the patient himself or his friends, after a careful and impartial statement of the chances of an operation in his individual case.

The circumstances and habits of a patient, as well as his bodily condition and conformation, will, in many cases, determine the propriety of an operative interference. If he has to get his living by bodily exertion; if his habits are active; his amusements athletic; his profession requiring bodily completeness, strength, and ability; his prospects in life or probable position far from Surgical assistance, as in emigrating or colonising—all these must be taken fairly into consideration in placing his position before the patient, or in advising his decision.

On the other hand, the severity of the case, its complicated character, and especially the age of the patient, should have each its due influence upon the mind of a Surgeon tending to negative the proposition for an operation. One chief rule, I may again mention in this place, and that is, entire reducibility of the contents of the rupture is (with very few exceptions) an indispensable condition of the operation for the radical cure of hernia. In the female, as a general rule, an operation is less called for, unless the rupture be so troublesome, painful, large, and disabling as to be burdensome to life, or the patient so young as to make the cure almost certain, operative interference is not to be advised, or may be left to the patient's own choice when the "pros" and "cons" are fairly stated to her.

In all cases in which the operation for the radical cure is contemplated it is very important to institute a searching exa-

mination of the thoracic and abdominal viscera to ascertain whether there be any lurking disease which may influence the success or safety of the operation. The tongue and pulse should be examined, the temperament and build scrutinised, the history of the patient's illnesses listened to, the heart and lung sounds ascertained by the stethoscope, and the urine carefully examined. The latter I would particularly enjoin, since the presence of phosphates, oxalates, or albumen may indicate the existence of lurking disease previously unsuspected by the patient. The presence of albumen especially indicates a condition of things in which it would be hazardous to attempt any operation not absolutely needed to save life, and especially those which may more or less affect the abdominal cavity.

In the female the condition of the ovarian and uterine functions should be ascertained; the liability of these organs to derangement, and their effect upon the abdominal circulation when disordered has an important bearing upon the propriety of an operation of this kind. In conclusion, it must be always kept in mind that operations for the relief of inconvenience, disability, and deformity belong to a class differing much from those which are performed under the more necessitous circumstances which endanger life, and cannot with propriety be pressed by the Surgeon upon the acceptance of his patient so strongly as where the risk of refusal is much greater. The patient himself, or his friends, must be placed in a position to decide for themselves upon the main bearings of the question.

At the same time, such operations are usually of a kind in themselves not so severe nor so dangerous to life as those which are usually considered as peremptory, and may, therefore, be recommended with less hesitation if there be a reasonable prospect of the patient escaping the accidental complications which may ensue upon any operative interference whatever. The probability of such accidental increase of risk from erysipelas, pyæmia, typhoid symptoms, Hospital gangrene, and the like, should be estimated by the Surgeon when choosing the time and place of operation. Sickly seasons should be avoided, and, as a rule, the hot and autumnal months, which, from the greater frequency of diarrhoea and other abdominal disorders, are much more unfavourable for abdominal and perineal operations than other seasons of the year. Operations of the nature of that for the cure of rupture can be fixed at the most convenient season usually, and may often be postponed with benefit to the patient.

With these precautions—good judgment, a sufficient amount of practical anatomical knowledge, coolness and skill in the use of instruments—the conscientious Surgeon may be assured that the operations for the radical cure of rupture described in the preceding papers are at any rate as safe and as successful as any that have been devised of like character and with like purposes, and which are admitted, without hesitation, among the armamenta of modern Surgery.

4, Montagu-street, Russell-square.

ON THE ADMINISTRATION OF CHLOROFORM IN CASES OF EPILEPSY AND CHOREA.

By WM. MURRAY, M.D.,

Physician to the Newcastle Dispensary and Hospital for Sick Children.

THE two diseases under consideration are admirably adapted for comparison and contrast—for comparison because their chief symptoms, and, perhaps, their physiological development, are nearly allied; for contrast because their course, termination, treatment, and its effects so widely differ. Epilepsy is a convulsive disease, resulting primarily no doubt, from irritability of nervous centres which discharge enormous shocks of nervous force, and then leave the cerebro-spinal system without controlling power to direct the force emitted. In its convulsive movements, and in that state of nervous system which, while generating nervous force, does not provide for the disposal of it, it closely resembles chorea. But in all that pertains to its fatality as a disease, its ultimate effects, the imminent peril in which it constantly exposes its victim, and the chances of its removal by treatment, it stands out in gloomy contrast with chorea, which is generally a slight and short disease easily amenable to treatment.

The two cases to which I beg to call attention are remarkable for the manner in which they run counter to the above rule, inasmuch as the one of chorea, at first mild, became one of the most frightful cases it has been my lot

to witness, and in spite of all our efforts went on to a fatal termination; while the other, of epilepsy, when first seen, though one of the gravest kind, and of very long standing, has been influenced by treatment in a very striking manner. As the chief agent used in both cases was the same, it seemed proper to me to lay the results of its action before the Profession.

At 10.30 one Saturday evening I was called to see a young lady, and found her suffering from choraic movements of the arms, face, and legs, and manifesting by jocular remarks evident hysterical symptoms. A somewhat confused account of her having experienced a shock to her feelings a short time before; sedentary occupation as a governess; and a hurried journey homeward from the West of England, during which the chorea set in, was all the history I obtained of the case.

The bowels were confined and the tongue coated, so I began treatment by a brisk mercurial purge, followed by an aloetic draught the following morning. On the Sunday evening and Monday morning she was much relieved, but had slept badly. I then prescribed a mixture of hyoscyamus and valerian with a pill of aloes and sulphate of iron, and a dose of chlorodyne at night. She slept better on Monday night, but was restless on Tuesday, and slept none at night. On the Wednesday and Thursday the choraic movements increased, and she had had no sleep, in spite of frequent ablutions of cold and hot water, large doses of hyoscyamus and chlorodyne. The restlessness now being severe, and the chorea violent, while there was an entire absence of pain in the head, I ordered, and she took, grain doses of morphia, to be repeated every two or three hours until sleep was induced; but no relief whatever followed. Diarrhoea set in, and the menstrual flow appeared on the Saturday morning. At one o'clock on that day things looked somewhat gloomy, as she had not slept for four nights, and the chorea had become so violent that she had to be held or tied to keep her in bed, I ventured to administer chloroform, which was followed by a placid sleep for an hour; it was administered a second time with the same results. As she became violently choraic and convulsed after waking each time, it was determined to continue the administration of chloroform without intermission until a decided effect was produced. This was done for no less than fourteen or fifteen hours with but one intermission of half an hour to give food. At the end of that time she remained, after removing the chloroform, perfectly quiet, became quite collected in her mind, and remained so to the last. It was remarkable that after the first hour or two had passed, a very small quantity of chloroform was found to obtain the desired effect, and for the last six or eight hours a very few drops per hour were sufficient to keep up its sedative action. When she came to herself, so collected in mind and so free from choraic movements, every effort was made to sustain the exhausted powers of life by nutritive and stimulating diet; but in spite of our efforts, the thread of life gave way, and though she remained calm and peaceful during the Sunday and Monday morning, she sank in the after part of that day, about forty hours after leaving off the chloroform.

I leave this case in all its obscurity as to diagnosis, etiology, and pathology, and proceed to narrate the other instance, in which large quantities of the same drug have been administered. (No post-mortem examination obtained.)

Epilepsy.—John B., aged 69 years, is a powerfully-built man, and wears well for his age. Has been the subject of epileptic fits of a very severe nature for nearly thirty years. The history of his case runs thus:—Till he reached his 40th year there was not, he says, a healthier or stronger man to be found. At that time, being of a desponding temperament, he was severely tried by grief, and had his first epileptic fit; a second attack after two years' interval has been followed by an annual seizure till four years ago, when, falling down in a fit in the street, he was taken to the Manor Police Station, and treated (as if intoxicated) by copious pailfuls of cold water. Since this severe and ill-advised treatment at the hands of these hasty and heroic therapeutists, our patient has been seized almost weekly by very severe epileptic fits; sometimes they are delayed for two weeks, but whenever they are so delayed, the longer interval is sure to be followed by a succession of several severe fits in one day. Very often the fits have occurred several times in one week, and he has never felt himself safe from them. Ever since the first fit, but especially during the last four years, his memory has been weakened, and most notably so before and after each fit. He had lost delight in all his favourite pursuits, he has been unable to read or to think from an utter want of power of concentration,

and when a fit was about to occur, during the preceding day, he became nervous, agitated, and incapacitated to do the simplest things—unable, as he says, “even to light his pipe.” Before some of the attacks he has a distinct warning, and has been able occasionally, by drinking hot and other fluids, to ward off the attacks. The warning consists of a fluttering over the cardiac region, accompanied by palpitation. As has been before hinted, some of the attacks are single and some are numerous, following each other in rapid succession for several hours.

He positively declares that scarcely a day has passed of late without some symptoms reminding him forcibly of his malady; the chief of these have been dizziness, apathy, wandering, irritability, and incapacity for the slightest exertion. During the thirty years of his disease he declares that he has wandered about the country and had advice from eight Dispensaries, ten Infirmarys, and many private Practitioners, without the slightest relief.

On November 15 last, he became my patient at the Dispensary, having had a fit on the eighth day of that month. For several reasons which I need not mention here, I looked upon his case as likely to be benefited by often repeated and somewhat powerful doses of a sedative, and chose to use chloroform as the agent. He began treatment by inhaling about ten drops from a linen cloth three times a day. Each administration was followed by a slight temporary excitement and partial loss of consciousness. I saw him once a week for four weeks, and each time he reported himself as relieved of the sensations and symptoms which had hitherto marred his health during the intervals of his fits. At the end of four weeks and three days, he had a severe attack, followed by a succession of lesser fits for six or eight hours. He was advised to persevere in the use of the chloroform, which he willingly did. During the next four weeks he frequently spoke of the entire relief he had experienced on the removal of all his sensations and symptoms. Exactly four weeks and four days after this he had another severe fit, which was followed by one or two minor attacks.

The interval now reached its seventh week, and the man declared he never felt better in his life. He says he had new energy, and was entirely free from the troublesome symptoms which before interfered with his comfort between the graver epochs of his malady. As the chloroform at this time was followed by sickness and shivering, it was deemed advisable to remit the treatment and see what had been done, and nine weeks' interval now elapsed before another slight attack occurred, but no bad symptoms exist in the interval, and he declares himself very well.

In conclusion, I may state that the chloroform has had no bad effect beyond the aggravation of a tendency to asthma from which he occasionally suffers. All other treatment except attention to the state of the secretions, diet, and regimen has been avoided. I may mention here that at an early period in the treatment, when he was subject to the disagreeable symptoms, a good dose of mugwort immediately dispelled them, as it often does in the case of even graver attacks in some patients. I have not read or heard of the above mode of treating this disease, but would be glad to be referred to any such on record. In this one case it has decidedly influenced the disease in prolonging the interval from one to four, five, eight, and ten weeks, in addition to which it has removed very decidedly the distressing symptoms of the intervals, and thus increased to no small extent the man's present comfort.

THE *Melbourne Argus* of March 10, 1864, gives a lecture, by Dr. W. Thomson, asserting the identity of measles and the bovine pleuro-pneumonia:—“In both there is the usual period of sickening, marked by the fever and ague, and soon followed in both, after some days of indefinite illness, by cough, cold, watering eyes, clammy mouth, and dry, wiry skin. In the human subject the period of eruption now sets in, and of thickened respiration. In the animal there is the corresponding bronchial disturbance, and ‘the bran-like dust in the coat,’ owing to desquamation of the skin. The disease upon this is on the brink of its third stage. Bronchitis, merging into pneumonia, expectoration, hepatisation, and foetid diarrhoea, recur in rapid succession or simultaneously, and the doom of both victims is pronounced. The next step for the one is the churchyard, for the other the butcher. When the last epidemic of rubeola visited this colony, pleuro-pneumonia spread simultaneously.”

REPORTS OF HOSPITAL PRACTICE

IN MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

SIX CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 588.)

Case 4.—Ovariotomy—Pelvic Abscess—Recovery.

A married woman, with some red Indian blood, 32 years of age, was sent to Mr. Wells for ovariotomy by Mr. Stretton, of Beverley, and was admitted March 22, 1864. A large ovarian cyst of between four and five years' growth had been tapped in Guy's Hospital four months before. Twenty-seven pints of clear fluid were then removed, and a “hard substance” left. It was two months before there was much increase, but latterly the increase had been rapid. The patient was healthy in appearance, but there were signs of cardiac disease which led to serious doubts as to the propriety of performing ovariotomy—viz., a small pulse, occasionally intermitting, a loud second sound, and a soft mitral murmur. But as the lungs were healthy, the urine normal, and there was no œdema of the legs, ovariotomy was performed on April 4. Dr. Koepl, of Brussels; Dr. Pickford, of Brighton; Dr. King, of Hull; Mr. Judd, Mr. Lord, etc., were present. An incision of only three inches long, midway between umbilicus and symphysis pubis, through a thick layer of fat exposed a non-adherent cyst, which was tapped, emptied, and withdrawn. But it was found that there was no distinct pedicle, the cyst being fixed between the layers of the right broad ligament in the iliac fossa, and close up to the bladder. Accordingly no attempt to isolate it was made, but the neck of the cyst was inclosed in a large clamp, and fixed outside. The left ovary having been found to be healthy, the wound was closed in the usual manner. Twelve pints of fluid had been removed from the cyst, which, with the secondary growths, weighed about two pounds.

The patient went on very well for three days. On the fourth day the clamp was removed. Some bloody discharge came on from the uterus in the morning, and in the afternoon there was a similar discharge in considerable quantity from the opening left for the pedicle. This continued both from the wound and the vagina during the three following days, when the uterine discharge ceased, and that from the pedicle became more purulent. Examination by the vagina and pressure proved that the collection had its seat on the loose cellular tissue about the right broad ligament. On the ninth day the slough had nearly all separated from the pedicle, but a very free, dark, fetid, serous discharge continued for some days later. This gradually lessened in quantity, became less fetid, more purulent, and at last ceased altogether. She was discharged May 17 in very good health.

Case 5.—Ovariotomy—Pedicle returned—Death from Peritonitis.

A childless, married woman, 50 years of age, was sent to Mr. Wells in November, 1863, by Dr. Guy, of Doncaster. She had a large multilocular ovarian tumour of very rapid growth, having been first detected less than three months before. There was œdema of the left leg, commencing emaciation, and a very unhealthy aspect. A course of treatment was advised with the hope of improving the general health, and she returned home; but increase still going on, she came to town again, and was admitted January 30, 1864. The largest cyst was tapped on February 2, and twenty-four pints of thick mucoid fluid were removed. Groups of secondary cysts were then felt on both sides, those in the right iliac region appearing to be firmly fixed there. She improved in health and left the Hospital February 12. On March 29 she was readmitted, suffering much distress from distension. She was tapped on the 31st, and eighteen pints of dark fluid were removed, with some relief, but with no great diminution in the size of the abdomen. Some bronchial congestion followed, but subsided, and (as the only hope of saving life) ovariotomy was performed on April 14. Dr. Koepl, of Brussels; Dr. Guy, of Doncaster; Dr. Playfair, etc., were present. An incision was made eight inches downwards from the umbilicus, through the very fat and

oedematous abdominal wall, and some extensive adhesions anteriorly were easily separated by the hand. A piece of adhering omentum about three inches broad was also separated. During the separation, the cyst gave way, but was easily removed, and a very narrow pedicle was secured temporarily by a clamp. The tumour was cut away, the peritoneal cavity cleaned by free sponging, the left ovary found to be healthy, and the wound closed as usual after securing the pedicle behind the clamp by a silk ligature (which was cut off short), removing the clamp, and allowing the pedicle and ligature to sink into the abdomen. Twenty-six pints of fluid were collected, and the semi-solid mass weighed seven pounds and a-half.

With the exception of occasional lumbar pains, she went on very well for twenty-four hours. The second night she also slept well, but early next morning vomiting came on, with tympanites, scanty concentrated urine, and the pulse rose to 140. All the sutures were removed forty-four hours after operation, as the wound was accurately united throughout. Some relief was afforded in the afternoon by the passage of a large quantity of flatus through a long tube passed into the rectum; but at night vomiting of dark greenish fluid became increasingly urgent, and she died exhausted sixty-four hours after operation.

The body was examined by Dr. Barratt. The right cavities of the heart contained adherent fibrinous clots. All the blood elsewhere was fluid and blackish in colour. The liver was very fatty; the gall bladder distended. About two pints of dark red serum had been effused into the peritoneal cavity, which contained neither blood nor ovarian fluid. The recent lymph was confined entirely to the lower and back part of the abdomen and pelvis; the peritonitis radiating from the pedicle, not from the wound in the abdominal wall, which was completely united, nor from a surface where the cyst had been adherent. There was no such attempt to capsulate the pedicle and ligature as there probably would have been had the patient been in better health. Mr. Wells expressed his opinion, when exhibiting the specimen at the Pathological Society, that the chances of recovery would have been greater had it been possible to keep the end of the pedicle outside the abdomen; and he stated that the trials which he had made of returning the pedicle seemed to teach that in young or healthy subjects, where circumscribed peritonitis and effusion of plastic lymph might be expected, the practice was a good one; but in debilitated or cachectic patients, in whom diffuse peritonitis and effusion of serum or of aplastic lymph might be feared, it would be safer (when the clamp could not be used) to leave the ends of the ligatures hanging out through the wound, and thus secure an opening for the escape of effused serum, and for the ligature itself with the tissues enclosed in it after their separation.

Case 6.—Multilocular Ovarian Cyst—Ovariectomy—Pedicle Returned—Recovery.

A married woman, 46 years of age, came from Banbury to consult Mr. Wells in September, 1863. She was in feeble health, and had an ovarian tumour of from two to three years' growth, filling the greater part of the abdomen. It was free from adhesions anteriorly, but the uterus was slightly pulled upwards. She was admitted to Hospital, and six and a-half pints of opalescent albuminous fluid were removed by tapping from the largest cyst on October 26. The uterus felt more free after the tapping, she became much more comfortable, returned to the country, improved in health, and was readmitted for operation on April 23. The connections between the tumour and the uterus appeared to be close anteriorly; but as there was no other unfavourable condition, Ovariectomy was performed on May 2. Dr. Campbell, of Boston, United States; Mr. Griffin, of Banbury; Dr. Wallace, of Aberdeen, &c., were present. Dr. Parson administered chloroform. An incision, five inches long from one inch below the umbilicus, exposed a non-adherent cyst, which was tapped, emptied, and withdrawn. The cyst was closely attached to the breadth of about three fingers to the right side of the uterus. The connecting medium was transfixed by a needle carrying a strong silk ligature, with which the broad ligament was tied in two halves, and the tumour was then cut away close to the ligatures, the ends being cut off short and allowed to sink inwards with the uterus and left ovary, which was healthy. The only bleeding was slight venous oozing from the sides of the incision. The wound was closed in the usual manner.

She required rather more than the usual amount of opium on account of pain, vomited occasionally, and was much

troubled with flatulence during the first and second day; but after this she recovered well. All the sutures were removed on the 5th (three days after the operation), the wound being accurately united throughout by first intention. The bowels acted on the 9th, and she was discharged in good health on the 21st—less than three weeks after operation.

Mr. Wells operated on another case on May 23. The patient was going on remarkably well on the 31st. The report will appear, with others, in a future number.

THE LONDON HOSPITAL.

ABSTRACT OF A CLINICAL LECTURE ON A CASE OF INTESTINAL OBSTRUCTION, FOR THE RELIEF OF WHICH AMUSSAT'S OPERATION WAS PERFORMED IN DECEMBER, 1861, AFTER EIGHTEEN DAYS OF CONSTIPATION. (a)

By JOHN ADAMS, Surgeon to the Hospital.

GENTLEMEN,—I present before you the poor man on whom I operated two years and a-half since in consequence of obstinate constipation lasting eighteen days, and with entire success, as you may now see. The man, although somewhat haggard in appearance, has nevertheless a not very unhealthy aspect, and has evidently been well nourished ever since the operation. The case is unusually interesting because of the long duration of life after an opening has been made into the descending colon—an operation attended, as far as my experience goes, with great success, and one performed with such facility and so little risk as to amply justify it in properly selected cases. I am really at a loss to conceive that any objection should be raised against the operation provided a due selection be made of the cases, for the relief is immediate and life may be prolonged to an indefinite period, as in the case before us.

I need only refer you to the former report of the case, and I think you will admit that the urgency of the case, irrespective of the success which has attended the operation, amply justified the means adopted.

The progress of the case since I last addressed you on the subject is this:—Soon after he left the Hospital he passed two small motions by the rectum, his fæces being discharged by the opening in the colon. He continued in fair health until December last, when he suddenly discharged a large quantity of blood per anum, by which he was very much reduced; a small quantity also escaped by the urethra. By this he was much prostrated, and since he has occasionally passed blood in small quantities by the bowel, and blood and pus have escaped by the urethra, the bladder being exceedingly irritable, and incapable of holding but a very small quantity of water, which is very foetid. He complains of pain in the loins and down his thighs, and appears to be labouring under some progressive disease. On introducing my finger per anum, it is arrested by a very hard mass, which conveys to me the idea of its being situated in the rectovesical pouch of peritoneum; and my impression is, that the sigmoid flexure of the colon has fallen into the fossa, and is either affected with schirrus, or has become matted by chronic inflammation to the bladder on one side and rectum on the other, and that a communication is established between these viscera by a small ulcer, which now and then becomes closed. The man's appearance and general condition is rather unfavourable to the idea of cancer, and I must own that the opinion expressed is at least problematical. The prognosis is unfavourable, and I shall watch the case as long as I can, but I shall not be able to detain him in the Hospital.

I wish you to look particularly at the opening in the left loin: it is much larger than is usually found in such cases; this is attributable to sloughing, which occurred after the operation. A large quantity of florid mucous membrane, in the centre of which is the opening into the gut, protrudes, and it is remarkable how readily it recedes when he lies on the opposite side. He retains it by a simple belt, which he removes when his bowels act. It is also remarkable that he gets a diurnal evacuation immediately after his breakfast, and has at this time a desire to evacuate. On the contrary, when the fæces are liquid, he possesses no control over the bowels, and he has not the premonitory desire to empty the bowels.

(a) See *Medical Times and Gazette*, April 12, 1862.

BIRMINGHAM GENERAL HOSPITAL.

ANEURISM OF THE BASILAR ARTERY FATAL BY RUPTURE AND EXTRAVASATION OF BLOOD.

(Under the care of Dr. JAMES RUSSELL.)

THE following case needs little comment. The age of the patient (28), conjoined with the circumstances that death was caused by rupture of the aneurism, and that no disease was found in the coats of the cerebral arteries, are in accordance with Dr. Gull's observation ("Guy's Hospital Reports," 1859), that "in the later periods of life aneurism is not unfrequently found associated with more or less extensive disease of the cerebral vessels, to which the symptoms and the fatal result may be owing, the aneurism being an accidental and not important concomitant;" whilst in younger subjects "aneurism commonly occurs without disease of the vessels generally, and is fatal either from rupture of the sac, or from pressure or softening around it." These facts form the foundation of another important statement by the same Physician: that "whenever young persons die with symptoms of ingravescant apoplexy, and after death large effusion of blood is found, especially if the effusion be over the surface of the brain in the meshes of the pia mater, the presence of an aneurism is probable."

Aneurism of the basilar artery, besides being the most frequent among intracranial aneurisms, is that form which, for obvious reasons, is most likely to be productive of direct symptoms; in the present case no symptoms are reported of earlier date than a week preceding death, and it is very uncertain whether the ailment of which he then complained had any reference to the aneurismal disease, though headache (a symptom specially noticed by Dr. Gull) was prominent. Such immunity is probably explained by the situation of the aneurism; it was buried in the third ventricle, and so entirely free from the various important organs at the base of the brain, that after I had carefully examined the arteries of the base, I remained ignorant of its presence until I had nearly ended the dissection.

The occupation of the patient, that of a labourer, agrees with a suggestion by the the author I have already quoted,— "that mechanical causes, acting locally, have much to do with the origin of the disease;" and it is worthy of note that rupture of the aneurism took place during bodily effort. Death occurred in four hours and a-half after rupture. Rupture of intracranial aneurism does not necessarily induce the most rapidly fatal form of apoplexy. Of eighteen cases quoted or reported by Dr. Gull, in which the duration of the symptoms is specified, death occurred in less than one hour in six cases; from one to twelve hours in eight; from three days to seven in four. In my case the situation of a portion of the effused blood, by causing compression of the medulla oblongata, determined rapid death.

P. M. aged 28, labourer, of not very temperate habits. He had been ill during the week preceding his death with feverishness and headache. His bowels were much constipated, and required the administration of croton oil for their relief. His brother ascribed his illness to drink. He was perfectly well at the end of the week, and returned to work, when, as he was carrying a hod of bricks, he suddenly fell back to the ground. The attack took place at half-past three. An hour afterwards he was admitted into the Hospital, and was reported by Dr. Anderson, the House Physician, to be quite insensible; his face slightly livid; his breathing noisy and at times gasping, with intervals of tranquil inspiration; his pupils were considerably contracted; no convulsive movements occurred. He died at ten minutes to eight—four hours and twenty minutes from the moment of his seizure.

Autopsy.—Veins of the dura mater rather full; the sinuses contained much liquid blood. At the base of the brain considerable ecchymosis existed beneath the arachnoid around the pons and medulla oblongata, but not perfectly concealing these bodies, extending as far forward as the locus perforatus. The effused blood was entirely removed with the membrane, leaving the surface of the brain uninjured. The fourth ventricle was full of recent coagulum. The tissue of the pons, medulla oblongata, and crura was perfectly sound. There were more bloody points than usual in the right cerebral hemisphere. Each lateral ventricle contained a fresh clot, moulded to the shape of the cavity. The superficial fibres of each thalamus, of the under surface of the corpus callosum, and of the cerebral substance enclosing the ventricles, were roughened rather than torn. The third ventricle was full of blood, and just at

its lower part a deep stain of the tissue of its walls drew attention to a small aneurism projecting into the third ventricle, about capable of containing a pea. It sprang from the basilar at its very termination. The coats of the aneurism and of all the arteries at the base were perfectly healthy. The lungs were gorged with bloody fluid, and the large veins of the thorax were full of blood. Heart weighed 12 oz. It was healthy, save that some fat was collected at its base; the mitral valve was contracted; the aortic valves were a little thickened; the interior of the aorta was irregular. Liver, 3 lb., 13 oz. (avoir.) was gorged with dark blood; spleen, 6 oz.; kidneys, 11 oz., deeply livid from congestion, otherwise healthy. The urine in the bladder was clouded by heat and nitric acid; it did not contain sugar.

SATURDAY, JUNE 4.

ARGUMENT FOR A VETO ON THE LIQUOR TRAFFIC.

THE efforts of the teetotallers are unhappily marked by a fanaticism which repels the sober part of society. Most of us shrink from joining in the most laudable effort, if it be necessary to subscribe at the same time to doctrines which are contrary to reason and daily experience. We know that wine and beer properly used are wholesome aliments and beneficent medicines; we know that the excessive and deleterious abuse of them, however deplorable, is no argument for the total destruction of them and the abolition of the trade. Nevertheless, we think the trade ought to be controlled more effectively, and that there are arguments for this control so simple and decisive that we wonder they have never been made proper use of—not even by Dr. F. R. Lees, the ablest and most learned of all the voluminous temperance writers.

Our argument is founded on the existence of the Poor-law. It is sufficiently notorious that the people of any given parish may be divided into two portions—they who pay poor's rates, and they who receive those rates. One portion supports itself; the other, on every emergency, flies to the "parish,"—i.e., to their self-supporting neighbours. If a so-called working-man is out of work he goes to the ratepayers for bread; if he is ill, or his wife or children, he goes to the Parish Doctor, is treated with medicines, or, it may be, wine and beef-tea, at the ratepayers' expense; and when old and helpless, whether from unavoidable misfortune or want of thrift, he accepts such board, lodging, and clothing as the workhouse affords at the ratepayers' cost. Any one who knows the condition of some small struggling ratepayers, and how little they can afford to drink if they are to pay their Poor's Rates, must feel that if they have some hardships they ought to have some privilege to match. That the man who pays should have some sort of control over those who receive, is an axiom which we think cannot be disputed.

On the other hand, it is notorious that the rate-eaters—the idle and thriftless, are also most wasteful in this one point—viz., the consumption of alcoholic liquors; and that these

liquors aggravate tenfold the evils for relief of which they come upon the abstemious ratepayers.

One instance is as good as a dozen. On Monday morning, the 23rd, the writer of this was called up at 3.30 by a person who rang furiously enough to wake up the whole household. He was requested to come directly to a child dying. He went, and found a boy of two, son of a "working man," threatened with convulsions. Cause:—The parents had been out on a Sunday railway excursion the day before, and had let the child drink ale, which had made it ill overnight. The child was attended to, and its parents said that at daybreak they would send to the "parish doctor."

Let us add that it is an acknowledged fact that all out-patients' institutions are most crowded with cases of so-called "diarrhœa," "cholera," "bilious attacks;" or, in other words, effects of beer and gin, on Mondays.

Now, without pointing out the inconsistency of stepping in by law, and hindering the "working man" from doing any useful work on Sunday, whilst the law gives him every facility for making himself a beast and a burden to his neighbours, let us ask on what grounds can people who get drunk on Sunday demand Medical attendance at the expense of their sober fellow-citizens on Monday?

Our Hospitals and Dispensaries show in large letters the words "Supported by Voluntary Contributions;" and Englishmen glory thereat. But we may point to another place supported by voluntary contributions—the Gin-palace.

Look at this inconsistency! If the "working classes" can support by their drink large temples, as grand as *compo* can make them, with plate glass, flaring lights, gaudily-dressed young women to serve out the liquors, and fat, portly landlords, who keep gigs and smoke the best of cigars, why, then, should they call upon us to keep up that Dispensary?—that shabby, ricketty, sordid-looking old house, where a committee of sober people bargain for cheap drugs, to be served out by a starved apothecary in a rusty-black coat, who can hardly keep soul and body together? The Dispensary is made necessary by the gin-shop, and they who drink the gin ought to pay for it.

However, let that pass. No one is obliged to subscribe to a Dispensary. We are obliged, however, to pay poor's-rates; and we claim that, if we pay, we have a right to some control over those who receive; and, in especial, over that peculiar traffic in which they squander their own earnings, and render it necessary to dip their fingers into the pockets of their sober neighbours.

The "working men," we are told, are free. Let them make us free also. If they are free to drink, let us be free to button up our pockets. But if they claim the right of dipping into our pockets when sick, we claim the right of muzzling their jaws; and the people who pay ought to be found—(unless they be beguiled basely to give up their political trust to the so-called "working men")—too strong for the people that don't pay. Does any one ask, why should the working man be hindered from drinking any more than the man at a club in St. James's-street? Because the working man comes on the rates, and the man at the club does not.

We could, did space permit, follow out this argument into the minutest detail. We have said enough to show that the ratepayers of every parish should have in all equity a *veto* upon all places where the rate-eating portion of the working classes squander what they have, and make themselves and their families recipients of that Poor's rate which is now wrung from the sober and industrious. The liquor traffic will never be abolished, but it may be put under better regulation if the ratepayers will it.

There is not the slightest chance for "the Permissive Prohibitory Bill" which we believe Mr. Lawson and Mr. Bazley are to bring before the House of Commons on June 8. It would be impossible to shut up and confiscate all the public-houses in any district; but it ought to be possible to have a *veto* on any new ones or on new occupiers, and to close some of the old ones. The results of our own inquiries are these:—

If you ask the proprietor of small "weekly" tenements, he will say that his tenants were pretty sober till the new landlord came to the public-house at the corner. They used to be a humdrum *beer*-drinking set of *men*, but since the new landlord had put in plate-glass and flaring gas, and had added other adventitious aids, the whole population, especially the *women*, had taken to *gin*, and rents had got into arrear. It ought to be in the power of the ratepayers once a year to close any house which exercises abnormal and unusual temptation, and does mischief to match.

ALLEGED BREACH OF PROFESSIONAL HONOUR.

It is not often that our Professional brethren are guilty of breaches of Professional honour. They cannot often be accused of violating confidence, of revealing secrets, or of forming and acting upon surmises, based upon imperfect observation, and injurious to the character of those who consult them, and who rely on them as friends.

Yet exceptions will occur from time to time. Some years ago great scandal was caused by a Surgeon, since dead, who informed the friends of a young lady who had consulted him for fistula, that she was not a virgin. Enormous and fruitless misery was caused to many persons by this gratuitous and thoroughly indefensible act of the Surgeon's, who was felt to have gone out of the path of Professional honour.

We are reminded of this painful subject by some remarks of extreme severity which Dr. West has inserted in the third edition of his lectures, lately reviewed in our journal. Dr. West is treating of the practice of excising the clitoris, with the view of preventing a certain vicious habit. He expresses his belief that the prevalence of that habit has been exaggerated, and that the remedy is worthless and unjustifiable. The disease is, if anywhere, in the *mind*; and not to be cured by mutilating the body. But his indignation knows no bounds at the conduct of some members of our Profession, who are alleged to perform this act of mutilation, and to brand their victims with the moral stigma it implies, without a shadow of evidence of the habit for which the operation is supposed to be a remedy.

"I know," he says, "a lady, aged 53, whose youngest child was more than 20 years old, who had suffered from a painful fissure of the anus, for which she underwent the usual operation of dividing the mucous membrane of the fissure. The Surgeon who did this, without saying one word to the lady or to her husband, or hinting in any way what he was about to do, cut off her clitoris. The stump of the amputated clitoris became the seat of pain, such as sometimes follows amputation of a limb, and for months the patient was in a state of almost ceaseless anguish, which, after the lapse of between two and three years, abated, but has not yet altogether ceased. In answer to her inquiries why some other operation had been performed in addition to that which she knew was requisite, after some evasion she at length learned what had been done, and, further, had the humiliation of discovering that the justification of the outrage was, that she was assumed by the Surgeon to be addicted to a vice with the very name and nature of which she was alike unacquainted."

Dr. West is evidently no convert to the degrading £ s. d. doctrines of the *British Medical Journal*. "Our Profession," he continues, "ought to be a noble one. The ring and the sword in some Universities of the Continent still symbolise the knightly vows taken by the candidate for the Doctor's degree; and it is in the spirit of chivalry alone that Medicine can be safely practised. I have written this history in all sadness as a warning to my younger brethren how, if they are not watchful, it is possible, 'as noblest things find basest using,' that they may pervert their talents and degrade their manhood, until they sink so low as to find opportunities for mischief in the practice of their art, instead of occasions for the exercise of that power of healing which is most God-like."

It is of little use to ask who was the Surgeon implicated—whether he were guilty or not; and whether he have any explanation to offer. The true offence—if Dr. West's statement be true—seems to us to have been going out of the proper

track of professional duty, entertaining ideas which could only spring from a nasty and most prurient imagination, and which, whether well or ill founded, had no relation whatever to the case which the Surgeon was called upon to treat. The subsequent mutilation performed without the knowledge and consent of the patient and her friends, although, as Dr. West calls it, an outrage, and one for which condign damages would be given did the patient think fit to sue for them, is as nothing compared with the primary moral offence out of which it sprung. We need scarcely say that London Surgeons would not like to have it supposed that they often indulge in such filthy imaginings concerning patients who consult them.

THE WEEK.

THE APPROACHING ELECTION AT THE ROYAL COLLEGE OF SURGEONS.

ALL those Fellows of the Royal College of Surgeons of England who are unwilling that the College shall be governed by an exclusive clique of London Hospital Surgeons will be glad to hear that Mr. Gulliver intends again to offer himself for election into the Council. When Mr. Gulliver's name was passed over by his colleagues in the election into the Court of Examiners he very properly sent in his resignation. It turns out that the resignation was not accepted, so that Mr. Gulliver has been, up to the present time, a member of the Council, although since the election into the Court of Examiners he has not exercised any of the functions of a Councillor. In now offering himself for re-election, he gives all the independent Fellows of the College an opportunity of expressing by their votes their sense of the injustice with which he has been treated, and their determination that the Council of the College of Surgeons shall really represent the Surgeons of England, and the Court of Examiners British Surgical science. We are confident that Mr. Gulliver will meet with powerful and effective support.

"MILK" AND "FLARE" *versus* BUTTER.

A TRIAL in the Vice-Chancellors' Court on May 30 lets us into some of the secrets of the butter trade. An ingenious personage had a process of converting rancid Irish butter into double its weight of best "Dorset;" and the sole agent in this miraculous act of conversion and increase was said to be water. A partner was taken in, whose sense of right and wrong was acutely disturbed at finding that materials known "technically" as "flare" and "milk," but known to untechnical mortals as pig fat and beef fat, were indispensable adjuncts to the water; and, moreover, that the "technical" process did not pay. Hence he desired to extricate himself from the concern, to say nothing of £1500 which he had embarked in it. The Vice-Chancellor gave him very little comfort. We believe that Dr. Ballard has paid considerable attention to the adulteration of butter, and perhaps can tell the world if there be any test, save that of the palate, which will distinguish butter from this counterfeit stuff.

THE EPIDEMIOLOGICAL SOCIETY AND VACCINATION.

A DEPUTATION of the Epidemiological Society, consisting of Dr. Milroy (President), Dr. Walter Lewis, Dr. Mackay, R.N., Dr. Francis Bowen, Dr. Camps, and Mr. J. N. Radcliffe (Honorary Secretary), had an interview with the Lord President of the Council and Vice-President on Friday, the 12th inst., and submitted to them a report on vaccination and small-pox. The report states the various points required to make the vaccination acts more efficient. Parents should be compelled, under fine, to register the vaccination of their children. The fact that a child is not vaccinated should be *prima facie* an offence, and there should be no need to require proof that the parents were served with a vaccination notice in registering the birth of a child. The committee properly advocate *arm-to-arm* vaccination. They also desire that the control of vaccination should be taken from the Poor-law Board and given to the Privy Council.

PARLIAMENTARY.

ON Monday, May 30, in the House of Lords, Lord Lyttelton asked the President of the Council a question of which he had given him private notice respecting the intentions of the Government in order to secure the more effectual enforcement of vaccination. The returns of the Registrar-General showed a large amount of preventible disease and of deaths from small-pox, and it was very desirable that something should be done.

The Earl of Shaftesbury said the subject was one which eminently deserved the consideration of the Government. His Lordship, in confirmation of this opinion, quoted some extracts from the report of the Epidemiological Society.

Earl Granville replied to the question of the noble Lord, but his answer was perfectly inaudible.

In the House of Commons the Royal College of Physicians Bill was read a second time.

On Tuesday, in the House of Lords, the Penal Servitude Acts Amendment Bill was read a second time.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XVIII.—MARCH 12.

Anatomy of the Orang continued.—The tongue of the orang approaches more nearly than that of the chimpanzee to the human form, the circumvallate papillæ being arranged in the form of a V. On the other hand there is no uvula to the soft palate. The stomach is considerably elongated; its cardiac extremity is round; the pyloric portion tubular and curved. Sandifort describes the presence of valvulæ conniventes in the small intestines of the adult orang, but they have not been noticed in the young specimens which have been dissected in this country. There is a long appendix vermiformis to the cæcum. The liver resembles that of man in all its essential features, as does the heart. The origin of the great arteries differs usually from that found in man, and the previously-described great apes, inasmuch as the innominate artery gives rise to the right subclavian and both carotids, and the left subclavian alone arises separately from the aorta. Sandifort, however, found the arrangement of these vessels following the human type. The lungs are entirely undivided into lobes. Owing to the peculiar mode of attachment of the diaphragm, the cavity of the chest is greatly restricted as compared with the same part in the other great apes. The kidneys have only a single papilla.

The brain has about the same volume as the chimpanzee's, the largest measured being twenty-six cubic inches. In all its most important characters it corresponds with those already described; but the height of the cerebral lobes in proportion to their length is decidedly greater than in the gorilla and chimpanzee. Looking at the upper surface of the brain, the cerebellum is completely concealed by the cerebral hemisphere. The lobes and convolutions agree generally with those of the chimpanzee, but the external perpendicular fissure is less distinct, being partially obscured by the greater development of the annectant gyri. The interior of the hemisphere, as has been recently described by Professor Rolleston, and was demonstrated in the lecture by specimens from the College Museum, has its lateral ventricle, with anterior, middle, and posterior cornua, hippocampus major and minor, and eminentia collateralis as in the brain of man and of the other anthropoid apes.

The reproductive organs in the adult state are only known from Sandifort's description. The penis has two retractor muscles, the testes are situated on each side of the root of the penis, close to the inguinal canal. This canal was found open on one side and closed on the other; in young specimens it is always open on both sides. In females the clitoris is large, and the uterus of the ordinary form in the anthropoid apes. In a specimen in an early condition of pregnancy, a well-marked decidua vera and reflexa were found. The law regulating the growth of the young animal after birth resembles that in the chimpanzee.

The sexual differences, independently of those directly connected with the reproductive function, are well marked. The

female is smaller, has a much smoother skull, and canine teeth greatly inferior in size to those of the male. The pelvis presents peculiar differences, the lower part, or pelvis proper, being proportionally larger in the female, as the following measurements show:—Height—male, $9\frac{3}{4}$ inches; female, $7\frac{6}{10}$. Width between anterior-superior spines of ilia—male, $10\frac{1}{4}$; female, $8\frac{1}{4}$. Antero-posterior diameter of brim—male, $5\frac{2}{10}$; female, $4\frac{6}{10}$. Transverse diameter of brim—male, $4\frac{2}{10}$; female $3\frac{2}{4}$. Inter-sciatic diameter—male, $3\frac{2}{10}$; female, 3. Like the other great apes, the orangs, though inhabiting a very limited geographical area, present a very great amount of variation in their colour, the proportions of the limbs, and their osteological and dental characters.

The remaining animals belonging to the group of man-like apes form the genus *Hylobates*. Vrolik, Lartet, and other eminent naturalists, struck by the great resemblance to the human type seen in some of their anatomical characters, have held that they approach nearer to man than any of the others; but the whole organisation taken together forbids us giving them so elevated a place in the scale. The gibbons, or long-armed apes, as they are commonly called, consisting of several species, are limited in their geographical distribution to the islands of the Indian Archipelago, and some parts of the adjoining mainland. They are arboreal in their habits, and the most active of any known apes, swinging themselves from bough to bough with extraordinary agility, actions to which their conformation well suits, their limbs being immensely long, their body light, and their head much smaller than in the larger anthropoid apes. When on the ground, they can walk upright readily, aiding themselves with their knuckles, or using their long arms as balancing-poles. They all possess exceedingly loud voices.

The distribution of the hair upon the body and limbs resembles that of the preceding species; the proportions of the limbs are, however, exceedingly different. Both arms and legs are long in proportion to the body, and are to each other as 5 to 3. The hand is longer than the foot. The foot is shorter than the tibia. The hand is very much shorter than the forearm. Their comparative inferiority of type is shown in the greater length of the radius to the humerus. The vertebral column is less curved, even than in the orang. The number of dorso-lumbar vertebræ is eighteen, either thirteen dorsal and five lumbar, or fourteen dorsal and four lumbar. The spines of the middle cervical vertebræ are not prolonged as in the gorilla, but short, as in man; but this, and likewise some other characters to be mentioned hereafter, do not necessarily approach *Hylobates* to the higher type, as has been supposed, for we find them equally characteristics of some of the lower groups of monkeys. The lumbar region is elongated; the last lumbar vertebra does not appear ever to have its transverse processes enlarged and ankylosed into the sacrum. The last-named bone is remarkably broad in proportion to its length, but is very little excavated in front; the coccygeal bones follow in the same curve. The scapula differs very widely from that of man, the two fossæ being nearly equal, and the spine very oblique to the internal margin. The acromial and coracoid processes are of great length and strength. The clavicle is long and strongly curved, the humerus long and slender, the radius arched so as to leave a wider interosseous space. The hand is very narrow. The carpus contains nine bones. The thumb is better developed than in the orang, but not so much so as in the gorilla. The pelvis exhibits in many respects notable characters of degradation. It is set on at a more acute angle to the plane of the sacrum. The ilium is comparatively narrow, flat in front, and with a well-marked posterior concavity. The subpubic arch, distinct in all the other great apes, has almost disappeared, the symphysis pubis being inordinately long. The tuberosities of the ischia, when seen from below, form an extremely open angle, and widen out into flat or slightly concave surfaces for the attachment of the dense, naked patches of integument, which constitute the "ischial callosities" found in the gibbons in

common with the lower Old World apes. The antero-posterior diameter of the pelvis is long and narrow. The femur is still a little larger than the tibia. The ankle joint presents the same peculiarities of form as in the other great apes. The calcaneum has a very small projection behind the ankle. The entocuneiform bone has the usual peculiarities of the ape. The proportions of the different regions of the foot are still further removed from those of man, than in the gorilla, chimpanzee, and orang; but there is a decided superiority to the last, in the greater development of the hallux, which reaches nearly to the extremity of the base of the first phalanx of the second digit.

The skull is much smaller in proportion to the body in the gibbons than in the larger anthropoid apes. The orbits are large and the supra-orbital ridges greatly developed. There is no downward projection of the mastoid process. The occipital foramen is situated as far back as in the posterior fifth of the base. The planes of this foramen, the ethmoidal plate, and tentorium have all a greater inclination than in the higher apes. The union of the frontal bones over the junction of the presphenoid and ethmoid is very distinct. The inner surface of the petrosal bone generally presents a fossa. The craniofacial angle is greater than in the orang. The extensive union of the great wing of the sphenoid with the parietal is a remarkable character, as, though general in man, it was not met with in the chimpanzee and gorilla, and only occasionally in the orang. The nasal bones are broader than in the orang, and very soon become ankylosed together. The maxillo-premaxillary suture persists until after the eruption of the permanent teeth. The palate is long and narrow. The lower jaw shows great prolongation of the horizontal ramus, and want of height in the ascending ramus. The siamang (*Hylobates syndactylus*) is the only ape which has anything like a mental prominence.

FROM ABROAD — FRENCH APPRECIATION — BRUSSELS REGISTRATION RETURNS.

OUR Parisian contemporary, the *Union Médicale*, in appreciating the recent session of our Medical Council, seems to think the Profession in this country in a far more desperate condition than is really the case—so difficult is it, even with the best intentions and by the aid of documents, to represent the exact condition of the institutions of a foreign country. We are told:—

"As the results of feudality and the liberty of legislation in England, an infinite multiplicity of learned bodies, private societies, and even individuals, enjoy the privilege of granting degrees, constituting licensing bodies for the healing art under conditions which are so various, so different, and, in several cases, so easy of fulfilment that they become complete illusions. This, joined to the liberty of teaching which prevails among our neighbours in Medicine as in all other Professions, led to such crying and dangerous anarchy that, aided by accidents, calamities, and law-suits, a general feeling was at last entertained that some endeavour should be made to place order in this strange confusion of studies and titles. Hence the Medical Act. The decreeing this was nothing. But its application had to follow; and then, according to the maxim of Montaigne, so eternally true, the difficulties appeared in all their light, as did the evil in all its extent. Diplomas from all quarters, the origin of some of which had not been even suspected, were exhibited. In answer to a question of Colonel French in the House of Commons, the right of the Archbishop of Canterbury to confer a Doctor's degree, without any preliminary examination by the College of Physicians, was publicly recognised by the Secretary of State. Was ever investiture more sacrilegious than this? On the other hand, official examiners, without qualifications or knowledge of the matters on which they have to examine, have been recognised. A pretty guarantee this! Finally, there is a complete absence of legal prescription for uniformity of examination, or for regularity and authentic proof of study, no conditions respecting age and preparatory studies; but, in place of all this, an assemblage of obsolete, incoherent, and contradictory laws and ordinances. Such is the English Medical code!"

We have no need to point out the exaggerations and inaccuracies in the above extract; but these are hardly to be wondered at when we ourselves have some difficulty in realising our exact position.

We make one more extract from the same writer, who is noticing the discussion in the House of Commons upon the dearth of candidates for the Army Medical Department:—

“‘The service is not popular,’ says one. ‘Promotion is too slow,’ exclaims another. ‘The rank is inferior and the subordination humiliating,’ adds a third. ‘All baubles,’ replies the Marquis of Hartington, without any shame; ‘the question is purely a matter of money. Pay more, and all vacancies will be speedily filled.’ Major O’Reilly, in fact, showed that, while the expenses of the English army are on the whole double that of the French, as regards the Medical services the cost is nearly equal. The solution of the enigma has been discovered: all is reduced for these proud islanders to an affair of pounds and shillings. Money, money, always money! This is not the side we shine on in France. Disinterestedness and professional dignity are what we prefer, and which are not without their merits.”

M Janssens, a Physician attached to one of the statistical bureaux of Brussels, has just published an interesting account of the movement of population and mortality in that city during 1863. It appears that on January 1, 1863, the population was 181,799, and that by the end of the year 3133 inhabitants were added. This took place chiefly by immigration, as the excess of births over that of deaths only amounted to 790; the entire number of *births* for the year were 5927 (2990 male and 2937 female), more than a fourth—viz., 1400 (704 male and 696 female)—being illegitimate, but only 3 foundlings. The proportion of births to inhabitants was 3·2 per cent., and the proportion of births to deaths was 115 per cent. Of these children, 412 (45 legitimate and 367 illegitimate) were born at the Maternity. There were 75 twin children born living (37 male and 38 female). Besides the above children born living, there are returns of 352 who died prior to delivery, 86 being premature births. There are from 19 to 20 born dead for every 10,000 inhabitants. Of the 352 born dead, 200 were males and 152 females. The number of *marriages* contracted in 1863 amounted to 1715, giving a proportion of 1 marriage for 106 inhabitants. In 1861, for the whole of Belgium, there was 1 marriage for 141 inhabitants. By comparison with the number of legitimate births for the year, this is found to be 2·64 for each marriage, that for the kingdom at large being 4·4 per marriage. During the year 28 *divorces* were granted. In 1861, the proportion of divorces to marriages in Brussels was 1 in 61, while for entire Belgium it was 1 in 603. The influence of towns on the number of divorces is further shown by the fact that, of 56 divorces granted in Belgium in 1861, 48 were pronounced in towns with a united population of 1,266,780 inhabitants, while only 18 were pronounced in rural districts, with a combined population of 3,515,476. The *deaths* during 1863 (including the stillborn) amounted to 5137. During the last 10 years, 1854-63, the mean annual number of deaths has been 5037; so that, allowing for increase of population, the number for the present year is about the normal proportion. The proportion of deaths was 2·80 per cent., or 1 death for 35·5 inhabitants—a proportion which is nearly identical with that of the last ten years. Since the commencement of the 19th century, however, the mortality of Brussels has diminished nearly one-half. With respect to *sex*, of the entire deaths 2594 were male and 2543 female,—the slight excess of male mortality acquiring more importance from the fact that the female living population exceeds the male by about 5000. The predominance of male deaths persists to 5 years of age (1078 male, 949 female), then disappears during adolescence and until 40 (329 male, 378 female), to again preponderate between 40 and 70 (631 male, 539 female), and finally disappear after 70, when there were 170 male to 342 female deaths. As to the influence of *age*, infancy below 1 year furnishes a contingent of 1046 deaths, or 22 per cent.—little less than a fourth of the whole mortality. During the

2nd, 3rd, 4th, and 5th years respectively the mortality diminishes to 498, 238, 139, and 106; the total mortality below 5 years amounting to 2027, or 42 per cent. of the total. Below 10 years the mortality is 45·4 per cent.; from 10 to 20, 3·7 per cent.; from 20 to 40, 15 per cent.; from 40 to 60, 15·7 per cent.; and above these ages 20 per cent. Of 4718 deaths, one-half took place before 25. Of 4718 deaths, 2984 (63·2 per cent.) were of unmarried individuals, 1110 (23·5 per cent.) married, 234 widowers, and 390 widows.

THE JOURNALS.

THE *Australian Medical Journal* for January details an instructive case of aneurism of the external iliac artery, where the common iliac was ligatured by the posterior operation as performed by Sir Philip Crampton, and again, in 1846, by Mr. Stanley, and recommended by Mr. Skey in his work on “Operative Surgery.” The man on whom the operation was performed was thirty-four years of age. It was done by Mr. Lempriere on October 20. The artery was easily found. On the 22nd the skin of the foot was purple, and there was numbness of the soft parts; and on the 25th the foot was rather more shrivelled, and the sensibility of the skin doubtful. The temperature was kept up with hot water-bottles. On the 26th a tendency to moist gangrene was observed, and the bowels were relaxed. In the afternoon of the next day he became suddenly worse, and sank and died. On post-mortem examination it was found that the ligature had been applied at a little over an inch from the bifurcation of the aorta, and had been fairly secured, and that there were two inches from the ligature to the division of the artery. A firm fibrinous coagulum was found above, but none below the ligature. There was no peritoneal inflammation. The wound was healthy, and no important parts had been injured in the operation.

In the *April* number of the *Journal of Mental Science* we find Dr. Hitchman’s (of Derby) account of his interview with the convict Townley, and his report on the subject to Townley’s solicitor, Mr. Leech. The case is so important a one, in a Medico-legal point of view, that, at the risk of wearying our readers, who, doubtless, think they have had enough of Townley, we transfer a portion of his report to our pages. He gives it as his opinion—

“That he possessed a feeble intellect, associated with strong emotions; that these conditions, aided by an hereditary predisposition to mental disease, may, at no distant day, cause him to become insane; but that, at the present time, he was a rational and responsible person.”

The conclusion of the report was as follows:—

“I infer a proneness to insanity in Mr. Townley from the eccentricity of his opinions and habits; from the strength and violence of his emotions; from his physiognomical expression; from the configuration of his head; from these in combination, but chiefly from the fact that some of his relations, one of whom I have seen, have died from acute mania. I *allege* that Mr. Townley is not now insane, in the legal sense of that term, because he is under no hallucination; because, absurd as are his dogmas in reference to man’s responsibility, they are theories entertained by hundreds of persons who are capable of all the duties of social life, and who describe themselves as ‘Necessitarians,’ or by other sectarian titles. Moreover, the theory has been eloquently, however fallaciously, advocated by the distinguished poet, Percy B. Shelley. Again, although Mr. Townley refers to a wife as *property*, yet he does so in the same sense as an American slaveholder describes his slave as a ‘chattel;’ and in regarding betrothals as equivalent to marriage, and as an insurmountable impediment to marriage with another party, he is in harmony with our ecclesiastical laws prior to the reign of George the Second, and (as I believe) in accordance with the present laws of Scotland. His wild opinion that the violation of a betrothal vow is equivalent to an act of adultery betrays a gross error of judgment, but not an *insane* conclusion; the punishment he allots to the crime of adultery finds precedents in Jewish and Roman law, under such wise legislators as Moses and Constantine, and cannot be regarded as an insane decree, however wicked it may be when

inflicted by an individual, without a proper appeal to the public tribunals of his country;—from which facts—but primarily and mainly because the feeling which prompted Mr. Townley to the criminal act *did not spring from an hallucination,—from a subjective imagination within his own mind, but was excited by the conduct of a second person,—was created, in fact, by a real and deep injury inflicted on him by an individual to whom he was warmly attached, and from whom he had a right to expect better things—I infer that Mr. Townley is, at the present time, a rational and responsible person.*”

The May number of the *Dublin Quarterly Journal* opens with an article by Dr. Law, in which he maintains his preference for a mode of treating acute rheumatism which he held nearly twenty years ago, and which, we believe, has been extensively tried in this country, with varying results. It consists in a single moderate bleeding, rarely repeated, and the use of colchicum. Five cases are related in proof of the rapidity of cure under this system, but we cannot avoid noticing that opium was an element of treatment in each of them—a remedy of no small value in the opinion of the majority of Practitioners.

The *Pharmaceutical Journal* for April contains an abstract of a paper read by Mr. Whitelaw to the Philosophical Society of Glasgow on the Utilisation of Brine, in which he proposes to separate, by dialysis, the salt and nitre of brine, leaving the extractive matters which it is known are drawn from the meat in the process of salting. A simple mode of operation consists in filling bladders with the brine and suspending them in vats of water, removing the water about once a-day. The operation is usually completed by the end of the third or fourth day. Two gallons of brine yielded 1 lb. of solid extract, containing the coagulated albumen and colouring matter. For the production of the same directly from meat, something like 20 lbs. of lean beef would be required. He believed that in Glasgow alone over 60,000 gallons of brine were thrown away yearly, equal in soup-producing power to 187 tons of meat without bone. Estimating the meat at 6d. per lb., this amounted to a loss of £10,472.

In the last number of the *Chemical News* Mr. Whitelaw applies the same principle to the separation of salt from cured meats, and the restitution of the extractive matters removed in the process of salting. The meat is thus rendered “fresh” again, at any rate to a great extent. The process recommended is applicable at sea, and is thus likely to prove a boon to mariners.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF THE POTTERIES.

(Continued from page 601.)

DWELLINGS OF THE PEOPLE—VENTILATION.

The whole of the inhabitants of the Pottery district seem to me to be exceedingly well housed. In this respect I can bear out fully the observations of Mr. Scriven in his report on the sanitary state of England. The houses are well built, overcrowding seems to be rare, and cleanliness appears to prevail generally. The ventilation of the houses is, however, not attended to here any more than in other parts of England; that is to say, no systematic plan has been adopted either for window ventilation, the introduction of chimney valves, or any systematic plan.

DIET OF THE PEOPLE.

The inhabitants of the Potteries appear to me to be exceedingly well dieted; their resources in this respect are not limited, as is the case in Stafford, nor yet confined to any special article of food—such as pork—as in Wolverhampton. The people generally are sober and simple in their mode of life, and though not given to extravagance, as a rule enjoy, like many of the middle classes of this country, even the luxuries of existence in a moderate degree. In these respects the operatives differ from those of all the other towns I have yet visited, and indeed there is about the district altogether an orderliness, quiet, and content which it is very satisfactory to observe.

PROSTITUTION.

Prostitution is not carried on in the Potteries, as a profession, to any extent. But few regular brothels exist in the neighbourhood, and the women who may be considered degraded are usually of the lowest class, and are often exceedingly young. In the Infirmary there are generally two or three women of this kind, and from four to six in the workhouses, who are suffering from syphilitic diseases. There are no statistics extant respecting the number of prostitutes in the district. Infanticide is very rare.

EPIDEMICS AND ENDEMICS.

Accurate records as to the amount of epidemic and endemic disease in the Pottery districts are wanting. Scarlet fever is a prevalent disorder, and of rather frequent occurrence. Typhus and typhoid fevers are not infrequent, especially in the poor lodging-houses. Diphtheria has occurred, but, compared with other localities, has run a limited course. Cholera has visited the neighbourhood severely. In 1849, in the district of Newcastle, then including 19,489 inhabitants, there were 241 deaths from diarrhoea, and 24 from cholera, giving a total of 265. In Newcastle itself there were 239 cases of cholera, and 19 of diarrhoea. The first cases were those of diarrhoea, and occurred in the workhouse on the 8th and 13th of June; both died. On June 19 a girl, aged 14, died of cholera in the workhouse, after seven hours' illness. The disease then spread into the town in a malignant form, and at the end of August 129 persons had died, 14 having died on one day—the 17th of August. The lowest parts of the town were those most influenced. In 1854 there was no death from cholera at Newcastle, and only 15 from diarrhoea during the great epidemic. In the district of Wolstanton, including 32,666 inhabitants, there were 79 deaths from cholera in 1849, and 65 from diarrhoea, making 144 in all; and in the district of Stoke-upon-Trent, with a population of 47,951, there were 103 deaths from cholera and 63 from diarrhoea, making 166 in all, in 1849. In 1854 these two latter districts were scarcely affected by the epidemic. It was observed in the epidemic of 1849 that the disease broke out in Stoke late in the summer, the first case occurring in the workhouse on the 15th of August. The disease stopped on the 7th of October. Eighteen deaths occurred in the Stoke workhouse alone. The exact cause for the prevalence of the disorder in the district is not accurately ascertained, but Mr. Garner informed me that in Stoke it evidently was traced to the arrival of an infected person from another district. Small-pox is occasionally met with in the Potteries, but of late years has not been a prevailing epidemic.

VACCINATION.

Vaccination is carried on pretty effectively in the Potteries. In Newcastle, in 1860, the infant vaccinations per cent. on registered births were 67. The number of vaccine districts was 3, and of vaccinators 3. In Stoke-on-Trent, the vaccinations numbered 63 per cent. on registered births, the number of vaccine districts being 6, and of vaccinators 18. And in Wolstanton and Burslem the vaccinations were 73 per cent., the vaccination districts 2, and the number of vaccinators 15. In the mixed schools of the district, Dr. Stevens found the typical cicatrix present at two points on the arm in the majority of cases examined.

ETIOLOGY.

We have seen that the prevailing diseases of the Pottery district are those of phthisis, bronchitis, or potters' asthma, and struma, with more acute cases of lead poisoning, of paralysis, and the usual epidemics. There are other diseases, which are not uncommon, such as calculus, consisting mainly of the uric acid variety, in the very young as well as in the old. That this is not uncommon in children is proved by the circumstance that Mr. Garner has operated twice upon girls. Goitre is also frequently seen. Cases of tetanus are rare, six only having occurred in the district for fourteen years, and two of these being mild. Only one case of hydrophobia has been known in North Staffordshire for thirty years. As to the origin of these diseases, I need touch only on the most salient points. Goitre, in the opinion of the Medical residents, has no relation to the presence of lime in the water drunken. It is rare in the better classes, is confined to females, and usually dates from puberty or the first child-bearing. Mr. Garner is of opinion that it bears an approach to cretinism. Bronchitis appears to be brought on mainly by exposure in the Potteries to great variation of temperature; and the potters' asthma, as we have

already seen, is produced by the inhalation of the particles of dust diffused through the manufactory.

Lead Paralysis.

Of the paralysis arising from lead poisoning, the statements as to the cause appear conflicting. The disease is most common amongst the "dippers," or those who are employed in dipping the earthenware utensils into a solution containing lead; but the boys who take the earthenware from the dipper and the women who are employed to brush the ware after dipping are sometimes affected as well. Various reasons are assigned for the occurrence of paralysis, viz., that the lead was absorbed by the skin, that persons of different constitutions were differently affected, and that extent of work—that is to say, overwork in times of pressure—gave rise to the disorder. Taking the whole of the evidence that I could collect, especially from two very intelligent and experienced workmen in the manufactory of the Messrs. Wedgwood, I believe that the explanation of the cause is very simple. It seems to me that the lead is not absorbed by the skin at all, but that it is taken in by the mouth. Men of dirty habits leave the dipping-tub, wash their hands imperfectly, take up their food in their hands and eat, absorbing with the food considerable quantity of the wash with which the hands are covered. The men themselves state, in fact, that it is very easy to produce the lead disease by neglecting to wash before going to meals; and one man who was a scrupulous washer reported that he had worked for fourteen years, on nearly every working day, without suffering once from the effects of the lead; while many who worked in the same room had at various times been affected. I suggested to Mr. Wedgwood, jun., that the best remedy of a preventive kind would be to teach the men to eat all their food, whether consisting of bread, meat, vegetables, or aught else, with a knife and fork; and I have little doubt that this simple process would soon reduce the number of cases of lead poisoning in the Potteries to a minimum. In extreme cases of chronic paralysis from lead poisoning, the nervous centres seem seriously involved. Mr. Garner, who, from his long experience, has been able to make many examinations, tells me that atrophy of the corpus pyramidalis, and of the crus cerebri, on the side opposite to the affected side of the body, is a frequent lesion.

Pulmonary Consumption.

The next great etiological point to be considered relates to the cause of pulmonary consumption in the district. This subject was reported on by Dr. Greenhow in his papers addressed to the Medical Officers of Health in 1849, and again, at greater length, in 1860. Dr. Greenhow's opinion was very strongly expressed that there are various unhealthy influences at work in the Pottery district, quite independently of the particular industrial occupation; and he showed, in support of this view, that children under five years of age, and who are, of course, excluded from the occupation, showed a high pulmonary death rate. This evidence, very striking from the exceedingly careful and accurate manner in which it is put forward, is not, however, implicitly received by those Medical men who live in the district. Amongst them the opinion prevails that the great mortality from pulmonary disorder is traceable to the deteriorating influence of the potters' work. The whole question, from the local view of it, is very ably summed up in the following observations from Dr. Arlidge:—

"The number of male potters in Stoke aged 20 and upwards is, according to the last census, 5813, which is equal to 31·25 per cent. of the whole male population living at the same ages; in other words, the male potters constitute less than one-third of the adult male population.

The registers of deaths in Stoke parish, excepting those of the district of Longton, fail to show in a large number of instances the occupations of those deceased. This sadly lessens their value as public documents, and particularly when needed to solve the question of the relative mortality of any special occupation. We can go no further in discovering and noting the occupation than the registers aid us, but reference to the careful records kept at Longton clearly indicates that many of the deaths in the other registration districts were those of potters, though not specified to be such. In Longton the mortality among potters to the whole number of such workmen living equals 3·47 per cent., and that in the whole of Stoke parish may be estimated at 3·25 per cent., allowance being made for a possibly higher ratio of deaths among potters in Longton than elsewhere.

A table of the number of deaths among male potters, com-

pared with the number of deaths of males of all other occupations at different ages, in decennial periods, shows that in the ten years from 50 to 60, nearly one-half of the whole number of deaths occurred among potters; and that in each decennium, from 40 to 50, and from 30 to 40, more than one third happened among those artisans.

The conclusion deducible is, that the occupation of potters is connected with a rapidly rising rate of mortality after the 20th year, which attains its maximum in the decennium between the 50th and 60th years. Taking the whole period from the 20th to the 60th year, the deaths among male potters have equalled 37·91 per cent., although the proportion of such workmen in the whole male population is only 31·25. From various calculations it may be inferred that the mortality among male potters is 8 per cent. greater than among other males at the period of life in question. Whereas only 17 male potters in 100 survive the 60th year, 35 males of other occupations do so. Of 223 males who attained the 50th year and upwards, potters constituted only 27·80 per cent.

The mean age at death of male potters who had arrived at the 20th year and upwards, was 46·50; whilst that of other males was 52. The mean age of such males in England is 56. Allowing for casualties, the mean age of males in Stoke may be put at 54—potters excluded.

Mortality of Potters from Lung Diseases and Phthisis.—Among potters aged 20 and upwards, these maladies killed 1·34 per cent., or 13·41 per 1000 living. In Longton they destroyed 2·42 per cent., or 24·20 per 1000 living.

Among 210 males at 10 and upwards, who died from those diseases in Stoke, 85, or 40·47 per cent., were potters.

Of 148 male potters, 47, or 31·75 per cent., died from phthisis alone, and 85, or 57·43 per cent., from that malady and lung diseases together. In Longton considered apart the proportion is increased to about 60 per cent.

On comparing the mortality of male potters at 15 and upwards from diseases of the lungs and phlebitis together, with that prevailing in England at the same ages, it is as 57, or (if the registration were correct) 60 per cent. to 32 per cent. of the deaths that take place.

An examination of the ages at which death has occurred among male potters from phthisis and diseases of the chest respectively, shows that the maximum mortality of the former disease is reached in the decennium between 30 and 40 years of age, and that of the latter group of maladies between 50 and 60. It is especially in the circumstance of the high mortality from chest diseases that the excessive ratio of deaths among male potters finds its explanation. In not a few towns in this country the death-rate from phthisis is greater than in the parish of Stoke; but in much fewer is it larger from diseases of the lungs; and when the ratio of deaths in Stoke caused by the latter class of maladies and consumption is compared with the average proportion in England and Wales, the excess, though very considerable in the case of phthisis, is much more striking in that of the non-tubercular diseases of the respiratory organs.

Again, when we come to inquire into the relative prevalence of the diseases in question in the two sexes in Stoke, we find that both are considerably more rife among males than females; but the class of diseases in which the preponderance is found is more especially those of the lungs.

That the maximum mortality of potters is reached in the decennium from 50 to 60 has been already noticed; and on further examination it is seen that between the ages of 40 and 60 almost one-half of the whole number of deaths of potters who have reached manhood occur.

A consideration of the foregoing facts leads to the inference that, unless predisposed to consumption, when they die in a larger proportion between 20 and 40 years of age, potters suffer from the injurious effects of their occupation in a rapidly advancing ratio after the fortieth year, which ratio reaches its maximum short of the sixtieth year."

Struma and Degeneration.

The last point etilogically bears on the prevalence of strumous disease, and of that general deterioration of system allied to it, which, undefined by the nosologist, is easily recognisable by the practised eye as indicating a degraded health, and which may be said to be almost general amongst the young engaged in the earthenware manufacture. The conditions named spring, I think, without doubt from the nature of the occupation, and especially from the employment in it of young children, whose little strength is overtaxed at the time when it is all wanted for the development of the

organism. In the factories the boys are employed in processes some of which are exceedingly laborious; and children so young even as five or six years of age may be found earning their bread. In some of the factories, too, the boys work even longer than the men, coming, as Mr. Tonge has shown, to light the fires and the stoves, first in the morning, and remaining after their elders have gone, to clean up the shops and empty the stoves. The work to which they are subjected is heavy. Some of them act as "jigger turners," at which work they are engaged turning a horizontal wheel, which sets in motion the centre on which the potter turns his ware. Others run with plates from the turner into the drying-room or stove, in which proceeding they may have to move many hundred times a-day from a temperature of 50° to 130° F., as I proved by direct observation in one case. Others work at the "batting out" process—that is to say, in preparing the batts of clay for the manufacture of saucers. Others dust and clean the earthenware, or receive the plates from the dipper; and others, again, are engaged at what is called "wedging the clay," which process consists in lifting up a mass of clay above the head and throwing it down on a slate or on another mass of clay many times, in order to drive out the air which is present in the clay, and which, if left in, would prevent the perfect working of the material afterwards. Of all these operations, those of plate carrying, jigger turning, and wedging seem to be the worst, and no one, I am sure, could watch the last-named process without wondering how for hours at a time such feeble limbs could carry on such terrible labour. Of late, in some manufactories truly, a mill called a "pug-mill" has been introduced, through which the clay passes before it comes to the wedger, and by which considerable labour is saved. But still the work is out of all reason, and it is physically impossible for a child to mature who is constantly engaged at it. The force, in fact, which should be developed in nutrition is expended on the clay. The result is as may be expected: the children are indifferently developed; they grow up to become fathers of undeveloped children, and, not to mince the matter, the race is deteriorated. Various remedies have been suggested, and, under the influence of a governmental supervision, which will probably soon come into force, much good may be done; but if children are employed at all in these heavy processes, no system can, I think, combat all the evils. How can it, indeed, when the broad fact stands out in the eyes of all who have carefully inspected a pottery manufactory, that the adult artisans are positively employed in tasks which, in so far as the evolution of force is concerned, are relatively lighter than those performed by their youngest child-companions? The true remedy lies, I believe, in the plan of allowing steam or water power to produce the force which is now supplied by these youthful martyrs to labour and routine. Steam power could easily turn the jigger, and one can scarcely doubt that, in these days of mechanical skill, a machine could be made that would supplement the defects of the pug-mill, and perform the wedging process, at least, under the guidance of the hand, without strain upon muscle or exhaustion of nerve.

SUGGESTIONS OF THE CHILDREN'S EMPLOYMENT COMMISSIONERS —MEDICAL INSPECTORSHIPS.

I referred briefly in my first paper on the Potteries to the late report of the Children's Employment Commission. I may state, at greater length, that these Commissioners, whose labours have been carried out with very great care and exactitude, have come to nearly the same conclusions as those stated above in respect to the injurious influence of the present system of pottery work on the young. I have waded through all the evidence collected by the Commissioners, since writing the account of my own observations, and I am happy to find that there is in that evidence more even than substantiates that which the reader has already perused. The remedies proposed by the Commissioners are physical and moral.

In the way of *physical* remedies, the Commissioners suggest—1. That there should be an improved ventilation and a reduction of the temperature in the potters' stove rooms. 2. That the ventilation of the work-rooms of the finishing department should be improved. 3. That specific regulations for the protection of health in certain departments of the manufacture should be carried out in accordance with the precedent of the Factory Act. 4. That, in accordance with the provisions of the same Act, young persons should be secured from working overtime. 5. That the young should have secured for them regularity of meal-times.

In order to improve the *moral* condition, the Commissioners

are of opinion—1. That the potteries should be placed under the Factory Act with special reference to the limitations of age and hours of work, school attendance, and the other regulations of the half-time system. 2. That greater security for education should be afforded by requiring a certificate of a certain amount of education on attaining the age of thirteen years.

After entering into various other details, the Commissioners propose, as a mode of legislative interference, that a Medical Inspector should be appointed for a limited period by the Secretary of State for the Home Department. The powers and duties of the Medical Inspector are thus defined:—

"1. Power of entry (as under the Coal Mines Regulation Act) into all potteries.

"2. To inspect and examine into the state of the places of work in reference to their construction, ventilation, and other arrangements, so far as they may affect the health of the children and young persons working therein.

"3. On finding any place of work deficient in ventilation, or otherwise injurious to the health of such children and young persons, to serve notice in writing on the owner or occupier, stating the particular grounds on which he is of opinion that such place of work is deficient in ventilation, or otherwise injurious to health.

"4. If within fourteen days the owner or occupier does not signify to the inspector in writing his intention to remove such grounds of complaint within a specified and reasonable time, in a manner satisfactory to the inspector, the inspector to call upon the owner or occupier to nominate a civil engineer, architect, or other competent person, and the inspector to nominate another; an arbitrator to be appointed before proceeding to determine the matter in difference, as directed by the Mines Regulation and Inspection Act, 1860, s. 13. The arbitrator to be a person entirely unconnected with the district.

"The decision of the three persons so appointed to be final, and to be enforced by the justices of peace for the district, under penalties for non-fulfilment within a definite period. No justice of peace to act who is owner or occupier of a pottery, or the father, son, or brother, or agent of any owner.

"There being only 180 pottery works in the Staffordshire district, and of these, as has been seen, probably not many more than 100 which would require any, or more than slight, improvements in the particulars under consideration, and the whole lying near together in a district of only eight miles long from north to south, and from one to three miles broad, it does not appear probable that the continuous services of the Medical inspector would be required for more than one year. His occasional services might be required during one year more."

While these recommendations, following as they do on the most careful evidence, demand the greatest respect, they do not go sufficiently far to meet the acknowledged and fearful evils now present. As a temporary *legal* measure, I cannot but think the proposition of the committee of working potters, to the effect that no child should be allowed to work until he has attained the age of ten years, is preferable to the half-time system at eight years. But I must maintain that this also is insufficient, and that there is but one true remedy for the physical regeneration of the young potter—the introduction of machine for human power.

MEDICAL BIOGRAPHY OF THE POTTERY DISTRICT.

Mr. Garner, of Stoke-upon-Trent, has paid great attention to the Medical biographical history of the county of Stafford. I hope some day he will publish an account of his interesting researches in full. He has supplied me with particulars of one or two Esculapian worthies of the Potteries.

Mr. Bent, Surgeon.—Mr. Bent was a Surgeon of considerable eminence in Newcastle-under-Lyme. He is noted as being one of the first, if not the first, who excised a diseased shoulder joint. The operation was entirely successful, and the particulars were published in the *Philosophical Transactions*. Bent, who was a martyr to gout, which he would insist on treating by means of cold effusion, ultimately became deranged in intellect, and committed suicide by opening the carotid artery.

Dr. Chowner, M.D.—Dr. Chowner was a Practitioner of Burton, and at the beginning of this century enjoyed an immense reputation throughout the whole of the district. He was consulted by all classes of the community; and was a very successful surgical operator, particularly in lithotomy. He once cut four patients for stone in one morning. He

was as great (says my informant) with the bottle as with the scalpel, and for the term of fifty years indulged in a bottle of strong spirits—gin or brandy—daily. It stands against teetotalism, nevertheless, that the alcoholic Doctor lived to the age of 90 years, and was the father of no less than twenty-seven children. In the latter part of his life, he became stone blind, but was still largely consulted.

Mr. Coombe, Surgeon.—Mr. Coombe was a Practitioner very eminent in his district, especially in Surgery. He was rough in dress and demeanour, but was an exceedingly cool, collected, and dexterous man. He was specially called for in cases of accidents in mines, and was accustomed to recount with great gusto the number of operations he had performed by the light of a farthing candle. I have no particulars of the death of this Surgeon.

Now, I must close this history of the Potteries, not that the matter which I was able to collect is exhausted, but because the necessities of the work before us remind me that it is time to stop, and to move into a new locality.

REVIEWS.

Geschichte, Natur-und Gesundheitslehre des ehelichen Lebens.
VON EDUARD REICH, M.D.

The History, the Nature, and the Healthful Conditions of Married Life. By E. REICH, M.D. Cassel. 1864.

DR. REICH has endeavoured to give in this book an abstract of all that has been written on the marriage customs and sexual relations of every nation, adding thereto the results of various statistical and other investigations into the questions which the theme suggests. He appears to have been moved to this task by a strong feeling of the importance of marriage, the due fulfilment of its duties, and maintenance of its honour, as the foundation of all that is valuable in social life, and by a deep and indignant conviction of the sad shortcomings of the present age. His views are mixed up with so strong an anti-theological bias that it is difficult for every reader entirely to sympathise with them; and we may hope, although they seem to be the fruit of much study, that they are tinged by somewhat too much of bitterness. "The increasing celibacy of our day," he says, "must be regarded as a sign of social disease, which, on the one hand (and this especially), is connected with bad economical principles, and on the other with the enervation of the younger generation and with the unexampled licentiousness and viciousness of men. So long as the public finance, instruction, and education rest on so rotten a foundation as is unhappily the case at present will prostitution and celibacy become more extended, poverty deeper, dissipation, vice, and brutalisation more extreme." Even if extravagant, these words touch upon a veritable social ulcer, whose dimensions we shrink from probing. Perhaps it would not be wise to assume too readily that the voice of warning is one of exaggeration. Speaking in another place of sodomy, Dr. Reich says, while admitting that it had its origin in the East, that "our larger and smaller capitals probably contain more practisers of sodomy than the cities of Asia; and we need only read Tardieu's reports and listen to the descriptions given by the organs of the secret police of Berlin, Vienna, etc., almost to despair of the manhood of Europe." Probably we may justly believe that English life in this respect is less contaminated than Continental—thanks to a more healthy physical training; thanks, also, perhaps in part to abstinence from the attempt to regulate prostitution. It appears that Julius Rosenbaum, who studied this crime as it existed among the ancient nations, ascribed its origin to the fact that in Asia (as also in Italy and Spain) the female organs, like the rest of the body, undergo a great relaxation. In respect to the practice of self-abuse, the author, to his horror, has met with parents who have themselves induced the habit in their unconscious children. For the evils which he points out, however, he suggests no other remedies besides the general ones—which are doubtless among the best—of a better and more active hygiene and a more practical education.

Statistics showing the advantages of married over celibate life in respect to longevity, insanity, suicide, etc., are detailed, but these contain nothing new. Dr. Reich has found marriage of blood relations injurious, and adds his testimony to the affirmative side of the argument. The preponderance of sex in the issue of marriages he holds, with Hofacker and Sadler,

to be dependent on the relative ages of the parents: the greater number of children are of the sex of the elder parent.

Among some of the Indians of Brazil there exists a custom of drawing the prepuce over the glans and tying it there. The reason assigned is the exclusion of insects. Others enclose the member in a sheath of dry issara-leaves, which they call a giucann. The wives of the Guaycurus, if pregnant before the age of 30, procure abortion, in order to be more attractive to their husbands. Only children conceived after that age are reared. If an infant at the breast is made captive in war, the women of the conquering tribe (it rests on the authority of Alves de Prado) receive the child and suckle it at their own bosom, even though they have never been mothers.

Among the Kalmucks abortion is practised by long-continued friction of the abdomen, and by laying glowing coals contained in the sole of an old shoe on the region of the uterus. The gipsies, who, in Asia, are extremely lax in morals, have a curious custom. When a husband is found unfaithful the wife's male relations come and *tan* (?) his skin according to all the rules of the art. A cruel Persian, Strauss reports, on one occasion flayed alive one of his wives in a fit of jealousy, and nailed up the skin in a room in his house as a warning to the rest. Strauss saw the skinless corpse thrown into the street and dragged away. Here our author diverges to affirm that he has it on good authority that the Croats, in 1848, flayed alive some unhappy Vienna students who fell into their hands.

An account is given of the Probenacht, or proof-night, as it existed among the lower classes of Europe during the earlier part of the middle ages. It appears to have been the almost universal custom for those who contemplated marriage to pass the night together "until either both parties were satisfied of their mutual suitability, or the girl became pregnant. Then the peasant formally engaged himself, and the wedding soon followed." It was exceedingly rare, says Fischer, for such an engagement to be broken off, especially in case of pregnancy: it would have drawn down the universal execration of the village. No girl's character suffered by the passing through the "proof-time" in vain; nor would a second suitor be deterred. But if the same result frequently recurred, a certain reproach attached to her, as having some hidden defect. It seems to be the opinion of the authors on the subject, that in a simple and rude state of manners the institution of the "proof-night" tended to preserve rather than to deteriorate morals. Such a view is, perhaps, possible, however undesirable it might be to revive the custom. The spiritual teachers of the people at last succeeded in eradicating it, but it continued to be practised even in the highest circles till the close of the fourteenth century. A similar custom is said to have prevailed among the Mongols. There still exist remnants of it, probably, in the practice of "bundling" in the more backward districts of our own country.

We find from this volume that there is a strong reaction against polygamy among the Mormons. The following passage is quoted from a member of their legislative assembly:—

"Polygamy is a manifest evil, an institution which is opposed to the best interests of the people. It banishes the best women (that is, they seek to escape the shame by early flight); it hinders instead of favouring the increase of the population. Polygamy obstructs the formation of families; makes an orderly education of children impossible; and is the fruitful spring of widespread vice and misery. Have the priests and elders a right to impose an institution so hurtful indissolubly on the community? Shall the free Mormon people submit to see its best interests buried, that these men, who are just as fallible as we are, may have a better prospect of gratifying their lusts? What is their sensuous pleasure in comparison with the great interests of the commonwealth?"

The Senses and the Intellect. By ALEXANDER BAIN, M.A.,
Professor of Logic in the University of Aberdeen. Second Edition. London: Longmans, 1864. Pp. 640.

THIS book by Mr. Bain, first published about nine years ago, has taken a position among the standard works relating to the science of mind. It is so well known and so fully appreciated as a text-book, that on the appearance of the second edition all that we have to do is to point out in what respects it differs from its predecessor. We cannot do this more briefly than is done by the author himself:—

"The explanations of the nervous system and the senses have been amended according to the best recent authorities on physiology. The definition of mind has been somewhat

differently expressed. The systematic plan of describing the feelings has been modified, and all the detailed descriptions recast. An attempt has been made to generalise the physical accompaniments of pleasure and pain. The instinctive foundations of volition are stated more explicitly. In the second part, the Introduction to the Intellect has been revised, with a view to rendering as precise as possible the natural subdivisions of this portion of the mind. The doctrine referring to the physical seat of revived impressions has been discussed anew, and applied to clear up the difficulties attending the explanation of sympathy. The associating principle of contrast has, on further consideration, been treated as the reproductive aspect of discrimination or relativity. The origin of our notions of space and time has been more minutely traced; and some additions have been made to the handling of the great metaphysical problem relating to the external world."—Preface.

It may readily be credited, then, that a good deal of the volume has been re-written.

Phthisis and the Stethoscope; or, the Physical Signs of Consumption. By RICHARD PAYNE COTTON, M.D., F.R.C.P., etc. Third Edition. Churchill and Sons. Pp. 104.

THIS is a third edition of a very short and clear account of the physical signs of phthisis so far as they are revealed by the stethoscope. The character of the work is, that it deals with matters of fact and observation, without venturing upon speculation or hypothesis. It treats of what it professes to treat, in a methodical and intelligible way, and of nothing else. There is one chapter, on the physical signs of *arrest of phthisis*, which is new and interesting, and which seems like an intimation that a relief or retardation, if not cure of phthisis, may be looked for from those modern improvements in diagnosis and practice to which the author has contributed his share.

FOREIGN CORRESPONDENCE.

GERMANY.

BERLIN.

Dr. Kühne, of this University, has lately made some interesting experiments on resuscitation of animals poisoned by oxide of carbon, and come to the result that transfusion of arterial blood is by far the best means of reviving them. The pernicious effects of the gas just mentioned are due to its expelling the oxygen from the blood. Oxide of carbon thus takes the place of oxygen, whereby the blood is rendered incapable of absorbing fresh oxygen; and, as we do not know of any means for removing the oxide of carbon thus combined with the blood, the corpuscles, after having once been poisoned, remain totally unfit for respiration. This is the reason why, after severe poisoning with charcoal fumes, artificial respiration does not restore life. Only a fresh supply of blood, which is capable of respiring, may save those poisoned, and transfusion of blood would, therefore, seem to be the best means of resuscitation in cases of this kind.

The experiments made by Dr. Kühne have shown,—1st. That animals which have been so far poisoned by inhaling oxide of carbon that the conjunctiva is quite insensible come to life without any artificial aid, if there is a minimum of two respirations per minute. 2nd. Animals which have been so far poisoned that there is only one inspiration per minute, die unless artificial aid is given. In most cases the withdrawal of a moderate amount of blood is sufficient to restore the sensibility of the conjunctiva, respiration, and the heart's action. 3rd. If respiration has for several minutes been suspended, life will not be restored by bleeding and simultaneously induced artificial respiration, even if the heart may still continue to beat. 4th. Even after respiration has ceased for several minutes (the maximum observed was seven minutes), and at a time when there is no arterial pulse, and no heart's action perceptible through the walls of the thorax, when the animal, after violent spasms or tetanic stretchings of the whole body, lies relaxed and flaccid, even then transfusion of fresh respirable blood restores life anew. At first respiration begins in a scarcely perceptible manner, but after ten minutes there may be as many as sixteen inspirations per minute, the pulse becomes regular, and at the same time rises to from 100 to 120 beats. The animal then rapidly regains consciousness, cries out lustily, and a few hours afterwards nothing but a slight trembling denotes that it has been at all interfered with.

Subsequently neither the poison nor the transfusion leave behind any perceptible disturbances.

In all experiments where transfusion was performed, dog's blood which had been defibrinised and carefully filtered through linen was used. This, if beaten, became of a bright red colour, and rich in oxygen; it was then again heated to about 98° Fahr. and injected through one of the jugular veins, while from the other vein a corresponding quantity of poisoned blood, which had a cherry colour, was withdrawn. In none of the experiments was the amount of blood injected and withdrawn more than one-fifth of the total quantity of blood of the animal.

Some time ago the Medical Society of this capital chose a committee for drawing up a report on the use of gymnastic exercises for girls, and which has now been sent in to the Ministry with the view of inducing the authorities to give to gymnastic exercises a place amongst the educational subjects taught in public schools for girls. Experience abundantly proves that girls, especially such as live in large towns, are subject to disturbances of health in a far greater ratio than boys, and which not only tend to deteriorate the physique of the individuals affected, but also that of their future progeny. General weakness of the muscular and nervous system, all kinds of nervous complaints, chlorosis, defective growth, asthma, and curvature of the spine, are about ten times more frequent in girls than in boys. The reason for this is not the more delicate organisation of the female sex, but the neglect of a most essential element of physical education in those years which are of the greatest importance for the physical development, viz., from the sixth to the fifteenth year. While boys take a great deal of exercise, and are allowed to run, climb, jump, and to enjoy all sorts of games and sports, together with gymnastics systematically pursued, girls are left without these means of strengthening the body. They are left, during the greater part of the day, in badly-ventilated schoolrooms, and, if they come home, they are employed with French and English exercises, sewing, drawing, music, etc., so that there is no bodily exertion equal to that of the mind. It is evidently, therefore, the duty of Physicians to see "*ne respublica feminina aliquid detrimenti capiat.*" Besides swimming, skating, and games in the open air, methodical gymnastic exercises are the most essential means for combating the evils just alluded to. By them the muscular system is strengthened, the position of the body improved, the chest more expanded, the movements become more graceful and firm, and the normal development of the limbs and the whole body is promoted. As motor power is increased, the balance between the two systems of motor and sentient nerves is preserved. The more delicate structure of the bones, and the weakness of the muscular system in girls, does not forbid the use of gymnastic exercises; but these circumstances should most certainly be taken into consideration in regulating them. They must be proportionate to the strength, age, and power of perception of girls. Exercises which require much muscular power, or such as are dangerous or not compatible with female decency, should not be done, and different ones substituted for them. Where the spine, the shoulders, or the hips have already assumed a defective position, of course a special treatment should be directed to such conditions previous to the adoption of the ordinary gymnastic exercises. Drs. Eulenburg, Löwenstein, and others have seen in several private institutions, where ordinary gymnastic exercises were taught to girls, the best results follow, even in cases where curvature of the spine and other affections of the locomotive apparatus were hereditary. They therefore strongly recommend the Government to see that gymnastics for girls should be taken up throughout the country.

Some experiments on the physiological and therapeutical action of the continuous galvanic current upon the organ of hearing, which have recently been undertaken by Dr. Brenner, of St. Petersburg, are sufficiently interesting to deserve mention. He found that if the negative pole was applied to the ear, by means of water in the meatus, the nerve responded to the galvanic stimulus on closing the circuit, and while the current continued to pass, but, if the positive pole was in the ear, there was an effect only on opening the circuit. On the other hand, no effect was produced on opening the circuit if the negative pole was in the ear, nor on closing the circuit, or during the time the current passed, if the positive pole was in the ear. The greater the power of the current, the stronger were the sounds heard. The auditory nerve, therefore, obeys the same law which has been established for the motor nerves by the researches of Dubois Reymond. The excitability of

the nerve is sometimes increased during the operation, so that the nerve may respond to a lower force of current than it did previously. In a therapeutical point of view, the current has chiefly answered in such cases of deafness where the normal reaction of the auditory nerve to the galvanic current appeared to be altered; and has also proved of great service in numerous cases of noises in the head and ear. Those who are interested in the subject will find it more fully mentioned in the third edition of Dr Althaus' book "On Paralysis, Neuralgia, etc."

Professor Traube still continues his researches on febrile symptoms and their physiological explanation. At one of the last meetings of the Medical Society of this place, he directed attention to the redness of the face and the increased production of urea in acute diseases. I have already mentioned that the learned Professor explains the whole of the febrile symptoms—not only those which have been known from time immemorial, but also such as have only been shown to exist by applying the thermometer—by assuming a tetanic condition of the smallest arteries. It would seem at first sight that the feverish redness of the face was rather due to a paralytic condition and consequent expansion than to contraction of the smallest arteries and capillary vessels, especially if we take into consideration the results of Bernard's researches on the section of the cervical sympathetic nerve. But, nevertheless, such a supposition proves erroneous on careful analysis of the case. Some time ago Professor Traube had in his wards a young woman who had been confined the day previous to admission. During delivery there had been exceeding dyspnoea, which had, however, subsided after the expulsion of the child. The patient's face was intensely red all over, and a good deal swollen. Nevertheless, the radial arteries and the carotids were smaller than usual. The physical examination of the chest showed that the patient suffered from stenosis of the left ostium venosum, a form of valvular disease in which the arteries are always unusually small. The redness was not at all of a cyanotic character, but of a very bright hue, such as is usually observed in fever. The patient died a few days afterwards from an inflammatory affection of the organs of respiration. Within these last days the redness became more cyanotic and somewhat pale, as the bleeding, which had been considerable during delivery, still continued. This case showed that at a time when the supply of arterial blood to the capillary vessels of the skin of the face was much diminished in consequence of valvular disease, yet the face had as bright a red colour as in fever, which may be explained in the following manner:—The blood corpuscles become darker during their passage through the capillaries, those found in venous blood being greatly darker than those in arterial blood. If the velocity of the current of the blood is retarded, the corpuscles absorb even more carbonic acid and give off more oxygen, so that their colour becomes still darker than it is under ordinary conditions. The same results if persons with a delicate skin expose themselves to cold air. By this the smallest blood-vessels are contracted, the face becomes very red, and if the action of cold continues for some time, whereby the contraction of the vessels is increased, the face becomes blue, resembling the cyanotic hue. This is only due to there being more carbonic acid in the smallest blood-vessels. If an intense cold acts for a certain length of time on the skin the contraction of the vessels reaches its maximum, whereby a cadaverously pale colour is imparted to the skin. In fever the succession of symptoms is the reverse of that just mentioned. If there are very considerable rigors there is at first paleness and cyanotic colour; afterwards, if the contraction of the blood-vessels diminishes, there is intense redness of the face. That there really is such a diminution of contraction may be easily ascertained by watching the radial pulse.

The increased production of urea which is observed in the commencement of most febrile diseases, and which continues during their whole course if they are of short duration, would also seem to furnish a *prima facie* case against Professor Traube's fever theory. Urea is a product of the oxidation of albuminous matter, and it would, therefore, appear that, if all the arteries of the body are contracted and the velocity of the current of blood is retarded, there would be, on the contrary, diminished oxidation of albumen and diminished formation and excretion of urea. But there are several facts which go far to show that such is not the case. M. Rosenstein has found that in diabetes the quantity of urea excreted is very much increased, while the temperature is not only not increased, but rather diminished. From this, as from some experiments of Bischoff and Voit, it follows that there may be increased oxidation of nitrogenous

bodies without simultaneous increase of animal heat. Professor Traube considers urea not to be a product of the general waste of tissues, but as produced by direct oxidation of the albuminous matter of the blood, and without much, if any, influence in producing heat, which is, on the contrary, produced by the oxidation of hydrocarbons. If, therefore, in fever, a nearly normal quantity of oxygen is absorbed by the blood, but less oxygen is supplied to the tissues by contraction of the smallest arteries, there is a surplus of oxygen in the blood, whereby the oxidation of albumen, and consequently the production of urea, is augmented. This latter symptom is, therefore, by no means indicative of increased, but, on the contrary, of diminished, oxidation of tissue.

Fresh instances of trichina disease, on which an able essay lately appeared in your columns, are continually being brought forward by the Medical press. From 1859 till 1862 there was an epidemic disease in Blankenburg, in the Hartz mountains, in the duchy of Brunswick, in which no less than 278 of the soldiers stationed there suffered. The nature of the epidemic was not recognised at the time, but that it was nothing but trichiniasis has lately been shown in an interesting manner. A gentleman who had become affected there in 1859, on being informed that the disease had been probably caused by the immigration of trichinae, offered to become the victim of science, and requested his Medical attendant to excise a piece of flesh from him, and to search for the parasites. A small piece of the biceps having been cut out by Dr. Griepenkerl, it was found that a piece not larger than a pea contained seven encysted trichinae. The cysts were not completely calcified and sufficiently transparent to allow the organisation of the worms to be clearly perceived. On rupturing one of the cysts and gently heating the animal, this began to move about, at first slowly, afterwards more rapidly. It was, therefore, beyond doubt that the patient had not only recovered from trichiniasis, but that he has also sheltered for nearly five years an immense number of such worms without being any the worse for giving a *habitat* to them. If a person similarly affected should ever become a prey to men-eating Fans or other savages, the results which would no doubt follow might put a more effectual stop to cannibalism than the most ardent endeavours of zealous missionaries have hitherto done.

GENERAL CORRESPONDENCE.

ROYAL MEDICAL BENEVOLENT COLLEGE.

LETTER FROM MR. ROBERT OKE CLARK.

[To the Editor of the Medical Times and Gazette.]

SIR,—In consequence of the leader which appeared in your Journal of the 14th inst. (I had heard nothing at all of the matter before) I went to town and attended the annual meeting of the Governors of the Royal Medical Benevolent College, of which meeting I doubt not your Number for this week will contain a full notice.

The annual report read to the meeting congratulated the governors that the council "had been able to continue the good work for which the College was founded;" a matter of real satisfaction to the large number present. But this agreeable sensation was soon to be dispelled as regarded the future. In due course the council brought forward their proposition to admit sons of laymen as Exhibitioners of the College school, at a higher fee. I ventured to protest, in common with a great number of those present, that this was not the "good work for which the College was founded," and it was very ably argued that the proposed measure, if carried, would in time entirely alter the character of the school, now so deservedly looked upon as a boon to the Profession, and to which I hope to send three sons in succession, one being already there.

In the course of the discussion, Mr. Propert (than whom, I am sure, there is no one who is a greater wellwisher to the College school) assured the governors that "so long as there was a single application for admission outstanding from the son of a Medical man, it should have the preference to the application of a layman." With some difficulty it was elicited that there were now nineteen applications of this kind! therefore the dormitories will not accommodate all those who are desirous of entering the school. But supposing the dormitories to be enlarged, I ask, will Mr. Propert, speaking as, of course, he did, in the name of the council, be able to maintain his promise? If these lay scholars are wanted so as to enable

the council to devote the extra £23 to be paid by them towards educating some lads at £25 a-year, I maintain that in the ordinary course of such matters a plausible excuse will be found for admitting the £63 boy, whilst the £40 boy goes to the wall, in spite of what Mr. Probert may conscientiously promise to the contrary.

But apart from all considerations of this kind, I am still at issue with the Council, and agree with the legal gentleman who addressed the meeting, "that the Council would be infringing their Act of Incorporation if they venture to admit any but the sons of Medical men, or to spend any of their funds in building accommodation for such;" and I entirely coincide with Mr. Catlin (in the sense in which he used the expression—which Sir Thomas Phillips, I think, very unnecessarily deplored—as Mr. Catlin meant nothing offensive), that the admission of lay scholars would be a "breach of faith" with the original subscribers towards the foundation of the College, many of whom were truly good friends of our Profession, but who have since passed away. For can it be for a moment denied that the public were asked for funds to build the College as a "benevolent" College for the families of Medical men only? And did not many of our patients become subscribers on that account alone—feeling, as I am thankful to acknowledge many do, that some tangible act of gratitude was due to a Profession whose highest aim and desire is, and I hope always will be, to be labouring for the welfare and happiness of their fellow-men?

I venture, Sir, through your columns, still more publicly to utter my protest against the proposed alteration of the 2nd Bye-law; and whatever our esteemed Treasurer and the Council may say to the contrary—for I doubt not they will "pooh-pooh" my fears, and, I am afraid, carry their point at the next special meeting, by using as a sop the concession to Mr. Catlin's advocacy of the claims of our poorer Professional brethren—I am most truly convinced that if lay scholars are admitted to the School, and the distinctive character of it thus destroyed, it will soon cease to hold the high place it now has in the opinion of the Profession; it will soon cease to be a truly Benevolent Medical College School; and, as far as the Profession is concerned, we shall have to use Lord Eldon's famous words—"its sun has set."

I feel keenly for those hard-working members of our noble Profession, especially in the country, who are, like myself, striving against every obstacle to do the best they can for their children, when I see one of their few good things being snatched from them, or I should not have ventured to intrude, and at such length, on your valuable space. Will you kindly permit this to be my apology, whilst I urge every "poor doctor" to consider what advantages he is letting slip from him by his supineness in this matter; if he is not a governor himself, and therefore unable to vote at the meeting, let him press the subject upon the consideration of some friend who is. In praise of the school itself in all its details, especially under such management as Dr. Thornton's, to whom the boys are all attached, too much cannot be said; were it otherwise, the battle would not be worth fighting.

I am, &c.

Farnham,

ROBERT OKE CLARK.

ARMY SURGEONS' GRIEVANCES NOT ALL REAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—I would venture to address a few words to that section of the Army Medical Department who indulge in an extremely military—if not an extremely professional—view of the grievances of the Department.

In the pages of the military journals there occasionally appear letters, with the spirit and tendency of which I do not think the majority of Medical officers agree. Under this category I may include such suggestions as—that the names of Medical officers should be placed in the army list among the combatant regimental officers, in the order of their relative military rank, the assurances that some of the best men were leaving the service because this was not done, and those effusions which advocate or employ such titles as captain-Surgeon, etc. This is a section of the Department which I cannot help thinking are doing an amount of injury to it out of all proportion to their numbers or intelligence. Their effusions are evidently welcomed by the editors of military journals, in the columns of which they crop out with a disagreeable prominence, which sufficiently attests how glad are the supporters

of the Horse Guards to be furnished with such weapons from the hands of their enemy.

I am fully aware that the Government can scarcely blame those members of the Department who desire to see their position, as defined in one document, inserted into all, as the only protection they have against the recurrence of the present state of things. Surely, however, these men scarcely desire to conceal and merge the justice of their cause under notions of this kind? A man may be alike false to his professional dignity and self-respect by so enlarging the officer as almost to conceal the prefix Medical. The Medical officers have to regret that the question of relative rank has been forced into a very prominent position by the conduct of the Horse Guards. As far as regards their rank and position, they will be quite contented with a restitution of the warrant of 1858. They desire no more, and they conceive that strict justice entitles them to nothing less.

They may safely take their stand upon this ground:—You gave us a warrant in which our position was defined; that position was not our seeking, but the result of a commission appointed, by proper authority, to investigate and recommend where we ought to stand; the abrogation of that warrant involved a breach of faith, and has given an opening for all those invidious distinctions and discussions which ought to have been, once for all, settled by it. I am, &c.

A MEDICAL OFFICER.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 24.

JOHN HILTON, F.R.S., Vice-President, in the Chair.

A PAPER, by Mr. BERKELEY HILL, was read on

THE OCCURRENCE OF A STERNO-CLAVICULAR MUSCLE.

I have lately found a muscle on each side of the body which passed between the front of the first piece of the sternum and the fore part of the clavicle. The subclavii, in this instance, were quite distinct from this rare muscle, and had their usual disposition. The muscles were well-marked rounded slips, tendinous at their attachment to the sternum, and fleshy at their clavicular attachment. The occasional occurrence of such a muscle is mentioned, as far as I know, by Haller only, in his "Elements of Physiology." All the other authors who advert to peculiarities of the subclavius muscle merely describe its attachment to the coracoid and acromial processes of the scapula. Among the commoner animals which have a clavicle, Meckel says that the bat has a well-formed subclavius, and I find by dissection that the mole's subclavius arises altogether from the sternum. But these instances are hardly sufficient to establish any homology between the sterno-clavicular muscle and the subclavius in lower animals.

Mr. CHARLES H. MOORE communicated an account, by Dr. Murray, of a

CASE OF ANEURISM OF THE ABDOMINAL AORTA, WHICH WAS CURED BY COMPRESSION OF THE ARTERY IMMEDIATELY ABOVE THE TUMOUR.

The patient is a spare man, aged 26 years. His occupation as a pavior has required him to use a large wooden rammer for driving paving stones into the ground. Often in making strenuous exertions he has over-reached himself, and subjected the trunk of his body to severe straining. Eleven months ago after hard work he was seized with severe pain in the back. Two months later the same pain began to be felt in the abdomen, catching his breath, and very severe. About two months ago he began to feel a beating in his belly, and shortly afterwards became a patient at the Newcastle-on-Tyne Dispensary under Dr. William Murray, who, after a few examinations, became convinced that he had an aneurism of the abdominal aorta. This opinion was shared by the Medical Officer of the Dispensary. The following was the condition of the patient previous to the treatment:—His abdomen was somewhat spare, so that a distinct pulsation can be seen opposite the umbilicus. On applying the hand a hard, and slightly moveable tumour, of a distinctly globular form, is to be felt. It pulsates very strongly, and the pulsations impinge upon the hand with a sudden stroke, and

the expansion of the tumour very distinctly separates the hands when applied to it. The tumour is of about the size of a large orange; when "the pressure" is made on the aorta above it, all pulsation ceases, and when it is removed a distinct thrill is felt to accompany the rush of blood into the tumour. A slight bruit is heard over the tumour. (A line drawn across the abdomen over the umbilicus touches at either end the margin of the last rib, and encloses between the free borders of the ribs a triangular space—the epigastric region. Over the left half of this space there is just room enough above the tumour to compress the aorta against the spine.) The aorta below the tumour can be felt, and its pulsations seem in no way to depart from their normal characters. Bowels slightly constipated. Pulse good and normal. General health good; but he is worn out with pain and consequent loss of sleep. No evidence of degeneration of arterial system. All palliative treatment having failed to relieve him, I proposed to apply a tourniquet (an ordinary horseshoe tourniquet) above the aneurism, and thus attempt to cure by compression. It happened, as I have before shown, that the aorta could be compressed above the tumour; and this was most completely accomplished by the tourniquet, one blade of which was applied over the spine and the other over the spot above indicated. Having taken my patient to the Northumberland and Durham Medical Society, I obtained there, from the President (Dr. Heath) and others, ample confirmation of my diagnosis; at the same time I proposed my plan of treatment. On Saturday, April 16, the patient was put under the influence of chloroform, pressure, by means of the tourniquet, was kept up for two hours. On removing the pressure, no apparent effect had been produced. The pressure completely commanded pulsation in the tumour, except during occasional momentary displacement of the instrument. After an urgent entreaty on my part, the patient again submitted to the treatment on Tuesday, April 19. After careful re-examination by Dr. Heath and myself, it was concluded once more that there could be no reasonable doubt of the nature of the disease. The pressure was again used and maintained, with but momentary intermissions when the instrument became displaced, but even these were avoided during the last hour, as I carefully held the instrument in its place, and had the patient very fully under the influence of chloroform. After about five hours the pressure was removed, and its removal showed that now very little pulsation existed in the tumour. Beyond a little shivering and numbness, with coldness of the feet and legs, nothing of an untoward nature followed. In the evening, after a most careful examination, I failed to detect the slightest pulsation in the tumour or in the aorta below it. On Wednesday, April 20, the patient was restless and sore; legs feel numb, and a sensation of pins and needles in the feet. In consultation with Dr. Heath, the following observations were made and confirmed by that gentleman:—"There is no pulsation in the tumour, which is now perfectly stationary, hard, resistant, and lessened in size; nor are any pulsations to be felt in the aorta below the tumour, in the iliacs, or femoral arteries." Thursday, April 21.—The patient is much better. Says "he is more free from pain than he has been for several months." No pulsation in tumour or femoral. Pulses can be felt at one or two points in the abdominal wall. Friday, 22nd.—With Mr. Lightfoot, who carefully examined the case, the following points were made out, and verified by that gentleman:—"A solid, hard tumour, of about the size of an apple, lying to the left of the umbilicus, can be felt, and during deep expiration can be seen. It is motionless to the eye, and, by the hand, the slightest possible forward movement can be distinguished at its upper border, as if communicated from the aorta pulsating above." No expansile movement, thrill, or bruit can be made out. All numbness is gone from the legs, and the patient declares he is quite well. Monday, 25th.—Still improving; is moving about freely. No pain since treatment. The tumour is now much diminished in size, and no pulsation can be distinguished in it. The patient has been out this morning, and walked about a quarter of a mile. His legs failed him once or twice during his walk, owing, he says, to a sensation of numbness in them. When his exercise terminated he felt a numbness from the umbilicus downwards for several minutes. Several Medical gentlemen examined him at this period, and their unanimous conclusion was that all pulsation had ceased in the aorta and the large arteries below the tumour. Among these were Dr. Gibb, Messrs. Fips and Armstrong, Mr. Rayne, etc. May 1.—Patient still improving, and walking in the open air daily. No pain or pulsation. May 5.—Patient still improving; has been out for three hours

and walked a considerable distance without other discomfort than slight weakness and numbness in legs. The most careful examination in the presence of several Medical gentlemen fails to detect any movement in tumour, which is now hard and further diminished in size. May 9.—Everything in a most satisfactory state. *Remarks.*—We note in the first place that here we have a complete triumph for the advocates of compression in the treatment of aneurism, for a hitherto fatal disease has yielded to treatment lasting but a few hours, and requiring the use of a very simple expedient. Secondly, here is proof that the aorta can be blocked without violent symptoms or great inconvenience ensuing; and lastly it adds another instance of the value of chloroform, without which the tremendous pressure here used could never have been borne, even though it were to save the patient's life.

Mr. C. H. MOORE said that he heard the first half of the paper with incredulity, but in the latter half the author satisfactorily showed that the aneurism was obliterated. The chief proof was the obliteration of the vessels below the aneurism, as the cure of no tumour, except aneurism, would produce this symptom. It was strange that after such sudden occlusion of the iliac arteries there should have been no gangrene of the toes, and no anæsthesia. The diminution of the tumour to one-third its size was another proof that the tumour had been an aneurism. He (Mr. Moore) thought the slips of the tourniquet had very likely been favourable, and that the cure was by coagulation of the centre mass of blood in the aneurism.

Dr. SYMES THOMPSON inquired whether any estimate could be formed of the force required to restrain the pulsation of the abdominal aorta in this case? It would, he thought, have been satisfactory had this point been ascertained by the use of the tourniquet brought before the Society last year, by means of which the exact pressure in lbs. exercised upon a part was indicated on a graduated scale attached to the instrument. The danger to be apprehended from severe pressure upon the solar plexus must be great, and, when the patient is unconscious from the influence of chloroform, it would seem really important to have some indication of the force employed. A knowledge of the pressure necessary in one instance might also act as a check against unrestricted compression in future cases.

The AUTHOR said that the force required to arrest the flow of blood would depend very much on the state of the abdominal parietes, and on the condition of the viscera. In this case it was possible to arrest it by pressure by the thumb. The amount of pressure had not, however, been accurately estimated.

Mr. HILTON asked if the author had arrived at any conclusion as to the precise seat of the aneurism—as, for instance, if it were near the cœliac axis, or the origin of the renal arteries.

The AUTHOR said that an artery was to be felt beating near the tumour, which he fancied was the superior mesenteric artery. After the first attempt at compression there had been suppression of urine for thirty hours.

Dr. STEWART thought that one of the most remarkable features in this case was the absence of gangrene. He related cases in which gangrene ensued shortly after occlusion of arteries.

A paper, by Dr. W. H. DICKINSON, was read

ON THE TREATMENT OF ALBUMINURIA IN CHILDREN.

The granular kidney appears to be unknown in childhood. The only form of disease which produces albuminuria at this period of life is that which produces enlargement of the kidney and gives it a smooth mottled exterior. This is, in fact, a renal catarrh. The tubes become obstructed by an excess of their own epithelial growth, and hence arise all the evils of the disease. If only there is a free escape for the contents of the tubes the vascularity of the gland will be relieved by secretion, and the disorder will soon be at an end. The principle of treatment must be to send as much water as possible through the organ. This fluid is devoid of irritating properties, and probably passes through the gland rather by filtration than true secretion. With these views the patients were restricted to a fluid diet. They took from two to four pints of distilled water daily, and small doses of the infusion of digitalis. When the active symptoms had subsided iron was given. Twenty-six cases were adduced in which this treatment had been pursued. Twenty-two recovered completely; three were lost sight of while improving, but while still having a small quantity of albumen in the urine; one case did badly, and eventually died under other treatment. Many of the cases were of great severity.

These results appear better than those afforded by other methods. Among the in-patients at the Children's Hospital otherwise treated, 11 died out of 39; and of 69 cases treated by Dr. Miller in Dispensary practice, 8 died. It was found that on an average the little patients were restored to apparent health in 30 days, while 15 days more were needed to get rid of the last traces of albumen. The use of the water did not seem in any case to increase the dropsy, but the contrary. It was usual, however, when the swelling was great to let the digitalis set up a certain amount of diuresis before ordering the full quantity. The subsequent use of iron was believed to correct the effects of the disease, without influencing the disease itself. On the occurrence of secondary disorders, such as convulsions, or acute inflammatory attacks, it was argued that the treatment of the renal mischief should be sedulously persisted in, with such additions as might be called for. The anæmic state of brain in uræmic convulsions, and their frequent occurrence after the exhaustion of diarrhoea or vomiting, were urged as reasons for abstaining from depressing remedies. A case was cited in which, under these circumstances, small doses of opium had been used successfully. A case was also given in which acute pleurisy had passed off under the use of only local measures. The paper professed to deal only with the albuminuria of childhood.

Dr. FULLER had had opportunities of witnessing the author's treatment, but chiefly in adults, in whom it was not so successful as in children. In adults the renal affection was of longer standing. He had tried it in a child in private with success. It was successful in the dropsy of adults, but not so uniformly so as in dropsy in children after scarlet fever. If Dr. Dickinson's views were correct it was easy to understand that it should be more useful in children than in adults.

Dr. BASHAM said there were many points of practical value in the paper, and yet one or two things for comment. First, in cases where the renal affection followed scarlet fever, let the treatment be what it might, the majority of patients did well. No doubt the diuretic influence of water was beneficial, but he thought the theory brought forward was open to a difference of opinion. He ventured to think that there was not merely a blocking up of the tube, but also some change of the gland-cells—they had become effete cells, and accordingly were thrown off, and these, of course, obstructed the tube. But we know that nature tries to get rid of them, and no doubt diluents are of help in this way. He should, however, think the natural tendency of such cases to do well had more to do with recovery than the treatment.

Dr. HILLIER had tried Dr. Dickinson's plan, and had found it scarcely so satisfactory. He (Dr. Hillier) agreed with Dr. Basham, that such patients, however treated, if seen early, would nearly always do well. His plan of treatment was to keep them in bed, to use hot air baths, to give purgatives and good diet. Occasionally he had under care a severe case, and then had tried the water plan, but had been obliged to resort to other means. Perhaps, however, he had been too timid. In one case purpuric symptoms came on. There was considerable hæmaturia and epistaxis. With the water treatment the patient did worse, but when it was given up and gallic acid was administered, the patient recovered.

The AUTHOR, in reply, said that he was quite aware that the majority would get well if left alone, but a great number would not. He had been able to collect a large number of cases of deaths in the post-mortem books of St. George's Hospital. In reference to Dr. Basham's remarks, he said that the first changes were, he believed, in the quantity and not in the quality of the epithelium. In reference to Dr. Hillier's want of success, he would fall back on the explanation which Dr. Hillier himself had suggested, viz., that the treatment was not persevered in. The only fatal case in the paper was the one in which the vapour bath had been used.

Mr. BAINBRIDGE asked if the treatment would have been equally successful without the digitalis? He had seen many such cases during the last month, and the patients generally were thirsty, and, as a consequence, without any special direction, drank a great deal of water.

The AUTHOR said that the water treatment had been tried alone in three cases.

Dr. STEWART related a case of dropsy following scarlet fever occurring in a woman who had recently been confined. Suddenly convulsions came on, followed by unconsciousness. Cupping the loins, and other measures, were followed by success, and he thought it a case in which the use of diluents would not have led to an equally favourable result.

Dr. BASHAM said that he thought that if any patholo-

gist well versed in the use of the microscope would examine the gland cells of the kidney of a child who had died by accident, and then those of one who had died from renal disorder, he would find a well-marked difference. In the latter the cell was cloudy, and the nucleus obscure. It had become an effete and imperfect cell.

Dr. FENWICK said that he had examined the mucous membrane of the stomach in scarlet fever patients, and had found changes in the epithelium there as well as in that of the kidney.

In reply, Dr. DICKINSON said that no doubt there was a change in the cells, but not primarily.

A paper, by Dr. EDWARD HEADLAM GREENHOW, was read on a

CASE OF CONGENITAL IMPERFECTION OF THE MAMMÆ, SEXUAL ORGANS, AND HEART.

The subject of this very rare and remarkable case was an unmarried female servant, aged 22. She had been all her life subject to difficulty of breathing when in exercise, and liable to cough from exposure to cold, but had become worse in these respects since she had been employed as maid-of-all-work. Had never menstruated, nor had any vicarious hæmorrhage. Appearance, hair, and voice feminine. Pulse variable, and very small and irregular in the erect position, more frequent, of better volume, and quite regular when patient lay down. There was a remarkable depression in the sternum, and an exquisitely tender spot about the middle of the ensiform cartilage. No trace of mammary glands could be discovered, but there were rudimentary nipples. No evidence of pulmonary disease, but præcordial dulness much extended, and there was a triple heart sound—the third sound, intermediate between the systole and diastole, being sometimes supplanted by a murmur. Pelvis abnormally small, and genital organs, as far as examination could be made, imperfectly developed, no os uteri being discoverable, nor any ovaries felt on examination either per vaginam or rectum. Dr. Greenhow had found only four cases on record in any respects similar to the one he described, all of which he quoted, showing that they also differed materially from it in various characteristic symptoms. He regarded the case as a very interesting one of congenital imperfection, the result of arrested development.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 3.

Mr. PRESCOTT HEWETT, President, in the Chair.

Mr. TEEVAN exhibited specimens from

TWO CASES OF ANEURISM OF THE ARCH OF THE AORTA.

The first aneurismal sac was nearly as large as a child's head, and caused the death of a powerfully-built man, aged 44, by bursting into the right pleural cavity. It was of about six months' duration, and a blow on the sternum would seem to have been the exciting cause of its origin. The point of interest in the case was that there was an extensive varicose condition of the veins of the front of the abdomen caused by the pressure of the aneurism on the vena cava superior, thus retarding the flow of blood through the internal mammary veins. The second sac was not quite so large as the first one, and was taken from the body of a woman, aged 45. It was nearly filled with laminated fibrin, and by its pressure had caused absorption of part of the second right rib. Death would seem to have resulted from bronchitis, brought on by the implication of the pneumogastric nerves in the tumour.

Dr. BOWEN exhibited a specimen of

SYPHILITIC CARIES OF THE SKULL.

A man 29 years of age, had been eleven years in the army. He was admitted into Newport Hospital eleven months before his death on account of syphilis, whether it was primary or secondary, or whether he was treated with mercury, was unknown. After remaining there nearly five months he rejoined his regiment, but was unable to do duty. Three months later he was admitted into the Tower Hospital, London, where he died January 7, 1855. The patient was under Dr. Bowen's care during the last three weeks of his life. He had nodes on both tibiae, and the scars of old scrofulous glands on the neck. Three sores appeared on the head, two over the frontal region, another at the junction of the occipital and parietal. One on the forehead was deep—the bone was destroyed, and the dura-mater was plainly visible; this presented a vascular appearance, but there was nothing like acute inflammation present.

In the other two, though the bone was carious, it was not perforated. There was no cerebral excitement at any time; on the contrary, he was generally torpid. Pain of a continuous, but not severe, character was experienced in the head. There were old pleuritic adhesions on each side. In the right lung, in its upper lobe, there was a deposit of tubercle, hard, and about the size of a filbert. The left lung was studded with miliary tubercles, and its apex contained two abscesses, each the size of a walnut. The heart was small and flabby: the mitral and aortic valves were covered with warty excrescences. In the abdomen, the liver and omentum were attached to the anterior wall by old peritonitic bands of lymph. The liver weighed five pounds seven ounces, and was waxy in appearance. The corticle substance of the kidneys was pale. The spleen was large, and firmer than usual. The mucous membrane of the large intestines was covered with ulcers, varying in size from a split pea to a six-penny piece. On removing the scalp, all the bones of the skull were seen to be extensively carious; in some places the pericranium was destroyed; in others it was raised by a puriform fluid, which, being allowed to escape, showed an excavation in the skull. There were six perforations beside that one seen during life. The pericranium was firmly adherent around the openings. The dura-mater was not destroyed anywhere: it was thickened and adherent around the perforations. There was considerable effusion of serum in the subarachnoid space, and each lateral ventricle contained about two drachms of fluid. The brain substance appeared healthy. Dr. Bowen remarked that the perforations and excavations followed the ordinary rule by beginning in the outer table and spreading inwards. Considerable interstitial absorption had gone on in the neighbourhood of each ulcer, especially in the immediate vicinity of each perforation. With such an aggravated form of constitutional cachexia, it is not surprising to find that there is no effort towards repair visible in the bone worth speaking of. It was probable that he was affected with primary syphilis for the first time at some period within the last eleven years. He did not know whether he had any secondary affections of the throat or skin; and, as far as the history extended, he first came under treatment within the eleven months preceding his death; neither was there any history of excessive mercurialisation. If scrofula, syphilis, and mercurial cachexia had all allied themselves in this case, the rapidity with which it ran its course was not to be wondered at.

Dr. GIBB exhibited

GROWTHS FROM THE LARYNX, PARTLY REMOVED THROUGH THE MOUTH AND PARTLY THROUGH THE POMUM ADAMI.

The patient was a young lady of 29, whose voice was affected for two years, and who had obstructed breathing for two months with hoarseness. The right wing of the thyroid was decidedly prominent and painful for five months. The laryngoscope revealed a large growth, with irregular outline, of an ashy grey colour, springing from the root of the epiglottis, extending to the right side of the larynx, involving the false cord, and covering the whole of the true vocal cord, as well as the anterior part of the left true cord. This left a small space for the passage of air posteriorly. The under surface of the vocal cords, together with their free borders, were normal, as speech was tolerably fair, although hoarse. On March 29 about one-third of the soft projecting portion of the tumour was readily removed with the laryngeal écraseur, followed by some bleeding. This produced great relief for fourteen days, when she was seized with the most urgent dyspnoea, for which tracheotomy was performed by Mr. Holthouse. Eight days later, her general health being much improved, chloroform was given, and Mr. Holthouse extended his original incision upwards, and divided the thyroid cartilage through the pomum Adami, the lateral halves being held apart by retractors. Dr. Gibb then introduced his finger upwards and removed the remainder of the growths in the larynx, partly with his fingernail and partly with curved scissors, the tumour being soft and friable in some parts and firm in others. The latter condition extended into the right subglottis. No untoward consequences followed. Five days later she was sitting up in a chair, and on the fourteenth day she was comparatively well, eating hearty and getting stouter. Some days later the laryngoscope showed the larynx clear. Various portions examined by Dr. Andrew Clarke revealed in some the transition stage of simple into malignant epithelial tissue. Dr. Gibb had no doubt of the connexion between the growth in the neck and that in the larynx, and the operation he considered as most satisfactory.

Dr. MORELL MACKENZIE said that he should like to ask Dr. Gibb whether the pathological specimens submitted to Dr. Andrew Clark were those which he had removed with the wire-loop, or whether they were those which Mr. Holthouse had taken away after the larynx had been opened. He considered that it was useless to attempt to remove an excrescence, the base of which extended over half the larynx, by means of a cutting operation conducted through the mouth. Such cases could only be satisfactorily treated by means of escharotics. Chromic acid had been lately tried by Dr. Lewin, of Berlin, for this purpose. Dr. Mackenzie said that he had tried this agent, as well as nitric acid, but that he found nothing answer so well as Vienna paste. This might appear a hazardous remedy to employ, but he observed that he frequently used it with the most satisfactory results, and without a single bad consequence.

Dr. GIBB replied that the fresh portions of tumour examined by Dr. Clark were what he himself had taken away at his second operation, and although the growth was broad-based, its soft nature and lobulated form readily permitted of the removal of a portion in the wire loop of his écraseur. All the preparations in the London museums he had carefully examined, and tabulated in his work lately published, and the majority of the tumours could have been readily removed with the écraseur without any risk, the growths in many being foliaceous and disseminated, rather than broad-based. He strongly deprecated the use of Vienna paste, and pitied the unfortunate patients submitted to its use, when other and better means of relief could be applied.

Dr. MACKENZIE said that many of the specimens described in catalogues as pedunculated growths were not so in fact. In many of these so-called pedunculated growths the base was as broad as the extremity. In all the museums in London there was scarcely one growth that could have been removed with a wire loop, except, perhaps, the specimens in King's College, which Mr. Ryland had described, but had these growths been divided they must have fallen into the windpipe, and suffocation would have ensued. Whatever might be the problematical danger of employing escharotics in the larynx, Dr. Mackenzie said that experience proved that if they were skilfully applied no evil consequences, but great benefit, resulted from their use.

Dr. GIBB likewise exhibited a specimen of

DETACHED NECROSIS OF THE CRICOID CARTILAGE

From a man aged 39, admitted into the Westminster Hospital July 6, 1863, under Dr. Radcliffe, with acute laryngitis. Tracheotomy was performed the same night by Mr. Holthouse. In October the odour of necrosis was present; he subsequently left much improved, but was re-admitted in April in a moribund state, and died the next day from extensive pneumonia. Besides old laryngeal disease, the posterior part of the cricoid cartilage was found lying quite loose and bare within the larynx.

Dr. MORELL MACKENZIE exhibited a specimen of

TUBERCULAR THICKENING OF THE INTER-ARYTENOID FOLD OF MUCOUS MEMBRANE.

The specimen was taken from a young lady, aged 21, who had had aphonia for eight months and great dyspnoea for four. Tracheotomy had been skilfully performed by Mr. Mason, and the patient was in a fair way of recovery when she took cold, and bronchitis and rapid consumption came on, and she died two months after the operation. In this case the laryngoscope had been of great value, for with it it was at once ascertained that the inter-arytenoid fold of mucous membrane was greatly thickened, and when, in addition to this the false cords became swollen, and the laryngeal canal greatly encroached upon, the necessity of opening the windpipe was at once perceived.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—WINTER SESSION, 1863-64.—Scholarship in Medicine, Surgery, and Midwifery—J. W. Snook; 2. W. V. Lush. Scholarship in Anatomy, Physiology, and Botany—F. Bateman and T. Cole (equal); 3. R. Robinson. Wix Prize—T. Cole. Bentley Prize—W. V. Lush. Practical Anatomy—Foster Prize: R. P. Simpson; 2. R. G. Rogers; T. Cole and T. Cuddeford (equal); F. Bateman and W. Iliffe (equal); 7. A. C. Farrington; 8. E. Renshaw; 9. G. F. Webb; R. D. Broughton and J. Goodall (equal). Treasurer's Prize: W. Square; 2. R. B. Moore; 3. J. Quick; 4. F. H. Lovell; F. Ewbank and E. J. Leverton (equal); 7. W. H. Ellis; 8. W. Sedgwick.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, May 26, 1864:—

George Huntsman Shaw, St. Bartholomew's Hospital; Alexander Clement Rayner, Bedford; Spencer Henry Simpson, Stowmarket, Suffolk; William Griffith Williams, Haverfordwest.

The following gentleman, also on the same day, passed his First Examination:—

William Livcly Shepard, St. Bartholomew's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BULLEN, DENIS B., M.D. Edin., has been appointed Consulting-Surgeon to the Mercy Hospital, Cork.

BULLEN, DR. FRANCIS, has been appointed Senior Surgeon to the Mercy Hospital, Cork.

CALLAGHAN, RICHARD, L.R.C.P. Edin., has been appointed Junior Physician to the Mercy Hospital, Cork.

CREMEN, DAVID, M.B. Dub., has been appointed Junior Physician to the Mercy Hospital, Cork.

FOWLER, JAMES, M.R.C.S. Eng., has been elected Honorary Surgeon to the Wakefield Dispensary and Clayton Hospital.

ISDALL, JAMES, M.D. Glasg., has been elected Examiner in Midwifery at the Royal College of Surgeons, Ireland.

LEDGARD, JOE A., M.R.C.S. Eng., has been appointed Medical Officer for the Workhouse of Wetherby Union, Yorkshire.

MACKENZIE, G. W., M.R.C.S. Eng., has been appointed Assistant Medical Officer to the Fisherton Asylum, Salisbury.

MAPOTHER, EDWARD D., M.D. Q.U.I., has been elected Professor of Hygiene in the Royal College of Surgeons, Ireland.

MARSACK, BLACKALL, M.R.C.S. Eng., has been elected Surgeon to the Tunbridge Wells Infirmary.

O'CONNOR, DENIS CHARLES, M.B. Dub., has been appointed Senior Physician to the Mercy Hospital, Cork.

O'KEEFE, WILLIAM, M.D. St. And., has been appointed Junior Surgeon to the Mercy Hospital, Cork.

TAYLOR, DANIEL, M.R.C.S. Eng., has been elected Medical Officer to the Union Workhouse, Bury, Lancashire.

WYCHERLY, GEORGE J., M.D. St. And., has been appointed Junior Surgeon to the Mercy Hospital, Cork.

DEATHS.

DAVISON, THOMAS, M.D. Edin., in the Avenue de la Porte Maillot, Paris, on May 28, aged 65.

FELD, JOHN A., M.R.C.S. Eng., at Milford Haven, Pembrokeshire, on May 3, aged 45.

FERGUSON, J., M.D., at Gracefield, Keir, Dumfriesshire, on May 18.

FRANKLIN, FRANCIS, M.D., at Grove-street, Leamington, on May 25, aged 85.

HANNAH, WILLIAM, L.F.P.S. Glasg., at Erskine-street, Liverpool, on May 11, aged 56.

LYNCH, PATRICK, M.D. Glasg., of Donegal-plaec, Belfast, on May 19.

MAHONY, JOHN, L.K.Q.C.P.I., at Cappoquin, Co. Waterford, on May 24, aged 27.

RILEY, JOSEPH, M.R.C.S. Eng., of Percy-street, Tottenham-court-road, on May 22.

STIRLING, PATRICK, M.D. Glasg., at Johnstone, Renfrewshire, on May 17, aged 44.

WALL, WILLIAM B., M.R.C.S. Eng., at Falkner-street, Liverpool, on May 16.

UNIVERSITY OF CAMBRIDGE.—Dr. Humphry gives notice that his course of lectures on "The Principles and Practice of Surgery" will commence on Friday, July 1, and be continued daily.

The annual dinner of the Fellows of the Royal College of Surgeons will be held at the Albion Tavern, on Thursday, July 7 next, J. M. Arnott, Esq., F.R.S., has consented to take the chair.

ROYAL SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS.—The Council have announced that they are about to offer a premium of £50 for an essay against Vivisection in English, and 1000 francs for a similar one in the French language, which they hope will continue the agitation against that practice which they have instituted.

ON Tuesday, the 17th ult., an interesting case of aneurism of the abdominal aorta cured by pressure was shown to the Royal Medical and Chirurgical Society, a report of which will be seen in our columns. The case commands special attention, not only as a successful attempt to cure a hitherto uncured disease, but as the first demonstration of the physiological fact that the abdominal aorta in man can be suddenly blocked up without causing violent symptoms, paralysis, gangrene, or anæsthesia.

CONVERSAZIONE AT APOTHECARIES' HALL.—On Tuesday, May 21, the Master and Wardens of the Society of Apothecaries gave a brilliant microscopical *conversazione* at their Hall in Blackfriars. Very seldom in this country has such a magnificent collection of microscopes and microscopical objects been brought together. All the great manufacturers of microscopes contributed instruments. It would be impossible to give anything like a full list of the varied and beautiful objects displayed. We may notice, however, a few of them. Amongst those exhibited by Messrs. Powell and Lealand was the circulation of the sap in the Vallisneria, shown by a $\frac{1}{2}$ -inch object-glass. Mr. Warrington exhibited, in a small aquarium, Phoronis Hippocrepia, the Annelidan homomorph of the Hippocrepian Polyzoa. The Hippocrepian tentacular plume, with the œsophagus and the vessels conveying the blood to and from the ciliated tentaculæ, were beautifully shown. Mr. Ross exhibited some objects under Kelner's large field eyepieces. A number of binocular microscopes were shown by Messrs. Crouch, Murray and Heath, Edmund Wheeler, Gould, Smith and Beck, and others. Mr. Jabez Hogg contributed a beautiful specimen of trichina spiralis. But, besides microscopes and microscopical objects, there were many other things exhibited of great scientific interest. Dr. King and Dr. Stephen Ward showed a series of very interesting ethnological water-colour sketches taken from life by Mr. Say, Mrs. Stephen Ward, Miss F. Corbaux, etc. We were especially struck with the "Study of head of young Bushman," by Mrs. Ward. Mr. Carruthers exhibited some of the first original sun-pictures on metal plates, with etchings from the same, executed by M. Niepce in 1827. The Messrs. Wheeler showed various experiments illustrating the allotropic conditions of several elements. They also electrolysed water, making use of carbon poles; and showed that when these were employed carbonic acid was obtained at the negative pole in place of oxygen. Another experiment illustrated the bleaching effects of nascent hydrogen, the gas, at the moment of disengagement, decolorising a solution of indigo, but having no effect on the same solution when passed into a wash bottle containing it. On Wednesday morning, when the microscopical exhibition was visited by a large number of ladies, the same gentlemen made a series of brilliant experiments with twenty-four cells of a carbon battery of their own construction. With this battery they produced a powerful electric light, and showed the arc of the thallium flame on the screen. Iron and zinc were burnt with ease by means of the battery. They also exhibited the magnesium light, and showed beautiful experiments illustrating the fluorescent property of a solution of sulphate of quinine. There was a very large attendance both on the Tuesday and Wednesday; on the latter day of ladies.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.—The Eleventh Annual General Meeting of the Governors of this Charity was held at the offices in Soho-square on Wednesday, May 18. Sir Charles Locock presided, and the meeting was one of the largest and most important that has been held for some years. The Report, which is too long for insertion here, stated, among other things, that eight of the College boys have, during the last year, passed the preliminary examination at the Royal College of Surgeons, one that at the Royal College of Physicians, and five the matriculation examination of the University of London; among the latter, two (Taylor and Randall) were placed in the first class, and obtained honours. There are 190 resident boys, and 10 day scholars. Dr. Albert Bernays had been appointed Lecturer on Chemistry and Natural Philosophy, and commences his lectures this year. The report then stated that "since the last Annual General Meeting the Council have considered with much attention the often mooted question whether it is desirable that the scholars should be confined to one class, viz., the sons of Medical men; and they have come to the conclusion that the usefulness of the College as an educational establishment would be enhanced by the admission of a certain number of pupils the sons of gentlemen not belonging to the Medical Profession, and such a proceeding is desirable for the purpose of obviating various reasonable objections often raised against schools intended exclusively for a particular class. The Council are of opinion that the presence of a few day scholars, the sons of other than Medical men, is insufficient to counteract the disadvantages adverted to, and they consider that, under proper supervision, infusion of a variety of elements into a school such as that which is maintained by this Institution is likely to improve and elevate the general tone, and to facilitate and increase opportunities for that

mutual training among the boys which gives a public school the just character of being the best preparation for the work and battle of life. With a view to carry out this plan, when circumstances shall permit, the Council will propose to this meeting that the present 2nd bye-law, the terms of which preclude the admission as resident scholars of any but sons of Medical men, be rescinded, and the following bye-law adopted in its place:—'The school is intended for the education of 200 boys, between the ages of 8 and 19, none being above 15 years old on admission. 180 boys shall reside in the College, 40 of whom shall be foundation scholars, the remainder being exhibitioners, and such boys, not being the sons of Medical men, as shall be permitted by the Council to receive their education at the College. The foundation scholars shall be entirely educated, boarded, clothed, and maintained by the College. The exhibitioners shall pay a sum of £40 a-year each for education, board, lodging, and washing, without any extra charge for the use of books, instruments, etc. The scholars not the sons of Medical men shall pay £63 a-year each for the like advantages. All payments shall be made in advance at the commencement of each term.' As will be gathered from the terms of this proposed bye-law, it is intended that the scholars not the sons of Medical men shall pay a sum which will leave a considerable profit upon their cost, and for this profit a special use can be found. The Council are aware that some Governors of the College have long held and advocated the opinion that a certain number of the sons of the less affluent members of the College shall be admitted at a lower rate than is charged to those more successful men who can afford to pay a liberal sum for the education of their children; and the Council do not at all wish to deny that such an arrangement would be a great boon to many whose circumstances do not render it fitting that they should apply for foundation scholarships, but who, though fully sensible of the value of such an education as that given at the College, are unable to afford £40 a-year for each boy whom they desire to educate there. The legal difficulties which, according to the Council, forbid their admitting exhibitioners at any sum below cost price are then stated; and it is observed that the profits derived from the lay scholars may be applied to this purpose." The meeting ordered that the report be "received and entered on the Minutes." The ten members retiring by rotation were proposed for re-election. Dr. Webster and Mr. Catlin protested against the system adopted by the Council of always proposing for re-election the retiring members; it was contrary to the spirit of the Act of Parliament, and was a bad system. The latter gentleman had protested against it before, and as the proposed members were on this occasion men of especial value and efficiency, he took this opportunity of again protesting against the system, and not the men. They were then re-elected. Mr. Birkett proposed, and Dr. Webster seconded the proposed alteration of the bye-law. Inquiries were made as to whether the admission of lay scholars would exclude the sons of Medical men; and Mr. Propert replied that it was not intended to elect a lay boy while the son of a Medical man was in want of admission. It appeared, however, that there were nineteen names on the books for admission next term. Mr. Catlin said if lay scholars were introduced it could only be to the exclusion of the sons of Medical men, and that ought not to be done, unless some equivalent were given to the Profession. He offered as a suggestion the following resolution as more desirable than the Council's. He could not, according to the laws of the Institution, move it as an amendment: "The School is intended for the education of 200 or more boys between the ages of 8 and 19, none being above 15 years old on admission. 180 boys at least shall reside in the College, forty or more of whom shall be foundation scholars; the remainder shall be exhibitioners and commoners, the sons of Medical men, and such other boys, not the sons of Medical men, as shall be permitted by the Council to receive their education at the college. The exhibitioners and commoners shall be admitted in such relative numbers as the Council shall from time to time determine. The foundation scholars shall be entirely educated, clothed, and maintained by the College. The exhibitioners shall pay £30 a year for education, board, lodging, and washing, without extra charge for the use of books, instruments, etc., and they shall be the sons of Medical men whose means will not allow them to pay a higher sum. Such commoners as are the sons of Medical men shall pay £40, and those not the sons of Medical men shall pay £63 a year for education and the like advantages. The schools were not founded for the rich. It was the original intention

of the founder to admit scholars at £30 annually, even if the funds were taken to make up the deficiency." Dr. Sieveking (one of the Council) supported the suggested resolution in a powerful speech. He hoped to see the school extended to admit even 400 boys. Sir T. Phillips (one of the Council) was fully alive to the importance of Mr. Catlin's suggestion, and thought it would be very unwise to take a vote upon either the motion of the Council or upon the suggestion of Mr. Catlin. He took it to be one of peace, and recommended its reference to the Council, for their careful and serious consideration. After considerable discussion, Dr. Cholmeley (one of the Council) moved, and Mr. Kesteven seconded, a resolution to the effect that the recommendation of the Council and the suggestions of Mr. Catlin be referred back for the reconsideration of the Council, for them to report thereon as speedily as possible at an extraordinary general meeting to be convened for the purpose. This was carried. After some other business, the meeting then adjourned.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

The Physiological Test for Poisons.—*L'Union Médicale* reminds its readers that MM. Ninet and Giraud, of Clermont, had made use of this test in a case of poisoning by white hellebore. They made experiments on a chicken with matters extracted from the bodies of the victims. Their report will be found in the *Gazette Hebdomadaire*, August 2, 1861.

We have received a copy of a shabby newspaper, published at Chester-le-Street, and containing a fulsome puff of a Medical Practitioner, who, it is alleged, had cured a case of heart disease which the most eminent Physicians had given up. It is singular that the Editor of a newspaper in a civilised country should (we suppose as an act of kindness) puff a Medical Practitioner in a style that can be acceptable only to the vendors of quack medicines.

Sentiment is in general a bad guide in the investment of money; nevertheless, the European Cattle Importing Company, of which Mr. Burge, of Hammersmith, is a chief promoter, promises not only to supply a social want, but also to prove remunerative.

Sarsaparilla Proposed for Rickets and Mollities Ossium.—In the course of his researches concerning the life of the plant-cell, Mr. Gulliver has been led to notice that the specimens of Red Jamaica and Honduras Sarza, obtained from Apothecaries' Hall, are remarkably rich in starch and in raphidian cells, while the Guatemala Sarza, from the same authentic source, differs only in containing very little starch, and that the fresh leaves of Smilacæ also abound in the same raphides. No wonder, then, that two former Sarzæ should have been found so useful in venereal cachexies connected with disease of the bones, and that in such cases the patients often become fat after a full course of this medicine. The lime of Sarza has been regarded as existing in the form of an oxalate; but as so many of the acicular crystals in plant cells are known to consist of the phosphate of that earth, these raphides of Sarza were concluded to have the same composition; and specimens of them having been sent to Dr. Davy, were subjected by that eminent physiologist to analysis, who confirmed this conclusion. Hence, Mr. Gulliver observes that the Red Jamaica and Honduras Sarzæ possess exactly the composition, and in an organic form, that we should be led to look for, as a drink or addition to the diet in those sad and intractable diseases of children, of which a leading feature is a deficiency of phosphate of lime in the bones. We believe that the late Sir Benj. Brodie, from the quantity of lime existing in bran, was in the habit of prescribing bran-bread and bran-tea in such cases. As to the so-called American Sarza (*Aralia Medicaculis*), Mr. G. found it both destitute of starch and raphidian cells, though abounding in Sphaeraphides.—*Ann. Nat. Hist.*

IODINE AS A DISINFECTANT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—On perusing a letter in the last number of your journal by Dr. Druitt, recommending iodine as a disinfectant, I find he gives Dr. Richardson the credit of having been the first to point out this peculiar property of iodine. I am sure Dr. Richardson with his usual liberality will admit that it was at my personal solicitation that he was first induced to employ iodine as an antiseptic and disinfectant.

In a paper of mine on the treatment of scrofulous diseases, etc., read before the Royal Medical and Chirurgical Society on the 27th of November, 1860, published in the *Proceedings*, this passage occurs:—"After the evacuation of the pus the iodine lotion was applied immediately to the diseased part, as, independently of its therapeutic action, its antiseptic properties were of great advantage."

In addition to the great disinfectant properties of iodine, I am satisfied that it is equally valuable as a preservative of animal matter, although I am fully aware that the Academy of Medicine of Paris some few years ago came to the conclusion that iodine was not a disinfectant (*vide my paper*). I may here observe that I have been in the habit of using iodine as an antiseptic and disinfectant somewhere about fifteen years.

As an antiseptic in the offensive discharges of cancerous affections I find nothing so efficacious as solutions of bromine.

I am, &c.

A. WYNN WILLIAMS.

20, King-street, Portman-square, May 25.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Master of the Rolls in Ireland having just decided that the King and Queen's College of Physicians, Dublin, have no right to grant the title of M.D., it would be greatly to the advantage of the College to grant the licence on the same terms as that of Edinburgh. At present the charge for the former is £15 15s., for the latter £10 10s.; besides which the K.Q.C.P. require the English Apothecary to give up his certificate and "not be registered." None will do this, as the L.S.A. Lond. has been examined in the "science and practice of Medicine," and "is qualified to practise." By lowering the fees for the licence, and allowing the Apothecary to retain his qualification, the K.Q.C.P. would have many more candidates. At present their fees are higher. They take away a legal qualification, and do not give an adequate compensation.

I am, &c. SCALPEL.

AN EARTHENWARE PESSARY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your number of the *Medical Times and Gazette* for May 21, in the article on the "Medical History of the North Staffordshire Infirmary," Dr. Richardson has done me the honour to notice, in favourable terms, a pessary which I have lately had made of earthenware. To prevent mistake or disappointment, should any parties think well to give it a trial, it might be proper to state that, like most other instruments of the kind, it requires the assistance of a perineal pad and bandage to be worn at the same time.

These, any woman who has the ordinary use of her fingers can make. I usually give the following directions:—A double strip of calico to pass round the body, just above the hips, about the breadth of three fingers, with tapes to tie in front; a similar piece of the same material, fastened to the back of the former, and split at the loose end, to be brought between the thighs up each groin, and tied to the circular band. To this latter piece, where it covers the perineum, a pad, about three inches long and the thickness of the thumb, made of wash-leather, covered with oiled silk or gutta-percha tissue, and well stuffed with cotton-wool, should be attached. This pad can be changed as often as is required for the purposes of cleanliness. It should be braced up pretty tightly so as to press firmly on the perineum by the under strap when in use.

The instrument should be removed every night after resuming the recumbent position, and replaced in the morning before rising, so as to give the parts subject to pressure, both internal and external, during the day, rest for the night. In this manner both soreness and tenderness are avoided.

Burslem, May 26.

I am, &c.

JOSEPH WALKER.

NAVAL ASSISTANT SURGEONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—At a time when the military authorities are at their wits' ends endeavouring to fill up the vacancies in the Medical Department of the Army, it is pertinent to inquire by what magical means the Admiralty replenish the ranks of the Assistant-Surgeons in the Navy.

I suggested that they accomplish their object by picking up the waifs and strays of the Army competitive examinations, and really until the candidates for both services are examined by one common, competent board, I do not see that my suggestion can be said to be ill-founded.

In the naval service Medical men have many grievances to be redressed; they are worse paid, worse housed, and treated with as scant consideration as they are in the Army, and it is therefore contrary to common sense to suppose that, in these days of open competition, the Navy gets competent men if the Army cannot. If the Horse Guards have broken faith, so has the Admiralty; if justice is withheld in one branch of the service, so it is in the other; and with all the disadvantages of a life on board ship added to all this, it would be folly to suppose that the candidates who pass the Navy Board could, if they chose, pass the Army competitive examination.

I might enumerate several subjects of grievance which the Naval Medical Officers of the present day have to complain of, but I know it would be useless to do so while the present state of things exist. Neither Horse Guards nor Admiralty will redress grievances so long as they can get a sufficiency of candidates, and they care very little whether the Professional quality of the candidate be good or bad. Happily for the army, there is a competent tribunal which the candidate must pass, and the appointment of Mr. Prescott Hewett, *vice* Paget, gives evidence that the character of that tribunal will be sustained.

June 1.

M.D., R.N.

MEDICAL EDUCATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It is positively refreshing to read the unflinching, outspoken remarks of Dr. Parkes in the debate appertaining to the Medical Council, as reported in the *Medical Times* of May 14 inst. Now-a-days, things are improving; clinical teachers are more alive to their own interests, and give better value for money to those whose after-career depends much on the acuteness and energy of their instructors; and students are becoming more alive to the responsibility of the task in store for them. Where are these young men who go straight from the Hospitals and schools to the earnest struggle of life—where are they to gain the necessary knowledge and tact for daily duties, unless at the hands of their teachers? Some, it is true, will teach themselves from sheer love of their art, and these, after all, become good Practitioners; the ready eye, willing ear, and indomitable will displace advantages which others have and use not;—such men never could be the dullards Dr. Parkes describes!

I have seen your crack men at the grind-class completely impotent at the bedside of the patient, replete with the cons and quibbles of grinders' lore—"ever learning, but never coming to a knowledge of the truth." Crowds follow the teacher of clinical Surgery, whose repute is as great as his retinue; they hear his remarks, which may or may not be treasured; they see him operate, if fortunately near enough to him; but where lies their chance of practice? Does the Hospital furnish cases for them all? Too often the Surgeon hands over the case to his pupils; the resident pupils monopolise, the clinical clerks engross more than their share, but the "young man from the country" is happy in dressing stray ulcers, or making a "parcel delivery" of some unhappy patient's molars. Why, my young man, did you not stay at your Provincial Hospital, and you may have had a fracture all to yourself, or, may be, a dislocation, as an extra piece of luck? but if more fortunate youngsters than you can attain the money-bought privilege of "pupilage to some worthy," your desire for practical attainments will often go a-hungering. What are the use of large

Hospital Dispensaries if the general student is not taught in the same manner as the articulated pupil of the Surgeon? What is the use of talking to students, the youngest and the oldest, without precision, taking for granted that they know what they do not know? The want for students will be found in men who will "think aloud," giving some reason for the hope that is in them. How gratefully many hard-working Practitioners bless such men, and remember the kindly look or word of encouragement—the helping hand on the Hill of Toil! What is the practical benefit from half the lectures? Two years would amply suffice for them, and five of well-directed Hospital and Dispensary work would send men into the busy world decently equipped, at least, for earnest duties. It is grievous to see healthy lives wantonly sacrificed, and to hear the comments of outsiders—"Oh, another of Mr. So-and-So's patients! Mr. — always leaves his mark wherever he goes." Such men gain nothing for themselves, and are a lasting reproach to the schools who produced, and the Colleges who sent them forth; they mutilate nature in her best intentions, and seem to have "no bowels of compassion." Would that we had more men like Graves, who felt the responsibility of teaching, nor shrank from inculcating the sacredness of a mission that must needs be for good or evil!—the most heedless and reckless might be warned, self-sufficiency disarmed, and good, plain, honest, working material sent into the market.

There is more practical benefit to be derived from the plan of taking cases and lecturing on the actual clinical report than in disquisition on the curiosities of Medical practice from the times of Hippocrates to the present,—cases, perhaps, of an incurable nature, and, consequently, of passing interest compared with sterner realities that await every man whose occupation is hardly less than sacred.

I am, &c.

HENRY USSHER, Med. Bac., Surgeon.

BULLEN; EPIDEMIOLOGICAL SOCIETY; Mr. JAMES FOWLER; Mr. JOSEPH WALKER; Mr. SYLVESTER RICHMOND; ROYAL SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS; APOTHECARIES' HALL; Dr. HUMPHRY; KING'S COLLEGE, LONDON; ETHNOLOGICAL SOCIETY; Dr. ANDREW CLARK; SCALPEL; F.R.S.

BOOKS RECEIVED.

Appendix to the Ex-parte Statement, entitled, "The Case Stated between Dr. Moon and Dr. Purvis." Greenwich: H. S. Richardson.

* * There are some matters whose perfume is not enhanced by agitation, and this is one. Dr. Purvis really was the first offender, and confesses as much in the following passage:—"As to the alleged refusal to meet Dr. Moon, it must be borne in mind that only twelve days before the 10th of July last, Dr. Purvis met Dr. Robert Finch (his junior by many years) in consultation on the case; and that he had, about six weeks previously, induced Dr. Palfrey to visit the patient. Both these gentlemen agreed with Dr. Purvis that the disease was uterine, and that his treatment of it was the best that could be adopted; the cure of the disease being, to all human appearance, impossible. Moreover, some time prior to Dr. Palfrey's visit, Mr. Busk had, at the request of Dr. Purvis, and on his account, gratuitously seen the patient, and consulted with him upon the case. When therefore Dr. Purvis, after all these consultations, was asked to meet Dr. Moon (who was then a stranger to him), he declined to do so, not because he was a younger Practitioner than himself, but for no other reason than that he could not help feeling there seemed to be a want of confidence in him on the part of the patient and her friends, which led him to suggest that it would be better for them to dispense with his services altogether, and to obtain other Professional advice: it was therefore arranged that Dr. Purvis should visit the patient the next day as usual, and then it should be decided who was to attend in future. In using the words attributed to him, that 'Dr. Moon came into the town with no particular prestige,' Dr. Purvis intended merely to allude to there being no particular speciality attached to that gentleman's name in relation to diseases of the uterus without meaning in the slightest degree to depreciate the Profession status of Dr. Moon, or to insinuate any doubt as to his Professional acquirements." The whole case lies in a nutshell. Dr. Purvis could not keep the patient, and should have let her quietly go. All subsequent interference and curiosity on his part were *infra dig*. As for Dr. Moon's omission in his certificate, we cannot see how it could benefit him or injure Dr. Purvis, and it would have been but a liberal act from one Professional brother to another if Dr. Purvis had acquiesced in Dr. Moon's explanation.

Compulence: its Diminution and Cure, without Injury to Health. By John Harvey. Second Edition. London: John Smith and Co., Long-acre. 1864.

* * Mr. Banting, the upholsterer, grew prodigiously fat whilst he indulged in milk and farinaceous substances, and recovered a more human figure after he had been put by Mr. Harvey, of Soho-square, upon a rational diet. This diet excludes the sugars and starches, but allows plenty of meat and wine, and such aliments as are necessary for a man who takes abundant exercise, and who is used to good living. Mr. Banting has told the world of his wonderful cure, and for the present the Banting system of diet is the popular Medical absurdity which is enjoying its nine days' vogue. It has extinguished the Turkish bath, lemon-juice, etc., etc., and is adopted by the intelligent public without considering whether it suits them or no. In the midst of this blaze of popularity, out comes Dr. John Harvey with a pamphlet on compulence. He justly remarks that his pamphlet is "original," and we fully agree with him that it has nothing borrowed from the science of our time. Amidst a mass of what we should think rubbish if it did not rest on Dr. John Harvey's authority, comes a preposterous diet table, containing three or four daily meals of bread and meat and wine, without fruit and vegetables!

On the Anomalies of Accommodation and Refraction of the Eye. By F. C. Donders, M.D. Translated by William D. Moorc, M.D. The New Sydenham Society. Vol. XXII.

* * This is a work to be studied, not reviewed. That the Society has done well in undertaking its translation, does not admit of question. There is no other book in our language which enters so fully into the questions discussed. But for all this we think the Society might have done better had it issued in its place some book more likely to be generally read. We fear that, except with Ophthalmic Surgeons, Donders' work will be taken from the book-shelf less frequently than any other volume of the Society's publications.

Report of the Liverpool Dental Hospital. Liverpool. 1864.
 * * It contains two tables, showing the liability of the different teeth to decay, which demonstrate very forcibly the fact long known to dentists of the great tendency to early decay exhibited by the first molars, especially of the permanent set, a tendency most marked in the lower jaw.

A Plea for the immediate Establishment of a Reception House or Hospital for the Treatment of Zymotic or Contagious Diseases of Children. By T. Radford, M.D., F.R.C.P. Edin. Manchester. Sold by J. E. Cornish, Piccadilly.

* * We commend this pamphlet to all our readers. Probably we shall recur to the subject elsewhere.

Glaucoma, and its Cure by Iridectomy. By J. Soelberg Wells, M.R.C.S. London: John Churchill and Sons. 1864.

* * Practical, and not too long—two important elements in the success of any monograph now-a-days.

Edinburgh Veterinary Review. May, 1864. Edinburgh: Maclachlan and Stewart.

* * Dr. Stark's proposed New Classification of Diseases for Statistical Purposes. We shall consider this shortly.

The Journal of Mental Science. April, 1864. London: John Churchill and Sons. No. 49.

* * In this number there is an account by Dr. Hitchman of his interview with the convict Townley, and an important statistical paper by Dr. Hugh Grainger Stewart on Hereditary Insanity.

New Observations upon the Structure and Formation of Certain Nervous Centres. By Lionel S. Beale, M.B., F.R.S. London: John Churchill and Sons. 1864.

* * We shall take an early opportunity of reviewing this important paper

Lines of Demarcation between Man, Gorilla, and Macaque. By G. B. Halford, M.D., Professor of Anatomy, Physiology, and Pathology in the University of Melbourne. Melbourne: Wilson and Mackinnon. 1864.

* * Dr. Halford places the anatomical differences in parallel columns, as they relate to the Cranium, Cranial Measurements, Dentitions, Vertebrae, Extremities, Muscles of the Thoracic Extremity, and Muscles of the Pelvic Extremity, so that the work is tolerably exhaustive.

Edinburgh Medical Journal. May, 1864. Edinburgh: Oliver and Boyd.
 * * Contains a good paper by Dr. Hjaltelin on Epidemic Pneumonia in Iceland.

Life and Health Assurance for the Working Classes. By Wm. Hardwicke, M.D., M.R.C.S., Deputy-Coroner for Central Middlesex.

* * This pamphlet may be taken as a contribution towards the efforts now being made to emancipate the labouring classes from the tyranny of the public-house club and friendly societies.

Manual of Instructions for the Guidance of Army Surgeons in Testing the Range of Quality of Vision of Recruits, and in Distinguishing the Causes of Defective Vision in Soldiers. By Deputy-Inspector-General T. Longmore, etc., etc. London: W. Clowes and Sons.

* * The introduction of the rifle in the army in place of the old smooth bore musket has laid a new duty upon Army Surgeons. To assist in its performance, this manual is supplied by the Deputy-Inspector-General.

On the Advantages Derivable to the Medical Profession and the Public from the Establishment of Village Hospitals. By Alfred Napper, M.R.C.S. London: H. K. Lewis. 1864.

* * This pamphlet embodies the fourth report of the Cranley Village Hospital, thus enforcing precept by example.

Practical and Pathological Researches on the Various Forms of Paralysis. By Edward Meryon, M.D. London: John Churchill and Sons. 1864.

* * We like the plan of this book, and shall review it at length as early as possible.

Statistical Tables of the Patients under Treatment in the Wards of St. Bartholomew's Hospital during 1863. By George N. Edwards, M.D., and Alfred Willett, F.R.C.S. 1864.

* * Consisting entirely of tables, this pamphlet forms a contribution to the statistics of Medicine and Surgery. We should be glad to see the adoption in future of a plan more in accordance with that in use by the Registrar of the Borough Hospitals. Why should not the registrars meet and agree upon an uniform system?

The Archives of Dentistry; a Record of Dental Knowledge, Medical, Surgical, Microscopical, Chemical, and Mechanical. No. 1. Edited by Edwin Truman, Dentist in Ordinary to Her Majesty's Household, etc., etc. London: John Churchill and Sons, New Burlington-street.

* * In this, the first, number of the "Archives" we recognise some distinguished names as those of contributors. We wish the Journal all success.

Journal of the Scottish Meteorological Society. No. 2, April, 1864. Edinburgh: W. Blackwood and Sons.

* * There is an article in this number which will be read with interest on the "Isothermals of the British Isles for April and October," by Alex. Buchan. We shall have something more to say upon it, probably.

The Dental Review, a Quarterly Journal of Dental Science. April, 1864. London: R. Hardwicke, 192, Piccadilly.

* * This Journal, the second number of which has been just issued, bids fair to fill a recognised gap in Surgical literature.

The Ophthalmic Review; a Quarterly Journal of Ophthalmic Surgery and Science. Edited by J. Z. Laurence, of London, and T. Windsor, of Manchester. No. 1. April, 1864. London: R. Hardwicke, 192, Piccadilly.

* * A new journal. It contains amongst other articles one on "Paralysis of Accommodation Treated by the Calabar Bean," which will be read with interest.

The Australian Medical Journal. No. 34. February, 1864. Melbourne: Wilson and Mackinnon, 78, Collins-street East.

* * In this number is a case in which the common iliac artery was tied by Mr. Lamproiere, the posterior operation being preferred.

Treatment of Diseases of the Skin. By Dr. W. Frazer. Dublin: Fannin and Co. 1864.

* * Our first impression of this book is favourable. It has the advantage of brevity.

The Dublin Quarterly Journal of Medical Science. May, 1864. Dublin: Fannin and Co.

* * Contains an interesting historical paper entitled "The Hebrew Medieval and Modern Leprosies Compared," by Dr. Belcher; and a paper by Dr. Law on the "Treatment of Acute Rheumatism," in which he advocates the use of the lancet and colchicum.

The Classification of Skin Diseases. By W. Tilbury Fox, M.D. London: Robert Hardwicke, 192, Piccadilly, W.

* * Dr. Fox reviews the several systems of classification most in use, and suggests a mixed method of his own.

Report of the Directors of the Aërated Bread Company. 1864.

* * The company appears to be extending its business, and pays 12½ per cent. per annum. It has fifteen bakeries and twenty-four depôts for sale. One of the arguments used has been that, by making bread in large quantities, the waste and expense of numerous small establishments might be saved. But the company appears to multiply small establishments.

The Prescriber's Analysis of the British Pharmacopœia. By J. Birkbeck Nevins, M.D. Second Edition. London: John Churchill and Sons. 1864.

* * A second edition of a little work which we lately noticed favourably.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warrington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—**J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.**

In Bottles, 1oz, 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

TOWLE'S CHLORODYNE.

OF KNOWN COMPOSITION.

For Formula, &c., see back Numbers.

Extract of Letter from Dr. C. KIDD (Author of Standard Works on Chloroform).—"SIR,— . . . Of the value of Chloroform given internally I have no doubt; it appears to me in that form an anodyne, *sui generis*, that no other anodyne can approach. I have resolutely opposed the use of *secret* compounds of chloroform, and in every way I can encourage the use of the 'Chlorodyne' (if we must have it at all) that is made by you, as you state that its composition is known. Many Medical men think with me, and recommend your compound, but will never prescribe a *secret* remedy.—CHAS. KIDD, M.D.—Sackville-street, Piccadilly, London, April, 1862.—To Mr. A. P. Towle."

Extract of Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J. P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession.—To Mr. A. P. Towle."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; 4 oz., 4s.; and 8 oz., 8s.

SOLE MANUFACTURER—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

LIQ. CHLOROFORMI CO. (TOWLE'S).

This preparation is identical with "Towle's Chlorodyne," *sine* Ol. Menth. Pip. (dose 5 to 20 minims, as in Chlorodyne).

The Proprietor having for some time past, at the request of several members of the Medical Profession, made a preparation of Chlorodyne without peppermint, has lately, on account of the frequency of these demands, prepared the same for more general use, under the designation of LIQUOR CHLOROFORMI CO., which, possessing the Medical properties of Chlorodyne, may be prescribed in all cases where the Ol. Menth. Pip. is disapproved, and overcome the objection so generally felt to the use of the term "Chlorodyne."

May be obtained, as an introduction, from the following Wholesale Houses, in 2 and 4 oz. bottles, at 2s. 6d. and 4s. each:—London: Barclay and Sons, 95, Farringdon-street. Birmingham: Southall, Sen, and Dymond. Liverpool: Clay, Dod, and Case. Edinburgh: Duncan, Flockhart, and Co. Glasgow: The Apothecaries' Company. Dublin: Bewley, Hamilton, and Co. Manchester: Jas. Woolley; and the

Proprietor—A. P. TOWLE, 99, STOCKPORT-ROAD, MANCHESTER.

ORIGINAL LECTURES.

LECTURES

ON THE

PROGRESS OF SURGERY DURING THE
PRESENT CENTURY.

DELIVERED AT

The Royal College of Surgeons,

By Professor FERGUSSON.

LECTURE I.—MONDAY, JUNE 6, 1864.

MR. PRESIDENT AND GENTLEMEN,—When the honour was conferred upon me of being appointed Professor of Human Anatomy and Surgery to this College, I felt uncertain as to the manner in which I could best fulfil the duties pertaining to such an important office. Considering the vast fields of Anatomy and of Surgery which I had to choose from, the difficulty of selecting subjects for six lectures seemed at first far from great; yet reflection indicated that already the labourer had been at work in most departments, that the harvest had been stored, and that little remained to be gleaned or garnered, which could possibly be put in comparison with the knowledge already in man's possession. To one who has been a labourer in our Profession for well-nigh forty years, such a selection might at first thought seem easy; a teacher of Surgery for more than thirty years might scarcely feel at a loss for material; but that very fact in a manner tells the real difficulty, for as a teacher one is necessarily in almost constant contact with the Profession, and whatever he may have fancied new or of value has already been made public by the usual channels. In conversations with assistants and friends, in lectures, in the operating theatre, in the pages of public Professional journals, in papers for societies, in pamphlets, and even in portly volumes, the teacher of old standing and fair repute has already communicated his ideas to his Professional brethren so freely and amply, that in his later years he stands literally unburdened of all to which he may at any time have had original claim. It has been his glory to spread knowledge as readily and rapidly as it may have come within his own ken; and such originality as may have been his own has long since become the property of his Profession. Now, the dilemma with me was, that I had nothing new to say. More than twenty years' teaching in a London College and Hospital theatre had, in a manner, used me up; and thinking of the kind of audience I might naturally expect within these walls, I had hesitation and doubt as to what might best suit the occasion. Two courses came prominently before me. I might select a single subject, and say all about it that had been said before by others, and repeat or add all that I myself had said or thought further; or I might select several subjects, in which I had myself taken special interest and had peculiar opportunities, and lay them before my hearers in such a way as to give novelty and attraction to an audience assembled in the heart of London, and in the metropolitan abode of English Surgery. Of the two courses I preferred the latter. If I have nothing new to say, that is, new to my own mind, I may still labour, though in a somewhat novel sphere, to impress such truths as I have learned from experience, to raise doubt where I have reason still to do so, and to venture such suggestions and forecasts of thought as may become one who has spent his whole professional life in teaching, and who now finds himself in the responsible office of Professor of Human Anatomy and of Surgery in this great Corporation.

About the year 1825, when my first intimate connexion with the Profession began, there was a period of calm—at least, that is my impression—such as had not been for many years, and such as none of the present generation has seen. There was literally nothing new in British Surgery, and little from abroad to attract special attention. The great impulse given by Hunter and his disciples had been in a manner embodied with, or, as some might think, had become the embodiment of the Profession. On the Continent, among Surgeons, Dupuytren stood supreme, whilst Graefe, Lisfranc, Larrey, Dieffenbach, and Roux were but a shade behind. The latter had written his celebrated "Parallel," and already Velpéau had indicated his growing worth. In America the names

Mott and Warren were associated with the boldest deeds in Surgery; here, among ourselves, Home, Cline, Blizard, Abernethy, Cooper had passed away, or were well-nigh fading from the scene. The same might be said of Tod and Colles. In Dublin Crampton, Carmichael, and Cusack worthily held the highest places in that city; and Brodie, Travers, Wardrop, Guthrie, Anthony White, Key, Stanley, Green, and others yet alive, whose names, indeed, inspire veneration, held sway in this great metropolis. In Glasgow John Burns laboured, I may say, and all unknown, in a field which had been previously occupied by himself and his worthy brother Allan. In Edinburgh the reputation of the Monroes gave a high character to the anatomical and pathological aspect of Surgery, and the family reputation was maintained by the third of the name. The brilliancy of John Bell had, in the early part of the century, given to this school great *éclat*, which was enhanced by his brother Charles, whose name may be honourably included among the worthies of London at the time I speak of; and the solid worth of Benjamin Bell had given a high character to Edinburgh Surgery.

About this date the field of Surgical practice in the northern metropolis was held by gentlemen of high social position and Professional standing; but they were neither professed teachers nor long-experienced Hospital Surgeons; each had served a few years only as full Surgeon in the Royal Infirmary. One, Mr. Wishart, had published translations of Scarpa's works on aneurism and on hernia; but others were unknown to more than local fame. From this list I may bring out and except the name of Russell, the author of an original and still standard work on necrosis, and at that time revered as a surviving pupil of John Hunter. He was, moreover, the first Professor of clinical Surgery, and the only one bearing such a title in the United Kingdom. His position as a model Surgeon was, moreover, by no means prominent; and the pure Surgery of Edinburgh, as the term goes, was little different from that which might be found in any of the large provincial towns in Britain. There was no chair of Surgery in the University; that of the College of Surgeons, which was shortly afterwards abrogated, was held by a clever man, whose health and temperament prevented his taking a foremost rank in practical Surgery; and there seemed little hope for a continuance of the great reputation of this school, when suddenly there appeared on the scene three men, whose labours have added substantially to the renown of the Scotch school, and whose names will be imperishably associated with the history of British Surgery. These men were John Lizars, Robert Liston, and James Syme. I trust that I may be pardoned for making pointed allusions to these Surgeons; but as it was from them that I chiefly gathered many of my own early views on Surgery, I should not wish this opportunity to pass without giving them that honourable mention which, in my opinion, they richly deserve. Mr. Syme still lives in active manhood, with a world-wide reputation, second to none among living British Surgeons. It is considered unbecoming to say that of one yet alive, and yet active on the scene, which may be said in after years. Modern Surgery owes him much, as I shall hope to show in after lectures. Eulogy might seem to partake of flattery; and for my present purpose it may be sufficient to state that at the date referred to this gentleman evinced all that energy of character and aptitude for clinical teaching and for practice, for which he has since become so distinguished. Mr. Liston's fame at this date, particularly as an operator, was well-nigh as great as at any period of his comparatively short but brilliant career. In after years his soundness as a pathologist became more conspicuous, and the numerous valuable preparations in the museum of this College which formed part of his collection bear ample testimony to the greatness of his doings in practical surgery. Both he and Mr. Syme had already published those remarkable essays on amputation which, with the example set by their practice, went far to give that development to the flap operation since attained. Many circumstances contributed to give this Surgeon early fame in Scotland. A well-developed frame, a broad forehead, a strongly-marked, handsome countenance, indicative of great courage and decision, an eye of piercing brilliancy and great expression, at once impressed those who sought his aid with a conviction of his powers. With these were associated a hand alike marvellous for its great size, its silent expressiveness, its vigorous firmness, its lightness, and its dexterity. It was aptly said of it by a distinguished contemporary and admirer, the late Lord Robertson,—“If hard as iron and true as steel in the theatre of operation, it is soft as thistle-down

when applied to the throbbing pulse or aching brow." Some operations of great magnitude and comparative novelty, aided by a certain amount of jealous opposition, which merit is sure to call forth, brought his fame impressively before the public; and among his achievements may be mentioned the successful removal of a scrotal tumour of more than forty pounds weight, the first operation of the kind ever performed in this country, and a successful ligature of the subclavian, which had been essayed in vain by Ramsden and others in Britain. When personal recollections have passed away, there will remain much to associate Mr. Liston's name with Surgery, but the greatest features of his teaching powers will be forgotten. With a less than average facility of speech, he had a manner in all that he did before his pupils that produced the deepest impression, and there was a style in his operations which has had more influence in this department, among a large number of pupils, than has ever been produced, in as far as I can make out, by any other man in the history of Surgery. Only those who have seen him can thoroughly appreciate what I am now saying. Of Mr. Lizars there is now probably less known than of the two gentlemen just referred to, but his fame was great at the time. His folio work on anatomy, with which he incorporated most of his views on operative Surgery, had contributed largely to his reputation. Initiated to the profession by John Bell, to whom he served a pupilage, he seemed to have imbibed some of the characteristics of that great Surgeon. He was a very successful teacher, both of Anatomy and Surgery, an excellent pathologist; a brilliant and daring operator, his name will ever remain associated with the early history of modern operations on the upper jaw. He was the only man in Scotland who had placed a ligature on the innominata. The operation was unsuccessful, but it went far to prove what was then not so well recognised as now, that secondary hæmorrhage in such cases is more likely to come from the distal than from the proximal end of a tied vessel. He was the second to perform ovariectomy, and its practical originator in Britain. Like many pioneers in art and science, he was for this assailed by a certain amount of ridicule, associated with vigorous opposition; and thus was thrown into abeyance an operation which, thirty years later, has produced as much excitement as has been associated with the early history of any great Surgical proceeding. Whatever may be the fate of ovariectomy, the name of John Lizars must always be associated with it.

I may be wrong, but the impression is strong in my mind, that an impulse to the more accurate study of Surgical anatomy arose coeval with the development of the Hunterian operation. Before I knew the Profession all the great arteries had been tied, from the superficial femoral to the abdominal aorta and the innominata, on the principles of our great Surgical philosopher. The Surgical anatomy of the arteries had occupied the attention of many first-rate anatomists of the early part of this century; and whilst the operations in question were excitingly attractive, others were not overlooked, and hence Surgical and regional anatomy took a wide field, and the works of Charles Bell, Abraham Colles, Astley Cooper, John Shaw, Hargrave, and of others, testified to the zeal and curiosity of Surgeons in those times in anatomical pursuits having direct relation to their calling. It is an anecdote worth bearing in mind, that when Astley Cooper was engaged in his great and interesting labours on hernia nothing would satisfy him but a sight of the fact that the obturator artery might encircle the inner side of the neck of a crural hernia. The first preparation that gave this proof was in the museum of the famous professor of anatomy in Edinburgh, John Barclay (now incorporated in the collection of the Royal College of Surgeons of that city), who actually forwarded it to London to satisfy the hesitation of the great Surgeon. It was returned with most complimentary thanks; and this anatomical fact, now familiar to the simplest novice, was soon after made extensively known to the Professional world. There were manuals of anatomy in those days, written by men who have since held the highest Professional positions, which have really left little for the practical Surgeon to desire. In fact, the subject was in a manner exhausted. Whatever was essayed as novel seemed in reality but a repetition of something already done and known, and with an occasional exception there was little left for the modern anatomist but transcendentalism and minute observation. Investigations on ill-defined and obscurely-developed quantities have, I fear, taken largely the place of wholesome surgical anatomy; and whilst I shall not go so far as to say that they are not of great value to the education of the practical Surgeon, I may

state that I have often felt inclined to protest against a system which seems to draw little or no distinction between this kind of so-called philosophy and that common-place but common-sense anatomy which is of essential service to the practical Surgeon. With some it almost appears as if the bulk of the two-thousandth part of an inch were of equal importance to the Surgeon as the outlines of the sterno-mastoid or deltoid muscles; and with many it seems to me that there is really little or no difference of essential value between, we will say, blastema and bone, molecule and muscle, cytoblast and cellular membrane—nay, actually, that once familiar term is now in some degree tabooed, and a man's acquirements are suspected, if he does not use instead the modern one of areolar tissue. In Surgical pathology it was known that a person might live with an obliterated aorta, and might survive the loss of an upper or lower extremity. Inflammation, with denudation of bone, was commonly believed to necessitate amputation; and diseased joints, with ulceration of cartilages, particularly denoted by crepitation, were generally deemed incurable, excepting by removal of the limb. Tumours of enormous size were frequently met with; and the disease then familiarly known as fungus hæmatodes was more common than in the present day,—in both instances, doubtless, from timidity on the part of those who feared to meddle with what the modern Surgeon arrests in early progress. But a vast amount of important material had been accumulated by the practical men of the day; and the works of Lawrence on "Hernia," Brodie on the "Joints," Thomson on "Inflammation," Hodgson on the "Arteries," and Cooper on "Dislocations," may be referred to as types of the most valuable and precise Surgical pathology which had been given to the Profession. Pupils and Practitioners had for study and reference in Surgery, and to some extent in anatomy, the standard works of Boyer, of Benjamin Bell, of John Bell and Charles Bell, of Abernethy, and of Samuel Cooper, whose "First Lines" was for long the favourite text-book, and whose famous dictionary has perhaps not been excelled even to the present day.

Some naval and military Surgeons had contributed largely to our general knowledge. Besides the labours of Hunter and of John Bell in these departments, it is in accordance with the intended spirit of this lecture that I should refer to those of Veitch, Copland Hutchison, Larrey, Hennen, and Guthrie. Although I am myself disposed to take exceptions to some of the doctrines of these gentlemen, so far as they claim to be invariably applicable to the practice of Surgery in civil life, I willingly acknowledge the great merits of those who gave us so much information after the cessation of our wars with Napoleon I., and that much additional material of unquestionable novelty and value has been added to our stores by the publication of the so-called Military Surgery of that eventful period. In Smiles's "Lives of Engineers" a dozen or more of those who first worked in this noble science are told off, each with a brief yet interesting memoir comprised within a few pages; but as engineering has advanced in progress of time, the works of Laboulaye and Myddelton, of Metcalfe and Brindley, seem to be surpassed by those of Smeaton, Telford, and Rennie, until at last a whole volume is required for the life of the elder Stephenson. Were we to compute the progress of Surgery in a similar manner, to what limit might the lives of great Surgeons not go? To look within the present century, volumes might be written, in which most of those names already mentioned would stand pre-eminent; and it would not be difficult to mark out many of the living generation with whom the progress of Surgery is closely associated. It is the boast of those who live in the nineteenth century that progress in all that pertains to civilisation has been greater than in any similar period in history. I cannot venture to claim for Surgery the world-wide impression that has been made by steam, by electricity, by engineering, or by mechanics; yet our art and science have not stood still. If there have been changes and reforms in our laws and civil institutions, for the improvement of our social atmosphere—and who can entertain a doubt on the subject?—we may point to *our* changes, *our* reforms, *our* improvements also.

Few things have struck me as more remarkable than the simplicity of appliances and dressings in modern Surgery among the best class of Practitioners. This arises, I believe, from a better appreciation of the powers of nature, and a more humble idea of our own, as to forcing that which can only come in time. It is perhaps in the increased knowledge and better treatment of wounds that the philosophy of Surgery has been most evinced in modern times. The days of the secret dressings and of sympathetic powders have passed

away, and such a man as Kaulbach, whom John Bell designated as a respectable quack, or a pretender like Sir Kenelm Digby, even if, like that famous man, secretary to a king, would have no influence on the Profession, and little on the public now-a-days. Yet Digby, had he belonged to our Profession, would nearly have been a philosophic Surgeon. If, after bringing the edges of a wound into accurate contact, and keeping them so by simple means, instead of affecting mystery and enacting the part of a mountebank, he had told his patient he had done all that man could do, and that nature and time would do the rest, he would have struck the key-note of that which constitutes, in my opinion, a great feature in modern practice. The secrecy and sympathy consisted in reality in simplicity; and it remained for John Hunter and for what John Bell called the London School to give us our present views on such subjects. Professor Hughes Bennett, of Edinburgh, has in recent years insisted much on what he calls rational medicine, the term evidently implying the existence of a converse. It is not for me, in my present position, to say much about the practice of physic, but I do not hesitate to say that there is room for rational Surgery to make useful way. "I cure," or "we cure," is too much in our vocabulary; and it would be more in accordance with the knowledge we possess of nature's actions were we to affect less in this respect, whilst there is a broad margin on which the guiding hand of the Surgeon might take full credit. It has, indeed, been truly said that Surgery is the handmaid to nature, and when the service is judiciously administered our work appears in the greatest perfection. Nature, in many of her inscrutable ways, does that which offends our common humanity: she brings us fevers, atrophies, consumption, cancers, over which we have but little control. Livingstone has told us that, in parts of Africa where the lights of civilisation have not yet appeared, most of those diseases which are at present the scourge of Europe have not yet been seen. May it not be that our boasted civilisation has brought upon us many of those evils which, with a sort of negative consolation, we say, in poetic language, that flesh is heir to? Does not the very style of living interfere with nature's healthful actions in civilised man? Who in these isles can boast of success in lithotomy such as that obtained by our Surgeons who practise in Asia? Were cases of elephantiasis scroti prevalent among us, is it likely that we could boast of saving twenty-two patients out of twenty-four operations? Yet such success has been recently recorded by Professor Ballingall, of the Grant Medical College, Bombay. With all deference to our friends and contemporaries, it cannot be admitted that this success comes from superior skill or dexterity; it is from the subject on which they work—the nearest approach to perfect nature, irrespective of what we fondly call civilisation, civilised habits.

In speaking of wounds, I should not be doing justice to my own views and experience, nor to the efforts of others, were I to omit reference to the more common use of stitches than was sanctioned some thirty or forty years ago. When early and perfect union is desired in a line of considerable length, they far surpass other methods, and, when judiciously applied, possibly, in many instances, with a due share of additional support, they are of the utmost value. Throughout my experience I cannot say that I have seen the slightest evil arise from them, whilst the best possible good has often been derived; in fact, some of the greatest triumphs of modern Surgery are associated with this simple mechanical process; for how else could so much have been done with those vesico-vaginal fistulæ which so baffled our forefathers, and are so amenable to skilful operative management? How else could the operation for cleft palate have been successfully accomplished? How else could we have dared to lay open the walls of the abdomen to the extent of six, twelve, or fifteen inches? Much has been said in recent times of the superiority of wire over thread, as the material for the stitch; but, for my own part, I deem the matter of comparatively little importance, whilst I do not hesitate to proclaim my preference to common silk thread for general use. Until within the present century there was no positive remedy for stone in the bladder, but a painful and dangerous operation—a cutting operation. The highest talent, skill, and manipulative dexterity have been evoked to set aside the dangers of that proceeding; Surgeons have cut twenty, thirty, fifty patients, losing, perhaps, only one; but a more extended experience has had the effect bringing the average of fatality down to the certain loss of one in six or ten. Men have vainly prided themselves on their success—some because of the peculiar shape of their knife, some on the supposition that they have

operated more dexterously than others, and superior success has even been claimed on account of a special prayer and appeal to the Almighty just before commencing. We know full well how, in the mysterious ways of Providence, man's best efforts have failed, his holiest aspirations have seemingly been thwarted. Happily we of the present day have lived to see the perils and uncertainties of lithotomy set aside, in a large number of instances, by the less formidable, and possibly more successful, proceeding of lithotripsy. The development of this operation has been within our own time; it is of foreign origin, and British Surgeons have taken slowly to it. Until within these twenty years, it was practised by few, but latterly it has come into more general use; and if patients would but apply at an early date, when the stone is small, the judicious application of this operation would go far to supersede the use of the knife, and make lithotomy exceptional. As evidence of the high and useful character of the operation, it has been applied alike to the peasant, the artisan, and the wearer of a crown. Whilst we do all honour to the labours of Costello Heurteloup, and especially of Civiale, in developing this proceeding, it is worthy of note that the essential features of the instrument now in use are of English origin, these features being the male and female blades, with the sharp curve at the end, where the crushing force is to be effected, and the screw for that special purpose. This instrument and these devices have resulted from the efforts of our celebrated instrument-maker, Mr. Weiss.

For my own part, I am almost disposed to consider that the treatment of distortions by division of tendons muscles and fascia—a treatment founded on a better appreciation than formerly of anatomy physiology and pathology—constitutes, perhaps, the most striking example of modern improvements which I could bring under your notice. What can be more creditable to Surgery or to our character in the nineteenth century than such a sight as this (pointing to a drawing)? Here is a very tolerable human figure turned from such a distortion as this—(pointing to another). I take the greater pleasure in referring to this case, as it was treated by one of our provincial Surgeons, Mr. Wiblin, of Southampton, who, in the discharge of his duties, like many of his fellow labourers, undertakes the treatment of most ailments that come within his cognizance with energy, skill, and success, such as may well be admired, or possibly envied, by his metropolitan contemporaries. Cutaneous puncture and subcutaneous division, with a narrow blade, so as to prevent the access of air, make Stromeyer's name worthy of all honour in all time to come; and the development of new tendon in some of these cases is a fine illustration of what nature will do when man judiciously interferes with some of her imperfect works. How hopeless was our practice for strabismus in former times! We neither knew the cause nor the means of cure. Now observe the effect of the scientific reasoning of Dieffenbach. In the generality of such cases the division of the internal rectus of the eye restores the symmetry of these important and attractive organs. Here the simplicity of the idea almost leads us to overlook its magnitude and scientific character. The illustrious Roux thought his achievement great when he could close by operation the cleft palate, as if it were a hare-lip, and be successful in securing union in two cases out of every three operated upon. It is my intention to show you in some future lecture how, by division of the levator palati on each side, the operation may be rendered almost as certain in its results as that for fissure in the lip, and that the average failure is about one in twenty-seven or thirty. The skill with which raw surfaces are made and approximated says much for modern progress. Our plastic operations are more marvellous than ever entered the imagination of Taliacotius or the poetic mind of Butler. The almost fabulous transplanting of one part of the body to a distant surface has been realised,—the skin on the back of the neck has been lifted forwards to supply a deficiency in the front, and a portion of the skin of the abdomen has been made to do permanent duty on the forearm. Among plastic operations, and as illustrations of the value of union by the first intention, I may here refer especially to reparation of the face, and to the closing of wounds and unnatural openings in the urinary organs and parts of generation, particularly in the female. A word of praise in these departments is justly and specially due to our Transatlantic brethren; and among ourselves there are many whose triumphs in these cases do the utmost credit to modern Surgery. The application of the stethoscope to Surgical diagnosis, the extensive use of the microscope in pathology, the invention of the laryngoscope and its recent

application in practice, are all interesting features in modern Surgery. The ophthalmoscope, too, is one of the most ingenious and clever inventions to which Surgery is indebted; nor can there be a doubt that in special cases the speculum also is of much service. I must leave it to greater enthusiasts, and those more skilled than myself, to dilate upon the marvels divulged by these instruments, and to fix upon their relative value as additions to the Surgery of the present century. Ophthalmic Surgery has made wonderful strides within our own time; but I do not profess myself competent to dwell on such a theme. It is pleasing to see that those who excel in this department, particularly among ourselves, are gentlemen who, from their education and competency, are fitted to hold the highest places in general Surgery, and that many of them have held, and now hold, foremost rank in our Profession. Let me here express a hope that some future Professor in this chair may be able to say as much for all who may devote themselves to the specialities of modern custom.

Excisions or re-sections—the words seem synonymous—have claimed a large share of modern attention; for although we owe to the last century many such proposals, and several examples, it is within the present that much has been said about them. Here is a sketch showing the whole of the ulna, with an inch and a-half of the lower end of the humerus, which were removed by Staff-Surgeon Williamson. The other part of the picture shows the arm twelve days afterwards. There was a rapid recovery from the wound, with a useful arm and a hand, including free motion of the joints. Unfortunately, this person died of consumption between two and three years after; but the case is one among many showing the progress of modern Surgery; and ere these lectures are done I shall have many of a like kind to refer to.

But time presses, and I shall conclude this my present address by a reference to some matters which need not be dwelt upon in other lectures. Of these, that of anæsthesia may be deemed most remarkable. No single appliance in Surgery can, in my opinion, be compared with it; for, long before its discovery, most, if not all, of the great achievements of our art had already been accomplished. The amount of suffering which can now be set aside enables us to relieve surgery of much of its horrors, and to exclude from the patient's senses that which was anguish, suffering, and torture; whilst generally it permits the Surgeon to perform his study with a serenity of thought and action far different to his predecessors. On this subject America again must have the palm of precedence. There sulphuric ether still holds the first place as the anæsthetic agent; whilst with us chloroform, whose influence was first observed and made public by one of our distinguished contemporaries, is considered the most useful.

Not long ago Dr. Marion Sims, with laudable enthusiasm, claimed for metallic stitches the honour of being, in our Profession, the greatest discovery of the nineteenth century. Few Surgeons of practical experience will endorse this idea; but I see nothing which has transpired in the present century which in magnitude and importance can compare in our annals with anæsthesia; and in my mind it ranks in value to mankind scarcely less than the results of the labours of Harvey and Jenner.

We congratulate ourselves that we have been permitted to live in times when man has displayed his mastery over steam and electricity; and with us, in our special profession, there have been agencies at work whose usefulness may be said to be literally beyond calculation. I allude to the improved facilities for education, to our social professional customs, to the modern press, and our own special literature. Our schools have increased in number; our great public Hospitals associate more extensively than ever education with charity; our handbooks, our works of reference, our means for learning, our appliances for teaching, are beyond compare, and facilities for studying anatomy have, by wise legislation, been placed lawfully within reach. Our societies and professional gatherings have encouraged and facilitated the diffusion of knowledge; man meets man face to face; thoughts flash almost simultaneously from brain to brain; and there is no longer a difficulty with those in places distant from the metropolis to find out even some roundabout way of communicating interesting or useful knowledge to the Profession. A Surgeon to a Liverpool Hospital in the present day need not, as Park did in 1782, address himself to a leading Hospital Surgeon in London, to give currency to his aspirations; nor need the Munros of our day keep their originality under the cold shade

of an academy or a corporation. Besides the facilities for individual and independent publication, there are our quarterly, monthly, and weekly journals, to carry knowledge to the ends of the earth. We pride ourselves in this country on the liberty of the press; we fondly call it our fourth estate;—politically and professionally it may be called the pulse of the public mind, and among ourselves, and in our own time, it beats with a healthy vigour, indicative of all those changes for the better which I have thus endeavoured to sketch, although, I fear, but feebly, within the limits of a single lecture.

ORIGINAL COMMUNICATIONS.

NOTES ON ANIMAL MECHANICS.

No. I.—ON THE MUSCULAR MECHANISM OF THE HIP-JOINT IN MAN. (a)

By the Rev. SAMUEL HAUGHTON, M.D.,
Fellow of Trinity College, Dublin.

INTRODUCTION.—In the course of the following notes on the muscular mechanism of the joints in man and other animals I shall have occasion to use certain principles, or postulates as I prefer to call them, which are not yet employed generally by anatomical writers; and for this reason I shall here give a few words of explanation respecting them.

These postulates are two in number, and are as follows:—

Postulate 1.—That the amount of Work done by a muscle in a given time is proportional to its weight, *i.e.*, to the number of muscular fibres in contraction.

Postulate 2.—That the mean lengths of the different muscles employed at each joint are proportional to the perpendiculars let fall from the centre of motion of the joint upon the directions in which the muscles act.

In the statement of the first postulate there is, of course, a slight error, arising from the different amounts of cellular tissue and fascia entering into the composition of each muscle. This, however, only introduces an error proportional to the differences of the cellular tissue and fascia in the different muscles, which may be regarded as small. So far as my experiments have led me, I incline to the opinion that such muscles as the heart and psoas, composed nearly altogether of muscular fibres of fine texture, are capable of giving out their work for a longer time than muscles of an opposite character, such as the glutæus maximus and deltoid; but that for an interval of time less than that requisite to produce fatigue, the work given out is the same for both classes of muscles within small limits.

The reasonableness of the second postulate may be shown from the following considerations:—

1. The distance through which the point of application of a muscle is moved by its contraction is proportional to the mean length of the muscle.

2. It is geometrically evident that the perpendiculars let fall on the directions of the muscles are proportional to the spaces moved through by the points of application.

3. The Divine Contriver of the joint has made a perfect mechanism, and therefore employs a minimum expenditure of force.

If the third of these considerations be admitted, *Postulate 2* follows from the first two considerations, for otherwise there would occur a waste of force, some of the muscles having ceased to act before the others had expended their store of force.

Professor Donders, of Utrecht, has, indeed, proved by direct measurement that the lengths of the muscles acting on the human elbow are nearly proportional to the distances of their points of application from the joint; and I believe that he would have found a still more exact agreement if he had used the perpendiculars instead of the distances. The following corollary follows from the two postulates employed:—

Corollary.—The moment of each muscle, with respect to the centre of the joint, is proportional to its weight. Let F be the force of the muscle, p the perpendicular let fall upon its direction from the centre of the joint, x the space through which the muscle contracts, and l its mean length. The work done by the muscle is Fx , which is proportional to F^2l , and therefore to Fp by the second postulate; but Fx is also proportional to the weight of the muscle by the first postulate; and therefore Fp , which is the moment of the muscle, with

(a) Read before the Royal Irish Academy in January, 1864.

respect to the centre of the joint, is also proportional to its weight Q.E.D. Hence it follows that—

Corollary 2.—The weights of the muscles surrounding the joint may be regarded as moments of the forces, and may therefore be compounded by the law of composition of moments or couples.

The action of the muscles that move the thigh upon the hip is usually referred by anatomists to three classes of motion:

- a. Rotation outwards or inwards,
- b. Flexion or extension.
- c. Abduction or adduction.

If we imagine three rectangular co-ordinates drawn at the centre of the acetabulum in the following manner:—

- a. Vertical axis,
- b. Horizontal lateral axis,
- c. Horizontal antero-posterior axis,

it is easy to see that rotation round these axes corresponds with the three recognised classes of motions, and as every motion, however complex, of the thigh upon the hip must be a rotation round some diameter of the sphere of which the acetabulum forms a portion, it is evident that every such motion may be interpreted correctly in the usual way, by the aid of the composition of rotations.

Such a method of interpretation, although exact, is not simple, as the axes of co-ordinates are not chosen with reference to the forces and directions of the muscles themselves, but with reference to directions, vertical and horizontal, arbitrarily assumed beforehand.

In the following note I shall endeavour to establish the existence of three axes of co-ordinates, to which the motions of the hip-joint may be referred, and which possess not only greater simplicity than other systems of axes, but also other properties of great interest and importance.

The centre of the acetabulum is the centre of motion of the thigh upon the hip; and the centre of motion of the body upon the pelvis is situated in the junction of the fifth lumbar vertebra with the sacrum. If these two centres of motion be joined, we have a geometrical line to which the motions of the hip-joint ought to be referred. In the erect posture in man, this line is the axis of the neck of the femur, and is essentially an oblique line, making acute angles with all the three axes of anatomical writers.

The anatomical and mechanical problem which I propose to solve is the following:—

“To find the simplest planes passing through the centres of motion of the body on the pelvis, and of the hip on the thigh, to which the forces of the muscles of the hip-joint can be referred.”

I shall commence by recording the observations made upon a human subject, which was a female, aged 40, weight 82 lbs., and height 65½ inches. I selected a female subject, in consequence of my first comparative dissections having been made on a female Cercopithecus.

The weights of the body, viscera, and muscles of this subject were found to be as follows:—

TABLE I.—PHYSICAL DATA (WOMAN).

(a) *Body and Viscera.*

1. Body	82 lbs.	1312 oz. av.
2. Brain		53¼ ”
3. Heart		7¼ ”
4. Right kidney(b)	7½ oz.	} 16¼ ”
5. Left kidney(b)	9 ”	
6. Liver(b)		119¼ ”
7. Spleen		7¼ ”

(b) *Posterior Muscles of Hip-joint.*

1. Glutæus maximus	11½ oz.
2. Glutæus medius	7½ ”
3. Glutæus minimus	2½ ”
	— 21¾ oz.

(c) *Anterior Muscles of Hip-joint.*

1. Iliacus	2¼ oz.
2. Psoas magnus	1½ ”
3. Psoas parvus(c)	0¼ ”
4. Pectinæus	0¼ ”
5. Adductor longus	1¼ ”
6. Adductor brevis	1¼ ”
7. Adductor magnus	11¾ ”
8. Gracilis	1 ”
	— 21 oz.

(b) Both kidneys were fatty, and the liver was fatty and enlarged.
 (c) I have placed this muscle among the muscles of the hip-joint, because the connection of its tendon with the fascia iliaca enables it to modify the action of the *M. iliacus*.

9. Sartorius	2¼ oz.
10. Tensor vaginæ femoris	1½ ”

(d) *Flexors of the Knee-joint.*

1. Biceps femoris	3¼ oz.
2. Semi-tendinosus	1¼ ”
3. Semi-membranosus	2½ ”

(e) *Extensors of the Knee-joint.*

1. Rectus femoris	2¾ oz.

Posterior Muscles of Hip-Joint.

The posterior muscles, or *glutæi*, act on the hip-joint in the manner represented in the annexed diagram (Fig. 1), which shows the sacrum, os coccygis, and innominate bone of the left side.

FIG. 1.

The *glutæus maximus* produces a rotation round the centre of the acetabulum in a plane passing through the line *a*; the *glutæus medius* in a plane passing through *b*; and the *glutæus minimus* in a plane passing through *c*.

The angle between *a* and *b*, measured at the centre of the sphere, is 49°; and the angle between *a* and *c* is 64°.

Taking the Moments of the three muscles with respect to the centre of the sphere, we find the resultant of all supposed to be in action together, as follows:—

Measuring X along *a*, and Y at right angles to it, we obtain,—

$$X = 11.5 + 7.5 \cos. 49^\circ + 2.75 \cos. 64^\circ,$$

$$Y = 7.5 \sin. 49^\circ + 2.75 \sin. 64^\circ.$$

from which follows—

$$X = 17.62 \text{ oz.}$$

$$Y = 8.15 \text{ ,,}$$

and $\sqrt{X^2 + Y^2} = 19.41 \text{ oz.}$

$$\frac{Y}{X} = 0.4625 = \tan (24^\circ 49').$$

The resultant direction of the gluteal muscles is represented by the line yx , which nearly coincides with the ilio-pectinæal ridge, and lies somewhat inside a tangent plane from the centre of the acetabulum to the greater ischiadic notch. (d)

The resultant plane xy passes through the body of the fifth lumbar vertebra, and between the spinous processes of that vertebra and the first sacral vertebra.

Anterior Muscles of Hip-joint.

The first eight of the ten anterior muscles have the following action:—

- | | |
|--------------------------|-----------|
| 1. <i>Iliacus</i> , | } 4½ oz., |
| 2. <i>Psoas magnus</i> , | |
| 3. <i>Psoas parvus</i> , | |

move the head of the femur in the plane a' , which is found to be the prolongation of the diameter a ; and their action, therefore, is directly the opposite of that of the *gluteus maximus*.

- | | |
|-----------------------------|-----------|
| 4. <i>Pectinæus</i> , | } 2½ oz., |
| 5. <i>Adductor longus</i> , | |

move the head of the femur in the plane containing the ilio-pectinæal ridge, or very nearly in the plane of the resultant of the *glutei* muscles.

- | | |
|-----------------------------|-----------|
| 6. <i>Adductor magnus</i> , | } 13 oz., |
| 7. <i>Adductor brevis</i> , | |

produce motion along the line b' , which is opposite to b , the direction of the *gluteus medius*; and, lastly, the

- | | |
|-----------------------|--------|
| 8. <i>Graecilis</i> , | 1 oz., |
|-----------------------|--------|

moves the head of the femur in the plane e' , opposite to e , the direction of the *gluteus minimus*.

Compounding the moments of these muscles as before, and using the line $a a'$ as our origin of X, we obtain—

$$\bar{X} = 4\frac{1}{2} + 2\frac{1}{2} \cos. 25^\circ + 13 \cos. 49^\circ + \cos. 64^\circ.$$

$$\bar{Y} = 2\frac{1}{2} \sin. 25^\circ + 13 \sin. 49^\circ + \sin. 64^\circ.$$

$$\sqrt{\bar{X}^2 + \bar{Y}^2} = 19.89 \text{ oz.}$$

$$\frac{\bar{Y}}{\bar{X}} = \text{Tan. } (36^\circ 47')$$

The close agreement in magnitude between the resultant of these muscles (19.89), and that of the *glutei* (19.41) is very remarkable; and the difference of angle between them ($11^\circ 58'$) is not more than might have been anticipated from unavoidable errors of observation.

The resultant of the anterior muscles is shown in the figure by the line $x' y'$. The bisector of the angle between the lines xy and $x' y'$ is a tangent to the ischiadic notch, and coincides with the ilio-pectinæal ridge.

The diametral plane of the acetabulum just found containing the ilio-pectinæal ridge and touching the ischiadic notch possesses many remarkable properties.

1st. It passes through the centre of the anterior line of junction of the fifth lumbar and first sacral vertebrae; *i.e.*, through the centre of motion of the body on the pelvis.

2nd. It gives, both as respects distribution of matter and geometrical form, the section of the pelvis, which offers the maximum resistance to forces acting from the outside.

3rd. It is the plane of the resultant of the muscular forces acting on the hip-joint, both with respect to the posterior and anterior muscles. This plane may be called the ilio-pectinæal plane, and is the plane of maximum moments acting on the hip-joint.

Remaining Muscles of Hip-joint.

In addition to the eleven muscles, whose action has been already considered, there are six others which act upon the hip-joint. They all act upon the joint, so as to cause it to rotate upon the head of the femur in a plane at right angles to that already found to be that of the resultant of the posterior and anterior muscles. This plane passes through the tuberosity of the ischium, and falls just inside the interior rim of the ilium. Three of the muscles in question act on one side, and three on the other side of the centre of motion, and in the erect posture their movements on the head of the femur are exactly balanced. They may be called the ischia and iliac muscles, with reference to their action on the hip.

Iscia and Iliac Muscles (Flexors of Knee).

- | | |
|---|----------|
| 1. <i>Biceps femoris</i> (part) | } 7¼ oz. |
| 2. <i>Semitendinosus</i> | |
| 3. <i>Semimembranosus</i> | |

Iliac Muscles (Extensors of Knee, in part).

- | | |
|--|----------|
| 1. <i>Tensor vaginae femoris</i> | } 6½ oz. |
| 2. <i>Sartorius</i> | |
| 3. <i>Rectus femoris</i> | |

The resultant plane of the portion of the *biceps* attached to the ischium, and of the two internal ham-string muscles, is at right angles to the ilio-pectinæal plane; and the resultant of the action of the *tensor vaginae* and of the *sartorius* coincides with the plane of the *rectus*, and also is at right angles to the ilio-pectinæal plane.

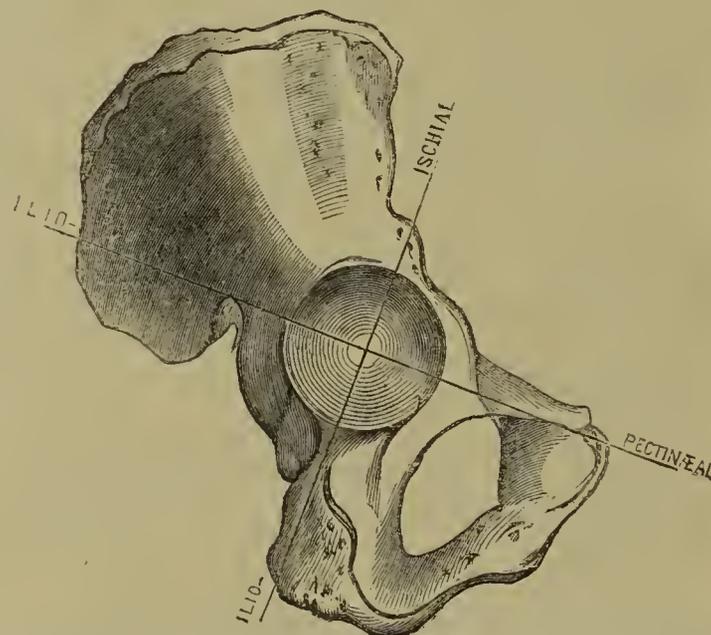

Considering that only a portion of the *biceps* acts on the hip, and that in the erect posture the leverage of the muscles on the head of the femur is equal and opposite, it is manifest that these two groups of muscles, as well as the posterior and anterior groups, balance each other's actions. This plane of resultant forces may be called the ilio-ischiatic plane; it is at right angles to the ilio-pectinæal plane, and intersects it along the line joining the centre of the sacrolumbar articulation with the centre of the acetabulum, that is to say, the line joining the centre of motion of the body on the pelvis with the centre of motion of the hip upon the thigh.

In the erect posture neither of these planes are vertical, and the diameters of the acetabulum corresponding to them make angles of about 45° at each side of the vertical diameter.

The ilio-ischiatic plane makes a section of the os innominatum, not so strong as that made by the ilio-pectinæal plane and its curvature is in the opposite direction, being slightly concave outwards, while the curvature of the ilio-pectinæal section is strongly convex outwards. From this and other considerations it follows that the ilio-ischiatic plane has relation rather to the support of the weight of the body than to resistance to forces acting from without.

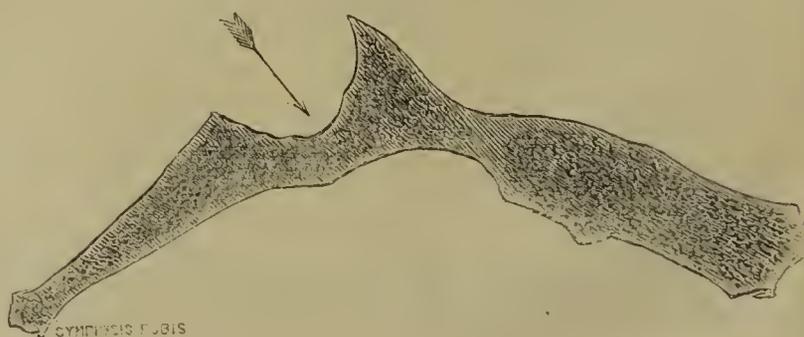

The accompanying figure (2) represents the os innominatum of the right side, drawn from a point of view situated on the line joining the sacrolumbar articulation with the centre of the acetabulum, and, therefore, shows the traces of the ilio-pectinæal and ilio-ischiatic planes, as two right lines intersecting at an angle of 90° .

FIG. 2.

The Fig. 3 shows the section of the os innominatum made by the ilio-pectinæal plane, in which, as I have shown, the resultant couples of the principal muscles acting on the hip-joint are situated. The cancellated portion of the bone is dotted, and the dense part is shaded in lines. It would require a separate paper to show how admirably adapted this form of

FIG. 3.

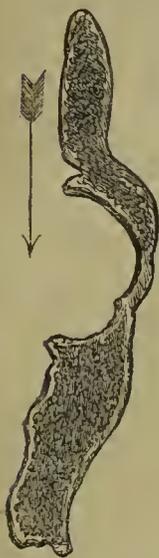

(d) It was through this notch that Mesiones was in the habit of piercing the bladders of his flying enemies; II. E. 65—68 and II. N. 650—655, and the bone mentioned is the *ilium*, and not the *pubes*, as the commentators suppose. It is very possible that Homer may have seen such a wound inflicted through the buttock, for his description of the wounded man wriggling on the ground like a worm could only have occurred to an eye-witness, and the sciatic nerve was necessarily divided by the blow.

section is, either to resist a shock acting in the direction of the arrow, which the bone receives in jumping down from a height on one foot or to counteract the strain produced by the muscles acting from the periphery of the bone upon the femur.

In Fig. 4 I have shown the section of the os innominatum made by the ilio-ischial plane, at right angles to the ilio-pectineal plane.

FIG. 4.

This section of the bone is rarely called upon to resist any strain in a transverse direction, and when the cavity of the acetabulum is completely filled by the head of the femur, its strength to resist vertical pressure, as in sitting, is very great.

Some interesting deductions may be made from the weights of the muscles, classified into groups, suggested by the preceding analysis.

The total weight of the muscles of the hip and knee-joints, named *b, c, d, e*, is found to be 73.50 ozs.; of this amount 21.75 ozs. are included in the three *glutæi*, 21 ozs. in the group of eight muscles antagonistic to the *glutæi*, 23.5 ozs. in the extensors of the knee (including the *tensor vaginæ*, which aids the *quadriceps extensor*), and 7.25 ozs. are included in the flexors of the knee-joint.

Expressed in percentages of the hip and knee-joint muscles, these groups have the following values:—

- | | |
|-----------------------------------|------------------|
| 1. Posterior muscles of hip-joint | . 29.6 per cent. |
| 2. Anterior muscles of hip-joint | . 28.6 " |
| 3. Extensors of knee-joint | . 31.9 " |
| 4. Flexors of knee-joint | . 9.9 " |

The first three groups of muscles are here of nearly equal force, while the fourth is about a third of each of the first three.

SURGICAL INQUIRIES.—No. II.

A SIMPLIFICATION OF THE EXTRA PERITONEAL OPERATION IN THE SEVERAL VARIETIES OF STRANGULATED HERNIA; WITH OBSERVATIONS ON THE ANATOMY OF HERNIA.

By FURNEAUX JORDAN,

Surgeon to the Queen's Hospital, Senior Surgeon to the Birmingham Eye and Ear Hospital.

WHEN a Surgeon desires (there are cases of strangulated hernia which he does not desire to return by the taxis) to effect reduction in any given case of strangulated hernia, but is unable, even with the full assistance of chloroform, to attain his object, it is not a little surprising that he should refuse a measure which, in the great majority of cases, will give to the gentlest pressure a successful result;—a measure, too, which, if unsuccessful, involves no delay, and entails no disadvantage in the resort to further proceedings. An operation simple, slight, based on clear principles, and intrinsically free from danger, gives the Surgeon the power of employing the taxis with an almost certainly felicitous result. If a contrast be made between the following wounds the surprise will not diminish:—In one an almost subcutaneous incision is made into the fibrous margin of the constricted aperture, the peritoneum is uninjured, and, in the operation I perform, unapproached. Such an incision in a state of health would be altogether free from danger. In the other, long incisions are made through numerous tissues, the peritoneum (frequently the seat of pathological processes) itself being freely divided. Such incisions in a state of health would be almost certainly fatal. It is true that the peritoneum of a hernial sac is placed under special conditions, but this fact does not remove the striking difference between the two operations to which I draw attention.

It may be said compendiously that there are two classes of cases of strangulated hernia which require operative relief. In one the extra-peritoneal operation offers the greatest prospect of success; in the other it is necessary to open the sac. In the second class may be placed, 1, cases of gangrene, and, 2, cases that cannot be returned after the extra-peritoneal incision. All other cases may be placed under the first category. It is rare in Surgery to meet with so clear and unmistakable a rule of practice. In every case of strangulated hernia, except where gangrene is present, the Surgeon

should first adopt the simplest method of relaxing the fibrous structures which strangle the protrusion, and apply the gentlest possible taxis. In the few cases in which this proceeding fails, a second stricture having been sought for (especially in inguinal hernia), but not found, the sac may be opened in the usual way.

My experience coincides with that of numerous observers to the effect that the presence of gangrenous bowel may be very certainly diagnosed. When inflammation reaches the coverings of the sac, as indicated by redness of the skin, infiltration (œdema) of the subcutaneous tissue, and loss of distinct definition of the tumour, with complete cessation of pain, the bowel is already sphacelated. Constitutional symptoms lend confirmation. Flickering pulse, physical and mental prostration, and the other phenomena of collapse are present.

Mrs. J., aged 60, had constipation five days, and vomiting, which had been stercoraceous for several days. Unfortunately, the hernia was not discovered until too late. At the request of the Medical attendant I saw the case. I found in the right groin a flattened, hard, red swelling, extending from the pubes to the ilium, and one inch above and two inches below Poupart's ligament. The collapse was marked. Incisions disclosed black shapeless bowel. There were no faeces in the sac, but a copious flow followed division of the margin of Gimbernat's ligament. I gave a most unfavourable prognosis; she sank next day.

I would emphatically observe here that if there be a condition of the bowel which, beyond all others, is irreparably injured by exposure and handling, it is where inflammation is far advanced and gangrene is imminent, without being actually present.

In irreducible hernia there is now no difference of opinion as to the impropriety of opening the sac. In these cases strangulation occurs not from constriction of the neck of the sac, but from the protrusion of additional bowel. Opening the sac in a large irreducible hernia is one of the most fatal of Surgical proceedings, and the more direct the communication with the abdomen the greater the fatality, as in cases of irreducible umbilical hernia. Here to practise the simplest means of securing the return of the recent protrusion should be our highest aim.

In cases which are reducible prior to strangulation it is difficult to conceive that strangulation can occur in a certain number of hours from changes in the neck or contents of the sac. To conceive this we are required to believe that in an inflammation of a few hours' duration, developed under circumstances antagonistic to formative results, adhesions are formed so firmly as to be incapable of rupture on the application of the taxis subsequently to the relaxation of the firmer extra-peritoneal structures. It is a significant fact (I do not claim for it more than it is worth) that strangulation never occurs in those rarer forms of hernia which pass through openings, devoid of fibrous margins, although such herniæ have sacs and the sacs have necks. Practically we find that cases (perfectly reducible prior to strangulation) in which reduction cannot be effected after the firmer structures cease to constrict are remarkably rare. The following cases show that after many days of strangulation genuine adhesions do not form:—Mrs. F., aged 38, brought into Queen's Hospital five days after occurrence of strangulation, (and eight after parturition). Sac distended with dark fluid, and bowel claret coloured, but no adhesions or gangrene. Recovered rapidly after division of stricture. I was requested by a practitioner in the country to see Mrs. C., with similar phenomena and result. Another practitioner in the country called me to see M. H. with strangulated inguinal hernia of six days' duration. The bowel was sticky from inflammatory products, but no real adhesions were present. The patient died. These cases occurred before I performed the operation to be described. I believe, from cases in which I have myself operated, that in many instances where irreducibility continues after division of the less yielding tissues, it is the result of irreducibility of a small portion of the contents which has not been observed, but has existed before strangulation. Fresh protrusion, a noticeable tumour, and strangulation occur together.

When cases of strangulated (reducible) hernia occur which actually require the extra-peritoneal to be converted into the peritoneal operation, one, two, or three conditions will be found—constriction of the neck of the sac, adhesions within the sac, or increased size of the contents of the sac. Each condition is produced by processes occurring subsequently to strangulation.

I have so far spoken of the constricting agency as lying either in the non-distensible structures which surround the several outlets at which herniæ occur, or in the neck of the sac itself. The crural sheath does not constrict in femoral hernia, or the fascia transversalis (except at the inner ring as a special structure) in inguinal hernia; the fascia transversalis is never the seat of strangulation in umbilical hernia; the subperitoneal fatty fascia is never a constricting agent in any variety of hernia. All these tissues are, of course, compressed into a small space within the several fibrous outlets, and, after death, such compressed tissues present considerable rigidity; during life, however, they are not themselves compressing agents. Why, then, should these tissues be divided if the really compressing structures lie externally to them?

It is the object of this paper to show that all that is necessary in practice is to relieve the tension of Gimbernat's ligament in femoral hernia, of the conjoined tendon or fibrous apertures in inguinal hernia, and of the linea alba in umbilical and the more common forms of ventral hernia. As a rule, these structures can be reached and relaxed, the cutaneous tissues only being divided prior to the use of the hernia knife.

The great excellence of Mr. Gay's, contrasted with the previous extra-peritoneal, operation consisted in this:—The incision was much more limited, and was made at a distance from the tumour. In Mr. Gay's operation, however, the sub-peritoneal tissue was reached both in the operations for femoral and for the other varieties of hernia; it was, nevertheless, an immense stride in the progress of hernial Surgery.

I have now frequently in cases of strangulated hernia, especially in femoral, the variety which most commonly requires operative relief, performed, with strikingly satisfactory results (especially in the extreme shortness of the convalescence), an operation of which the following are the chief characters, and which, since it aims at keeping as far as possible from the peritoneal structures, I would suggest might be termed the pre-taxoid operation. A short incision is made through the skin and superficial fasciæ near the neck of the tumour, and sufficiently large to admit the end of the finger. The superficial fasciæ are divided (not necessarily completely) to an extent which will enable the finger nail to detect the interstice or boundary line between the firm, immovable, unyielding apertural margin and the more moveable and yielding tunics of the hernia. For example, in femoral hernia it is not necessary to cut through every flake of connective tissue down to Gimbernat's ligament. It is enough if the finger nail discovers with ease and certainty the margin of that structure. As the hernia knife (blunt pointed, but cutting to the point) is insinuated along the finger nail, close to the firm constricting margin, it may advantageously carry before it a little connective tissue; thus all tissues are divided to the least possible extent, and the knife is much less liable to perforate the peritoneum. The practical rule, then, in all cases of hernia is to divide the skin and just enough of the subcutaneous connective tissue to permit the tense margin to be felt which it is proposed to relax. Anatomical knowledge is applied here not to determine how much tissue shall be divided—that is best decided by the touch—but to determine the precise direction in which and the precise point to which the finger nail is to be carried. I regard it as an important feature of the pre-taxoid operation that a lamina of tissue (crural sheath, fascia transversalis, etc.) shall, if possible, come between the peritoneal structures and the hernia knife. The herniatome is next used in the most sparing manner, not only in the very limited application of the edge, but, which is even more important, in the limited introduction of the point, for the peritoneal structures are stretched thin and closely applied to the abdominal aspect of the apertural structures. In few cases should the herniatome pass beyond the finger nail, and in umbilical hernia not at all. Incision of the tense margin is followed by pressure with the nail and tip of the finger in the direction in which the incision was made. Pressure must on no account be made towards the abdominal cavity; neither fingers, directors, nor knives should be carried in this direction. If the finger be passed into the abdomen before the margin is relaxed there is no strangulation, and no operation should have been performed; if strangulation be present, the introduction of the finger after the limited use of the herniatome is more likely to injure, and seriously injure, the bowel and peritoneum than to effect any useful dilatation. Gentle and momentary application of the taxis to the unwounded coverings completes the operation.

It is not inopportune to remark here parenthetically that certain points in the anatomy of hernia, even at the present time, give rise to great difference of opinion. These differ-

ences of opinion disclose on both sides the adhesion to a school of anatomy which is fast becoming antiquated, if not obsolete. The philosophic teachings of Reichert—in the main accepted by our most reputed histologists—applied, as they assuredly ought to be, to Surgical anatomy, show most clearly that, say in femoral hernia, there are, as separate entities, no ligaments, no sheaths, no fasciæ, no tendons, but that there is one single indivisible mass of connective tissue, firm here and loose there, having one disposition here and another there, and being directly continuous with the skin in one direction and with the bone or an epithelial surface in another. With these firmer and looser tissues, their forms and localities, it behoves the practical Surgeon to make himself—there is only one way to do it—minutely familiar. It is perfectly idle to dispute whether the femoral sheath is a prolongation of the transversalis and iliac fasciæ, on the one hand, or of the fascia lata on the other, or whether the so-called saphenous opening does or does not exist, seeing that the femoral sheath, the fascia lata, the cribriform, iliac, and transversalis fasciæ, Poupart's and Gimbernat's ligaments, and the aponeurosis of the external oblique are all one tissue—a tissue without attachments, without junctions, without lines of demarcation.

There is one fact in modern histological anatomy of immense importance in relation to Surgical pathology. A basement membrane has no existence. The epithelium of surfaces is placed immediately on connective tissue, which is very dense underneath the epithelium, but becomes gradually less dense as it passes deeper. Now, in inflammation of all surface membranes, it is this less dense connective tissue which is the seat of the greatest pathological activity. Erysipelas, bronchitis, pleurisy, and peritonitis are illustrations of this remark. It is one of the principal objects I have in view in the pre-taxoid operation to avoid injury to that inflammable portion of the peritoneum which is called subperitoneal fatty fascia.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

PARALYSIS OF ALL PARTS BELOW THE NECK— DEATH—AUTOPSY—MALIGNANT DISEASE OF CERVICAL VERTEBRÆ.

(Under the care of Dr. BLACK.)

THIS case is of great interest in several ways. In the first place, the diagnosis of cancer was difficult, as there was no prominent symptom beyond the paralysis. It is true that there were pains in the shoulders; but these were not definite enough to lead to any certain conclusion, and, indeed, were, before he came to the Hospital, taken for rheumatism. It is only when pain follows the course of some definite spinal nerves that it can be of much use in helping us to locate disease in the spine. We have recently seen several cases of paraplegia in which the cause of the paralysis was cancer of the spine, and yet was not diagnosed during life. The sudden onset of paralysis is not likely at first thought to countenance the diagnosis of cancer; but we must remember that, although it may have been growing in the bones of the spine a long time, it may, as in Dr. Black's case, suddenly invade a part of the cord, the anterior columns, where are collected in a small space the motor fibres of the muscles of the four limbs and of the trunk.

It is said in the report of the case that the effect on the cord—*i.e.*, on the anterior or motor columns—was apparently the result of pressure only. It is certainly singular that there should be so much paralysis, and yet so little apparent damage to the cord. But this is very commonly so. In a case lately in Guy's Hospital, a patient had paralysis (of motion only) in both legs. He died; and at the autopsy, although at one point there was found cancer of the bones of the spine, yet the cord looked healthy, and nothing morbid was found in it by recent microscopic examination. In all such cases, however, it is necessary that a careful examination should be made on Lockhart Clarke's method after the cord has been hardened in chromic acid. This method would clear up many obscurities. Indeed, we may say without exaggeration that Lockhart Clarke's researches open out quite a new field—not in the physiology of the Nervous System only, but in its pathology too.

History.—David B., 35, had been out of health for about ten months, suffering from pains, supposed to be rheumatic, in the neck and shoulders. These were at times greatly relieved by Turkish baths. About three months before his death his figure began to alter, the neck becoming shorter and thicker, so that he could no longer button his shirt-collar; but he was able to continue at his work as a clerk in Pickford's warehouse up to one month before his death, complaining, however, at times of difficulty in guiding his pen. On the evening of Tuesday, February 23, he had a Turkish bath, but the pains, which had become very severe, were aggravated rather than relieved by it, and he passed a very bad night. The following morning, February 24, whilst at breakfast he suddenly found himself unable to raise his cup to his mouth with his right hand, and on attempting to walk into his bedroom he found that he had lost almost all power in the left leg. He was then brought to the Hospital, and the loss of power soon became complete and universal in the limbs and trunk; but the sensibility remained perfect up to within a few hours of his death, if not to the very last. He died somewhat suddenly, after an agony of about two hours, of dyspnoea.

Post-mortem.—Body sparsely nourished; still slightly warm; posteriorly somewhat livid. Rigor mortis present in muscles of lower jaw; the limbs flaccid. Head—The only appearances noticed were that the scalp was slightly adherent; the vessels of the pia-mater somewhat minutely injected, and a small bony mass in the falx cerebri. The ventricles contained about the normal quantity of fluid. Spinal cord and its membranes were apparently everywhere healthy, except opposite the second and third cervical vertebræ, and the corresponding interstitial cartilages. Springing from the bodies of those vertebræ with which it is intimately connected, and which are partially destroyed by it, the cartilages having suffered in a less degree, is a tumour the size of a walnut, by which the cord is greatly compressed, and softened apparently throughout. The tumour was also connected closely with the outer aspect of the theca, but had not penetrated to its inner surface, the spinal arachnoid being healthy, and the effect on the cord due, seemingly, to pressure alone. Under the microscope the tumour was found to consist of nucleated cells of irregular shapes, presenting the usual characters of so-called malignant growths. It contained no oil-granules or globules. No secondary deposits were detected in any of the neighbouring lymphatic glands. Heart—Twelve and a-half ounces; healthy. Pericardium contains half-an ounce of clear fluid. Pleuræ—Left, no adhesions; right, some slight adhesions at apex and posteriorly; no tubercle in either. Spleen—Nine and a-half ounces; soft and pulpy; greatly congested. Liver—Congested, but healthy. Gall bladder contains some yellow bile. Supra-renal capsules seemingly natural. Kidneys—Left, seven ounces; right, six and a-half ounces. Capsules retract slightly when divided; surface smooth, extremely congested, and mottled with numerous irregular, pale, white patches, the largest the size of a split pea. On section, extremely congested throughout. The bases of the pyramids slightly frayed out. On the surface of the section white patches similar to those on the exterior, with some of which they are continuous. Under the microscope only extreme congestion, except in the white patches, which appear anæmic, with a slightly granular condition of contents of tubules. Bladder contains a little urine; inner surface congested. Alimentary canal congested throughout, but in other respects normal. The rectum excessively distended with healthy-looking fecal matter.

THE LONDON HOSPITAL.

SEQUEL TO A CASE OF ANEURISM OF THE AORTA, IN WHICH THE DIAGNOSIS WAS AIDED BY THE LARYNGOSCOPE.

(Under the care of Dr. HUGHLINGS JACKSON.)

[Communicated by Dr. POWELL, late Resident Medical Officer.]

By referring to the Reports of Hospital Practice of this Journal for January 9, a case will be found in which the presence of an aortic aneurism was diagnosed with the laryngoscope at a time when the physical (thoracic) signs gave no evidence of such a condition. The symptoms were "a shrill and feeble voice," and "a crowing noise in the throat on exertion." The patient suffered from "a burning pain in the chest," and "he had several times spat up a few teaspoonfuls of blood."

With the laryngoscope, which Dr. Morell Mackenzie employed at the request of Dr. Hughlings Jackson, who

from the general symptoms had diagnosed aneurism of the arch of the aorta, "on phonation, the left vocal cord was observed to remain fixed, whilst the right advanced well to the median line." (For further particulars see Report.) Dr. Mackenzie therefore confirmed the diagnosis of the existence of an aortic aneurism pressing on the recurrent nerve. The patient left the Hospital at the beginning of the year, and died March 3 from exhaustion, after a painful paroxysm of angina pectoris, of which disease he latterly had repeated attacks. The laryngoscopic diagnosis was fully confirmed by the autopsy, of which the following are the particulars:—

The post-mortem examination was made twelve hours after death, and having to be conducted at the patient's house, was confined to the thoracic cavity. A tumour being evident in the region of the arch of the aorta, this, together with the larynx, heart, etc., was removed for more careful examination. The parts were subsequently dissected, and the following notes made:—On opening the right auricle, a pale mass of fibrine was found occupying the greater portion of its cavity, adhering to the appendix, and extending into the right ventricle, to the apex of which it was attached with considerable tenacity. The portion contained in the auricle was covered on the surface by some loose, dark coagula, while that in the ventricle was throughout firm and decolorised. The tricuspid valve was studded with small atheromatous patches. Semi-lunar valves and pulmonary artery healthy in appearance. Both divisions of the mitral valve were thickened, and presented patches of atheroma, best marked at the attached border of the valve. The aortic semi-lunar valves were also thickened. The ascending portion of the aorta was dilated to about twice its normal calibre, and presented evidences of extensive disease. It was much thickened, had lost its natural elasticity, and its surface was roughened by patches of atheroma, which in several places had undergone calcareous degeneration. At the upper part of the arch of the aorta was an aneurismal sac about the size of an unstripped walnut, and containing laminated fibrine. Its positions and relations are as follows:—It was situated partly on the anterior surface of the trachea, but its principal bulk lay to the left side of that tube. The anterior, upper, and posterior portions of the transverse part of the arch of the aorta were involved in the tumour. The innominate artery was pushed forwards and compressed by the tumour, which extended half an inch to the right of that vessel, but did not involve it, though the margin of the sac was only distant a quarter of an inch from its origin. The left carotid and left subclavian were neither involved nor compressed, and bounded the sac in their usual position. The left recurrent nerve was traced from its origin from the vagus round the arch of the aorta as far as the sac of the aneurism, with which it became incorporated, and could not be followed further. The sac of the aneurism encroached upon the left side of the trachea and anterior surface of the œsophagus. On slitting up the trachea along its posterior part, a projection an inch and a-half long by three-quarters broad was evident on the left side of that tube, just above its bifurcation, and extending to within a quarter of an inch of the opposite side. The mucous membrane covering it was dark and congested, and there were appearances of commencing ulceration. The cartilaginous ring in this situation had also undergone partial absorption. The œsophagus was opened, but presented nothing remarkable. The aneurism was of the false variety.

MIDDLESEX HOSPITAL.

DISEASE OF THE SUPRA-RENAL CAPSULES—DISCOLORATION OF THE SKIN—PELVIC ABSCESS.

(Under the care of Dr. GREENHOW.)

W. B., aged 24, married, engineer's labourer, admitted April 12, 1864. A slight man, under middle height, naturally of rather dark complexion, and with black hair. Stated that, with the exception of an attack of fever eight years ago, he had enjoyed good health until between eight and nine months previous to his admission, when an abscess formed in the left hypochondriac region. The abscess did not prevent his following his usual employment. In October last, a month or six weeks after the healing of the abscess, he had been seized with severe pain in the left hip, shooting downwards in the course of the sciatic nerve towards the knee. This pain had never since left him, though it had varied in intensity from time to time. Had been gradually getting weaker during these

months, and had very rapidly declined in strength during the last ten days. Had for some weeks had nausea and occasional retching, with, for the last few days, vomiting of food. Appetite much impaired during the last fortnight. Bowels, habitually costive, had become more so during his illness. Had suffered much from flatulence and gastralgia. Had lately suffered from attacks of breathlessness and faintness on exertion, and actually fainted while under examination in the waiting-room. These symptoms led Dr. Greenhow to suspect the case to be one of Addison's disease before he had observed any discoloration of skin; and the patient's wife and mother, on being questioned, said that they had observed his complexion becoming darker about three months ago. Capt. hst. potass. citrat. effervesc.; amm. cū. ferri, gr. v. ter die; port wine, 6 oz.

April 13.—Skin cool; tongue flabby, moist, coated on dorsum with a yellow fur; urine somewhat dark coloured, highly acid, copious, free from albumen, sp. gr. 1022; pulse from 94 to 100, variable, extremely feeble, small and compressible; heart's impulse feeble, and sounds exceedingly faint; resonance normal on percussion over both sides of chest; breathing sonorous, with very slight rhonchus; slight cough with scanty, tenacious, nearly transparent expectoration. Patient could scarcely be raised up in bed on account of tendency to faintness. General hue of skin a dusky brown, face somewhat darker, closely resembling that of a person of colour. Sides and back of neck, from hair downwards to shoulders, darker than face. Hands much darker than arms, and all the knuckles sensibly darker than surrounding surface, as were likewise several spots where the skin had formerly been abraded. Here and there, on the neck, were one or two well defined darker specks resembling moles. The skin over the spine, for about nine inches downwards from the eighth dorsal vertebra, was much darker than the rest of the back. Over the left hip, where a blister had been applied four months before, was an oblong surface, nearly four inches by five, much darker than any other part of the body, and on it were several spots, where apparently there had been superficial ulceration, which were almost as black as the skin of a negro. Nipples and areola very dark, almost black. Axillæ scarcely appreciably darker than the rest of surface, but groins sensibly so. Penis extremely dark. Thighs and legs less dark than body. The lips had a dark, almost black, stripe of varying breadth extending along their whole length. The buccal mucous membrane, with the exception of a few intervening paler spots, was also of a dark, almost black, colour, and there were several well-defined dark patches on the gums of the lower jaw. The conjunctivæ were clear and perfectly white. The skin was everywhere soft and free from eruption. Body somewhat wasted, but not emaciated. Pergat. Pil. coloc. c. hyosc., gr. x., horâ somni.

14th.—Has had much sickness during the night, vomiting almost everything he has taken. Bowels have acted once loosely. Pulse 108, exceedingly small and feeble. Is very languid, and feels more faint to-day than he has hitherto done. Complains much of pain in the chest, which is worst after food and before sickness. Urine copious, high coloured, sp. gr. 1019, no albumen. Hst. acid nit. mur., ʒj. ter die; port wine, ʒviii.; brandy, ʒj.

15th.—Much the same as yesterday with regard to pain in chest and vomiting of food, but is evidently weaker. Pain in hip persistent. Pt.

16th.—Has slept fairly. No pain in chest at present, but constant vomiting after taking food. Pulse 120, very small and feeble. Constant feeling of faintness. Surface cold and pale. Speaks slowly, as if unwilling to be disturbed. 8 p.m.—Looks anxious and exhausted. Pulse 144, almost imperceptible. Intellect unimpaired. Enema c. suc. bov., ʒiij.; spt. vin. gal., ʒij., statim et 4tis horis.

17th.—Vomiting still continues, faintness most intense, pulse scarcely perceptible, and heart sounds only audible on very close examination. Extremities cold and sight dim. He sank and died about 1 p.m., his intellect remaining unimpaired to the last.

Post-mortem Examination Twenty-six Hours after Death.—Rigor mortis well pronounced. Body spare, but not emaciated. General hue of skin dusky, but so much paler than it had been during life that if then seen for the first time it might have been regarded as the natural colour of a rather dark person. Face and neck were somewhat darker than the greater part of the rest of body. Thighs and legs apparently of normal colour. Skin of axillæ and of hip, where the blister had been applied, decidedly darker than the surrounding surface. Penis

and scrotum much darker than any other part of the body. Dark stains on lips and on buccal mucous membrane remained almost as during life. Muscles of normal red colour. Heart had much fat on its outer surface; muscular tissue somewhat pale; valves normal. Right auricle and ventricle were nearly filled with a large, firm, yellow clot, entangled in the cords of the tricuspid valve, and sending a process into the appendix auriculæ. Both lungs firmly adherent to ribs; lung tissue here and there slightly congested, but free from all traces of tubercle. Many of the mesenteric glands were enlarged, some being of the size of beans. Their surfaces were pale and yellow, and on section they appeared of a yellow colour, and had a dry, somewhat cheesy, texture. Microscopical examination showed these glands to be infiltrated with a finely granular substance, in which were numerous granular cells and nuclei, and many cells containing oil-globules. Vessels of small intestine much congested; Peyer's patches enlarged, prominent, of yellowish white colour, and remarkably opaque; the solitary glands scattered throughout, the ileum also enlarged; no appearance of ulceration. Supra-renal capsules were both closely invested with very dense connective tissue, containing a good deal of fat. The left capsule was one-third larger than the right, its weight was six drachms, and it measured longitudinally two inches and three-quarters, and transversely one inch and a-quarter; it was of very firm consistence, and on section no distinction was visible between cortex and medulla, the whole organ being converted into a mass of firm, yellowish-white tissue, in parts semi-transparent. Scattered through this mass were numerous opaque yellow deposits, varying in size from a hemp-seed to a pea, of cheesy consistence, mixed with gritty matter. On microscopical examination these cheesy deposits were found to consist of opaque, amorphous granular material, mixed with granular shrunken cells and nuclei, and some oily matter. The intervening portions, in addition to similar granular material, consisted of fibrous tissue. The right capsule weighed four drachms, and measured longitudinally rather less than two inches, and vertically one and a-half inches. In structure, it closely resembled the left capsule; but one of the cheesy masses was of the size of a small bean. On laying open the pelvic fascia at upper edge of true pelvis on left side, about half an ounce of thick creamy-looking pus escaped: the abscess communicated with carious bone at the left sacro-iliac synchondrosis. Blood much thicker and darker than usual, presenting under the microscope a great excess of red corpuscles.

SATURDAY, JUNE 11.

OUT-PATIENTS.

Much has been written and many strong statements have been made respecting the out-patient departments of our London Hospitals. Even now very opposite views are taken as to the amount of good they do, and as to their effect on the Profession at large. One writer in particular has dilated on the improper objects whom they subsidise with charitable funds, and has formed an estimate, which we cannot but think exaggerated, of the proportion in which recipients of gratuitous relief are fully competent to pay for advice from private Practitioners. But though there be overstatements, the evil

is a real one. It is worth while to look at the subject in its general bearings. If by such a course the opinion of the Profession can be fairly elicited, a great step in advance will have been made, and the way cleared for an organised effort to suppress a serious abuse of charitable foundations.

It is obvious in the onset that the question is not so simple and straightforward as it seems. Many causes, some of them private and difficult to investigate, drive persons bearing an outward show of comfort and competence to the Hospital and Dispensary. A few, indeed, may go from downright meanness, deliberately intending to shirk their Doctors' bills. But this is not a course very consonant with English character, and in our experience it only contributes a small percentage to the unqualified recipients of Medical charity. It is probable that a somewhat larger proportion go with the sophistical argument on their lips, which has damaged so many eleemosynary institutions—"Somebody," they say, "must obtain the benefit of the charity, and why not I?" If this is followed by vague lamentations on the uncertainty of trade, or an increasing family, and on the dearness of provisions, many an otherwise independent man will have reasoned himself into a frame of mind which will submit to any tests, and make the most damaging professions to qualify for the offered succour.

At the opposite end of the scale, but, in our opinion, fully as unfit for Hospital relief, is the downright pauper. Of course, we do not mean such as, although paupers, suffer from acute critical diseases requiring careful nursing and treatment, nor the victims of accident, nor such as need capital operations. To them, even if paupers, the Hospital should be open, both as out patients and as tenants of the wards; only let it be observed that what the parish pays for their sustenance in health it should pay to the Hospital for each such inmate. This being in some cases the present arrangement, we need not here dilate upon it.

Between the two extremes, intermediate to the thriving artizan or shopkeeper and to the recipient of parochial relief lies the class for which it is difficult, but expedient, to legislate. The diagnosis of unfit cases is not to be made by dress alone. We have heard it well remarked that money spent in dress, often to keep up a necessary appearance in professions, is money gone from its owner, and compensated by the starving of the stomach or the neglect of advancing sickness. Tutors, governesses, clerks, milliners—nay, even professional men and ladies of good birth, often cover the most abject poverty under an exterior of comfort. In one institution we have ourselves seen a clergyman—in another, an officer of the army receive charitable aid which could not have been more judiciously bestowed. Household servants, moreover, are often poorer than their outward show denotes; for the illness that extracts their little savings prevents them from earning more by their proper calling. "I had saved £80 in service," said one of this class to the writer not long ago, "but in a year's illness it has all been spent, principally in Doctors' bills; and now, unless I recover, I see nothing before me but the workhouse." And a similar but more painful case is worth citation. A young person of good appearance and education came to a London Hospital, saying she had been earning 25s. per week by her trade, and that she was engaged in marriage to a young man also making a good weekly sum as an engineer. Very honourably she had declined to fulfil her engagement to him on the first symptoms of illness. At the end of a year's lingering her savings were gone, her friends' help exhausted. She could just keep about, but could do no work, and found herself without any refuge but the workhouse. It was almost a relief when tubercular peritonitis complicating the pulmonary affection enabled her admission to one of our oldest and noblest general Hospitals, where, surrounded by kindness and commiseration, she slowly died. Here we believe charitable funds to have been most legitimately applied in what, at the first blush, was actually considered to be an improper case for out-patient treatment, on the ground of competence. In-

quiries as to circumstances in such cases not only often elicit sad tales, the more worthy of pity as being less obtrusive, but do an indirect good by letting it be known that glaring instances of unfitness will not fail to be detected. Indeed, we cannot help thinking that the very recognition of the evil and its frequent investigation in the presence of the assembled patients is one of the best means of preventing its occurrence. If the Medical officer—or, should this seem an invidious office for him, the secretary or clerk—publicly examine into suspicious cases, the very chance of the inquiry will frighten away more improper persons than it would itself detect, just as the occasional and unexpected inspection of excisable articles is found sufficient to restrain smuggling within very moderate limits. Moreover, when such an idea is once in the minds of the patients, they form an efficient detective force upon each other, and here, just as elsewhere, many a corrupt practice leaks out through the collision of rival cupidity.

We have reason to believe an impression exists in the minds of some who are well qualified to judge, that in the larger and richer endowed Hospitals a stipendiary officer might with advantage be appointed, whose duty it should be, like the relieving officer of the parish, to trace out the several cases to their homes, and ascertain their fitness for Hospital relief from personal knowledge. The great majority of Hospital out-patients notoriously come from the immediate neighbourhood of the institution itself, so that an active, intelligent man might, without any extreme difficulty, soon form a fair estimate of the genuineness of each case of distress which offered itself for assistance. He would also perform another function which, unfortunately, there is good reason to believe is no less necessary, namely, that of preventing the Hospital from becoming a mere offshoot of the Workhouse Infirmary. It cannot be denied that in the districts where large endowed Hospitals are situated, a deliberate attempt is often made to "plant"—if we may use a familiar term—all the sick paupers possible on the Hospital; and if the evil do not exactly take this particular form, it will be obvious, from a distressing case in the journals of the past month, that so many delays and difficulties are placed in the way of admission into the Workhouse, as may easily convert curable into incurable disease, and relieve the Union of one sick pauper, either by admission as an urgent case into the wards, or by the summary process of letting him die in the streets.

Hitherto we have considered two extremes, paupers and persons in good circumstances. There remain some other species of patients. The chief of these are artizans, whose time is their money, and who, in consequence, differ somewhat in their relations towards Hospitals; secondly, there is the class who, though unable to pay the large fees required by Practitioners in vogue, might, and would, pay a stated reasonable sum for first-class Medical attendance; lastly, we can hardly conclude this subject without noticing the modifications introduced into the Hospital system of London, and even of England, by the great development which special Hospitals have of late years assumed. To these topics we hope to revert ere long.

ARMY ADMINISTRATION.

MUCH service has been rendered to the country at large by the recent comparisons which have been instituted in the House of Commons between the expense of the French and English armies. It is very well known that the former country maintains an enormous standing army. Comparisons of this kind drag startling results out of dark official pigeon-holes and dreary Blue Books into a prominent position. No doubt the expenses entailed by a standing army in this country must be large, must inevitably exceed those of Continental nations, so long as every material of life is dearer here, men scarcer, work more abundant, and all salaries far higher. It may be allowed, as beyond all controversy, that neither officers nor men are overpaid, and yet we find every item of expense doubled, trebled, or quadrupled in the English as compared with the French

army. The only exception appears to be that of the Army Medical Department, the cost of which does not exceed that of the French army. If, then, the men who do the fighting and the men who treat and cure their wounds and diseases do not consume the money, where does it go? We think that we can put our finger upon one source. We will leave out the important items of expenditure on the manufacturers and contractors who arm, clothe, and supply the wants of the soldier, and turn to the subject of army administration. If a man of business habits—a member of Parliament like Mr. Stansfeld, for example—could have the whole machinery employed—its cranks, pulleys, checks, and strings—laid open before him, he could put his finger upon many a loose screw and many a crank, which was not only cumbrous, but worse than useless by the impeding incubus it exerted on other parts of the machinery. These are the things which put the screw on John Bull's purse with so terrible a pressure, that it yields under its force, and exudes taxes of all kinds, J. B.'s features meanwhile indicating the pain of the operation. The War Office and Horse Guards cut down the Army Medical Department. They yield to the wishes of the Government and the combatant officer, apply a slight pressure on Whitehall-yard, and the thing is done! Money is saved at the expense of the Medical officer and the sick soldier. The War Office, having expended a considerable sum in stationery for the amusement of some clerks' leisure hours, boasts aloud, "See what we've saved!" When we regard the enormous amount of official foolscap that is so necessary to our present very intricate and elaborate system of administration, we are tempted to wonder how the old Roman legions could have got on without it, and to picture what would be an old Roman general's mute astonishment at our modern ways. We gather the following from Mr. O'Reilly's speech in the House of Commons a short time ago:—In administration, our head department consisted of a secretary of state and commander-in-chief, the expense being £9442; while the French managed with one minister at a salary of £5200. The French officials—directeurs, chefs et commis—equivalent to our officials, from secretaries to clerks inclusive, were,—for the double-sized army only 501, at salaries amounting to £58,964, against 627 persons in our departments with salaries of £177,207. The total cost of the English administration, deducting the Quartermaster-General's department, was £1 7s. per man; while the French total, leaving out the *Depôt de la Guerre*, was about 4s. 6d. per man. Mr. O'Reilly said that "he thought if the Government, another year, did not diminish the cost of army administration, the House ought to enforce it upon them;" and we think so too. By the way, we wonder whether the charge of £973 for forage for the Commander-in-Chief is included in the cost of administration. There is very little doubt that the time is coming when the men as well as the officers of our army must be better paid, if we desire to maintain a thoroughly efficient force, and we imagine the nation will desire that the money voted shall really flow to the army, and as little as possible stagnate in, and adhere to, the desks of officials.

THE WEEK.

DISEASED MEAT FOR THE NAVY.

AN action was brought in the Court of Queen's Bench on the 7th inst., which proves that our sailors are at least as much exposed to the dangers arising from eating diseased meat—whatever they may be—as the rest of Her Majesty's lieges. The action was brought against two persons, named England and Curtis, who are meat contractors for Deptford Dockyard. The plaintiff Davies was foreman to Curtis, and was employed by him in cutting up the carcasses of cattle alleged to be diseased. One ground of the action was that the plaintiff had been infected by the disease of the cattle. The Court gave judgment for the plaintiff on the supposition that the defendants were aware of the diseased condition of the animals.

THE FRENCH POISONING CASE.

THE Court of Cassation has rejected the appeal on behalf of La Pommerais against the judgment of the Assize Court of Paris. The Paris correspondent of the *Times* writes:—

"It was only after much persuasion that the convict consented to the appeal; he was utterly weary of life, he said, and he had rather meet death at once than undergo the agony of suspense and the heart-sickness of hope deferred, of hope the faintest possible. There now remains but the mercy of the Sovereign when he comes to sign the warrant for execution; and for the exercise of mercy it is feared there are but slight grounds. The crowd that thronged the Palais de Justice was on this occasion as numerous as during the trial. Many imagined they were to see once more the unfortunate man who has acquired so infamous a notoriety, but they were disappointed. It was forgotten that the convict does not appear before the Court of Cassation. This Court, in its appellate jurisdiction, only examines the competency of the appeal. Its duty is not to examine the truth or falsity of the charge on which the criminal is condemned; it inquires merely as to whether all the legal forms have been scrupulously observed in the lower Court. It is divided into three chambers, and the third, the Chamber de Cassation Criminelle, is that which decides in criminal cases. In case of informality, the Court would pronounce no opinion as to the guilt or innocence of La Pommerais; it would only set aside the previous judgment, and send him to a provincial Court of Assize to be tried by other judges. The exceptions taken to the decision of the lower Court were set forth by the counsel for the defence, and developed at length in the report read by M. de Gaujal, counsellor at the Court of Cassation.

"M. de Bozerian supported the appeal, and in a speech of much ability enumerated all the reasons which existed for a new trial. These reasons seemed, however, more ingenious than real.

"M. Dupin, Procureur-General, replied at some length and with much force. In his requisition, which was a fine specimen of legal reasoning, he recalled some of the most celebrated cases of poisoning and the fate reserved for poisoners in ancient and modern times, from Locurta to the Marquise de Brinvilliers and Madame Laffarge. M. Dupin concluded by calling on the Court to reject the appeal and confirm the judgment of the Court below, there being no grounds whatever for disturbing it.

"At two o'clock the judges retired to their chamber, and remained only half an hour in deliberation. When they resumed their seats it was easy to see that, so far as the Court of Cassation was concerned, all hope was over. Amid the deepest silence the decision of the judges was read; it was, that the procedure in the lower Court was regular; that the text of the law had not been infringed; and that the appeal on behalf of Le Pommerais was rejected. The crowds lingered for a while in the *Salle des Pas Perdus*, or conferred together in groups in the square as to the chance of a commutation of sentence, if not for the convict's own sake, for that of his father, his wife, and his infant child."

PARLIAMENTARY.

In the House of Lords on Friday, June 3, Lord Shaftesbury explained the objects of the bill he had introduced for the amendment of the present law regulating the mode of sweeping chimneys. The practice of employing young children in this occupation had of late years much increased in some places, in consequence of the difficulties of procuring convictions under the existing Act. All he wished to do was to introduce such amendments as should render it easier to put the law in force against those who persisted in employing children in this trade. To prove the necessity of some interference he read numerous extracts from recent evidence of the revolting cruelty the masters were forced to employ in training children to the work. All this suffering, he asserted, was totally unnecessary, as chimney-sweeping by the machine, when properly done, was in all respects efficient. The employment of children had been abolished in Edinburgh, Glasgow, Leicester, and other large places. In no place was it necessary, as the machine was adapted to flues of every kind of construction. Nor were the master sweeps, as a body, opposed to the prohibition of children's labour. They stated that they are frequently compelled to employ it by the prejudices of householders, often of the wealthier classes, who will not allow a machine to be used in their chimneys. Having further described the manner in which

children are bought and sold for the trade, and reduced to a condition of slavery, he implored the House not to reject the bill, by which he had attempted to check a cruel practice unknown to any other civilised nation.

Lord Brougham expressed his hearty approval of the measure.

The House then went into committee on the bill, and agreed to the clauses, with some amendments.

In the House of Commons, on the same evening, a debate took place on the abuses of Greenwich Hospital. On the part of the Admiralty, Mr. Childers promised numerous reforms, both in the government and management of the Hospital, and in the mode of admission and the granting of out-pensions.

The subject of the preservation of Epping Forest for the use of the population of London was brought before the notice of the House by Mr. Torrens, who moved for the production of correspondence, but subsequently withdrew the motion.

On Monday, June 6, the attention of the House of Commons was called by Colonel Sykes to the position of the officers of the late Indian Company's army, but no special reference was made to the present deplorable condition of the Indian Medical Department.

On the vote of £17,306 to complete the sum necessary to defray the expenses of the Privy Council-office,

Mr. Augustus Smith asked for some explanation of an item of £10,000 charged for contingent expenses.

Mr. F. Peel stated that this sum was required to defray the expenditure of the Privy Council-office under the Public Health Act. £3000 was annually placed at the disposal of the Privy Council to pay Medical and other officers who were from time to time deputed to conduct inquiries and experiments; £2000 was for the National Vaccine Establishment; £2000 for vaccination inspection, and the remaining £3600 was a matter of account arising from the Medical Department of the Privy Council having been unaware of the rule that payments should only be made out of the votes for the current year.

Sir J. C. Jervoise called attention to the charge for expenses connected with the inspection of sheep to prevent the spread of disease, and maintained that the statements in the blue-book were calculated to create a panic among agriculturists. Every fifth animal, and by consequence every fifth mutton chop, was stated to be diseased, while there was not only death in the pot, but in the pail. The total loss by preventible diseases in cattle was estimated at £6,000,000 yearly. He wished to know who was to be held responsible for such statements, inasmuch as the Medical officer who had despatched eminent Veterinary Surgeons on commissions of inquiry, not only through this country, but abroad, disconnected himself in a note at the end of his report from the opinions put forward by them. The epidemic diseases were attributed in the blue-book to contagion originally of foreign origin, whereas the Medical officer attached to the Customs Department reported that not a single case of small-pox in sheep had entered this country.

Mr. Bruce said the Secretary to the Treasury had already explained from what source the cost of these inquiries was defrayed. The hon. member seemed not to deny the great ability and clearness of the reports, but apparently objected to the manner in which they were compiled. The subject of diseases in cattle was one upon which a great variety of opinions existed, and it was now receiving the attention of a select committee.

The vote was then agreed to.

The Government Annuities Bill passed through committee.

On Tuesday, June 7, the House of Lords went into committee on the Penal Servitude Acts Amendment Bill. A discussion took place on the clause requiring a convict liberated on ticket-of-leave to report himself once a month to the police. An amendment, moved by Lord Houghton, striking out the words "once a month," was negatived by a majority of 8.

In the House of Commons, on Wednesday, June 8, Mr. Lawson moved the second reading of the Intoxicating Liquors Bill. He assigned various reasons for bringing forward this measure, among which he included the vast number of petitions in its favour, signed by upwards of 300,000 persons, and he examined and replied to the objections urged against legislation upon this subject, especially the suggestion that it

was impossible to make people sober by Act of Parliament, which, he remarked, had not been suffered to obstruct other attempts at social and moral reforms. He showed what the grievance of which the advocates of the measure complained really was, and that it was acknowledged by persons of all classes; and he appealed to irresistible evidence of the evils resulting from indulgence in intoxicating liquors. Having shown the grievance, he stated the remedy he proposed in his bill, which could not come in force except by the will of the people.

Captain Jervis moved to defer the second reading for three months. He observed that the speech of Mr. Lawson was no defence of the Bill, which put an arbitrary power into the hands of two-thirds of the ratepayers of a parish. He was acquainted with the habits of the working classes, and he believed that drunkenness had diminished throughout the country, and not by penal enactment, but by education.

Mr. Bright said every one must agree that the evil in question was a very grievous one, and that if any measure could be taken that would not violate the recognised principles upon which the House acted, some further help would be afforded to the efforts of those who were making great exertions in the cause of sobriety. The question then was as to the remedy. There were two modes; one, the improvement and instruction of the people; the other, special legislation. He looked to the first for a permanent remedy; but something might be done by special legislation. He disapproved, however, the machinery proposed by this Bill, which might excite a resistance to its honest and good object. But although he did not see his way to supporting this measure, he suggested a mode of control by the people in the cause of temperance through the municipal councils.

Mr. Roebuck opposed the bill as a mischievous and unjust measure. The House, by passing it, would, he said, abdicate its functions. It was mainly directed against the poor, and was, therefore, a cruel bill.

Mr. W. Martin and Mr. Scourfield likewise opposed the bill.

Sir G. Grey was decidedly of opinion that the remedy proposed by the bill would be an intolerable tyranny over minorities and those who had no voice in the matter. Sympathising with the object of Mr. Dawson, he hoped, after the opinions which had been expressed in the House, he would not persevere in the measure.

Further discussion followed, and, upon a division, the second reading of the bill was negatived by 292 to 35.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE XIX.—MARCH 15.

Anatomy of the Gibbons Continued.—The dental formula in the genus *Hylobates* is the same as in man and the other anthropoid apes, and in their principal features, such as the proportionate size of the incisors and pattern on the molars, the teeth repeat the characters previously assigned to these groups. The canines are very long and pointed, and in the lower jaw have a posterior projection or heel, close to the base of the crown. In the order of succession there is this notable difference from the Gorilla, Chimpanzee, and Orang,—the permanent canine, instead of being the last tooth in place, emerges either before or contemporaneously with the posterior molar. This might be considered to bring the gibbons nearer to the human type, if it were not a character found extensively among the lower groups of monkeys.

The myology of *Hylobates* may be considered under the same heads as in the case of the previously-described apes. 1. Those muscles which are not commonly found in man are, as before, the levator claviculæ and the dorso-epitrochlear; the scensorius is not very distinctly represented; but there is a muscle, as far as is known at present, not found in any other mammal, it occurs in both hand and foot, arising from the second metacarpal bone, and inserted by a long tendon into the radial or tibial side, as the case may be, of the ungual phalanx of the same digit; it might be called "abductor tertii internodii indicis." 2. The muscles commonly found in man, which are absent in *Hylobates*, are the extensor primi internodii pollicis and the peroneus tertius, neither of which appear to be found in any apes. 3. Muscles differing essen-

tially in their origin. The biceps of the arm is a strong and large muscle; its short head has no connection with the coracoid process, but rises from the tendon of the pectoralis major. The flexor pollicis longus approximates in its mode of origin to the highest type, being mid-way between man and the chimpanzee; its tendon is distinct throughout its whole length, but the muscle is connected by fleshy fibres with the portion of the flexor profundus digitorum appropriated to the index finger. The soleus arises by a narrow tendon from the fibula alone. The flexor brevis pedis has only one head from the calcaneum, that furnishing the perforated tendon of the second digit, the remainder arises by three bundles from the tendon of the flexor longus. The dorsal interossei of the second space in the foot resemble those of the hand in their origin. 4. Muscles differing in their insertion. The supinator longus is inserted into the middle of the radius instead of its lower end. The extensor indicis gives tendons to the second, third, and fourth digits; the extensor minimi digiti only to the fifth. The great muscles which act as long flexors of the toes are very peculiar in their distribution; the flexor hallucis gives tendons to the first, second, third, and fourth digits, the flexor digitorum only to the fifth, and there is but a very slight connexion between them in the sole of the foot. There is no flexor accessorius. 5. Muscles which differ by subdivision. The extensor ossis metacarpi and the tibialis anticus have double tendons, with the usual insertion, but the division is scarcely carried into the muscle itself. The interossei of the hand are divided precisely as in all the preceding. On the whole, in the myology of its hand and foot, *Hylobates* may be said to depart further from man than either gorilla or chimpanzee, but less so than orang.

A laryngeal pouch at all similar to that found in the other anthropoid apes only exists in one species of *Hylobates*—the siamang (*H. syndactylus*). That this structure can have no relation to the production of the remarkable voice of that animal is proved by the fact that all the other species are equally loud howlers. According to Sandifort, it exists in the siamangs of both sexes, as a great globular bag attached to the front of the larynx, but it differs essentially from the previously described air sacs in not communicating with the ventricles of the larynx, but has an opening on each side higher up above the false vocal cords, so that it is in reality a development of the thyro-hyoid membrane, and forms an interesting transition to the air pouch found in the lower monkeys, which has a single median aperture in the thyro-hyoid membrane.

The uvula is present in the siamang. The stomach resembles that of the orang; the cæcum has a large and long vermiform appendix. The liver is essentially bilobed, but the spigelian lobe presents an approach to the elongated, pointed form it has in the chimpanzee. The left carotid artery arises from the innominate as in the lower apes. The right lung has four, the left two lobes. The brain shows a degradation of type as compared with the previously described genera. Its volume is smaller in proportion to the size of the body; the hemispheres are flattened and depressed; and the frontal lobe is smaller, more pointed, and excavated inferiorly. The most remarkable peculiarity is the great reduction of the posterior lobe, which in the siamang, alone among apes, as shown by Mr. Flower, does not completely cover the cerebellum. The convolutions and sulci have the same general distribution as in the other anthropoid apes, but are more simple and symmetrical; the internal structure is also essentially the same. The anatomy of the reproductive organs has not been fully worked out in adult specimens, nor are there materials at command for the study of the general character of the two sexes, and the extent of variation in the different species. The law of growth appears to be the same as that of the other great apes.

From the gibbons to the next succeeding group is a great and sudden step; it will be well, therefore, to pause and

review the principal characteristics which distinguish the group of apes we are just leaving, which may be called the "anthropomorpha." The characters which separate them from the lower forms we are not yet in a position to consider. Their differences from man may, however, be thus summed up. The hair is more abundant upon the dorsal than the ventral surface of the body. The nose does not project to anything like the extent it does in man. The size of the brain case is very notably inferior to that of man. They are greatly more prognathous and macrognathous. The premaxillary suture is far more persistent. The spinal curvatures, especially the sacro-vertebral angle, are much less marked. The radius is more curved, and the interosseous space larger. The pollex is less than half the length of the hand. The form of the pelvis differs considerably, its vertical height is relatively greater, the ilia are less curved, and the ischia more everted. The femur is shorter than the humerus. The tarsus less than half the length of the foot. The upper face of the astragalus looks obliquely inwards. The calcaneal process is shortened, and does not form an inferior tuberosous mass. The form of the articular facet on the entocuneiform bone is specially modified to allow of the mobility of the first digit. The whole foot has ceased to be an organ of support, and has become one of prehension. In the muscular system we have noted the absence of the extensor primi internodii pollicis, and of the peroneus tertius, and the presence of the levator claviculae and dorso-epitrochlear; the tendency to the subdivision of several muscles which are single in man; the origin of part of the flexor brevis digitorum from the tendon of the long flexor; the comparative freedom from each other of the flexor longus hallucis and the flexor longus digitorum, and the larger share taken by the former in furnishing the tendons for the toes; and lastly the union of the flexor longus pollicis and the flexor profundus digitorum. The viscera present no striking differential characters. The brain besides being smaller is more simple and symmetrical in its surface markings. In the dentition the roots of the premolars are more complex, the canines are much larger, and later in their eruption. Lastly, there is the very important and singular difference in the law which regulates the proportions of the body and limbs during their growth.

FROM ABROAD—RECOVERY OF M. FLOURENS—MEDICAL CONGRESS AT LYONS—COMPRESSION OF THE TEMPORAL ARTERIES IN CEPHALALGIA.

THE business of the Academy of Sciences was preceded the other day by one of those touching personal recognitions which men of science like to bestow on each other on the Continent, and which are too rare among ourselves. M. Flourens having been kept away from his duties as Secretary to the Academy for many weeks in consequence of a dangerous carbuncle, which entailed the necessity of free incision, on resuming his functions said "I beg to thank the Academy in general, and each of its members in particular, for the marks of sympathy with which they have honoured me during the painful disease I have just traversed. I owe my life to M. Velpeau, and happy am I in expressing my gratitude to him in the midst of the Academy itself." M. Velpeau replied that he had only done for M. Flourens what he would have done for any other, obeying in that the first and most imperious obligation of Professional duty. Happy, indeed, was he that his endeavours had been crowned with success, first as Surgeon, next as friend, and then as Academician, because he hoped that M. Flourens would continue long to fill his present post. "These reciprocal testimonies of esteem and affection," observes Dr. Legrand, "of which a kind of false shame, perhaps, renders the public expression too infrequent, are a good and reassuring thing. They show the man under the *savant*. They make us love the one and render—how shall I express it?—more agreeable and more human the admiration we may feel for the other."

The Medical Practitioners of Lyons, following the example given them last year by those of Rouen, have determined to

hold a Medical Congress in the second city of the Empire on September 26 and five consecutive days. No topic relating to Medical politics will be considered, and the following questions will be discussed:—1. Sanguineous concretions in the heart and vessels, the conditions favouring them, the symptoms which they give rise to, and the therapeutical indications. 2. Can we at the present time admit into the nosological scheme as morbid entities the different paralytic affections recently described under the names of *shaking palsy*, *progressive wasting palsy*, *ataxie locomotrice*, *reflex paralysis*, &c.? Does there run through these a symptom common to different diseases of the nervous centres? 3. Establish by exact facts the curability of phthisis, and distinguish among the varieties of this disease those which are and those which are not susceptible of cure. 4. The value of the different modes of treating complete and incomplete ankylosis, both with regard to change of position and re-establishment of motion. 5. What progress in Surgery is due to modern researches on the osseous system? 6. The modes of diæresis which can be most advantageously substituted for the cutting instrument with the view of avoiding the accidents consequent on wounds. (Cauterisation, *écrasement*, *ligature*, *arrachement*.) 7. On consanguinity in general, and especially on consanguineous marriages. 8. The production of parasites common to man and animals, especially in relation to public hygiene. 9. The nature of the contagion in the economy of a syphilitic subject, and the practical consequences to be deduced. 10. What are the services to be demanded from the forceps, and how far do the different varieties which have been invented fulfil the various indications? 11. The possibility and propriety of removing certain categories of the insane from asylums and placing them either in agricultural establishments or in their own families. 12. Of the value of iridectomy in glaucoma and other deep-seated lesions of the globe of the eye. Two of these subjects will be discussed in the order above mentioned on each of the six days on which the Congress is held, and any person having communications to make upon any of them must apprise the committee and forward his paper, or an abstract of it, at least forty-eight hours before the opening of the Congress. Letters to be addressed to the President de la Commission Exécutive, M. le Dr. Barrier, 26, Rue du Pérat, Lyon. Medical Practitioners not inhabitants of Lyons are not required to make any payment.

M. Guyon related, in a paper read at the Academy of Sciences, that, during the epidemics of yellow fever which he witnessed in the West Indies, he was often in the habit of feeling the pulse at the temporal artery. One day, having compressed it with more than usual firmness, he found that the intense cephalalgia, which is an accompaniment to this affection, was greatly relieved; and further trials made by compressing both temporals were attended with complete disappearance of this symptom. It became then a question whether this fact could be turned to practical account, and whether it would be attended with any notable inconveniences. The headache in yellow fever constitutes so predominant a symptom that some Practitioners have even resorted to scarifications and opening the temporal artery to obtain relief. Compression has, indeed, been used after a fashion by the native women, who, dividing a lemon in two, bind the halves on each temple by means of a bandage passed several times around the head. This cannot, however, be long continued without a certain amount of irritation of the skin being induced; but there can be no doubt that the pain is relieved or removed in this way as long as the pressure is continued. Moreover, as well as under a more effectual mode of compression, not only is the pain relieved, but the patient comes out of his state of torpor or somnolence, breathes freely, and replies cheerfully to questions addressed to him. The best mode of exercising compression is by a semicircular curved band of steel, provided at each end with a pad resembling that of a hernia truss, and which is moveable, so that the compression need not always be made precisely on the same spots.

Enough space should be left between the steel arch and the forehead to admit of the cold applications being made to the latter which are found so useful in yellow fever. M. Guyon feels certain that compression will also be found of the same utility in the cephalalgia of other forms of fever.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BRIGHTON.

PLACES of resort for the invalids of England have of late years become so numerous that it is a point of great difficulty at times for the Physician or the Surgeon to decide to which locality he shall direct the footsteps of his patient. During the last century the difficulty was not so great, Bath and one or two other towns monopolising all the "resort business;" but even then there were difficulties, and the Faculty was not at all times agreed as to the best. Satirist Swift, Dean and wit, must needs make an inquiry of his friend Arbuthnott whither he should go for the cure of a vertigo; and Arbuthnott, whose wit was greater than that of most of his comrades, and whose humanity was greater than his wit, replies by recommending "the Geronster waters, which will not carry from the spot;" by which he meant to indicate, in his terse style, that change only was necessary, and that it mattered little where the invalid resorted, so long as he found a place where the waters would not carry, but must be visited, and that there was a custom in his day of specially recommending certain districts, which custom was rather too artificial and fashionable to be strictly satisfactory.

A consultation in these days, and "where shall the invalid go for change" the subject of discussion? Suppose some one said, to the Geronster waters, or any waters or any seaside that won't carry. How dreadful would be the heresy! It would not do for thee now, learned Arbuthnott, though thou still couldst do everything except walk, and couldst talk better than Macaulay, or Brougham at his best. Thou must not use that dry wit again. Thou must take a list of towns, and of bays, and of mountains, and I had almost said icebergs, and settle the point flat, whither thy patient shall go, and if he ask thee for an extreme thou must be ready with an answer. Shall it be Iceland, or Panama, through Norway or gentle Italy, some new town in England, or a newer town still at the Antipodes?

And again, good sir, if you decide on a seaside resort, let the Geronster waters alone, for it will not do now to give answers with pregnant satire in them. This is a practical age. How many baths shall that sick man have per day, Sir, to a bath? Shall he go into the sea; and, if so, how many times a day, and for how many minutes at a time? Shall he swim if he can? Shall he be dried with a rough or soft towel, a flesh brush, a hair glove, or a diaper? If he have a warm bath, what shall be the precise temperature, and is it advisable to take a pocket thermometer? Shall he be shampooed, and, if so, for how long? Shall he take a little brandy before the bath or after it? These, and a hundred other questions, my dear fellow-graduate Arbuthnott, dead, and yet speaking, thou must answer, man—quickly, shortly, and surely; or that guinea that glitters so feebly behind a mountain of fist will be the last ridiculous mouse thou shalt deliver from the mountain.

Hard times these for the Faculty, when no man lives who, like Radcliffe, dares send a hypochondriac a month's journey to consult an imaginary doctor,—or talks of Geronster waters that won't carry, like the talk of Arbuthnott, or tells a great man, as did dying Garth, that the nearest Esculapian is the best to be consulted. Hard times, when all that is spoken must be by rule of thumb; when our science is so near the absolute that we must be absolute, and bid the sick man go at once to this or that place as authoritatively as an American General would tell a private soldier to walk into a cannon's mouth! Very hard times; harder than "very hard cash."

But so it must be; universal error is practical truth, and the errors of the people in regard to places of resort for the

sick are, in fact, not true, by virtue of their universality alone. There is something—it may be very small, but it is something—to be learned respecting the special facilities and advantages of particular towns for particular disorders. If Bath merely beat Bristol in that it possessed a Bath chair or two, while Bristol had nothing but dog-carts, Bath would be better than Bristol for patients with broken legs. And thus every place has its peculiarities, natural or artificial, and we must not be too proud or cynical in learning them.

We have dropped at last, in our historical meditations, on a watering-place, a very famous place now-a-days, sometimes called "London-on-the-Sea," once called "Brightelmston," and now, for short, Brighton. We enter it not as mere tourists, not as invalids, but to see what is in it medically that is worth seeing. The history of the town has been at various times well worked up. There is a first and excellent history of Lewes and Brightelmston bearing date 1795. The author's name is not given, but that of the editor and proprietor is given, and is that of William Lee. Lee dedicated this work to George, then Prince of Wales, and the book itself is good, but the dedication (which is without exception one of the most fulsome eraven "letters dedicatory" in existence) dishonours it. Another work of modern times, entitled "History of Brightelmston; or, Brighton as I View it and others Knew it," was published so late as 1862. This book was written by Mr. John Ackerson Erredge, but unfortunately was not quite completed by him, he having died suddenly while engaged on the last few pages. The work was brought to a close by the sons of Mr. Erredge, and it is a really good work, showing evidence of great research, of fairness of expression, and of careful style. It is a work that is truly historical; not a guide-book, to be read and thrown aside, but a book to be placed in the library for general reference as part of the universal history of England. Lastly in the Sussex Archæological Collections, volume ii., an excellent paper will be found from the pen of the Rev. Edward Turner on "The Early History of Brighton, as illustrated by the Customs of the Ancient Fishermen of the Town."

Surrounding the ancient history of Brighton, or, according to its first name, Brightelmston (*Brightelm*, the name of an early manor holder or local saint, and *Tun*, Saxon for "town"), there is not much light. One historian claims that the place was an early British settlement, whither the Druids were wont to repair and carry on the mysteries of their faith. The existence of Druidical remains in the neighbourhood has led naturally to this conclusion. There is further evidence, and more satisfactory, that it was a station, probably for fishing or hunting, held by the Romans, for according to the history published by Lee, "there was dug up near the town in the year 1750 an urn which contained a thousand 'denarii' of different impressions down from Antonius Pius to the Emperor Philip, and since that time there have been found in some of the burghs or burrows to the east of the town, ashes and fragments of human bones enclosed in urns of Roman manufacture."

During the Saxon time, it has been presumed that the town and manor were held by Thaness (Saxon nobles), and that they were of the line, or rather constituted the line, of the famous Earl Godwin, father of King Harold the Second, who fell at Hastings before Norman William. At the death of Earl Godwin it would seem that Brighton was divisible into three manors, two of which were left to Harold and another to one Brictric for his life only. Thus Brighton claims as one of its ancient Saxon lords, or thaness, the last and almost the purest and the bravest of the Anglo-Saxon kings.

But little important military fame attaches to the town. In the period previous to the Conquest it was probably purely a fishing station, consisting of a number of huts, with drying-grounds for the nets and small creeks or harbours for ports. There on that beach, which now is crowned by the Marine Parade, whither the richly-dressed subjects of Victoria congregate and walk and talk and hold such mixed and yet exclusive companionship, the subject of Earl Godwin and gallant Harold put in his caravel from Norwich or London, unfurled his sails, emptied his cargo, and away to his hut to eat and drink and sleep in a fashion that is now forgotten and can never be fully recalled.

The Conqueror, with his usual benevolence to his comrades, made over Brightelmston to William, Lord of Warren in Normandy. This nobleman was afterwards created Earl of Surrey, and in his line the possession passed downwards towards our time. But this was not the only effect of the Conquest. Soon afterwards Flemish adventurers, to whom, as we have before seen in describing Lynn, England was a

land of promise, flocked to Brightelmston in large numbers and added to its commercial activity.

The historians all agree that no correct idea of the town is obtainable earlier than the year 1545. There is in the British Museum a map bearing that date on which the town is depicted; at all events, its main features are given. The map shows the place as divided into the "Upper Town" and the "Lower Town." The upper town was on the cliff, and according to Mr. Turner represented the space that is now occupied by the East, West, and North streets; and this space was divided into shares or allotments, which the inhabitants used for the growth of the hemp out of which they fabricated their nets. This upper town was occupied by what were called the "landmen," consisting of the men who tilled the land, and of the manufacturers. The lower town, which was under the cliff, remained as a primitive place, occupied mainly by fishermen, or, as they were called, the "seamen." This lower town was destroyed by the great storm of 1703. What is now called the Steine was in those days out of the town altogether. It was a space used by the fishermen, says my authority above named, for drying their nets; and in the manor book during the 27th of Elizabeth an order was entered "That no hog go unringed on the Steine where nets lie under a penalty of 8d. toties quoties." Imagine an order that none in the way of pigs except they be ringed shall be allowed on the Steine at Brighton! How strange it reads to modern eyes.

Those who gain first possession usually retain power for the longest period. It was so at Brighton; the fishermen for many a long day were the masters of the landmen, and ruled the roost. But the landmen increased and multiplied, at length grumbled, and at last nearly rebelled; they were told to pay taxes and dues, and do as they were bidden, and as they did not see the fun of the thing, they protested, and eventually won their rights. Originally the town was governed by a council known as "the Twelve," who elected two executive officers called the "constables" or "headboroughs," who sat in the borough court and heard cases, the Twelve acting as censors or jurors if need be. The "Twelve" continued to be chosen from the "seamen" until the year 1578, when the Lords of the Royal Council were petitioned to nominate proper persons to inspect the ancient customs of the place, and select from them an equitable little code for the future adjustment of all public differences. The commission was at once appointed, and the members produced a code which for long years was agreeable to all the Brightonians, landmen as well as seamen, and the revised council of twelve continued to rule probably until the year 1772, in which year the appointment of town commissioners was legalised.

The diplomacy of the Lords Commissioners of Elizabeth was crowned with immediate and long-continued success; but their labours had also another advantage. When they arrived at Brightelmston, it was requisite for them to institute inquiries as to the rules and regulations of the past; and so they naturally began to move amongst the fishermen, and inquire of them as to their ancient customs and manners: the statements obtained were written down, and remain as great facts for modern antiquarian scholars, and which have aided them vastly in their researches respecting the first days of this early English and now famous town. Into these records I have not, however, time to inquire.

In the year 1558, owing to frequent threatenings of war from the French coast, the inhabitants of Brighton obtained permission to build a small fort, or blockhouse, and in 1613 this was enlarged with a wall extending 400 feet along the cliff at the part where it was most pregnable. A townhouse was also built behind, and a cell or dungeon for the incarceration of offenders. These efforts at defence, though they may have alarmed the French and held them at bay, were insufficient to meet the encroachments of another invader. For some years the Brighton coast was steadily encroached upon by the sea, and in 1703 and 1705, during two memorable storms, the little fort, with its gun-garden and all else, was undermined and buried. At this time in its history no town, surely, was poorer or more miserable than Brightelmston; the distress was such that the justices of the peace of the eastern division were led to make an abortive effort in 1708 to tax "the three rapes of the eastern division three halfpence in the pound towards the relief of the suffering Brighton community."

But little of importance seems to have occurred to attract attention at Brighton for many years after the flood of 1705. The inhabitants strengthened the cliff from the further encroachments of the sea by building up strong wooden barriers. In 1727 they dug a public well; and in 1733-4 they built a

Workhouse; but they were still poor, and borne down by taxation.

At last, about the year 1750, a great change came over the picture, and the foundation of modern Brighton as a flourishing town was laid. The whole credit of this change is due to one man, and that man a member of our own Profession. The Esculapian who worked the marvel is now but little known except at Brighton as an historical character. His name was Dr. Richard Russell, and he lived originally near to Lewes, at a place called Malling. The writer of Lee's history says of Russell "that he began about the year 1750 to revive and improve on the long-lost Medical use of sea water. By unwearied and successful attention to scrofulous and other glandular complaints under a marine course, he extended the fame of his practice and residence over the whole Kingdom. The erection of lodging-houses now became a profitable speculation at Brightelmston; and that late obscure fishing town began to increase in population and celebrity. The wonderful success of this industrious and deserving Physician appeared by several cases in his dissertation on the use of sea water. The most eminent members of the Faculty in England bore willing testimony to the great acuteness and the utility of his Professional investigations. The present flourishing state of Brightelmston (1795) and every benefit which the diseased have ever since received from sea-water, are therefore, in a great measure, to be imputed to the Medical labours and sagacity of this good man. He also caused a valuable Medical spring at Wick, about a mile from the town, to be enclosed within a basin; and a convenient little building was afterwards erected over it. The proprietors of a new street in Brightelmston named it after him in grateful commemoration of his services to the town; and the Rev. Dr. Manningham, of Jevington, has, in a great measure, ensured the truth of his prediction in the following epigram, by the elegant simplicity of its composition:—

"Clara per omne Ævum RUSSELLI fama manebit
Dum retinet vires unda marina suas."

Considering that the above is from the pen of a local and admiring writer, we are bound to accept it *cum grano salis*. At the same time the description indicates how sincerely and how clearly the inhabitants of the once obscure fishing town trace the advancement of their locality to this one source. Whatever real Medical knowledge Russell might or might not possess, we may infer safely that he was a man of the world who knew what were the elements of success, and who knew not a little respecting the "waters that would not carry." That he was sometimes engaged in doing what he need not, strictly, have been doing, is clear from the circumstance that he attributed certain of his curative results to the use of a remedy found on the coast, and called "strombolo." This, says Lee's author, "is a species of amepelites, or black bitumen, highly charged with sulphur and salt. At Brightelmston it is called strombolo, which is a corruption from strom-ballen, stream or tide balls, the name given it by the Flemings who settled in the town. It formerly was used by the poor inhabitants as fuel, but has of late years been neglected, or, indeed, rather prohibited, on account of the very offensive smell of the sulphureous part of it when burning." This strombolo was used rather largely by Dr. Russell, who, after it was rubbed fine and strewed upon coals, "used to apply its hot steam through a funnel to the swelled glands of scrofulous patients, after those tumours had been fomented with sea water."

Dr. Russell was succeeded by another Physician named Dr. Rhellan, who continued to follow out the practice that Russell had introduced, and who wrote a natural history of the town, which does credit to his learning, and which added not a little towards increasing the popularity of the district.

In eighteen or twenty years time after Dr. Russell commenced his labours, Brighton had emerged from its obscurity altogether. Its character as a mere fishing station was partly forgotten; it had its public baths, its amusements, and its lodging-houses; and to add to its advantages the roads leading to it, especially the roads from the metropolis, were subjected to rapid improvement, so that in time the London and Brighton road was the road of the kingdom. A few years later the Prince of Wales, afterwards George the Fourth, took a fancy to Brighton, as it was by this time called, and made it his summer residence. Straightway a race-course was opened, encampments of soldiers began to appear round about, the Steine was "enclosed and turfed," and so rapidly did the population multiply that the number of inhabitants increased above two thousand from the year 1784 to the year 1796.

I have already said that the primitive council of "The Twelve" ceased to exist about the year 1772. In 1773 Parliament passed an Act, by which Brighton was placed under sixty-four commissioners, elected by the inhabitants; the commissioners saw to the lighting, paving, and the general management of the town. In 1810 the number of commissioners was increased to one hundred, and in 1825 they were again increased to one hundred and twelve.

Speaking in reference to the working of this act, Mr. Eredge says that under its provisions some of the greatest improvements of the town were effected. Thus, there was built a sea-wall, forming the southern front of Brighton, the Market-hall, and the Town-hall. The members of the Council also lent, at times, valuable aid to the endeavours of private enterprise, and altogether they may be said, in so far as the improvement of the town is concerned, to have performed their duties honestly and well. They worked for a century in advance, at least, and they do well who work a year beyond their own time.

Taking a hint from Mr. Thackeray, "I turn the picture to the wall" as the life of Brighton during the career of George the Fourth, a Brighton resident—or I should have said *the* Brighton resident—comes into view. That the town improved as a town of bricks and stone and mortar during his "profligate" is admitted; that its numbers increased and its wealth rose during that "profligate" is admitted. That a massive, and almost artistic, structure called the "Pavilion" rose as a residence for the royal corruption is a fact to be told, but not to be dwelt on, for one almost weeps as one reads even the apologetical accounts of this marine royal home during the profligate period. It is difficult to say which, indeed, was worst, the prince who ruled, or the Brighton that slaved to passion and intrigue and grossness that is now unspeakable.

With the passing of the Reform Bill in 1832 Brighton gained her representative voice in the Commons House, in 1854 she obtained a charter of incorporation, and in 1860 the Local Government Act of 1858 came into operation. Since the period of incorporation, the corporate body has shown itself vigorous in the management of public affairs, and one of the active members of our own Profession, J. Cordy Burrows, Esq., has twice held the mayoralty. A Medical Mayor of Brighton in these days contrasts strongly with one Dr. Matthews, who in 1680 lived there, the only Esculapian, and attended midwifery everywhere in the town at two shillings and sixpence per case.

Modern Brighton altogether, indeed, stands forth strangely in comparison with the past. She is essentially a fast town, producing, in the way of population, on her own soil a goodly increase, and receiving, as all such towns do, a great influx from emigration. Let us look at the facts of population. The registration district of Brighton has now an area of 2320 statute acres; and the population in 1861 was 77,693. For the same year the marriages were 803; the births, 2368; and the deaths, 1583. Of the 2368 births, 189 were illegitimate, including 99 males and 90 females. Of the deaths, 774 were males and 809 females, the excess of births over deaths being 785.

Brighton is divided, by the registration returns, into three districts—Kemp Town, with a population of 13,589; St. Peter, with a population of 42,156; and The Palace, with a population of 21,948. In Kemp Town, the births and deaths in 1861 were—births, 345; deaths, 209; excess of births over deaths, 136. Of the births, 15 males and 7 females were illegitimate. In St. Peter, the births were 1551; the deaths, 1023; excess of births over deaths, 528. Of illegitimate births, there were 70 males and 69 females. In The Palace district, the births were 472; the deaths, 351; excess of births over deaths, 121; the illegitimate births being 14 males and 14 females.

A note in Lee's "Ancient and Modern History of Lewes and Brightelmston," 1795, may give some idea of the increase that has taken place in the population of Brighton since that time. It appears that in 1786 the population was a little over 3600; and in January, 1794, when the inhabitants were "carefully enumerated" previous to a general inoculation, they were found to number 5669. Mr. Eredge gives the following table showing the rise of population during the last hundred years. On reference to original returns from 1801, I find his figures strictly correct, and they may be trusted from the first:—

In 1761, population.	2,000
" 1786	3,600
" 1794	5,669

In 1801 population	7,339
„ 1811 „	12,012
„ 1821 „	24,429
„ 1831 „	40,634
„ 1841 „	46,661
„ 1851 „	65,573
„ 1861 „	77,693

While the population has thus changed, the modes of gaining a livelihood (the occupations of the people) have undergone no less a modification. Our census returns of occupations tell us that fishermen still live at Brighton to the number of 240, and that there is one fisherwoman; but beyond this there is no special business carried on marking either a staple manufacture or a staple industry. School-teaching and house-letting are the specialties, if any; but trades and callings of all kinds seem to flourish, and the business of the town is conducted so like that of London that it is only necessary for the Londoner to forget the town he is in when at Brighton, to feel that he is still in London, in so far as buying and selling and appearances of shops and style of articles and goods are concerned.

If we study the town by the method of the last census, and taking all the population above 20 years of age (including 44,672 persons) divide it into six classes—viz., the Professional, the Domestic, the Commercial, the Agricultural, the Industrial, and the Indefinite or Non-productive Classes,—we shall find them to stand in the following numerical order:—

1. *Professional Class.*—2734 persons, or 6.1 per cent.
2. *Domestic Class.*—18,905 persons, or 42.3 per cent.
3. *Commercial Class.*—2133, or 4.8 per cent.
4. *Agricultural Class.*—1452, or 3.2 per cent.
5. *Industrial Class.*—15,570, or 34.9 per cent.
6. *Indefinite and Non-productive Class.*—3878, or 8.7 per cent.

The present aspect of Brighton needs little description. Whoever has not been in Brighton, and has been in London and visited the West-end, has only to imagine that the Serpentine is the sea, with a grand sea-walk of some three miles long for an exercise, and he may know what he has to learn in the “Queen of Watering-places.” Let me stop; I must qualify this a little. He will find hills in Brighton, which are not in London, and he will find no great squares like those which are in London. Further, he will discover in the people he meets at Brighton more of fluctuation, and more gaiety, and also more chronic sorrow, for amongst the comers and goers there are in the main but two classes—the pleasure-seekers and the health-seekers, the first all lightness, the second careworn, pale, and feeble: a strange admixture.

Poverty appears less on the surface in Brighton than in London, for the reasons, I presume, that it is less. There is evidence of imported poverty in the way of professionals, who know how to beg wherever there are riches in sight; but of all places, I never saw a place where mendicancy in its most degraded, helpless, and hopeless form is less apparent.

The great town now stretches out before from the English Channel, as if it were a gift of the sea; its broad base resting on the sea. In the centre, looking from the water inland, is the little open space where once the nets lay to dry, and the unringed animals might not enter—the Steyne—and, running from it, into the town, the Grand Parade. To the extreme left, beyond the King’s-road, leading to Worthing, is the well-known chalybeate spring; nearer the centre the workhouse and cemetery; and still nearer the centre, the Eye Infirmary and Dispensary, the Self-supporting Dispensary, and the Lying-in Hospital. To the extreme right are the Blind and the Orphan Asylum; nearer the centre the Sussex County Hospital, the Deaf and Dumb Asylum, and the College; and nearer still, but respectively more remote from the sea, the German spa, the water reservoir, the water-works, and another cemetery. A town, in short, lies before us, built out from the sea, its main streets standing at right angles to the sea; its wings, right and left, not very deep; and its centre running far inland, with streets that at their extremes diverge on either side in gentle curves.

As we land, say by the magnificent pier called the Chain Pier, we will traverse the Marine Parade to the right, until we come to a turning inland called Paston-place, and now passing along a short ascent we reach the Sussex County Hospital, whither the foot of the Medical traveller would needs first repair. But before we make our way there, and before leaving this brief history of the town (for the details of which I am so largely indebted to the works of the eminent authors whose names have been quoted), let me add that as Brighton, in the first place, became important as a watering place through the labours of one Medical man, so the exertions of the members of

the same Profession as that to which Dr. Russell belonged have never slackened. We hear it often said that the Prince Regent made the town. It is true that the Regent made the town for a time notorious, but that he did not make it famous and permanently important is proved by the fact that on his demise, notwithstanding the after visits of King William the Fourth, royal special favour gradually declined, and in this reign has virtually ceased altogether. But withal, Brighton has gone on to flourish and prosper, and, perhaps, at no period in her history was she really so great and prosperous as she is at this hour. Not only so, but I think it will be generally admitted, that when she was compelled to throw off the patronage which the “first gentleman of England” forced upon her, she became not only a better but a wiser community. Then she cast away her political oppression, and since she has had political rights has used them on the whole well and soundly, in and for the advancement of freedom and learning. Whence, then, this steady progression after the assumed cause of all the prosperity was removed? Some of this may be traced undoubtedly to the position of the town, its nearness to London, and the comforts that the traveller meets there. But after all, an immense share of the prosperity is due to the influence of the Medical men of Brighton. They have been at all times untiring in their exertions; they have been active in the local councils, foremost in suggesting sanitary and social reforms, determinate in promoting institutions for the relief of distress or misery in every shape in which it has presented itself; and, above all, resolute in making the advancement of their own science, as well as of the collateral sciences, an important part of their daily work. In these days, when the captious public, led by the nose by any pseudo-body-cobbler who may have tact enough to hide his own ignorance, asks, as it often asks:—What instance is admissible of any great public effort performed by the Profession? we may point to the town of Brighton very fairly, and say, “Here is a coast town, advanced amongst the first in civilisation; an influential town politically; a wealthy town, with noble charities supported by its wealth. One hundred and twenty years since, this town was a fishing station of small account. But it was seen by a Medical man to be worthy of a better fate; it has been steadily supported by his followers in every stage of its progress; and there it is, essentially a Medical town, discovered, we may say, and founded, by a Medical man, and sustained when it might often have sunken by its Medical element, which has been more to it than royal—viz., *loyal and thoughtful.*”

REVIEWS.

The Classification of Skin Diseases: Containing a Tabulated Arrangement of all the principal Modern Classifications, and a Modified Scheme. By W. TILBURY FOX, M.D. Lond., Physician to the Farringdon General Dispensary. London: Hardwicke. 1864. Pp. 43.

The Nature of so-called “Parasites” of the Skin. By W. TILBURY FOX, M.D., etc. Richards. 1864. Pp. 24.

Treatment of Diseases of the Skin. By Dr. WM. FRAZER, Lecturer on Materia Medica to the Carmichael Medical School. Dublin: Fannin and Co. 1864. Pp. 174.

THE classifications which Dr. Fox in the first work of the above list undertakes to criticise are those of Alibert, Willan, and Bateman, and Dr. Gull’s modification of Willan’s scheme, Startin’s classification, those of Erasmus Wilson, Cazenave, A. B. Buchanan, Hebra, and Hardy. It cannot be expected that we should follow him through all his fault-finding. If a man wishes to become a Medical Ishmael, depend upon it there is no plan more likely to be successful than to start a scheme of classification of diseases. If the writer is himself dissatisfied with the results of other people’s labours in this direction, he may rest assured that he will some day be picked to pieces in his turn. It is not our intention, however, to perform this friendly act for Dr. Fox; we shall only say that his classification is very elaborate, containing pretty nearly as many divisions and subdivisions as there are diseases to be arranged; and that we are not certain that this is not practically objectionable, however fairly Dr. Fox may represent the pathological relations of morbid conditions. But upon this we cannot enter. We will permit Dr. Fox, therefore, to plead his own cause. He says:—“It will be seen at once that I am disposed to make use of anatomical criteria with rather a different

object than that generally held in view. Willan and his followers arranged skin diseases according to the aspect presented by anatomical features; I would rather classify according to the extent and seat indicated, and believe that our first grand division must be made in accordance with the latter.

We must, then, bring these criteria under subordination to the knowledge derived from a careful study of the causation of skin diseases—a most difficult and, at present, very little hopeful task—and arrange the latter upon a plan based upon an equitable combination of these two methods of inquiry.”—P. 16. “We may for completeness’ sake make two grand divisions into parasitic and non-parasitic diseases.” (We doubt whether every pathologist would accept this very first step.) “The *non-parasitic* may be arranged into two primary groups anatomically—1. Disease of the epidermis; 2. Disease of the dermis. The *parasitic* includes all affections due to the presence of animal or vegetable bodies, named respectively dermatozoa—dermatophyta. *Syphilitic* would signify another grand division, if need be. All the forms, however, rank under the second class of the new parasitic group, and it is only necessary to consider the modifying effects of syphilis in ordinary eruptions. . . . The tabular view defines the *limits* of disease generally, and the exact *extent* and *character* of the structure involved: it is also especially useful in a diagnostic point of view.”—P. 40. These extracts will sufficiently prepare our readers for what they will find in Dr. Fox’s modified scheme.

The second *brochure* on our list is essentially an attack upon an article by Mr. Erasmus Wilson in the *British and Foreign Medico-Chirurgical Review*, in which that eminent dermatologist maintains the derivation of skin parasites from a “granular degeneration” of normal tissues, interpreting this term by “the idea of an arrest of development of the cell-tissues of the epidermis at its embryonic stage, and the production of a tissue constructed of crude and imperfect materials, which represent an earlier period of cell generation than that which nature intended, and which, in consequence, is truly in a state of degeneration from the perfect type.” “The whole matter,” says Dr. Fox, “rests upon the solution of two questions. The one is, Are the so-called parasites vegetable in their nature? The other is, Can an animal by a retrograde metamorphosis ever become converted into a vegetable term?” The pamphlet is an attempt to meet Mr. Wilson on these issues.

Dr. Frazer’s book is of altogether a different character to the above, being devoted to the therapeutics of the diseases of the skin. It is a book adapted for students and junior Practitioners, inasmuch as it supplies brief descriptions of the principal maladies, and remarks upon questions of differential diagnosis. On the whole, it is a useful, and, we have no doubt, will be a popular book. Its small size is in its favour. Each chapter points out the application that is made of some one class of remedies in the treatment of skin diseases. Thus, there is a chapter on mercurials, on Fowler’s solution, and other arsenical preparations, one on alkalies, another on chalybeates, and so on. The objections which might be raised against this arrangement are we think fully met by a copious and excellent index, by the aid of which the student may readily ascertain all that the author has to tell him about any one disease that he may desire to become acquainted with. We cannot say we agree with all the author’s pathology, but the book is full of the soundest practical advice. It is a common error among young Practitioners to make their local applications in diseases of the skin too strong—an error which sometimes in our experience has been productive of very disagreeable and unintended results. Against this Dr. Frazer is continually warning his readers; as where he is speaking, for instance, of lotions of chloride of mercury, iodide of mercury, and nitrate of mercury, ointments and applications containing creosote, carbolic acid, etc. He regards arsenic as a remedy of the alterative and not of the tonic class; as promoting the absorption of effete and diseased tissues, and one which, by causing an improved state of assimilation, gradually replaces morbid by healthy parts. Still, he adds, “the results which it produces are, in some instances, so marked and sudden as to remind us of the old idea of a specific,” and he adduces “a case of chronic burrowing anthrax of the back occurring in an old gentleman of seventy, which had lasted for about seven months, and resisted all kinds of treatment.” In this case Dr. Peebles employed Fowler’s solution. “In forty-eight hours it had checked the progress of the disease, and the improvement was so rapid that it was difficult to believe it was due to the effects of the remedy;

it was then discontinued with a view of determining what had caused the change, but the sloughing recurred, and was finally arrested only by resuming the solution and continuing it until the danger was at an end.”—P. 22. His remarks upon sarsaparilla, too, quite coincide with our own views respecting this medicine. “I certainly never saw any decided results from it, as usually given; in former times, when this decoction was taken warm and in large quantity, and continued diaphoresis promoted by various means, it may have been more serviceable than at present, when, I believe, its Medical value is about equal to that of a cup of cold tea.”—P. 23.

Throughout the book there runs a vein of good sense, which goes far to redeem cutaneous therapeutics from the slur of quackishness which is sometimes cast upon its professors.

The Prescriber’s Pharmacopœia; containing all the Medicines in the British Pharmacopœia of 1864, arranged in Classes according to their Action, with their Composition and Doses. By a PRACTISING PHYSICIAN. Fifth Edition. London: Churchill and Sons. 1864. Pp. 156.

We are glad to welcome a fifth edition of this useful pocket volume. We fear, however, that in so far as it reflects the image of the new Pharmacopœia, it will be for some time less consulted than the older editions. But we do not see very well how the author could help himself.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

OUR most important subject of professional interest now is unquestionably that of hydrophobia. It is certain that an “epidemic” (if that word may be applied to dogs’ diseases) of rabies has been prevalent since the end of last year, and I am sorry to say that I have two more cases of hydrophobia to add to those already recorded.

The first is that of a man who was severely bitten by a dog on November 28. The ear, which was much torn, was completely removed by Dr. Petrie, to whom the man first applied. The surrounding bitten parts were cut out, and potassa fusa applied to the remaining surface. Up to April 18 he remained well. In the afternoon of that day he began to find some difficulty in swallowing, and on the 19th was admitted into the Southern Hospital under Dr. Cameron, and died thirty-six hours after his admission. The symptoms were very marked, the frightful spasm produced by any attempt to drink being unlike anything seen in other convulsive diseases. When with an immense effort the poor fellow had taken a cup of tea in one hand and a spoon in the other, and laboriously raised the spoon to his mouth, the first attempt to drink caused a convulsion which threw his arms violently out, flinging the cup one way, and the spoon another. The mere sight of water did not affect him, for it was noticed that when he had some difficulty in passing his water and some water was put into the bed-pan, he did not seem to be affected by it. A mere breath of air caused by waving the hand near his face brought on a convulsion. He was placed in a room by himself; opium was freely administered, first one grain by the mouth, then by hypodermic injections and by enemata, so that a quantity of morphia, etc., equal to twenty-six grains of opium was given in sixteen hours, and without producing more than a short sleep now and then. Beef-tea and brandy enemata were also used. The cause of death appeared to be failure of the heart’s action, and for some time before the pulse was imperceptible. The pupil was dilated, and it was noticed that while the inspirations were almost inaudible, the expirations were loud, sudden, and jerking, their sound being such as to remind one of the barking of a dog. The constant flow of ropy saliva was most distressing.

A post-mortem examination of all the viscera, the brain, and spinal cord, revealed not a trace left by the agent in this most horrible disease.

The last case was that of a boy, aged 11, who was bitten on the lip by a sheep-dog on April 10. He was admitted into the Royal Infirmary, as a patient of Mr. Long’s, shortly after the infliction of the bite. There was extensive laceration of the lip. Nitrate of silver was applied to the wound, which was afterwards dressed with turpentine ointment. He remained in the Infirmary; the wound healed, and the lad appeared to have recovered. He was employed in running

errands, etc., about the Infirmary until May 8, when he became dull and heavy; the nurse thought he had simply taken too much to eat, but immediately that Mr. Nash, the House-Surgeon, saw him, he noticed a peculiar wildness in his look, and that he huddled himself up under the bed-clothes in a very strange manner. Some water was poured out of one vessel into another, and the sound appeared at once to occasion convulsive movements; afterwards, if he even saw any one going to move a water-can which stood near, he entreated them to leave it alone. The pulse and respiration were both very much hurried. Tobacco enemata frequently repeated quieted his pulse, and morphia was also freely given. Some of the special hydrophobic symptoms were relieved, so that on the afternoon of the day on which he died he managed to swallow some water, with a great effort. He sank, however, about midnight on May 8, about sixty hours after the appearance of the first symptoms.

The full particulars of this very interesting case will, I believe, be published before long. It is not very satisfactory to be informed that the dog who bit this boy bit six dogs, of whom only three have been put to death. Stringent measures are being adopted by the police to secure the confinement of all dogs, and a large number of dog-owners have been fined for allowing their dogs to be at large, and all dogs now found in the streets are led off to a speedy execution.

A very interesting case of imperforate anus was brought before the Medical Society by Dr. Irvine. The child, a boy, was born on March 13; the bowels not being moved by the next day, an examination was made, and an imperforate anus discovered. The child had thrown up some castor oil which the nurse had given it, and strained a good deal. There was some enlargement of the abdomen. Dr. Irvine made an incision about half-an-inch in front of the coccyx and about half-an-inch in length. Having divided the integument, he passed his little finger along the hollow of the sacrum, dividing the tissues with the knife until at a distance of about an inch and a-half from the surface he felt a pouch. This was opened, but no meconium or flatus escaped; the wound was plugged with oiled lint. The next day the lint was removed and found to be stained as if with meconium, and some flatus escaped from the wound. The lint was not replaced, and a dose of castor oil was ordered. The next day Dr. Irvine found that there had been three motions, the fœces being liquid and yellow. The oil was repeated daily until the 21st, when he ceased to attend. On April 1st he was sent for, and found that for a few days there had been but little action of the bowels, and that the child had vomited two or three times daily. There was great abdominal tenderness. The child became worse from this time, and died on April 10.

Post-mortem.—The small intestines were healthy, the large intestines enormously distended and filled with fœces, some of which appeared to have remained since the child's birth. The rectum measured five inches in circumference and communicated with the bladder. It is remarkable that nothing had been noticed on the child's napkins coming from the bladder excepting the urine.

I have referred more than once to the evils that illustrate the abominable results which ensue from the practice of "pauper nursing" in workhouses, and it is with no small gratification that I record an offer made by "a Liverpool man" to the workhouse committee of this parish, to defray the cost of a staff of trained nurses for a period of three years by an annual gift of £1000. There are at present fourteen superintendents over the various sick and infirm wards, and about 150 paupers, called nurses, who are not paid, to attend to nearly 1000 patients. It is proposed to have a trained matron, a staff of about fifty real nurses, and to pay those paupers who may be employed under them in various subordinate offices about the wards. To work this system it is calculated that an outlay of about £2000 a-year will be required, in addition to £400 for the preliminary expenses involved in providing proper rooms, furniture, etc. Never will two thousand a-year be better expended than in this way. The economy and order that will be thus promoted are trifles compared with the relief of suffering which this system will secure, and the value of the lives which it will save. The "Liverpool man" who has made this noble offer, anxious to avoid all display, has confided his name only to one of the members of the Workhouse Committee, and it is likely to remain unknown.

I regret to have to record the death of Mr. Wall, Medical officer to the Toxteth Park Workhouse, who died on the 16th ult. from typhus fever contracted in the discharge of his duties at the workhouse. He had devoted himself with no ordinary

energy to his Hospital work, for which a period of ten years' service as House Surgeon at the Northern Hospital had been a very efficient training. A deservedly high tribute to the ability and unswerving integrity which had distinguished him was paid by the members present at the last meeting of the Toxteth Board of Guardians. A curious question arising out of the lamentable mortality among the Roman Catholic priests who visit the Fever Hospital of this parish has been agitating the select vestry—viz., whether one Roman Catholic chaplain should continue to take the whole charge, or whether, as was requested by the Roman Catholic bishop, the duties should be divided among seven. Unfortunately the matter was not decided upon sanitary grounds; and it is very much to be regretted that the one essential point—whether the danger to life is diminished by exposing seven gentlemen to the risk of infection once a week instead of exposing one to the same every day—seems to have been lost sight of entirely.

The two men, Brice and Scott, who so nearly murdered Dr. Rowe in the assault which I mentioned in my last letter, were fully committed for trial. Bail was still refused, and I see that an application is being made to obtain from the Court of Queen's Bench a reversal of the magistrate's decision in this matter.

GENERAL CORRESPONDENCE.

CONCERNING A HITHERTO UNNOTICED CONDITION OF THE URINE IN DISEASE.

LETTER FROM DR. ANDREW CLARK.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have been for some time in the habit of examining the urine of all my out-patients at the London Hospital; and, though the scope of these examinations, undertaken for clinical rather than chemical objects, has been restricted to the narrow limits which other duties impose upon personal labour of this kind, a few results have been obtained, which are certainly of interest and may be of use to both chemist and Physician.

As one of these results reveals a condition of urine and response to reagents hitherto unnoticed, touches a question still discussed by physiological chemists, and suggests fresh trains of thought about the relations of the transformations of matter to the induction of disease, perhaps you may consider even this hasty and imperfect notice of the subject worthy of a place in your columns.

In searching for sugar with Trommer's test, one tints the urine with a solution of sulphate of copper,^(a) adds caustic potash in excess, and notes that the colour of the mixed fluids before boiling is, according to certain circumstances, one of the many shades of blue or green.

But in the course of my examinations I have found a good many exceptions to this behaviour of urine with solutions of potash and copper; and it is to one of these exceptions that I desire, through the medium of this letter, to request the attention of your readers.

In fifteen cases examined by me within the last few months, the urine became, after the addition of copper and potash, neither green nor blue, but of a very bright violet colour or of some shade of purple.

These cases were divisible into two classes. In the first class, the purple colour disappeared after an interval of from one to ten minutes: in the second class, the purple colour remained for many days.

All the examples of the second class contained albumen: those of the first seemed to have no condition in common, and were certainly not albuminous.

In order to discover the cause of this peculiar reaction, I selected the cases in which it was transitory, placed the patients upon a scrupulously simple diet,^(b) and made arrangements to secure examination of the urine fresh from the bladder.

Of the seven non-albuminous cases submitted to examination, one was treated for bronchitis, one for pneumonic phthisis, one for dyspepsia, one for rheumatism, one for

(a) Always for the sake of comparison used by me of one strength—10 grains to the ounce of water.

(b) Breakfast: Bread and butter, with half a-pint of tea. Dinner: Meat, bread, potato, and half a-pint of water. Tea: The same as breakfast. No supper. No stimulants.

hysteria, and two for chorea. All the patients were "nervous," and suffered in common from such lesions of sensation as fidgets, fornication, and subjective numbness.

All the specimens of urine were above the average density, below the normal standard of colour, intensely acid, and gave indications of the presence of small quantities of bile. After much time and labour fruitlessly spent in various directions of inquiry, I fell at last into a line of observation and experiment which led me to the object of my search.

The first fact which I discovered was, that specimens of urine which when just voided gave a purple reaction to Trommer's test ceased to do so after from two to ten hours' exposure to the air.

For the sake of comparison among my further experiments, I selected a man, 37 years of age, the subject of neuralgic rheumatism, whose urine became of a bright violet on the application of Trommer's test before boiling.

On boiling a drachm of this urine in a test tube, pouring it from one test tube to another till cold, and then applying Trommer's test, the mixed fluids became of a pale brown colour with a scarcely perceptible tint of purple.

To a drachm of the same urine I added a like bulk of liquor potassæ, shook them together in a test tube for a few seconds, and then added five drops of the copper solution. The mixed fluids gave no purple reaction, but turned at once to a light blue colour, which persisted.

It was evident from these experiments that the cause of the violet coloured reaction was owing to the presence in the urine of some volatile substance, which disappeared after exposure to the air, to heat, and the action of caustic potash. That substance was in all probability ammonia; and in the following, among other ways, I sought proof of this assumption:—

In a test tube over a drachm of freshly voided urine, which yielded the violet reaction to Trommer's test, I suspended a glass rod moistened with hydrochloric acid. Immediately white fumes were formed and fell into the lower part of the tube. When the employment of this test was varied by the application of heat to the urine or the addition of caustic potash, the white fumes were instantly formed, and were much more abundant and dense.

In a second tube containing a like quantity of the same urine which had fallen to the temperature of 70°, I suspended a slip of moistened turmeric paper. In a few seconds it became brown.

Into a third tube I put a drachm of the same urine which had been passed four-and-twenty hours before, and had ceased to yield a violet reaction to Trommer's test. On suspending over it a rod moistened with hydrochloric acid a scarcely perceptible white cloud was formed and fell slowly into the urine.

It became thus evident that ammonia existed in the urine, and was given off immediately after extrusion from the bladder at the ordinary temperature of the atmosphere.

And when it was found that the intensity of the violet reaction varied with the amount of ammonia present, and was not given when the quantity of this substance fell to the level of health, it seemed also certain that the occurrence of the one was owing to the presence of the other.

I attempted to estimate the quantity of ammonia in the urine and to determine the amount necessary to the development of the violet reaction. But the difficulties surrounding the operation were so numerous and so imperfectly overcome that I forbear giving expression to the result.

It is to be remarked that the violet reaction to Trommer's test is not produced either by the ammonia of decomposition or by the mere presence of albumen under any circumstance.

Into the second class of cases, linked together by the common presence of albumen, cases in which the capacity of yielding the violet reaction is not fleeting, and in which the colour, when produced, remains, I do not intend at present to enter.

I think I have said enough to show your readers that there is a kind of acid urine which becomes violet on the application of Trommer's test for sugar; that this colouration is due to the presence either of ammonia in considerable quantities, or of some volatile substance associated with it and given off at the ordinary temperature of the atmosphere, and that the only circumstances which as yet appear to be common to this, *the first class of such cases*, are the presence of bile in the urine and the existence of nervousness and of such disorders of sensation as fornication, flushes, and subjective numbness.

It is probable that these symptoms are due to some sort of renal dyspepsia, which leads to the transudation of albumen

into the urine; and that the decomposition of the albumen anterior to the discharge of urine from the bladder is the cause of the presence of free ammonia or of lactate of ammonia before the setting in of alkaline fermentation. Such inferences, however, require confirmation or correction by further observation and experiment.

I am, &c.

ANDREW CLARK, M.D.

P.S.—I have assumed, as a matter of fact, though still a matter of dispute, the existence of minute quantities of ammonia in healthy urine.

LEGAL INTELLIGENCE.

CENTRAL CRIMINAL COURT.—JUNE 8.

PROSECUTION FOR KEEPING AN UNLICENSED LUNATIC ASYLUM.

(Before Mr. Baron BRAMWELL.)

Mrs. SOPHIA LEANDER, of Zion House, Turnham-green, appeared on her recognizance to answer a charge of misdemeanour for having received into her house two or more lunatics, the said house not being a licensed asylum or duly registered to receive lunatics under the provisions of the 8th and 9th Victoria, cap. 100, sec. 44.

Mr. Montague Smith, Q.C., and Mr. Giffard were counsel for the prosecution; Mr. Serjeant Ballantine and Mr. Robinson for the defence.

The prosecution was at the instance of the Commissioners of Lunacy, who were appointed by Act of Parliament to superintend lunatic asylums and houses where lunatics are kept. About 1855 the defendant opened Zion House for the reception of women of diseased intellect. The institution was supported partly by voluntary contributions and partly by those of the friends of the inmates. At first it was conducted by a committee of ladies, but ultimately the whole management devolved upon Mrs. Leander, the defendant. The attention of the Commissioners was called to the establishment as early as 1857, and various visits were made to it by two of their body. They were at length of opinion that from the paucity of its resources the house could not be conducted as it ought to be. The law enacted that no person should be allowed to have more than one lunatic in his house, and if any one received two or more lunatics, unless the house was an asylum and registered, or unless it was duly licensed, he should be deemed guilty of a misdemeanour. Many persons having been received into Zion House, and the defendant not being able to comply with the requirements of the Act, the Commissioners felt it their duty to institute the present proceedings. They had no wish to injure the defendant, but it was necessary to put houses of this kind under the supervision which the Legislature required for the safety and protection of the unfortunate persons who were received into them.

Dr. Thomas Beach Christie, resident Medical superintendent of Pembroke House, Hackney, for the reception of lunatics, stated that on April 19, he went to Zion House with Mr. Lutwidge, one of the Lunacy Commissioners, and saw Mrs. Leander. He found about eighty persons in the house, and examined several of them. Among others were Julia Robinson, Sarah Medwin, Susan Gladman, Elizabeth Stuart, and Maria Burgess, the whole of whom he found decidedly of unsound mind.

On cross-examination by Mr. Serjeant Ballantine he said Mrs. Robinson was subject to delusions, which he considered to be unsoundness of mind. The distinction was difficult to be drawn between weakness of intellect and unsoundness of mind, but he was not aware of any case where a person not able to take care of himself had been refused admission to a lunatic asylum. Susan Gladman's case was that of a total loss of memory. She could not tell whether she had been in the asylum for years, months, or days. Burgess was a confirmed idiot, and totally incapable of understanding anything. Stuart was labouring under chronic mania, with excitement.

On re-examination, the witness said that Robinson's physiognomy indicated that she was insane, and he had not the slightest doubt that she was of unsound mind. With regard to Gladman, loss of memory arose from a diseased mind. He saw other inmates whom he did not know, and their state was that of idiots.

By the Judge: There was no definite line between a low state of intellect and idiocy,—where the one ended and the other began.

Mr. Thomas Martin, chief clerk in the office of the Commissioners in Lunacy, proved that Zion House had neither been registered nor licensed.

This was the case for the prosecution.

Mr. Serjeant Ballantine then addressed the jury on behalf of the defendant. The case, although one of great importance, nevertheless lay in a very narrow compass. He could not complain of the mode in which the prosecution had been conducted towards the defendant, who, whether she had violated the law or not, beyond all question had been actuated by no selfish or improper motive. She had been the active instrument of what he believed to have been intended to be a very valuable charity, and had endeavoured with all her characteristic energy to serve the unfortunate inmates of her establishment. The question, however, was, had she or had she not violated the law? Because, if she had, whatever her motives or her object might have been, she was amenable to justice. He agreed that it was the duty of the Commissioners in Lunacy to take care that no asylum should be improperly conducted, and to protect those who were unable to protect themselves; but there was a class of people very different from those regarded as lunatics or idiots, who required equal care. There was a vast number of persons whose intellects were dull, whose powers of appreciation were small, and whose memory was very considerably weakened—especially those who had suffered from the terrible calamity of epilepsy—who, without being insane or lunatic, were almost or entirely incapable of taking care of themselves. For these an asylum was wanted different from that which was suited to persons of unsound mind. The wealthy had no difficulty in finding asylums of that kind for relations who were unfortunately afflicted. There were advertisements in *The Times* daily of such asylums from one end of the country to the other; but nothing of the kind existed for the poor; for them there was no refuge but the workhouse, and it was for the poor that the institution in question had been established and carried on for many years. The evidence, he submitted, was most unsatisfactory. For the purpose of placing a person in a lunatic asylum the certificate of two Medical men was imperatively required, and the world knew what fancies and theories Medical men had upon the subject of insanity; but here was a case in which the Commissioners rested the whole prosecution upon the testimony of a single man. The learned serjeant urged upon the jury that the defendant had acted upon the honest belief that she was quite justified in the course she was pursuing, and that under all the circumstances she was entitled to a verdict of acquittal.

Mr. Baron Bramwell, in summing up the evidence, observed that the defendant was indicted not for doing anything which was wrong in itself, or which, for aught the jury knew, might not be praiseworthy in its way, but for disobedience to an existing law. They must be satisfied that the cases which had been mentioned by Dr. Christie were cases of insanity which brought the defendant under the operation of the law. For his part, although Medical men were often heard in courts of justice to define insanity and lunacy, he thought ordinary men of the world were just as well qualified to form an opinion on those matters as they.

The jury, after a short consultation, returned a verdict of "Guilty."

Mr. M. Smith, Q.C., said, as the object of the prosecution was to close the asylum, he would not call on the Court for any sentence if that point could be attained.

Mr. Baron Bramwell said the best way would be to hold the defendant in her own recognizances to appear at a future day if necessary, and then arrangements might be made in the meantime for the removal of the present inmates of Zion House.

The suggestion of the learned Judge was adopted, and the defendant left the Court.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The twenty-second annual meeting of this Society was held on Monday, the 7th inst., at the King and Queen's College of Physicians, Dr. Corrigan, President of the College, in the chair. The report, which was read by Dr. M'Clintock, was favourable, it appearing that, while there was no falling off in the subscriptions, upwards of £600 had been added to the funded capital, chiefly through the bequest of Dr. Kingsley, the honoured founder of the Society.

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE. — CAMBRIDGE. — EASTER TERM, 1864.—SECOND EXAMINATION FOR M.B. DEGREE.—The following gentlemen were examined and approved:—

Alfred Godson, M.A., Trinity College; H. W. Hoffman, M.A., Trinity College; E. T. Leighton, M.A., Caius College.

(Signed) H. T. H. BOND, M.D., Regius Professor of Medicine.
G. E. PAGET, M.D., Linacre Lecturer on Medicine.
W. W. FISHER, M.D., Downing Professor of Medicine.

MASTER IN SURGERY.—The following gentleman was examined and approved for the Degree of Master in Surgery:—

Alfred Godson, M.A., Trinity College.

(Signed) W. CLARK, M.D., Professor of Anatomy.
G. E. PAGET, M.D.
C. LESTOURGEON, M.A.
G. M. HUMPHRY, M.D.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary Examinations for the Fellowship, were reported to have done so, to the satisfaction of the Court of Examiners, and at a meeting of the Council, on the 9th inst., were admitted Fellows of the College:—

Claudius Galen Wheelhouse, East Parade, Leeds, diploma of membership dated May 25, 1849; Wm. Henry Folker, Hanley, July 4, 1851; Robert Brudenell Carter, Stroud, Gloucestershire, December 12, 1851; William Webb, Wirksworth, April 30, 1852; Alfred Cresswell, P. and O.S.N. Co.'s Service, May 28, 1858; Henry Wotton, Gloucester-place, Portman-square, February 18, 1859; William Travers, Charing-cross Hospital, April 17, 1860; James Beddard, Edgbaston, Birmingham, April 30, 1861; Arthur Wolcot Nankivell, Torquay, Devon, January 30, 1862; Bowater John Vernon, St. Bartholomew's Hospital, April 22, 1862; and Henry Willey, Poplar Hospital, November 19, 1862.

At the same meeting of the Council the following members, who had been elected Fellows at previous meetings of the Council, were admitted as such:—

Josiah Henry Selwood, Ampton-place, Gray's-inn road, diploma of membership dated November 27, 1829; and Charles Samuel Webber, Connaught-square, March 25, 1836.

LICENTIATES IN MIDWIFERY.—The following members of the College, having undergone the necessary Examinations, were admitted Licentiates in Midwifery, at a meeting of the Board, on the 8th inst.:—

Samuel Mills, Consumption Hospital, Brompton, diploma of membership dated April 23, 1863; George Oliver, Bourne, July 30, 1863; Chauncy Puzey, Surrey-square, Old Kent-road; William Cubitt Lucey, Bermondsey, January 26, 1864; Frederick William Richards, Winchester, April 26, 1864; Henry Viant, Tatton, near Southampton, April 26, 1864; George Benson Baker, Bayswater, April 26, 1864; John Henry Salter, Arundel, Sussex, April 27, 1864; Albert Camberbach Reade, April 27, 1864; William Akerman, St. Just, Cornwall, April 28, 1864; and Henry Todd Broughton, Bradford, Yorkshire, May 10, 1864.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, June 2, 1864:—

Edwin Bold Pearson, Yeaneley, near Ashbourne; Henry Viant, Guy's Hospital; John Foot Churchill, Poole, Dorset; John Henry Salter, Arundel, Sussex; David Martin Williams, Camborne, Cornwall; Edward Casey, King's College Hospital; George Haycock, 172, Hackney-road; William John Wey, Edgumbe-street, Stonehouse; Charles Edward Squarey, University College Hospital

The following gentlemen, also on the same day, passed their First Examination:—

Henry Denne, Guy's Hospital; John S. S. Perkins, Guy's Hospital; Algernon Ewen, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

DAVIDSON, A., M.B., has been appointed Resident Medical Officer to the Bradford Infirmary and Dispensary.

GIBSON, R. C., M.R.C.S. Eng., has been appointed Resident Medical Officer to the Jersey General Dispensary.

HATHERLY, Mr. H. R., has been appointed Dispenser to the Derbyshire General Infirmary.

MILES, George, M.R.C.S. Eng., has been elected House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

SUTCLIFFE, W. H., L.S.A., has been appointed Physician's Assistant to the Manchester Royal Infirmary and Dispensary.

DEATHS.

BEWS, JAMES HAMILTON, L.R.C.S.I., Staff-Surgeon Army, at Jersey, on May 8.

BRIDSON, JOHN, M.D., Edin, at Douglas, Isle of Man, on May 24, aged 39.
 BURGON, J., M.R.C.S. Eng., at Sydney, New South Wales, on March 3, aged 39.
 CLARK, GEORGE, M.R.C.S. Eng., at Coney-street, York, on May 22, aged 76.
 CLOUGH, CHARLES F., M.R.C.S. Eng., at Bawtry, Yorkshire, on May 20, aged 30.
 COX, ABRAM, M.D. Edin., at Berne, Switzerland, on May 26, of Kingston-on-Thames.
 KENNEDY, WILLIAM S., L.R.C.S.I., at Comber, Co. Down, on May 27.
 MASON, S., Surgeon, at Stockton, on May 13, aged 51.
 MURPHY BROWNELL R., R.N., at sea, on board the Cape Mail steam ship *Briton*, on May 28, aged 28.
 O'SULLIVAN, WILLIAM V., M.D. Edin., at Mohera House, Castlelyons, Co. Cork, on May 21, aged 48.
 PENNINGTON, JAMES, M.R.C.S. Eng., at Needham Market, Suffolk, May 6.
 SHIPTON, MARTIN N., M.R.C.S. Eng., at Clevedon, Somerset, on May 18, aged 70.
 SHORTEN, CHARLES, M.R.C.S. Eng., at Sudbury, Suffolk, on May 25, aged 45.

WE are requested to state, that in the pass-list of the Royal College of Surgeons of England, May 12, the name of Mr. J. Ruffe was accidentally omitted.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the College, held on Monday, June 6, the following gentlemen were elected officers for the ensuing year:—*President*—Arthur Jacob. *Vice-President*—Samuel G. Wilmot. *Secretary*—Edward Hutton. *Council*—William Colles, William Hargrave, Robert Adams, James Barker, Hans Irvine, Edward Hutton, Robert Pentland, Richard G. H. Butcher, Thomas L. Mackesy, Awly P. Banon, Peter Shannon, Rawdon Macnamara, Hamilton Labatt, Benjamin M'Dowel, Edward Ledwich, Willim Jameson, Alexander Carte, William Healy, and James H. Wharton.

THE INDIAN ARMY MEDICAL DEPARTMENT.—We hear that at length, after a vast amount of delay and numerous unfulfilled promises, Government, finding it cannot procure Medical officers for India, has determined to extend to the Medical service in that country the rates of pay provided in the warrant of 1858, in addition to the Indian allowances, according to relative military rank. We congratulate the Medical officers on this tardy instalment of justice.

THE GREAT NORTHERN HOSPITAL.—The annual festival of this Hospital was held on Wednesday, June 8, at the Albion Tavern, Aldersgate-street, under the presidency of Sir L. Palk, Bart., M.P. We are very glad to find that many of the difficulties under which this Hospital during its early progress laboured are now disappearing. In its new situation in the Caledonian-road, Islington, it appears to be receiving not merely local, but a considerable share of general support. A handsome subscription list of at least £800 was read.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on Monday, June 6, William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair, the Secretary announced that his Grace the President had nominated the following Vice-Presidents for the ensuing year:—William Robert Grove, Esq., M.A., Q.C.; Sir Henry Holland, Bart., D.C.L., F.R.S.; Henry Bence Jones, M.D., F.R.S., Secretary; William Pole, Esq., F.R.S., Treasurer; Major-General Sabine, Pres. R.S.; the Lord Stanley, M.P., F.R.S. William Acland, Esq., was elected a member of the Royal Institution. The Secretary announced the following additions to "The Donation Fund for the Promotion of Experimental Researches":—Sir Roderick I. Murchison (2nd annual donation), £20; Alfred Hooper, Esq., £10. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

A CHLOROFORM THIEF.—Many of the Parisian pharmacians have been the victims lately of a curious form of theft. A lady of demure and respectable appearance enters the shop, and, after sitting down awhile, presents a prescription ordering fifteen grammes of chloroform for external use, signed by a well-known Physician, the frequent stamps around its margin showing that it has very frequently been made up before. The chloroform having been weighed out, the lady asks permission to be allowed to smell the bottle, and while carrying it to her nose lets all its contents fall, as if by accident, upon her handkerchief, which she has ready prepared for its reception. Returning the bottle, and apologising for her clumsiness, while a new quantity is being weighed, she applies the handkerchief to her nose and mouth and freely inspires the vapour; so that when the bottle is brought to her duly labelled and sealed, she is found in a deep sleep. The pharmacien awaits for her awakening with real anxiety,

and then demands the price of his chloroform, but she can only reply by showing an empty purse, declaring that she has forgot her money. It ends with her being turned out of the shop.

PRESENTATION TO DR. MACKESY, OF WATERFORD.—Few among us have laboured with equal, none with greater zeal, or with such unwearied energy in advancing the honour and promoting the interests of our Profession, as the above-named distinguished Surgeon, and it is satisfactory to see that his eminent services are not overlooked by the governing bodies of the Profession, or by his brethren. Dr. Mackesy, having already had the honour of being the only provincial Surgeon ever chosen to fill the presidential chair of the Irish College of Surgeons, and having since received from the University of Dublin the honorary degree of Doctor of Medicine, was on Monday last presented, in the Albert Hall in the Royal College of Surgeons, Dublin, with a most gratifying testimonial of the esteem and gratitude of a large number (400) of his Professional brethren. The testimonial, which was accompanied with an address, consisted of a portrait of himself by the eminent artist, the President of the Royal Hibernian Academy, Mr. Catterson Smith, and of a very handsome epergne, the vase of which is supported by three female figures, emblematic of Faith, Hope, and Charity, "not inaptly expressing the virtues which adorn the Christian Physician," while the base bears a suitable inscription. The attendance upon this interesting occasion, both of town and country Practitioners, was very large.

IRISH MEDICAL ASSOCIATION.—The annual meeting of the Irish Medical Association was held on Monday, June 6, in the Royal College of Surgeons, Dublin, Dr. Mackesy, of Waterford, in the chair. Among the important points brought forward was the necessity of procuring superannuation allowances for the Medical officers employed under the Poor-Law and Medical Charities Acts. In connexion with this subject, Dr. Harte moved a resolution to the effect that Sir Robert Peel be requested to re-introduce his bill of last year. A communication received by Dr. Mackesy from the Director-General of the Army Medical Department, conveying the satisfactory information that the Indian Government has sent instructions to India that Medical officers shall receive the beneficial pay of the Medical warrant of 1858, and the Indian allowances of their relative military rank, was alluded to in the report; but Dr. Martin, of Portlaw, remarked that something more was wanted; that army Surgeons who served in tropical climates broke down in health very quickly, and that it was consequently desirable that they should have early opportunities of retiring from the service. He, therefore, moved the following resolution, which passed unanimously:—"That, as the Indian service is now under the Imperial Government, the probability is greatly increased of military Medical officers having to serve the regular routine of duty in tropical climates; they should, therefore, have the privilege of retiring on adequate superannuation allowances at the expiration of twenty years' service; and that our Council be requested to give early attention to this important subject, and that the co-operation of the Universities and of the Medical Colleges be solicited in the effort to obtain this just and necessary arrangement." It was also resolved that steps should be taken to procure an amendment of the Medical Charities Act, as under the present provisions of the latter the Poor-Law Commissioners have no power to limit the indiscriminate issue of dispensary tickets, which constitutes a great abuse of poor relief, and is an imposition upon the rate-payers.

THE ASCOT RAILWAY ACCIDENT.—We are happy to be able to state that up to last evening the wounded by this calamity were all doing well, and there are only two cases for the results of which fears are now entertained. The names of the two most severely wounded, and whose lives are still in jeopardy, are Mr. E. Trigg, publican, of 34, Market-street, Brighton, and Louis Ray, the person who was mentioned as belonging to the household at Marlborough House, and who, it seems, is apprenticed to one of the cooks in that establishment. This lad, who is only 18, had the fore part of both his feet crushed and lacerated to such an extent that amputation was necessary to save his life. Mr. Fergusson accordingly went down yesterday to perform the operation, which he did with his usual skill and success. The foreparts of both feet were removed by cutting up diagonally through the soles of the feet, so as still to leave the heels and ankle bones untouched. The boy refused to take chloroform, and bore the operation with the utmost

fortitude. Last evening he was doing as well as could be expected, though, of course, still in a most critical condition. Mr. Trigg remains at Charing-cross Hospital, to which institution, as we mentioned, he was removed at his own request on the night of the accident. Yesterday he was better, and consciousness had returned. In addition, however, to a broken leg and broken ribs, he has sustained some severe internal injuries, which makes the termination of this melancholy case more than doubtful. The company have already received notice of minor injuries to eight persons who were enabled to proceed to their homes, in some cases merely notifying the injury and demanding small sums for compensation, which were at once granted; in others only stating that such cuts or bruises had been suffered by them. Beyond these eight cases nothing had been heard yesterday, but, of course, it is known that a very much larger number have been hurt, though in every case the injuries are believed to be comparatively trifling. With the exception of Ray and Mr. Trigg, all the others, it is known, were enabled to come up to town and drive away from the station in cabs. The coroner's inquest will assemble to-day at Egham at two o'clock. The proceedings will be entirely formal, and will be opened merely for the purpose of enabling the jury to view the bodies before they are delivered to their relatives for burial. The Company asserts that when the inquiry opens, which it is understood will be in a week or ten days hence, after its formal opening to-day, it will be prepared to prove that the accident was not caused by any defect in the signals or any dereliction of duty on the part of the extra signalmen who were on that day specially employed at intervals of half a mile apart along the whole length of the line from Waterloo to Ascot. It may be satisfactory to the Company to prove that their organisation in this respect was perfect; but this will not in the slightest degree affect the main question of the liability of the Company in damages to all who suffered by the accident. Their having already compensated some of the sufferers who were slightly hurt is a fair proof of the opinion which they, at least, entertain of their own liability. —*Times*, June 9.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Prof. Helmholtz.—We have received a copy of the six lectures, but no further communication has reached us.

Dr. Coghlan, Wexford.—The paper is intended for publication, and shall appear shortly.

We are glad to find that Sir William R. Wilde's lecture on "Ireland, Past and Present," has been published in a separate form by M'Glashan and Gill, 50, Upper Sackville-street, Dublin. It teaches more of European ethnology, *cito and jucunde*, than many other books of ten times the bulk.

An Old Practitioner.—The condition of things described by "An Old Practitioner" no longer exists. The University of St. Andrew's requires residence for its ordinary Medical degrees, as do the other Scottish Universities. The University of London makes up for the absence of University residence and discipline by the great number and stringency of its examinations. A license to practise Medicine from a Corporation and a Medical degree are not identical things, and to confound them would be, to our thinking, to introduce a fresh element of confusion.

A CHEMICAL QUERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have a large quantity of solution of sulphate of copper. Will any of your numerous correspondents kindly inform me how I can most readily obtain the metallic copper from the solution? I am, &c.
June 8.

QUESTOR.

A PROFESSIONAL GENTLEMAN (?).

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Is the following line of conduct correct?—A Surgeon is called to attend in her confinement the wife of a clergyman, the incumbent of one of the poorest parishes in Southwark. At the termination of the case the lady herself puts into the hand of the Surgeon £3 3s.; her husband, not knowing this, gave him a cheque for £5 5s. more. The next day the following conversation takes place:—"Oh, Mrs. A.," says the Surgeon, "your husband values his boy at a higher rate than you did; your estimate is three, his is five guineas." Mrs. A.: "Indeed; what do you mean? for I know nothing about it." Surgeon tells what has been done, and Mrs. A. assures him that her husband's conduct was a complete mistake. However, the Surgeon assures her that both she and her husband had done well, as he would have charged £2 2s. more for attendance during the month.

I don't know whether it is usual in town to charge poor clergymen £10 10s. under the circumstances alluded to, but, if so, such men either cannot pay it, or must let their wives die for lack of attendance.

I authenticate this case by saying that the lady in question is my own sister. I am, &c.
Bolton-le-Moors, Lancashire, June 1.

F.R.S.

"JOHN HARVEY, M.D." ON CORPULENCY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to your notice of a pamphlet on "Corpulency," in your Journal of last Saturday, I beg to call your attention to the fact that the name of John Harvey, M.D., London, does not appear in the "Medical Register" of this year. I fear, therefore, this is only another instance of a barefaced attempt of some unqualified Practitioner to make money by what you very properly designate as "the popular Medical absurdity" of Bantingism.

I am, &c.

M.R.C.S.

DIGITALIS A SPECIFIC FOR DELIRIUM TREMENS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Not very long ago I read in the *Medical Times and Gazette* an account of some cases of delirium tremens which had been successfully treated with digitalis, which was heralded into the notice of the Profession as if it was something new in the treatment of that disease.

A few days ago whilst engaged in making some references the following paragraph in the *Dublin Medical Journal* for 1836, vol. 10, p. 149, arrested my attention:—

"*Digitalis a Specific for Delirium Tremens*.—Dr. Cless, of Wurtemberg, states that he had found digitalis purpurea to be a specific in the treatment of delirium tremens. Of thirteen cases of this disease, in which he administered the remedy, all but two recovered; these two had a relapse. The digitalis was given in strong infusion, in doses of a spoonful every two hours. After symptoms of narcotism have made their appearance recovery ensues.—*Med. Correspond. Blatt. & Gaz. des Hospitaux*."

June 3.

I am, &c.

ENQUIRER.

IODINE AS A DISINFECTANT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have sincere pleasure in responding to Dr. W. Williams's request, and in stating that without doubt the first application of iodine for the purpose of disinfection in the way he names was made by him. Dr. Williams first employed iodine in the form of tincture or solution in the treatment of fetid sores and suppurating glands, for which it—iodine—is the local remedy, and for the discovery of which as a remedy the Profession will always be grateful.

After Dr. Williams, Mr. Hoffman, of Margate, quite independently, used iodine in the solid or metalloïd form by placing it in a chip box covered with "leno" near to decomposing organic matters, as, for instance, in the bed of a patient in cases of sore or wound.

The only credit that is due to me is, that after experimenting on a large scale on iodine as a disintegrating and destroying disinfectant, I have suggested its widest application for Hospital and domestic purposes, and have been so fortunate as to obtain a public hearing on this method of disinfection, which, by the way, is so simple and certain that it must, in the end, become universal.

It often happens in science—in fact, it usually happens so—that any new method or discovery is attached to the name of the man who was able to utilise it, or make it known as a general fact; and Dr. Drutt, in his excellent and suggestive note, was only following the common impression in assigning the credit of the discovery so kindly to me. But as the discovery of iodine as a disinfectant is likely to be considered very important in the future, Dr. Drutt will, I am sure, excuse me for setting him right, and, I hope, will think the better of me for the correction.

I am, &c.

B. W. RICHARDSON.

TOWN versus COUNTRY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I believe the following case to be a very unenviable exception; I should be sorry, indeed, for the day to arrive when the Profession in London was likely to follow such an unfriendly example, to say the least of it:—Some days ago I sent up a patient to Dr. —, and with him a note fully entering into his early history and the treatment pursued during his late attack, asking Dr. — to write me a line at his leisure, stating his opinion of the case, and ideas of treatment. Not hearing from the Dr., I wrote to my patient, residing for the time with his family in London. In his reply he says, "You need not be surprised at Dr. — not writing to you, as it is his usual custom not to communicate with country doctors." In spite of my patient's explanation, I cannot but express the surprise of a gentleman at Dr. —'s "usual custom," and trust that the rest of the Profession will not readily follow it, for, apart from all other considerations, the previous history of a patient is often of great importance to the physician. I am, &c.

Farnham, June.

ROBERT OKE CLARK.

** We can assure our correspondent that it is the custom of all respectable London Physicians to reply to country correspondents; but we may express our wonder that a respectable country Practitioner should send a patient to such a person as he names.—*Ed*.

DR. DE LA POMMERAIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—During the trial of this homeopathist for poisoning his mistress, it surprised me much that greater stress was not laid by the defence upon the fact that the body was so fresh after the lapse of fourteen days; as also upon another fact, that the heart was contracted. When a student, one of the first things I was told was, that the muscular fibres of the heart were relaxed and the blood fluid in those bodies where death had resulted from digitalis, and that speedy decomposition always set in. Experience has taught me that the instructors of my youth were right in making this statement. I will give an outline of one case that occurred some years ago on the Continent. An Englishman, strong and in the prime of life, had rheumatic fever, which attacked the brain and caused his death. For two or three days previous to his death he had taken large doses of foxglove. Among other symptoms, such as fainting, sickness, etc., which occurred shortly before dissolution, there was hæmorrhage from the nose and bowels; and on making a post mortem twenty-four hours after death, the blood was found quite fluid and the heart relaxed; and so rapid was the decomposition that the funeral was ordered to take place immediately. The smell from the corpse, even in the cemetery, was so offensive that the mourners, of whom I was one, were compelled to hold their handkerchiefs to their noses. I, as well as all who were acquainted with the particulars of the case, attributed this unpleasant phenomenon to the action of the digitalis. Were we right in forming this opinion or not? I am, &c.

A. V.

THE DEBATE ON DR. BRODIE'S PAPER ON THE STATISTICS OF QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The report of my remarks at the Medico-Chirurgical Society on Dr. Brodie's paper on the statistics of Queen Charlotte's Lying-in Hospital is scarcely clear. I said the mortality of the Guy's Hospital out-door Maternity Charity for the 15,000 cases recorded during the last ten years was 3½ per 1000. In this, however, I overrated the mortality; it should have been 2½ per 1000. I said since I had been attached to the Hospital I had not seen in the Maternity any cases of puerperal fever, properly so called—if, indeed, it exists as a distinct disease. All the cases which had been traced out arose from some zymotic disease in the same house. That there had been in the 15,000 cases only twenty-five of severe so-called puerperal fever, which included puerperal peritonitis, puerperal pyæmia, metritis, and their varied combinations. Of these half had died, making only about twelve deaths in the 15,000 cases. No doubt minor forms had occurred, but not of such severity as to give anxiety for more than a few days. The good results thus obtained I considered were in a great degree owing to the care observed in separating the attendant in any case where severe puerperal illness occurred from any further attendance on others till the nature of the disease was properly declared. Students dissecting are not allowed to attend labours. I remarked that, however contagious some forms of puerperal disease undoubtedly are, it was a curious fact that in two instances a student put to bed upwards of twenty cases, whilst attending a severe, and afterwards fatal, case of puerperal arthritis pyæmia without communicating that disease to either of the forty. I asked, in the event of an illness occurring at the charity in question, whether the nurse was kept entirely to the sick patient, as I considered that the best plan, when an illness threatened to confine the original attendant entirely to that case, obtaining a fresh one for the others. I may add, where possible, the same rule should be applied to the Medical attendant or midwife in such institutions.

I am, &c.

9, St. Thomas-street, London-bridge.

The Camberwell and Peckham Ratepayers' Association defended against the Camberwell Vestry. By George Clifford. Peckham: Foster. 1864.

* * It is something new to find an Association of Ratepayers demanding a more energetic sanitary action from their vestry. This pamphlet contains some excellent remarks, which we quote:—

"Every Medical man is indeed an officer of health in the families he attends. If the women and children are subject to low fever, and he finds an open drain near the house, he recommends them (often to his own loss and inconvenience) to remove to a more healthy district. If he remarks a tendency to diphtheria, diarrhoea, etc., in a family, he asks if they suffer from bad smells, and recommends them to have the sewers cleansed and the drainpipes trapped. What the private Practitioner is to the family, the Medical officer of health is to the aggregate of families which make up the parish.

"Here and there, it is true, may be found an ignorant and bigoted Medical man, who refuses to recognise these 'new-fangled' doctrines, and is slow to believe in deaths from bad drains. But, as a rule, the Medical Profession deserve infinite credit for the enlightened and disinterested aid which they have given to the work of sanitary reform and improvement. It is not doubted that many Medical men practising in Camberwell are called upon to visit unhealthy districts within the parish, and have a strong opinion upon the sanitary remediable measures they require. In so large a parish many causes of sickness, disease, and death doubtless exist, which may have escaped the notice of the parish authorities, but which are perfectly well known to some of our Medical men.

"The Ratepayers' Association respectfully entreat the co-operation of the Medical men in their design of laying before the parishioners an exact and truthful account of the health, sanitary condition, and mortality of the parish and the causes which lead to an excessive death-rate in particular districts.

"The Association will consider these communications from Medical men as confidential. The names of the writers will be published or withheld as they may desire. It is proposed to refer their reports to a sub-committee of the Association, who will digest the above and any other information from general sources which may reach them relative to health and disease within the parish.

"The Association hope by this means to obtain a body of reliable and unanswerable testimony, which, it is unnecessary to point out, will greatly strengthen the hands of the Medical officer in any measures which he may in future feel it his duty to recommend for the sanitary improvement of the parish.

"Communications from Medical men in the parish and neighbourhood are requested to be addressed to the Chairman or Secretary of the Ratepayers' Association."

We hope the Medical Practitioners of Peckham and Camberwell will heartily comply with the wish of the Association.

The Twenty-fifth Annual Report of the General Hospital and Dispensary for Sick Children. Manchester: Printed by Thomas Sowler and Sons, St. Ann's-square. 1864.

* * The most interesting part of this report is the table showing the result of the cases in death or recovery in the several diseases treated. We would suggest, as an improvement in future reports, that not only the age of the patients on admission should be tabulated, but the mortality at each age also, viz.: under 12 months, under 1 year, under 2 years, under 3 years, under 4 years, under 5 years, under 10 years, and at 10 years and upwards. This would make the tables a little longer, but afford the sort of information which it is most desirable that the Dispensary should supply to the Profession.

Annual Report of the Cambridge University Natural Science Society. 1863.

* * The establishment and success of this Society is a matter on which we heartily congratulate the University of Cambridge. A portion of the report before us is devoted to discussing the desirableness of some of the College Fellowships being attached as a reward to distinguished acquirements in natural science. Undoubtedly a natural sciences tripos would appear to demand some such redistribution of the material advantages which the University confers on its most learned members.

APPOINTMENTS FOR THE WEEK.

June 11. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Alexander Herschel, Esq., "On Falling Stars and Meteorites."

13. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

14. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Toynece, "On Sebaceous Tumours in the External Auditory Meatus." Dr. Dick and Mr. W. Adams, "On Subcutaneous Incision in Stricture of Urethra." Mr. E. Barker, Jun., "On Progressive Atrophy of the Tongue."

15. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.

16. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; West London Hospital, 2 p.m.

17. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

HUBBUCK'S PURE OXIDE OF ZINC.

Sold by the London Wholesale Druggists, in Boxes, 14 lbs. each, stamped by the Manufacturers.

DINNEFORD AND CO, PHARMACEUTICAL CHEMISTS,

Beg respectfully to inform the Medical Profession that they are now Dispensing Physicians' Prescriptions with the

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "*Pharmaceutical Journal*," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "*Times*," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

THE ORIGINAL CHLORODYNE.

INVENTED AND MANUFACTURED, IN 1844, BY RICHARD FREEMAN.

By the decision of Vice-Chancellor Sir W. Page Wood, R. Freeman is entitled to the SOLE right to use the word Original as a prefix to the word Chlorodyne.

The large and still-increasing demand which the Inventor has for this therapeutic is evidence of the high estimation in which its properties are held by the Profession generally; and on a recent occasion a number of eminent London Physicians and Surgeons of long standing in the Profession, and who hold public appointments, made affidavits to the fact that Freeman's Original Chlorodyne is a more certain and reliable, a more valuable and a preferable, preparation to that of any other maker's. It is offered to the Profession as the best preparation of the kind, and at a price which allows the poorest sufferer to enjoy its extraordinary beneficial effects.

MANUFACTURED BY THE INVENTOR,

RICHARD FREEMAN, PHARMACEUTIST, KENNINGTON-ROAD, LONDON, S.;

And Sold by all Wholesale Druggists, in Actinic Glass Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d. each.

ORIGINAL LECTURES.

LECTURES

ON THE

PROGRESS OF SURGERY DURING THE
PRESENT CENTURY.

DELIVERED AT

The Royal College of Surgeons,

By Professor FERGUSSON.

LECTURE II.—WEDNESDAY, JUNE 8, 1864.

MR. PRESIDENT AND GENTLEMEN,—Bearing in mind the intentions expressed in my first lecture regarding the subjects to be selected, I propose to-day to refer to one in which I have been long and deeply interested. That which has largely filled the mind throughout professional experience, and which has gained strength by years, naturally takes a foremost place. The grand object of Surgery is to cope with injury, and to cure disease. All professional men agree on this point; but there is considerable variety of opinion as to the means of accomplishing the end, and as to one form of cure being better than another. Patients, ignorant of our resources, say, "Give us a cure; that is all we want;" but some of us are critical, and think upon the kind best suited to the circumstances. We reflect upon the nature of the accident or disease, its probable issue, how long it may be before a cure can be expected; and that being realised in our anticipations, we think further of the patient's probable or possible condition when it is declared perfect. Here it may be said that we at once touch upon the grandest features of high Surgery. With a full philosophical reliance upon the powers of Nature, and a wonderfully accurate knowledge, gained from experience, of what she is likely to do in any given case, we take upon ourselves the task, at one time of waiting on Nature, but perhaps as frequently of guiding her,—it may be gently, or it may be with rude force, and still with reliance,—that she will not fail to do that which we desire, and so expect a cure which shall be beyond doubt better than that which she might bring about when unaided by human skill. To wait upon Nature is an easy task, compared with that in which we attempt to guide or coerce her. Few men are more disposed than I am to give full credit to Nature; but I believe it to be the mission of Surgery to struggle with her when she is in error, and he who does this most successfully is the greatest master of his art. As with many other things in social life, the ways of Surgery get grooved; they are hallowed in the estimation of some; because our grandfathers did so and so, it is often alleged that *we* cannot do better. Although our grandfathers were our seniors, it is overlooked that we are living at a date when the world is older by two generations. The man who steps from the groove is often held to be rash, and there are more to applaud the common wayfarer than to approve the conduct of one who may seem to doubt the entire wisdom of his ancestors, and who wishes to test, by rational experiment, if he can or cannot improve upon the known order of things. Who can say that we have reached finality, even in the grandest conceptions of the human mind? and who, when seriously questioned, can say this of Surgery? The vast additions to our resources within the present century show how far Surgery was behind sixty years ago; may it not be that additions equally great shall come within the next sixty? One thing is certain, that unless some men strike from the beaten track, improvement and addition can hardly be expected. I have known Hospital Surgeons say that they should like very well to do this thing or that, provided it would prove to them practical. Supposing all Surgeons alike in this respect, we should never get the proof. The man of inquiry may have at least three objects distinctly in view, when he digresses from beaten paths. He may wish to produce positive novelty, or to get proof that a certain practice is so good that it should be more largely followed out, or so bad that it should be positively abandoned.

Revivals are rarely attended with success; yet great results occasionally follow; and I cannot refer to a more striking instance than that of the treatment of aneurism by compression. Thanks to the courage and good sense of Dr. Hutton, of Dublin, a practice virtually abandoned was again brought

practically under our notice; thanks again to him, and his fellow-labourers in that city, it was shown to be of the greatest value. We often talk of schools of Surgery; and, without discussing the worth of the term, I may say for that of Ireland that no brighter emblem is associated with any other in these islands. Here was a revival, which set aside the use of the knife, in a large number of instances where it was thought indispensable, and a practice reintroduced, based upon principles almost identical with those which have been gradually developed since Hunter tied the superficial femoral artery for aneurism of the ham. Who among our fathers or grandfathers could have imagined that pressure was yet to become so valuable? and who among ourselves, ten years ago, supposed that a popliteal aneurism could be cured by the pressure of merely flexing the leg on the thigh? A simple mechanical process, indeed, yet founded on some of the best Surgical reasonings which we possess. Looking to the old age of Surgery, and the great men who have worked in the field, it is easy to perceive how rarely it must fall to the lot of any one to devise that which is new and also good. Even in such an instance, the worth of the novelty is seldom accurately appreciated. The story of Parè and the ligature is familiar to all who know a little of our Profession: may not a similar remark be made at some future day regarding Professor Simpson and acupuncture? It actually seems to have escaped observation that even our great idol himself, John Hunter, scarcely was aware of the full value of his operation, while it was derided and opposed by those in high places. Hunter spoke modestly and hesitatingly of his own opinions; Bloomfield and Pott gave them their decided opposition. Bloomfield, a leading Surgeon of the day, used the following words:—"An extravagant proposition has been suggested by some people to tie up the principal trunk of an artery in the extremities. I once saw an attempt of this kind in a true aneurism of the ham, on which I shall only remark that the patient died; and I do believe that the embarrassments that occurred, as well as the event of the operation, will deter the gentleman (meaning Hunter) who performed it from making a second attempt in a similar case." Such was the language held regarding the greatest philosopher in Surgery, and regarding the views and actions that led to the operation, which, in my opinion, contributed more to the brilliancy and progress of modern Surgery than any other that I can name. With such examples as these, let no man who has common sense on his side be daunted by the cry that Surgery is in danger when novelty is proposed. Good is likely to come out of honest labour, although the best hopes may be disappointed; and as fair instances of the kind, I may remind you of the operations of tying the abdominal aorta and the arteria innominata. A caviller might ask the value of these heroic proceedings, as death had followed in every instance. My answer is, that they may now be taken as important precedents that such proceedings should never again be attempted in the human body. Happily, men are found in every generation who do leave the beaten track, and their labours are looked upon with greater interest than those of others, for they are emphatically the men of the time; their doings in a manner instigate, invigorate, and regulate the practice of the day; and when they are gone, if even a footprint be left, their names will stand prominent among those who have contributed to the advancement of Surgery.

Among various characteristics of modern Surgery, I shall now venture to draw special attention to a field in which I have myself been a humble labourer. To save life and limb is a grand feat; it may be said to be the highest reach in Surgery. There is a stronger feeling abroad at the present time than when I was young that amputation should be avoided by every possible reasonable manner. Whilst watching on my own account I perceived around me indications that others as well were thinking on this subject, and already proof had been given that the amputating knife was no longer necessary in many instances like those where it had previously been freely applied. That such a result has finally come about no one can hesitate to admit; and as a familiar illustration, I may at once refer to the treatment of disease of the elbow-joint. If synovial membrane, cartilages, and bones seem irremediably affected, or, in other words, beyond hope of cure within reasonable time, instead of performing amputation, the tissues chiefly affected are removed by a local operation, and fore-arm with hand are left so little affected that the limb may ultimately, as has often been proved, be nearly as useful as its fellow. I feel almost ashamed to bring forward such a common-place illustration, as every well-educated Surgeon of the present day must consider it; but I

do so on purpose, for it is one which defies contradiction, and it is almost entirely a development of modern Surgery. The original suggestion of Parke, and its realisation by the elder Monro, produced but little effect either in this country or abroad, notwithstanding the clear manner in which they were brought before the Profession in 1806 by Professor Jeffray, of Glasgow, and it was not until the operation was taken up by Mr. Syme that it attracted any serious attention. Although claims have been put in for others leading the way in this direction, I cannot admit them as worth much consideration. Some of these cases are of mythical character. Those who dealt with them may be likened to the original settlers in Australia, who made roads and built bridges of the quartz in which gold abounded. Both were ignorant of the precious things they had in hand. I may refer to Sir Philip Crampton as one who zealously demonstrated the value of this operation; but even his influence would have been but little, and it was left for the energy of Mr. Syme, at the Surgical head of a great school, to place this operation on a sure footing, with a character of usefulness unexcelled in the range of Surgery.

But this is only one of the examples in which in modern times Surgery has triumphed in setting aside amputation; and to illustrate my present task, I must glance, although rapidly, at additional instances of success in this direction. I believe it to be a common opinion that when a piece of bone is bare or a joint grates there is no probability of recovery in the part, and that amputation is the proper course. This, however, is a great error, for bare bone is covered again in many instances, and a joint may still be so far restored that there may be a certain amount of motion in it; or, if not, there may still be a cessation of disease with a useful member. Even when bone is dead Nature causes a separation, and thus leads the way to its removal, either by spontaneous evolution or by the hands of the Surgeon, so that a limb may be retained with much of its original appearance.

These things are so thoroughly understood by most well-educated men of the day that it may seem strange to allude to them; yet my own experience has told me that fingers and thumbs, ay, even larger limbs, are frequently sacrificed, when a little waiting and judicious management might bring about a result far more creditable to Surgery and advantageous to the patient. It may seem to many almost beneath the dignity of my present position to bring such a case as this before you. A gentleman of active habits, and in charge of a large establishment, to whom the use of the pen was of vast importance, had a bad whitlow in the end of his right thumb. An abscess was opened in due time, when the distal phalanx was found bare. Amputation was thereupon urged, but the patient objected. He was then, on taking another opinion, advised to wait a little. In a few weeks the bare bone, consisting of about one-half or two-thirds of the phalanx, was removed by forceps through the original opening for the abscess, and ere long the thumb, seemingly entire, was as useful as it ever had been. There is the east of the thumb itself. Let me add another case. A shoemaker—shall I say, to make the case more interesting, a son of St. Crispin, a great cutter in his way?—had a thumb similarly affected, and he, too, was recommended to have amputation performed; but a dead bit of phalanx was extracted here also, and he, like the other patient, rejoices in a useful thumb to the present day. I might recite many similar cases, but doubtless most of you here have had experience of the kind. If so, you will think with me that amputation in such cases is not required, and that when done it is a deplorable example of meddling, bad Surgery. It is in reality because I have seen so many cases of error in this direction that I have made so bold as to bring them under notice in this theatre, where naturally only the so-called grand things in Surgery may be expected to be spoken of. Opinions may differ; but, for my own, I deem it a grand thing when by patience even the tip of a thumb can be saved. I have the additional reason, too, for alluding to such cases, that they serve to illustrate a kind of practice in which I have for two-thirds of my experience as a practical man been deeply interested, and to which I have ventured to give a name, as if it were a special department in our Profession. With a conviction, founded on practical experience, that many limbs and members had been sacrificed by amputation which might have been saved, that deeds had been done which, on a superficial glance, seemed as high art in our Profession, when in reality they were indications of weakness, being the very opprobria of our calling, I ventured to draw attention to such matters in a paper in the *Medical Times and Gazette*, published on January 3, 1852, wherein I first made

use of the term Conservative Surgery. It would, indeed, be arrogation were I to affect being the first in such a field of practice. In the paper referred to I showed how others had been before me; and it may be truly said that all Surgery is conservative, its grand object being to save limb and life; yet the phrase was new in Surgery, and was used in a particular sense, which it is partly my object to explain in this lecture. It is, indeed, with feelings of pride that I see and hear it used so familiarly. It is now a part of our common nomenclature. It is often in the mouths of those who know not its origin. It is used by military Practitioners as well as civil; it has become familiar in our provinces and colonies, and has resounded even from the Antipodes. It was in a manner hallowed when used as applicable to the practice of one of the last departed of our greatest worthies, Sir Benjamin Brodie; for the author of a memoir of that Surgeon thought it a high compliment to state that his practice was eminently conservative. Even now I know of no instance better illustrative of the subject than that which I described from Sir Benjamin's practice, in the paper alluded to. The memorable instance in which he amputated a leg for incurable pain in the tibia is one of the beacon lights of Surgery never to be forgotten. It was, if I mistake not, the model case on which all our modern ideas about abscess of bone are founded; and the pathological examination of that limb led to a line of practice of inestimable value, which even to the present day is, I imagine, scarcely appreciated at its full worth. Brodie saw that intolerable pain had been caused by a deep-seated abscess in the tibia, where the matter could find no escape. In the next case of the kind which came under his notice, he bored an opening in the side of the bone, gave exit to the matter, and so relieved the patient of pain, and, whilst curing his malady, saved the limb from amputation. The example has been followed again and again, and with great advantage; and I repeat that I know not even now a better illustration of conservatism in the whole range of practical Surgery. The operation was scarcely known when I began the Profession, and I confess that it was not until I had been many years in practice that I appreciated it at its full value; and in particular, to show to what it was, in a manner, the key, it led me to reflect on other instances where local operations had, or might have sufficed for, the sweeping mutilation of amputation; and I threw together a number of examples, wherein, after removal of parts locally, and even extensively, useful limbs had been retained. And thus I felt that the so-called opprobrium of Surgery, amputation, had in these cases been successfully set aside. As years have rolled on, this line of practice has been gradually developed into a kind of system, and many modern Surgeons are more proud of the number of members and limbs they can refer to as saved in this way, than others are of the comparatively common-place operation of amputation. Let me say, in extenuation of this expression, that no one can more thoroughly appreciate a well-performed amputation than I do; but I certainly appreciate more highly the operation which sets aside the necessity for that mutilation.

Since my views on conservative Surgery were first disseminated, I have observed with regret that some have alluded to the term without having a proper appreciation of its meaning. To treat a fracture in the ordinary way, to cure an ulcer, to deal successfully with a chancre with or without mercury, have been alluded to as examples of this sort of practice. Surgery is emphatically preservative or conservative in such cases; but the phrase was coined and used as applicable to a line of practice whereby the loss of a limb might be averted, and the meanest act of Surgery, namely, amputating a limb for a seemingly incurable local disease, might be superseded by a more perfect adaptation of Surgical science and art. I certainly should not presume to address you on this subject were it not that I have a strong conviction that Surgery has made great strides of improvement in this direction within the period of time to which these lectures are chiefly confined. Again I repeat that this kind of practice cannot be considered new—every saving act of Surgery may be so denominated—but the phrase in modern times has a peculiar significance, for it is meant to show that, instead of the sweeping and radical measure of total separation or amputation, a compromise may be made, whereby the original constitution and frame, as from the Maker's hand, may be kept as nearly as possible in its normal condition. When Hunter tied the superficial femoral artery for popliteal aneurism, he did a great act of conservatism. Here are his very words, in referring to amputation for aneurism in the ham, and to the old operation, which Pott objected to, owing to the state of the artery near

the disease—"Why not tie it up higher, in the sound parts, where it is tied in amputation, and preserve the limb?" His object was to avoid amputation; and he then initiated a long and successful career in that direction. It was a vast idea, and a vast triumph for the time.

But, instead of thus in a manner reiterating, let me rather bring forward modern illustrations of conservatism to show the sense in which I wish the term used. At first sight it may appear that in dealing with tumours, when the knife is applied, there is no room for such practice; yet here even I believe it to be peculiarly applicable. There is a poetic fallacy regarding the skilful Surgeon who boldly cuts beyond the seat of disease, by way of making sure of its eradication, which should have no consideration with the good Pathologist. Whilst, doubtless, this maxim is safe in cancers, I believe it to be fraught with great mischief in most other cases; and some of the finest things in modern Surgery are done seemingly in the very midst of disease. As illustrative of this, I may refer to excision of joints. A feature of these operations is that they are done in such locality. Here we see the difference between ancient theory and modern fact. There is no need in such instances of making sure that all the incisions are beyond disease. The articular surfaces, possibly some portions of the ends of the bones, are the really incurable parts; and if these are once removed, the surrounding swelling, which to the eye of the ignorant will appear as the chief disease, will soon diminish, and ere long pass away. Yet what monstrous mistakes have been made on this very point! Limbs have not only been amputated, but amputation has been performed far higher than needful, because of the mistaken idea that the knife must sweep away all semblance of disease. It may seem strange to many here that I should refer to such a subject, for they will say, "Who can be ignorant about it? Who has not seen the elbow-joint taken out from the midst of great swelling?" But there are many who have not yet seen even the elbow-joint taken out, and many who imagine that great surrounding swelling is a bar to such an operation. Here is the cast of an arm on which one of the earliest excisions of the elbow in London was performed. I say this advisedly, for twenty years ago the operation had not been performed a dozen times in this metropolis. The excision was done in public, and many of the on-lookers were amazed at the seeming folly of the practice. Only the articular extremities of the bones were taken away. Immediately after the operation the swelling seemed well nigh as great as ever, yet see from this other cast what a change took place in a few months. I believe that there are few doubts now on this subject as regards the individual locality; yet how many will deny the doctrine as applicable elsewhere! Are there six Surgeons in England who have amputated at the knee for white swelling? Is the scrofulous swelling round the diseased ankle—the foul ulcers and sinuses similar specimens—not even yet considered as serious, ay, insuperable, objections to amputations at that joint? And has it not been proved beyond doubt that the sinuses and ulcers close and the swelling subsides soon after the diseased articular surfaces are removed, as illustrated in such specimens as these?

In the removal of tumours which are prominent on the surface, it is a common practice to include an elliptical portion of the skin. Now, except in certain instances of cancers, where this texture is involved, and with a few other rare exceptions, I consider this to be a great error. For cysts on the scalp of, or above, the size of a walnut, this practice may be said to be the rule; yet the loose bag of scalp, if one is left, will very speedily contract to its natural dimensions, while, if an ellipse is taken away, there is apt to result a broad white furrow. In removing an enlarged testis the custom is to take away a portion of skin too; yet the scrotum is so contractile that soon after, although only a slit may be made in the skin, it may appear less voluminous than even on the untouched side. The example of contraction of skin in this locality is well exemplified in many instances of enlarged hydroceles, where after radical cure the scrotum soon assumes its normal size. It is seldom, indeed, that I remove any portion of the skin, where it is merely stretched and attenuated over disease; but here is an example to show the disadvantage of taking away a portion of merely over-stretched skin. This large tumour was removed by Mr. Liston in the Royal Infirmary of Edinburgh, shortly before he left that city for London; and in all my experience I think I never saw a more brilliant operation. Such a proceeding was then both novel and rare, and to the present time it is the largest growth of the kind in this locality that I have ever met with. A few minutes sufficed for the

operation, and the patient made a rapid recovery. But mark the history in this respect. The mouth was so drawn to one side, and the skin seemed so over-stretched, that the operator was induced to take away an oblong strip, about an inch or more in breadth,—not much, most would imagine, for the size of such a tumour as that—the stretch extending from the mouth to the temple or zygoma. The sides of the wound, from the angle of the mouth upwards, came nicely together at the time; but the skin contracted rapidly to its normal state, and union did not take place. At last there was left a large gap, extending from near the angle of the mouth up the cheek to the temporal region, ay, and the side of the nose, which exposed the tongue and lower part of the mouth as you see represented here. By the kindness of Mr. Nasmyth, of Edinburgh, I am enabled to show these illustrations. That gentleman by ingenious mechanism contrived to fill up the gap, and improve the poor woman's appearance.

When a part of the body is dead, or incurably diseased and must of necessity be removed, I am of opinion that conservative Surgery may be displayed in a variety of ways. The examples already quoted of caries, of necrosis, of diseased joints, and as regards over-stretched skin, are so palpable, that few will object to their being thus characterised. Operations on tumours of the jaws may be said to be performed to relieve distress, to obviate deformity, to give future comfort and immunity from further disease. A feature insisted upon by Professor Lizars, with regard to the operations on the upper jaw, was that the whole maxilla should be removed. Now, further experience has shown that in many instances no such extensive measure is required. The removal of the actual disease, wherever it may be, is all that is essential in such instances, provided the tumour is not malignant, for then even the removal of the whole bone is a questionable step. In these operations we can have conservatism, as regards preservation of parts and preservation of appearance, of both of which I hope to give you proof as we proceed with these lectures. In operations on the lower jaw conservatism may be, and is, displayed in a manner to which few give much heed; but I beg your particular attention to this fact,—that tumours of great size have been removed from this bone; the whole of one side thus implicated has been cut away by incisions across the bone, and the portions left have remained healthy throughout life. I myself have taken away, by a horizontal incision, as much of the lateral margin of this bone as sustained ten teeth; yet there was no return of the tumour, for which the operation had been performed. In the last of these proceedings there was conservatism, in not interfering with the base of the bone, and thereby preserving the face or chin from considerable deformity; in the first there was the like display, in not cutting away more than was necessary. How few have reckoned on the value of cases like these, as showing that in tumours of osseous tissue it is not necessary to remove the whole bone! Yet such a doctrine of destruction has got strangely, and, in my opinion, alarmingly prevalent. If a tumour shows in the tibia, even at the lower end, supposing amputation to be decided on, there are many who maintain that the operation must be performed on the thigh, for if any of the bone be left it would sure to be the seat of a return of the disease. The same doctrine is applied to the femur, and to every long bone; yet there are no just grounds for such a doctrine. Besides the instances to the contrary which I have already given, I may say that when disease does return after amputations for such tumours, it is seldom in the bone, but most generally in the soft parts, and often too at a considerable distance from the original seat of the disease. It is implied that there is a peculiar circulation in a long bone, whereby, if disease be removed by amputating one end only, the vessels will be sure ere long to work in a similar manner in the end that is left. Now, as your Professor of Human Anatomy and Surgery, I protest against this doctrine; there is positively nothing in anatomy to support it, and I can hardly admit a single instance in pathology; for where disease has shown itself in bone, after excisions or amputations, I am more disposed to think that there has been some of the original malady left than that the vessels in the remaining part have imitated the action of those concerned in the development of the original tumour.

But time warns me that I cannot dwell much longer on such topics at present. Suffice it to say that modern Surgery has given us plenty of instances to show that tumours may be taken from bones, involving the whole thickness thereof, so as to admit the preservation of a useful limb, and where disease has not returned. As examples of conservative Surgery, I may

name the varied cunning operations performed on the fingers and portions of the hand to keep that important organ as entire as possible. On the foot there are many of a similar character. The partial operations on the tarsus, by scooping out portions or removing the whole bone, such as the scaphoid are pleasing examples of this style of Surgery. Possibly in these days we have rather overlooked the vast merits of Hey's or Chopart's operations; and who can doubt the conservatism and advantages of amputation at the ankle by Syme's method, or that of Pirigoff, compared with the palpable mutilation of amputation in the leg?

But should there yet be doubt about what I mean by conservative Surgery, let me, in concluding this lecture, give you these further illustrations. Mott, Warren, Syme, and others have removed the whole of the clavicle, still preserving a useful extremity; and as further illustration of the practice of removing portions of diseased bone with good effect, I may refer to the instances recorded by Travers, Luke, South, and others of partial operations on the scapula. Here is a tumour, when entire, between ten and twelve inches in circumference, which involved the lower angle of the scapula, in removing which I sawed the bone across. Two years have nearly elapsed, and there is no appearance of return. Mr. Liston, in 1819, removed three-fourths of the scapula for a vascular tumour; the disease did return in the bone in that instance; but the operator could get no one to sanction the removal of the whole bone, with the arm, and half of the clavicle, although there was a kind of precedent for this in the instance in which Mr. Cumming, in 1808, amputated the upper extremity of the shoulder-joint, and removed the scapula immediately after. The project of removing the entire scapula, and leaving the rest of the upper extremity, was happily realised by Syme in October, 1856. The patient, about 70 years old, survived nearly two months, sufficiently long to encourage good hopes for future cases. In May, 1858, Mr. Jones, of Jersey, performed a similar operation; the whole scapula was removed, and the limb was preserved. Six years have now elapsed, and the patient lives in excellent health, with a useful limb. Here is the sketch of her figure from a photograph recently taken. In November, 1860, Mr. Syme removed the head of the right humerus, for a tumour, with the view of avoiding amputation at the shoulder-joint, which he felt would be required, if the growth were allowed to increase. A year afterwards some indications of further disease were evinced on the upper and back part of the shoulder; and so alarming did the symptoms appear that he recommended the removal of the scapula and the arm at the same time. The patient at first declined such an operation, but was not long in submitting to whatever the Surgeon might think best. The happy idea struck Mr. Syme that he might remove the scapula by itself, as with his former patient. In November, 1862, the scapula, with a portion of the clavicle, was removed by that enterprising Surgeon, the diseased mass weighing between four and five pounds; and in January of the present year, 1864, Mr. Syme reported that the patient remains in perfect health, with a wonderfully useful arm. Here is his figure, represented as but little distorted, considering the loss of scapula, the upper end of the humerus, and a portion of the clavicle. He is in the act of holding up a heavy chair with the preserved limb, to show the vigour still retained. Looking to the fact that this man had already lost the head of the humerus, the case seems to me the *ne plus ultra* of conservative Surgery. Contrast it, I pray you, with those recorded of total removal of the scapula and upper extremity recorded by Cumming, Gaetani, M'Lellan, Rigaud, myself, and by Mr. Syme. Great though these may be, as regards the magnitude of each operation, the cure of disease and the saving of limb, I decidedly give the palm to the operations of Syme and Jones. Here is a sketch of my own case of removal of the scapula, after the arm had been amputated at the shoulder-joint by some rash hand before. The loss of the arm seems deplorable, and looking at the case as having occurred some fifteen years prior to the operations of Syme and Jones, the contrast between these pictures speaks volumes in favour of the progress for which I now plead; and I know of no bolder conservative feats in Surgery than those of the two gentlemen just named. Here is the cast of an ankylosed lower limb, and here is one from another similar case. You see them represented here also. The leg is bent at the knee to a right angle; the knee is swollen, and there are openings and sinuses in all directions. The history of each case told of incurable disease of the knee of several years' standing; the probe indicated an open joint,

and besides bare articular extremities, a great stretch of necrosis of the femur, extending upwards four inches. The proof of extensive disease, the distortion of the limb, the state of hectic, all indicated the utmost hopelessness, excepting from amputation. The leg and foot were sound, as was the greater part of the thigh. Instead of applying the amputating knife, local measures were taken. These amounts of bone [exhibiting them] were removed, and this amount of bone from necrosis of the femur was removed at the commencement. Soon after the incurable surfaces were taken away; in other words, excision of the knee was performed, and here is a cast representing the knee, in this instance after that operation. Unfortunately this boy subsequently had disease of the hip, on the other side. Here is a cast of it, and here is the boy himself, with the leg that was preserved. He can stand upon it for hours, and walk miles daily. Of all my feats of conservatism, I know of none of which I am prouder.

ORIGINAL COMMUNICATIONS.

TWO CASES OF FRACTURE OF THE SKULL.

By JAMES DONNET, M.D.,

Staff-Surgeon Royal Naval Hospital, Lisbon.

F. H., aged 16; boy, second-class of H.M.S. *Revenge*.

On the evening of December 3, 1862, this lad attempted to fasten some washed clothes to the grating which covers the funnel-casing of the ship; in this attempt he lost his balance, and was precipitated headlong into the engine-room, a height of about thirty feet.

He was picked up in a state of insensibility, with fluttering irregular pulse, contracted pupils, and hemiplegia of right side of body; a large lacerated wound was discovered on scalp with a corresponding fracture of the skull. Another wound had been inflicted over crest of ilium. On the day following the accident he was brought to this Hospital.

4th.—On examination after admission, the right side of body is paralysed, a lacerated wound of scalp extends diagonally across left side over parietal bone; the left parietal bone is fractured and much depressed; the fracture commences about two inches posterior to coronal suture, and about three inches above squamous, and extends obliquely towards lambdoidal suture. The fracture can be seen the whole length of the wound, which is about four and a-half inches in length, and the roughness characteristic of a fracture can be followed beneath the partially raised scalp as far as the finger can reach. The depressed portion of bone, after tearing the meninges, had sunk into the cerebral substance, and had forced some of the cerebral matter outwards through the fracture. Another smaller wound extends from roots of hair over forehead for the length of two inches towards bridge of nose; a third and somewhat extensive and deep wound is found over posterior part of the crest of left ilium. Pupils generally contracted, though at times they dilate; pulse is irregular and thrilling, between 80 and 100 per minute. Frequent cries, but otherwise insensible; these cries are more severe after the act of deglutition has been performed. His left hand is raised frequently to head; breathing at times stertorous; frequent flushings of the face; passes his water in bed. An enema was ordered to relieve the bowels.

5th.—Unconscious; pupils contracted; swallows, but shrieks after he has swallowed; he does not vomit, he retains all that he swallows. At 10 o'clock a.m., with the valuable assistance Dr. William Duirs, the senior Medical Officer of the Channel Fleet at anchor in the river Tagus, the head being shaved where required, the trephine was applied, but the depressed portion—being deeply sunk and partially overlapped by the sound bone—could not effectually be raised until another portion of sound parietal bone was removed by means of Hey's saw; the elevator, after several trials, then raised the depressed portion to the level of the sound bone. The clots of blood mingled with some portions of cerebral matter were then washed away, the lips of scalp wound were brought together anteriorly by means of one suture and adhesive plaster, leaving an opening posteriorly and at the dependent part for the free exit of the matter. Cold lotion was then applied to head. 5 p.m.—His cries continue, the act of deglutition increases their frequency. Pulse irregular, at times bounding, at others small. Has swallowed some fowl broth. Enema administered yesterday having produced no effect, is to-day repeated; some

faecal matter followed its administration. After the operation the right forearm gradually flexed itself upon arm, and required some force to extend it, the flexion returning on removal of extending power. Left side of mouth drawn downwards.

6th.—Unconscious all day; cries as if in pain after swallowing. Pupils generally contracted, though they dilate at times; pulse varies, beating at times at the rate of 72, at others at the rate of 104 per minute. The left side of mouth is drawn down more than it was yesterday. There is less stertor to-day. Some cerebral matter, with shreds of dura mater, was washed away whilst dressing the wound of scalp. The wound over crest of ilium discharges freely, healthily, and abundantly.

7th.—Has been very restless throughout the night, crying frequently; his cry is like that of one in great pain; his face flushes during his cry. Has intervals of quiet between these cries; his appearance is then of one in a sound sleep, breathing quietly and normally. The stertorous breathing has become less frequent. He raises his hand as if to remove some cause of uneasiness, and, if not prevented, will tear the dressings from his head and loins. There is, consequently, consciousness of pain in these parts. The face, less contracted than it was yesterday, has an expression of suffering; left side of mouth less drawn. Herpes labialis has broken out on lips. Right leg motionless; right forearm flexed on arm. Swallows some fowl broth, and licks his lips after he has swallowed it. The bowels have been relieved by enema; has made water freely, though passed in bed.

8th.—Is very restless, and attempts to get out of bed; right arm is flexed upon arm; the toes of paralysed foot move when the sole is tickled; the left hand grasps objects firmly. Pupils contract and dilate alternately; feet warm; mouth becoming more natural.

9th.—Still restless. Pulse 80, regular. Opens his eyes, and for a short space of time looks about him with a passing expression of consciousness. Embraces with lips the tube of feeding cup. 8 p.m.—Very restless all day; frequent cries; left side of body moves convulsively; pupils dilate and contract frequently, the interval between dilatation and contraction being short. Face still flushes. Takes his broth, and is eased by cold applications to his head.

10th.—Lies quiet. Pulse 84; respiration 20; breathing natural. He seems like one in a deep, sound, natural sleep. 5 p.m.—Slept the greater part of the day; awoke several times, and then took beef-tea and milk with apparent relish. Bowels kept open by enemata. Has been obliged to be changed each time he wets his bed.

11th.—This morning is quietly sleeping; the flushings of face are decreasing. When awake, he cried out "Oh, my!" "Oh, Lord!"

13th.—Has not cried after swallowing since December 7. Has said several words with meaning. Left side of face natural; right leg has some slight motion; right arm continues flexed; is conscious of those around him; complains of his head. The wounds of head and loins discharge, though the discharge is decreasing; that from the wound in head is fetid. The pulsations of the brain are perceptible, sometimes more distinct than at others; at each pulsation the discharge from the wound is urged upwards.

15th.—Was very restless during the middle watch; face flushed several times. This morning is more composed; pulse, 74; breathing natural; discharge from wounds healthy; passes his water sometimes in bed, though he is aware of so doing, but cannot help himself; asks for urinal sometimes; the forearm is no longer flexed upon arm, but lies quietly by his side.

18th.—Has slept well; the discharge from both head and loins continues, though decreasing in quantity. He complains to-day of general itchiness of skin.

19th.—The skin, having been washed, has lost its itchiness; right arm and leg are motionless; when the sole of paralysed foot is tickled the toes of this foot move; he still wets his bed.

21st.—He complains to-day of being cold along the paralysed side; there is slight motion of thumb of right hand.

22nd.—Sleeps well; some motion to-day of fingers of right hand; is perfectly collected; his eyes are bright and full of intelligence.

24th.—Is able to move his right hand towards head.

28th.—To-day is able to move right leg and to flex the corresponding knee; the motions of upper limb are becoming freer daily; the tact of this hand is imperfect; the boy cannot tell the number of fingers of another's hand placed within his own; has been sitting up in an arm-chair; his appetite is

good; bowels are relieved only by injections; the wounds of scalp and crest of ilium are doing well.

January 16, 1863.—The motions of leg and arm are daily becoming freer; he is able to walk without much assistance; uses his right hand, though imperfectly; had a slight chill, followed by fever; the wound over crest of ilium looks angry; fomentations, followed by poultices, ordered to part.

17th.—Much discharge from wound in back; swelling and inflammation decreased.

April 7.—He has improved greatly since last report; wound of scalp still discharges, though in much less quantity; several spicula of bone have come away from wound; to-day a spiculum of bone, upwards of an inch in length, was taken away from beneath scalp; appetite good; enjoys his food; sleeps well, undisturbed by dreams; his intelligence is untouched.

August 6.—The wound of scalp is much contracted, though not healed; several small spicula of bone have at long intervals come away; although he moves about freely, the right side of body has not the same power as the left; he complains of some numbness of the right hand.

October 7.—Has been progressing favourably; he moves about readily; the wound of scalp still discharges, the quantity daily decreasing; the numbness of the right hand has not yet left him; he grasps less firmly with this hand.

February 26, 1864.—The lad is now, to all appearance, perfectly re-established. His intelligence is perfect; he is quick, ready, and willing to do anything to assist where required; when questioned, his answers are ready and intelligent; his memory and judgment are good, and his imagination lively; the numbness of the right hand has entirely left him; the pulsations of the brain are distinctly perceptible beneath the scalp, the wound of which is almost healed. There is, however, a slight difference between the muscular grasp of the right and that of the left hand. As the Channel Fleet takes its departure to-morrow, he is discharged from this Hospital for a passage to England.

This case is an interesting one, from the perfect recovery of this lad's faculties after the severe injuries he had sustained. From the extent of the wound of scalp, from the nature of the fracture, and depression of the bone, and the laceration of the meninges, and of the cerebrum itself, with the encephalitis threatening upon such injuries, the prognosis was an unfavourable one. The piercing cries he gave when in an unconscious state, and more especially their frequency and aggravation after the act of deglutition, denoted irritation of the medulla oblongata, and assisted in auguring ill for the issue. Most fortunately, his youth and the natural vigour of his constitution were in his favour, and the result proved a happy one.

The trephine was applied, and depressed bone raised thirty-five hours after the accident. The first sure token of consciousness occurred on the sixth day after the operation, after which there was progressive improvement, and the muscles of impaired side of body gradually regained their functions in the order generally observed.

The operation of raising the depressed portion of bone was followed by contracture of the right forearm. This, probably, was due to some reflex action exerting its influence upon some parts of the base of the brain and created during the operation of raising the bone. This seems probable, as the contracture followed shortly upon the operation, and vanished with the amelioration of the symptoms and the improvement of the patient's state.

Royal Naval Hospital, Lisbon.

(To be continued.)

TREATMENT OF ITCH AT ST. LOUIS.—The treatment employed by Dr. Hardy consists, first, in friction for half-an-hour of the whole body, except the head, by means of black soap, and which is continued by the patient himself during an hour while in a tepid bath. When he leaves the bath he is submitted to a rapid and general friction with the following ointment:—Lard 64, sulphur 20, subcarbonate of potass and water of each 8 parts. The patient then dresses himself without wiping off the ointment, as the contact of this is necessary for the destruction of any remaining acari, and of any that might remain in the garments. Of 37,429 persons so treated in 1852-62, only 535 required a second application.—*Gaz. des Hop.*, No. 67.

THE FRENCH POISONING CASE.—La Pommerais was guillotined on Friday, June 10. He made no public confession of guilt.

CURE OF INGUINAL HERNIA IN CHILDREN.

By REDFERN DAVIES, M.R.C.S.,
Surgeon to the Children's Hospital, Birmingham.

AN opening in the abdominal walls, which would naturally have become closed, may to an almost certainty be made so, by continuous and well-directed pressure. Thus, ruptures occurring at the time of birth or shortly afterwards, may be generally cured by constantly wearing a well-fitting truss.

This cure is effected by the truss pad keeping within the cavity its natural contents, occasioning a contraction of the abnormal outlet, in accordance with the general law by which all hollow bodies adapt themselves to their contents; and so the closure of those parts is effected which were intended by nature only as temporary means of communication, but from an arrest of development have become permanently so; at the same time there is set up a slow inflammation and thickening both of the empty sac and of the surrounding cellular tissue, which assists and accelerates the natural contraction of the neck, and the separation of the sac from the peritoneum.

The condition of the parts as observed by M. Cloquet, after an ample examination of the dead bodies of persons who had been affected with rupture, and cured by wearing a truss, is, that the mouth of the sac wrinkles, contracts, is thrown into folds, and lastly becomes obliterated. These folds, which he calls "stigmata of the hernial sac," (Laurence) are arranged in a radiated manner, gradually losing themselves in the surrounding peritoneal tissue, their opaque whitish appearance alone distinguishing them from wounds.

In cases, however, where a truss has been for some time worn, and failed to cure the rupture, or when the wearing of a truss has been attended with pain and therefore discontinued, I have endeavoured radically to cure the rupture by operation. In the years 1858, 1859, and 1860, in ten cases of inguinal hernia in children under 8 years of age, I used either the plan recommended by Wutzer, or a method that I detailed in a pamphlet published about that time, consisting in an attempt to invaginate a portion of the scrotum into the abnormal aperture. Of these cases nine are now quite sound; in the case that ultimately failed (though at the time appearing cured), partly from the occurrence shortly after operation of scrofulous disease of the vertebrae and lumbar abscesses, and partly from not wearing a truss, the rupture was gradually forced down again by a continuous cough. (a)

Mr. John Wood, for recent ruptures and for those occurring in children, operates by a couple of rectangular pins, whose transit along the interior of the sac sets up in it a due amount of adhesive inflammation which entirely obliterates its cavity. The description of his operation is so ingenious that I wish I could fancy it was correct. He says:—

"In this operation the conjoined tendon and the internal pillar are transfixed by a pin first applied, and the outer pillar is transfixed and included by the second. The sac is transfixed by both the pins, which lie for some distance in its interior. The whole of these parts are twisted together by the revolution of the one pin on the axis of the other, so that the posterior wall being drawn forward, and the anterior backward, the hernial canal is firmly closed, tightly embracing the cord which lies behind and between the pins, but without being included by them."—*Vide Wood on "Rupture,"* p. 135.

The plan that I now adopt and, from its equal efficacy and much greater simplicity, prefer, is thus:—

Passing the finger into the inguinal canal as deeply as requisite, I carry upon it a strong and well-curved needle, and thrust it through the internal and conjoined tendon. The eye of the needle is then thread with a common ligature and withdrawn. A similar proceeding is done on the outer pillar, the needle entering and emerging on both occasions at the same place.

The purpose of this ligature is to easily introduce into the parts through which it has passed a copper wire, which should be of about No. 20, freshly annealed, and having a small hole near each extremity for its attachment to the ligature. By pulling upon the ends of the wire when it has been thus passed, some of the scrotal fascia is easily separated from the adjacent parts, and drawn into the inguinal canal; at the same time the edges of the ring are approximated as much as possible. Twisting one wire upon the other over a compress of lint, the operation is completed. None of the integument

(a) As many of these cases as I could procure were shown at a recent meeting of the Midland Medical Society.

of the scrotum is invaginated, which, save for the needle puncture at about the middle, looks as usual. In a few days the wire is untwisted and easily withdrawn, it not being intended to remain permanently, as is done by Professor Chisholm, of Charleston, America, who appears only to convert a hernia into a bubonocoele, and that, probably, a temporary one.

A truss is applied in a day or so, when the child may go about as usual.

Throughout there is, or should be, little or no pain or discomfort of any kind, much less any ulceration or suppurative action in the parts.

After a little time the fundus of the hernia becomes obliterated and hardened into a solid mass of effusion within the scrotum, while the superficial ring is hardly able to be recognised.

A case upon which I had operated with Mr. Wood's pins, two months afterwards died from an attack of bronchitis. Upon examination of the parts, there was felt ascending from the bottom of the scrotum a linear mass of thickened tissue, which, upon dissection, was found to consist of the walls of the hernial sac united together. The internal ring was almost naturally closed, permitting the tip of the little finger to imbed itself for a distance of about one-eighth of an inch, resembling a well-marked fossa.

The principle which pervades all methods of curative treatment in children's ruptures, whether by wearing a truss or operation, is the same, and consists in the endeavour to excite in the inguinal canal a due amount of lymph or plastic matter so as to block it up, and at the same time to induce its walls to unite together. For my own part, I put an almost unbounded faith in the curative powers in children's ruptures of a properly fitting truss, continually worn, and regard an operation only as an adjunct to treatment by pressure, rendering it more certain and speedy. I entirely agree with Mr. Wood that the simplicity and freedom from danger of the operation—although I have had peritonitis in both kinds of treatment, truss and operation—constitutes a strong recommendation for its adoption. I do not present my recent experiences, because—though at present, and whilst wearing a truss, they seem cured—a sufficient time has not elapsed to pronounce positively upon them.

Remarks.—The following conclusions may be derived from the examination of the urine in the cases which I have here

related. The water is diminished in amount, and this diminution is most marked during the first week. It varied in each of the cases considerably, depending in some degree upon the amount of diarrhoea present. The reaction of the urine in every case was acid. The specific gravity was high in each case, the highest being 1028. In typhus there was throughout a lower specific gravity than in the cases of typhoid. During convalescence the specific gravity lowers. Dr. Parkes says that this occurs before there is any marked increase in the amount of water. The urea was in every case during the active stage of the fever much increased. In Case 1 the greatest increase was during the second week, in Case 2 during the first week. It seems as if the largest amount of urea was present, relatively and absolutely, while the fever was most severe (whenever that might be), differing, of course, in different cases, so that no definite rule as to days can be fixed with regard to it. Simon and other authors affirm that the urea is diminished in amount, but numerous others state the contrary; and there can be little doubt that the increase is considerable. The largest amount in one day in the cases of typhoid was 581.6 grains, which formed more than three-fourths of the whole solid matter in the urine. The chlorides in Case 5 were altogether absent, and in a patient of Dr. Thompson's they were almost so. A. Vogel, Dr. Parkes, and others attribute this diminution to the spare diet and to the passing off of the chloride in some cases by the bowels and skin. Howitz has advocated the same view, and states that, apart from pneumonia, febrile conditions have no influence on the chloride of sodium. This statement can hardly be strictly correct, for we find the chlorides absent sometimes in cases of rheumatism without any pneumonia. The spare diet cannot be urged as an argument in the case of R. T. (Case 1), nor can sweating, for the patient took large quantities of nitrogenous food, and had at the same time a hot, dry skin: moreover, there was very little diarrhoea. Dr. Parkes seems to think that the chlorides may be retained in the system, as in pneumonia. The uric acid was increased in every case, being thrown down abundantly when acid was added to the urine. The amount was not determined. The sulphates in one case were diminished. It is usual, according to Dr. Parkes, to find them increased. There was in all the cases an increase in the amount of pigment, probably from an increase of normal pigment, as no evidence of any other was obtained. The urates were found largely increased at the time of convalescence in three cases; in Case 2, before that period. Albumen was present in two of the four cases of typhoid, and in both cases of typhus. It occurred in 33.33 per cent. of Dr. Parkes's cases. In no case could any casts be found, although the urine was several times carefully examined for them. In a patient of Dr. Thompson's there were abundant fibrinous and granular casts, but it is probable that the kidney lesion had existed previously. Albumen seems to be far more common, and more abundant when present, in typhus fever. Its presence appears to be owing to some congestion of the kidneys from the existence of some poison in the blood; but whether any peculiar condition of kidney is produced seems uncertain. Most probably not, or we should not find the evidences of kidney lesion so transitory in their character. Although the results here described are drawn from too scanty data to be of any great value, yet they are interesting, inasmuch as they confirm to some extent the observations of others.

TURPENTINE IN HOSPITAL GANGRENE. — Surgeon Hachenberg reports that he has derived great benefit from the application of turpentine every three hours in Hospital gangrene, first cleansing the wound with warm water and any of the ordinary disinfectants. Fistulous openings are well injected with it, and when fasciæ are in the way of effectual application they are dissected out. Little or no pain is caused even by complete saturation, care being taken to prevent the fluid running on to the adjoining skin. In a few days the wound cleanses, the sloughs come away, and the tendency to granulation is active, while all the constitutional symptoms undergo corresponding amendment. The properties which render it so valuable an agent are its permeability, its solvent action on the broken-down adipose tissue, its local alterative, stimulating, and sedative effects, its antizymotic qualities and its antiseptic and styptic action. It produces no eschar, as do bromine and some other substances, which in consequence often cause the retention of the vitiated secretions of the wound.—*American Medical Times*, May 28.

SATURDAY, JUNE 18.

THE PROPOSED NEW SCOTTISH STATISTICAL CLASSIFICATION.

IN Edinburgh, Dr. Stark occupies a post in connection with the General Registry of Births and Deaths similar to that held by Dr. Farr in London; and, in virtue of his position as Superintendent of the Department of Medical Statistics, he has proposed a scheme on which the deaths registered in Scotland are to be classified. Whether this new scheme has been adopted by the Registrar-General for Scotland we do not quite understand. We hope not. We think it a pity that Dr. Stark and Dr. Farr do not agree in their views as to what sort of classification should be used in the offices to which they are respectively attached. We think it a pity that any impediment should be thrown in the way of comparison between the English and Scottish tables of mortality; and we think that, even at the sacrifice of his own views, Dr. Stark would have done better had he adopted the English classification of the causes of death until such time as a better scheme might issue from the joint labours of his English and Irish colleagues and himself, together with those of the heads of the Medical Departments of the Army and Navy. Dr. Stark only adds another to the many failures which have been made in this direction. We are not wedded to Dr. Farr's classification. In our eyes it possesses many and serious defects, but we must say that Dr. Stark's allegation, that it has been "drawn up on no fixed principles," and that it is therefore "unimproveable," and his insinuation that it "panders" to "Medical theory, which may be popular to-day and be refuted to-morrow," is not one of them. We are not going to fight through thick and thin for Dr. Farr's scheme, but we think that Dr. Stark might have expressed his opinion of it in less forcible language. It is a classification which has its undoubted uses; and although confessedly far from perfect, cannot fairly be taxed with "being drawn up on no fixed principles." We might retort upon Dr. Stark, but forbear. When we have said all that we have to say upon his scheme, our readers may form their own opinion as to whether our forbearance is the result of want of provocation. For the present, however, we have to do with Dr. Farr; and we affirm that whatever faults his classification exhibits, it is not the hap-hazard grouping of diseases that Dr. Stark would lead us to imagine it. It is true that the first English classification has been modified of late years, but this modification mainly consisted in a process of concentration, reducing the number of primary classes, and making some, which were formerly thus arranged, into subordinate groups. But the principle of the classification remains the same. What this principle is may be found by referring to a letter from Dr. Farr in the First Report of the Registrar-General for England, and to this we would refer his critic.

Dr. Stark's proposed arrangement embraces sixteen classes. 1. Fevers; 2. Diseases of the brain, etc.; 3. Diseases of the heart and organs of circulation; 4. Diseases of organs of

respiration; 5. Diseases of organs of digestion; 6. Diseases of urinary organs; 7. Diseases of organs of generation; 8. Diseases of organs of locomotion; 9. Diseases of skin and cellular tissue; 10. Diseases of uncertain seat; 11. Malformation; 12. Debility at birth and premature birth; 13. Old age; 14. Sudden deaths; 15. Violent or unnatural deaths; 16. Causes not specified. He tells us that this is a classification which is drawn up on a "clear and intelligible principle," "panders to no Medical theory which may be fashionable to-day, but refuted and abandoned to-morrow;" and, "therefore," that it is one which, once adopted, "would never hereafter require to be amended or departed from." The fixed principles referred to are that every death is tabulated under the *primary cause or affection* which led to the death, and that, so far as practicable, every disease causing death is tabulated under the *organ of the body* which was primarily or chiefly affected. He claims for his scheme that it is one that can be understood by the masses of mankind, as well as by the Medical profession. We say that the mass of mankind, who in their ignorance must be guided by professional opinion, can quite as readily comprehend the English arrangement; while, in regard to accuracy, there are quite as many faults, to our mind, and rather more, in Dr. Stark's classification as in Dr. Farr's. Such as have studied Buckle's "History of Civilisation" will perhaps recognise in the two classifications an illustration of the opposite philosophical tendencies of the Scottish and English mind. And as respects taking Medical opinion as a guide to statistical classification, we must confess we do not see how some reference to it is to be avoided, and the only alternatives which occur to our mind are to adopt the opinions of the day, the opinions of the past, or the possible opinions of the future. Not being gifted with "second sight," the two former are alone available to us Southerners, and of these we must give credit to Dr. Farr for the selection he has made. But apart from our objection that Dr. Stark's movement is retrograde, we assert that it is one which it is impracticable to carry out—that Dr. Stark himself could not carry it out; has not done so. In his attempt to render his arrangement popular, he has rendered it confused. Let us give some few illustrations. In his very first class of "Fever" he fails in carrying out his principle. He defines them as "a class of diseases affecting every organ of the body simultaneously." He includes in it diphtheria, on account of its pathological relation to scarlatina, and he excludes cynanche maligna and C tonsillaris (placing them among diseases of the digestive organs), although he holds both to be "undoubted forms of scarlatina"! Defined also as Dr. Stark defines it, such a class should include all the acute forms of inflammation, and notably acute rheumatism, pneumonia, and influenza, the former being actually placed among "Diseases of uncertain seat." The last-named class is that which, perhaps, as flagrantly as any transgresses against the "principle." Is gout a disease of uncertain seat? Are purpura and scurvy diseases of uncertain seat? Is "fistula" (in its popular signification) a disease of uncertain seat? Is dropsy a disease of uncertain seat? Why, if the organ primarily or chiefly affected is that under which a disease is to be registered, why is "the blood" to be ignored? Is it because the public generally never heard of "blood disease" or "blood poisoning"? Again, we find diarrhoea, dysentery, and cholera grouped in the fifth class with hernia, worms, and tabes mesenterica; childbirth among the diseases (?) of the organs of generation, and also metria, both of them as primary affections; and in the same group are the syphilitic diseases. Where would Dr. Stark place syphilitic lepra? Erysipelas is divorced from the febrile class, and grouped with non-febrile diseases of the skin.

And what, lastly, is to be said of a classification which takes no cognisance whatever of the large and important class of tubercular affections, but counts deaths from phthisis among those from bronchitis and whooping-cough, and

scrofula with cancer, hæmorrhage, and gout? What practical purpose, Medical or non-Medical, could possibly be served by such an arrangement? And after all this, we are told complacently that the classification is one which will "never hereafter require to be amended." For ourselves, we would far prefer a simple alphabetical arrangement with no feature of classification at all. There is, however, one good point in Dr. Stark's scheme, which, if any agreement should be come to with other statistical departments, we should like to see adopted, and this is that he includes poisoned bites and wounds, hydrophobia, alcoholic poisoning, starvation, and want of breast-milk as causes of death among the "Violent or unnatural deaths." It would be strange, indeed, if there were no redeeming feature.

THE WEEK.

THE LATE MR. CARTWRIGHT, F.R.S.

(From a Correspondent.)

ALTHOUGH we believe that the late Mr. Cartwright was never actually a member of the Medical Profession, yet he was so successful a cultivator of one of its auxiliary branches, and deserved so well of us by his magnificent hospitality, that we cannot allow him to pass away into the ranks of the departed without one word of commemoration. Even the youngest members of our Profession must have heard of Cartwright, as the most celebrated Dentist of his day, whose doors were besieged by crowds of the aristocracy, and who realised a princely fortune. His fortune, too, was not merely saved, but enjoyed. His hospitalities were on the most princely scale. It is well-known that when Paganini, the celebrated violinist, was in London, thirty years ago, creating a *furor* amongst fashionable *virtuosi*, Cartwright issued cards for an ordinary dinner party. When the guests arrived at the well-known door in Burlington-street, the porter announced, with his master's compliments, that an accident had happened in the kitchen, so that he must take the liberty of asking them to come on to the Clarendon close by, where he proposed to receive them. On they went accordingly, and then were conscious of the friendly artifice of their entertainer, who had taken this method of gathering together a much larger number of guests than his own dining-room could accommodate, and then, after a most sumptuous entertainment, produced Paganini, who gave them a private exhibition of his musical skill. There is a moral of a very homely sort to be drawn from Mr. Cartwright's life, which we venture to impress upon our younger readers. Some young men are apt to fancy that a fine figure, and flattering tongue, and ostentatious *ménage* may enable them to "get hold of the aristocracy," and make fortunes by adulation and other arts of humbug. That which led to Mr. Cartwright's rise and success was the direct contrary. He was a plain-looking, quiet man, who made his own way by simple means; he used the greatest industry in his profession; he strove to do everything in the best way; he got the credit of doing things better than any one else (and there could be no mistake where teeth were concerned); then, without running after success, success came to him. The writer of this notice well remembers that when a student, some years ago, he happened to be breakfasting with a well-known Professor, who, in the course of talk, said, "I'll tell you something that should be a model to you. Last night we elected Cartwright, the dentist, an F.R.S. There was a kind of row about it; some men said he ought not to be elected, but most of us felt that he was a very good fellow, and we carried him; and look here, here is his card; he called on me this morning before eight, and left his card in acknowledgment. That is the way to get on in the world. Be prompt and punctilious in acknowledging the slightest benefits. This shows you how Cartwright got on." So said our Mentor, who has now long since preceded us into the region of shadows. We bear witness to the benefits of Cartwright's splendid entertainments; how they brought men together, smoothed off asperities, cemented friendships, and

gave some poor struggling scientific men a glimpse of the brighter side of life. When the recording angel sums up, and strikes the balance, we are sure that he will remember to Cartwright's credit that to be "given to hospitality" was pronounced on the highest authority to be a virtue even in a bishop.

EARLY MAN AT THE BRITISH MUSEUM.

IN a case at the further end of the great palæontological gallery of the British Museum are now displayed a series of fossils, human and animal, which constitute perhaps the most important addition to the *data* for an early history of man which this country has acquired. They are a portion of the spoils of the cavern of Bruniquel, a cave situated in the department of Tarn and Garonne, in France, which have been purchased by Professor Owen for the trustees of the National Museum at the cost of £1000. These remains have already been made the subject of one paper by Professor Owen, which was read at the last meeting of the Royal Society, and it is understood that they, with the remainder of the specimens not yet exhibited, will furnish matter for a series of communications to the Society by the same accomplished palæontologist. Without endeavouring in any way to forestall information which will in due time be given to the scientific world, we would call the attention of our readers to the specimens now exhibited in the Museum. The human remains comprise a large portion of the hinder and middle part of a skull imbedded in *breccia* from five feet below the stalagmite floor of the cavern; a large portion of the occipital bone of another skull similarly imbedded; a tolerably perfect calvarium; numerous pieces of parietal and other cranial bones, some of which, from their thinness, have evidently belonged to early childhood; portions of jaw bones of adults and children—in one adult upper jaw the grinding teeth are seen to be much worn from within outwards—there is also the lower jaw of a child, in which the first molars are still retained in their bony cells. These remains, as far as we have been able to observe them, do not present any remarkable peculiarities, and give no evidence of anything like a transitional or progressive stage of development. The skulls appear to us rather to belong to the long-headed type, and to be of moderate capacity. There is no evidence of any unusual development of the frontal sinuses. Besides the cranial specimens, there are remains of long bones and ribs embedded in the same deposit from below the stalagmite. But these relics of man would in themselves be of only ordinary interest were it not for the works of art and animal remains with which they are now found associated, and with which they are undoubtedly contemporaneous. The latter comprise quantities of the antlers of the extinct reindeer (*Tarandus Priscus*). Many of these are marked with tools, some are in sections, and have been evidently used as implements. There are also the upper and lower jaws of the same variety of reindeer, which there can be no doubt was as useful to the ancient cave-men as his successor is to the Laplanders of our own times. There are also the remains of an extinct deer (*Cervus Palmulatus*); horn cores and jaw bones of a large chamois (*Rupicapra Christolii*); the upper jaw and horn cores of the bouquetin (*ibex Cevennarum*); remains of the wild horse (*Equus Caballus*); and portions of the upper and lower jaws of the great extinct bull (*Bos Primigenius*). Besides these, there are bones of the fox, wolf, red deer, hare, buzzard, partridge, raven, eagle, and salmon. The works of art, a portion of which are exhibited in a case in the British gallery, consist of worked flints, many of them arrow-heads, which appear to us to be far more regularly cut than the rude flint implements found by M. de Perthes in the drift at Abbeville. There are also pieces of bone ornamented with rude patterns, doubtless engraved with flint tools, and some bone needles, with the eyes in a perfect state of preservation, which look as if they might be used now for coarse work. It is useless at present to speculate as to the age of these remains; whatever it be it must be very remote, but certainly in them we have good evidence that the contem-

poraries of the extinct reindeer and gigantic bull were not ignorant of some of the arts of life; they were not even naked savages. Geology hitherto has furnished absolutely no evidence that man was ever anything essentially different from what we now find him.

PROPOSED MONUMENT TO SIR HUMPHRY DAVY AT PENZANCE.

It is a gratifying thing to see a distinguished member of our Profession at the head of a movement for perpetuating the memory of one of the most illustrious philosophers who has flourished since the rise of physical science. On Friday, June 10, Mr. Coulson, Senior Surgeon to St. Mary's Hospital, presided at a public meeting held for the above purpose at Penzance, and contributed by far the most interesting portion of the proceedings in the form of an admirable *resumé* of Sir Humphry Davy's life and labours, which we hope to see published in a separate form. Mr. Coulson laid before his hearers in agreeable review the philosopher's early life; his poetic tendencies; his apprenticeship to the Medical Profession; his intimacy with Dr. Beddoes, which led to the discovery of the respirable and intoxicating nature of nitrous oxide; his promotion to the Royal Institution, where he made those prodigious discoveries of the metallic bases of the earths and alkalis, than which no greater step has been made since; his safety-lamp, his discovery of chlorine and iodine, his "consolations," his fishing, his family history, and his death. If a statue be not erected to such a man in his birthplace, the disgrace lies at the door of his fellow citizens, unconscious of the honour that belongs to them. We hope that a monument durable as his native granite will show how the Cornish men value the privilege of having had so great a light of the world amongst them. If there be anything we regret, it is the attempt to add one of those mockeries of mediæval charity, an *almshouse*, to the monument of a philosopher. Anything more absurd and incongruous than such an intermixture can scarcely be conceived. Mr. Coulson was singularly unlucky when he mentioned Greenwich Hospital; and said that the names of William and Mary were gratefully remembered in its noble halls by many gallant veterans, etc., etc. He ought to have known that not even the almshouse department of the Royal Medical Benevolent College was worse devised, and more difficult to manage, than is Greenwich Hospital. The almshouse system is an unnatural, barbarous mode of relieving, with fuss, and ostentation, and Pharisaism, a few persons who were far better left to wear out the remainder of their days with their own family and friends, aided by such small benefactions as may be given them quietly and unobtrusively. We have heard that a right reverend prelate (whose experience of the almshouses and colleges within his own cathedral city for the relief of decayed clergymen and their families must be anything but agreeable) expressed his surprise that a modern and practical and common-sense set of men, such as members of our Profession ought to be, should be guilty of such an expensive absurdity as the gathering decayed and disappointed veterans into a mediæval quasi-monastery, instead of letting them live quietly amongst their families on the more liberal income which a society, unburdened with Gothic buildings, could afford to give them.

PARLIAMENTARY.

On Thursday, June 9, in the House of Lords, the Earl of Derby asked for certain reports in connection with the County Courts Act Amendment Bill, respecting the actual imprisonment of persons who had been unable to pay their debts.

The Lord Chancellor promised to produce them if they existed. In his opinion the reduction of the limitation in the case of debts under £20 to one year was the true conclusion to which they must ultimately come, but at the same time the transition would, at present, be great. He was therefore prepared to agree to the amendment to reduce the period in the first instance to three years. He held also that a measure of this description ought to be purely prospective, and not retrospective, in its operation. It was intended that the period of

limitation should be reckoned from the date of the last item supplied, or of the last part payment, or of any subsequent acknowledgment in writing of the debt after delivery.

Lord Chelmsford believed there would now be agreement among their lordships on this subject.

The lengthening the period during which debts under £20 can be recovered to three years instead of one will remove one great objection to the Lord Chancellor's bill.

On Friday, June 10, in the House of Lords, the report of amendments upon the Insane Prisoners Act Amendment Bill was received and agreed to.

The Chimneysweepers and Chimneys Regulation Bill was read a third time.

In the House of Commons, in answer to a question by Sir H. Verney, the Marquis of Hartington said the arrangements for the improved accommodation of the married soldiers in different camps had in some cases been carried out, and in other cases were in course of being carried out. The arrangements which had been in operation were that five or six families should be lodged in one hut. In some cases the quarters were separated by boarding and in others only by canvas. Now, however, a sum of money had been taken in the Estimates for separating those quarters in a more permanent manner. It was intended that not more than four families should occupy one hut, and a chimney would be erected in the centre, so that each family might have a separate fireplace. The families would then be completely by themselves, and although he could not say that sufficient money had been taken to carry out all the arrangements in the present year, still he believed very great progress would be made towards that end.

In the House of Lords on Monday, June 13, the Insane Prisoners Act Amendment Bill was read a third time and passed.

In the House of Commons, Sir J. Pakington asked the Vice-President of the Committee of Council on Education whether, in accordance with the statement of the Lord President last year, "that the Government were considering the best means of effecting an improvement in the Vaccination Law," and having regard to the great loss of life from small-pox which had lately occurred in London, it was the intention of her Majesty's Government to introduce any measure on that subject in the present Session.

Mr. Bruce said there could be no doubt that a very large and unnecessary loss of life resulted from neglect of the provisions of the Vaccination Act. The right hon. gentleman was aware that, although obligatory, the successful application of the Act depended on the active concurrence of Boards of Guardians, vaccinating Surgeons, and parents of the children. A similar question having been put this year to his noble friend the President of the Council, he stated that in his opinion there were only two methods by which the disease could successfully be grappled with. One way was by increasing the compulsory powers of the Act, the other by offering pecuniary inducements to the vaccinating Surgeons. Parliament, the noble lord thought, would not sanction greater compulsory powers, and he did not see his way to the application of the other alternative. He understood that notice had been given in the other House of an intention to introduce a Bill on the subject which would be referred to a Select Committee. He hoped that measure would have the effect of strengthening the law and removing the evil now complained of.

The Lord Advocate obtained leave to bring in a bill to continue the Deputy-Commissioners of Lunacy in Scotland, and to make further provision for the salaries of the Deputy-Commissioners, Secretary, and Clerk of the General Board of Lunacy. The bill was subsequently brought in and read a first time.

In the House of Commons, on June 14, Mr. Bruce moved the second reading of the Factory Acts Extension Bill, which had been introduced, he said, in consequence of a report made by Commissioners appointed by the late Sir G. C. Lewis to inquire into the condition of the children employed in certain manufactories. In stating the recommendations of the Commissioners, Mr. Bruce detailed very fully the documentary and statistical evidence bearing upon the subjects of cleanliness and ventilation of the factories and places where the children were employed; the effect upon their health and life; of injurious and dangerous occupations, and protracted daily employment and overworking; and their education. He examined and discussed the remedies suggested for the multi-form evils disclosed in the report of the Commissioners, and

the objections offered to the application of the Factory and Mines Inspection Acts to the manufactures in question, and the principles embodied in the bill, observing that the Government would be ready to give the fullest consideration to any suggestions for carrying them out.

After some discussion, the bill was read a second time.

Mr. Hubbard called attention to the operation and extent of the direct and indirect taxation now levied, with especial reference to the income-tax, and to the prospect of its continuance. He moved the following resolution:—"That the inequalities and injustice attending the operation of the existing property and income-tax disqualify it for being continuously reimposed in its present form as one of the means of levying the national revenue."

After a debate, in which the Chancellor of the Exchequer opposed the motion, it was negatived upon a division by 67 to 28.

FROM ABROAD—PROFESSIONAL REMUNERATION—FRENCH ARMY
MEDICAL REPORT—INTERMISSION OF PULSE AS A RESULT OF
EXCESSIVE SMOKING.

DR. HERPIN, of Geneva, has recently published some articles in the *Union Médicale*, in which he makes some propositions for reform in the mode of Professional remuneration, which, he states, are the result of mature deliberation. He recommends that the payment by fees or charges for visits should, except under special circumstances, be discontinued, and that all engagements should be by subscription, or what we should call by contract. The position of the practitioner would at once become changed, his office being to take charge of the health of his employer. One of his first duties would be to thoroughly acquaint himself with all the family antecedents, and acquire that information respecting hereditary and individual peculiarities often so difficult to obtain when he is only called in at the moment of sickness; and how often he would be in the position to prevent the occurrence of disease by the development of the resources of hygiene taken in its widest acceptation, need not be pointed out. In the event of the occurrence of acute disease, the delay in seeking aid, so fatal and so common, will be avoided, while any frequency of visits that may become necessary cannot be attributed to sordid motives. It is, however, in chronic ailments that the advantage of the plan becomes more obvious, seeing the insidious character of the approach of many of these, and their tedious duration. The subscription should include, in M. Herpin's opinion, all visits or consultations at home as well as the performance of the minor operations. There are, however, other attendances which should be paid for apart, as consultations with other practitioners. These may be sometimes asked for capriciously or unnecessarily, and, at all events, they derange the regularity of daily practice, and cause a great expenditure of time. Other circumstances which should also be separately charged are confinements, visits made at night, and those which are made at great distances or occupy an unusually long time. The servants should be included with the rest of the family in the subscription.

As to the important point, the amount of the subscription, M. Herpin fixes this upon the rather moderate basis of from a fiftieth to a hundredth part of the presumed revenue of the patient. This would amount to from 20 to 40 francs per annum for an income of 2000 francs; 100 to 200 for 10,000; 500 to 1000 for 50,000; and 1000 to 2000 for 100,000 francs. Gratuitous services should be eschewed, although, to encourage the independence of persons of narrow means who wish to avoid resorting to the public charities, the tariff may in their cases be reduced as low as 20 francs per annum. Various circumstances will cause the subscription to oscillate between the fiftieth and the hundredth parts of the revenue, such as the number of the family and servants, the distance of residence, and the reputation of the practitioner. Whether in annual or quarterly payments, the subscription should be discharged in advance. According to M. Herpin's calculation, this rate of remuneration would well-nigh double the present receipts, while patients would derive

proportional advantages. In reply to the objection that this innovation upon old habits will be difficult to introduce, M. Herpin replies that this mode of remuneration has long prevailed in various public institutions, and with several private individuals. That as regards his own practice, having more especially devoted himself to the treatment of epilepsy, a disease the management of which under the most favourable circumstances calls for minute exactitude, patient treatment, and a prolonged perseverance, he has found it desirable to have recourse to this mode of payment; and that its applicability and utility, easily comprehended and appreciated by the patient, while profitable to the practitioner, have now been for several years amply demonstrated.

The French Government has followed the example of our own in publishing a volume of Army Medical Statistics, which is to be continued annually. Considering the army under three divisions accordingly as it is stationed in France, Algeria, or Italy, we find the proportions of the numbers admitted into Hospital were very different. The entries in 1862 were 258 per 1000 for the Interior, 406 for Algeria, and 422 in Italy; but the mean duration of treatment was in the inverse order—viz., 28 days per patient in the Interior, 20 in Algeria, and 24 in Italy,—this arising from the diseases in the two latter countries being of the intermittent type, rendering relapses frequent, but recoveries rapid. In the whole army there were admitted during 1862, 13,595 cases of primary syphilis and 2938 of constitutional syphilis. In the Interior 1 death took place in 39 patients, or 26 per 1000; in Algeria, 1 in 43, or 23 per 1000; and in Italy, 1 in 24, or 40 per 1000. The slight mortality in Algeria was in some measure due to the exceptional dryness of the winter 1861-62, the marsh exhalations being, therefore, much less considerable than usual. In Italy, on the other hand, the weather was very bad and marsh fever prevalent. The mortality of the army in 1862 was 9.42 per 1000 in France, 12.21 in Algeria, and 17.69 in Italy—total, 10.14 per 1000.

M. Decaisne, in a communication addressed to the *Académie des Sciences*, exhibits another clause in the heavy bill of indictment against the abuse of tobacco. He states that in the course of three years he has met, among eighty-eight inveterate smokers, twenty-one instances of marked intermittence of the pulse, occurring in men from 27 to 42 years of age, and not to be explained by organic lesion of the heart. The absence of such lesion or other condition of health capable of inducing intermission of the action of the heart, and the fact that in nine of these instances, in which the use of tobacco was abandoned, the normal action of the organ was restored, M. Decaisne believes, will justify him in concluding that, in certain subjects the abuse of tobacco may give rise to a condition which may be termed "narcotism of the heart," characterised by intermission in the movements of that organ and in the pulsations of the radial artery; and that, in some cases, a suspension or diminution of the practice of smoking is sufficient to cause an entire disappearance of this irregularity.

PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND
CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE
ROYAL COLLEGE OF SURGEONS.—LECTURE XX.—MARCH 17.

The remainder of the catarrhine apes form a very natural group, which may be called *Cynopithecina*. They are all inhabitants of the old world. Their body is hairy, the colour of each individual hair being often annulated, the nails of the pollex and hallux are flattened, those of the other fingers and toes are more compressed and pointed. They have all large ischial callosities. As in the higher apes, the septum between the nostrils is very narrow. The nose is generally flat; in one species, however, produced to a remarkable extent. The ears retain their rounded form and the general configuration seen in man and the anthropoid apes. The teats are pectoral, and the penis pendant. They are nearly all provided with a tail, though in none is this organ prehensile, nor carried in a

curled position, but generally hangs down nearly straight. In the whole of the monkeys of this group the femur and tibia together are longer than the humerus and radius, the reverse of what takes place in the anthropomorpha; and they differ from these last and from man in being essentially quadrupeds, walking when on the ground naturally on all four extremities.

The Cynopithecina are divided into six minor groups or genera. 1. *Semnopithecus*, exclusively Asiatic. 2. *Colobus*, African. 3. *Cercopithecus*, African. 4. *Macacus*, Asiatic. 5. *Inuus*, African, and found also on the rock of Gibraltar. 6. *Cynocephalus*, chiefly African. The first four genera are generally known as "monkeys," and are mostly arboreal in their habits. The last are "baboons," and are principally terrestrial. A complete gradation in external appearance may be seen between the first and the last, marked chiefly by the lengthening of the face and moving of the nostrils to the extreme end of the snout.

The vertebral column in this group of Primates has very little curvature: it is arched in the dorsal region, but the lumbo-sacral angle is very open. The regular number of dorso-lumbar vertebræ is nineteen, of which twelve or thirteen are dorsal (with a corresponding number of ribs) and seven or six lumbar. Thus the latter region is more elongated than in the preceding groups. The middle cervical vertebræ have short spines, which are not bifid at their extremities. The spines of the dorso-lumbar vertebræ present a remarkable character, common, however, to most of the lower Mammalia, though not found in the highest forms; the front ones slope backwards, and the hinder ones forwards towards a point situated near the lower end of the dorsal region. The lateral processes of the lumbar vertebræ are much developed and curved forwards. The sacrum is broad and strong, but differs from that of man and the anthropomorpha in being usually composed of but three vertebræ. The number of caudal vertebræ varies, but there may be as many as thirty-one. Subvertebral or V-shaped bones are attached to the under surface of the anterior portion of this region. The thorax is compressed laterally, and the pieces of the sternum, following the manubrium, exhibit a corresponding narrowing. In the scapula the spine is placed nearly at right angles with the internal border, and the supra-spinous is much smaller than the infra-spinous fossa. The axis of the articular head of the humerus, instead of being directed upwards and inwards as in the preceding groups, looks backwards and upwards, and the bicipital groove is placed on the inner side; the upper part of the axis of the shaft of the humerus, instead of being straight, is slightly bent. These modifications have relation to the function of the upper limb becoming less prehensile and scansorial, and more that of an organ of terrestrial progression. The radius is modified to the same end; its head is larger, transversely elongated, and placed more forward on the ulna, taking a larger share in the articulation with the humerus. The carpus possesses the ninth bone seen in the orang and the gibbons. The pisiform is long and strong, making a kind of heel to the hand. The trapezium has its characteristic saddle-shape, and the pollex is generally well developed. The pelvis presents an exaggeration of all those characters which distinguish it in the anthropomorphic apes from man. It is longer generally; the ilia are narrower and more excavated posteriorly. The axis of the ilium and that of the ramus of the pubis, nearly in a straight line with each other in man, and forming a very open angle in the higher apes, are here nearly at a right angle. The symphyisis is exceedingly long, the subpubic arch being very much reduced. The eversion and enlargement of the tuberosities of the ischia for the attachment of the callosities is very marked. The round ligament of the hip-joint is present in all the species that have been examined. The ankle-joint presents in the main those characters seen in the higher apes; the calcaneum is somewhat more expanded and flattened than in them. The entocuneiform bone presents the usual distinctive character, and the hallux is well developed. The phalanges are less

markedly curved than in the higher apes of more strictly arboreal habits.

The skull presents a considerable range of modification in the different genera, being more round, with a smaller straighter face and a high vertical ramus to the lower jaw in *Semnopithecus* and *Colobus*, and passing through *Cercopithecus* to *Macacus*, where the supra-orbital ridges are so developed as to obscure the forehead, the nasal bones become quite flat, the jaws project greatly, and in the inferior maxilla the horizontal is very large as compared with the vertical ramus. These last characters are carried to a much greater extent in the *Cynocephali*, in many of which the brutish appearance of the skull is increased by the development of great longitudinal ridges on the surface of the maxilla. There is an entire absence in all of any mental prominence to the lower jaw. The mastoid process has no downward development, and the styloid is not ossified. The parietals do not meet the alisphenoids. As in man and the anthropomorpha, the osseous external auditory meatus is well developed. In the interior of the skull, there is still an exaggeration of those characters by which the higher apes were distinguished from man. The brain-case is flatter and more elongated, the roofs of the orbits projecting further into it. The olfactory fossæ very deep, and even tubular in form, their entrance being contracted by the considerable mass of the frontal bone passing across the union of the presphenoid and ethmoid. The basi-cranial axis is longer in proportion to the length of the cavity, and the occipital foramen is placed still further back, being in the posterior sixth of the base of the skull; its plane is also more oblique. In the lower forms, the palate is greatly elongated, and the premaxillary suture disappears only in old age.

The dental formula is the same as in all the preceding, and the upper inner incisor is still larger than the outer. As in the anthropomorpha, the premolars have three roots in the upper jaw and two below; the canines are even larger, and the crown of the inferior anterior premolars have the anterior margin so greatly prolonged as to resemble scissor blades, which cut against the edge of the upper canines. In the following characters the teeth of the cynopithecina differ completely from those of the previously described forms. The outer lower incisors are not larger than the inner, but owing to the obliquity of the outer edge, often smaller. The upper premolar has its outer cusp peculiarly sharpened and modified. The pattern of the true molar teeth is quite different. Both upper and under teeth have two transverse ridges, of which the extremities are somewhat raised, so as to make them quadricuspidate. Sometimes the inferior posterior molar has an additional ridge on its hinder edge. Similar differences are met with in the milk dentition. A remarkable and fundamental distinction from the great anthropoid apes is seen in the order of succession of the teeth, as in the whole of the present group, the canines make their appearance before, or at least contemporaneously with the hindermost true molars.

UNIVERSITY OF CAMBRIDGE.—DOWNING COLLEGE.—At a meeting of the Master, Professors, and Fellows on the 10th inst. the following elections took place:—Foundation scholarships of £50 a-year, with rooms and commons: Collins, Schroeder. Minor scholarships of £40 a-year: Brailey and Lankester (distinguished in natural science), Hare (distinguished in classics), Payne (distinguished in law and French). £20 was awarded to Dickson for distinction in natural science. At the same meeting it was agreed that a chemical laboratory should be built upon the college grounds for the use of students in medicine or natural science, and be placed under the superintendence of Dr. P. W. Latham.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of candidates who passed the Major Examination June 15 as Pharmaceutical Chemists:—Robert Bird, Newark; Edward M. Holmes, London; Thomas P. Iliffe, Nuneaton; Sidney Payne, Stratford-on-Avon; William F. Chave, Uxbridge; John Mills, Derby; Jonathan Phillips, Godalming; Alfred R. Squire, Bristol.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BRIGHTON.

THE SUSSEX COUNTY HOSPITAL.

HISTORY AND ADMINISTRATION.

The Sussex County Hospital was opened in the year 1828, on the 11th of June. It was originally called the Sussex County Hospital and General Sea-bathing Infirmary, but the latter part of the title has been dropped, owing to the difficulty of obtaining sea baths for the use of the Institution. The Infirmary originally sprang from the Brighton and Hove Dispensary. This Dispensary was founded in 1809, and in 1811 the President of the Institution—the Earl of Chichester—suggested that a Sea-bathing Infirmary might be added to the Dispensary, a plan which was carried out from November, 1812. The new institution was called the Sussex General Infirmary. In 1823 the committee of the Dispensary and General Infirmary alluded to a contemplated scheme for a County Hospital. The scheme went on fructifying. In 1827 it approached its completion, and in 1828 became an accomplished fact. When the new County Hospital came into operation, the Infirmary department of the Dispensary subsided, but the Dispensary itself has remained, and still continues, as I shall eventually show, in active operation.

The Hospital is situated to the east of the town, and at a distance of from three to four hundred yards from the sea. It faces the south, and commands a magnificent sea view. The building is of stone, and is four stories high. The architecture is good, and the site elevated. In front there is a small garden, and behind rather extensive grounds, with the Downs in the rear. Compared with London Hospitals, this Hospital most resembles the Middlesex. Since its foundation, the building has been enlarged by the addition of one wing in 1839, another in 1841, and two others in 1854. The main building was designed by Sir Chas. Barry; the first two added wings, the Adelaide and Victoria, were designed by Mr. Herbert Williams; and the two last, the east and west wings, were designed by Sir Chas. Barry.

NUMBER OF PATIENTS TREATED.

The number of patients treated at the Hospital amounted in 1863, to 1268 in-patients, and 5813 out-patients. The daily average of in-patients was $128\frac{1}{3}$. Since the foundation the number of in-patients admitted has been 28,515, and of out-patients 74,220. The increase in the number of admissions has risen from the first year of the existence of the Hospital from 224 in-patients and 72 out-patients until the present time, and it is singular to observe how gradual the progression has been, as indicating the increase in the population of the town and district.

RULES FOR ADMISSION OF PATIENTS.

Benefactors of 25 guineas or more are Governors for life; and subscribers of 2 guineas or more per annum are Governors during the continuance of their subscription. Benefactors of 50 guineas and upwards, and annual subscribers of 5 guineas, have a seat at the Board of Management.

Subscribers of 10s. 6d. annually may recommend two out-patients annually; and subscribers of one guinea may recommend four out-patients annually.

Subscribers of 2 guineas, or benefactors of 25 guineas, may recommend one in-patient and four out-patients annually.

Subscribers of 3 guineas, or benefactors of 30 guineas, may recommend one in- and six out-patients annually.

Subscribers of 4 guineas, or benefactors of 40 guineas, may recommend two in- and eight out-patients annually; but can only have one in-patient in the Hospital at a time.

Subscribers of 5 guineas, or benefactors of 50 guineas, may recommend three in- and ten out-patients annually; but can only have one in-patient in the Hospital at a time.

Subscribers of 10 guineas, or benefactors of 100 guineas, may recommend six in-patients annually, and out-patients without limitation; but can only have two in-patients in the Hospital at the same time.

Subscribers of 20 guineas, or benefactors of 200 guineas, can recommend patients without limitation, providing that no contributor has more than two in-patients at the same time.

Any person who, by individual exertion or otherwise, presents the sum of 5 guineas, may recommend 1 in- and 2 out-patients; 10 guineas, 2 in- and 4 out-patients; 15 guineas, 3 in- and 6 out-patients; 20 guineas, 4 in- and 8 out-patients

during one year from the date of payment, provided only 1 in-patient be in the Hospital at the same time.

Clergymen and ministers, from whose places of worship congregational collections amounting to £10 or upwards are received for the Hospital, are, in virtue of such collections, governors for one year from the day on which the same is paid to the treasurers or secretary, and are entitled to all the privileges of annual subscribers of 5 guineas. Where such collections amount to any less sum than £10, they are entitled to the same privilege of recommending patients as is conferred upon annual subscribers of a like amount for one year from the day of payment. If the collections made at different times amount in the aggregate to £500, the parties are governors for life, and entitled to the privileges of subscribers of 5 guineas.

A nominee of contributors to boxes and collections has the same right of recommending patients as an individual subscribing the like amount.

One executor, under any one will, is entitled to the same privileges as a donor of the same amount.

Patients are received on any Wednesday, at the weekly board. Patients cannot be admitted at any other time, except on sudden emergencies, when they are received without delay at any time of the day or night. The sick and lame poor of every county and nation are entitled to admission into the Hospital.

No woman in an advanced state of pregnancy; no person disordered in intellect, or suspected to have the small-pox, itch, or other infectious disease; nor any that are in confirmed consumption, can be admitted into the Hospital as in-patients. Children are admitted into the institution.

The number of patients in the Hospital suffering under scrofulous complaints may at no time exceed fifteen. Such patients are admitted in rotation; but none can remain beyond twelve weeks, unless the Medical officers, after a consultation, shall recommend it.

Patients labouring under typhus fever, scarlet fever, other contagious fevers, or measles, may be admitted into the wards of the fever department according to the rules for admitting other patients. Such patients must bring two changes of linen at the least.

Vaccination.—The poor may be vaccinated at the Hospital gratis (without any letter of recommendation), on any day of the week (Sundays excepted), at ten o'clock in the forenoon.

INCOME AND EXPENDITURE.

The Hospital and grounds are freehold property. There is standing stock held in the name of trustees to the amount in round numbers of £20,000. The annual income averages from £5000 to £6000. The income is derived mainly from voluntary subscriptions.

The average cost of each bed is £50 per annum; this includes every expense—furnishing, building, salaries, and the like. The actual maintenance of each in-patient averages 9s. per week, and of each out-patient 1s. 6½d.

SAMARITAN FUND OF THE HOSPITAL AND PATIENTS' LIBRARY.

The late Thomas Hankey, Esq., founded, in 1853, a fund called the Samaritan Fund, for patients of the Hospital who were in abject poverty. This fund, which now amounts to £200 a year, and is managed by a committee, is distributed in subscribing to the Metropolitan Convalescent Institution, in conveying destitute patients to their homes, in admitting accidents without recommendation, for assisting convalescents, for providing special Surgical instruments, and for providing warm clothing and other creature comforts in cases of extreme necessity.

THE MEDICAL STAFF.

The Medical staff consists of Drs. E. L. Ormerod, M.D., William Kebell, M.D., Henry Moon, M.D., Physicians. Drs. C. J. Beard, M.D., A. F. Seymour, M.D., Assistant-Physicians. Edmund J. Furner, Esq., Harry M. Blaker, Esq., G. Lowdell, Esq., Surgeons. F. W. Jowers, Esq., F. A. Humphry, Esq., Assistant-Surgeons; and N. P. Blaker, Esq., House-Surgeon. Pupils are allowed to reside in the Hospital, and out-door pupils are also admitted to the practice. There are generally from six to eight pupils studying in the Hospital. The Hospital is recognised by the examining boards.

SANITARY ARRANGEMENTS.

THE WARDS.

The wards of the Hospital are thirteen in number. They consist of one double accident ward for males and one single accident ward for females, three ordinary Medical wards and one ordinary Surgical ward for males, two ordinary Medical wards and one Surgical ward for females. There is a small

occasional ward for males, and a male and female fever ward; besides which there is a room adjoining each fever ward which is used as a lock ward for females, and for extreme or violent cases amongst males. The fever wards are capable of receiving six beds each; but they are rarely full. The ordinary wards receive from eleven to fifteen beds.

The cubic space varies very much in different wards. In No. 3 ward Medical the cubic space to each bed is 1300 cubic feet; in a small ward adjoining there are 630 cubic feet to each bed. In No. 6 ward Medical, the average is 1633, and in No. 10 ward, also Medical, the average is 1166 cubic feet per bed. In the fever wards the space runs to 1852 cubic feet per bed. In the Surgical wards the average cubic space per bed may be taken at 1100 cubic feet.

The Drainage is as free as can be wished: from the position of the Hospital there is a natural drainage flow into the main sewer, and so into the sea. There are still some cesspools, which are very deep. The water from the house generally is discharged into an open short channel outside the Hospital, whence it flows into a drain. It is thus impossible for effluvia to rise from the drain into the house.

The bedsteads are of iron, with one or two Earle's bedsteads for special cases. Curtains are allowed round the head of the bedsteads; they are "white check" in colour. The bedding consists of a single horsehair mattress.

Ventilation and Warming.—The ventilation of the Hospital is by the windows and also by an artificial method. This artificial method consists of a large cowl, like that seen on a malt-house, which is placed at the back of the Hospital, on the borders of the Downs. This cowl collects the air, and from it the air descends into the Hospital by a main shaft, which communicates by minor shafts ascending from the base with every ward through openings near the floor. The plan works moderately well. In some of the wards the plan known as Bird's system of "costless ventilation," is adopted. There are also in the wards near the ceiling escape flues for the exit of air, protected by small hoppers. In ward No. 2 the syphon ventilation has been tried, and has not been found to answer.

The Warming is carried out entirely by the open fire grate. There is no attempt anywhere at warming either by hot air or water. The heat of the wards is easily maintained by the open grate system, which leaves nothing to be desired.

Sunlight is freely admitted into every ward, and the Hospital is excellently situated for securing this important agency.

The Water Closets are abundant; there is one in every ward. They open, in the old wards, directly into the wards, protected by double doors. In the new wards there is an ante-room between the ward and the closet. The closets are lighted by two windows and ventilated. They are now free from smell, but in one or two cases formerly there was difficulty in keeping them sweet.

Lavatories and Sinks are provided for every ward, but each lavatory is placed in an ante-room between two wards.

The Water Supply is from the Water Company. At the upper part of the Hospital grounds, above the Hospital level, is a water reservoir. The supply of water is free and constant. The drains are thoroughly flushed.

Baths are provided for each ward. They are constructed of copper; each bath is furnished with a supply of hot and cold water. There are baths in the out-patient department, and these are found extremely useful and convenient. There is no hot air-bath in the institution.

The floors of the Infirmary are of deal. They are cleaned once every week at least, by washing and scrubbing. The dry process has never been used.

The Decoration of the Wards is indifferent. The walls are painted shoulder high, and above are whitewashed. In all the wards there are a few illuminated scrolls, but these are too conspicuous from their singleness. Pictures are not as yet introduced, but flowers are cultivated, and the cultivation is rather encouraged.

THE NURSING SYSTEM.

There is one head nurse to each ward, who is provided with an under nurse and a scrubber. There are, in addition, two night nurses, who are sent to wards where they are most required. The nurses are very attentive and active. One nurse has been in the Hospital for the long period of twenty-nine years. The system is not the most modern, but it works fairly here. All the nurses are under the disposition of the matron.

THE DIET.

The diet is very liberal, and the extra diet list is carried out on a plan that is original. I subjoin a table of diet with special rules.

Sussex County Hospital Diet-Table for the In-patients.

Meals.	Extra Diet (Meat).	Ordinary Diet (Meat and Soup).	Broth Diet.	Fish Diet.	Milk Diet.	Low Diet.
Breakfast, 8 a.m.	Tea (or coffee by order). Bread and butter.	As in Extra Diet.	As in Extra Diet.	Milk 1 pt. Bread and butter.	Milk 1 pt. Bread and butter.	Water-gruel, barley-water, arrow-root, or sago, with beef-tea or mutton-tea, 1 pt. daily. sugar not exceeding 1 oz. to each pint of water-gruel, etc.
Dinner, 1 p.m.	Meat 7 oz. cooked, without bone; potatoes 8 oz., or other vegetables—daily. Mutton—Sunday, Tuesday, Thursday, Saturday. Beef—Monday, Wednesday, Friday.	Meat 4 oz. cooked, without bone; potatoes 8 oz., or other vegetables—5 days. Soup 1 pt., rice pudding 16 oz., sweetened with sugar or treacle 2 days, viz.:—Wednesday and Saturday.	Mutton broth 1 pt., rice or other farinaceous pudding 16 oz., sweetened with sugar or treacle—daily.	Fish 6 oz., rice or other farinaceous pudding 8 oz., sweetened—daily.	Rice or other farinaceous pudding 16 oz., sweetened, daily.	Special Diet. The same general allowances as in Ordinary Diet.
Tea, 6 p.m.	Tea, bread and butter.	As in Extra Diet.	As in Extra Diet.	As in Extra Diet.	As in Extra Diet.	Children.
Daily allowances to each patient.	Meat 7 oz. Bread 14 oz. Butter 1 oz. Potatoes 8 oz. or other vegetables. Milk ½ pt.	Meat 4 oz. or soup 1 pt. with pudding 16 oz. The rest as in Extra Diet	Broth 1 pt. Pudding . . . 16 oz. The rest as in Extra Diet.	Fish 6 oz. Pudding . . . 8 oz. Bread 10 oz. Butter ¾ oz. Milk 1¼ pt.	Pudding . . . 16 oz. The rest as in Fish Diet.	Children under 10 yrs. of age to receive two-thirds of these allowances unless directed otherwise.
Weekly allowances.	Tea 1 oz. Sugar 8 oz.	As in Extra Diet.	As in Extra Diet.	Tea ½ oz. Sugar 4 oz.	As in Fish Diet.	All patients to be put on Broth Diet till a diet is ordered.

Mutton broth to be made with 1 lb. of meat to 1 gallon of pot liquor, thickened with rice, pearl-barley, or oatmeal, and 1 oz. of onions. Beef-tea or mutton-tea to be made with 1 lb. of meat to 1 pint of water. Soup to be stronger than broth, and to be thickened with rice, pearl-barley, or peas. Beer, wine, etc., are only given on special order of the Medical Officers.

All the articles of diet in any one of the classes in the list given below may be substituted for one another by the House-Steward, with the concurrence of the Medical Officers, according to the state of the market, or of the supplies in the Hospital.

MEATS.

- | | | |
|--|--|---|
| <p>a Mutton chops.
Lamb chops.
Calf's head or feet.
Tripe, stewed or fried.
Minced meat.</p> | <p>b Haricot mutton.
Stewed beefsteak.
Meat pies or puddings.
Sausages or black puddings.
Pork chops.
Pickled pork.
Eggs and bacon.
Liver and bacon.
Bacon and greens.</p> | <p>c Rabbit.
Pigeon.
Chicken.
Game.</p> |
|--|--|---|

FISH.

Soles, eels, skate, whiting, sprats, plaice, herring, maekarel, brill, according to the market and the season.

PUDDINGS.

Batter, or custard, sago, tapioca, semolina, rice, baked or boiled, bread and butter, fruit tarts or puddings.

THE USE OF ALCOHOLICS.

Ale and porter are allowed to the patients in moderate quantities, according to order. The average amount of malt liquor used per patient per day is not more than half a pint. The average allowance of wine per patient per day is rather more than half an ounce, and the amount of spirits the sixth of an ounce.

PRACTICE OF THE HOSPITAL.

The Medical practice of the Hospital presents not many cases of acute disorder. Rheumatism is common in the sub-acute and chronic stages, and, perhaps, is the most prevailing acute malady. Phthisis pulmonalis is, of course, a prevailing disease, and struma in its various forms. Epidemic diseases are comparatively rare, and such fever as is seen is mainly of the continued type. Dyspeptic cases are abundant, as well as disorders traceable to the abuse of alcohol as their main cause.

On the Surgical side, strumous diseases of bones and joints prevail largely. Calculus is not uncommon, but the cases presenting it come mainly from villages on the other side of the Downs, not from the town. Accidents of a severe kind are comparatively few. As yet ovariotomy has not been practised in the Hospital.

Statistics of the operations performed in the Hospital, and of their results, have not been kept with sufficient accuracy to allow me to use them with any degree of certainty. Operations for hernia have been almost uniformly successful. Lithotomy has not been very successful. Excision of the joints in various cases has been rather largely tried. It has succeeded in every instance where the elbow-joint has been operated upon. In the knee it has been less successful. In one case, of somewhat recent occurrence, the excision seemed at first to answer, but a secondary operation—amputation—had to be performed, from which the patient sank. Pirogoff's operation is very favourably received here. Mr. Blaker has performed it four times, and Mr. Furner twice; and every case has made an excellent cure. The subclavian has twice been tied in the Hospital recently: once by Mr. Furner and once by Mr. Blaker. In Mr. Furner's case the patient—a man—made an entire recovery. In Mr. Blaker's case the patient—also a man—lived fourteen days after the operation, and then died from hæmorrhage. It was found after death that there was extensive atheromatous disease of the arterial system, from which, in fact, the patient may be said to have died. Ligature of the external iliac has been successfully performed by Mr. Furner, and of the femoral by Mr. Blaker. There has also been a successful case of amputation of the shoulder-joint, performed by Mr. Lowdell on a man who had been crushed by the wheel of a railway carriage.

CHLOROFORM.

Chloroform has been administered at least twelve hundred times in the Hospital. It is always administered on a hollow sponge. Snow's inhaler was once obtained for use, but is thrown aside. The administration of chloroform is entrusted to the House-Surgeon, who attends to it exclusively. There has been no death from chloroform in this Hospital, nor any untoward case. Attention is paid to the symptoms produced rather than to the quantity of chloroform inhaled.

MORTALITY.

On the method of calculation proposed by Dr. Farr, the mortality of the Sussex County Hospital ranks high compared with other provincial Hospitals. Taking the mortality of the year 1861 as his basis, his table yields 66·06 per cent. as the mortality of the institution for that year. This is the highest mortality we have yet met with in our Hospital inquiries, being 30 per cent. higher than at Norwich or Stafford, and 16 per cent. above that of Etruria. Considering the difference in the class of cases in the Hospital at Etruria, and the great advantage which the Sussex County Hospital possesses over the Etruria Hospital, it is exceedingly difficult to account for such a difference in the mortality of these institutions.

The reader will bear in mind that Dr. Farr's calculation is deduced, not from the division of the deaths by the average number of patients admitted during the year, but by the number of patients present on one particular day in the year. He must also remember, in using Dr. Farr's tables, that in saying 70 per cent. it is not implied that of every 100 patients that enter the Hospital 70 die, but it is meant, in describing the percentage, only to strike a comparison between one Hospital and another on a certain basis. For example, on the 8th day of April Dr. Farr finds 99 patients in the Hospital at Etruria, and 109 patients in the Hospital at Brighton; but he finds, again, that the deaths in the year 1861 were 50 at Etruria and

72 at Brighton. By this standard, therefore, the number of beds yielding fatal cases was 50·51 at Etruria, as compared with 66·06 at Brighton. For the matter of comparison between Hospitals this method is sound and practical; but it should always be taken by the side of another calculation showing the absolute number of deaths in a year by the number of cases admitted during the year.

On this last-named method of calculation I find, from a statistical table drawn up by Robert J. Rogers, Esq., late House-Surgeon to the Sussex County Hospital, that the average number of admissions of in-patients during the last ten years has been within a fraction of 1165 annually, and the average of deaths 75. This would yield a percentage mortality of a little more than 6 per cent. on the whole admissions in each year, or at least 2 per cent. more, on the same basis of calculation, than the Hospital at Norwich. I confess I do not see why there should be such a comparatively high mortality in the Brighton Hospital; neither can I detect any error in the data on which the calculations are founded.

POINTS OF PRACTICE.

On both the Medical and Surgical sides the treatment of disease by stimulants finds little favour. On the Medical side the treatment of rheumatism by the alkalies is much relied upon. The method has been extensively employed by the Physicians, with the effect, in their opinion, of diminishing the number of cases of disease of the heart, and in shortening the duration of the disorder. The expression of this opinion was made to me by Dr. Ormerod and Dr. Kebbell, with equal confidence. In the treatment of phthisis small doses of cod-liver oil (a teaspoonful) are now employed in preference to larger doses, and it is believed with advantage.

In the treatment of diabetes an attempt has been made to utilise common oil-cake as a food instead of the almond biscuits, which are found useful, but too expensive for Hospital purposes. The object aimed at has been to purify the oil-cake and to make it palatable as food, an attempt which, Dr. Ormerod tells me, promises to be successful.

A case of hydatids in the abdominal cavity, which occurred some time ago, under the care of Dr. Ormerod, gave occasion for a unique and successful mode of treatment. The hydatid tumour was tapped through the abdomen, and the hydatid cysts were drawn out by means of suction by a stomach pump. Hydatids were also discharged from the rectum and through the bladder. The case was under observation for five months, and the stomach-pump was used in the way described three times, at intervals of from two to three weeks. The patient made a perfect recovery.

Dr. Kebbell has been for some time past using chlorodyne very largely as an anodyne and sedative, and he thinks with the happiest results. This is worthy of note, as contrasting with an opinion expressed by Dr. Robertson, in respect to the value of chlorodyne in asylum practice, and which will be given in the sequel.

I have said that the operation of hernia is exceedingly successful in the Surgical department of this Hospital. Connected with this fact I may state that, as a general rule, the sac is opened, and that, specially, after liberating the strictured bowel the practice is not to attempt to relieve the bowels by a purgative, but to give an opiate.

THE LIBRARY.

There is a Medical library attached to the Hospital containing from 550 to 600 volumes. The books have been exceedingly well chosen, and include not only the current works of the day, but a considerable number of classical works relating to Medicine and the allied sciences.

THE MUSEUM.

The museum of this Hospital is exceedingly good; not equal as yet to that at Norwich, but promising much. There are numerous specimens, all well mounted, and presenting points of much interest.

The specimen of most value is the skeleton of a man who died of mollities ossium. Owing to his extreme deformity, the man during his life was a subject of remark in the town. He was one of six children of a family, and was born with both his arms broken, an anomaly accounted for by his friends on the ground that his father had kicked his mother in the stomach during her pregnancy. The man, who grew up ricketty, was brought up as a shoemaker. At the age of thirty he married, and became very poor, when the changes in the structure of his skeleton began rapidly to advance. His case has been admirably described by Dr. Ormerod. At the age of forty his bones were so brittle that he sometimes

had no fewer than seven fractures of different bones at one time; but he lived on to be sixty-eight, and died at last "worn out," says Dr. Ormerod, "by the constant pain caused by his distortions, and by some ulcers on his legs." He measured, as he lay on his back at full length, no more than $39\frac{1}{2}$ inches.

Dr. Ormerod states that, although the body was so deformed, the mind of this man possessed considerable power. He had four children, two of whom lived several years. Both suffered like their father; one, a boy, died at sixteen, of small-pox; and the other, a girl—who used to be carried from one pot-house to another as a deformity to sing or jest—married, and died after undergoing the Cæsarian operation. The head of the skeleton in the Museum is large. The spinal column is contorted in two curves, and the distance from the atlas to the sacrum is fourteen inches. The ribs are overlapped and contorted, and the end of the tenth left rib shows a fracture still ununited. The scapulæ are mere shells. The humeral bones are fractured, the bone having a powdery appearance in the upper part. The pelvis is enormously reduced in size; the shafts of the femur are bent into sharp curves; and the bones of the leg, to use Dr. Ormerod's words, "under the weight of the body, and the traction of the muscles, have bent till the fibula forms a curve, of which the radius is no more than $3\frac{1}{2}$ inches."

Amongst Museum specimens of deformities of the skeleton, I have known of but one which approaches to this skeleton in the Brighton Hospital Museum, and that was the skeleton of a deformity who used to be seen in London some years ago, and was known as the "clarinet player." His skeleton—I believe he sold it himself, by the way, while he was living—came into possession of my once friend and colleague the late Mr. George Pilcher, and was preserved for many years in the Grosvenor-place School of Medicine. It was a wonderful deformity, but pathologically it wanted many points of interest as compared with the skeleton now at Brighton, the which I would recommend every one interested in osteological pathology carefully to study.

The Museum is very rich in specimens showing disease of the bladder, and I regret I have not time to enter into a description of them. They are worthy of study by any one engaged in inquiries having reference to vesical maladies.

A specimen showing a remarkable injury to the hand is preserved. It consists of phalanx of the right fore finger, with about nine inches attached of the tendon of the flexor profundus digitorum. The phalanx was torn off by machinery, bringing out the tendon with it. The patient recovered without a bad symptom.

A specimen of a skull which has been extensively eroded in consequence of malignant tumour of the left orbit, is of value as indicating the extent to which destruction of the bones of the orbit and the face may be extended. The patient, a boy, attributed the disorder to his having been stung in the eye with a sea-nettle. In the course of the disease the left eye, which is also in the Museum, was removed by operation.

A specimen is shown in which the bodies of the fifth, sixth and seventh dorsal vertebræ have been eroded by the pressure of an aneurism of the aorta. The cancellous structure is exposed.

A rare specimen of a case in which there was a tubercle on the spinal cord, opposite to the ninth dorsal vertebræ, is preserved. The tubercle was composed of a fibrous struma with some ganglionic cells and many fat granules, and some exudation cells. The patient suffered from complete loss of both motion and sensation in the lower limbs, commencing in the left leg. He laid for seventeen weeks in this condition previous to death.

In a specimen of a foot recently amputated, from which foot the cuboid bone was removed two years ago by Mr. Furner in consequence of strumous disease, it is found that the cartilages at the end of the metatarsal bones, which once formed, with the cuboid bone, the articulation, are still perfect and natural.

A specimen is present showing ligature of the subclavian in the patient operated on by Mr. Blaker. The man lived fourteen days, and died of hæmorrhage from both ends of the artery. The whole of the large vessels were atheromatous.

There is a specimen of ulceration of the larynx, from syphilis, with great disorganisation. The muscles of the neck of this patient, a man, were infested with trichinæ spiralis.

A specimen of diseased lung is preserved in which, in a large cavity, an hydatid cyst lies imbedded. The cavity is lined by a smooth thin membrane.

A good specimen is retained of a thick plate of earthy matter removed from the pleura of a man aged 40 years.

The palate is nearly half an inch thick in parts, and laminated. The patient, a convict, died of bronchitis.

A specimen is retained of an atrophied kidney, with great enlargement of the supra-renal capsule. The pelvis of the kidney is dilated, and the ureter, which is much dilated, is studded with vesicles filled with a brown opaque fluid. It is the only specimen of the kind I have seen, and the nature of the disease is obscure.

Lastly, there is an almost unique specimen of stricture of the œsophagus below the line of the larynx. The patient, a woman, who died of phthisis, suffered for fifteen years from difficulty of swallowing, but could take liquids. The narrowness of the stricture amounts almost to obliteration of the canal, but there is no surrounding thickening whatever. The woman said that her difficulty followed on a confinement. She never suffered from corrosive poisoning.

Should the Museum of the Brighton Hospital progress as it has commenced, it will soon be one of the best in the provinces. Much credit is due to Mr. Blaker, the present House-Surgeon, for the attention he pays to the curatorship. I have to thank Mr. Blaker very heartily for his kindness in putting all that he could at my disposal.

The sum placed to the Library and Museum account amounts to about £21 annually.

As time goes on the necessity for still further enlargement of the Brighton Hospital again becomes obvious, and a general court is proposed to be held on the 29th instant to consider the propriety of effecting such enlargement. At various times the question has been discussed of the possibility of having sea-baths within the walls of the Infirmary. The distance of the building from the sea and its elevation have up to this time prevented the carrying out of this very excellent measure. To ensure success a pumping apparatus would be required, the expense of which would encroach too greatly on the current income of the Institution.

We have seen many reasons why the inhabitants of modern Brighton should be proud of their town, but taking it all in all, there is no institution on which they need look with more satisfaction than on the Sussex County Infirmary and its noble sister institution, to which I am now about to ask the reader to follow me.

THE SUSSEX LUNATIC ASYLUM, HAYWARD'S-HEATH.

Next to the Sussex County Hospital, the Sussex Lunatic Asylum at Hayward's-heath demands special notice. This asylum was opened on July the 25th, 1859. It is intended purely for the pauper lunatics of the eastern and western divisions of the County of Sussex and of the borough of Brighton. It is conducted under the supervision of a committee of Justices of the Peace, fourteen of whom belong to the eastern division of Sussex, eight to the western division, and two to the borough of Brighton. Edward Smith Bigg, Esq., is chairman of the committee. Dr. Lockhart Robertson is the able Medical superintendent, and Dr. W. V. Browne is the Assistant Medical officer.

The asylum is situated on what is called Hayward's-heath. It is about twelve miles distant from the sea, but hidden from it by the range of the South Downs. The heath is now enclosed under the provisions of the Enclosure Act, but the character of it as a heath is not yet lost. The scenery, which reminds one much of that which is afforded at the Crystal Palace at Sydenham, is wide and beautiful, and the sea air finds its way across the expanse. The building is of brick, and, if the expression be allowable, is of the English Byzantine order. The front, which faces the south, is straight Italian, with the offices in the centre, and receding wings for the workshops, the Infirmary, and the refractory wards. The chapel faces the north entrance, and is a spacious and beautiful building, the internal decorations being singularly subdued and effective. To the surrounding neighbourhood the asylum is a conspicuous object. It may be seen for a dozen miles in all directions, and the approaches to it are very pretty. Around the building is an estate of two hundred and thirty acres, consisting of pasture land and wood. The soil is Sussex weal, a poor clay, not worth in its original form a rental of ten shillings an acre. This estate, as I shall show by-and-by, is, however, now yielding important advantages to the Institution.

The inmates, as has been stated, are all paupers belonging to the County of Sussex. The mean population resident last year in the asylum was two hundred and thirty-five male and two hundred and fifty-six female, giving a total of four hundred

and ninety-one. The asylum was constructed at first for two hundred and fifty patients in equal proportions of the sexes, but it has recently been enlarged by the addition of one hundred and twenty-five beds for females. The total cost of the asylum, buildings, land, etc., etc., was £100,000.

Water Supply.—The water of the asylum is derived from an Artesian well on the farm, sunk to a depth of 217 feet. The supply is apparently boundless. When the pumps are not in operation the well overflows at the rate of a hundred thousand gallons per day. The water is good, but unfortunately, in spite of every effort to prevent infiltration, is impregnated with a little iron, 0.54 per gallon. This gives to the water a dirty iron colour, which cannot be removed without the filter, and which discolours the linen.

Drainage.—The drainage of the house is very complete. The main drains are all of ten inch glazed tile. The sewage is conveyed to the farm, and is there utilised, as will be explained in the sequel.

The Water Closets are arranged on Finch's plan. The seat is free from woodwork, and consists of a double circular case of porcelain. The closets open out of the wards.

Space.—The space allowed to each patient is, by superficial measurement, fifty superficial feet in the night, and twenty superficial feet in the day wards. This is the Commissioners' minimum space, and for day-room accommodation is too little. There is double the space in the day-rooms at Hanwell and Colney Hatch than is allowed here. It is proposed to build detached dining-halls for each sex, a step not less useful than urgent, to relieve the over-crowding of the wards.

The Wards.—The wards are six in number on each side; they are arranged on the old asylum plan of day-room, dining-room, and gallery, with bed-rooms opening into each, and the asylum is almost peculiar in that it possesses an upper storey, devoted to sleeping-rooms only. In a new wing, which has been built on a plan devised and drawn out by Dr. Robertson, the sleeping-rooms are built distinct from the day-rooms, and the asylum gallery system is abandoned,—an abandonment that is generally admitted by the Profession to conduce to the quiet and order of the patients, by approximating their habits of life to those of the sane.

The reason for the introduction of the gallery system into asylums is peculiar, and is, I believe, well explained by Dr. Robertson. The earliest asylums, according to him, were religious houses, which, at the suppression of the monasteries, were devoted to the reception of the insane. The long gallery and the cells adjoining constituted the structure of the

monastery, and when the buildings were adapted to the use of the insane were retained, the gallery acting as a promenade for the mad. That which was a place of retirement for the exercise of religious devotion by the monk, thus became in after time a theatre for the full development of the ravings of the insane man. In going through the Royal Hospital at Bethlehem we see this gallery system still strictly carried out, the house having been rebuilt for the third time on the model of the veritable Hospital of St. Mary of Bethlehem, whither for refreshment came, in the olden time, the wearied pilgrims from the Bethlehem of Judea. In a few years we shall hope to see a remodelled Bethlehem on a country site, and a Bethlehem applying its princely resources to the full relief of the insane of the middle class whose present condition is now the most neglected of any. In a few years also we shall hope that in every asylum in England the gallery of the monk will be as great a curiosity as is the monk himself.

To return, the wards and rooms of the Sussex Asylum are decorated with less art than those of the Stafford Asylum and are less spacious, but there is, nevertheless, great attention paid to decoration; the light is very good, and every provision is made for the comfort of the inmates. The ventilation is almost entirely dependent on open fireplaces and open windows; a plan which, in the main, is found to answer best. The wards at the time of my visit were all very sweet and pure. The floors are of pine, and are washed every other day. Warming is carried out by the open fire grate. The furniture of the rooms is in stained deal, and suits well, the patterns of the furniture being in harmony with the style of architecture; the floors are covered throughout with cocoanut matting, which is made in the house by the inmates.

Baths.—There is a bath in every ward; the baths are of porcelain, on Finch's patent, and have a cold water douche pipe attached to them. There is also a Roman bath, constructed three years ago at an expense under £150. This bath has been found of great service. At the present, Dr. Robertson has under construction a general bath-room, with a Russian bath attached to it.

Bedsteads and Beds.—The bedsteads are made of birchwood, French polished, with sacking bottoms and horsehair mattresses. The mattresses are manufactured in the house.

Diet.—The dietary is very liberal: full eleven hundred pounds is expended annually on wines, spirits, ale, and porter. The food is not weighed on being given to the patients individually, but a fixed amount is sent to each ward. The following is the diet scale:—

Diet Scale.

	Breakfast, at 8.0 a.m.								Dinner, at 1.0 p.m.								Supper, at 6 p.m.

DINNER.

	Male Patients.	Female Patients.	Male Patients.	Female Patients.
Sunday ..	Bacon and greens.	Boiled pork.	Thursday ..	Meat pie.
Monday ..	Mutton broth.	Meat pudding or Irish stew (alternate).	Friday ..	Roast beef or pork.
Tuesday ..	Meat pie.	Meat pie.	Saturday ..	Mutton broth.
Wednesday ..	Roast beef or pickled pork.	Roast beef or 7 oz. fish (alternate).		
				Bread, beer, and vegetables daily.

Extra Diet for Sick.—Mince meat, steak, mutton chop, fowl, fish, eggs, mutton broth, beef-tea, essence of beef, milk, arrowroot, rice pudding, batter pudding, sago, barley water, gruel, oranges, biscuits, calf's foot jelly, porter, port wine, sherry, brandy, gin, whiskey, rum, lemonade, soda water.

Extra Diet for Working Patients.—½ pint beer, 2 oz. bread, 1 oz. cheese, at 11 a.m., and ½ pint beer at 4 p.m.; the laundry patients, ½ pint tea. Tobacco and snuff given as required.

Attendants and Servants' Diet.—Men, 1 lb. uncooked meat; women, ¾ lb. ditto; 1 lb. vegetables, 1 lb. bread, 2 pints beer, daily. 2 oz. tea, ¾ lb. sugar, ¼ lb. coffee, ½ lb. butter, 1 lb. cheese, weekly. ¼ lb. meat may be exchanged for pudding or pie, at the discretion of the housekeeper.

Cocoa for One Hundred Patients.—3½ lb. cocoa, 6½ lb. treacle, 3 gallons milk, or more, if the dairy yield it.

Coffee Ditto 1½ lb. coffee, ¼ lb. chicory, 4 lb. sugar, 2 gallons milk.

Tea Ditto 1 lb. tea, 4 lb. sugar, and 2 gallons milk.

Mutton Broth Ditto The liquor of the cooked meat, bones, &c., 25 lb. Meat, 3 lb. Scotch barley, 6 lb. rice, 50 lb. turnip, cabbage, parsnip, leek, onion, artichokes, or other vegetables, herbs, salt, and pepper.

Meat Pie Ditto Dripping crust, 31 lb. flour, 50 lb. potatoes, 13 lb. meat.

Meat Pudding Ditto 25 lb. meat, 30 lb. flour, boiled.

(Signed) C. L. ROBERTSON, M.D. Cantab., Medical Superintendent.

Expenditure: Cost of Maintenance.—The cost of maintenance in our public asylums presents many variations. It is most important that this practical fact should be known, and that a correct understanding should be arrived at, so as to ensure some approach towards uniformity that shall be consistent with sufficiency of maintenance on the one hand and economy on the other. The cost of maintenance is materially modified—first, by the liberality of the diet; secondly, by the rate of wages in the district; thirdly, by the cost of fuel; and lastly, by the varying practice of the visitors in those items which are included in the repairs charged on the county rate. Some asylums charge all additional furnishing arising from increase of patients to the county rate; others to the maintenance. The following summary of average weekly cost in the under-mentioned asylums is extracted from an elaborate and most carefully prepared table of comparative expenditure in the annual report of the Sussex Asylum for the year 1863 by Dr. Robertson. It is a summary to which I would respectfully direct the attention not only of Medical officers, but also of visitors of asylums for the insane.

Average Weekly Cost for each Patient for the Year 1862.

Amusements.—The patients are provided with every possible reasonable occupation and amusement. A table in the last annual report affords some exceedingly interesting particulars of the manner in which the day is spent by the various sufferers, and obviates the necessity of any further remark on this head, except that the patients and attendants have formed a brass band, which makes “most excellent music” and is a source of great delight.

Table showing Patients' Daily State and Employment.

Government of the Asylum.—The asylum may be considered as under the sole governance of the Medical superintendent, who is responsible to the visitors for the detailed management of every department. In this respect it differs, as do the other county asylums, from Hanwell and Colney Hatch, where the visitors themselves attempt to govern at their weekly boards (no pun is intended), and to regulate by their minutes the smallest details. At Colney Hatch the Medical officers, I believe, are required to record in a book kept by the nurse the hours of their visits to each ward, while the assistant Medical officers are confined to barracks after ten p.m. At Hanwell the porter, I am informed, actually enters in his gate-book the hours the Medical officers are absent from the building daily: a turnstile that will register the passage of no one except a doctor is, in fact, a desideratum at these institutions, and the geniuses of England had better look carefully at the advertisement-sheet of *The Times*, or they may one day miss a fine opportunity of gaining a premium for their inventive skill. “A Medical turnstile wanted immediately!” Such a heading could not fail to tell.

Of course the trust that is imposed on the superintendent of a county asylum, and the confidence that is reposed in him, is a source of strength in his government, and of advantage alike to the patients and officers; while to the Profession it is a mark of respect which is fairly deserved. The visitors of the Sussex Asylum have from the first recognised these principles in their fullest extent; and that they have not been mistaken may be proved by any one who will take the trouble to inspect their institution carefully: the order that prevails and the wonderful quiet are as remarkable as they are assuring, and contrast favourably with what is seen and felt in houses where everybody is master and nobody is in command.

PRACTICE OF THE ASYLUM.

Mania from Local Irritation.—There is a form of mania not sufficiently understood, even by the Profession, and entirely unknown out of it, which has important bearings in relation to the influence of obscure diseased conditions on mental acts. In the cases to which I refer, the sufferers having a strong hereditary predisposition to insanity remain well until they are exposed to some kind of local irritation. Then they suddenly show extreme maniacal excitement, which only subsides as the local disorder is relieved. Some years ago I reported a case at the Medical Society of London, in which an attack of pneumonia brought on mania in this way, and Dr. Robertson informs me that he has had many cases introduced into the asylum of what may be called phthisical mania; but the best illustration of the relations recognised in phthisis and pneumonia as subsisting between maniacal exaltation and irritation of the organs of the body was related to me by Dr. Robertson in the history of a female patient, aged 33, who was admitted at Hayward's Heath in May, 1861, with persistent symptoms of violent mania, noise, sleeplessness, and refusal of food.

On examination a large tumour, the under surface of which was ulcerated from pressure in sitting, was found growing in the perineum, and attached by its base to the wall of the vagina. In July it was removed by Mr. Jowers, of Brighton, the patient having been placed under chloroform. The wound healed kindly, and the maniacal symptoms at once abated. In November she was transferred convalescent to the Oxford Asylum, from whence she was subsequently discharged cured.

She continues well. The tumour with its attachments is now in the pathological museum of the Brighton Hospital.

Bathing.—In the treatment of the insane Dr. Robertson places great confidence in the employment of water and of baths. In all cases of cerebral excitement, recent mania, or mania following epilepsy, he employs packing in the wet sheet, the sheet being changed hourly, and being followed by the dripping sheet or cold douche. In the treatment of melancholia extensive recourse is had to the Roman bath. The temperature of the bath is raised to a high point—to 180° or even 200° Fahr. Since the introduction of the Roman bath there has been no occasion forcibly to feed any melancholic patient for determinate refusal of food. In cases of refusal the patient is simply placed in the bath for half an hour, with the cold douche afterwards. The result of this treatment on the disordered secretions, from which the refusal of food mainly arises, has been attended with uniform success. The bath has also been used here in the treatment of uræmic mania, and with equally good results. In one case of mania with albuminous urine and dropsy, in a man, the use of the bath twice a week, for three months, led to complete recovery.

Sedatives.—As a medicinal agent, Dr. Robertson is strongly in favour of digitalis, in doses of half a drachm of the tincture, especially in the management of the mania of general paralysis. The Indian hemp is much used here as a sedative, and is considered of great value. The following form is the sedative mixture of the Asylum, and is worthy of extensive application: R. Tincturæ digitalis; tincturæ cannabis indicæ, liquoris opii (Taylor) atheris chlorici, singulorum unciam. Dose ʒss. to ʒj. Chlorodyne has been rather extensively tried, but is reported on by Dr. Robertson unfavourably. It does not act efficiently on the insane.

In speaking of sedative treatment, I must not omit to mention that the patients who smoke are never deprived of tobacco; and that, in the opinion of the Medical officers, they derive more benefit from the use of this sedative than from any in the Pharmacopœia. The bill for the tobacco used in this Asylum last year was £88.

Purification of Air by Iodine.—For purification of the air, Dr. Robertson has introduced the plan of diffusing iodine through the air by means of heat, on the principle described by myself in an address at the opening meeting of the Epidemiological Society last year. The method is entirely successful, and is considered as peculiarly applicable in Asylum management. The metallic iodine is simply placed on a heated fire-shovel or plate, so as to volatilise the iodine and diffuse it in vapour through the apartment. The destruction of impure odours is immediate.

The number of cases dismissed annually from the Asylum are: as "cured," 30 per cent. on the admissions; and as relieved, 10 per cent. The mean annual mortality is 10 per cent. in the males, and 6 in the females.

THE ASYLUM FARM.

The farm supplies the house with milk, pork, and vegetables, and the "Visitors" are now about to fatten and kill their own beef and mutton. Should they succeed in this last-named attempt, their success will be a new and important feature in Asylum economics. The farm is worked entirely by the inmates, and on one of the days when I was at the Asylum six lunatics were to be seen actively engaged mowing a heavy crop of grass. No danger was thought of in entrusting them with the scythes. Twenty-five years ago I fancy the keeper who should allow a lunatic to work with a scythe would himself have been considered "out of his mind," and placed under restraint.

Sewage and its Utilisation.—The whole of the sewage of the Asylum is applied to eighteen acres of grass land, as well as to the vegetables of the garden, on a plan suggested by Mr. Alderman Mechi. The sewage, as it comes from the house, is applied in dressings over limited areas; about thirty thousand gallons a-day of sewage thus pass over the land and flows from it almost as free from visible impurity as spring water. The value of this sewage on the grass land is such, that it has raised the estimated rent of the meadows it has fertilised from ten shillings to three pounds an acre. The Italian rye grass flourishes most under its influence. I saw a third growing crop of this grass sprouting on the 11th of the present month, and I also saw a second crop which, without exception, was the heaviest grass crop I ever observed in my life. The present value of the sewage may be safely taken at fifty pounds net profit per annum.

In conclusion, in the Sussex County Asylum as in the Staf-

ford, epidemic diseases find no *habitat*. They come in not to kill men, but themselves to die out at once. Thus sanitary science proclaims again here, that the spreading communicable disorders are one and all preventible.

REVIEWS.

Glaucoma and its Cure by Iridectomy: being Four Lectures delivered at the Middlesex Hospital. By J. SOELBERG WELLS, Ophthalmic Surgeon to, and Lecturer on Ophthalmic Surgery at, the Hospital. London: Churchill. 1864. Pp. 86.

THESE are very excellent lectures, clear and concise. The author commences with a brief historical summary of his subject up to the time when our views upon the disease were revolutionised by the genius of Von Graefe, who, recognising the tension of the globe of the eye as the condition on which all the other phenomena he observed depended, and finding that the customary remedies for inflammation, mydriatics and tapping, all failed in giving permanent relief, and recollecting the benefit which in some other diseases resulted from iridectomy by the diminution of pressure it ensured, first tried the operation in 1856. Mr. Soelberg Wells next describes the methods practised to determine the important symptoms of increased tension and diminution of the field of vision, and then passes on to give a full account of what is to the ophthalmic Surgeon the most important stage of the disease—namely, the premonitory stage—most important, because it is on the recognition of the disease in this stage that the success of his treatment will chiefly depend. He dwells then upon each of its symptoms, increased tension of the eyeball, marked increase of any existing presbyopia, venous hyperæmia, haziness of the humours, dilatation and sluggishness of the pupil, periodic dimness of sight, the appearance of halo or rainbow round a candle, intermittent pains about the eye, and contraction of the field of vision. In the second and third lectures acute and chronic inflammatory glaucoma, that form which is named by Donders "glaucoma simplex," and in which it is not settled whether the glaucoma is inflammatory or not, and glaucoma occurring secondarily to iritis, posterior staphyloma, traumatic cataract, and projecting corneal cicatrix are fully discussed, and their indications and progress described. While pointing out the ophthalmoscopic symptoms, he shows how the excavation of the optic nerve from glaucomatous pressure is to be distinguished from congenital physiological excavation, and that arising from atrophy of the optic nerve. The fourth lecture is devoted to the subjects of prognosis and treatment by iridectomy. He taxes, and, we believe, not altogether without grounds for doing so, the opponents of the operation with an unfair representation of the amount of benefit which its advocates claim that it is capable of conferring, and at the same time with rejecting it on the plea that its *modus operandi* is inexplicable. The latter point he admits is still *sub judice*; but in an empirical art such as ours this objection goes for nothing, otherwise some of our best remedies in disease might be discarded for a similar reason. No one yet knows how arsenic cures psoriasis or quinine ague. He dwells repeatedly on the vast importance of *early* operation. He says:—"As long as the premonitory symptoms only occur at distant intervals, and the intermissions are complete, the eye returning to its normal condition during the intervals, we may postpone the operation with safety. . . . If the intermissions are no longer complete, but there are only remissions of the symptoms; if the periodic obscurations, the ciliary neurosis, the iridisations, occur at short intervals of a day or two; if the eccentric vision become impaired or the field even contracted, the vessels congested, and the eyeball tense, it would be dangerous to delay the operation any longer."—P. 64. "In *acute inflammatory glaucoma* the prognosis is also favourable if only the operation is performed sufficiently early," and "we may generally expect a nearly perfect result if iridectomy be had recourse to within a fortnight after the outbreak of acute glaucoma; always remembering, however, that at least good quantitative perception of light must still be present."—P. 65. "In *glaucoma fulminans* the operation must be performed as soon as possible."—P. 66. "In *chronic inflammatory glaucoma* the prognosis must also be guarded. . . . Iridectomy will, however, generally arrest the disease and preserve the existing amount of vision, or even improve it."—P. 68. "In *glaucoma absolutum*, in which all sight, even the quantitative perception of light, is lost, iridectomy is never indicated except to diminish a y

inflammatory symptoms or severe pain."—P. 70. Here, then, is his programme of benefits which the operation can confer—a very different statement indeed from one that would pretend that the supporters of iridectomy "claimed for it the power of restoring sight in all cases of glaucoma, whatever their stage or nature might be." In the last place, Mr. Wells describes the operation itself. We commend these lectures to the perusal of all who desire to obtain a definite insight into the modern doctrines relating to this malady.

New Observations upon the Structure and Formation of Certain Nervous Centres, tending to prove that the Cells and Fibres of Every Nervous Apparatus form an Uninterrupted Circuit. By LIONEL S. BEALE, M.B., F.R.S., F.R.C.P., Professor of Physiology and of General and Morbid Anatomy in King's College, and Physician to King's College Hospital.

ALL that is required to establish the doctrine of an uninterrupted circuit is its anatomical demonstration, and this Dr. Beale has now provided. Until it was provided, analogical argument and deduction went for little. They furnished a ground for speculation approaching the truth with greater or less degrees of probability, but that is all. Physiologists, for instance, have speculated about the analogy that exists between the arrangements of the nervous system and the ordinary circuit of a galvanic combination, and have been willing to regard the circulation of force in the latter as typical of the origin and circulation of nerve force in the former. It is true, Dr. Beale makes no allusion to this in his paper, but no one can read it without being struck with the fact that the demonstration he has made of the bipolar or multipolar character of nerve cells goes far in support of the analogy. The ordinary opinion among anatomists has hitherto been that in vertebrate and certain invertebrate animals there are in connection with the nervous system, not only multipolar, but also unipolar and apolar cells. Dr. Beale, however, says that he has been "compelled to conclude from anatomical observation, that, although many ganglion cells exist which appear to be destitute of fibres, none do really exist without them;" and that from studying the question in different animals, from mammalia down to the annulides, he feels justified in drawing the following general conclusions:—

"1. That in all cases nerve cells are connected with nerve fibres, and that a cell probably influences only the fibres with which it is structurally continuous. 2. That *apolar* and *unipolar* cells do not exist, but that all nerve cells have at least two fibres in connexion with them. 3. That in certain ganglia of the frog there are large pear-shaped nerve cells, from the lower part of which two fibres proceed—a, a *straight fibre* continuous with the central part of the body of the cell; and, b, a *fibre, or fibres, continuous* with the circumferential part of the cell, which is coiled *spirally* round the straight fibres. 4. These two fibres, after lying very near to and in some cases, when the spiral is very lax, nearly parallel with each other, at length pass towards the periphery in opposite directions. 5. Ganglion cells exhibit different characters according to their age. In the youngest cells neither of the fibres exhibit a spiral arrangement; in fully-formed cells there is a considerable extent of spiral fibre; but in old cells the number of coils is much greater. 6. These ganglion cells may be formed in three ways—a, from a granular mass like that which forms the early condition of cell structures; b, by the division or splitting up of a mass like a single ganglion cell, but before the mass has assumed the complete and perfect form; c, by changes occurring in what appears to be the nucleus of a nerve fibre. 7. During the development of a ganglion cell, there is reason to believe that the entire cell moves away from the point where its formation commenced, so that the fibres connected with it will become elongated. 8. There are 'nuclei' in the body of the cell; and there are nuclei connected with the spiral and also with the straight fibre. The nuclei in the cell are found upon its surface and also in its substance. 9. The matter of which the 'nucleus' is composed has been termed by me 'germinal matter.' From it alone growth takes place; and in all cases the matter (formed material) of which the nerve fibre consists was once in the state of germinal matter. 10. The 'nucleolus' consists of germinal matter. It may be regarded as a new centre, which originates in a pre-existing centre. 11. The ganglion cells of the frog are connected with dark bordered fibres, and also with fine fibres. 12. Contrary to the statement of Kölliker, that apolar cells and unipolar cells are to be demonstrated in the cardiac ganglia, all the cells in these ganglia

have two or more fibres emanating from them. 13. The muscular coat of all arteries in the frog, and probably of other animals, is supplied with nerve fibres. 14. Nerve fibres are not connected with the connective tissue corpuscles. 15. The so-called nucleated capsule of the ganglion cells in the ganglia of mammalia usually consists of nerve fibres, many of which are connected with the cell. 16. As nerve fibres grow old the soluble matters are absorbed, leaving a fibrous material, which is known as connective tissue. A corresponding change is observed in other textures in health and disease."—P. 26.

Practical and Pathological Researches in the Various Forms of Paralysis. By EDWARD MERYON, M.D., F.R.C.P., late Lecturer on Comparative Anatomy at St. Thomas's Hospital. London: Churchill and Sons. 1864. Pp. 215.

THERE is a certain class of books on practical Medicine which is invariably successful. We may illustrate the class we mean by mentioning the practical works of Abercrombie, and more lately Budd's book on the "Diseases of the Liver," or Habershon's on "Diseases of the Abdomen." They consist less of exhaustive treatises than a string of clinical reports. Such a book also is Dr. Meryon's. We must say that the greater part of its illustrations are culled from the published works of distinguished writers on diseases of the nervous system, and from that large storehouse of facts which is furnished by British and foreign periodical literature. We do not complain of this. We are thankful to any one who will take the trouble to put the crude mass of facts, which otherwise only serve to embarrass us, into a digestible form, searching honestly for truth and discarding error, while, at the same time, correcting the distorted conclusions of writers who view their special subjects with minds not altogether free from hypothesis and prejudice. Dr. Meryon's book is a sound one, and will, we have no question, be consulted in those difficulties which all of us so frequently meet with in the practice of our art.

We need say no more to interest our readers in favour of Dr. Meryon, and shall, therefore, pass on to a notice of the more particular construction of the volume. Oddly enough, it is a book without a preface. Of the two ordinary kinds of prefaces, certainly the preface apologetical would be out of place; while we presume Dr. Meryon thought that the preface explanatory was just as well substituted by a table of contents. By way of introduction to his subject, he gives us in his first chapter an account of the "Minute Structure of the Nervous Centres." This occupies the first twenty pages, and then he dashes in *medias res*, the succeeding chapters being severally devoted to "Paralysis from Affections of the Spinal Cord," "Paralysis from Affections of the Brain," "Paralysis from Blood Poisoning," "Paralysis from Reflex Action," and "The Progressive Forms of Paralysis."

As an example of Dr. Meryon's style, as well as of his moderation, we quote, in conclusion, his remarks upon "Blood-letting in Apoplexy:—"

"With respect to treatment, if we except the aberrations of quackery, there is one remedy which has been universally adopted by all Physicians in apoplexy; and if the maxim of Hippocrates (rather with a view of preventing serious consequences than of removing them after they have come on) had ever been borne in mind, probably no remedy would have been employed with less modification. The argument which has been used against it, founded on the assumption that no abstraction of blood can diminish the absolute quantity of that fluid in the brain, which is out of the influence of atmospheric pressure, is clearly a fallacy; for the immediate effect of venesection is to contract the area of vessels, and thereby to facilitate the restoration of the relative proportion between arteries and veins, and so far to relieve the excited action of the arteries of the brain. But M. Trousseau questions the tranquillising effect of bleeding in an excited circulation, and, therefore, even in severe cases of apoplexy seldom bleeds, on the plea that, extravasation having occurred, it is difficult to see the good that blood-letting can do. 'Extravasation on the brain,' says he, 'is like extravasation elsewhere, and no one would think of bleeding for extravasation of blood under the skin or mucous membrane. It would not facilitate absorption.' Yet it is not denied that venesection diminishes the force of arterial action; and although it may produce what is called reaction of circulation, it is calculated to relieve congestion, which, M. Trousseau admits, may lead to cerebral hæmorrhage, and to prevent the further escape of blood when any has taken place. The propriety of blood-letting ought to be determined by the special circumstances of every individual case, and not by any

general rule of treatment. If the pulse be full and strong, and there be nothing in the history of the case to contra-indicate the operation, there can be no question as to its expediency. If, on the other hand, the pulse be small and irregular, and the surface of the body be cold, the remedy would be fatal."—P. 107.

The Illustrated Horse Management, containing Descriptive Remarks upon Anatomy, Medicine, Shoeing, Teeth, Food, Vices, Stables; together with Comments on Grooms, Dealers, Breeders, Breakers, and Trainers; also on Carriages and Harness, etc. By EDWARD MAYHEW, M.R.C.V.S. London: Wm. H. Allen and Co. Pp. 612.

We have here a book evidently got up by the publishers in their best style, with abundance of illustrations, and everything to render it most attractive. On reading through the preface, however, we discover a harshness in the style which does not altogether disappear in the body of the work; but assuredly if a man has something to say he should not be deterred because his style is not so graceful as it might be.

We may begin by saying that this book will be useful to any one who will take the trouble to read it; and as Medical Practitioners, as a body, have a direct interest in horseflesh, which forms a part, as it were, of their stock in trade, we do not think they would do amiss were they to invest a little cash in the "Illustrated Horse Management." The first and primary object in this work appears to be to enforce the importance, not to say the duty, that every man who keeps a horse should treat it with a greater amount of consideration than is usually the case. For instance, what more simple than to walk into the stable occasionally to see whether there is a proper amount of ventilation; what more easy than to reprimand a groom for flogging a horse when he shies, which, by the way, nineteen servants out of every twenty do.

We would make one suggestion to the author, namely, that he should bring out a cheap edition of his book at a smaller price, there being a large amount of matter not really required by the ordinary public. We read descriptions of how a stud should be managed, and see drawings of stables full of quadrupeds, but what is most wanted is a volume which shall give in a few words all that can be said of a practical nature to those who keep, it may be, a single brougham horse, a saddle horse, or a pair.

We must confess to being rather partial to horseflesh, and in common with the generality of Englishmen, have an idea we are somewhat able to form an opinion of the equine race; but when our author states, as he does at page 327, that a loose box should be eighteen feet square, we are rather inclined to stand aghast and picture to ourselves the expense of a place for a horse as large as a good-sized dining-room, and as experience tells us that twelve feet square is sufficient for every purpose, we must beg to demur. The recommendation that loose boxes should take the place of stalls, is admirable, and one that we have always deemed essential, as after an animal has had its poor head lugged this way and that way at every whim of its driver, it seems but fair it should be enabled when in the stable to move or to turn which way it likes.

Our space will not permit us to go more into detail, suffice it to say that much money and not a little annoyance might be saved if every owner of a horse would make himself acquainted with the management of the animals in his stable, and not take for granted that because the groom says "The bay's legs is very bad," that therefore the animal cannot go out; and because this same worthy says horses should not be in a loose box because they invariably eat more when treated in this humane manner, that therefore it is so.

The Entomologist's Monthly Magazine. Van Voorst.

THIS publication will be very welcome to that large section of the community which amuses its leisure hours with the study of entomology. This first number contains several able articles, and is full of scientific interest. The Magazine is conducted by five gentlemen well known as zealous workers in this special branch of science. We wish them the success they deserve.

THE COLLEGE LECTURES.—Professor Fergusson delivered the last of his interesting course of lectures on the "Progress of Surgery during the Present Century" at the College of Surgeons yesterday (Friday).

FOREIGN CORRESPONDENCE.

TURKEY.

CONSTANTINOPLE, May 24.

As the condition of the British Army Medical Department is one which appears at the present time to attract an unusual share of attention, I think that some information concerning the state of the same branch of service in the Turkish empire may be read with interest. All subjects of the Porte, whether Mohammedans, Christians, or Jews, are allowed to enter the Army Medical Service; but there is this qualification, that two-thirds of all the Medical officers must be Turks, and only one-third may be selected from amongst Christians and Jews. It therefore frequently occurs that the most talented young men are refused admission into the service; while, on the other hand, men who have scarcely any knowledge of anatomy or pathology, and are extremely unlikely ever to get it, enter the Department merely because they belong to the ruling race and possess influential connexions. The same partiality is observed in granting degrees of M.D., and the result is deplorable; for, as I have already mentioned in a former letter, the habits and turn of mind of the present young generation of Turks are peculiarly inappropriate for the acquisition of a sound scientific and practical Professional knowledge.

The pupils turned out by the Medical School of the Capital are sufficiently numerous to take care of the health of the army in time of peace; but experience has shown that their number is totally inadequate in time of war, and during the campaign in the Crimea, the Director of the Army Medical Department was therefore obliged to supply the deficiency by calling civil Surgeons to his aid, most of whom were foreigners. The position of those Army Surgeons who emerge from the Medical School, and those who are taken from amongst the Profession generally, presents some differences which are worth mentioning.

The pupils of the Medical School on first entering the army acquire the military rank of captain; they are afterwards promoted to that of major (chef de bataillon), lieutenant-colonel, and colonel; the latter is the highest rank for army Surgeons, with the only exception of the Physician to the Sultan, Marco Pasha, who has the rank of brigadier-general. At first sight it would therefore appear that there was a real amalgamation of Army Surgeons and officers as regards rank; and this is indeed the case as far as outward position and salary are concerned; but after all it is only apparently so, for the Medical men do not receive a nomination decree (firman) which is given to officers, and whereby position and salary are guaranteed to them not only during the time of active service, but also if they are on leave; and whereby a pension is promised in case of their being invalided. The Surgeon, on the other hand, whatever may be his rank, only draws his salary as long as something is found for him to do; but if the authorities should not want him any longer, he is dismissed the service without any payment, until such time as he may again be required, or until he may succeed, by the influence of powerful friends, to get another place. No pension, as a rule, is given to Army Surgeons, and if a few of them enjoy it, it is by special favour only. This special favour is the sore point in the whole Turkish administration; neither the promotion nor rewards given to Surgeons are regulated by any law whatsoever. It is decided by favour whether the young Surgeon is to take his place in the capital or in the provinces; whether he is to be promoted or not etc. A certain rank, therefore, does not in the least correspond to a certain time of service, for a Surgeon may, according to Fortune's turn, one day be captain or major, and the next lieutenant-colonel or colonel. There is only this rule, that all higher charges must be in the hands of Turks, whatever may be their qualifications or those of their less favoured Christian colleagues. All the chief Surgeons of Army Corps and the chief superintendents of Hospitals are Turks; the highest rank which may fall to the lot of a Christian is mostly that of lieutenant-colonel—a Christian colonel being, indeed, a *raris-sima avis*.

The natural consequences of this arbitrary system of administration are the absence of all ambition and legitimate rivalry as regards the acquisition of Medical knowledge and zeal in the service; and, on the other hand, a most unworthy servility against those powers which divide the spoils; and I may safely aver that the position of the whole Turkish Army

Medical Department could scarcely be more undignified. For this not much blame can attach to the Medical men, since it is the system of administration which is at the root of the evil. The directors of the Medical School have often endeavoured to bring about a change, but all in vain. At the time of the accession of the present Sultan, fresh hopes of a regeneration of the Department were conceived, principally because Marco Pasha, his Physician in Ordinary, was himself a pupil of the Medical School, and was believed to nourish ideas of reform; but all hopes of any improvement being likely to result have vanished long ago, and things seem, in fact, to have gone from bad to worse.

I will now say a few words concerning the civil Surgeons who are temporarily received into the Army Medical Department, if they are required by the Government. They have no military rank and a very modest salary (from 15 to 30 Turkish pounds per month). Under such circumstances it is, of course, only the least talented members of the Profession who will follow the call of the Government; and they have, indeed, always been much below the average standard of the pupils of the Medical School. At the present time there are only very few civil Surgeons in the army; in Constantinople itself there are altogether seven of them, five of whom are employed in military Hospitals.

The following is the way in which the Medical men are apportioned to the troops. Each regiment is provided with a Surgeon, an Assistant-Surgeon, and an Apothecary; and each army corps has a Chief Surgeon, who takes the rank of colonel. The Hospitals of the capital, and of those provincial towns which are seats of the command of an army corps, have their own Medical *personnel*, consisting of a Chief Surgeon and several divisional Surgeons, who have, according to favour, rank varying from that of captain to that of colonel. The number of these latter is proportionate to the number of patients, one Surgeon being allowed to fifty patients. Each divisional Surgeon has his department assigned to him by the Chief Surgeon, who controls the doings of his subordinates, and in difficult cases aids them by his advice. The divisional Surgeon visits the patients, accompanied by the Apothecary. The rules made by Marco Pasha, the Inspector-General of the Hospitals, prescribe that after the Surgeons have visited their patients in the morning they shall all meet in consultation, and discuss the requirements of the Hospital, relate interesting cases under treatment, and talk over scientific questions, etc.; and that minutes of these proceedings shall be daily sent in to the Inspector-General. But as there is a total lack of scientific ardour amongst the Medical staff, and great dissatisfaction prevails amongst its most talented members on account of systematic neglect of merit, nothing whatever comes out of these daily meetings. Zeal for the service and interest in the progress of science cannot be made according to rule, but can only be produced by encouragement and reward of merit.

The medicines prescribed by the Surgeons are made up by the Apothecaries in the Hospital pharmacies. These Apothecaries are partly mere empiricists and partly pupils of the Medical School. They have rank varying from that of lieutenant to that of captain, and are placed under the surveillance of a Chief Apothecary, who has the rank of captain or major, and who keeps the accounts of medicines received and used. The medicines and surgical instruments for the whole of the Turkish army are furnished by the Director of the Central Pharmacy, M. Della Sudda, who is Brigadier-General, and as such has the name of Fayk Pasha.

The chief fault to be found with the organisation of the Turkish Army Medical Department is, that the pupils of the Medical School, after having received a very rudimentary professional training, are at once appointed full Surgeons to regiments or Hospitals before having served a thorough practical apprenticeship under the guidance of experienced Medical Practitioners. This want is chiefly felt, not so much in Medical cases, but where Surgical operations are to be done; and on the field of battle the Turkish army may therefore be pronounced as being quite devoid of an efficient Medical staff. This, of course, holds also good for the Navy Medical Department, which is provided for in much the same manner as that of the army. Smaller men-of-war are generally only provided with an Assistant-Surgeon, whose horizon does not go beyond cupping, bleeding, pulling out teeth, and giving enemata. Larger men-of-war have a Surgeon, an Assistant-Surgeon, and an Apothecary. The military rank of the navy Surgeons is also quite arbitrary; some of them being captains, others majors, lieutenant-colonels, and colonels. Some men-of-war

are provided with so-called officers of health, that is, persons who have, during time of war, been received in the Army Medical service before having finished their course of studies in the Medical School, but have been allowed to continue in their appointments in time of peace.

GENERAL CORRESPONDENCE.

THE APPROACHING ELECTION TO THE COUNCIL OF THE COLLEGE OF SURGEONS.

LETTER FROM PROFESSOR GULLIVER.

[To the Editor of the Medical Times and Gazette.]

SIR,—As incorrect statements are abroad concerning my being a candidate for re-election to the Council of the College of Surgeons, perhaps you will permit me to explain, through your columns, the reason for my conduct on this occasion.

Since the last election to the Court of Examiners, I have held no communication with the Council. At that time I instantly tendered my resignation, because it appeared to me that the combination of the Surgeons (with one or two honourable exceptions) of the metropolitan Hospitals, to exclude from the office of examiner any one not belonging to their own body, was plainly declared and likely to be perpetuated; and more especially as, at the preceding election, that same combination had well-nigh deprived the Court of the services and countenance of an anatomist of European reputation.

I should have disregarded the open and covert attacks to which I have been subjected, and thought no more of the College of Surgeons, had the question merely concerned that body and myself; but it now appears to me as a public one, and, therefore, a duty which I owe to the Fellows to appeal to them at the approaching elections.

The consideration of some decisive measures as to the constitution of the Court of Examiners cannot be much longer delayed by the electors of the Council; and, among other questions, some such as the following must arise:—

1. Whether the Metropolitan Hospital School of Surgery be not rather a part than the whole of the English school?
2. And if so, whether the Metropolitan Hospital Surgeons of the present Court of Examiners represent anything more than a fraction of the English school?
3. And then, whether there be not a Provincial school entitled to quite as much respect as that fraction of a school?
4. Whether it be for the interest of the public and the Profession to allow those Surgeons of the London Hospitals virtually an exclusive right to the examination of those very pupils whose fees have before been pocketed by one or other of those very examiners?
5. And, if this be decided in the negative, whether it might not be expedient to have an annual election of the examiners, comprehending a due proportion of disinterested and distinguished men from external sources to fill up the vacancies in the Court?

The last part of this question might never have occurred, while that Court was at once supported and adorned by the names of such illustrious men as Abernethy, Astley Cooper, Brodie, and Green—all Surgeons at the same time of the different London Hospitals. And as to the former part, annual elections are found to work well at Edinburgh, leaving in office for many years the best examiners, and affording an annual opportunity of removing such as may not have performed the duties satisfactorily.

I am, &c.

Edenbridge, June 13.

GEORGE GULLIVER.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

“Nemo sibi vivat.”

LETTER FROM MR. FREDERICK MANBY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having long felt much interest in all matters connected with the College at Epsom, and having of late experienced some apprehension as to the effect of the proposed alteration in its second bye-law, I am particularly struck with Mr. Clark's letter upon the subject in your number of June 4. It expresses so fully my own ideas that I would fain be concise and endorse every word he writes, the chief difference between him and myself being that I have already had one

son educated at the College, have three now there, and another rising up for the like training.

From this fact, added to my having acted for many years as Hon. Loc. Sec., I may be supposed able to judge of it and the effect of its endowments upon the Profession, so I crave permission to insert a few observations, feeling at the same time that I may subject myself to remark from some, if not displeasure from our much esteemed friend and founder, Mr. Propert; and although this would pain me, yet I cannot forbear to speak upon principle, especially as the matter of reduced premium has for some time past occupied my thoughts.

I, for one, became induced in the first instance to devote my energies and feeble support to its funds, under the impression that it was, and would become, a real boon to us all, and that by increasing support I had hoped ere this that the premium per exhibitor would have been brought to the sum of £25 or £30, as originally proposed, and thus truly have fulfilled "the good work for which the College was founded."

But as to the subject of admitting lay-scholars, I confess I do not see it. To all intents and purposes the Charter was incorporated under the name and title of "Royal Medical Benevolent College." Then, why admit any but the sons of Medical men? It may be said, "See how vast a sum has been subscribed by lay-patrons." And most truly; so it is. Yet it is also obvious that such contributions have undoubtedly been made as the best means laymen had of evincing their appreciation of the unwearied toil incurred by, and in many cases extorted from, a liberal, yet ill-remunerated Profession. Lords A., B., or C. never contemplated sending their sons to Epsom; they have their schools. The clergy and military men never contemplated it; they have their Colleges. The middle-class men never contemplated it; they have their schools also—to wit, the College recently established in Suffolk for middle-class and agricultural pupils, who are to receive first-class education and maintenance for £25 per annum.^(a)

While I give full credit to our noble founder that he would wish the sons of Medical men to have priority of admission, yet—*e.g.*, if only six lay-boys be admitted this year over and above all the Medical candidates there may be for admission—still next year there will be fresh applicants, when at least six must "go by the wall," because six places are previously filled up.

As my energies have been "heart and soul" in the success of the College, as I have from time to time asked, written, entreated—nay, implored—my Medical brethren to contribute to the support of such an institution, so I would implore the Council to consider well before they rescind a bye-law which of necessity must cancel and do away with the original good design of its instigator.

As a Local Secretary, I feel pulses also, and from what I feel and hear I have no hesitation in asserting my impression that a death-blow will have been inflicted; and further, that far more of the guineas now contributed will be withdrawn than would be made up by the extra £23 upon lay scholars.

Whereas I would much rather offer some concluding remarks to the members of the Profession (so oft repeated in truth), hoping they may yet see the great necessity for joining in uniform, universal, and hearty good-will to increase the funds by annual subscriptions.

What, I would ask, might be the state of things if every Medical man in practice would contribute his half-guinea or guinea? I believe, as Mr. Propert once intimated his belief to me, that in such case every orphan boy might be gratuitously educated! What matter for thought and reflection when we refer to the recent election papers, and find forty-four candidates for six vacancies!

Sir C. Locock, at the late College dinner, made allusion to the inadequacy or lack of provision "for a rainy day" being made for our wives and families by life insurance. Alas! I lament with him that there are, indeed, with many members many, many rainy days also—that in a vast proportion such a provision is wholly impracticable.

On the contrary, I do not believe there can be a man found (professing to practise only) who could not, if he chose, give 10s. or 20s. to these funds, thus doing as much as in him lies for the benefit of the sons, at least, he may leave behind. A guinea a year is a fraction short of fivepence per week—the price of a cigar! (Not that I smoke or commend the habit, in Medical men especially.)

^(a) Also the admirable schools in Sussex, Lancing, Hurst, etc., with fees from thirteen guineas upwards.—Ed.

I am again ready to admit that there are a very great proportion of needy men amongst us. I unhappily know some, and I chance also to know those who would like to send a son or sons to Epsom; but £40, with travelling and other contingencies, after all, they say, "is no great boon; we must be content to send our boys to a second or third class commercial school." A friend expressed this to me some time ago.

Now, dare I ask the cause of this lack of subscriptions? and does it arise from want of means? With the same boldness I answer no! but from an indifferent, apathetic, selfish feeling which, I regret to allege, must and does exist in men with well-to-do means and good practice;—without a child to work for, and who labour but "to heap up riches, not knowing who shall gather."

Hence it is I blush for us all when I read the annual reports of the College and behold something over £3000 annually subscribed; granting or presuming that two-thirds of this may be from Medical men, numbering, as I suppose we do, some 15,000 or 20,000.

Before concluding (if not encroaching too much upon your valuable space), I would make slight further allusion to the reduction of premium as moved by Mr. Cattlin in Council. I most fully agree with him also, that in every case it should not exceed £30 a-year, but I will concede the amendment in exceptional cases—in need, that is; and, further, where two or three from one family go at the same time, consideration should be made, as in all minor schools.

Referring to the former part of this letter, I feel that I lay myself open to remark as seeming interested, but this I disclaim, cling still firmer to the justice of it, having heard my boys speak of instances of Major! Minor!! Minimus!!! Quartus!!!! and, I *think*, Quintus!!!! and thus I fight others' battles with my own; at the same time, with heartfelt thanks, give praise to Whom praise is due, that to this time I have been enabled, by my own single-handed exertions, in a hardworking village practice, to send so many boys, exhibitors, and am free also to confess, though hard it is (yet 'tis a boon), harder still to have procured so sound an education at one-third increase upon this as schools are now constituted. Hence "our good fight;" and I conclude my observations by special endorsement of Mr. O. Clark's concluding paragraph, as to the scholastic discipline of the College, yet have trembling fears that "the battle will be to the strong."

I am, &c.

Rudham, June 10.

FRED. MANBY.

ON THE TREATMENT OF NÆVI MATERNI BY THE SUBCUTANEOUS INJECTION OF SOLUTION OF PERCHLORIDE OF IRON.

LETTER FROM MR. ROBERT B. CARTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—Some months ago you did me the honour to publish the history of a case in which the subcutaneous injection of a solution of perchloride of iron into a nævus involving the lower half of the nose, was followed by the immediate death of the patient, an infant eleven weeks old.

By the kindness of Mr. Nathaniel Crisp, of Swallowfield, near Reading, I have been favoured with an account of a similar occurrence, which recently happened in a colonial Hospital. A post-mortem examination showed that the point of the syringe (the nævus being on the cheek) had penetrated the transverse facial vein, and that the blood in the right cavities of the heart had been immediately coagulated. Mr. Crisp did not mention what quantity of the fluid was injected.

In my own case the quantity was precisely five minims; and this was injected with a slight jerk. The action of the piston, a common sliding one, had been interfered with by the chemical effect of the fluid.

I have been induced to address you again upon this subject because I find that Mr. Erichsen, in the last edition of his work on Surgery, recommends the use of subcutaneous injection of perchloride of iron, without a single word of caution about the danger attending it. In nævi of the tip of the nose he thinks it the best method of treatment. It is true that Mr. Erichsen recommends the use of Bravaz's syringe, which, by its screw piston rod secures the gradual introduction of the fluid, and prevents the jerk that happened to me. But he does not say why this syringe is better than others; and there is no evidence of any jerk in the other fatal cases that have been recorded.

I think I am justified in saying that the subcutaneous injection of perchloride of iron should not be practised, unless it is possible, by pressure with fingers or forceps, by acupressure, or even by the temporary application of ligatures, to close for a time the channels of the efferent veins; where this can be done, the remedy is free from danger, and will usually be effectual; but, without such a precaution, it entails so much risk to the patient that only the most exceptional circumstances would permit us to advise or to employ it.

I am, &c.

ROBERT B. CARTER, F.R.C.S. (Exam.).
Stroud, Gloucestershire, June 11.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 6.

Dr. OLDHAM, President, in the Chair.

THE following gentlemen were elected Fellows:—J. M. Granville, Esq., Dr. J. F. Leeson, Dr. H. C. Phillips, and Dr. A. Wynn Williams.

Dr. OLDHAM exhibited an Ovarian Tumour removed from a lady under his care by Mr. Spencer Wells.

Dr. GREENHALGH exhibited a specimen of simple Hypertrophy of the Cervix Uteri, removed by the wire-rope écraseur.

After some remarks by Dr. HICKS and Mr. BAKER BROWN,

Dr. RITCHIE exhibited, and described the mode of using, Dr. Braun's Cephalotribe and Perforator.

Dr. BARNES considered it an objection to the perforator that it required two to work it, and was complicated. He thought the cephalotribe of Dr. Braun better than the French, and that the instrument had been perhaps too much overlooked in this country.

Dr. GRAILY HEWITT showed a cephalotribe from Paris, used by Pajot, which he considered more simple than Braun's.

A paper, by ROBERT BARNES, M.D., was read on,

SPONDYLOLISTHESIS; WITH AN ACCOUNT OF A CASE OF PELVIC CONTRACTION, IN WHICH PREMATURE LABOUR WAS INDUCED BY THE AUTHOR'S METHOD.

The memoir embraced a history of the literature of this affection and a summary of the cases hitherto recorded. It was first described in 1853 by Kilian, who defined it as a slipping downwards and forwards of the last lumbar vertebra upon the sacrum, so that one or more of the lumbar vertebræ fall into the cavity of the pelvis, encroaching upon the space required in labour. In several cases the Cæsarean section had been necessary in order to deliver. The author added a case in which he believed this form of distortion was the cause of difficult labour. A woman, previously healthy, had been injured in the back. Considerable contraction of the pelvic brim followed. There was a marked depression in the lumbar region, and a projection internally above the promontory of the sacrum. Dr. Barnes brought on labour by this method at about the eighth month. The child was extracted by turning with some difficulty, still-born. The entire labour occupied less than five hours. The mother recovered. The remainder of the memoir was devoted to the discussion of the causes of the deformity, concerning which very conflicting views were entertained in Germany.

Mr. W. ADAMS observed that he had listened to the paper with great interest, as the vertebral deformity or displacement described was but little known, and required further investigation. It seemed to him that the condition described as spondylolisthesis might depend upon several causes. Rickets might give rise to it; but this would be at once apparent by the general evidences of rickets in the development of the skeleton, distortion of the legs, &c. Caries of the first sacral bone might give rise to it; and some years after destructive disease had ceased, and anchylosis produced, the prominence forward of the last lumbar vertebra might encroach considerably on the pelvic cavity. Mr. Adams had seen a few examples of this, and had one now under his care at the Orthopædic Hospital. In this case the girl presented extreme lordosis in the lumbar region, with corresponding projection of the stomach, and a sharp posterior angular prominence corresponding to the first and second sacral bones. In all probability this girl, now twenty-one years of age, could never have a living child, in consequence of the projection of the last lumbar vertebra into the pelvic cavity. Congenital dislocation of both hip-joints produces extreme lordosis in the lumbar

region, and, therefore, would probably give rise to the condition described as spondylolisthesis; and Mr. Adams had also seen it produced to some extent by a sharp rotation movement, and lateral distortion affecting the lower lumbar vertebræ, as in a case described by him in the *Medico-Chirurgical Transactions*, vol. xxxvii. It was evident that a variety of causes might produce the vertebral displacement mentioned by Dr. Barnes, whose analysis of the cases recorded in the paper would form the basis of further observations on this subject.

Mr. BRODHURST observed that this was a subject which had not received much attention in this country. He considered that the affection in question was not a true dislocation, as it was described by the author of the paper, and that it differed materially from ordinary lordosis, and from those forms of lordosis which are produced by congenital dislocations of the heads of the femurs by some very rare forms of caries of the bodies of the vertebræ, &c.; but it was induced, he said, by softening of the bodies of the vertebræ, and especially by softening and yielding of the ligaments which unite the lumbar vertebræ and the sacrum. Thus was occasioned some displacement of the bodies of the lumbar vertebræ downwards. The positions of the spinous processes showed that caries was not the cause of this affection, as had been suggested, and a section of the bodies of the vertebræ showed this fact still more clearly. He contended that this condition was due to rachitic inflammation and softening of the osseous and ligamentous structures.

Dr. BARNES said that in studying the subject he had felt the want of a more extended practical knowledge of diseases of the bones than he possessed, and was therefore glad to have the assistance of Mr. Adams in discussing it. He was quite prepared to believe that caries of the upper part of the sacrum might cause the deformity. It was one cause, and did not exclude the possibility of other causes; nor did he gather from Mr. Adams's observations that that gentleman regarded caries as the sole cause. The case of the child figured by Robert, of Coblenz, was not an undoubted case of spondylolisthesis; and he was much interested in the suggestion of Mr. Adams, that the deformity was probably due to disease of the hip-joints, causing extreme lordosis of lumbar vertebræ without dislocation. He wished it to be borne in mind that this deformity consisted in a real slipping down of the fifth lumbar vertebra from the sacrum. It was a true dislocation, and not simply a curvature, of the spine. It was seen quite independently of rickets. It caused serious obstruction to labour, even in cases where the pelvis itself was free from distortion. He believed that this and other vertebral deformities possessed a great obstetric interest, and would, when more attention was directed to the subject, receive further illustration.

PRINCELY BENEFICENCE.—The Hon. Rustomjee Jamsetjee Jejeebhoy, member of the Legislative Council of Bombay, son of the late Sir Jamsetjee Jejeebhoy, placed some time since at the disposal of Mr. Crawford, M.P. for London, the sum of £15,000 for the purpose of appropriation to charitable purposes in London, in connexion with the name of his late father, more especially the charities of the City of London, of which his father was a freeman, under the following condition:—"The charities selected to be those which have in view the alleviation of the wants of the poor and indigent, the infirm and helpless, and not societies which are of a religious character." The Medical charities so selected are enumerated in the following list, the ruling principle of the appropriation being the selection of those institutions whose doors are always open to every class of sufferers on the instant, without reference to any other consideration than the merits or urgency of the particular case in need of help. The appropriation to the London Hospital is in connexion with the new wing, of which the foundation-stone is to be laid on July 4 by the Prince of Wales, and the fact that the London is pre-eminently the Hospital of the commerce of the port of London:—"Hospitals—London, £2000; University College, £1000; Metropolitan Free, £1000; Royal Free, £500; Middlesex, £500; King's College, £500; London Fever, £500; City of London for Diseases of the Chest, £500; for Sick Children, £500; Royal, for Incurables, £400; British Home for Incurables, £400; Asylum for Idiots, £400; for Diseases of the Skin, £300; total, £8500. Dispensaries—City, £500; Farringdon, £500; City of London and East London, £400; Royal General, £400; Metropolitan, £400; Western City, £200; Finsbury, £200; City Orthopædic, £200; Queen Adelaide's Dispensary, Bethnal-green, £200; total, £3000."

NEW INVENTIONS.

AN UTERINE SOUND, WITH MOVEABLE HEAD.

By J. LUMLEY EARLE, M.D., Obstetric Surgeon to the Queen's Hospital, Birmingham.

By referring to the woodcut, the working of the instrument will be readily understood. The portion of the sound, from A to C, is $2\frac{1}{2}$ inches in length, the ordinary length of the normal uterus. It is set in motion by an internal rod, one end of which is connected with the joint at C, the other being shown at E. The head of the sound may be made to move to any point along the dotted lines from A to B by turning the screw at D from right to left.

The instrument was devised chiefly to obviate the constant bending which is necessary in the immovable sound to make it tally with the varying obliquity of the uterus in different individuals. It possesses the advantage of being able to be set in motion while in the vagina or uterus. It may be passed perfectly straight to the os uteri, and then, gradually as it passes along the canal of the uterus, may be made to take the angle suitable to the case before us.

By using the moveable sound at certain intervals for some time it may prove beneficial in curing some cases of anteversion or retroversion. Take an instance of anteverted uterus, in which the moveable part of the sound lies at right angles, C to B, to the shaft of the instrument. By reversing the action of the screw at D, turning it from left to right, the uterus may be made to assume the perpendicular position; and, if necessary, even may be retroverted by turning the handle of the instrument round, and setting the bulbous portion again in motion.

There are other cases in which a moveable uterine sound might prove useful. It would probably remove a great deal of the difficulty generally experienced in bringing on labour in certain cases of retroversion of the pregnant uterus, as it can be passed to the os in a straight position, and made to take a suitable angle gradually as it passes through the os and cervix.

The instrument may be procured from Mr. T. P. Salt, Surgical instrument maker, 21, Bull-street, Birmingham.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, June 9, 1864:—

George Edmund Legge Pearse, Regent-street, Westminster; John Holden, Ardwick and Ancoats Dispensary, Manchester; Henry Todd Broughton, Bradford, Yorkshire; Edward Maundrell, Rutland-street, Hampstead-road.

The following gentleman, also on the same day, passed his First Examination:—

Charles Meymott Tidy, London Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

HANCOCK, DAVIS W., M.D.Q.U.I., has been elected Medical Officer and Public Vaccinator to the Checkley District of Cheadle Union, Staffordshire.

KEALY, JOHN ROBERT, M.D. St. And., has been appointed Surgeon and Agent for the care of Sick and Wounded Seamen and Marines, at Portsmouth Harbour, by the Lords Commissioners of the Admiralty.

MACINTYRE, J. MAC G., L.R.C.S. Edin., has been elected Surgeon to the Daylesford Hospital, Victoria, New South Wales.

RATTRAY, DR. ANDREW M. T., has been appointed Surgeon to the Haswell and Shotton Collieries in the county of Durham.

TURNER, J., M.D., has been elected House-Surgeon and Apothecary to the Dumfries and Galloway Royal Infirmary.

WATTS, HORACE N., M.D., has been elected Assistant Medical Officer to the Nottingham County and Borough Lunatic Asylum, Sionton.

WOODMAN, W. BATHURST, M.D. St. And., has been appointed Resident Medical Officer to the London Hospital.

DEATHS.

BULL, EDGAR, L.S.A., of Blockley, Moreton-in-Marsh, on May 20.

FORBES, WILLIAM W., M.D. Edin., of High-street, Inverness, at Edinburgh, on June 2.

SAUNDERS, THOMAS V., L.S.A., late of Bruton, Castle Carey, Somerset, at Bradford-on Avon, on May 21, aged 60.

SMITH, EDMUND, M.D., of Ilkley Wells House, Otley, Yorks, at the Rectory Richmond, Yorks, on June 5, aged 60.

WALLACE, WILLIAM, M.D. Edin., late of the 14th Regt., at Morningside, Edinburgh, on June 8.

ROYAL COLLEGE OF SURGEONS.—The annual election of Fellows into the Council on the 7th proximo promises to be a more spirited affair than is usually observed at these meetings, as, up to Monday evening last, when the time expired for sending in applications, no less than six candidates had offered themselves—viz., Professor Gulliver and Mr. Hancock for re-election, and, in chronological order, Messrs. Thomas Turner, Moseley-street, Manchester, admitted a Member of the College, May 3, 1816; Andrew Melville McWhinnie, Serjeants'-inn, Fleet-street, January 1, 1830; Thomas Blizard Curling, Grosvenor-street, December 7, 1832; and Frederick Le Gros Clark, St. Thomas'-street, February 15, 1833. For the re-election of Mr. Gulliver, there are a great number of Fellows who feel that this distinguished Professor has not been fairly treated in his exclusion from an Examiner's Chair, and who are using great efforts to bring him in; all, however, are agreed that it would be a great injustice to exclude Mr. Hancock, who has only enjoyed the sweets of office for one year. His return is considered quite safe. To fill the vacancy caused by the death of Mr. Green, the Provincial element is represented by Mr. Turner, who will no doubt receive, in addition to the votes of a considerable number of provincial Fellows, those also in this metropolis in favour of seniority, Mr. Ransom, of Manchester, also offered himself, but at once retired from the field in favour of his colleague. Mr. McWhinnie, formerly of St. Bartholomew's Hospital, offers himself, in addition to his other high qualifications for the office, to uphold seniority. He will, no doubt, receive all the powerful support of our largest metropolitan Hospital, with which he was so long connected. The remaining candidates, Messrs. Curling and Le Gros Clark, are both Hospital Surgeons and good men, and the struggle, it is said, will be with these gentlemen, and the "plumping" system, we have heard, will be carried out to a greater extent than on the memorable occasion when Professor Fergusson was elected. We have been requested to announce that official notices of the election have been sent to all the Fellows of the College in the United Kingdom whose addresses are known at the Royal College of Surgeons.

THE ROYAL MEDICAL FUND BENEVOLENT SOCIETY.—At the annual meeting of this Society, on June 6, at the King and Queen's College of Physicians, Dublin, Dr. Corrigan, President of the College, who occupied the chair, said that the report expressed a feeling of regret that in many parts of the country four-fifths of their brethren had not contributed to the funds of the Society. In that report he fully coincided; but he did not think that their not subscribing arose from any disinclination, coldness, or apathy; but he feared in too many instances it arose from their inability to do so. Within the last few years all the necessities of life had increased 100 per cent. Horses, carriages, vehicles,—those portions of a Medical man's establishment were absolute necessities,—had increased to double or treble their former value; but he was sorry to be obliged to say that through the country districts of Ireland private practice had not increased, nor had salaries increased, so that, with greater expenses to meet, the means to meet those expenses were diminished. There had contributed to this a cause that would continue to operate for years—that is, the emigration of the people, the result of which was that nearly all the country towns in Ireland were diminished in size and population; many of them were verging to decay, and the Medical Practitioners in the country districts must necessarily suffer severely under those circumstances. All the efforts which had been lately made had been unavailing to secure retiring pensions for our Medical officers. With them it was

nothing but work as long as they were able, with no power to lay by, and no prospect of a pension to retire upon in their old age. When the Registration Bill was introduced last year, that College made all the efforts in its power to have the same justice done to the Irish Practitioner that was done to the English or Scotch Medical man. The College left no measure untried to procure an equal rate of justice for the Irish Practitioner, but without effect. The English Registrar got £2 10s. for performing a certain duty, the Scotch Registrar got £4, and the Irish Registrar £1. That was not an equal amount of justice. He was sorry to say that, with regard to the remuneration of Medical men throughout the country, there was not that feeling which ought to exist. The chairman of a public board lately told him that he saw no reason why they should not contract for Medical advice as well as for anything else required for the use of a workhouse. That, he said, was true political economy. The only remedy he could suggest was, that the young men who had talents and information to enable them to go to the Medical Profession must learn that there were other sources of employment open to them in the present day in the colonies and abroad, and that they should sell those talents for the highest price they could get. After some remarks on the wretched state of the Army Medical Department, and of the Profession in general, he said "they had come to this pass through a registry that put all men on a level. (Hear.) The Medical corporations were all notoriously engaged in competition, not as to who would raise education and keep it at a high price, but to lower the standard of education, and sell it at a low price." Sir W. Wilde, whilst denouncing the notion that men of 40, worth their salt, could be got to accept 10s. per diem, still thought that was enough for young men who accepted a temporary army appointments directly after passing.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

An account of the recent poisoning at Birmingham by *Jatropha* nuts will appear in our next Number.

Mr. J. Ruffe.—The correction was made last week, June 11.

A Country Surgeon.—"Medical Hints for Emigrants," published by the Society for Promoting Christian Knowledge.

Oxon.—In London there are two forces—the Metropolitan and City Forces, the Metropolitan under the West-end authorities, the City under the Corporation. The Medical Department of the Metropolitan force consists of a Superintending-Surgeon who is paid by salary, and seventy-three district Surgeons, paid by contract, according to the following allowances for each man per annum, calculated on the maximum number of men in the district under the Surgeon's charge during each half year. Superintendents, 10s.; inspectors, 10s.; sergeants and constables, 3s. 6d., if residing within two miles of the Surgeon, and 7s. if residing beyond that distance. 5s. in rural districts where there are few men. In cases of casualties, when prisoners are taken ill, &c., and the Surgeon is called in, the following allowances are made:—Day, 3s. 6d. each case; night, 7s. 6d. each case; with, in some cases, extra charges. The Surgeon to the City Force is paid by salary; there are no divisional Surgeons.

Our attention has been called to the following letter, regarding which we will only say that it seems a pity that members of our Profession, who have the privilege of making known to their Professional brethren any ideas that they may have on points of practice, should write letters addressed to the public in the style of the following communication to *The Field* newspaper:—

"EFFECT OF MEDICINES AS TO CONIULENCE.

"SIR,—It strikes me at present that there is a tendency on the part of the public to esteem every diminution of weight or fat in the system as due to diet or healthful, but this is wrong as to some constitutions, and some medicines act as diet is supposed to do. Perhaps I might add the following two cases to those previously published. A consumptive young lady came to me, some five years ago, with curious nervous symptoms: she said she felt the ground 'sinking always under her,' a disease, I now believe, of the cerebellum. In conjunction with the late Dr. Todd, I ordered a certain medicine, which cured her perfectly. Dr. Todd said, 'Let her take it for nine months without stopping: she may grow fat, but that is no harm.' This poor lady, when we saw her, it should be said, was a perfect skeleton—skin and bone, a mere shadow. She went on for a year taking the medicine; she found it did her good. I lost sight of her till about four or five months ago, as she lives in Wales. To my utter amazement, she is now one gigantic mass of fat, but otherwise in admirable health. Dr. Todd's observation did not strike me then, but it has since I read the Banting controversy, so instructive, in the excellent pages of *The Field*. I have no doubt this medicine helped the assimilation of carbon or fatty matters in an undue degree.

"Let me now give you an opposite case. An enormously fat 'city' gentleman consulted me, about a year ago, on account of an unwieldy mass of fat that prevented him moving. There was not a word then about the 'Banting system,' (due to my excellent friend, Mr. Harvey, of

Soho-square). This gentleman was something like 24 stone, and could not sit at his desk. I ordered him one medicine that I have never found to fail in reducing fat. He has made no appreciable alteration in his diet either as to quantity or quality, yet he has lost about 3 stone of fat, and is now quite another being, as he sits easily at his desk.

"There is one fact lost sight of in the controversy, viz., that young people—say up to thirty-five—put up fat much more quickly than people after sixty; and to restrict the latter as to quantity or quality is a mistake, and may lead to bad consequences.

"Sackville-street, May 31.

"CHARLES KIDD, M.D."

TOWN versus COUNTRY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE

SIR,—I am obliged by your note at the foot of my last letter, as it has opened my eyes to a fact of which I was not previously aware; I trust, therefore, you will kindly allow me space to explain that my patient himself named Dr. —, of whom I had not previously heard, saying that "he was their family Doctor," and asking me to write him a few lines about his case. Had I known what I know now, I should most decidedly have declined the honour (?) of such a correspondence, and can only express my astonishment at his being the family adviser of any one holding so high a position as my friends do in the city of London.

I am, &c.

ROBERT OKE CLARK.

NAVAL ASSISTANT-SURGEONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As a sequel to my last letter on the above subject, I will proceed to place before your readers, in a concise form, a few of the relative advantages and disadvantages of the two services.

POSITION AND PROSPECTS OF A MEDICAL OFFICER.

In the Army.

Roomy quarters, and all the comforts of a life on shore uninterrupted.

Duty done, he is free to walk out where and when he pleases, unrestrained by any cause whatever.

Commodious Hospital and an efficient staff, completely apart from the barracks, and free from all petty annoyances.

Continued service on full pay, and, therefore, ability to serve the allotted period without a break.

Considerable increase of pay on foreign service and in the field, with an equitable share of prize money according to relative rank.

The rank of Surgeon-Major acknowledged in the *Gazette*, and promotion to the higher grades tolerably certain, and pretty free from the taint of favouritism from any quarter.

A comparison originating in no spirit of envy might be continued much further, but enough has been said for my purpose. I have shown, I hope satisfactorily, the absurdity of supposing that, in these days of competitive examination, the navy gets competent candidates when the army cannot. It is very unlikely that any man who could pass the examination at Chelsea would forfeit his independence and solicit an appointment in the navy; and it is to my mind very certain that it is high time we had one common board of competent examiners for both the army and the navy.

June 8.

I am, &c.

M.D., R.N.

PRESCRIBERS' COMPANIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I do not think that practical men are asking too much in requesting those gentlemen who oblige us with those most useful little manuals called "Prescribers' Companions," if they would use a little more caution and exercise a little more discretion in their compilations. In looking over an excellent little work of this kind, by Dr. Meadows, I find, at page 110, among the list of emetics, Tinctura Lobeliae B. P.: dose for an adult, ʒj. to ʒiij.; for a child a year old, ʒx. to ʒxx. But who, with the slightest regard for human life, would use this powerful remedy in such doses? Again, on the same page, I read—Vinum Tabaci B. P.: dose for an adult, ʒj. to ʒiij. I looked in vain for the authority of the Pharmacopoeia for such an alarming innovation. There is no such preparation in the B. P., and the only one of the kind I know of is that of the now defunct Ed. P., in which the dose is given as ʒx. ad. xxx. I need say nothing, I think, about giving gr. ii. of the alkaloid veratria, or gr. xx. of powdered squills as emetics. I am not aware that any practitioner of experience or education would be guilty of such folly.

Again, let us look into the list of narcotics. At page 42 we read of Tr. Acouite,—"This preparation is one-fourth the strength of that in the Ph. Dub.," whereas the B. P. tells us it is one-third, an important difference with such a potent remedy. I should advise Practitioners to watch carefully even the minimum dose of ʒx. given by Dr. Meadows at page 43. Extr. Cannabis Indicae B. P.: dose for an adult, gr. iii. to viii. But Dr. Garrod, in his lectures, says the dose is from gr. ¼ to gr. i. Now this is a very serious blunder. Then, at page 50, we are told that the minimum dose of morphiae hydrochlor. is gr. ½ to an adult.

As I do not write at all in a captious spirit, I will not extend these extracts. I feel sure Dr. Meadows will correct them in a future edition. I am one who considers that the B. P. has in some instances been very unjustly accused, and I think I have discerned motives beneath such abuse. I think it requires but little revision to make it as perfect as a work of this kind can be. A posological table, a recurrence to our old

weights, a good index, and the addition of some valuable medicines which have been omitted, are what strike me as the principal desiderata. I am, &c. C. R. BREE, M.D., Senior Physician to the Essex and Colchester Hospital.

P.S.—I find that the Tr. Aconite B. P. is really one-fourth the strength of that of D. P. Therefore, the mistake is that of the editor of the Pharm., and not of Dr. Meadows. I still, however, stand by my criticism of the dose. C. R. BREE.

THE GUILLOTINE.

OF the origin and history of this famous instrument of punishment an erroneous idea generally prevails. The popular version is that it was invented in 1785 by Joseph Ignatius Guillotin, an eminent Physician, and deputy for Paris in the Constituent Assembly. This is not correct. An instrument differing from the guillotine only in its heavy and cumbrous construction already existed in Italy. It was known in Genoa by the name of manaja, and it was by the manaja that Beatrice Cenci was beheaded at Rome in 1605. The "maiden," an instrument not unlike the guillotine, was long known in Scotland, and it was employed on the Regent Morton, who is said to have introduced it. It was used also in Halifax, Yorkshire, in the reign of Queen Elizabeth. The Duke of Montmorency was beheaded at Toulouse in 1632 with the manaja.

All that Dr. Guillotin, who was a man well known for his humanity, had to do with the matter, was preparing the draft of a law in the Constituent Assembly, in 1789, to the effect that the mode of inflicting death on criminals should be the same for all alike, without any distinction of nobles or plebeians; in fact, that it should be uniform. Before the revolution of 1789 the inequality that existed during life was maintained in death; the noble was beheaded, the villain hung from the gallows. But the inequality was a trifling grievance in comparison with the cruelty which accompanied the execution. There was the stake and faggot for those convicted of sacrilege or heresy; the tearing from limb to limb by horses for regicide; the breaking on the wheel, with the additional refinements of barbarity for crimes of other descriptions.

The bill proposed by Guillotin was voted, and the Assembly enacted, on January 21, 1790, that "in all cases where the law pronounced the penalty of death the punishment should be the same, whatever might be the nature of the crime; and, moreover, that the criminal should be beheaded by means of a simple machine." The same Assembly also introduced in the Penal Code (October, 1791) this clause, "the penalty of death shall consist in the simple taking away of life without the accompaniment of any sort whatever of torture; and the convict so condemned shall be beheaded." The clause stands the same at the present day.

Decapitation being thus declared the only legal mode of inflicting death, the next step was to invent the simplest mechanism and the least painful for the purpose. The Committee of Legislation directed Doctor Louis, who was then Perpetual Secretary of the Academy of Surgery, to draw up a report on the best mode of decapitation to be applied to criminals. The report was presented to the Committee on March 7, 1792, and on the 20th of the same month the Assembly passed a law, which was sanctioned on the 25th by the King, declaring that the penalty of death should be carried out in the manner recommended in the Report of the Perpetual Secretary of the Academy of Surgery. In this paper Doctor Louis did no more than suggest the plan on which the instrument should be constructed; but he was enjoined to get one constructed according to his plan. A German, named Schmitt, a maker of harpsichords, was employed for the purpose, and on April 19, 1792, De Louis informed Roland, then Minister of the Interior, that "experiments had been made with Schmitt's instrument at the Bicetre on three dead bodies, and that the heads were cut off with such precision that he was astonished at the strength and celerity of its action." It was at once introduced, and the "experiments" made with it soon after the date of the latter, and for a long time afterwards, were not of the harmless nature of those at the Bicetre. In the memoirs of Sanson, the famous headsman, recently published, a full account is given of the instrument. The first execution for which it was used was that of a highway robber, which took place on the 27th of May, and the first political execution was that of Collenot d'Anglemont, on the 21st of August following.

The machine was at first popularly known by the name of Louison, or Louissette, from the inventor's name. By some unaccountable change of public opinion, or caprice, it soon got the name of guillotine, which it keeps to this day, and will probably do so as long as it remains in use, though Dr. Guillotin had nothing whatever to do with its invention or construction, and had merely proposed the measure of uniformity in the mode of execution. There is another error also very generally spread, that Guillotin himself died on the scaffold during the revolution by the instrument of which the invention was falsely attributed to him. Dr. Guillotin long survived the revolution, and died quietly in his bed in 1814.—*The Times' Paris Correspondent*, June 11.

Notes on Clinical Medicine. By Willoughby Francis Wade, M.R. No. 3, on Rheumatic Fever. Birmingham: H. Wright. 1864.

** This little pamphlet is a very valuable contribution to practical medicine. When we think of the vast amount of disease that depends on rheumatic fever, we feel glad of any help either to prevent it in those predisposed, or to carry the patient well through it when it has begun. Dr. Wade insists that rheumatic fever generally follows anæmia. He writes, "I venture, then, to affirm that in most cases of rheumatic fever we shall be able to elicit a previous history of that debility which is so common a concomitant of deficiency in the red globules of the blood."

As regards treatment, Dr. Wade follows Dr. Chambers' plan of bedding in blankets. He also wraps up each affected joint in a thick layer of cotton wool. In some cases he medicates the wool with an alkaline solution, and recommends the same application to the chest when pericarditis is threatened. He then gives a dose of five or ten grains of calomel with from thirty to sixty grains of compound jalap powder.

He urges that the use of the calomel is to be defended on the ground that it does good, and that the recent researches tending to show that it does not act on the liver do not invalidate this position. When the patient has taken a purgative before he comes under care he still gives the calomel, but combines with it ten or fifteen grains of Dover's powder instead of the jalap. Dr. Wade has not much faith in the opiate treatment, but occasionally gives a dose of opium if the patient be unusually irritable, restless, and bears pain badly. Dr. Wade having thus paved the way, begins the more special treatment of the disease. He gives the following mixture in ounce doses every two, three, or four hours:—℞. potass. nit., ʒj.; potass. acet., ʒiii.; aqua, ʒviiij. But he insists apparently more than all on copious diluents. As soon as ever there is a distinct remission of the symptoms, i.e. from twenty-four to seventy-two hours, he gives quinine, two to four grains every three or four hours, but continues to give the former mixture every night and morning. When the quinine is given the patient may have meat if he likes. When the rheumatism is quite gone iodide of iron is ordered.

The chief point in the paper seems to us to be the one referring to the antecedent anæmia, but the paper is full of interest to the Practitioner.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warrington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

In Bottles, 1 oz., 3s.; 2 oz., 5s.; 4 oz., 8s.; 10 oz., 15s.

Neither Physician nor Surgeon in plaintiff's suit even mentioned Freeman's compound; so much for the *truth* of its being the *preferred* medicine, as stated by the defendant. It is equally untrue that the Vice-Chancellor intimated in the slightest degree that the defendant had the right to the sole use of the prefix Original, as quoted in his advertisement in the "Pharmaceutical Journal," March 1, 1864.

The observations of the Vice-Chancellor, as reported in the "Times," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Original Chlorodyne had obtained world-wide fame.

TOWLE'S CHLORODYNE.

OF KNOWN COMPOSITION.

For Formula, &c., see back Numbers.

Extract of Letter from Dr. C. KIDD (Author of Standard Works on Chloroform).—"SIR,— . . . Of the value of Chloroform given internally I have no doubt; it appears to me in that form an anodyne, *sui generis*, that no other anodyne can approach. I have resolutely opposed the use of *secret* compounds of chloroform, and in every way I can encourage the use of the 'Chlorodyne' (if we must have it at all) that is made by you, as you state that its composition is known. Many Medical men think with me, and recommend your compound, but will never prescribe a secret remedy.—CHAS. KIDD, M.D.—Sackville-street, Piccadilly, London, April, 1862.—To Mr A. P. Towle."

Extract of Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J. P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession.—To Mr. A. P. Towle."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; 4 oz., 4s.; and 8 oz., 8s.

SOLE MANUFACTURER—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

LIQ. CHLOROFORMI CO. (TOWLE'S).

This preparation is identical with "Towle's Chlorodyne," *sine* Ol. Menth. Pip. (dose 5 to 20 minims, as in Chlorodyne).

The Proprietor having for some time past, at the request of several members of the Medical Profession, made a preparation of Chlorodyne without peppermint, has lately, on account of the frequency of these demands, prepared the same for more general use, under the designation of LIQUOR CHLOROFORMI CO., which, possessing the Medical properties of Chlorodyne, may be prescribed in all cases where the Ol. Menth. Pip. is disapproved, and overcome the objection so generally felt to the use of the term "Chlorodyne."

May be obtained, as an introduction, from the following Wholesale Houses, in 2 and 4 oz. bottles, at 2s. 6d. and 4s. each:—London: Barclay and Sons, 95, Farringdon-street. Birmingham: Southall, Son, and Dymond. Liverpool: Clay, Dod, and Case. Edinburgh: Duncan, Flockhart, and Co. Glasgow: The Apothecaries' Company. Dublin: Bewley, Hamilton, and Co. Manchester: Jas. Woolley; and the

Proprietor—A. P. TOWLE, 99, STOCKPORT-ROAD, MANCHESTER.

ORIGINAL LECTURES.

LECTURES

ON THE

PROGRESS OF SURGERY DURING THE
PRESENT CENTURY.

DELIVERED AT

The Royal College of Surgeons,

By Professor FERGUSSON.

LECTURE III.—FRIDAY, JUNE 10, 1864.

MR. PRESIDENT AND GENTLEMEN,—My first formal operation in Surgery was for hare-lip, in the year 1828. The patient was a youth seven years old, and, as was expected, the result was satisfactory. The gap in the lip was complicated with one in the palate. For thirty-six years at least since then my attention has been given, more or less zealously, to these subjects; and, judging from what I have observed during that considerable period, I fancy that my experience on both has been as much as that of most men in this country. During that time I have seen many hundreds of both kinds of cases; and being about to frame a lecture for the present occasion, the question naturally arises, Have I anything new to say? I have in a manner exhausted the subject, as far as my knowledge goes, in my clinical teaching; but as a number of years have elapsed since I published either cases or observations I believe that I cannot do better than refer to them both, and, whilst recapitulating some principal points, bring forward such others as may with you appear in some degree novel.

To begin with hare-lip: I may state that there is no such resemblance to the lower animal in the human subject. The fissure in that animal [pointing to a diagram] is invariably in the mesial line; in man it never is. Of the many cases which I have seen I have never met with an instance in which there has been in the mesial line either a single or a double fissure; the defect has been always on one side, or both; and when it has extended to the alveolar ridge, it has also appeared on one side or both; whilst the mesial line, both in bones and soft parts, has been in a manner perfect.

There is great variety as regards the mesial part of the lip: often it is slender, in all dimensions. In those instances where it is slender, it does not extend to the pro-labial or free margin; and where there is much deficiency, it is usually associated with a flat nose and short columna; in other instances it is of fuller dimensions in all respects. In many examples of double fissure, the central portions are apparently thrust forward, and seem of extraordinary development; but these features, as also the flat alæ and expanded nostrils, I am inclined to attribute chiefly to defective bulk in the lateral portions of the alveoli. Here are specimens to illustrate these remarks. I have no doubt that an erroneous impression has sometimes arisen in this way. Here is a likeness, after an operation for hare-lip, showing the cicatrix exactly in the mesial line; and with some this might appear as a direct refutation of what I have stated. But here is the face before an operation was performed, and the gap was as large on the other side, and it was as marked an instance of cleft under each nostril as could be; in the operation the middle projection of bone has been taken away, whilst the mesial portion of lip has been used chiefly to form a columna for the nose. The result is a cicatrix exactly in the mesial line; and thus, I imagine, a most glaring example of the lateral fissures has been supposed to be a positive proof of defect in the mesial line. I repeat, that I have never seen an instance of the kind; whilst I have seen some rare examples of fissure in the face elsewhere, such as in the eyes, cheeks, and lower lips. In the cheek I have seen a congenital fissure extend from the angle of the mouth to the malar bone, as it did in this instance before the sketch was taken, the fissure not being in the position where the ordinary fissure in hare-lip is. Indeed, in this instance there was a split lip in the usual position, on the left side; and in another instance I have seen a fissure extend from the angle of the mouth outwards towards the masseter or angle of the jaw, as represented here. In one rare example I have seen a congenital gap in the lower lip, as represented in this diagram, extending from near the left angle of the mouth to the base of the lower jaw. It is the only instance of such congenital malformation that

I have seen. As you may perceive, it is amenable to operation, and the gap was accordingly closed.

In most cases of this malformation, where there is a fissure through the alveoli, as well as the lips, the central portion usually presents difficulties to the satisfactory accomplishment of an operation; and it has often been a nice question what should be done, either as to retaining or removing the part. In some rare cases there is no protrusion beyond the ordinary line. There is comparatively little protrusion in this instance to which I am pointing; you will see examples where the protrusion is much less conspicuous than there; but in the majority, if there is only a single gap, there is a projection forwards, which may seriously impede the exact approximation of the edges at or soon after an operation. Before deciding such a question it might seem highly advisable to know what this part really is, and what may be its apparent importance.

The most striking way in which I can bring the subject before you is to take the example of double fissure in the alveoli, such as you may suppose represented on this sketch. Now, whether the central part projects forwards or not, there is a round knob, like the tip of a finger or thumb, according to age, which is familiarly known as the inter-maxillary portion—a bone or bones; and while it has usually been referred to as single, it has also been spoken of as analogous to the premaxillary bones in animals of a lower grade. Some anatomists, such as Von Ammon and Vrolik, have displayed great research on the subject; but I know of no more minute anatomy in the English language than that in my own work on Surgery. There it was shown, that this projection consisted of two portions of bone, joining in the middle under the columna nasi, as in the normal junction of the superior maxillary; and you see before you the first specimen that I was ever acquainted with, illustrative of that feature. Two portions have been macerated in this specimen, and purposely held asunder, so as to show the gap between them in the mesial line. The first specimens that I had of this were procured by clipping the projection off during the operation, at its narrow neck above, in the line of the vomer. I have subsequently examined more entire specimens from the dead body. Here is a specimen, which I may show you as a contrast to that which you have just seen. The two portions are still held together, as in the normal condition of that malformation. I say, I have subsequently examined more entire specimens, procured from the dead body, and found that the united portions form a projection, extending upwards and backwards, by a narrow neck, until they join by a kind of symphysis with the lower and front end of the vomer. There is here a very strongly-marked example of cleft palate, the cleft being remarkably large; and what makes it more peculiar is, that the septum of the nose has been thrust on one side; the pre-maxillary or inter-maxillary portion is also carried by it, or thrust to one side; and it so happens, that this gives a more available illustration than we usually meet with of this fact, which, in as far as I know, may be looked upon as an original illustration. Here is the vomer from this specimen, magnified considerably; here is the inter-maxillary portion, also magnified; and here is the junction—the symphysis, as I have called it. Now, in the specimens procured from the living body we generally cut the two portions of bone at the narrow neck, through, where I am touching; and this remains ever after lost sight of. So far as I know, we have no dissections or illustrations illustrative of these points, on the adult subject, after operations have been performed.

When the palate is split, as it very generally is, in the double fissure through the alveoli, the vomer sometimes has its only support below, in this inter-maxillary portion, or rather, the projection seems to be an appendage to the vomer; for it appears to be supported in its position by that bone, and by the cartilaginous fibres and mucous tissues associated in the septum. Even in the youngest foetal human upper jaw it is difficult to detect the distinction between the inter-maxillary portions, equivalent to the pre-maxillary bones in the lower animals, and the true superior maxillary portions of this bone; but, curiously, whilst no line of the kind can be traced in the well-developed foetal skull, in the *front* part of the alveolar ridge, the suture remains tolerably distinct in the posterior portion of this bone, until a late period of adult life. In fact, fissure can be detected, in a very large number of specimens, on the palate, whilst in front it cannot be detected at birth, in the generality of instances, or at all events in comparatively early life. In the central portion, the two central incisors, deciduous and permanent, are each at the

proper time usually tolerably perfect. The lateral incisor on each side, both deciduous and permanent, is generally of imperfect development, or altogether wanting, and instead of projecting downwards usually slopes into the fissure; or, instead of projecting downward perpendicularly, it will project sometimes in a horizontal, and sometimes in another direction. It is often shed at an early period, from decay of substance, or from actually falling out entire, having a very indifferent socket. The canine, or eye tooth, generally makes a fair show, and is of tolerable use, although it projects inwards in many instances, and is rarely to be compared with the normal tooth, or, I might say, the same tooth in the normal jaw. These are specimens very well worth looking at by those who are interested in the subject. So far as I know, they are comparative rarities, few Surgeons having taken the pains and trouble to preserve them after operations, or look after specimens of the kind.

Now, this inter-maxillary portion may be looked upon practically as one mass in the deformity now under consideration. It may vary in size, breadth, and thickness, also as regards its prominence; but it is always found in the skeleton as I have represented. I look upon this as a peculiarly valuable specimen; for it may be considered as a specimen in the adult—the inter-maxillary, with the two front incisors tolerably perfect. Here, for the purpose of illustration, the two parts have been parted and kept asunder; and in examining the alveoli, or examining the mass altogether, there is no appearance of any other teeth having been there at all, although I have no doubt there would be some rudimentary appearances, probably, of imperfectly developed teeth, at a somewhat earlier period of life. When there is only one fissure in the alveoli, the mesial portion on that side has often a tendency to project forward, so as to endanger the success of the operation for the remedy of the malformation. In such a case I consider it best to cut the part away. The blade of a scalpel can readily be passed in the line of junction in the middle, and the division can be easily effected with a knife, if the subject be young. Here are several specimens of the kind; and here are specimens of one half of the maxillary bone or bones.

When the fissure is double, it has been proposed to bend the projection back by pressure, or after breaking its narrow neck; but I have noticed, on trying both plans, that the mass has been an impediment to a very satisfactory operation on the lip; and whilst I do not positively object to the occasional use of either of these plans, I decidedly give a preference to the removal of the projection altogether. If bent backwards, it will probably be at the damage of the vomer and septum. Whether bent or broken, the teeth will be thrown on a new plane, and will be likely to project backwards. I have recently heard it proposed, to cut out a portion of the narrow neck, so as to let the knob fall backward into a better place; but if this were done, I should doubt if the knob would not die from the want of circulation. Of course, if the part can be preserved in its natural position, that will be best; and if there be any slight projection, that will be gradually remedied by the pressure of the lip after the operation. However wide the gaps in such cases, it is remarkable how they close, as years roll on; for in many instances the opposite sides approximate so closely, that a fissure will almost elude observation in the adult subject. I have never seen a complete osseous closure. Close approximation gives strength to this condition of the upper jaw. In early years, where there is no lateral support, the inter-maxillary portion and the central incisors must be of little value as regards prehension, incision, or mastication, for the narrow vomer will give little stability in such case.

Now, as to the causes of this defect, whether in the lip or jaw, I have no explanation to offer. I look upon most of the theories on the subject as proofs of how easily even educated men give a loose rein to the imagination. If this be the case among ourselves, it is not to be wondered at that, among the non-initiated, particularly females and mothers, the influence of the imagination is supposed to have a baneful effect. When we hear of mothers producing boys or girls at will—a son and heir, for example, or a daughter when the boys become more numerous than the governor may think right—then I shall believe in the influence of imagination. If imagination had much effect, there would never be a male heir wanted for our estates. If I may, or dare, venture a theory of my own, I am of opinion that the defect arises from the breed, and that it occurs when there is a predisposition in the parents. I fancy I can detect this in the features of father or mother, or both.

Regarding the operation itself, my experience extends to between 300 and 400 cases. Prior to 1850, I kept notes of only a few such cases. At that time I was asked to operate on one which had baffled the best efforts of Mr. Liston and Mr. Lonsdale, and at the same time to use a spring or truss, to push the sides of the lips forward—an invention of Mr. Hainsby, the father of the child. The operation proved successful, and I had good reason to be satisfied that the instrument had been efficacious. It is the instrument I hold in my hand, and you will see it in action in several specimens before you on the paper. Since the time I first used it, I applied it in upwards of 250 instances, and have every reason to recommend it as superior to any straps or other means that have been used for *drawing* the parts together. Its influence, you perceive, is for *pushing* the parts. Now, of these cases particular notes were taken, some of which are interesting: 146 out of 250, for example, were males; showing a large preponderance on the male side, which has not been explained, or much referred to: 153 were on the left side, showing a large preponderance there too. That is a fact that has been frequently observed by others; but here you have it in considerable numbers. Fifty-three were double fissures, and no less than 208 out of the 250 were associated with cleft palate: 169 of these operations have been performed in King's College Hospital. As to the results, three of these patients have died seemingly from the proceeding, not from bleeding or shock, but from some child's ailment supervening, such as the thrush or diarrhoea. I have never seen a single instance of convulsions afterwards, at any period of life, and I have operated at all ages, from a few days old up to thirty-six years. Taking all things into consideration, I am of opinion that the earlier the operation is performed the better—assuredly before teething, and I decidedly prefer about the end of the first month. In a simple case and a healthy infant it may be done any time earlier, to within a few hours of birth. If the child is weakly, and the gap large, particularly if complicated with split palate, I strongly advise delay for some months, until additional strength is acquired, and also that the parts may be pushed closer in apposition by the use of the truss referred to. I have sometimes made babies wear this for many weeks or months before, and have always noticed its great value.

In double fissure I have generally operated on both sides at the same time. Occasionally, however, I have taken first one and then the other, selecting the simplest, and performing the second operation a few weeks, possibly a few months, after. In some of these double clefts the middle portion of the lip has been so split, that I have used it for the columna, particularly in instances where the nose has been flat, when it has seemed needful to take away the mesial projection. The closure of the gaps or gap has always been a very easy matter; but where this part has been prominent, there has often been cause for much anxiety as to the result. The tension of the lip over this part has threatened to be too much for recent adhesions. In only one instance has there been total failure of union, and in that I afterwards repeated the operation with success. In several cases there has been serious threatening of a non-union, by the gap opening an hour or two, or a day or two, after the stitches have been removed; in such instances I have scraped the surfaces, introduced needles again, and put all up as at first, and thus made the process appear only as one. This method I have rarely seen fail. On one occasion a child was running about eight days after a very successful operation for a single fissure. It unfortunately fell on its face, and at once split the union open. Although eight miles off, it was brought to me within a couple of hours, when I introduced needles afresh, and with the ordinary care the result was as perfect as could be desired.

After trying a variety of lines of incision, and seeming cunning devices, for adaptation of opposite surfaces, so as to give the best possible appearance to the lip, I confess that, with few exceptions, I consider the old-fashioned straight line, from the root of the cleft to the free margin of the lip appears to me to be the best. If a notch or irregularity is left in the lip, it arises generally, I believe, from too little having been cut away. To make sure of a good and easy approximation of surfaces, I strongly recommend the free separation of each side of the fissure from the alveoli. Some have said, the frænum from the mesial line in a single fissure should not on any account be cut. It is often unusually large in such cases, and I confess that, from my experience, I see no reason why it should not be cut as readily and freely as any other part of the mucous membrane from the lip to the jaw. To take a

refined view of a perfect operation, I myself find the most difficult part to be that of bringing the opposite sides so accurately together that the margin between the mucous membrane and skin should meet on a proper level. It is a very common thing, to have the red part on one side a little higher than the other; and, with all the pains one is inclined to take in these cases, I have often myself been disappointed as to the result. There are many sketches here illustrative of that circumstance. It is one kind of consolation, that in some of these cases the operation may be repeated at some future day.

The position of patient and Surgeon during the operation deserves some notice. I have often seen the operator sit or stand in front of the patient; and in general, before the work has been finished, his face and dress have been splattered over with blood, saliva, and mucus. A far better plan is to be behind, or at the side, so that all the annoyance referred to may be avoided. In infancy the head should rest between the Surgeon's knees; he should sit; and in the adult the operator may stand behind a chair on which his patient sits, or the head or side of a table on which he may lie. In either of these postures he may escape the unseemly damage to personal appearance to which I refer. A few of my infantile patients have taken the breast after the operation; but most have been fed by hand, and some modern devices with sucking bottles have been of great service. Many of these observations are of no novel character; but possibly the experience that I have had may render them of additional value. It may perhaps be thought that, in bringing this minor subject of Surgery before you in these lectures, I deal but lightly with my position. You may have noticed already, that I look upon some of the so-called minor subjects in Surgery as by far more important than some imagine. But, in extenuation of my present course, I may refer to the circumstance that the illustrious Roux, in writing the experience of forty years of Surgical practice, did not disdain this topic, and actually made it the subject of one of his famous letters to "Cher Lawrence," his equally distinguished and experienced contemporary.

Experience in hare-lip naturally implies some experience in cleft palate; and I hope that I am not taking an additional liberty, in placing this subject in association with that already referred to. In further apology, I may state that both the surgery and anatomy of cleft palate are entirely of modern date, and within the time to which I have limited the scope of these lectures. The early history of the operation for cleft palate sounds like a romance. In 1819 a Medical student applied to Roux, then one of the Surgical luminaries of Paris, with a defect of this kind. Roux pared the edges of the cleft, and brought them together with stitches; union followed, and the palate became like a normal one; and when the youth appeared among his friends again, the change in his voice was such that he could scarcely be recognised as the same person. I doubt if this case, although fairly made public by Dr. Stevenson, in his general dissertation on velosynthesis, when taking his degree at the University of Edinburgh in 1820, produced the full effect on the Surgical mind that it should, even when further elucidated in the famous essay by Roux, published in 1825. Possibly, the rarity of the occurrence and the difficulty of the operation led to apathy; and, down to the period of Roux's death, no one seems to have had any experience on the subject at all equivalent to his.

Like others taking their early surgical lessons in the third decade of the present century, I was attracted by the romance referred to; but I had seen little to absorb special attention. While busy in dissecting-room work, a subject with cleft palate came under notice. At that time, as even now, I suppose, few students took the pains to dissect the palate; but it was my fortune to have this one to luxuriate upon. I made a careful dissection of all the muscular parts, and came to the conclusion that I had rarely seen it so highly developed, although the palate and throat were small, being those of an aged female. The whole matter fell aside for years. I had performed the operation on the living body, and I heard of others doing so, without success.

The subject, on this side the Atlantic, at all events, in a manner slept, with the exception of the doings of Roux himself; but about 1840 all Europe, in a Surgical sense, rang with the brilliancy of Stromeyer's operation for club-foot and Dieffenbach's for strabismus; tenotomy and myotomy became the fashionable Surgical mania, and I bethought me of my former dissection of the cleft palate. For anything I knew, it was original. I compared it with the normal condition

anatomically and physiologically, and then reflected on what I had heard and seen of Surgery, as applied to this condition, by Roux and others. My zeal was further stimulated by a paper by Dr. Warren, of Boston, which told of a larger proportion of success by Dr. Mutter, of Philadelphia, and himself, than to my knowledge had yet been attained by any others, not even excepting Roux. On additional reflection I fancied that I had fallen upon new views in anatomy, physiology, and Surgery, and my conclusions were embodied in a paper which was submitted to the Medical and Chirurgical Society of London in December, 1844. That paper was honoured with a place in the volume of *Transactions* for 1845. Its main features went to show how the cleft was closed in deglutition, by the action of the superior constrictors of the pharynx—how the palato-pharyngei in cleft palate acted differently in this state than in the normal palate, and instead of closing the opening between the pharynx and the larynx, in reality tended to draw the parts asunder,—an act which was overbalanced by the vigour of the upper constrictors of the pharynx. Above all, looking to the Surgical aspect of the malformation, I gave it as my opinion that the action of the levatores palati probably exercised such an influence on the lateral portions of the palate after the operation of Roux as to mar its good intentions. I showed, in as far as one could, by reference to the dead and living parts, how the levator muscle on either side had such free and uncontrolled action, that whenever excited it drew the margins of the clefts upwards and outwards, and so tugged upon the stitches put in by the Surgeon, that ulceration in their sites and separation of the junction was a most probable result—that, indeed, which had caused the failure of Roux's operation in so many instances. The inferences which I drew were, that if the palato-glossus, palato-pharyngeus, and levator-palati on each side were divided, the soft flaps would hereafter for a time be so relaxed, that in all probability the mesial line of adaptation would be so little disturbed, that union would take place. The tensor-palati, I considered, would have little disturbing influence; nor did I put much importance on that of the palato-glossus. My impression was, that the action of the palato-glossus and palato-pharyngeus, particularly that part in the posterior pillar of the fauces, was likely to prove detrimental; and, in accordance with the somewhat novel and already popular practice of myotomy and tenotomy in other directions, I recommended the division of these muscles, as adjuncts to the ordinary operation for cleft palate.

By modern custom the department of anatomy associated with the Professorship of Surgery in this College has been held of comparatively little account, although both my predecessors have displayed remarkable acquirements in this direction, which they have turned to great account in the field of Surgery. As your Professor of Human Anatomy, I hope I may not be out of order in claiming to be the first who solved the problem of how the cleft in the soft palate is closed during deglutition. The drawing influence of muscles has been most recognised; the pushing has been less taken into account, although it is very considerable. Swallowing, the vermicular action of the intestines, defecation, are notable examples of this force, just as palpable in the estimation of the anatomist as the drawing of the biceps in flexing the arm. Anatomy without physiology would be in a manner senseless; but when joined together they give life and soul to Surgery. The influence of the constrictor muscles of the pharynx in the process of deglutition was well known to physiologists; but how, during that process, the gap of cleft palate was closed in the vacant space which I point to in these various sketches was an enigma, until I had the good fortune to show that the parts are pushed together by the action of the superior constrictor particularly, so that the gap between the pharynx and nostril is completely closed during deglutition, as if the velum were entire.

Then for the Surgical aspect. After the investigation I showed that by temporarily taking off the influence of such muscles as in common action tend to draw the two portions of the cleft aside, there was a probability of such entire rest that union in the central line was most likely to take place—certainly, at any rate, more likely than with these muscles in full vigour, irritated as they might be by the wounds, by the inflammation, and by the presence of stitches. The almost intolerable distress, the depressing influence, the actual danger, in the injunction against swallowing, laid down by Roux and others, made the early operations of this kind examples of human endurance which few could follow

out to the full extent. Such injunctions had been occasionally disregarded; and Sir Philip Crampton gave some notable examples of the kind. Since I showed, anatomically and physiologically, that during deglutition the parts are actually pushed together, the process is no longer forbidden; and now a fair share of suitable nourishment is freely permitted,—a matter of great importance, as regards the successful issue of any operation. With a single exception, which shall be nameless on such an occasion as this, I am not aware that any anatomist or Surgeon of repute has controverted my views, as expressed in the paper referred to; nor need I do more than advert to the amiable and flattering device of a Continental admirer, in bringing them all out anew in a few years after, as if they were his own. I have heard of nothing yet to impugn the anatomical explanations which I first gave of how various hap-hazard incisions might or might not facilitate the approximation and the adhesion of the margins of the cleft in the soft palate. The knife for dividing the levator-palati was my own device; and here are many of the instruments which were used by my own hand at an early date.

Those who have devoted attention to cleft palate during the last twenty years must have been surprised at the recent dispute as to the priority of separating the soft from the hard palate, with a view to close the cleft in the hard. Dr. Mason Warren described his process in 1843, and it was referred to in my original paper. I myself performed it in January, 1845, and have since repeated it on all fitting occasions. The late Mr. Avery devoted special attention to this portion of the palate, and after his death the subject was further ably developed by Mr. Pollock, in a paper published in the *Medical and Chirurgical Transactions* for 1856. The first idea that I had of this portion of the operation for cleft palate was obtained from Dr. Mason Warren. I deem it but fair to the reputation of that distinguished Surgeon to state that I know of no originality before his, and that I look upon all modern claims to such originality as arising either from ignorance or a desire to rob the fair reputation of a name which, in son as in father, will stand for generations among the brightest in Surgery.

Although working at the subject of cleft palate since the date of my first paper, I cannot pretend to add much that is novel to the views which were then expressed. I have little to add, and little to retract, from the anatomy and physiology which I have ventured to submit as original. I am still as much convinced that the tensor-palati has little or no influence on the soft palate—certainly that it has none to counteract the closing of the gap. The palato-glossus, I am of opinion, has no practical influence, and, except in rare instances, I am convinced from experience that there is no necessity to interfere with the palato-pharyngeus in the posterior pillar. I am equally convinced of the value of dividing the levator palati. There is ample experience to show that union has taken place, despite muscular action to the contrary. The experience of Roux and others has proved that; but I know of no experience equal to my own to prove what I contend for—namely, that, by taking off the muscular action for a time, union can be rendered more certain than by leaving the muscles untouched. Since I entertained the views referred to, I have operated on 134 cases, and of these 129 have been successful; in two union failed entirely; and in three it was so partial and imperfect that I placed them as unsuccessful. Forty-five of these operations have been performed in public; in a considerable number an aperture has been left in the hard palate, and much benefit has been derived, in many such cases, from the use of an obturator.

I have never attempted the operation in infancy. I consider instances most favourable at or above the age of puberty; but I have frequently operated successfully at ages between ten and fifteen, where patients have been steady and courageous. I have never operated under chloroform; and whilst I do not deny the possibility of doing so, and cases of the kind have been recorded, I am of opinion that, as a rule, it is absolutely requisite to have the patient conscious, so that he may facilitate the steps in a variety of ways.

This enumeration includes all kinds of cases, and refers chiefly to the cleft in the soft palate. In many instances of cleft in the hard palate it is utterly impossible to contend against nature; and even in the soft the parts are occasionally so scanty that there is literally no material to work upon. In so far as I know, the greatest success recorded, before my own views were made public, was that achieved by Mutter, of Philadelphia. In 1843 he had operated successfully in nineteen cases out of twenty; and Mr.

J. Mason Warren, of Boston, had been successful in thirteen out of fourteen. These instances are both of hard and soft palate. What may have been their success since I cannot say. It has been related of Roux, since his death, that he had operated on 120 cases, and that of these one in every three had failed. I attribute Roux's comparative want of success to the circumstance that the levator-palati and the back part of the palato-pharyngeus were left untouched; and I consider that Warren's success may have resulted from the free incisions which he made through the palate, outside the pillars of the fauces. My own success, if I may so call it, I attribute chiefly to the division of the levator-palati; and next, to the relaxation which the wound for that division involves. For mere relaxation, the incision of Dieffenbach, which I show here, is probably the most perfect. I know that it has been particularly successful in Mr. Skey's hands, and in Mr. Pollock's; but, with all deference, I am still disposed, from all I know of the subject, to prefer a free incision above the soft palate, whereby the levator-palati may be divided to a certainty. In addition, I look upon this wound as of great service in this respect. The lymph effused upon it acts as a splint, whereby the palate is kept fixed as on a board, until union in the mesial line is complete.

As to attitude in this operation, the patient may sit or lie, as may best suit convenience. Latterly I have made most use of the recumbent; I find that the head can be kept best on the same line in this position; and as regards my own views on the anatomy and physiology of the parts concerned, I deem the subject of some importance. For instance, if the patient sits, with the head slightly thrown backwards, the palato-pharyngei, when irritated, pull the soft palate downwards, as my own do at the present time, in the attitude my head is in, so as to leave a space between the palate and the base of the cranium; but if the head be thrown far backwards, as I throw it now, the axis of action is altered, and these muscles draw the soft parts upwards, or, in other words, bring the soft palate towards the base of the cranium, and thus add to the difficulties of the Surgeon, by limiting the space above the soft palate, where he has to work with needles in introducing sutures. I say upwards, with reference to the base of the skull; but in reality, when the head is much bent, it would be drawing downwards, as it were. Here, as in hare-lip, the Surgeon has generally stood before the patient; but I invariably select his right side in preference to all other places.

The grand practical object of this operation is to improve the voice and articulation. Defective deglutition from this malformation is what attracts the mother's or nurse's attention in early years. The cries of infancy are in nowise peculiar in tone; but when definite articulation commences, or, rather, should commence, the value of an entire palate is then appreciated. The air and sound, in passing outwards from the larynx, escape in part through the nostrils, from the split in the palate; a nasal twang is the result, and articulation, as in the normal state of the parts, is impossible. Immediately after operation the modification in the voice can be at once detected. It is customary to keep those operated upon from speaking for eight or ten days; it is, however, a needless restriction, as regards my operation. In reality, few care to speak under the circumstances; yet I do not think it would do harm. In the course of eight or ten days, when the fever or distress following the operation is gone, the tone of the voice is at once perceived to be changed for the better; improved articulation, however, comes more slowly; years, many years, are required for distinct articulation, when the whole organs are, to all appearance, in perfection; and after the most successful operation for cleft palate months and years are required to alter defective sounds. Voice and speech have to be modified anew. With some the changes come slowly and sluggishly; with others they are so rapid and perfect that in a few years the original defect cannot be detected, excepting by a practised ear.

PARIS ACADEMIE DES SCIENCES.—M. Magnus, of Berlin, was nominated by a large majority as Correspondent Member for the section of Physics, vacant by the death of Professor Barlow. The other candidates were—Dove, Berlin; Henry, Philadelphia; Jacobi, St. Petersburg; Joule, Manchester; Kirchoff, Heidelberg; Plucker, Bonn; Riess, Berlin; Stokes, Cambridge; and Weber, Göttingen—a truly noble phalanx the Academy had to choose from.

ORIGINAL COMMUNICATIONS.

TWO CASES OF FRACTURE OF THE SKULL.

By JAMES DONNET, M.D.,

Staff-Surgeon Royal Naval Hospital, Lisbon.

(Continued from page 665.)

The following case of fracture of the base of the skull contrasts with the former, and will be read with interest:—

Thomas P., aged 34, one of the carpenter's crew of H.M.S. *Defence*, was admitted into this Hospital on January 11, 1863, his ship having just come into the river Tagus.

From the history which accompanies the patient, it appears that whilst employed on the evening of January 8, about 11 p.m., the night being very dark, he tripped and fell through the ash-shoot, which leads from the upper deck into the stoke-hole—a height of about thirty-five feet. He was picked up in a state of insensibility and conveyed to the sick bay. In less than half an hour after accident voluntary motion was restored, and shortly after he became sensible to external impressions. Breathing stertorous at times. Vomiting occurred at 1 a.m. of the 9th, and at 5 a.m. of the same day he spoke, and complained of much pain in the right temple. The pulse was full, slow, and labouring. The temporal arteries on both sides were opened at an interval of several hours, and about three ounces of blood taken from each. His bowels were opened by means of croton oil, and the head was kept cool.

On admission into this Hospital on January 11, he is able to get into bed without assistance. He complains of much pain of head, which he refers chiefly to the forehead over the orbits. The eyelids are heavy, and give a vacant expression to his countenance. Pupils are sensible to light. There is strabismus, and likewise diplopia. Pulse, 56, beating measuredly, but not full. There is no oozing of serum nor blood from ears or nose. Bowels are loose from the action of the croton oil administered on board. A cold lotion was applied to the head, and quiet was strictly enjoined.

January 14.—Pulse, 60. He sees objects double when both eyes are opened and fixed; but by closing one eye he is enabled to see the object single, and the features of persons become likewise distinguishable.

15th.—To-day there is confusion of ideas; he is incapable of using the words he wishes; talks incoherently, and seems conscious that he does so. Eight leeches to be applied to temples and sinapisms to the calves of the legs. Bowels are open.

16th.—Less strabismus; pupils are sensible to light; attempted several times to get out of bed; yawns very frequently; put his hand to his head and says, "Take it away;" talks incoherently, and in a tone almost inaudible. The leeches applied yesterday bled freely.

17th.—Pulse 64; bowels opened once; repeats all the questions put to him, but does not answer; he relapses after being questioned into a state of semi-stupor. The head is kept cool by means of cold lotions.

18th, 8.30 a.m.—Appears more collected this morning and has a less stupid look; puts his hand to his forehead and to back of head to show where the pain is. Recognised one of his shipmates, and was able to name the ship to which he belonged. At 1 p.m., breathing having become laboured, I was sent for. I found him comatose, breathing laboured, pupils dilated; shortly after he foamed at mouth; pulse became irregular, quick, mounting to 170 per minute, with intermissions of 10, 15, and 20 beats, then hurrying on at the rate of 168 and 170 per minute; pupils are insensible to light; there are some convulsive movements of the upper extremities. The face then became congested; respiratory movements laboured; large crepitation in bronchi and trachea, with discharge of frothy mucus from the nose and mouth. This state lasted for twenty minutes. Sinapisms were applied to thighs and legs; an injection of turpentine and castor oil administered; cold lotions and affusions to the head. At 2.50 p.m. he became moribund, and he died at 3 p.m.

Post-mortem Examination Twenty Hours after Death.—Rigor mortis well pronounced. Hypostases of dependent parts of body well marked. On cutting through scalp blood is found effused in its cellular tissue. On raising calvarium the dura mater presented a bluish-black appearance all over, but more especially on the left side. A clot of blood two inches in diameter each way, and about three-quarters of an inch in thickness, was found on the lateral and posterior part

of dura mater. On slitting up and raising the dura mater a sheet of blood covers the surface of the left hemisphere; the greatest thickness of this clot corresponds to that of the clot described above. The base of the skull between dura mater and arachnoid membrane contains much clotted blood, especially in the middle fossa. The left middle lobe of cerebrum is torn, and several portions of cerebral matter are attached to the inner surface of the dura mater, commingled with clots of blood. A fracture commences at the posterior part of the right parietal bone, extends to lambdoidal suture of the left side passes along the course of the suture as far as the posterior inferior angle of the left parietal bone, and radiates forwards and inwards to the foramen lacerum, and upwards and outwards as far as middle meningeal groove, where it appears to terminate.

Those who have had but little experience in cases of fracture of the base of the skull are astonished to find the extent of injuries a post-mortem examination reveals, and wonder that such severe mischief should accompany the apparently insignificant symptoms observed during life.

In the case of T. P., the measured slow pulse, the strabismus and diplopia; the idiotic expression of countenance; the frequent yawnings; the loss of power of saying the right thing, with the general restlessness, betokened injuries of a very severe nature, but the quantity of blood and the great extent over which it was effused, with the laceration of the middle lobes of the cerebrum and the fracture, which not only was of great extent, but ran along the course of the lambdoidal suture—an occurrence not frequently met with—were injuries greater than seemed warranted by the symptoms observed during life.

Had the post-mortem examination alone been witnessed by me, without any knowledge of the previous history of the patient, I should have said, "This man died immediately after the accident;" or I might have qualified it by saying "that he had lived a few hours after the accident, partly recalled to a state of consciousness after recovery from the first shock, but chiefly in a comatose state, with total or partial loss of sensibility and motion." The patient on the morning preceding his death appeared more collected than he had been since his admission, was able to answer questions, and did not relapse into that state of semi-stupor which was observed the day before; he even remembered one of his shipmates, and mentioned the name of the ship to which he himself belonged—symptoms which aroused a degree of hope, and discarded any suspicion as to so rapid a dissolution. The epileptic fit which followed shortly after, and which immediately preceded his death, must have been caused by a further effusion of blood occurring at the time, and pressing upon the vital centres; the quantity of blood found at the base of the cavity of the cranium seemed to warrant this opinion.

This case is so far instructive that it teaches us to consider all injuries of the head with just caution, and its study tends to make us guarded in the diagnosis and prognosis of similar cases.

ODONTOLOGICAL SOCIETY.—The last meeting of the Session was held on the 6th at the Society's Rooms, 32, Soho-square, the President, E. Saunders, Esq., in the chair. Various presentations were made to the library and museum. Mr. Coleman read a case of closure of the jaw that was successfully treated at the Dental Hospital by Mr. Cartwright. Dr. Thomas Ballard read a paper "On the Constitutional Ill-effects of Fruitless Sucking, and the Diagnostic Value of Deformed Jaws in relation thereto." The adjourned discussion on the paper read at the previous meeting by Mr. Cartwright was resumed in conjunction with that on Dr. Ballard's paper. The thanks of the Society were unanimously voted to Dr. Ballard, and the Society adjourned to November.

THE Governors of the Apothecaries' Hall of Ireland entertained at dinner, on Thursday, the 16th inst., at his residence, Harcourt-street, Dublin, the Court of Directors and Examiners of the Hall, and also the following distinguished members of the Profession:—Dr. Stokes, Physician in Ordinary to the Queen in Ireland; Dr. Jacob, President of the Royal College of Surgeons; Dr. Wilmot, Vice-President of the Royal College of Surgeons; Dr. Adams, Surgeon in Ordinary to the Queen in Ireland; Sir William Wild, Dr. Ireland, Dr. Banks, Dr. Bigger, Dr. Kidd, etc. Dr. Corrigan, President of the King and Queen's College of Physicians, was, in consequence of a previous engagement, unavoidably absent on this occasion.

Medical Times and Gazette.

SATURDAY, JUNE 25.

SCIENCE AT THE COLLEGE OF SURGEONS.

THE history of institutions for promoting the professions of civilised society is marked by stages as distinct as any which the geologist can discover in the history of the earth's crust. First there is a period of chaos, during which every one does what is right in his own eyes, and gives himself any title that suits him. At a certain epoch any one may practise as Surgeon, dentist, chemist, actuary, engineer, surveyor, as the case may be, and assume any of these titles respectively at will. The next stage in this free country is that of voluntary association. The best men amongst the Surgeons, or dentists, or chemists, or architects form themselves into a society, institute, college, or guild for discussion, co-operation, and mutual protection. As time goes on, it becomes a creditable thing for all the young men in each respective profession to join the voluntary institute; and then follows the next step. Public authority is appealed to, and gives the voluntary association a legally recognised existence—a charter, common seal, the right to sue, and the like. As a next step, the members of the chartered body claim for themselves the preference in all public appointments, or perhaps the Government may decree that preference shall be given to them in such appointments. And now comes the next and most important stage—that of exclusive privileges. The chartered body next claims, not only that its members are the best in their particular calling, but that they are the only ones fit to practise at all, or to use a designation implying that they are fit to do so. The Medical body has passed through all these stages; and any one who will cast a glance at the history of the pharmaceutical chemists, of the dentists, architects, district surveyors, and schoolmasters may see in them examples of other professional bodies which are step by step attaining to the same grade of organisation.

But exclusive privileges and lucrative offices under corporations can only be maintained on grounds of public utility; and there comes unluckily, a stage in the history of most corporations, when the love of science becomes mingled with love for the loaves and fishes; and when the corporation decomposes, as it were, into separate cliques and factions, each with interests adverse to that of the main body.

Such is now the position of the Royal College of Surgeons. There is a fight going on for seats in the Council—the post of honour—and through this, for seats in the Court of Examiners—the post of profit.

The chief and dominant,—we may truly say, justly dominant party, is that of the Surgeons to London Hospitals. No one disputes their claim to the largest share of College honours and emoluments; but they have no right to the whole.

A second party is that of scientific men, who, though Surgeons, yet make their Surgical pursuits subordinate to those of anatomy and physiology. It is not too much to say of anatomy—exact, minute anatomy—that it is in the first

place invaluable as a mental discipline; secondly, that it is the basis on which sound Surgery rests; and that the enlargement of the bounds of anatomical research, by means of the microscope, follows in necessary order the cultivation of the minute naked eye anatomy, and that it may, and probably will, do for *Medicine* in another age, what the study of parts visible to the naked eye has done for *Surgery* in this. And here let us allude to Professor Fergusson's lectures. Even he, a genial, good-tempered man, a scientific anatomist, *par excellence*, whilst demonstrating the improvements he had effected in an important Surgical operation by means of his own laborious dissections—dissections which probably some wise head of forty years past might have rebuked as impracticable and unnecessarily minute—could not forbear a fling at “scientific” anatomy. He had raised a laugh, too, at microscopic anatomy in his first lecture! This little incident shows the prevailing sentiment. Nevertheless, anatomy, in its widest sense, is of such unspeakable importance as a branch of the student's education; it is a pursuit which may so well occupy a man's life, and not merely the few years of leisure before a Hospital Surgeon gets into practice, that it ought to be represented in the Council, without reference to the fact whether the scientific anatomist hold a Hospital appointment, or even practise Surgery at all. Such men as Sharpey, Kiernan, Owen, Huxley, Gulliver, Ellis, though they might never feel a pulse nor handle a bistoury, ought to be found on the Court of Examiners of a College of Surgeons, if the whole of Surgery is to be there represented.

A third party who ought to be represented are the Hospital Surgeons of the great towns of England. The Royal College of Surgeons of *England* ought not to be a mere *London* College. There are several points in the Charter which ought to be altered, in order to give the country Fellows greater facilities of voting. But this matter is in their own hands. If they prefer not to elect councillors from amongst themselves, that is their own affair.

Lastly, the Council of the College and Court of Examiners ought to include some representatives of Military and Naval Surgery. It was, we believe, one of the earliest customs of the old Company, from which sprung the present College, that the King's Serjeant-Surgeon, whose duty it was to attend on the Royal person in war, should be a member of the Court of Assistants. Although our Queen does not go forth at the head of the army, it is quite right that the Surgeons who attend her soldiers and sailors, and whose functions are of such tremendous importance, should have every stimulus to exertion, and should not be shut out from College honours by any technical difficulty.

Let us ask this plain question: If the Royal College of Surgeons of England were a perfect representative of English Surgery, and its Fellows fulfilled the duties of Teachers and Examiners completely, what need would there be of the College of Military Surgery at Netley?—of a second Court of Examiners?—and what scope would there be for the damaging, but unanswered, criticisms of the younger upon the work of the elder Institution?

THE “MEDICAL TIMES AND GAZETTE” FOR 1864.

If ever it were allowable for the conductors of a journal to boast, we think that we may do so, as we close our first volume for 1864. Seldom has any Medical periodical supplied its readers with information so weighty, varied, and original. We may refer first to the lectures on Acupressure—one of many inventions of the versatile and thoroughly practical Professor of Midwifery at Edinburgh, the future value of which is confidently prognosticated by Professor Fergusson in his second lecture at the College of Surgeons. Professor Garrod's lectures on the British Pharmacopœia were greedily devoured by Practitioners, who were delighted, not, indeed, with his able defence and explanations of that unpopular book, but with the multiplicity of shrewd practical hints and

evidences of fair experimental research in therapeutics with which they abound. The demonstration of the valuelessness of arnica was universally considered a convincing proof of Dr. Garrod's acuteness as a scientific therapist, and a condemnation of the silly favouritism of the Pharmacopœia compilers, who ventured to give this worthless drug a place which they denied to many others of larger use and repute. The lectures of Professor Harley on the Urine, and the series of essays by Mr. John Wood on Hernia bring before the Practitioner those details of his daily duties with which he ought to be most minutely familiar; whilst those remarkable lectures by Professor Helmholtz on Conservation of Energy will give him a birdseye view of the most recondite speculations of philosophers as to the connexion of life with the manifestations of other force in the universe. The reports of Professor Huxley's lectures will interest the comparative anatomist. We need not mention the lectures by Professor Fergusson, now in progress, nor yet the contributions which come from Paget, Rev. S. Haughton, J. W. Ogle (whose case of Tetanus, by the bye, is the latest authority on the latest plan of treatment), Priestley, Peacock, Handfield Jones, Le Gros Clark, Murchison, Ramskill, Laycock, F. Jordan, Bulley, Walker, Althaus (on the trichina) and J. Z. Laurence. The "Medical History of England" has been the means of raising a controversy, which is by no means settled yet, on the actual mortality of Hospitals, and will serve as the standard account of the position and working of our Profession for many a day. When we mention briefly our own efforts to vindicate the honour of our Profession, and to make good its claims to be an honourable, humane, and scientific pursuit, and not a mere trade, we are sure that our readers will agree that we have given them a good volume, and one which will be often taken down for reference.

THE WEEK.

THE LATE PROFESSOR MILLER.

IN another column will be found an account of this estimable and lamented Professor, who has been snatched away, like so many others, in the prime of life, and at the very time when—so popular, so beloved by his friends and patients, so forward in every good work—he should have been most able to serve mankind by his great and undoubted talents and beneficence. Is there any warning or moral to be drawn from his career? We think there is. It is currently said that he was killed by a review of his "System of Surgery," which appeared two months ago in a contemporary weekly Medical journal. This, of course, is an exaggeration; yet there is no doubt that he was deeply mortified, and that this accidental annoyance may have given the last shock to a nervous system worn out and ready to fall into disease at the smallest provocation. We have read the review in question, and believe it to be temperate, courteous, and altogether just. For our own parts, having had some experience with reviewers and the reviewed, we can well understand that a man may be nervous about any book that he brings out. It is a grave thing to do; but if a man of sense is himself satisfied that his book is a good one, and that he has done his best with it, he may rest on the justice of the public and on his own self-consciousness; and may snap his fingers at any unjust review, even should one appear. The really strong men who write good books don't care for reviews; it is the weak men who write poor books who cry out at a review, even though their own books may contain bitter assaults upon half a-dozen of their contemporaries. And Professor Miller was essentially a weak man, so far as he may be judged by his writings; brilliant, but not solid or deep; possessing immense powers of verbal manipulation, but apparently not so capable of sound and solid argumentation. His style was quite that of a popular preacher who addresses women. In noticing a work of his, entitled "Nephalism," about three years ago, we were painfully struck with the unsoundness, the recklessness of his statements. Even then, probably, a too excitable and anæmic brain, not quietly work-

ing at its legitimate occupation, but fretting with all sorts of religious controversy, such as is known only in Scotland, was falling into disease. And in one of his pet doctrines lay a fatal source of mischief. He was a teetotaler, and consequently did not give his brain that rest and refreshment, that power of discarding and wiping out irritating and exciting trains of thought, which wine, temperately used, will confer. Had he taken a little wine, and excited himself less, he would have written a better book, and might have laughed at reviewers.

THE TRUE HERO OF THE "ALABAMA."

THIS too celebrated ship has finished her career, and no part of it was so creditable as its close. To attack unarmed merchantmen, and trust to her heels for escape from fighting ships, may have been compelled by the necessities of war, but was not a sort of work to boast of. On the other hand, to come out for honour's sake and fight an antagonist better armed was a deed more worthy of a hero. Our readers will be glad to learn that Captain Semmes's wound is not likely to prove serious. He was struck by a splinter from a shell which burst near him, carrying off the arm of one of his sailors, and inflicting on himself some injury to the soft parts of the back of the right hand. There is a good deal of pain and puffy swelling, but he is going on well, and we have little doubt that he is quite safe under the care and skill of Dr. Wiblin, of Southampton, of whom Professor Fergusson made mention in his first lecture at the College. Such of the officers and men, too, as landed at Southampton were tolerably free from injury; as was evident from the fact that they owed their escape to their powers of swimming. Nine men were killed and twenty-one wounded during the action, and the latter were received on board the *Kearsage* and taken to Cherbourg, where they were landed with her own wounded, and consigned to the charge of the Hospital authorities of that port. But alas! the real hero of the day was lost! As the ship was sinking, and the boats were being filled with the wounded, a sailor unhurt tried to get into one of them. The Surgeon held him back. "See," he said, "I want to save my life as much as you do, but let the wounded be saved first." "Doctor," said the officer in the boat, "we can make room for you." "I won't peril the wounded men," was his reply. The Surgeon was the only officer lost. He died as an Englishman should: in the discharge of his duties. His name was Ernest George Thomas Llewellyn, M.R.C.S. 1859, son of the Rev. David Llewellyn, appointed in 1835 Rector of Puddington, near Crediton, a parish of 210 souls. Nelson was son of a country curate. We can imagine a young man rushing into any wild life to escape from the monotony of Puddington. We can but give utterance to the feeling of disgust with which we regard the official report of the action rendered by Captain Semmes to Mr. Mason, agent for the Confederate Government, and published in the *Times* of June 23. He gives due credit to his first lieutenant, Mr. Kell; not one word of condolence for the loss of poor Llewellyn.

MIDDLE CLASS EDUCATION.

IT is a remarkable fact—one of the anomalies of our system—that the classes receiving extrinsic help in the education of their children are at the two extremities of the social scale. Our great public schools to which the higher classes send their sons have been made what they are by royal endowments, and from time to time their condition is scrutinised and their defects ventilated by a royal commission and Parliamentary discussion. On the other hand, a costly national machinery is provided for educating the children of the labouring man. There is a Board of Commissioners with a minister of the Crown at their head, and a legion of inspectors and schoolmasters paid out of the public purse, and directly under the supervision of Government. The middle is the only class who are left in this matter entirely to their own resources of

money and intelligence. It is not necessary to define who the middle class are. In this country sharp social definitions are impossible. We may consider them as including persons who are capable of paying from £25 to £40 annually for a child's maintenance and education. In such a category many a man in our Profession finds himself—all, in fact, who are blessed with large families and moderate incomes. A doctor who has six children to educate, and a practice of £700 a-year, with its contingent expenses to meet, cannot well spare more than £200 for his children's training, or something less than £35 a-year each. Where is he to send his boys? The State does not help him to answer the question. If he could pay six times that sum, or if he could pay nothing at all, there would be no difficulty about the matter. But as he is in neither of these positions, he is left to chance and the advertising columns of the *Times*. The Royal Medical Benevolent College is above his mark. Our correspondent of last week, Mr. Manby, in his genuine and earnest letter, told a home truth when he wrote:—"I am again ready to admit that there a very great proportion of needy men amongst us. I unhappily know some, and I chance also to know those who would like to send a son or sons to Epsom; but £40, with travelling and other contingencies, after all, they say, 'is no great boon; we must be content to send our boys to a second or third class commercial school.'" But even if the Epsom College were all it ought to be—if it gave a sound classical and mathematical education, with suitable board and lodging, for £30 a-year to the sons of Medical men, it would meet only a very small part of the want: nine-tenths of our boys would still be at the mercy of irresponsible speculators and under-bred and half-educated ushers. In France the State interposes. Take, for instance, the Lyceum at Toulouse, which has been made the text of Mr. Arnold's book, "*A French Eton*." There you have from 300 to 400 scholars, partly boarders, partly day scholars. The boarders pay from £32 to £36 a-year each, and for it they get an excellent education—classical, mathematical, and scientific—board, books, writing materials, the care of their wardrobe, Medical attendance, and washing. This is, in fact, a Government establishment—a public school for the middle classes—partly supported by the public money. We do not expect that our Government will interfere to provide similar establishments, although sons of the trading and professional classes have, at least, the same claims as those of others on the care of our rulers. The *laissez aller* creed is too fashionable with us at present. But there is already a machinery existing which might be utilised for the purpose. There are some hundreds of grammar schools which are in the enjoyment of endowments from various sources, and which are never heard of beyond the country towns where they slumber away peacefully year after year under the shadow of the parish church. We are glad to see that the Social Science Association have directed attention to this view of the matter. On Saturday, June 18, a deputation, which included Lord Brougham, Earl Fortescue, and the Bishop of London, waited on Lord Palmerston "to represent the expediency of issuing a Royal Commission to inquire into the grammar schools and other endowed schools in the United Kingdom not yet reported upon, and generally into the state of education of the middle classes." Lord Palmerston has promised to give his attention to the subject. We hope that, whatever Government may be in power, the Social Science Association will not allow this matter to rest. If they succeed in getting a Commission appointed they will deserve the thanks of the whole trading, manufacturing, and professional bodies, and of none more than the Profession of Medicine.

PARLIAMENTARY.

In the House of Lords on Thursday, June 16, the Earl of Carnarvon asked when the report of the Commissioners would be produced respecting the death of a needlewoman in a millinery establishment at the West-end, partly by overwork,

and partly by the abominable and discreditable condition of the room in which she was employed,

Earl Granville promised that the report should forthwith be presented.

On Friday, June 17, the Lord Chancellor said that, after careful consideration, he for the present withdrew all further consideration of the County Courts Amendment Bill.

Various clauses in the Penal Servitude Acts Amendment Bill were agreed to.

The House of Commons at the morning sitting was occupied, in committee, in discussing the details of the Factory Acts Extension Bill.

The proposal of the Government to exclude from the operation of the Bill, by omitting from the first schedule, persons employed in certain processes in warehouses and in packing textile fabrics gave rise to a debate.

Ultimately this amendment was withdrawn, and the Chairman was ordered to report progress, to sit again on Monday week, Mr. Bruce undertaking in the meantime to consider the best mode of dealing with this part of the measure.

In the evening, on the order for going into a Committee of Supply,

Sir J. Hay rose to move a resolution "condemning the want of foresight displayed by Her Majesty's Government in landing forces on the Gold coast for the purpose of waging war against the King of Ashantee, without making any sufficient provision for the preservation of their health." Our necessary limitation as to space prevents our reporting the whole of Sir J. Hay's remarkable statement; we, therefore, extract such portions of his speech as refer to the neglect of the commissariat and Medical departments, for which the Government authorities are responsible, and the conditions which led to the sacrifice of so many English officers and men. Sir J. Hay, in describing the circumstances under which the troops were placed, said:—

"Cape Coast Castle, as was well known, was a settlement 1100 miles from Sierra Leone, the only civilised town, if even it deserved that title, in that part of the world. It was an old castle, built originally by the Portuguese, upon a granite rock which projected into the sea. To the eastward of it was a small river, which during the rains was a flood, but during the greater part of the year was a swamp, and the water of which was not fit for the use either of human beings or of animals. Along the sandy spit between the river and the shore extended the town of Cape Coast Castle, principally inhabited by a native population, under the protection of the fort, which generally numbered about 10,000 persons. The water for supplying the town was collected in tanks, of which there was one to every house, during the rainy season; and the water so collected was supposed to be sufficient to supply the normal wants of the population during the dry portion of the year. The fort of Cape Coast formerly had very large and ample tanks; but many of them were now out of repair, and those that were in good condition were only sufficient to supply with water a force of about 250 men, which was the usual garrison. It was true that since these operations commenced, some six or seven months after the troops were sent there, in the month of January, her Majesty's Government sent a distilling apparatus to Cape Coast Castle, to supply the troops, but unfortunately that apparatus was not in order until early in May, so that there was no additional supply of water for the additional influx of troops until the rainy season had again set in, and the necessity for the distilling apparatus was not so apparent as it had been. There were at Cape Coast Castle no animals suitable for the food of man, no sheep or cattle. There was no herbage to feed them, and as soon as cattle were brought to the settlement they were killed. As much of their flesh as possible was consumed fresh, and the rest was salted for future use. The food supplied to the troops was, therefore, mainly salt provisions and navy biscuit."

After showing that blame was not to be attributed to the governor, and giving an account of the original cause of the war—a runaway slave who had stolen some property belonging to the King of Ashantee, and had taken refuge within the British territory, he continued:—

"He did not question the policy which her Majesty's Government had thought proper to adopt, but having decided to institute war upon the Gold Coast, he was entitled to inquire how they had conducted it. One would imagine that

every comfort for troops serving in such a deadly climate would have been immediately sent out—(cheers)—and as there was no water there, and no supplies could be obtained on the spot, one would imagine that roomy and ample transports conveying the expedition would have been moored in the anchorage off Cape Coast Castle to afford a base of operations; that steam transports would have been forthcoming to convey fresh provisions from Sierra Leone, or any other place from which it was thought desirable to draw supplies; and further, that Hospital ships to receive the sick, and steamers to take them away to a position where they might recover from disease or from gunshot wounds, would have been provided. (Hear.) It would also have been desirable that the steam transports should have been employed, as in the Crimea, in distilling water for the use of the troops. With such appliances, the war, though still dangerous and deadly, would not have been as fatal as it proved; and her Majesty's Government, having made up their minds to send 1800 men upon such duty, were bound to supply them with materials other than a distilling apparatus that would not work, brackish water remaining for the use of 200 men, and salt provisions, while the thermometer stood at 94 in the shade. (Cheers.) He did not wish to state the case more strongly than it deserved; he did not wish to make an unjust attack upon any department; but as the war was estimated to have cost £14,000 a month, he must say that all which could be necessary for the safety of the troops or the efficient conduct of hostilities ought to have been supplied; and that her Majesty's Government, which had thought proper to incur this expense without the sanction, and, indeed, without the knowledge of the House, would have done well either to have consulted the House or else not to have starved the war and killed the men. (Hear.) War to be successful ought to be conducted so as to bring matters to an issue as speedily as possible; but in the present case it seemed that this maxim, and indeed the dictates of common sense, had been lost sight of."

He went on to describe the circumstances under which an expeditionary force under Colonel Conran, and a volunteer force under Lieutenant Hay were despatched into the interior. To the latter no Medical officer was attached. One had been promised by the Governor, but he was not sent,—

"So that the officers and men were there without any Medical advice, the blame of which, however, did not rest with the officers who despatched them. Those officers volunteered for that service, and there were no Medical men to send. Her Majesty's Government sent out twelve Medical officers. Three were dead, three invalided, and the remaining six had been described to him as walking skeletons who had been left to do duty at Cape Coast Castle."
"Throughout last winter there was great sickness at Cape Coast Castle. He had examined the return laid on the table, and he had endeavoured to ascertain how many had died. The return gave 64 officers and 1745 men, and it gave 1348 men as fit for duty. There must, however, be some mistake here, because there were 35 out of the 64 officers who were dead or invalided, and 9 were ineffective, in addition to those in Hospital in Cape Coast Castle. Out of 1745 men 1348 were said to be efficient. That left 397 to be accounted for, whereas the return of the number of men dead and invalided was 127, which left 270 men not accounted for. They were "missing," in military parlance, which meant dead or deserted. As it was not likely they would desert to the King of Ashantee, he came to the other conclusion. On the 9th of April this year the *Tamar* was sent to take reinforcements from the West Indies to Cape Coast Castle. She took 661 men and 29 officers. This did not exactly agree with the official return, but he adhered to his own information. At that time there were troops at various places, but there were between 200 and 300 men sick at Cape Coast Castle, and 15 officers also ill in the Castle. The *Tamar* landed her men on the beach of Cape Coast Castle. She brought no provision for the mass of wretchedness there. The troops already there were in native huts, and those brought by the *Tamar* were marched to the front and put under canvas. Before the *Tamar* left 120 of the men she brought were down with sickness. The Medical officer said he would have given his own life to have had those poor men put on board the *Tamar*. Captain Stirling, an excellent officer, took compassion on a poor lady, and against orders took her to Gibraltar and saved her life. The *Tamar* had orders to have nothing to do with the expedition. With the usual red-tape routine, she was ordered, after landing her troops, immediately to proceed on another service, and

to take a regiment that was going to Malta, and these poor sick men from the ramparts saw her steaming away for a western sky, and with her the last hope shrunk within their breasts. They nearly all died. One would have imagined that the Government, when sending a steamship to this part of the world where there was no one to give orders—for the Governor was gone to sea, ill, Colonel Conran was up the country, and the commanding officer at Cape Coast Castle was delirious with fever—would have given orders to the captain of the *Tamar* to bring away with him any men who might have been wounded or suffering from fever. But the captain had positive orders to proceed on another service. The captain was probably not aware of what was going on on shore, and he steamed away in obedience to his orders, leaving these men to die. It would be rather too painful to him to read the names of the officers whose services had been in this manner lost to their country. Some few men recovered; but he had been told by a Medical man that the effect of the fever was so debilitating upon the constitution that those who died were almost happier than those who lived. When the last mail left there—for the African mail called there—there were nine officers and twenty-five men left in the apology for an Hospital in Cape Coast Castle, who were living on brackish water and salt beef."

In the debate which followed Government was defended by the Marquis of Hartington, Lord A. Churchill, Lord Palmerston, and other speakers. A narrow majority of seven in a very full house saved the Cabinet from a vote of censure. But it was clearly felt that the allegations of Sir J. Hay were entirely proved, and in whatever quarter the blame really lay, the whole transaction afforded a flagrant instance of official mismanagement and neglect, unrivalled since the Crimea.

The Chimney Sweepers Regulation Bill was read a second time.

In the House of Commons, on Monday, June 20, the Government Annuities, etc., Bill was read a third time and passed.

On Wednesday, June 22, the House went again into committee upon the Weights and Measures (Metric System) Bill, taking up the discussion at the new clauses, commencing at the second clause with the substituted schedule of tables of values of the denominations of weights and measures on the metrical system, expressed by means of the legalised denominations, the new clauses being framed in concurrence with the Government.

The clauses and schedule were agreed to, after considerable discussion, without amendment.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BRIGHTON.

THE BRIGHTON AND HOVE DISPENSARY.

THE Brighton and Hove Dispensary, situated in the Queen's-road, is a thriving and very useful institution. The Dispensary-house is a fine building, and would admit of being applied to the reception of six or eight in-patients. Indeed, at the present time it is under consideration whether it would not be advisable to open two wards in the Dispensary for the purpose, at least, of admitting urgent cases, such as severe accidents for which an operation may be demanded. The Dispensary, once called the Dispensary and General Infirmary, was the parent Medical institution of Brighton, having been founded so early as 1809. Recently a branch Dispensary has been opened in the Farm-road, Hove. The Dispensary affords Medical relief to about 12,000 poor each year. These are not only supplied with Medical advice and medicines, but with extra diet in special cases. This latter arrangement, which is novel, I think, in Dispensary management, is found to be of very great service, and is conducted on a simple method. There is a fund connected with the Dispensary called the Jubilee and Samaritan Fund, of which Mr. J. G. Young is the treasurer. The fund is placed under the supervision of a committee of management, who apply it to the purchase of food for the poor under the special directions of the Medical officers. In the treatment of many cases occurring in Dispensary practice where food rather than medicine is required, the hands of the Medical officers of this Dispensary are thus unbound, and they are enabled, as Medical

officers of institutions everywhere ought to be, to use food for physic when food is the true remedy.

THE MEDICAL STAFF.

The Medical staff of the Brighton and Hove Dispensary is composed of the following members:—Dr. King, Consulting-Physician. B. T. Scabrook, Esq., Consulting-Surgeon. Dr. Hall, Dr. Addison, Dr. Phillips, Dr. Withers Moore, Physicians in Ordinary. J. P. M. Smith, Esq., Joseph Dixon, Esq., R. Branwell, Esq., J. J. Murray, Esq., Surgeons in Ordinary. Mr. J. H. Browne, Honorary Dentist. Mr. Crawford J. Pocock, House-Surgeon. Mr. R. Glaisyer, Dispenser. Mr. T. J. Cooper and Dr. Barker are the District Medical Officers. At the Western Branch, 4, Farm-road, Hove, Mr. Badcock is the Resident Medical Officer.

The practice of the Dispensary affords a good insight into the more important disorders affecting the poor of Brighton. From a table of the mortality of the patients attending the Dispensary in the year 1863, which has been drawn up for me with much care by the House-Surgeon, Crawford J. Pocock, Esq., I find that the leading fatal disease is consumption. In 1853 this disorder yielded 15 per cent. of the fatal cases treated. Next to this stands measles and its sequelæ, then scrofula, and after these scarlet fever and its sequelæ. Inflammation of the lungs and of the pleura holds rather an important place, causing over 6 per cent. of deaths; and bronchitis is little less formidable. I need not analyse the facts further, but may give the table itself, placing the diseases in order according to their fatality. The table shows that the mortality is at the rate of rather more than 2.91 per cent., a mortality comparatively low.

Increase 774

The cost for drugs at the Dispensary may be taken at 8 1/2d. a case per annum, but these figures do not include 4917 patients who are attended at their own homes during the year. In addition to the ordinary prescribing practice, the Dispensary gives out trusses to poor persons afflicted with hernia, and the children of the poorest of the population are vaccinated by the Resident Medical officer.

THE SUSSEX AND BRIGHTON INFIRMARY FOR DISEASES OF THE EYE.

Near to the Brighton and Hove Dispensary is the Eye Infirmary, a very neat building, containing wards and accommodation for the reception of several patients. The Infirmary was founded in the year 1832 by Dr. Pickford, of Brighton, so well known in the Profession by his excellent and useful work on "Hygiene." Patients labouring under purulent ophthalmia and accidents are admitted at all times without recommendation, but children under 7 years of age, except in cases of great injury, or where an operation is necessary, are not admitted; pregnant women, persons of weak intellect, and persons suffering from epidemic diseases are also not admitted. Patients have to find their own changes of linen and washing.

The diet table of this Institution, framed with special reference to the requirements of the class of cases received into an eye infirmary, is as follows:—

The number of patients admitted annually to the Eye Infirmary is from 1150 to 1200. Last year the numbers were 1186, of whom 48 were received into the House. Of the latter, 25 were discharged cured. The cost of each in-patient, including all expenses, is a little under £2 12s. per patient in the year. The cost of medicines per annum, including in and out patients, is little more than 7d. per head; last year £35 3s. 9½d. only were spent in medicines. This fact implies very strict economy, and indicates how widely different Practitioners of our art differ in the expenses attendant on their methods of prescribing.

MEDICAL STAFF.

The Medical staff consists of—Dr. Pickford, as Physician; and of Henry Penfold, Esq., R. P. B. Taaffe, M.B. Lond., and J. Jardine Murray, Esq., as Surgeons.

BRIGHTON AND HOVE LYING-IN INSTITUTION.

The Lying-in Charity of Brighton, situated in West-street, was founded in the year 1830 by the late Dr. Lyons. It affords gratuitous attendance to poor married women in their own houses, advice and medicines to women suffering from uterine diseases, and to infants suffering from any form of disease; and it admits within its walls a limited number, not exceeding four, cases of midwifery at a time, the recommendation being that the cases are urgent or difficult. The Institution allows the attendance of midwives, but none are permitted this privilege unless they prove to the Medical officers that they have received a proper education, and are competent to practise.

A very noble act was performed last year by the Profession of Brighton in reference to this charity. A case of a difficult and serious kind having been admitted into the emergency ward, several members of the Medical body other than the officers of the Institution attended to give their advice and assistance. Not content with this important service, they subscribed the sum of £78 9s. 6d. towards the maintenance of those really necessitous women whose labours threaten to be more than usually severe.

The practice of the Institution is extensive and very successful; since the foundation 13,309 women have been attended during delivery. Statistics have, I believe, been kept of these cases, and they would form an important record if they were collated and analysed. I am forbidden from want of space from asking to be allowed to undertake such a task, but I may give the results of the year 1863 in a line or two. In that year 740 labours were attended by the officers of the charity. Of these 728 were cases of natural labour, and 15 were preterm. There were 3 cases of twins, and the males amongst the children born numbered 8 more than the females. Of still-born children there were 29, 14 being males and 15 females; and 27 were children born prematurely. The actual working expenses of the Institution amount to about £400 a-year.

MEDICAL STAFF.

The Medical Staff consists of—R. Tayler, Esq., J. Oldham, Esq., Consulting Surgeons. J. K. Tuke, Esq., J. Dixon, Esq., J. N. Winter, Esq., Honorary Surgeons Accoucheur. W. Seabrook, Esq., is House-Surgeon.

THE PROVIDENT DISPENSARY.

The Brighton Provident Dispensary, established in 1837 as the "Brighton Provident and Self-supporting Dispensary," was one of the earliest of the self-supporting institutions. Its offices are held in Middle-street, and its objects are to enable the labouring classes in the borough of Brighton to ensure to themselves and their families efficient Medical advice and medicine during illness by periodical payments during health. The rules of the institution allow the application of donations and of voluntary subscriptions as well as of the members' fund. We may leave the honorary assistance in order to refer to the sums paid by the *bona fide* members and to the rules of membership. The rules are in brief as follow:—

The members must consist of the labouring classes, whether male or female, and their children, not receiving parish relief, and others who are unable to pay for Medical advice in the usual manner. Any such person wishing to become a member must leave his or her name, age, residence, and occupation with the clerk at the office of the institution, state the name of the Surgeon by whom he or she wishes to be attended, and deposit four weeks' subscription, which is returned in a month if the depositor be not admitted. Every member above twelve years of age must pay one penny, and under that age one halfpenny a-week, excepting in a family consisting of more than two

children, when one penny a-week is considered sufficient for the whole number under twelve years of age. Domestic servants, who may be considered eligible by the committee must pay five shillings a-year, and in not less than half-yearly payments. No person can be admitted as a member who is above 50 years of age without a double payment. The payment of members is made in advance. No one is entitled to the benefits of the institution if in arrear, unless he or she pay a fine of one penny for the arrear of every week. If any member be more than three months in arrear, his or her name is erased from the books, and all moneys already paid are forfeited.

No one actually labouring under sickness is admitted a member, unless he or she can procure two healthy persons above twelve years old to enter at the same time, when all three must pay one year's subscription in advance; any such person unable to procure two others to enter with him or her may, by paying five shillings, be entitled to the privileges of a member for one month, and may afterwards continue a member by paying the usual rate of subscription, if considered eligible by the committee.

Every member may make choice of either of the Medical attendant officers, but if any other Medical attendant be selected than the one appointed to the district in which the member may reside, the member must first ascertain that such other Medical attendant will be willing to attend, and no member may change his or her Medical attendant during illness. If any member should wish to change his or her Medical attendant at any other time, he or she is at liberty to do so upon giving one month's notice thereof to the clerk, provided the Medical attendant proposed to be substituted be willing to give his attendance.

Any married member being pregnant may have the attendance of the Surgeon under whom she may have been enrolled on paying at the office ten shillings one month before her expected confinement, which sum is to be given to the Surgeon. No married member is entitled to the benefit of this rule unless she has been a member at least twelve months, or has paid twelve months' subscription in advance. Infants, during the first month, are included in the mother's membership.

The patients have to find their own bottles, or pay the Surgeon for them. No person is admitted a member unless he or she has had the small-pox, or has been or will consent to be vaccinated.

As regards the results of this effort, I may state that during the year 1863 the amount subscribed by the members reached the sum of £268 3s. 1d., the whole of which was transferred in cash to the Surgeons. All the extra expenses were met by the governors' fund, and left a balance of £4 14s. 3d. in the hands of the treasurer.

The statement of the accounts of the Brighton Self-Supporting Dispensary is satisfactory, and I put it forward in response to many requests made to me from various towns in England that I should offer in these papers every possible information relative to the "self-supporting" movement. The reader must judge for himself whether or not the movement at Brighton is successful. I think it is; but I am bound to add, that amongst the Profession there, at large, it finds little favour.

MEDICAL OFFICERS.

The Medical officers are:—W. District—W. King, Esq., M.D.; E. District—W. Kebbell, Esq., M.D.; N. District—A. W. Seymour, Esq., M.D.; Cliftonville District—B. Phillips, Esq., M.D., consulting Physicians. John P. M. Smith, Esq., 118, Western-road; J. J. Sewell, Esq., 39, Grand Parade; S. Barker, Esq., M.D., 18, Eaton-place; Heckstall Smith, Esq., 30, Albany-villas, Surgeons. J. T. Whatford, Esq., 10, St. James's-street, is Honorary Surgeon-Dentist.

In leaving the Medical charities, I may add that some time since, through the exertions of Mr. Wood, a project was drawn out and nearly completed for the formation of a Dental Hospital. After some consideration it was determined to try and connect the new Institution with the County Hospital, but the endeavour failed. The whole question is now in abeyance, but there is a feeling that it must one day be reopened. In London the Dental Hospitals have proved most successful, and the plan of a separate Institution has been found to be by far the best. In Brighton, where there is ample scope for a Dental Hospital, there can be little doubt that, by a vigorous and united effort, an Institution might be founded that would prove of great service to the poor, and be an excellent school for students of Dentistry. Such an institution, if ably conducted, would, in fact, be recognised by the examining

boards, and the pupils of Dentists resident in Brighton might begin and complete their education there,—an important advantage both to the teacher and the taught.

MEDICAL SOCIETIES OF BRIGHTON.

THE BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

There has been more than one attempt to establish a Medical Reading Society in Brighton. The present Society, called the Medico-Chirurgical, bids fair to become a permanent institution, for it has entered on the eighteenth year of its existence, and has lost nothing of its early vitality. It has a handsome library at the Dispensary, where its meetings are held by the courtesy of the governors of that charity. It possesses a rapidly-increasing collection of books, now numbering more than 2000 volumes, and a beautiful microscope, purchased by subscription among the members during the past year.

The Society numbers from seventy to eighty or more members. It is governed by a president, who is elected annually, two secretaries, and a committee of six besides the past presidents. A meeting is held on the first Thursday evening in every month for the reading of papers or cases and discussions, and every Wednesday evening there is a meeting for the study of microscopic pathological anatomy. An annual dinner is also an institution of the Society, which the members think, with Harvey, is not the least important means of maintaining good-fellowship.

A Natural History Society has grown, in some sort, out of the Medical Society, which contributes a large proportion of its members. The objects of this Society are, however, only indirectly connected with Medical science.

PAROCHIAL MEDICAL PRACTICE.

The parochial districts of Brighton are four in number. The Medical practice is epitomised as follows:—

District.	Medical Officers.	Acreage.	Annual Fee.
Central .	W. Verrall, Esq.	120	£105
Eastern .	G. Geere, Esq.	223	£105
Western .	D. Richardson, Esq.	299	£105
Northern	J. J. Sewell, Esq.	240	£105

THE UNION WORKHOUSE.

The present Workhouse was built in 1820; it is situated on Church Hill, in the western quarter of the town. Connected with the house, and standing a little in the rear, is the Infirmary, and further on an establishment for the reception of lunatics. I have been so criticised for speaking out on the subject of workhouses that I ought to be cautious for my own sake. Nevertheless, I should speak again now, but for the one simple fact that the Workhouse is doomed to come down. In 1820 it probably was a model house; in 1864 it is—I will be very mild—it is unfit for the “Queen of watering-places.” Crowded, squalid, dark, worse than a prison, down with it!—for the sake of Brighton as an advanced town, down with it at once. That is the only remedy.

D. Richardson, Esq., is the Surgeon to the Workhouse and Infirmary.

CLUB PRACTICE.

Club practice in Brighton is on a better footing than in most other towns. The Odd Fellows' order is predominant, but there are various other clubs. The pay to the Medical men for club practice is from 3s. to 4s. per head per annum.

THE CHARITIES OF BRIGHTON.

The charities of Brighton are very extensive. In addition to the Workhouse there are three noble asylums, the Asylum for the Blind, the Asylum for the Deaf and Dumb, and the Orphan Asylum, together with many minor charities most useful in their way.

BRIGHTON ASYLUM FOR THE INSTRUCTION OF THE BLIND.

The Asylum for the Instruction of the Blind is situated in Eastern-road, at a short distance from the Sussex County Hospital. It was instituted in the year 1841, was reconstructed and reopened in 1861. Children of both sexes are admitted, and there is accommodation for sixty inmates, in equal divisions of thirty. Children cannot be admitted until they are 8 years of age; but admitted, they remain until they are provided for. In special cases adults are admitted. The average duration of residence is seven years. At the taking of the census in 1861 there were 19 inmates, 6 of whom were males, and 13 females. In 1853, the number of blind under instruction was 39, of whom 37 (19 males and 18 females) were

boarded in the house. The expenditure was £703 5s. 3d. for the year 1863, or about £81 below the income. The institution is supported by annual subscriptions, donations, and payments on behalf of the children; and for each child from 8 to 12 years of age a sum of not less than £9 per annum has to be paid in advance by quarterly payments. Accommodation is afforded for a limited number of adult blind females in special cases. These have to pay for their board, but the payment is regulated by the circumstances. Every child and adult admitted must be really blind, but must not be deficient in intellect, nor suffering from fits, nor labouring under any infectious disorder. Every inmate must have been vaccinated.

The method of teaching adopted is on Moon's system, and Mr. Moon himself is the teacher.

Mr. Bird, a member of our own Profession, who has been deprived of sight, has raised a very important subject for discussion in reference to the teaching of the blind. He has suggested that in the main the asylum system is not good, and that the home and social system is the best. I, for one, entirely agree with Mr. Bird; but in saying so much, I would add that, in the Asylum at Brighton, the idea of an asylum is as far removed as is possible from the inmates; that music and other amusements are provided for them, and that they are clothed and fed on the most liberal scale.

In addition to the teaching of reading, writing is also taught on the plan invented by Professor Leone Levi, and various useful trades, such as basket-making, chair-mending and knitting: knitted shawls and quilts, exhibiting exquisite workmanship, were shown to me as the productive labour of the blind in this Institution. Dr. Pickford is Physician, H. Penfold, Esq., is Surgeon, and C. Fox., Esq., is Dentist to the Asylum.

THE INSTITUTION FOR THE DEAF AND DUMB.

Unhesitatingly one of the most interesting studies afforded in Brighton to the physiologist and psychologist is to be found in the Deaf and Dumb Asylum, or, as it is officially designated, the “Brighton Institution for the Instruction of Deaf and Dumb Children of the Counties of Sussex, Hampshire, and Kent.” The Institution, situated in the Eastern-road, and very unpretending in appearance, was founded in 1840. It is supported by subscriptions, donations, and the payments of the children taught. Children of both sexes are admitted, and there is accommodation for 110 altogether. There are rarely any vacancies, and the numbers of each sex are usually nearly equal. It is a rule that no child is admitted who is of deficient intellect, is subject to fits, or is under seven or over twelve years of age. A payment, in quarterly instalments, of not less than eight pounds a-year is required for each child.

The sanitary condition of the Institution is most satisfactory, and the girls are taught general housework and sewing; the boys are taught no industrial occupation. But that which is most interesting to the visitor is the marvellous facility with which the pupils converse with each other and with the teachers. Mr. Sleight, the head-master, and one of the most accomplished living scholars in his department, was so good as to have several of the scholars before me, and to show me the method of conversation. The facts have to be seen to be realised. I may epitomise them by saying that the language spoken is all by signs: not merely by talking with the fingers through an alphabet—that is a minor part of the system—but by certain fixed signs for everything, which signs are learned over and over again until they can be communicated as rapidly as in speech. When two men, foreigners, meet each other, not knowing how to converse, they make signs; the sign language of the deaf and dumb is the same mode of communication, elaborated, systematised, and rendered so perfect, that soon the deaf and dumb of all nations will be able to speak as by an universal language. A deaf and dumb German came to Brighton a short time ago, and wanted some important information. He could write nothing in English, and could make no one understand him. At last he was directed to Mr. Sleight—who, by the way, knows nothing of German—and he was immediately at home. The two gentlemen conversed as freely as if the deaf and dumb could hear and speak. In some sentences and expressions the sign language is more rapid than the spoken, and Mr. Sleight communicated a variety of thoughts to the boys by signs quicker than I could speak the same. The communication also seemed to be absolutely unlimited. I asked, through Mr. Sleight, for a planet, as apart from a fixed star, and at once on his board, or rather on the wall, one of the boys answered me. I asked for a comet and a meteor; a sign as rapid as the spoken words was given, and the

words were written. Questions, such as "When did you see your parents last?" and "What is your native place?" were answered quite as rapidly as in common conversation. Even abstract points are capable of being taught, and the acts of writing and reading follow almost as a natural sequence. Lectures delivered in the sign language are as well understood and appreciated as when given orally. It is curious, too, to observe how quickly the language is acquired. In my short visit I could make myself intelligible on many questions of an elementary nature. The Medical man may also learn a valuable lesson in diagnosis in this Institution;—I mean in the diagnosis of intellectual capacity in cases where a child is deaf and dumb. How often we are asked as Professional men whether a certain deaf and dumb child is or is not deficient in intellect? and we know how difficult the question is to answer. At this institution the solution of the answer is reduced to a certainty, simply by the response made to signs in the sign language. Cases pronounced as idiotic have thus been rescued, and the wandering intelligence brought to a state of efficiency as remarkable as it is satisfactory. The pupils in some instances show wonderful abilities; one of them, who unhappily died lately, was a profound mathematician, another gained a medal last year at the South Kensington Museum "for designs," and they all seem to turn out in handicrafts quite as well as other and more favoured scholars. No light has been thrown here on the causes of congenital deafness. Hereditary tendency seems admitted, but intellectual deficiency appears to be an exception in the born deaf and dumb.

Dr. Kebell is Physician to the Institution, T. B. Winter, Esq. and George Lowdell, Esq. are the Surgeons, and E. Eden, Esq. is the dentist.

THE ORPHAN ASYLUM.

The Orphan Asylum for female orphans who have lost both parents is another important charity of Brighton; it is situated near the Hospital. The children admitted are over six and under ten years of age, and must be inhabitants of Brighton or Hove. Messrs. Scott and Humphrey are the Surgeons to the Asylum. The asylum was instituted in the year 1823. The sanitary condition is exceedingly good.

BREAD AND MILK FUND.

I must not close this notice of the charities of Brighton without referring to an useful and unassuming charity, called the bread and milk fund. This charity, which has been in existence for sixteen winters, is in operation every winter from December to April inclusive. The funds of the charity, are expended for supplying tickets to ladies and gentlemen who visit the poor at their own homes. The ticket procures for the bearer of it a pint of new milk and a pennyworth of bread on payment of a halfpenny. Last winter 9,118 tickets were thus distributed, and were of great service in sustaining the healthy life of the poorest inhabitants. A "bread and milk fund" is a charity which through the Medical Profession might be extended with incalculable benefits to every town in the kingdom during the months of winter.

Of the other charities I have only opportunity of noticing, and that, in a word, St. Mary's Hospital—a penitentiary for aged females, with an Infirmary and Hospital for sick children; and the Industrial Schools on the Downs at the Warren Farm, where pauper children are taught trades and useful arts.

SANITARY CONDITION OF BRIGHTON.

The direction of Brighton in sanitary matters is vested in the Sanitary Committee of the Town Council, on which all members of the Medical Profession who are on the Town Council are placed almost as a matter of course. There are inspectors of the meat and vegetable markets, of nuisances, of lodging-houses, and all the usual executive required to carry out the Public Health Act, the provisions of which are gradually being enforced.

The sanitary condition of Brighton, like that of most other large towns of the present day, is progressive; each step having to be determined by experiment before its adoption. The townspeople are keenly sensitive of the importance of the purity of the air and the water, and are conscious that a mistake in the management of the sewage might ruin the prosperity of the town for their generation. Probably to this cause is due the delay in adopting any general system of drainage, rather than to any supineness on the part of the authorities; for the town had been surveyed several times, and plans of drainage had been obtained at great expense from the most eminent engineers, before the present plan, which has been always called the town plan, was determined on.

DRAINAGE.

At present there are about eleven miles of sewers, chiefly carried along the main streets; while about twenty-five miles of the smaller streets have no sewers. It is proposed, as soon as the main outlet is completed, to carry a new main drain up the Steyne, and gradually to extend this into all the streets which can be reached from this point. The same process will be adopted as regards the outfalls east and west of the town, and ultimately every house will be put into communication with one or other of these drains.

The activity which at present prevails in making the main outfall, and the complete scale on which all the work is being done by the contractors, Messrs. Aird, are a guarantee that before long Brighton will enjoy the advantage of being thoroughly drained on the best plan that experience can suggest or money or skill can carry out.

Some account of these drainage works may be of interest. The great engineering difficulty in the drainage of Brighton is the steepness of some of the hills, down which, after any sudden storm, the water pours with great violence. Probably many know well what Brighton rain is when it does come, and some may have witnessed the storms of rain and hail which more rarely occur at longer intervals. Singularly, these tremendous storms generally occur at high tide; and the effects on the basements of the houses lying low are most disastrous. This difficulty has been fairly met by the formation of a large chamber at the land end of the outfall. The flood water now cannot rise to any dangerous height, a wide opening having been arranged to allow of the escape of any such deluge of fresh water on the beach; while under ordinary circumstances the sewage and the usual rainfall will not reach this escape, but will be carried out to sea by the tube to the distance of half a mile from the sea wall.

The different pieces of the tube, each twelve feet long by three feet in diameter, and weighing about two tons, are joined together to the length of about a hundred yards. The joints are made tight with melted lead, the ends of the tube stopped, and the heavy mass rolled gently into the sea down ways which have been laid for it. The tube is then towed out to sea, the mass of about fifty-four tons floating like the sea serpent on the still water, and lowered into its place under the guidance of divers, by whom it is finally pinned down to the chalk. Of course the process does not always succeed, the tube breaking up and the water rushing in unless every part of it is floated at the same time, in which case the process of making all the joints watertight has to be gone over again.

As the beach shelves almost imperceptibly, there will be no difficulty in carrying the tube out any distance, should the sewage return. But, from the experiments which were made before this plan was determined on, there is no reason to apprehend that any of the sewage will ever be thrown back on the shore.

Probably, at no very distant time, means may be found for disinfecting the sewage and detaining the fertilising part, while the sea shall only receive that part which is useless for agricultural purposes. It is believed, in such case, that the present contemplated outfalls will prove useful for surface water. In any case the people of Brighton will have no reason to regret having spent so much money to make their town what it ought to be. To them the pure air and the pure water are everything, and they would regard with complacency any seeming waste of the sewage if they could but get well rid of it, which they seem thoroughly determined to do.

However perfect the sewers and outfalls may be, the internal drainage, the state of the closets and sinks, on which so much depends, is altogether beyond municipal control. These are not likely to be so good, or in such good order, in lodging houses as in private establishments. We all know how negligent servants are in a house where there are only temporary occupants. Unless these domestic necessities receive the same attention in a hired house as in one's own, annoyance and disease are sure to follow; not to acquit Brighton of all blame in the matter, it must be acknowledged that many complaints of bad drainage and its consequences which have found their way into the public journals have had no better foundation than the neglect of servants. The best drains are no good unless the house ends of them are well attended to.

WATER SUPPLY.

The supply of water is unlimited; the water is pure, only containing a small quantity of carbonate of lime in solution. It is intercepted in large chambers in its passage through the chalk, and more chambers could be cut to supply the town,

to whatever size it might increase. The pipes of the constant and intermittent service are laid throughout the town, and it is optional for any one to be connected with either. Within the last four months measures have been taken to make the supply of water to every house in the town compulsory on the landlord. Public baths and wash-houses are in contemplation, but nothing of the kind has as yet been carried out on a large scale.

VENTILATION.

The ventilation of the dwellings of the poor has engaged attention. The Lodging-house Act is strictly enforced in all its details. No new building is allowed to be inhabited until it has been certified as habitable by the inspector. Over-crowding is a danger to which Brighton is particularly liable, not merely as concerns the hotels and better lodging-houses on the eve of a review, but as regards whole districts. In the decennial period of 1851 to 1861, the population had increased from 65,000 to 77,000—speaking in round numbers. The greater part of this increase was in the north district, and this rapid growth was accompanied by an increase in the mortality of the town. More closely examined, this mortality was clearly traced to the rapidly growing over-crowded northern district. This knowledge has not been thrown away on the town authorities, who have adopted every means in their power to prevent the working-class from incurring such a danger in their natural desire to establish themselves without delay in the neighbourhood of their work.

Slaughter-houses still infest the town, and have not been removed even from the main thoroughfare to and from the railway station. But they are all under inspection, and the Town Council, having been foiled for the present in their attempt to establish an *abattoir*, only wait the opportunity to eradicate, one by one, what they had hoped to remove at one sweep.

At the present time the public will be glad to hear that, whatever may be the state of the law on the subject, the organ grinders are kept in good order at Brighton; and if the sufferer be so disposed, which all are not, he can get rid of the whole tribe of Blacks, Germans, Italians, and their instruments by the willing aid of the police, without paying black-mail.

EPIDEMICS.

Brighton is so essentially a part of London that whatever epidemic diseases prevail in the metropolis are nearly certain to appear before long in this town. Convalescents from scarlatina, families panic-stricken by diphtheria or flying from cholera, do as much as lies in them to introduce these diseases into Brighton, over and above what may fall properly to its own share. The large number of schools supply a constant field for the diseases of childhood. In the poor, dirty parts of the town fever prevails at certain times, generally of that kind to which the name typhoid has been particularly applied. Very rarely the form of fever which is called typhus occurs. But there is nothing in the occurrence of these diseases peculiar to Brighton; dirt and poverty produce the same results here as elsewhere.

Curiously enough, ague sometimes occurs in the higher parts of the town on the chalk. These cases, however, are rare, the ague cases in the Hospital being mostly supplied from the basin of the Ouse below Lewes, and the Adeer above Shoreham.

On more than one occasion small pox has crept gradually over the town. Twice within the last fifteen years this has been the case. On the first of these occasions the progress was very gradual from west to east; on the second, this gradual progress was not so distinctly marked. The panic which such an occurrence will occasion among those who are trusted with the lives of other people's children, particularly delicate children, is more easily conceived than described. But Brighton has no reason to complain. To the same popular rumour which spread the fame of her shortcomings through all the country she owes her reputation for her good doings; and, much as the inhabitants may be annoyed at their faults being kept well before the public eye, the town is just as much a gainer as the public in the end.

ETIOLOGY.

Rheumatism is a very common disease at Brighton, young people, servant girls, and mechanics being its chief subjects, as in London. Perhaps the great alternations of temperature have not much to do with the frequency of this form of disease, but the results of these alternations of temperature, and especially of exposure to the cold winds which stream down

the cross streets, appear in the frequency of acute pulmonary affections in children. A cold north wind in March or May is pretty certain to produce cases of pneumonia in infants, whom their nurses have detained at the corners of the streets. On the whole, patients with pulmonary affections will do well to be careful before selecting Brighton as their residence. The class of cases of consumption which get benefit from a winter in Canada do very well in Brighton. But where bronchitis is, as so generally happens, the most prominent symptom of phthisis, a residence in Brighton can scarcely be advised. The advantage of being able to go out more days in the year than at most other places, and the almost entire absence of other consumptive patients, render Brighton a desirable and cheerful residence for those whose comfort depends on their living much in the open air, and who have no resources indoors. But even these must be compelled to stay indoors sometimes day after day during the keen weather which they might have avoided in other winter quarters. The air of Brighton is as inimical to the sufferers from tracheal affections as to those liable to bronchitis.

CLIMATE.

No Medical account of Brighton, however brief, would be complete without some notice of that peculiar condition of the air which has, in fact, made Brighton. This condition is to be found in its highest degree in Kemp Town or on the Downs. It is lost as soon as the passenger emerges on the Weald from the Clayton Tunnel, or descends into the open country beyond Hove. Patients fly to Brighton for protection from hay fever, but most asthmatic patients find that Brighton air is too exciting for them. Many of the cases with which Brighton permanently and entirely disagrees have some tubercular tendency. This, however, must be expressed with much reserve, and as applying rather to adults than to children. For while, on the one hand, adults will do well to try Brighton for a year before establishing themselves permanently, there is scarcely a child, especially a scrofulous child, who may not confidently be sent to Brighton.

The natural historian turns with interest to the Aborigines of any place in his inquiries as to the effect of its climate on human beings. Such a race can scarcely be said to exist in Brighton. The inhabitants of the little fishing village have been almost entirely swallowed up in the flood which has swept, from all quarters of the kingdom and from India, over these dry chalk cliffs, as their former habitations have been by the inroads of the sea. The fishermen are quite a different race to what they used to be, thanks to the kind care which has most actively interfered for their moral and physical benefit. Their occupation will always keep them distinct from those who earn their living on the land, but they are not numerous enough to represent Brighton, as it is now, in any sense of the word. A visitor, who does not dream of the existence of streets upon streets of mechanics near the railway, and whole rows of houses tenanted by the families of the various dependents on the wealthy, is rather puzzled to know where the poor people are. And from a short visit to Brighton, he would carry back the impression that the Aborigines of Brighton were the scores of happy little beings who may be seen, in every extreme of fashion, crowding that Elysium of children, the Western Esplanade.

VALUE OF LIFE.

The Registrar-General's returns on the value of life in England, which have as yet only appeared in these histories, yield the following facts in respect to Brighton:—

Average Annual Mortality in Brighton from Different Causes, to 100 Living, from 1851 to 1860.

	Males.	Females.
All causes	2.499	1.971
Typhus094	.089
Cholera, diarrhœa, and dysentery136	.101
Other zymotic diseases366	.267
Cancer030	.067
Phthisis328	.275
Scrofula, tabes mesenterica, and hydrocephalus127	.090
Disease of brain291	.212
Disease of heart and dropsy150	.137
Disease of lungs282	.210
Diseases of stomach and liver114	.107
Diseases of kidneys050	.017
Violent deaths095	.028
Other causes436	.371

Average Annual Rate of Mortality in Brighton from all Causes, at Different Ages, to 100 Living, during the Ten Years 1851-60.

	Males.	Females.
All ages	2·499	1·971
Under five	8·098	6·998
Five to ten	·871	·908
Ten to fifteen	·419	·457
Fifteen to twenty	·612	·519
Twenty to twenty-five	·989	·698
Twenty-five to thirty-five	1·160	·919
Thirty-five to forty-five	1·579	1·224
Forty-five to fifty-five	2·120	1·583
Fifty-five to sixty-five	3·722	2·709
Sixty-five to seventy-five	6·823	5·753
Seventy-five to eighty-five	14·639	13·454
Eighty-five and upwards	37·917	28·413

SOCIAL FACTS.

The beer-shops and licensed houses are very numerous. Of the former there are in the Parliamentary borough 240, and of the latter 270.

Prostitution is rife. There are reported to Government as prostitutes 25 girls under 16 years of age, and 330 above that age. These are professionals, who make no secret of their practices. In addition there are an equal number of women known under the technical name of "slys," and who are, in fact, prostitutes. To both these classes must be added a fluctuating extraneous population of the same character, the numbers of which it is impossible to estimate.

Crime is gradually on the decrease in the town. There are about 80 known thieves, from 50 to 60 receivers, from 150 to 200 vagrants, and over 190 suspected persons.

MEDICAL BIOGRAPHY OF BRIGHTON.

Brighton has as yet produced no great scientific man in the Medical history of her past; nor, in truth, has her Medical representation ever been so good as it is at this present.

Dr. Russell, who founded the town as a watering place, has been already referred to, and full credit has, I hope, been given to him. He was born at Lewes, in 1687, his father being a Surgeon there, and he ran away with, and married, the daughter of a Mr. Kempe. Russell visited Leyden, and studied under Boerhaave. On his return to England he first lived at South Malling, and then moved to Brightelmston, where he practised for eight or nine years. He died in London in 1759, and was buried at South Malling. The Medical visitor who would see his likeness will find it in the Telemachus-room of the Ship Inn.

Dr. Rhellan, who followed Dr. Russell, practised for some years, and won a fair fame in Brighton. Rhellan was a scholarly man, and in a book on the natural history of the town, published in 1650, he evinced great skill and care as a writer. I know of no other remarkable incident in his career.

Dr. Axsiter, of whom, also, no biographical memoir remains, was locally known as the founder of the first thorough system of baths in Brighton. These were erected in the year 1768, "at the pool between the Stein and the sea."

CONCLUSION.

It has been impossible in the above report to condense into reasonable space all that may be said of the Medical History of Brighton. I have endeavoured to select those points which are of most interest to Medical men, and must leave the rest. Of the town as a residence for invalids, sufficient has been stated to enable any Practitioner to form his own judgment without his receiving any bias or impression from me; and I will merely say, further, that there are in Brighton two special advantages which deserve to be named. First, for boys who, during their education, may require a seaside residence, there is an admirably-conducted College, in which scientific teaching is blended with classical teaching, and in which chemistry is practically taught by one of our most able teachers, Dr. Wood; secondly, that at what is called the German Spa, the various medicinal waters of Germany are all manufactured, and that a more instructive day could not be passed by the scientific Medical observer, than one spent in learning how, by steam-power and human ingenuity, nature may be imitated so perfectly that her products in the way of medicinal waters can do no more than rank equally with those artificially made at the "Queen of English watering-places," "London-on-the-Sea."

PROVINCIAL CORRESPONDENCE.

BIRMINGHAM.

POISONING BY THE SEEDS OF THE CURCAS PURGANS (PHYSIC NUTS—JATROPHA NUTS).

(From our Special Correspondent.)

By order of the London and North-Western Railway Company an auctioneer was engaged for several days in selling by auction, at the railway station, Birmingham, a large quantity of unclaimed goods accumulated during the past twelve months or more. Amongst these unclaimed goods were three or four sacks of jatropha nuts, sweet and pleasant to the taste, but poisonous. They are useful in some branches of industry—lamp-oil is extracted from them; when boiled with oxide of iron they form a varnish, and they are frequently imported to this country as veterinary medicine—so constituting, at our sea-port towns, a not unfrequent source of poisoning. The oil, too, is sold occasionally at drug sales as what is called croton-oil. These nuts were allowed to lie scattered about the floor, and some boys employed adjoining the place at which the sale was conducted obtained access to them, and carried quantities of them home in their pockets at dinner-time. These boys ate the nuts themselves, and treated their friends with them, the consequence being that above thirty persons were taken so ill as to require to be brought to the General Hospital, where some of them arrived in an alarming and dangerous condition. The scene in the waiting-room, as so many persons suffering from poison presented themselves for treatment, may more easily be imagined than described.

The curcas purgans (Adanson) jatropha curcas (Linnæus) or English physic nut, belongs to the Euphorbiaceæ, and is met with on the West Indian Islands, the Brazils, Ceylon, and the Coromandel coast. The fruit is a three-celled capsule, containing one seed in each cell, and is of about the size of a walnut. The seeds are not unlike the seeds of the castor-oil plant in shape, but are chocolate brown or almost black in colour, and marked with numerous minute cracks, which communicate a sense of roughness to the touch. They are oval, about eight lines long, flat on one side, convex on the other, and the two sides present a slight longitudinal prominence; the kernels are covered with a fine white pellicle, are sweetish and pleasant to the taste, and it appears pretty certain from the observations of those who have studied the action of the drug, that if the cotyledon leaves dividing the kernel into two parts be extracted, the albumen has little activity. This can be very readily done, and Mr. Hamilton in a paper on the subject in the *Pharmaceutical Journal* for September, 1849, says,—“The seeds possess when recent a strongly emetico-cathartic quality, insomuch that the new comer who, tempted by the agreeable flavour of the kernel, imprudently eats even so much as a single seed, is usually attacked with a severe vomiting and purging within a few minutes after. This effect may be counteracted, as far as the emetic operation is concerned, as an American captain whom I met in the West Indies informed me, by splitting the kernels in two, and carefully removing the cotyledon leaves, in which the emetic principle appears wholly to reside. Thus prepared he constantly carried them about with him, and found four or five eaten in the morning relieve his bowels without sickness, pain, or griping.” I made the following experiments, which go far to prove the correctness of the above statement:—I gave a dog eight seeds entire, and another dog eight seeds with the cotyledon leaves carefully removed. The former was sick, and vomited in an hour and ten minutes; the latter being purged, without vomiting, about the same time. After the lapse of several hours I gave to the first dog eight seeds with the cotyledon leaves removed, and to the second the cotyledon leaves only of eight seeds, and the result was exactly the converse of the former experiment. Although both dogs after having the leaves were very sick, and seemed to vomit the greater part of the poison almost in the state in which it was given them, the dog that took the eight seeds entire was much the more severely affected as to sickness. It is not a little remarkable that in a natural family numbering so many plants dangerous to life several should be found having starch in very large quantity, which when thoroughly deprived of poisonous matters by various processes becomes excellent material for food. I might instance the jatropha manihot, which is cultivated for food over the entire tropical world, and has a large root sometimes weighing thirty pounds, containing intensely

poisonous juice, but by rasping, bruising, and washing the roots, and heating them upon iron plates the delicious cassava is obtained, and the feculent powder which floats off during the washing is the universally known tapioca. The oil of the curcas purgans seed is met with as an adulteration communicating drastic and emetic qualities to the oil of the argemone Mexicana, a bland purgative possessing anodyne and narcotic qualities belonging to the Papaveraceæ, and met with in the Antilles; when pure it purges in the dose of 12 to 15 drops, and is analogous in its action to croton oil, though less powerful. It differs from castor and croton oils in its slight solubility in alcohol. Dr. Christison in his *Dispensatory*, page 794, says that one sample expressed from Barbadoes seeds acted precisely like castor oil in the dose of 10, 15, or 20 drops, but that another from Jamaica seeds sometimes caused the same severe sickness and watery evacuations as croton oil, and at other times was inert in the dose of 30 drops. There is room for very little doubt that the investigation of the oils belonging to this natural family is eminently entitled to the attention of those wishing to cultivate the capabilities of our West Indian colonies, and it is very certain that should any one be fortunate enough to discover an oil belonging to them which either simply, or by some superior method of preparation should possess all the admirable qualities of castor oil without its unpleasantness, a large fortune would be his reward.

In the *London Medical Gazette* for July, 1848, Mr. (now Dr.) Letheby, Lecturer on Chemistry at the London Hospital, relates a case of "poisoning by the seeds of the *Jatropha curcus*, or physic nut," which presents many points of analogy with the cases treated in Birmingham:—A labourer in the London Docks ate the kernels of five nuts. In about a quarter of an hour he suffered from a burning sensation in his mouth and throat, with pain and distension of his abdomen; violent sickness supervened in a few minutes, and within an hour he vomited five times and was severely purged; he was hot and feverish, covered with perspiration, became extremely weak, giddy, and ultimately insensible. He recovered, and applied for treatment at the Hospital, suffering from the symptoms above mentioned, and was relieved by an opiate and a cordial so far as to be able to return home.

On June 9, 1864, no less than thirty-three persons were admitted almost at the same time to the General Hospital, under the care of Dr. Russell, suffering from the poison above described; and, although many of them had already vomited, it was thought advisable to treat them all in the first instance with an emetic of sulphate of zinc and ipecacuanha, although not a few of them, as will be seen in the detailed cases, required other after-treatment, owing to the extreme and, in some cases, alarming depression from which they suffered.

It will be observed from an attentive perusal of the cases that some of the patients, even young boys, ate as many as fifty of the nuts, while others ate only three or four; that the symptoms appeared in some cases as early as ten minutes, and in others not until two or two and a-half hours had elapsed after the taking of the poison; and that the main symptoms taken in their proper sequence were, pain and burning in the throat and fauces; pain and distension of the abdomen; giddiness, vomiting, drowsiness, and, after an interval, purging, the stools being copious, mucous, and not unlike the well-known rice-water stools. In some instances the depression was very great, in many there was dysuria; the after effects were invariably thirst, fever, hot skin, with quickened pulse, and the state of the pupil was either normal or, in the opinion of several who observed the cases, was markedly dilated in those who had taken a large quantity of the poison. The drowsiness was so marked—many of the patients having fallen asleep in cabs on their way to the Hospital, and many dropping off to sleep repeatedly in the waiting-room—that, were it not for the fact that they could all be immediately aroused, I should be inclined to put it down to a narcotic influence; but remembering the extreme depression of the vascular system in the severe cases, I am disposed to think that it was no more than the sleepiness resulting from the excessive prostration, almost approaching syncope. One of those outside was so prostrated that he fainted and fell, after being sick and violently purged; most of the patients vomited without any emetic; all, without exception, had an emetic given them on their arrival at the Hospital, and almost all were severely purged. They all, without exception, made excellent recoveries.

Case 1.—T. M., aged 14, ate forty to fifty of the nuts at 2.30 p.m., and in half an hour afterwards complained of dryness and pain in the throat, giddiness, and pain, with a sensa-

tion of heat in the bowels. He vomited several times before his admission, at 4.15 p.m., when he was given an emetic, which acted freely again, and he was purged three or four times. During the evening he was in a state of great prostration, with frequent and weak pulse, and required the application of warmth to the extremities and the administration of weak brandy-and-water. The next day, June 10, in the morning, he was very feverish, with a pulse of 120, drowsy, complained of slight pains in the bowels, and difficulty in making water. On June 11, with the exception of slight feverishness, he was almost in his normal state of health, and was judged sufficiently recovered to be able to leave the Hospital.

Case 2.—T. W., aged 14, took from thirty to forty of the nuts at 1 p.m. In half an hour afterwards he felt sore-throat, sickness, giddiness, pain in the bowels, and immediately vomited. States that he perceived portions of the nuts in the vomited matter. He was drowsy and very thirsty, and half an hour after admission (4.15 p.m.) was seized with severe cramps and pains in the legs and feet. In an hour and a half after this he had profuse mucous diarrhoea; after which, on being summoned to him, he became almost pulseless, dropping off to sleep every half minute, although easily aroused. The same treatment was pursued, with very much the same results as in the case above noted.

Case 3.—G. R., aged 12, ate two handfuls of the nuts at 2 p.m., and in about two hours after suffered from dryness of the throat, sickness, pain in the stomach, vomiting, and cramps in the feet and hands. On June 10, in the morning, he was very hot and feverish; had copious diarrhoea, with watery stools, after which he felt much relieved, and was enabled to leave the Hospital.

Case 4.—H. C., aged 16, ate twenty-four of the nuts, and in an hour and a-half suffered from burning in the throat, giddiness, and pain in the stomach very severe. He did not vomit till treated with an emetic at the Hospital, nor had he any purging. On June 10 he complained of giddiness and pain on raising his head, and of pain in the stomach with pyrosis, but rapidly recovered with appropriate simple treatment.

Case 5.—C. W., aged 15, ate twenty nuts at 2 p.m., and was seized in an hour with giddiness, sickness, dryness, and burning of the throat, and vomited copiously, after which he became very drowsy, hot, and feverish, but recovered the next day without any bad symptoms.

Case 6.—C. W., aged 15, ate more than two handfuls, and in an hour afterwards complained of his throat, thirst, and sickness, which ended in his vomiting freely. During the evening he was seized with violent cramps, dysuria, and severe purging, with tenesmus. On June 10 he was quite recovered, with the exception of slight fever, as indicated by rapid pulse, hot skin, and dry tongue.

Case 7.—T. F., aged 14, took one handful, and the symptoms of dryness in the throat, vomiting, giddiness, and palpitation, followed by great depression of the vascular system, made their appearance in an hour and a-half.

Case 8.—T. H., aged 12, ate a dozen. Symptoms as in the above case, with the addition that he was severely purged, and complained of slight pain in the bowels.

Case 9.—T. O., aged 15, took a dozen, and was attacked in an hour by the throat symptoms, vomiting, drowsiness, and dysuria. No purging.

Case 10.—T. M., aged 18, took a dozen. Symptoms came on in three-quarters of an hour. Throat affected, vomiting, giddiness. Purged three or four times very copiously; thirst and slight cramps.

Case 11.—W. F., aged 12, took eighteen. Symptoms came on in two hours and a-half, consisting of dryness and burning of the throat, pain and distension of the abdomen, vomiting, purging, and dysuria. The same evening he was perfectly well, and begged to be allowed to go home.

Case 12.—T. H., aged 14, took a dozen. In an hour and a-half felt pain in the throat and in the belly; took salt and water at home, which caused him to vomit freely; was very drowsy on his arrival at the Hospital; no remarkable symptoms.

Case 13.—W. H., aged 16, took a dozen. In one hour afterwards his throat became hot and dry; he was very giddy and sick, vomiting freely, after which his bowels were moved very copiously upwards of a dozen times, his stools being mucous and watery; he was very drowsy and prostrated, and suffered from most severe cramps in the arms and legs. The

hypercatharsis and cramps, for what reason I cannot tell, were more severe in this than in any of the other cases.

Case 14.—G. R., aged 13, took five of the nuts, and in about a quarter of an hour suffered from thirst, pain in the stomach, vomiting, purging, drowsiness, and slight cramps.

Case 15.—J. M., aged 13, took ten, and was affected in ten minutes afterwards with giddiness, pain in throat and stomach, and inclination to drowsiness; in half an hour he vomited several times, but was not purged; he was hot and feverish during the evening, but slept soundly during the night, and was quite well next morning.

I have now related about half of the more severe and interesting of the cases, and I shall be more than repaid if this letter will contribute any additional information on the subject of poisoning by *Jatropha* nuts, and more especially if it should be fortunate enough to draw the attention of any one capable of dealing with the subject to the fact that it is one of the greatest desiderata in medicine that we should obtain an oil from the *Euphorbiaceæ* possessing all the so well known, admirable, and unequalled qualities of castor oil without the disadvantages of its taste, odour, and bulk.

GENERAL CORRESPONDENCE.

THE ALTERATION IN THE PAY OF THE INDIAN ARMY MEDICAL SERVICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am very much afraid you have been rather premature in congratulating the Profession, in your last impression, upon the supposed advantageous provisions of the new scale of pay lately adopted for the Army Medical Service in India. If you carefully examine the same, it will be seen that an increase of pay is conceded to Surgeons-Major and Assistant-Surgeons, and that the Surgeons will be material and serious losers; in fact, the scheme has been so devised that the saving to the Indian Government finance by this curtailment of the pay of Surgeons will go a long distance, if it does not entirely cover the additional expense incidental to the increase of pay of the other grades! An ingenious way of carrying out that old, but not over-honest principle of "robbing Peter to pay Paul!" May I beg to be informed upon what principle of honesty or propriety is the pay of Surgeons to be thus reduced? What crime have they been guilty of deserving such curtailment?

Is it reputable in any government to resort to such discreditable shifts in thus treating the members of a liberal profession, whose services the State cannot dispense with, but whose prospects and interests it has always been the practice of narrow-minded officials, who watch with a most jealous care their own salaries, to repress and tamper with?

Will you kindly ventilate this important and vital subject? London, June 13. I am, &c. AN INDIAN SURGEON.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—An additional ordinary meeting of the Fellows of the Society will be held on Tuesday, July 5, at 8 p.m., to receive the report of the Scientific Committee on the uses and effects of chloroform.

THE LEVEE.—At the levee, held by command of the Queen, by the Prince of Wales on Wednesday, June 22, the following members of the Medical Profession were presented:—Bird, Mr. Peter Hinckes, Assistant-Surgeon Volunteers, by Lieutenant-Colonel Wood. Bryson, Dr., R.N., on appointment as Director-General of the Medical Department by his Grace the Duke of Somerset, K.G. Christie, Surgeon Alexander, late Bengal Medical Service, by Major-General Christie. Down, Dr. Langdon, M.D., by the Right Hon. Earl Granville. Mason, Dr. Thomas E., by Lieutenant-Colonel Harcourt. Martin, Mr. William, by the Secretary of State for India. Reed, Assistant-Surgeon Baynes, 12th Regiment, by the Adjutant-General. Skey, Mr., President of the Royal College of Surgeons of England, by Lord de Tabley. Stern, Dr. Moritz, senior resident Medical Officer, Government Hospital, Jamaica, by the Right Hon. Edward Cardwell. Young, Dr. James, R.N., Her Majesty's ship *Racoon*, by Captain Count Gleichen. The following attended the levee: Sir Henry Holland, Physician in Ordinary to the Queen. Doctors.—Walter D. Jones, M'Sheehy, Hinxman, Acland, Michael Faraday, J. H. Paul, Breslin, Billing, and Ashley. Deputy-Inspector-General Graves, Mr. Propert, etc., etc.

OBITUARY.

PROFESSOR MILLER.

(From our own Correspondent.)

EDINBURGH.

THE Medical Profession in this country, and wherever the noble art of Surgery is practised and respected, will read with sorrow the announcement of the death of James Miller. One who for the long period of twenty-two years taught directly from a professor's chair, and through his writings indirectly, hundreds of young men, must have many professional children to lament his early death.

Professor Miller became ill on May 19, and died June 19. He had for several weeks complained of symptoms which he thought were caused by derangement of the liver or the heart, or both; he became much depressed, and had gloomy forebodings. His frame, apparently so stalwart, had already been tried by frequent serious illnesses, and at last he sank into stupor, the result of exhaustion. He was conscious for a few hours before death, and bade farewell to his family and servants. About a year ago he had ptosis of the left eye. A post-mortem investigation threw no light on the symptoms of his malady. He was only fifty-two years of age, and until the last few weeks he seemed to have every appearance of health.

Professor James Miller was the son of the late minister of Monikie, near Dundee. After receiving the usual home education, he went to St. Andrew's University, and thence to Edinburgh, where he resided for fifteen years a pupil of Liston. For five years before Liston went to London Miller assisted him in private practice, was introduced to his patients, and employed by most of them after the great Surgeon's departure.

In 1842 he succeeded Sir Charles Bell as Professor of Surgery in the University, and since then prospered as a teacher and practitioner. He possessed nearly every element of success, a fine position attained at thirty, a large connexion of friends, a handsome person and captivating manner, with "the ease, which marks security to please," and a great faculty for watching the progress of events, and "grasping the skirts of happy chance," till at last he became one of the most influential citizens of Edinburgh, and his name was familiar to every one, rich and poor, in Scotland.

At the disruption (the technical term for the secession of many members of the Presbyterian Church), Miller joined the party who call themselves the "Free Kirk," and has ever been its keen supporter. His fearless and ready eloquence will be sorely missed by that most militant of churches here on earth. But he was on good terms with all denominations, and although some may wonder at a Medical Practitioner becoming so prominent in purely church matters, the wonder must arise from ignorance of Scotland, especially Edinburgh, where appointments to public institutions, prosperity, and popularity in any vocation, are so largely influenced by the clergy and their lay officers. It is, therefore, only natural that a man of any ambition desires to be one of the most influential party. Of course Professor Miller's adherence to the Free Church was quite unselfish, and it gave him many opportunities for usefulness in public and private.

As a Practitioner he was greatly beloved by his patients, and though practising chiefly as a Physician, when a surgical case presented itself he readily undertook it. As a lithotomist his style greatly resembled Ferguson's, the long, shapely finger soon entering the bladder, and the forceps, with Listonian dexterity, rapidly removing the stone.

From time to time he published memoirs on Surgical subjects. His Text-book has gone through several editions, and the article, "Surgery," in the "Encyclopædia Britannica," has been much admired.

But of late years he devoted his pen more to social subjects, written in a peculiarly diffuse, but pleasant style, in which "apt alliteration's artful aid" was often called in to assist. He was fond of such titles as "Labour Lightened, not Lost," or, "Design in Disease." His favourite subject was abstinence from alcoholic stimulants, the evils of which he must have been deeply impressed with in early life, and he wrote and spoke eloquently against indulgence in them. His oratory was like his writing, diffuse but telling; he had a great flow of words, a great voice, and appropriate action. Constant practice enabled him to speak on any subject for any length of time. His lectures were full of anecdote, and very popular with the students. After he had served the usual length of

time as Surgeon to the Infirmary, the directors allowed him wards *ex officio* for the illustration of his lectures, a privilege his predecessors had not enjoyed. He was appointed lately Surgeon to the Chalmers Hospital, a beautiful little building opposite the Braid Hills, and was also Surgeon to the Sick Children's Hospital, a pretty little nursery where maiden ladies play at being mammas. He filled many other important positions, and no public meeting, especially with religious tendency, was complete without him.

Professor Miller was a Fellow of the Royal Society and most others, but seldom appeared at any of them, being in that respect no exception to the rule in Edinburgh.

His great charm was his geniality and kind manner. In this world where a stranger is too often entertained by a cold shoulder garnished by a few bows, such exceptional characteristics are not forgotten; and though it went very likely no further, Miller's hearty shake of the hand was quite exhilarating to the new-comer. It will be long, I trust, ere the citizens of Edinburgh for whom he worked so hard will forget his cheery voice, merry laugh, and earnest counsels, his handsome fearless face, with its sharply-cut features and lips ever trembling in a smile, his intellectual head, with the fair flowing locks brushed back off the forehead. Fifty-two years of this hard world seemed to have made but little impression on his strongly-built figure. On June 22 his colleagues, who have scarce had time to wipe away their tears for Ferrier, will lay him in the Grange Cemetery, commonly called the Saints' Rest, for there are buried many Scotch worthies, Chalmers, Agnew, Hugh Miller, and many others.

The name of James Miller may well be added to theirs: like them he led a good and useful life; why should we grudge his joining the great nations of the dead?

LEGAL INTELLIGENCE.

OLDBURY COUNTY COURT.

MANLEY *v.* HOOPER.

THIS was an action brought by Mr. John Manley, a Surgeon of West Bromwich, against Mr. Edwin Hooper, the Coroner for the southern division of the county of Stafford.

Mr. Fitter, solicitor, Birmingham, appeared for Mr. Manley; and Mr. Motteram, barrister, of the Oxford Circuit, for Mr. Hooper.

Mr. Fitter, in opening the case, said that the action was one of debt upon a statute, for the recovery of one guinea, being the fee claimed by Mr. Manley for attending an inquest, on the body of a woman of the name of Elizabeth Collins, in pursuance of a summons issued by the Coroner, and the case was of considerable importance to the Medical Profession, because it raised the question whether the Coroner by issuing a summons, instead of an order of a special kind as provided by the Act of Parliament governing such cases, could deprive a Medical witness of his fee of one guinea to which he would be entitled, *quâ* a Medical witness, and remunerate him by payment of 2s. 6d., the remuneration allowed to non-Medical witnesses. Mr. Fitter called his Honour's attention to some of the facts attending the inquest on the body of the woman, the reports of which appeared in this paper in the month of February last, and pointed out that there was in the first instance an imputation of negligence by the Coroner against the plaintiff or his assistant, accompanied by strong personal observations, and that finally the defendant summoned the plaintiff to give evidence at the adjourned inquest. The plaintiff attended in pursuance of the summons, and demanded the statutory fee of one guinea, which defendant refused to pay, and tendered him 2s. 6d., which the plaintiff refused to receive. Mr. Fitter referred to the Acts of Parliament on the question at some length, and contended that on the proper construction of them the plaintiff was entitled to a guinea.

The plaintiff having deposed to the necessary facts in support of his case,

Mr. Motteram contended at some length that the plaintiff was summoned by the defendant as a non-Medical witness, and was only entitled to 2s. 6d., and examined the defendant as to the circumstances under which the plaintiff was summoned, and the nature of the evidence he gave on the occasion.

His Honour summed up at considerable length, observing in strong terms upon the fact the plaintiff was summoned either to explain away an alleged charge of negligence on his part or that of his assistant, for which there did not appear to be any foundation, or to give Medical testimony as to the

cause of death. As to the former his Honour observed that the coroner had no jurisdiction to inquire into the mode adopted by him, and, for the credit of the coroner, he would take it that he summoned the plaintiff to give evidence as a Medical witness as to the cause of death, and he would in the latter case be entitled to his guinea. His Honour gave plaintiff a verdict for the amount claimed, with costs.—*Birmingham Daily Gazette.*

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held on Friday, June 17, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Josiah Court, Guy's Hospital; John Foot Churchill, Croydon; Robert Leamon Bowles, Folkestone; Charles St. John, 6, Foulis-terrace, Onslow-square; William Clunie Wise, M.D. St. Andrews, Plumstead; Frederick Charles Dodsworth, Turnham-green; George Frederick Cooper, Reading; and Charles Hammond, Southampton.

At the same meeting, the following gentlemen were reported by the Examiners to have passed the Primary Professional Examination:—

Thos. Cuddeford, St. Bartholomew's Hospital; James Taylor, Glasgow; and James Henry Worsley, Bury, Lancashire.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, June 16, 1864:—

Benjamin Jones, Llangefin, Anglesea; Charles Moss, St. Helena; Charles Franklin, Maida hill; Edmund Woods Hawkins, Commercial-road; Ebenezer Snell, Plymouth; Chauncey Puzey, Surrey-square, S.; Charles Edward Martin Shaw, York-street, Portman-square; Henry Dawson, Church-road, Islington.

The following gentlemen, also on the same day, passed their First Examination:—

Frederick Barham Nunnely, University College; Henry Weeks, Guy's Hospital; Richard B. Nowell, Guy's Hospital; George Christopher Tayler, St. Bartholomew's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BUTCHER, HENRY O. F., M.R.C.S. Eng., has been appointed House-Surgeon to the Clayton Hospital and Wakefield General Dispensary.

HAWKEN, C. ST. AUBYN, M.R.C.S. Eng., has been appointed Resident House-Surgeon to Westminster Hospital.

PEARSE, G. E. L., L.S.A., has been appointed Resident House-Physician to Westminster Hospital.

DEATHS.

BALY, GEORGE, M.R.C.S. Eng., Staff Assistant-Surgeon to H.M. Forces, at Warwick, on June 13, aged 34.

DAVIS, JOHN, M.D. Edin., Surgeon R.N., at 34, Wilson-street, Portland-square, Bristol, on June 17, aged 73.

DE RENZIS, DR., Professor of Clinical Surgery at the University of Naples, and the Author of the most complete work on Surgery in the Italian language, died last month, having been seized with apoplexy while visiting a patient.

FREEMAN, T. D., Surgeon, formerly of Leigh, Worcestershire, on May 27, aged 69.

GLASCOTT, DR. JOHN, at Constantinople, on June 2.

HILL, JAMES P., M.R.C.S. Eng., at the District Hospital, Daylesford, Victoria, Australia, on April 8, aged 34.

MACDOWALL, ALEXANDER A., M.D. Glasg., at Helensburgh, Dumbartonshire, on June 10.

MILLER, JAMES, F.R.C.S. Eng., of 29, Charlotte-square, Edinburgh, at Corstorphine, on June 17, aged 52.

FRANCE, J. CONNELL, M.R.C.S. Eng., at Richmond, late of Maidstone, on June 14, aged 76.

ST. BARTHOLOMEW'S HOSPITAL.—On the retirement of Mr. Skey from the office of Surgeon to the Hospital, in January last, a subscription list was opened for the purpose of presenting him with some token of the regard and esteem in which he is held by his friends and old pupils. The sum raised, which amounted to about £250, has been expended in the purchase of a handsome silver centre-piece and two candelabra, and these will be presented to Mr. Skey, in the great hall of the Hospital, on Thursday, the 30th instant, at 3 p.m.

CONVERSAZIONE AT THE ROYAL COLLEGE OF PHYSICIANS.—The President and Fellows gave their annual evening entertainment at the College on Saturday, June 18. An unusual number of non-Professional and Professional guests attended, and a large collection of scientific novelties was exhibited for their amusement. The interest of the evening was also considerably heightened by the presence of their Royal Highnesses the Prince of Wales and Prince Louis of Hesse, who arrived punctually at the hour of invitation—9 o'clock—and remained until about 10. Their Royal Highnesses were conducted round the rooms by Dr. Watson, the President, and examined with evident interest and curiosity everything displayed, from Caxton's Recuyell of the Historyes of Troye, which it will be remembered was discovered accidentally a short time ago in the College Library, down to the new German harpoon for extracting muscular fibre from the human subject when in search of the *trichina spiralis*, exhibited by Dr. J. Ogle. Without giving a catalogue of the objects shown, we may notice the beautiful microscopic preparations of the liver, kidney, and medulla oblongata; and the exhibition of the circulation in the web of the frog's foot in a state of inflammation by Professor Lionel Beale; Dr. Thudichum's successful demonstration of living trichinæ in several stages of development, and of a new cysticercus from the sheep; and Mr. E. Hart's new ophthalmoscope, showing the deep structures of the eye-ball without the necessity of darkening the room. Dr. Ogle also exhibited, in addition to the above-mentioned harpoon, some exceedingly good photographs of the disease termed "Progressive Muscular Atrophy," and several other pathological specimens and drawings. He also contributed a specimen of the snake-stone from Ceylon, used by the natives to prevent the effects of the bites of poisonous snakes. He has found that a microscopical examination of this supposed stone proves it to be in reality bone. Amongst the visitors were Lord Chelmsford, Lord Wensleydale, Lord Belper, the Lords Justices Erle, Turner, Knight Bruce, the President of the Royal Society, the President of the College of Surgeons, and many other celebrities.

ROYAL COLLEGE OF SURGEONS.—The official circulars, giving the names of the eligible Fellows who are candidates for seats in the Council at the ensuing election on the 7th proximo, have now been sent to all the electors, and the following analysis of the same may interest our readers. Mr. Thomas Turner, of Manchester, the senior of the new candidates, who offers himself as a provincial representative, is nominated entirely by provincial Fellows—viz., Messrs. Southam, Bates, Windsor, Mellor, Lund, and Boutflower, all distinguished townsmen of the candidate. Mr. Andrew Melville McWhinnie, of Serjeants' Inn, Temple, adopts the ingenious plan of obtaining three provincial and three metropolitan Fellows to nominate him—viz., Messrs. Green, of Bristol, Mayo, of Winchester, Dayman, of Southampton, Bishop, an ex-Member of the Council, Holden, of St. Bartholomew's, and Harrison, of Lambeth. The third and fourth candidates, Mr. Thomas Blizard Curling, of Grosvenor-street, and Mr. Frederick Le Gros Clark, of St. Thomas's street, may be considered the representatives of the metropolitan Hospitals, as they are nominated, the former, by Mr. Paget, of St. Bartholomew's, Mr. Hewett, of St. George's, Mr. Eriehsen, of the University, and Mr. Critchett (his colleague) of the London Hospitals, and two well-known provincial celebrities, Mr. Symonds, of Oxford, and Mr. Page, of Carlisle. Mr. Clarke is altogether supported by metropolitan Hospital Surgeons—viz., Mr. Simon, his colleague at St. Thomas's, Mr. Birkett, of Guy's, Mr. Coote, of St. Bartholomew's, Mr. Eriehsen, of University College, Mr. Moore, of the Middlesex, and Mr. Carr Jackson, of the North London Hospitals. Messrs. Gulliver and Hancock, the retiring members of the Council, offer themselves for re-election, and altogether the contest will, it is said, be a very spirited affair.

A NEW PHARMACOPŒIA FOR INDIA.—The authorities at the India Office have, we learn, recently had under consideration the publication of a Pharmacopœia for India, to be issued under the supervision of a special committee of Indian Medical officers of experience. Such a work, if it embraces, as it should, the more valuable Medical products of the East, would be a great boon not only to the European portion of the Profession in India, but also, indeed, principally to the native students and graduates of the great Presidency Colleges, and to the Medical subordinates generally. Such a work is a desideratum, and we shall rejoice to see it carried out. We

have heard the name of Assistant-Surgeon Edward J. Waring, of the Madras army, author of a "Manual of Practical Therapeutics," and other works on *Materia Medica*, mentioned as the probable editor. It could not be entrusted to better hands. We understand that the scheme has already been sent to India for the sanction and opinion of the Governor-General.

THE Birmingham people have an extraordinary liking for pigs, no matter how badly provided they are as regards the required space for a sty for that not very clean quadruped. If they have not got a sty, why then piggy is kindly taken in as one of the family, and has a happy time of it in the cellar. Sometimes, and I can assert it with truth, the pig has a sty erected in some out-of-the-way corner in the house. The working classes, too, have a fancy for rabbits, which they keep in the cellars, besides having two score of fowls in the same place. Sooner than lose their "pets" they will, no doubt unconsciously and labouring under erroneous impressions, have their children's health and that of others too sadly impaired from the abominable stench proceeding from a pigsty, a rabbit pen, or fowl roost. Such a practice cannot be too strongly condemned, as both an abomination and a disgrace.—*Birmingham Paper*.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Mr. F. A. Bulley.—The paper has been received.

A Physician and Surgeon.—If you are not practising *bonâ fide* as a Physician, don't.

Amicus, Exeter.—The first number of this journal appeared on the 28th of September, 1839. A complete set is scarce. The Library of the College of Surgeons possesses one.

Mr. Wm. Prowse is, we believe, the originator of the Griffin Testimonial Fund. He will be happy to act as Treasurer and Secretary to the Fund for the provinces.

The letters of Professor Oswald Home Bell and "Beta" shall appear next week.

Rahere, Fowey, Cornwall.—To Abernethy is due the sole honour of establishing the Anatomical School of St. Bartholomew's. The first Hospital for sick persons was founded at Canterbury by Lanfranc, Archbishop of that diocese, in 1070. The office of Serjeant-Surgeon was instituted in 1461.

Hunter's Chair.—No; the chair, which also forms a library-ladder when extended, and which was made by the great physiologist, is in the Conservator's office at the College of Surgeons. The chairs to which our correspondent refers were sold by the College authorities some years since; the wood of which they were made was brought over by the great circumnavigator Cooke, and presented to Hunter. It has never been ascertained what the wood is. See the *Medical Times*, vol. xxv., p. 347, *et seq.*, "Old chairs to sell!" Inquire at the College of Surgeons.

A Fellow, F.R.C.S., Manchester, and others.—The 15th section of the Charter of the 7th of Victoria granted to the College is very clear on the subject. On reference to it our correspondents will find that the voting at elections of Members of the Council by the Fellows in person is not regulated by bye-laws, but is a provision of the Charter, which states "that the Members of the Council of the College shall hereafter be elected by the Fellows of the said College, including the Members of the Council as such; and such Fellows, whether Members of the Council or not, shall be allowed to vote in person only, and not by proxy," *et c.*

ALLEGED BREACH OF PROFESSIONAL ETIQUETTE—ACCIDENT ON THE GREENWICH RAILWAY.

* * At the moment of going to press we receive the following. As it has already become a public document, we give it a place in our columns; but it must be remembered that it is purely an *ex parte* statement; that every portion of it is susceptible of denial, or of explanation; and that till Mr. Adams's counter-statement be weighed in the balance, it would not be fair to consider him guilty of the breach of etiquette, or the bad manners, which the alleged transaction would involve. We do not conceal our dislike to any interference by railway Surgeons in money matters, compensation, *et c.* But here there is no allegation of the sort. Mr. Adams is accused of having done an act which in itself may be considered innocent or laudable in a way which may be called unmannerly: Let us wait and hear what he says.—*ED.*

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have sent a copy of the annexed letter to the body to which it is addressed, and I should feel very much obliged by its insertion in your next. I am, &c.

Gray's-inn, June 22.

J. JONES.

"To the President and Members of the Council of the Royal College of Surgeons." "An accident happened on the Greenwich railway, on the 20th of May last, by which several persons were injured.

"In the evening of the following day Mr. John Adams, Surgeon to the company to which the railway belongs, called at the residence of a young gentleman in Greenwich, who had suffered on the occasion, and entered

into conversation with his mother; he gave no card, nor did he introduce himself either by name or profession; he affected ignorance of any accident having occurred, and on being told that the patient was upstairs in bed—without inquiring whether he was under Medical treatment, of which there were unmistakable signs on the table—without even allowing the mother time to announce to her son the presence of a stranger—he entered the sick room, and proceeded forthwith to make an examination of the case.

"These are facts which I am instructed to bring before your notice, and I am sure you will feel yourselves compelled to inquire strictly into them.

"The matter concerns your body, of which Mr. Adams is a member; it concerns the whole of the Profession you represent very nearly; and it concerns society and the public no less.

"I have the honour to be, gentlemen,

"Your obedient Servant,

"J. JONES, Solicitor.

"12, South-square, Gray's-inn, 13th June, 1864."

THE COLLEGE OF SURGEONS' SCHEDULE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The schedule of certificates for the Pass Examination of the Royal College of Surgeons of England contains at the end a "declaration," to be signed by the candidate, to the effect "that the foregoing certificates are, in every respect, correct and true." Now, one of the said certificates is "that N. N. has attended the courses of lectures on clinical surgery, and that each course consisted of not less than one lecture in each week."

In certain recognised Hospitals clinical lectures have not been delivered once in each week, but that is not the fault of the student, who can have no control over his teacher, yet the "declaration" on his schedule makes him answer for the required number being correct and true.

No other Examining Body requires such a "declaration," and I write to ask you, Sir, if it be not most unfair to ask us to sign it? Or if it be signed by the candidate in the sense that it is correct as far as he could make it so, then is it not untrue? and is there not reason for omitting it?

I am, &c.

TRUTH.

[* "Truth" should state his difficulty to the Surgeons of his Hospital, and obtain from them a special certificate, stating the number of clinical lectures given and attended.]

AN APPEAL FROM THE WIDOW AND FATHERLESS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged if you would kindly insert the following few lines in your widely circulated paper:—I am a widow of the late Edgar Bull, Surgeon, etc., of Blockley, Worcestershire, whose melancholy death was reported in the newspapers some few weeks since. I am left wholly destitute, and with a family of four children, three of whom are entirely dependent upon me for support. Having no means at my disposal to commence a small business in order to obtain a livelihood for them, which I am anxious to do, provided I could obtain some assistance, I have thus been induced to make this painful appeal to the members of the Medical Profession.

The Rev. H. Bromfield and Admiral Collier, of Blockley, have most kindly consented to receive any small donations which may be kindly forwarded for carrying out the above benevolent object.

I am, &c.

Blockley, Worcestershire, June 20.

ELLEN BULL.

CONSERVATIVE SURGERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—On reading Professor Fergusson's lecture in the *Medical Times and Gazette* of the 18th instant, my attention was arrested by some remarks of his on conservative Surgery, from which the casual reader might infer that the practice was of comparatively recent origin, and unheard of in the world of letters prior to 1852.

I am sure that the learned professor has unwittingly omitted to give credit where credit is due, and with your permission I would fill up the gap in his lecture by stating that a retired member of the Profession, and an accomplished man of letters, practised conservative Surgery in one of our public Hospitals as early as 1843-4, with remarkable success; and that he published the result of his practice in the columns of the *Lancet*.

Sir James Prior, Deputy-Inspector-General of naval Hospitals and fleets, when in charge of the Royal Naval Hospital at Woolwich, if he did not invent, was the first to my knowledge to give prominence to the term "conservative Surgery," and I well remember one case of injury to an elbow-joint, which he treated successfully, although the dock-yard Surgeons who sent the man to the Hospital, and every other Surgeon who saw the case—your humble servant amongst the number—were of opinion that the arm ought to be amputated. Full twenty years have now elapsed since that case occurred, but it made an impression on my mind which time has not obliterated.

I am, &c.

June 20.

A STAFF-SURGEON, R.N.

I enclose my card.

PRESCRIBERS' COMPANIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You will, I am sure, allow me to trespass a little on your space in reply to the criticism of "The Prescriber's Companion" by Dr. Bree in your last issue.

First, I wish to thank him for not exhibiting any "captious spirit" in his remarks; I wish I could also thank him for accuracy in his quotations. I do not of course believe that he has wilfully misrepresented, but as his letter may, for a week at least, create an impression that "The Prescriber's Companion" is untrustworthy for the very purpose for which it was compiled, I think I have some right to complain that greater care was not taken to ensure correctness in the charges made.

Dr. Bree says that I have given the dose of Tinctura Lobeliae and Vinum Tabaci, for an emetic as \mathfrak{zj} . to \mathfrak{zjij} .; whereas, if he will look more carefully, he will see it is \mathfrak{zj} . to \mathfrak{zjij} . Then, again, he says that I have given the minimum dose of morphia hydrochlor. as gr. $\frac{1}{2}$ for an adult, instead of which, as every one may see, it is gr. $\frac{1}{4}$.

Dr. Bree objects to the largeness of the doses given. In reply I have only to say that I was very careful in all cases where I was ignorant of the proper dose (and no one, I imagine, can suppose that I, or any one else, have experimentally tried all the medicines in the Pharmacopœia) to take such as were recommended by what I considered a competent authority. I hope Dr. Bree will allow that the work of Dr. Pereira is a safe guide on such a question; if so, if he refers to page 1551 of the third edition he will find that the dose of Tinct. Lobeliae which is there given is

"as an emetic $\mathfrak{f}\mathfrak{zj}$. to $\mathfrak{f}\mathfrak{zjij}$. repeated every two or three hours, till vomiting occur," and "for children of one or two years $\mathfrak{℥x}$. to $\mathfrak{℥xx}$." Again, at page 1435 of the same work the dose of Vinum Tabaci is $\mathfrak{℥x}$. to $\mathfrak{℥l}$. as a "sedative and diuretic." I do not think, therefore, that I was very far wrong in giving \mathfrak{zj} . to \mathfrak{zjij} . as the dose for an emetic. With reference to Veratria, Pereira gives gr. $\frac{1}{2}$ to gr. $\frac{1}{4}$ as a moderate medicinal dose three times a day, I therefore put the emetic dose at gr. $\frac{3}{4}$ to gr. 2. Then, as to the Tinctura Aconiti, Dr. Bree complains of my ordering $\mathfrak{℥x}$. to $\mathfrak{℥xv}$. Pereira says that the dose (of the old tincture) is five drops, and this dose I have given over and over again; the new tincture is just one-third the strength of the old, therefore, I ordered $\mathfrak{℥x}$. to $\mathfrak{℥xv}$. Lastly, with reference to the Ext. Cannab. Ind., the dose I have given is gr. 3 to gr. 8. I have reason to believe that this dose is too large, but in justification I must add that Dr. O'Shaughnessy, who made many observations on this subject, remarks that whereas in India he had seen marked effects from half a grain or even less, and had been accustomed to consider a grain and a-half a large dose, in England he had given ten or twelve, or even more grains to produce the desired effect.

I will not trespass on your space further than to add my thanks to Dr. Bree for his remarks on what he is pleased to call my "excellent little work," and to assure him that I shall be glad of as many more as he may care to make through you, or direct to me, all of which shall be carefully attended to "in a future edition."

I am, &c.

9, Cavendish-place, Cavendish-square.
