RADFORD LIBRARY,

Saint Mary's Hospital, Manchester.

No. ~~73~~ ~~504~~ ~~P 211~~ Q. 168

This Book to be returned in _____ days.

Fine for overtime _____ per day.

Note.—No book can be renewed if wanted by another reader, nor unless brought to the Library for that purpose.

It is requested that the leaves of books may not be turned down,—that no person will write in them,—and that the greatest possible care may be taken of them.

EXTRACTS FROM THE RULES.

That each Medical Officer shall be allowed not more than two works out of the Library at one time, and not more than two volumes of each work.

That Registered Medical Students shall be allowed to take out books every Tuesday and Saturday, from eleven till one, or at such hours as may be ordered from time to time by the Board.

That each Registered Medical Student shall be allowed to have not more than one book out of the Library at the same time, unless the work consists of two or more volumes, and in no case more than two volumes.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN,

By J. Y. SIMPSON, M.D., F.R.S.E.,

Professor of Medicine and Midwifery in the University of Edinburgh.

ON ACUPRESSURE.

GENTLEMEN,—Acupressure—or the artificial arrestment of the hæmorrhage from cut or wounded arteries by the pressure of a needle passed across their mouths or tubes—is a subject that scarcely comes, it may be argued, within the scope of clinical lectures on female diseases. Some of this class of diseases, however, are purely Surgical in their character and cure. The very first idea of acupressure sprang from the study of one of these female Surgical diseases,—viz., vesico-vaginal fistula. And again, the first operations in which I employed it were cases belonging to the same department, namely, cases of excision of the mamma. In speaking, however, of acupressure in the following observations, I shall not limit myself to its application to Obstetric Surgery, but shall rather discuss its application to General Surgery. The fact that acupressure is as yet imperfectly understood, and little, or not at all, described in any of our Surgical works or lectures, may plead, perhaps, as an additional apology for my attempting to impress your young and unprejudiced minds with its relative advantages. Were it necessary, I might plead further the paramount

Importance of the Doctrine of Surgical Hæmorrhage and Surgical Hæmostatics.

Hæmorrhage forms a subject of the very highest Surgical moment, because it constitutes a complication in almost all varieties of severe Surgical operations—in all in which the knife is employed. Hence, any question of moment connected with it is a question which is at once connected with nearly the whole range of Operative Surgery. Supposed improvements in individual operations, for example, as in the extent, or the size, or the shape of the incisions or flaps in any special amputation, affect that one special amputation only, and have little or no bearing on General Surgery. Any leading question, on the contrary, connected with hæmorrhage involves its application, not to any one special amputation, but to all amputations and to all other operations in which the Surgeon uses cutting instruments. “Indeed,” as was remarked half a century ago by my beloved and sagacious master, Professor Thomson, “the suppression of hæmorrhage and the reunion of divided surfaces are in every wound and in every operation the first and the ultimate object of the Surgeon’s attention.”—(*Lectures on Inflammation*, p. 249.)

IMPEDIMENTS TO THE PRIMARY UNION OF WOUNDS.

I take it for granted that it is the object and desire of every philosophic English Surgeon to heal, when possible, all his wounds by the “first intention,” as it is called, or by primary adhesion. In the olden times of Surgery, when the hæmorrhages accompanying operations were arrested only by cauteries and caustics, all thoughts of effecting union by the first intention were of course idle and vain; for the existence on the surface of the wounds of the resulting dead sloughs and burned crusts totally prevented all primary adhesion. But even after the deligation of bleeding arteries became general, it was with difficulty that the idea of primary union, broached originally by Alanson, and other English Surgeons, in regard to amputation wounds, gradually and slowly gained ground. Led away by the high authority of Pelletan, Larrey, and others, some foreign Surgeons still methodically reject the attempt in many wounds, possibly because, from their peculiar mode of operating, and especially of dressing wounds, they have found their failures so constant as to make them despair of success. But when wounds, instead of healing by the first intention, heal by granulation and suppuration, or by the “second intention,” they close slowly and painfully, with more or less prolonged discharges and suffering to the patient, and often with the loss of health, and sometimes of life. The regulation of the closure of wounds in Operative Surgery by the first intention or by the second intention occasionally depends upon the state of constitutional health of the

patient. It always, however, depends also more or less, and generally almost entirely, upon the local character and circumstances of the wound. And the question before us is this—Is Surgery as yet prepared, or yet able, to take an additional step forwards, with the hope of rendering its management of wounds such that their primary union should prove much more general than heretofore? If so, the Practitioner might, when successful, abridge the cure of amputation wounds, for example, from long weeks, as it were, to almost days only; and he would doubtless add very greatly, in doing so, alike to the happiness as well as to the safety of his patients.

Now, there are some wounds that heal with nearly perfect certainty by primary union, although from certain correlative circumstances they seem not to be very favourably situated for such a result. Thus, the raw edges of a vesico-vaginal fistula almost always cohere, despite the constant contact of urine; the lips of a ruptured and revived perineum, despite the irritation of the intestinal contents; and the wound in harelip, despite the presence of the saliva. The wounds in all “Plastic Surgery” are expected to unite by primary adhesion. Why is it that these classes of wounds commonly heal throughout by the first intention, and wounds in General Surgery rarely do so? For, confessedly, the complete and entire primary union of a wound such as is left by the removal of a limb, mamma, or tumour, is very rarely seen in general Surgical practice. I believe that the answer is this. In the obstetric operations named, and in Plastic Surgery, no ligatures of the arteries are used. On the contrary, in the wounds of General Surgery which fail to cohere by primary union, ligatures are used in greater or less number to arrest the arterial hæmorrhage. It is the absence or the presence of these ligatures tied around the ends of the bleeding arteries that makes the marked and distinctive difference between wounds likely to heal and wounds not likely to heal by the first intention. But there arises the next question,—

Why do the Ligatures interfere with the Primary Adhesion of Wounds?

Arterial ligatures prevent the primary union of the lips of wounds in two ways—

1st. Each ligature acts itself as a mechanical foreign body placed between the opposed sides of the wound; and when it is composed of silk or other organic material, it rapidly imbibes animal fluids into its substance, which dead fluids speedily decompose and render the threads morbidly poisonous and irritant agents to the contiguous lining tissues. In other words, each arterial ligature is formed speedily into a small or miniature seton; and it produces, like a seton, suppuration along its tract. Suppuration, however, and all the higher grades of inflammation, are locally antagonistic of adhesive inflammation or primary union; and they tend to impede and subvert those processes of cohesion and repair which constitute union by the first intention. But—

2ndly. Ligatures counteract the simple adhesion and healing of wounds in another and far more marked mode. They inevitably set up at all the ligatured points and ends of the tied arteries themselves, stages of inflammation higher than the adhesive—the stages, namely, of ulceration, suppuration, and mortification. For at the point of deligation every ligatured artery has its two inner coats mechanically torn through by the thread, and its outer coat strangulated by it; and before the separation of the ligature can be effected, it requires to cut through the strangulated tube by a process of ulceration or molecular disintegration and gangrene. Further, there are set up, as a consequence, in the immediate vicinity, the processes of local disjunctive inflammation and suppuration; and the part of the arterial tube embraced in the noose of the ligature constitutes a small, dead, decomposing *slough*, as well as the isolated and strangulated end of the artery below the ligature, except in instances in which this isolated end is preserved from death by adhesion to the contiguous surfaces. If two, four, or six arteries, therefore, are tied in a Surgical wound, then, in consequence of this deligation, there exist two, four, or six points of destructive *ulceration* and *sloughing* in the depths and walls of that wound. And, of course, complete primary adhesion of its sides becomes an improbability, or rather an impossibility.

All our best Surgical pathologists acknowledge this ulceration and sloughing as the inevitable and invariable result of the ligature of arteries. Generally the dead tissue is thrown off in small slough masses; to a considerable extent, also, it seems to be melted down and discharged in the form of disintegrated ulceration molecules. We tie and strangulate the

necks of piles and polypi to make them ulcerate and slough off, just as the tied and strangulated ends of arteries do. Mr. John Bell, when treating of the effects of the ligature of the artery, uses this very expression:—"The part of the artery below the ligature is (says he) destroyed like a polypus, fades and dyes; and it is the fading of the lower part thus *mortified* that allows the noose of the ligature to slip off." Or, to quote the words of Dr. Wise (a very careful observer, and a gentleman who has specially attended to this department of pathology), after deligation of an artery—"an *ulceration* of the compressed part takes place about the fifth or sixth day, and the ligature is slowly discharged about the twelfth or fourteenth day, being thrown off by a *gangrenous* process, together with a small portion of the vessel which had been compressed by the ligature." "Every Surgeon knows," observes Mr. Spencer Wells, "that the part of the artery beyond the ligature *must be killed* by it, and that a piece of *sloughy* tissue cannot do any good when confined among the living tissues of the body."—(*Medical Times and Gazette*, May, 1860.) I might, if it were necessary, cite for you Guthrie, Cross, Brodie, Hodgson, Erichsen, Pécot, Velpeau, Nélaton, and others, as all describing the portion of every artery strangled and isolated by the ligature as killed, and requiring to *slough* off. Let me, for brevity's sake, however, content myself with adducing the statements on this point given by the authors of three of the latest and best works on Systematic Surgery, published respectively in America, France, and England:—"That portion of the artery (I quote the words of Professor Gross, of Philadelphia) immediately embraced by the ligature *mortifies*, and comes away in the form of a *slough*."—"(*System of Surgery*," 1862, vol. i., p. 700). "The portion of artery," remarks M. Chassaignac, of Paris, "embraced by the ligature *necessarily mortifies* a little sooner or a little later, according to the degree of constriction put upon it; and it is only in consequence of an eliminative process, similar to that which in gangrene separates dead from living parts, that it is detached from the tissues which surround it."—"(*Traité des Opérations Chirurgicales*," 1861, tom. i., p. 233). "The noose (of the ligature) and its contained *slough* are," remarks Professor Miller, "to all intents and purposes, foreign matter; as such their presence will be resented by the surrounding living textures; and as such they will be extruded by supuration."—"(*System of Surgery*," 1863, p. 224.)

If any Surgeon, desirous, as all ours are, of producing primary union, had the hardihood to propose, as a new mode of treating wounds (such as those produced by amputation), that there should be placed between their flaps a series of four or five small seton-threads, and that each individual seton-thread should, for a week or two, be firmly fixed and anchored down in the depths of the wound to a corresponding number of small masses of strangulated, dead, decomposing, sloughing tissue—would not such a suggestion, I say, be met by the profession with perfect amazement, and denounced as ridiculous and discreditable, or something worse? Yet, in reality, this, as we have just seen, is the principle followed at the present hour by our Surgical brethren when they staunch the hæmorrhages which follow their knife by tying silken ligatures around the drawn-out and isolated ends of the bleeding arteries. Is it a great marvel that primary union so seldom occurs in wounds so managed? Would it not be a still greater marvel if union by the first intention followed oftener under such adverse circumstances?

We cannot hope, I believe, for any great and decided improvement in the treatment of wounds, and we cannot expect primary union to be frequent in them, till we have attained some means of arresting hæmorrhage without strangulating and sloughing the ends of the bleeding arteries. For the accomplishment of this object, other simpler and safer means than acupressure may, and probably will, be discovered; but, in the mean time, it has been found capable of occluding wounded and cut arteries without producing upon them any physical laceration, such as the ligature produces, without strangulating and sloughing their isolated extremities, and without leaving any foreign bodies in the wound after the vessels are occluded. Their use is founded upon the general pathological principle—that, whilst silk and other dead organic ligatures and substances excite irritation, suppuration, &c., when they are buried in the living structures of the body, there is, on the contrary—

A Tolerance of Metallic Bodies by the Living Tissues.

We have ample proof of the truth of this great general law in many kinds of observation, as in the tolerance—some-

times for long years—of bullets, small shot, pins and needles, imbedded in different parts of the body; in the non-irritating character of threads of iron, silver, platinum, &c., when used as Surgical sutures; in the employment by all our best Surgeons of metallic pins or needles in the union of hare-lip; and in the safe retention, during several days, of a metallic needle passed through a fold of the peritoneum itself, in the operations of Wutzer, Rothmund, and others, for the radical cure of hernia. The use of a needle in the cure of hernia and of hare-lip—where the whole aim and the deliberate object of the Surgeon is to secure and establish adhesion and adhesive inflammation—only shows that a needle, when used to close and compress an artery, as in acupressure, is not likely in itself to lead there to any higher stage of inflammation than the adhesive—and consequently will not interfere, when used as a hæmostatic, with the primary union of wounds. At the same time, let me qualify this remark with another:—if a metallic acupressure needle, or a metallic suture thread, be made to press too long and too strongly on any given point of living tissue, that point will ulcerate. But the ulceration, under these circumstances, is not the result of the pressure of the metal needle or thread, as metal; it is not, in acupressure for example, the result of the pressure of the needle as a needle; but it is the result of the *pressure* of the needle simply as pressure, morbidly excessive in its amount. And any similar degree of linear pressure, by any other mode whatever, will produce the same ulcerative appearances.

That even very long needles may be borne with perfect impunity embedded for days in the living body, is attested by numerous experiments that were performed on the human body, some forty years ago, by various Surgeons, when acupuncture was more studied and practised than now. "It is a remarkable circumstance (observes a writer on this subject) that the acupuncture needles never cause inflammation in their neighbourhood. If they are rudely handled or ruffled by the clothes of the patient, they may produce a little irritation; but, if they are properly secured and protected, they may be left in the body for an *indefinite* length of time without causing any of the effects which usually arise on account of the presence of foreign bodies. In one of M. Cloquet's patients they were left in the temples for eighteen days; and in cases in which needles have been swallowed, they have remained without causing inflammation for a much longer period. It appears probable, from the facts collected on this subject, that metallic bodies of every kind may remain imbedded in the animal tissues without being productive of injury."—(See the *Edinburgh Medical Journal* for 1827, p. 197.)

EFFECTS OF ACUPRESSURE NEEDLES.

Needles, then, are—as metallic bodies—tolerated by the living structures. To occlude a vessel, they require, as experience has amply shown, to be retained for a few hours, or a few days at most; and further, when passed with this view across the mouth or tube of an artery, they merely place the internal surfaces of the vessel in close contact; without isolating the vessel from its attachments; without lacerating its two internal coats; and without strangulating, ulcerating, and mortifying the constricted portion of the tube, all of which injuries and lesions are, as we have found, inevitably produced when the deligation of arteries is adopted. In thus using against hæmorrhage acupressure needles instead of ligatures, we attempt to bring all bleeding wounds in General Surgery to the condition, as far as possible, of wounds in Plastic Surgery, where union by the first intention is the expected and general result. We secure the bleeding arteries by unirritating metallic needles, and we withdraw them as soon as we can, so as to leave ultimately *no foreign body whatever* in the wound. Ligatures cannot be withdrawn for an indefinite period, or till, after days or even weeks, they have ulcerated and sloughed through the tied vessel. We can at once remove, on the contrary, our acupressure needles always at will, and whenever we deem that they have produced their occluding effect. But I am forestalling some observations; for, before considering how short or long a time the needles should be left in, we have another matter than this to consider first, namely, the—

APPARATUS REQUIRED FOR ACUPRESSURE, AND THE METHODS OF APPLYING IT.

The instruments required for the employment of acupressure are of the simplest kind. They are chiefly applied in three modes. In the first method, the only instrument required is a long needle (Fig. 1) headed with glass or sealing-

wax to allow of sufficient pressure upon it for its introduction; in the second method, a short common sewing needle (Fig. 4) threaded with iron-wire or with silk; and in the third

FIG. 1.

FIG. 1.—Acupressure Needle. The form first used.

method, the same needle along with a loop of very slender wire thread (Fig. 6) of four or five inches in length. The three chief methods of applying the needles are as follows:—

1st Method.—This was the mode which I generally adopted in the first acupressure operations. It usually consists in passing a long needle twice through the flaps or sides of a wound, so as to cross over and compress the bleeding artery or its tube, just in the same way as in fastening a flower in the lapelle of our coat, we cross over and compress the stalk of it with the pin which fixes it, and with this view pass the pin twice through the lapelle. (See Figs. 2 and 3.) The only portion of the needle

FIG. 2.

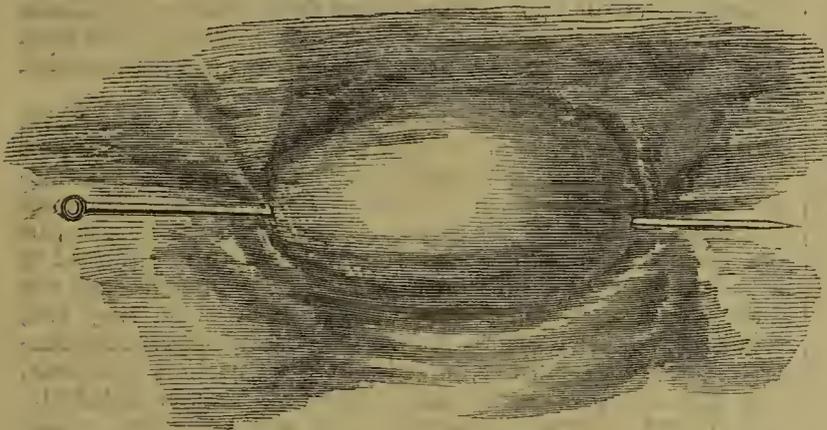

FIG. 2.—Cutaneous surface of a flap, in which an artery is secured by an acupressure needle, according to the first method.

FIG. 3.

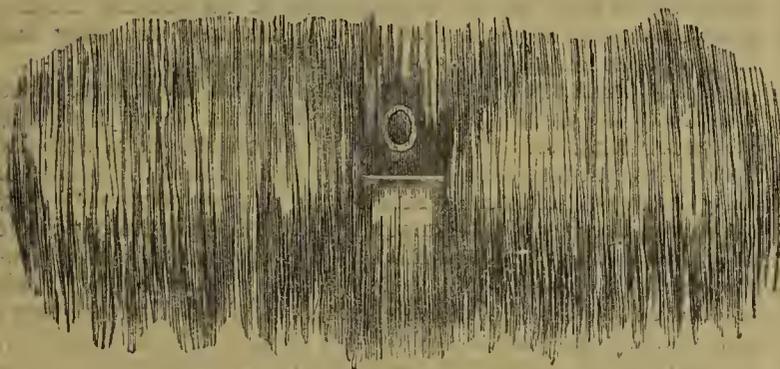

FIG. 3.—Wound surface of the same flap, showing the bridge of the acupressure needle compressing the artery. In this, and the woodcuts Figs. 5 and 7, the open mouth of the artery is represented as further removed from the needle than it perhaps generally is in practice.

which is left exposed internally on the fresh surface of the wound (Fig. 3) is the small middle portion of it, which bridges over and compresses the arterial tube at its bleeding mouth, or a line or two or more on the cardiac side of it. More or less of both extremities of the needle, viz., its head and point, are exposed externally on the cutaneous surface of the side or flap of the wound (Fig. 2). When passing the needle in this method, the Surgeon usually places the point of his left forefinger or of his thumb upon the mouth of the bleeding vessel, and with his right hand he introduces the needle from the cutaneous surface, and passes it right through the whole

thickness of the flap till its point projects for a couple of lines or so from the surface of the wound, a little to the right side of the tube of the vessel. Then, by forcibly inclining the head of the needle towards his right, he brings the projecting portion of its point *firmly* down upon the site of the vessel, and, after seeing that it thus quite shuts the artery, he makes it re-enter the flap as near as possible to the left side of the vessel, and pushes on the needle through the flesh till its point comes out again at the cutaneous surface. In this mode we use the cutaneous walls and component substance of the flap as a resisting medium, against which we compress and elose the arterial tube. But in some wounds a neighbouring bone or other firm unyielding texture forms the best and readiest point of resistance against which to pin and compress the artery by the acupressure needle. In such cases, the end of the finger at the bleeding point is sometimes necessary to assist the needle in duly pressing it down upon or against the open vessel. In both those modifications of acupressure a thick flap or a vessel situated deeply requires a proportionally longer needle; and the amount of pressure upon the artery is easily regulated and increased, when required, by the acuteness of the angle which the needle makes in its passage over the arterial tube. The degree of compression required to shut an artery by acupressure is generally by no means great, especially if care is taken to pass the needle as near as possible to the arterial tube, and without a layer or layers of elastic tissue intervening between them. This needle can be withdrawn at will, at any hour or time, by pulling at the head of it; which, I have said, is placed externally.

There are some objections to using such long needles in acupressure when they can be avoided. They are liable to be passed so as to compress the included tissues too strongly; they compress, however slightly, an unnecessary extent of tissue; and, being partly external, they are liable to prove unwieldy and incommodious in putting on dressings, etc., to the wound, provided we do use such applications to it.

In the method of acupressure which I have described, the long needles are introduced from the cutaneous surface, and their extremities left out *externally*. In the two other methods, where sewing-needles are used, they are introduced on the raw surface of the wound, and are all situated thus altogether *internally*, or between the lips of the wound.

2nd Method.—A common short sewing-needle (Fig 4), threaded with a short piece of iron-wire for the purpose of afterwards retracting and removing it, is dipped down into the soft textures a little to one side of the vessel, then raised up and bridged over the artery, and then finally dipped down again, and thrust into the soft tissues on the other side of the vessel (Fig. 5). In bridging over the vessel care must be taken

of the noose open after they bridge across the artery, and *tie* them below or behind the eye end of the needle, in the form of a common single or double knot. But this tie takes much longer time than the twist, and is not more efficient. When

FIG. 7.

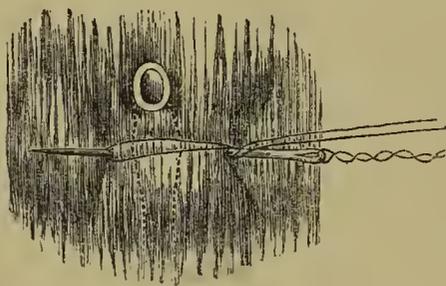

FIG. 7.—The third method of acupressure by means of a common sewing needle and a loop of iron wire.

in either case the operator wishes to remove this simple acupressure apparatus after a period of, say five, twenty, thirty, or more hours, all he has to do is to withdraw the needle by pulling it out, by dragging at the twisted wire with which it is threaded. The noose of wire-thread is thus at once loosened and liberated, and can be withdrawn also. To distinguish easily between the wire-thread passed through the eye of the needle and the duplicature of wire, it is always convenient to mark the former by having it plaited or twisted. (See Fig. 4.)

[The second part of this lecture on Acupressure is in type, and will appear in our number for January 9.]

THE PARIS INSURANCE CASE.—A great sensation has arisen in Paris by reason of the arrest of a Physician on suspicion of his having poisoned his wife or mistress. She was quite a young woman, and he had insured her life for the large sum of 550,000 francs. She died after the payment of the first premium, and sufficiently suspicious circumstances were present to cause his arrest. It is said that at the autopsy no poison was found. It seems that he is a homœopathic doctor, and also possesses a title of nobility. He only received his doctor's degree in 1854.

to press the end of the needle down upon the mouth or tube of the bleeding artery with force sufficient to arrest the hæmorrhage. The end of the finger pushed against the projecting portion of the point's-end of the needle is often required thus to compress and close the vessel adequately, before the tip of it is sent outwards and fixed in the tissues beyond.

3rd Method.—This consists in compressing the vessel between the threaded sewing-needle (Fig. 4) and a duplicature of passive iron thread (Fig. 6). Here, as in the method last related, the cutaneous surface is left intact; but the needle is passed *below*, instead of over or above, the artery. The point of the needle is entered a few lines to one side of the vessel, then passed under or below it, and afterwards pushed on so that the point again emerges a few lines beyond the vessel. The noose or duplicature of wire (Fig. 6) is next thrown over the point of the needle; and, after being carried across the mouth or site of the vessel, and passed around the eye end of the needle, it is drawn sufficiently tight to close the vessel, when it may be fixed by a half-twist or twist around the stem of the needle. A slight half-twist usually fixes a rigid wire-thread sufficiently (Fig. 7). If the operator prefers, he may keep the two threads

COURSE OF
LECTURES

ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

IN beginning a course of lectures on the urine, intended as an aid to the diagnosis and treatment of disease, the first question requiring an immediate answer is—

WHAT IS URINE?

Urine is nothing more nor less than a collection of the liquid and solid effete products of the frame, and its composition fluctuates in exact proportion as the processes of life fluctuate.

Consequently, it differs very materially in different species of animals, and even varies with the varying conditions of the same animal.

The state of the urine has, with justice, long been regarded as a key to the condition of the body; and hence we find that the Physicians of antiquity, like those of modern times, sought, in the composition of the urine of their patients, a clue to the nature of the diseases under which they laboured, an index to their prognosis, and a guide to their successful treatment.

It is true that uroscopic charlatanism has, more or less, in all ages, laid human credulity under contribution, and thereby brought discredit upon, and retarded the advance of legitimate science; but this must not deter the honest Practitioner from reaping the advantages which a knowledge of this secretion affords.

An examination of the urine not only enables us to arrive at a correct diagnosis of diseases attacking the urinary organs themselves, but in many cases yields most important information regarding the nature of morbid changes occurring in other and distant parts of the frame. You must not, however, be led away with the idea that the urine is the royal road to knowledge, or you will be doomed to disappointment; nor must you flatter yourselves that its study is an easy one, requiring neither previous preparation nor subsequent application; for on the contrary, in order to make urology bear fruit, you must bring to its cultivation both perseverance and skill.

It is not a little remarkable that this secretion, which inspires most of us with a feeling of aversion, should not only have rendered incalculable service to clinical Medicine, and yielded brilliant discoveries to chemistry, but also solved many of the most obtruse problems in physiology. Notwithstanding all this, it has not done nearly as much as it might have done, nor as it ought to have done; but this is owing to no defect on its side, but in consequence of its votaries having always been too eager to profit by its pathology ere they had mastered the first rudiments of its physiology.

In fact, until within the last year or two, men have been constantly attempting to place, as it were, the pyramid of Medical science on its apex instead of on its base, and the result has naturally been that they reaped little benefit from their labours. It seems, indeed, as if they were only now becoming alive to the all-important fact, that physiology is the only true basis of rational Medicine, and that in direct proportion as they adopt its principles is the success of their labours in advancing the healing art. Such being the views now held by the pioneers of clinical Medicine in all countries, you will readily understand why, before entering on the pathology of the urine, I first try to give you a succinct account of its physiology.

It has been said that urine is nothing more than a collection of the effete products of the frame, and, consequently, that it differs in different species of animals. If we cast our eyes over the whole animal economy, we shall discover that all urines are not necessarily liquid; on the contrary, we shall find that there are many species of animals that pass solid urine; and thus at the very threshold of our inquiry we perceive this secretion naturally dividing itself into two great classes—the *solid* and the *liquid* urines.

SOLID URINE.

In all animals devoid of a urinary bladder, and in which the ureters open into the rectum, the urine is solid.

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

Thus, for example, the urine of serpents is passed in a compact mass, varying, with the size of the animal, from that of a pea to that of an orange. Yet, notwithstanding the peculiar appearance of this specimen of urine from the boa constrictor, it differs from liquid urine in only one particular—the absence of water. By the simple addition of distilled water to it I can produce as perfect a urine as that of the human being; for, solid though it be, it contains all the urinary ingredients,—urea, uric acid, phosphates, etc. Here, for example, are two spatulas, on one of which I place a fragment of serpent's urine, and on the other, some of the solids from evaporated human urine; to each is added a couple of drops of strong nitric acid, and you observe that both effervesce. I now heat them over the flame of the spirit-lamp in order to drive away the excess of acid, and to their yellow-coloured residues add a drop of strong liquor ammonia, when instantly, you perceive, both assume a magnificent purple tint. This colour is due to the presence of purpurate of ammonia, produced by the action of the reagents on the uric acid contained in the urines. You observe, too, that the urine of the snake—for it has become much more crimson than the other—appears to be the richest in that material. The uric acid of commerce is indeed almost entirely obtained from serpent's urine; consequently, these excrementitious masses sometimes cost as much as thirty shillings per pound.

Hitherto in these lectures I have generally said that all reptiles have solid urines; but, as this has occasionally led my hearers into a mistake, from the fact that, in common language, frogs and toads are reptiles, while, scientifically speaking, they do not belong to the class *Reptilia*, I must mention that these animals have distinct urinary bladders, and possess liquid urines. Frog's urine, for example, is a clear, transparent liquid, containing urea, phosphate of lime, chloride of sodium, and other urinary ingredients, just like human urine. The true reptile, on the other hand, has always a solid urine. Thus it is that the chameleon, which, like the serpent, is a true reptile, passes excrements containing urates, oxalates, phosphates, and, according to Kletzensky, even xanthic oxide,—one of the rare urinary substances. Do not for a moment imagine, however, that solid urine is one of the characteristics of the lower animal. On the contrary, we meet with it even in the higher classes. Birds have solid urines. Guano—the excrement of the sea-fowl—is in great part urine, and besides the principle, guanine, contains urate of ammonia, oxalate of lime, and ammoniaco-magnesian phosphates.

Again, we find solid urines throughout the whole insect tribe. The red excrements of the butterfly contain both urates, phosphates, and oxalates, and so it is with the excrements of all other species of insects. We see, then, as was before said, that the only difference between the solid and the liquid urines is in the absence of water.

LIQUID URINES.

Having made these remarks on solid, we shall now inquire into the nature of the liquid urines. The liquid urines are found throughout the whole class *Mammalia*, and present three such well-marked varieties, both as regards physical appearance and chemical composition, that it may be said they naturally divide themselves, according to the species of animal, into the three separate groups of carnivorous, herbivorous, and omnivorous urines.

The urine of the first class (carnivora) is characterised as being a clear, transparent, light-coloured liquid, possessing an acid reaction, and rarely depositing anything on cooling.

The urine of the second class (herbivora), on the other hand, is recognised as being a dark coloured liquid, with a strongly alkaline reaction, and depositing a copious sediment within twenty-four hours after being passed.

The urine of the third class (omnivora) lies, as it were, between the two. It is clear, slightly acid, somewhat darker in colour than that of the carnivora, but considerably paler than that of the herbivora, and only occasionally deposits a sediment on cooling.

In chemical constitution these urines present as marked features of difference as they do in physical appearance. Thus, for example, while uric acid (Fig. 1), a beautiful crystalline body, exists in the urine of the carnivora, it is entirely wanting in that of the herbivora.

The urine of the herbivora, on the other hand, contains, in its stead, a quantity of a totally distinct organic acid, namely, hippuric, which not only differs in chemical composition, but also in crystalline form, (Fig. 2.) The urine of the omnivora

is again found to stand between the two, and contains a portion of uric as well as hippuric acid.

Even in the nature of their inorganic ingredients, these urines differ materially; for, while both alkaline and earthy phosphates are abundant in the urine of the carnivora, they are entirely absent from that of the herbivora. Their place being there supplied by alkaline and earthy carbonates. Here the urine of the omnivora still occupies the medium position, and claims a share of both.

FIG. 1.

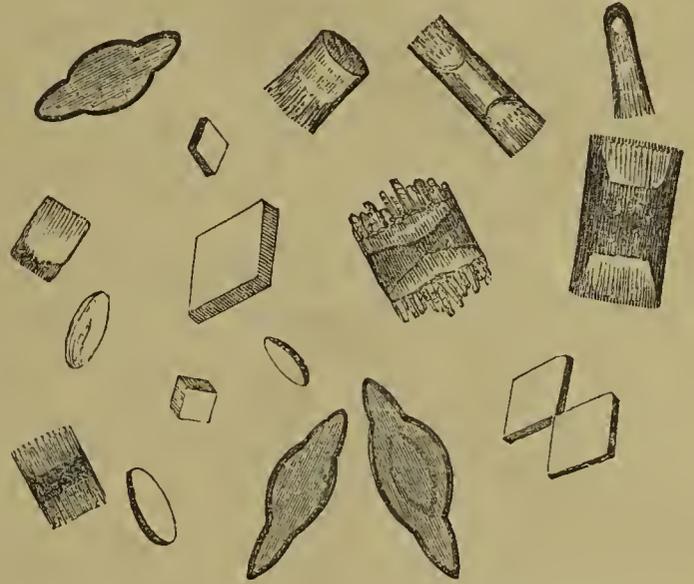

FIG. 1.—Uric acid from human urine, magnified 250 diameters.

FIG. 2.

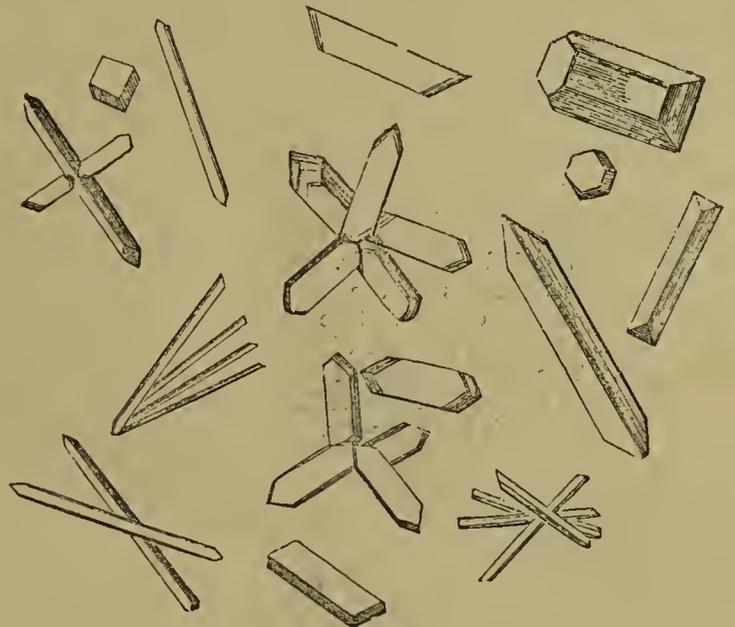

FIG. 2.—Hippuric acid from human urine, magnified 80 diameters.

Having now seen that the urine varies in the different species of animals, we are in a measure prepared to consider how and why it should vary at different times in the same animal. The variations both as regards quantity and quality we shall find to depend upon the state of the body, the kind of food and drink, the amount of exercise, the climate, and an infinite number of minor causes, the influence of which will afterwards appear.

(To be continued.)

ACADEMIE DES SCIENCES.—The Academy has filled up the vacancy left among the corresponding members by the death of Sir B. Brodie, by the election of Mr. Lawrence. The other candidates proposed were Professor Rokitansky, of Vienna, and Professor Simpson, of Edinburgh.

THE WIGWELL GRANGE MURDER.—In consequence of the report of a Medical commission employed by Government to investigate the mental condition of the convict Townley, he has been respited until the further commands of Her Majesty are known.

ORIGINAL COMMUNICATIONS.

RECORDS OF A CASE OF
PROPTOSIS, GOITRE, PALPITATION, ETC.,
WITH REMARKS.By C. HANDFIELD JONES, M.B., F.R.S.,
Physician to St. Mary's Hospital.

THOUGH cases of the following kind are by no means rare, the one I am about to relate contains several well-marked points of interest, which may be studied with advantage. The various phenomena seem capable of being referred with great probability to a sufficient cause; and the tracing of the operation of this in several instances is instructive, not only as regards the case in question, but many other conditions of very frequent occurrence:—

C. B., female, aged 40, dressmaker, seen February 2, 1859. She was an in-patient in St. Mary's Hospital, under Dr. Markham's care, who kindly drew my attention to the case, and asked me to take charge of it. She was in a state of extreme debility and great emaciation, but not anæmic; unable to lie down. There was marked proptosis; the eyeballs could only be partially covered by the lids. The thyroid gland was greatly enlarged; the middle and right lobes chiefly. On applying the hand to the right side of the neck above the enlarged thyroid, a purring thrill is felt in the superior thyroid artery of that side. The thyroid seems to press to some extent on the trachea, and to occasion the orthopnoea and a cough, which distresses her a good deal. The condition of the thyroid has suggested tying the thyroideal arteries. Heart not enlarged; sounds normal, except a soft, systolic bruit at the base. There is great palpitation, which disturbs her even at night, and extends up to the neck. On examination of the chest more particularly ten days later, no dulness was found, but the breath-sound was extremely weak; the movements frequent and shallow. Bronchial breathing was, however, audible over the upper part of the sternum, owing, probably, to pressure made by the thyroid on the trachea. Pulse 111, soft and weak. Appetite good until lately; food has made her sick the last ten days. Tongue natural. Bowels regular. No catamenia for eight months. She has taken iodine and pot. iod., and applied ungt. hydr. iod. to the thyroid without any benefit; but leeches to the part have given great relief, but only for a day or two. She has been suffering as at present for six months, but her disorder has been coming on four years. The goitre appeared first about the end of 1856, after some extra anxiety. The swelling came on suddenly, but did not enlarge much for one year. About a year before her first admission into the Hospital the tumour enlarged much, and cough set in. The chief cause of her great prostration and debility seems to have been her working night and day in the endeavour to support a relative who was dependent on her. She continued in the Hospital under my care till about March 26, when she was discharged to be an out-patient, considerably improved. She slept well, and lay down at night; took food fairly, and had gained strength. The goitre had not materially diminished, but distressed her much less; the proptosis continued. For about fourteen days after she came under my care she suffered very much from coughing and vomiting at night, with diarrhoea every now and then. Some nights were much quieter, and then again she would have very bad ones. The urine, before notable amendment had taken place, was of very deep colour; sp. gr. 1018, clear, not albuminous. After she had improved, it was extremely pale, sp. gr. 1011, feebly acid, cloudy from diffused mucus. She derived great benefit from the frequent application of ice to the thyroid; it certainly seemed to check its enlargement. Strychnine and quinine were given at first, but without advantage; the cough and vomiting were uncontrolled. Opium at night, and in smaller doses during the day, did not appear to be of much advantage, except in quieting the diarrhoea. On the other hand, nitrate of silver and hydrocyanic acid appeared really to be of efficacy in calming the irritability of the mucous membranes. After this had been accomplished, she began to take quinine gr. i.; tannin, gr. iv.; opii, gr. i., in two pills, ter die, with manifest advantage, and continued the same till the beginning of August, long after she had ceased to be an in-patient. Ammonia and valerian, and afterwards citrate of quinine and iron, were also given.

In May and June I tried the administration of tr. ergot and of liq. calcii chloridi, in the hope of reducing the size of the thyroid, but without any success. On one occasion I ventured to inject m x. of perchloride of iron into the tumour, but the result was so alarming that I never dared to repeat it. Her head appeared to her to be on the point of bursting; she lost all vision for a short time, and lapsed into a state of semi-syncope, in which she remained about a quarter of an hour. There was no hysteria in the matter, nor was it the effect of fright.

During August she was at the Convalescent Asylum at Walton, where she improved decidedly, and immediately after she went to work in a lady's family at Deal, whence she returned in the beginning of October, looking very well, and, as she declared, with such an appetite, that she was ashamed of it. The goitre was unchanged, but the proptosis had disappeared; she could close her eyelids completely. She had gained a good deal of flesh, and felt as well as ever she did, except that her breath was short on ascending a hill or going upstairs.

After this I saw no more of her till May 5, 1860, when I was urgently requested to take charge of her. She had over-worked herself again to provide for some relatives, and had gradually got much worse. I found her in bed, with a very flushed, red, anxious face, extreme agitation, breathlessness, muscular tremor, and debility, but no delirium; her stomach very irritable, rejecting all food; her bowels relaxed and loose; no sleep; pulse rapid and tense—about 100; breathing in lungs clear and free. Opii gr. i., 2 dis hōris; milk and beef tea in teaspoonfuls half hourly, and perfect quiet.

6th.—No sleep; bowels quiet; is not worse. Pt. To sip brandy-and-water often.

7th. Slept four hours, and was much better after it; has become worse again. Pt. Rum and milk.

10th. Last night excellent, and feels greatly better; the night before she had four or five hours' sleep; stomach quiet, no desire for food. Opium during the last two days has been taken 3 tiis hōris.

24th.—Stomach remains very weak and irritable, often has vomiting, sometimes great palpitation; can only take Oswego corn, beef-tea, and milk; had a severe attack of pain at epigastrium and dyspnoea, lasting about three-quarters of an hour, three days ago; none since; sleeps very well; is very weak. Opium every two or three hours.

28th.—Doing well; pulse 111, small and weak; it is notably smaller than it was; face very notably paler, and eyes less prominent.

June 2.—Is very prostrate, and stomach very sick again; she cannot raise herself in bed. Strychniæ, gr. $\frac{1}{16}$ th, ter die.

3rd.—Feels decidedly better, and has less sickness.

6th.—Is very much better; sitting up on the side of her bed dressed; stomach quieter.

8th.—Has been out, and enjoyed the air much; has more appetite.

22nd.—Gone to Walton; appetite very good before she left.

October 25.—Is in good health; no proptosis; the goitre remains *in statu quo*.

The prominent phenomena in this case were the proptosis, goitre, palpitation, cough, vomiting, high-coloured urine, and the extreme and peculiar debility, without any drain or manifest cause to produce it. The beneficial effect of strychnine, opium, argenti nitras, and country air are also highly noteworthy. The immediate cause of the illness on both occasions was excessive toil and insufficient repose. Starting from this, we may fairly assume, as the "grundleiden," a state of prostration and exhaustion of nervous power, and we shall proceed to consider how far this condition may have given rise to the several above-mentioned phenomena. Could it have occasioned the proptosis? It would seem probable that it might, for with returning strength the proptosis diminished and disappeared. Yet the result of dividing the cervical sympathetic is opposed to this view, for in this case the eyeball sinks in the socket, while it projects when the nerve is galvanised. If, therefore, we suppose the sympathetic to be in a parietic state, like the rest of the nervous system, the condition ought to be the reverse of proptosis. I am not aware that any post-mortem examinations have demonstrated the exact state of the parts concerned in this affection, so that we can only form an opinion by reasoning on probabilities. It is worthy of remark that proptosis continues during sleep, which surely would not be if it depended on any active contraction of the muscles. On the other hand, it seems quite possible that a relaxed or enfeebled state of the recti muscles may be

at least one element in its causation. Venous congestion is certainly a sufficient cause of proptosis, as shown by cases of strangulation, and by a case of intra-cranial tumour pressing upon the cavernous sinns (*vide Dublin Hosp. Gaz.*, May 1, 1860). In some cases, however, of extreme congestion there is no proptosis: a patient of Dr. Sibson's died lately in whom the superior cava was almost obliterated by an aortic aneurism; the face and upper extremities were swollen, dusky, and livid from congestion, but there was no remarkable prominence of the eyes. Neither is proptosis observed in numerous cases in which considerable remora of the venous current is occasioned by heart disease. Moreover, in the cases in question there is no apparent cause to produce congestion of the orbital veins. I doubt, therefore, that we are warranted in assuming the proptosis to be occasioned by venous congestion. It is quite certain, as remarked particularly some years ago by Mr. White Cooper, that there is no enlargement of the eyeball itself. We seem, therefore, to be reduced to the supposition either of an increased growth of adipose tissue in the orbit, or of serous effusion. (a) The former is evidently utterly improbable in a case of great general emaciation, and we decide, therefore, for the latter. The seat of this effusion is probably between the globe of the eye and O'Ferrall's tunica vaginalis oculi. In a case of aortic aneurism obstructing the superior cava, recorded by Dr. Watson in his lectures, "the face, neck, and arms were tumid and anasarcaous to an enormous degree," and "the eyes seem starting from their sockets." Here there was not only congestion, as in Dr. Sibson's case, but also serous effusion. (a) The experience of Bernard above quoted is against ascribing this effusion to the impairment or lowering of sympathetic nerve influence. Yet it should be remembered that there are many common instances of effusion taking place under conditions of evident nerve-debility, and again disappearing under the influence of tonics, much in the same way as proptosis does.

(To be continued.)

CASES OF UNUSUAL SLOWNESS OF PULSE, WITH REMARKS.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,

Physician to St. Thomas's Hospital, and to the Hospital for Diseases of the Chest, Victoria-park.

(Read before the Hunterian Medical Society, December 2, 1863.)

IN 1838 Mr. Mayo (b) read a paper, at the Royal College of Physicians, containing notices of several cases of remarkable slowness of pulse, in some of which the condition had existed for considerable periods. In 1842 (c) I reported a similar instance, which interested me much at the time when it occurred; and in 1846 Dr. Stokes (d) published several cases of the same description, with remarks upon them. Since this time other instances have been placed on record, affording further information of the various circumstances under which the condition occurs, and enabling us more satisfactorily to explain the cause upon which it depends. I propose, therefore, to bring the subject before the Hunterian Society, believing that it will prove interesting to the members. The remarks which may be made must not, however, be supposed to apply to the cases in which the pulse becomes slow only during the last periods of life, nor yet to those, not of unfrequent occurrence, in which, though the pulse at the wrist be slow, the heart beats with its usual frequency, but the alternate pulsations being very feeble, are not propagated to the radial artery. I propose, indeed, to confine the attention of the Society to cases in which the impulse of the heart and the beat of the pulse correspond, and in which the slowness is of long duration.

Mr. Mayo classed the cases which he collected into, first, those in which "the pulse was known to have always been the same, or at least was not known at any period to have been different;" and secondly, those in which the pulse was originally of average frequency, "but fell to a lower rate under the influence of causes that, for the most part, were determinable." These forms he further regards as distinguished by the injurious effects which attend the action of stimulants

in the former class, and the relief which they afford to the sense of sinking and depression in the latter.

As examples of the original slowness of pulse he quotes two cases. In one of these, a gentleman, thirty-five years of age, had a pulse for many years ranging from 38 to 52. In the other, a gentleman who died at the age of thirty-two of obstruction of the bowels, and possessed considerable muscular activity, had a pulse of 36, occasionally rising to 42 or 44. In neither of these cases does it appear to have been distinctly ascertained that the pulse had previously never been higher; though in the first the rate had been low for fourteen years, and in neither was there reason to suppose that any change of rate had suddenly taken place. I have not myself met with any case in which remarkable slowness of pulse was apparently an original defect, unless possibly the third, which will be quoted in the paper, be of that description.

The other cases which are quoted in Mr. Mayo's paper are regarded by that gentleman as due either to "lesion of the brain," to "great depression, exhaustion, and reduction of strength," to "disorder of the digestive organs," or to affections of the heart. Of these various causes, it may be doubted whether any cerebral disease can persistently lower the rate of the pulse. We know that in cases of concussion and compression of the brain, in the early stages of hæmorrhagic apoplexy, and in coma originating in other forms of disease, the pulse is usually slow and labouring; but if the patient survive, and the symptoms of compression subside, it uniformly becomes more or less accelerated. It seems most probable, therefore, that in all cases of cerebral disease the slow pulse can only be a temporary condition. A case is, however, reported in the *Medico-Chirurgical Transactions*, (e) which has been regarded as affording an example of syncopic attacks with remarkable slowness of the pulse, depending on injury of the medulla oblongata. The following are the particulars:—A gentleman, sixty-four years of age, sustained in a fall from his horse an injury to the back of the neck, the nature of which was not clearly understood. From this he recovered in the course of a year, with, however, some difficulty in moving the head remaining. Two years after he was suddenly seized with a fainting fit, and while in this state his pulse beat only 20 times in the minute. The syncope returned at intervals on any unusual excitement; his ordinary pulse was 32, but during the fits it fell to 12, 10, 9, 8, and, on three or four different occasions, as low as 7. He died suddenly in one of these attacks, five years and a quarter after the receipt of the injury. On examination, the medulla oblongata was found small and very firm; the antero-posterior diameter of the foramen magnum was greatly diminished; the odontoid process pushed back, the occiput, atlas, and dentata firmly ossified together, and the canal so small as only to admit the little finger. In this instance it is by no means clear that the syncopic attacks were dependent on the lesion of the medulla oblongata. Cases of remarkable compression of that portion of the cerebro-spinal axis have been placed on record in which no such symptoms were observed; and the syncopic attacks did not come on till two years after the injury, and no paralytic symptoms at any time occurred. We are further informed by Mr. Liston, who performed the post-mortem examination, that the heart was large, the parietes of the left ventricle rather thin, the lining membrane very much thickened generally, the left auriculo-ventricular aperture large and the right auriculo-ventricular aperture very large. We may, therefore, reasonably conclude that the syncopic attacks depended rather upon the state of the heart than on the condition of the medulla.

It may also be doubted whether disorder of the digestive organs, however greatly, as we know, it may temporarily influence the functions of the heart, can permanently interfere with its rate of pulsation, and I know no case which affords support to such an idea. Dismissing, therefore, these supposed causes of slowness of pulse, there remain the existence of some form of cardiac disease and the influence of general exhaustion, which are considered by Mr. Mayo to give rise to the peculiarity.

1. The occurrence of slowness of pulse in connexion with cardiac disease has been long familiar to practical men. Two at least of Mr. Mayo's cases afford examples of the coincidence. In one of them, a gentleman of seventy years of age, the pulse sank somewhat suddenly, first, to from 38 to 40, and then to 28. In another, a gentleman of fifty-two, the rate of the pulse became from 30 to 34, and occasionally as low as 28, 26, or

(a) In a case at present under my care the fluid bulges forward the skin of the upper eyelid.

(b) *London Medical Gazette*, vol. xxii., p. 232.

(c) *Provincial Medical and Surgical Journal*, vol. iv., p. 68.

(d) *Dublin Quarterly Journal*, vol. ii., 1846, p. 72.

(e) Vol. xxiv., 1840 and 1841, p. 76.

24. In a third case, in a gentleman of fifty-nine, the pulse became very slow, then recovered its ordinary frequency, and afterwards sank to 30 and occasionally to 22, and continued permanently slow. In this instance, though there were symptoms of cardiac disease, its precise nature was not ascertained. Chomel met with a case of disease of the heart in a young man at La Charité, in which the pulse beat regularly 28, and sometimes did not exceed 20 in the minute. Mr. Worthington has related two cases in which, in conjunction with symptoms of cardiac disease, the pulse was very much reduced in frequency. In one of these, a gentleman, between forty and fifty years of age, who had a pulse ordinarily of 75, the beats sank to only 40. In the other, a gentleman of seventy had a pulse of only 26. Dr. Addison mentioned at the Medico-Chirurgical Society, in the discussion on Mr. Holberton's paper, that he had seen a case in which, with epileptic paroxysms and a loud bruit at the heart, the pulse was as low as 24, and sometimes even as 20. Dr. Stokes, in the paper referred to, relates two cases of remarkable slowness of pulse, in both of which there were symptoms of cardiac disease. The patients were sixty-eight and fifty years of age, and the rates of the pulse were 28 and 32, and 35 and 40 respectively; and in the first case there were also pseudo-apoplectic attacks at intervals.

(To be continued.)

SUB-ACUTE GLAUCOMA OF BOTH EYES— TREATMENT BY IRIDECTOMY.

By J. G. HILDIGE, F.R.C.S.I.

THE following case shows in the most marked manner the beneficial effects of iridectomy in arresting glaucomatic inflammation, Medical treatment having been previously had recourse to without effect:—

Miss M., aged 35, residing in this city, consulted me on November 24, suffering from glaucomatic inflammation of the left eye. She stated that she had always had good sight of that eye until about ten days previously, when she commenced to remark that everything she looked at with it appeared as if enveloped in mist. This continued to increase, and after four or five days, intense pain set in in the eyeball and temple, followed almost immediately by partial loss of vision. She consulted a Medical man, who prescribed for her, but, as the remedies failed to produce any effect on the disease, she was referred to me. On examination, I found the eye in the following state:—Eyeball of stony hardness, slightly prominent, and painful on pressure; conjunctiva injected, particularly in the neighbourhood of the ciliary ligament; ciliary vessels prominent and tortuous; pupil dilated; iris discoloured, of a greenish hue, and arched forward so as almost to obliterate anterior chamber; the lens and its capsule were quite transparent, but the vitreous humour was so clouded as to prevent ophthalmoscopic examination. She had lost all useful vision with the eye, being unable to recognise the features of persons standing close to her, or to distinguish a single letter of No. 20 of Jager's test-type, letters about one inch long, when held close to her face. The pain in the eyeball and temple was continuous, and almost intolerable. The right eye was commencing to show symptoms of the disease also, but as yet there had not been any pain in it, and the sight of it was still good. I performed iridectomy on the left eye, on the following morning, her sight having been tested immediately before the operation by Mr. Colles, President of the Royal College of Surgeons, Ireland, and found to be in much about the same state as on the previous day. On visiting her in the evening, she expressed her satisfaction at the complete relief from pain resulting from the operation. During the night intense pain set in in the other eye, and on the following day this eye also was found to be attacked by glaucoma in its sub-acute form. Iridectomy was immediately performed, with almost instantaneous relief; no irritation following either operation, which, in both instances, was done upwards, the slight irregularity of the pupils being completely covered by the eyelids. Vision of both eyes gradually improved from this date up to December 16, on which day she called on me at my request for the purpose of having her sight tested in the presence of Mr. Colles, and other professional friends whom I had invited to be present at her examination. Both eyes had recovered their normal tension, no injection of conjunctiva, pupils of normal size, and the irides had assumed their natural colour (grey). The left lens was slightly hazy towards its external margin; the right

was perfectly transparent. Both optic discs presented appearances of congestion, and were difficult to distinguish from the surrounding parts of the retinal field. Vessels scarcely discernible. Vision was now so good that she could count the panes of glass in a window at the distance of between thirty and forty yards with the naked eye; she read No. 8 of Jager's text type also without glasses, and with No. 2½ cataract glasses she read small type with each eye separately, to the amazement of the bystanders.

I have not the slightest doubt on my mind that, had iridectomy been delayed but a few days longer in this case, both eyes would have been irretrievably destroyed.

Seven years ago, while pursuing ophthalmological studies at Berlin under my illustrious friend and teacher, Professor Von Graefe, I had the pleasure of translating into English an article written by him, in reply to an attack made on the employment of iridectomy, by Messrs. Wharton Jones and Maekenzie, published in the *Medical Times and Gazette*. These gentlemen denounced that operation as an absurdity, and a proceeding devoid of common sense. It is with sincere pleasure I learn that the former of these gentlemen has found out his error, and has the magnanimity to confess it. In the last number of the *British Medical Journal* he makes the following statement:—"In cases of arthritic posterior internal ophthalmia, or, as it is called, acute glaucoma, lateral excision of the iris has been often followed by a very satisfactory subsidence of the inflammation, with a corresponding improvement of sight. The operation in such cases has appeared to promote the subsidence of the inflammation more effectually than simple evacuation of the aqueous humour."

If I am not very much mistaken, many others, who are now fierce opponents of iridectomy, will, before long, also find out their error, and follow in the footsteps of Mr. Wharton Jones.

Dublin, December 22, 1863.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

CHARING CROSS HOSPITAL.

ANEURISM OF THE SUBCLAVIAN ARTERY— LIGATURE OF THE AXILLARY ARTERY— FAVOURABLE PROGRESS.

(Under the care of Mr. CANTON.)

JAMES J., aged 32, a negro, from Barbadoes, was admitted into the Charing Cross Hospital, on December 1, 1863, under the care of Mr. Canton, for an aneurism of the right subclavian artery. Three months before he felt a sudden and severe pain at the inner end of the clavicle, just after driving a large nail with a very heavy hammer. This was followed by a pulsating swelling at the same spot. It was at first small, but had since much increased. His health had become more and more impaired, and his voice very weak. When admitted he had no appetite; his nights were sleepless from constant pain in the arm and hand of the affected side, accompanied with numbness and some amount of swelling of the limb. The fingers were very much clubbed, contrasting remarkably with those of the opposite hand.

Examination showed a pulsating tumour behind the middle third of the clavicle, prominent both above and below this bone, and extending four inches in an oblique and outward direction. Pressure on the axillary artery stopped the pulsation, and by the stethoscope an aneurismal bruit was very distinctly heard. *Fremissement* was most felt over the innominate at the inner end of the clavicle. The pulse on the affected side was 98 and weak; that on the opposite side, however, was small also.

After his admission, opium was given in full doses to relieve pain, with but trifling effect.

On Saturday, December 12, Mr. Canton tied the axillary artery; the tumour immediately ceased to pulsate. The limb was wrapped in cotton wool. In the evening, the patient expressed himself as very much relieved; the temperature of the limb was but slightly diminished, and the following day the temperature of the two limbs were the same.

The artery was tied at the inner edge of the coraco-brachialis, as high up in the axilla as possible. On separating this vessel a small branch was wounded near its origin from

the main trunk. Mr. Canton, therefore, after passing the double ligatures under the axillary artery, tied it by one of the threads above, and by the other below, the origin of the wounded branch.

In this case it seemed clear that the inner third of the subclavian artery was affected, as well as the outer two-thirds. Not only was there evidence of this in the fact, that pain was first felt in the right sterno-clavicular region, but at the time of the operation there was *fremissement* in this position. This was further confirmed by the remarkable change in the voice, which showed that in all probability the recurrent laryngeal nerve was affected. To have tied the subclavian would have been impossible; and, therefore, the only choice was to perform the distal operation, ligature of the axillary—Brasdor's operation. Ligature of the subclavian in the first part of its course has been performed seven times, but never successfully. "The operation," says Erichsen, "is bad in principle, and unfortunate in practice." The distal operation for the cure of aneurism of the lower part of the common carotid has been successfully practised, but then it must be remembered that this part of the artery gives off no branches; whereas, a very large trunk, the vertebral, opens into the subclavian. "Dupuytren (we quote again from Erichsen) ligatured the axillary artery under the pectoral muscles in a case of subclavian aneurism, two arterial branches being divided in the incisions through the fat and cellular tissue; and the patient died on the ninth day. This is the only instance, to my knowledge, in which the distal operation has been attempted for the cure of this disease." Still, no other operation than the distal could have been performed in Mr. Canton's case, and the patient was at once relieved of pain; has had to this date, December 30, no unfavourable symptoms; the pulsation is less, and the tumour is firmer. His voice also is stronger than before the operation.

THE ROYAL LONDON OPHTHALMIC HOSPITAL.

CASES OF RETINAL DISEASE OCCURRING IN THE COURSE OF KIDNEY DISEASE.

(Cases under the care of Mr. HULKE.)

PATIENTS suffering from chronic kidney disease not infrequently have defective sight. In many instances the defect commences as a slight dimness, which slowly increases, but not always at a uniform rate, for it is sometimes suddenly intensified, and again decreases. The eyes do not outwardly exhibit any signs of disease recognisable by the unaided observer, except a large sluggish pupil. When one eye only is affected, the sight of this may be nearly lost before the patient is aware of it, if the other eye remains good. Usually both eyes are similarly affected, though in unequal degrees. The following are examples:—

Case 1.—A brassfounder, aged 50, out of work, and badly fed, thought one day that his sight was dim, and, shutting his left in order to try his right eye, found that this was "quite blind." Three weeks afterwards, when he came under my care, the obscuration had decreased, so that with the right eye he could distinguish my spread from closed fingers at six inches distance, though he could not count them. The field of vision was very small. When the left eye was covered the pupil of the right eye dilated, and remained motionless. His complexion was pale; his eyelids were slightly puffy; and his urine was albuminous. He had had ascites and anasarca, which lasted nearly a year, nine years before.

Ophthalmoscopic Appearances.—A dull, greyish opacity of the optic nerve disc, so that the vertical portions of the vessels are hidden. The surrounding retina, in a zone about twice as broad as the diameter of the disc, is grey and opaque, concealing the choroid, which first becomes visible towards the border of the zone where the opacity of the retina decreases, and is not sharply definable till some distance further towards the equator of the globe. The opaque zone, and especially the yellow spot, are powdered with minute, shining, white dots. The retinal vessels seem to end in a tapering manner at the surface of the optic nerve disc, and are indistinctly seen in the opaque zone, where the calibre of the veins appears to be smaller than in the transparent part of the retina beyond the zone, where the veins are swollen and tortuous. The blood-column in the arteries is thin. The arterial coats appear to be thick, and the calibre diminished. In the fork, between the two lower primary branches of the retinal vein, there is a large patch of extravasated blood.

Case 2.—A short, stunted, poek-marked shoemaker came to the Hospital July 24, 1863, complaining that his sight had begun to fail eight weeks before. He read No. 20 of Jager's test types with his left, and No. 14 with his right eye, slowly and hesitatingly.

Ophthalmoscopic Appearances.—A reddish-grey opacity of the right optic nerve disc, affecting the periphery more than the centre. A similar opacity of the entire left disc. In each eye the disc was surrounded by a belt of dull, opaque, grey retina, in which the arteries were nearly hidden, and the continuity of the veins was apparently often broken. In the left retina there were numerous patches and brushes of extravasated blood, which generally radiated from the optic disc.

Boiled with nitric acid, his urine deposited nearly one-third of its bulk of albumen. He had had dropsy in July, 1862, and a former attack twenty-six years before, which was followed by jaundice.

Case 3.—A seamstress, just convalescent from dropsy, was affected with sudden dimness of both eyes, and a fortnight after this came to the Hospital. She was very feeble, had a blanched complexion, a cough, had not menstruated for three months past, and before that very irregularly. With the left eye she reads words in No. 18, with the right, words in No. 20 test type, spelling letter by letter, and unable to see more than a word at one time.

Ophthalmoscopic Appearances.—In both eyes reddish opacity of the optic nerve disc. A slight satiny haze of the yellow spot, stippled with minute, shining, white orbs, and flecked with punctiform extravasations of blood. A month later the retina around the nerve disc had become hazy.

Her urine was albuminous. She had had two former attacks of dropsy eight years before.

Case 4.—A painter, aged 54, who drank three or four pints of beer a-day, and was "tipsy once in a way," happening to close his left, found that his right eye was nearly blind. Eight months after this discovery he came to the Hospital. He thought his health good, but he had a sallow, waxy complexion, and his urine was loaded with albumen. With his right eye he could only just distinguish light and shade. When both were equally exposed to light, the left eye did not show any sign of disease; but when the left was covered, the pupil of the right eye was large and nearly motionless.

Ophthalmoscopic Appearances.—The optic disc had an opaque, dull, light grey colour. The retinal artery and its branches had a remarkable chalky whiteness. In its primary divisions at the optic disc, and for some distance beyond this, there was a broken axial red streak, bounded on each side by a white line, the contour of the vessel. In some parts the red streak was more sharply defined and of more equal breadth than in others. Its edges faded off, and where broken the ends of the streak tapered. In the secondary divisions of the artery the red streak was thicker, occupying more of the vessel, was less interrupted, and there were short lengths of vessel where it filled the whole contour and broke the continuity of the white thread. In the tertiary divisions the red streak was still less broken; the smallest visible arteries were merely studded at increasing intervals with white dots. A branch of red coral, coated with whiting, and scraped so as to allow the red to glimmer through the white, would give a rough idea of the appearance of the artery.

On inquiry, he replied that his left eye had been failing two months. Its optic disc was red and opaque, and the primary divisions of the retinal vessels were slightly masked.

Remarks by Mr. Hulke.—The structural alterations which give rise to these morbid appearances have been ably worked out by German investigators, with whom the retinal disease appears to be more common than with us. Summed up briefly, the greyish opacity of the nerve-disc and retina proceeds from serous infiltration, from sclerosis and hypertrophy of the connective tissue, and from a nodular thickening of the nerve fibres, which acquire such dimensions that some have maintained them to be sclerosed ganglion cells. The small, brilliant white dots are groups of large, granular oil-corpuscles, situated in the layer of the outer and of the inner granules. Schweigger supposes that they originate in the connective tissue corpuscles. The redness of the optic disc is from capillary congestion, and perhaps also from the presence of new vessels. The apparent interruption of the vein is due to the intervention at those spots of a thicker layer of opaque retinal tissue between them and the observer. The white appearance of the arteries is caused by amyloid changes in their walls, with corresponding diminution of their calibre. The hæmorrhages proceed from - a, the disturbed vis

capillaris resulting from the morbid state of the blood produced by the kidney-disease; *b*, an increased mechanical resistance to the free efflux of blood through the veins at the nerve-disc offered by the sclerosed connective tissue; *c*, and in some cases, hypertrophy of the left ventricle, which urges the blood more freely into the retina than it is able to escape from it. These are the morbid changes which cause the loss of sight. The sudden obscurations (distinguished from accidentally-discovered pre-existing dimness) depend on hæmorrhages, and their recession coincides with the removal of the extravasated blood. Some cases are susceptible of considerable improvement by treatment. That which I often follow consists in putting a leech to the temple once a week, and the internal exhibition of the tinct. ferri muriatis. Corrosive sublimate, so useful in some forms of retinitis, has not appeared to me to be serviceable here.

HOSPITAL NOTES.

INTERNAL ADMINISTRATION OF BELLADONNA IN CASES OF SEVERE BURN.

EXPERIMENTAL physiologists have recommended belladonna for use in the treatment of burns, in the belief that it diminishes that state of the nervous functions under which reflex inflammations are likely to be originated. They assert, on the other hand, that of all remedies opium is the one most powerful in increasing this peculiar state, and that it ought consequently to be avoided. In clinical practice, however, we believe that this opinion is wholly disregarded, and that opium is the form of anodyne most commonly resorted to in these cases. Yet it is generally suspected that the causes of death after burns are, in a majority of instances, connected with reflex inflammations, *e.g.*, ulcers of the intestine, pneumonia, &c. In a series of cases under Mr. Hutchinson's care in the London Hospital during the last six months, the belladonna treatment has been tried. In some remarks at the bedside of a patient the other day, Mr. Hutchinson stated that he considered the general results to have been fairly satisfactory. He adverted to the extreme difficulty of forming a trustworthy conclusion on such a matter, since these cases are, in their nature, never stationary, but always tend either to improvement or the reverse, and often with great rapidity. If, therefore, the remedy were commenced when the patient was very ill, it might chance to be just at the time when improvement was about to set in; and if, on the other hand, the patient got worse, it might fairly be alleged that the remedy was used too late. If, on the other hand, we should give it in cases in which, as yet, no serious symptoms had appeared, we might again be much led astray, since a great majority of burn cases do well without any special plan of medication. Mr. Hutchinson stated that the cases in which the remedy had seemed to be most useful, were those of children in whom general febrile symptoms, attended with restlessness, loss of appetite, &c., had set in without any local complications. In several of these, there could be no mistake that the feverish state had passed away quickly and very satisfactorily under the use of belladonna. In no cases had he witnessed any ill results. If the burn itself was very painful, and the patient unable to get sleep on account of the pain, then the belladonna seemed comparatively inefficacious to procure ease, and morphia was far more efficient. As a rule, no opium had been given to the cases treated by belladonna; but in a few, and those chiefly in adults, it had been found requisite to give an occasional night dose. Possibly more benefit might have been obtained had the administration of the belladonna been pushed to larger doses. The usual dose given had been a third of a grain three times a day. In speaking of the less frequent results of burns, Mr. Hutchinson mentioned a recent case in which acute inflammation of one hip joint, followed rapidly by dislocation, had occurred in a child who had been severely burnt on the arm and chest. He was in doubt whether to regard it as a reflex inflammation, or as a consequence of pyæmia.

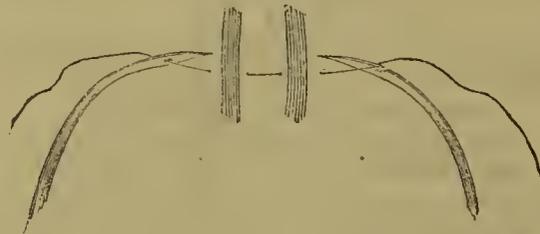

A SIMPLE MEANS OF INFLATING THE TYMPANUM IN SOME FORMS OF DEAFNESS.

Mr. Hinton, Surgeon Aurist to Guy's Hospital, in forms of deafness dependent on obstruction of the Eustachian tubes from thickening of the mucous membrane, or from accumulation of mucus, has frequently used a method of inflating the tympanum, which has been recently introduced by Politzer,

of Vienna. The plan of treatment is founded on Mr. Toynbee's discovery, that the Eustachian tube is naturally closed, but that it is opened by the tensor and levator palati muscles during the act of deglutition. Acting on this fact, Politzer conceived that air introduced with moderate pressure into the nostrils during the act of swallowing, the nose being at the same time closed, would be a very efficient means of overcoming any resistance which might exist in the internal auditory passages. During swallowing, the velum palati is raised, and, if the nostrils are also closed, the upper part of the pharynx forms a shut cavity, within which the in-pressed air operates with great effect, while the tube is at the same time expanded by the above-named muscles. The method Politzer proposed was the use of an Indian rubber bottle, to which a portion of flexible bougie is attached in place of the ordinary nozzle. This being introduced into the nose, and the nostrils firmly closed over it, the patient, who has previously moistened his mouth with water, is told to swallow, and at the same moment the bottle is compressed by the hand of the Surgeon. Air seldom fails to enter the tympanum, and its entrance may be heard by means of the ordinary otoscope, or its effect upon the membrana tympani witnessed through the speculum. Mr. Hinton has found that a simple piece of Indian rubber tubing answers every purpose, and is often even more efficient. One end of the tube is introduced into the patient's nose, which is firmly closed over it, the other is placed in the Surgeon's mouth, who then blows while the patient swallows. In the great majority of cases the method is at least as efficient as the introduction of the Eustachian catheter, while it is free from many of the objections to which indiscriminate Eustachian catheterism is open. The results are often very striking.

USE OF TWO NEEDLES IN PLASTIC OPERATIONS.

The annexed cut represents a very easy method of passing sutures in staphyloraphy and some other plastic operations, recently introduced by Mr. Spencer Wells:

The needle to the left is the ordinary needle, with the eye near the point, and the shaft fixed in a wooden handle. That to the right has, instead of the eye, an open curve or notch, as in Mr. Brooke's aneurism needle. After paring the edges, the needle to the left is first introduced, and that to the right almost immediately afterwards. Indeed, the introduction of the two needles may be nearly simultaneous. The thread near the eye of the first needle is then caught in the notch of the second, and, on withdrawing both needles, the thread is left in its place. As it is quite as easy to catch the thread with the second needle as with forceps, much time is saved by this simple contrivance. Wire may be used instead of silk if desired, or the silk may be used to draw wire after it; but Mr. Wells has almost discontinued the use of wire for sutures, finding that good silk is equally useful, and free from many of the disadvantages of wire.

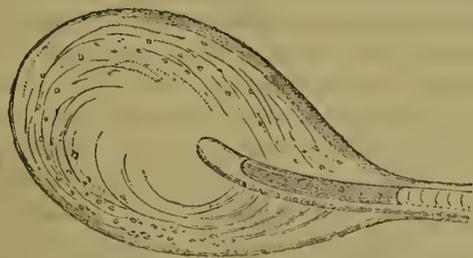

PEMPLIGUS CURED BY ARSENIC.

A very instructive case, in proof of the almost specific virtue of arsenic in relapsing pemphigus, came under notice amongst Mr. Hutchinson's out-patients at the Metropolitan Free Hospital a few weeks ago. The patient was a girl of about fourteen, who had been under treatment, in the first instance about three years ago, on account of severe pemphigus. She had then suffered from the disease for several months, and had been under much treatment on account of it. The eruption was freely out in large blebs, and she was emaciated and feeble. Immediately on commencing the use of arsenic she began to improve, and in the course of a fortnight she was quite well. Not a single fresh bulla showed itself after the first few days of the treatment. In the end, not only was the eruption quite cured, but the girl's general health was very much benefited. Mr. Hutchinson remarked at the time on the great tendency to relapse which this disease usually shows; and stated that, according to his experience, although arsenic almost invariably cured it at once, yet that relapses

must be expected once or twice in the twelvemonth. If, however, on each occasion arsenic were resorted to, the patient's state of health would gradually improve, and each successive attack might be expected to be milder than the former ones. In this instance the mother of the patient was charged to bring her again should the eruption return. No relapse occurred, however, until the one which brought the patient under our observation a few weeks ago. It was a very slight one, and not more than a dozen bullæ were out. They were, however, quite characteristic of the disease in question. Arsenic was again prescribed, and in about ten days the girl was quite well.

LITHOTRITY IN THE FEMALE.

At the Samaritan Hospital, last week, Mr. Spencer Wells showed nine drachms of fragments of a calculus which he had removed from a female, at one sitting, after breaking the stone by an ordinary lithotrite. The accompanying drawing represents the end of the double current catheter through which many of the fragments were washed. It will be noticed that jets of water are thrown by the syringe along the under or convex side of the instrument. The object is to wash up

any fragments which gravitate to the most depending parts of the bladder, and to force them towards the large opening on the concave surface of the instrument. This opening may be closed or increased by pushing forwards the strong spring slide, which, though sufficiently strong to crush any small fragment, leaves a very free channel for the passage of anything smaller than a pea. The instrument is made by Mathieu, of Paris. Mr. Wells states that lithotripsy is so easy and successful in the female, never being followed by incontinence of urine, that dilatation of the urethra, or any form of lithotomy, should only be performed under some very rare or exceptional circumstances. He finds that, both in the male and female, the plan of removing the whole of the stone at one sitting can generally be accomplished; and the chief objection to lithotripsy (namely, the irritation caused to the bladder by the fragments, and to the urethra by their passage) is thus safely obviated.

INSUFFLATION OF POWDERED ALUM IN CHRONIC CATARRH OF THE MUCOUS MEMBRANE OF THE AUDITORY MEATUS AND TYMPANUM.

Mr. Hinton has found the application of alum in powder very effective in certain forms of chronic catarrhal inflammation of the meatus and tympanum, which are otherwise often tedious in yielding to treatment. It is especially suitable when there exists a red and granular condition of the membrana tympani, or mucous membrane of the tympanum, with or without minute polypoid growths, such as often lasts from childhood even to the latter years of life, and which are so frequently met with, all acute symptoms having long ago subsided. The alum is easily introduced, after the ear has been gently syringed, either on a moistened camel's hair brush, or, which seems often more efficacious, it may be blown into the meatus through a piece of India-rubber tubing. After a few applications, efficiently made, the unhealthy condition will often be wholly removed, and with it the discharge, the hearing being at the same time, unless other lesions are present, greatly improved.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Alexander Thom, Esq., A.M. of the University of Aberdeen, of Crieff, has been recently elected a Fellow of the Royal College of Surgeons of Edinburgh.

ACADEMIE DE MEDECINE.—For the ensuing year M. Grisolle has been elected President of the Academy, M. Malgaigne, Vice-President, and M. Béclard, Annual Secretary.

TERMS OF SUBSCRIPTION.

Twelve Months (Prepaid) stamped for post £1 10 0
Six Months (do.) 0 15 0

Regularly transmitted by Post throughout Great Britain, and to the most distant of the British Colonies.

The Journal can be obtained of all Booksellers and Newsmen, Unstamped, for £1 6s. per Annum.

Post-office Orders and Drafts on Army or Navy Agents, should be made in favour of Mr. JAMES LUCAS, 11, New Burlington-street, W.

Medical Times and Gazette.

SATURDAY, JANUARY 2.

ANNUS MEDICUS 1863.

ONCE more our ever-onward march brings us to one of those divisions of time when we may well pause for a few moments to cast a glance back, and recall the principal events, concerning our Profession, of the past year—when we may take stock, and note our gains and losses in the year 1863.

The Great Reaper has, as usual, been busy among us. The death-roll is long and heavy; it contains the names of some who were gathered-in in "the serc, the yellow leaf," after lives of great and continued fruitfulness, of unwearying activity and pre-eminent usefulness, accompanied and crowned by all

"That which should accompany old age—
As honour, love, obedience, troops of friends."

Such men were, among others, Evans, of Belper; Jones, of Derby; J. Soden, of Bath; and W. Kingdon, of London. Some, on the contrary, were taken in the very spring-tide of Professional life, just as they were putting forth a rich promise of bud and blossom—as Dr. Pardey and Mr. Wakefield Skey. And some, again, fell in the midsummer or early autumn, in the full vigour of fruit-bearing, when we were looking that they should still add to our stores for years to come, as they had done in the years past. Such were Drs. Challice, Nelligan, and Allan Webb; Messrs. Ancell, Quiller Couch, H. C. Johnson, and Peter Martin.

Lives of all these gentlemen will be found in our columns. Of various gifts, and various degrees of talent, they were all of them true, hard, unsparing—in some instances, alas! fatally-unsparing—workers; noble examples of men giving themselves and all their energies, with untiring devotion, to the practice of the Profession they had chosen. And, even as we write, the passing bell tolls for another, and one of the most eminent of our brethren,—the nephew, pupil, and successor of Cline, the colleague of Sir Astley Cooper, the eminently-successful practical Surgeon of twenty years ago, and ever since one of the most honoured among the fathers and dignitaries of the Profession—the man of whom Samuel Taylor Coleridge was especially the "guide, philosopher, and friend"—Joseph Henry Green, as stately in thought and speech as he was of form, a king among men, rests from his labours, leaving a vacancy which no living Surgeon is competent to fill.

Worldly honours and distinctions ever observe, in their visits to our Profession, the manner and fashion attributed to angels. Such as have fallen to our lot in the past year were well and worthily bestowed. The Court appointments, in the households of Her Majesty and of the Prince of Wales, were made with a degree of discrimination and judgment that justly gratified and excited the approbation of the whole Profession. The extensive changes lately made in the Crown nominees to the General Medical Council caused some surprise, but certainly no disapproval. Whatever the merits

and eminence of those who enjoyed the distinction of being the first Crown nominees, the gentlemen who replace them are equally well fitted for the appointment by their position and standing among their brethren; while, from their being younger men, they will probably have more sympathy, and a better acquaintance, with the wishes of the Profession at large on the subjects that may come before them; and one of them is well known to have made "State Medicine" his special study. The Crown has set a good example in not making re-election a matter of course. Full details of the last session of the Medical Council were given in our current numbers. It is to be hoped that the infusion of new blood will give more vigour and decision to their proceedings, so that these may not so forcibly remind us of the story of the statesman who, to his sovereign's question, "Well, what have you passed this session?" replied, "May it please your Majesty, six weeks."

An attempt has been made, in one of the higher courts of law, to call in question one of the few acts of the Council—the removal of a person's name from the Medical Register for "infamous conduct in a Professional respect;" but the judges refused to entertain the matter, affirming that jurisdiction lay solely and entirely in the Medical Council.

As to the new Pharmacopœia, it would appear as though "Man never is, but always to be blest." The Pharmacopœia committee "confidently predicted that it would be published by October at the latest," and it is still "*in futuro*." We are happy to observe, however, that it is advertised to appear shortly, and that the Lords of the Treasury have settled its price.

In Parliament, Acts were passed "to extend and render compulsory the practice of vaccination" in Scotland and Ireland. In both bills the principle which always guides the Legislature, when our Profession is concerned, of requiring as much as possible from the Medical man, and paying him nothing, or as near it as possible, was well kept in view, and carried out with a degree of success highly encouraging—to the Government.

Small-pox has been epidemic in England, and its prevalence has been partly accounted for in a valuable report published by the Medical Officer to the Privy Council, showing how very unsatisfactorily and imperfectly the English Vaccination Act works. It appears, for instance, that in the elementary schools examined by the inspectors, from 30 to 40 per cent. of the children had not been vaccinated at all; and of the vaccinated, not more than half could be considered as well protected, vaccination being so often carelessly or unskilfully performed.

At the annual election of Councillors of the Royal College of Surgeons in 1862, the Fellows plainly intimated that they intended in the future to exercise a more potent influence in the management of the College, and they did so at the sacrifice of a highly respected and esteemed member of the Council, who, retiring by rotation, presented himself for re-election. In 1863 they repeated the lesson more strongly and unmistakably, rejecting *two* old members. The Fellows seem thoroughly determined that the Council of their College shall no longer be an obstructive body, stagnating in secret conclave, and barring the way to reforms in Professional education and progress.

The Army Medical Service, which ought to be highly attractive and popular, remains at a heavy discount. We have at various times in our columns fully discussed the grievances complained of by the department. Some of them may be, and doubtless are, exaggerated, but some are genuine and weighty, and they seem likely to work their own cure. It is understood that, at the last Army Medical Examination, only forty-five candidates presented themselves to "compete" for ninety-five commissions; thirty-three of the forty-five passed, none in the first class, the majority in the third. Facts like these are arguments of irresistible force, and the Horse Guards' authorities are taking alarm at the dearth of Medical officers.

They will be compelled to make such changes as are necessary to restore the efficiency and popularity of the Service; and, having done so in their Royal Mistress's name, they will not again venture to sully it by breaking faith with those who, on the strength of such changes, accept her commission.

The new Warrant for the Indian Medical Service—said to be of a highly liberal character—has, it is understood, been objected to, at the last moment, by certain authorities, and is, unhappily, shelved: it was, we suppose, too wisely and justly liberal to go down with the military authorities. Dr. Charles Hathaway, the private secretary to the new Governor-General of India, is an eminent officer of the Indian Medical Service, who, after having filled several important appointments, was, in 1862, Special Sanitary Commissioner. His appointment to such a post as he now fills is encouraging, as it will secure increased regard and consideration for the Service from the highest authority in India at any rate, whatever degree of narrowmindedness and "combative officer" exclusiveness may prevail at home.

La Rochefoucauld, in one of those cynical maxims which owe all their pungency and force to their being based on a certain degree of truth, declares that the greater the benefit one man receives from another, the more likely he is to prove ungrateful. "Almost every one," he says, "takes a pleasure in requiting trifling obligations: many people are grateful for moderate ones; but there is scarcely any one who does not show ingratitude for great ones." Now, it may be affirmed that, family relationships being left out of the question, there are no social conditions under which one person receives more direct and personal benefit from another than does a patient from his doctor; it is therefore, perhaps, only to be expected that under no other conditions should there occur grosser instances of ingratitude and repayment of good by evil. Vivid and painful illustrations of this, and of some of the dangers incurred by Medical men in the most honest and straightforward discharge of the plainest and most necessary duties of their Profession, have been afforded during the past year by the actions of *Russell v. Adams*; *Morgan v. Lingen*; *Bromwich v. Waters*; *Hodge v. Chalmers and Others*; and of *Symm v. Fraser and Another*. All these cases are bad enough, but in the last, vindictive recognition of benefits received, and hostility perfectly groundless except on the above hypothesis, seem to have reached their climax; the force of ingratitude and of legal license and injustice can no further go. Even the fertile imagination of the author of "*Very Hard Cash*" would find it difficult to conceive grosser and more unfounded calumnies against our Profession than the prosecuting counsel permitted himself to utter to the jury in this instance; and no more flagrant example can be adduced of the dangerous facility with which a patient can find legal tools to take up a case, however weak and iniquitous—legal instruments wherewith to torture and pillory a Medical man for performing, in the most humane manner, his bare duty. Fortunately, in all of these actions, the defendants obtained a verdict—but at what a ruinous expense!—at what an incalculable cost of mental anxiety and suffering!

The whole Profession is deeply indebted to the Lord Chief Justice of England for the clear and admirable exposition of the duties and responsibilities, the social importance, and public usefulness of Medical men, contained in his lucid and forcible summing-up in this case.

Some other trials directly affecting, or of special interest to, the Profession have taken place. In *Gibbon v. Budd* it was decided that a member of the Royal College of Physicians has a legal right of action for his fees without a special contract. This right arises from a by-law of the College. We much regret it, as likely to lower the *status* of a Physician in the estimation of the public. Some of the disadvantages and difficulties that may arise from his being thus lowered to the level of a trader, and losing the custom of receiving "his fee while the tear is in the e'e," have been further illustrated by the case of *Freund v. Bolderman*.

In the Malton County Court, a lodging-house keeper recovered damages against a gentleman who sent into the house some members of his family just convalescent from scarlatina. The fever spread to members of the lodging-house keeper's family, and the defendant was held responsible.

The Grosvenor-place Medical School—the last of the independent schools—the descendant of the Hunterian school—has ceased to exist. The immediate cause was the expiry of the lease of the School buildings; but the establishment of the Schools of St. George's and St. Mary's Hospitals had absorbed the students of that end of London, and the Grosvenor-place School had been lately in a languishing condition. It had in its day rendered eminently good service, and among its pupils may be enumerated many men of mark, as W. E. Page, A. J. Sutherland, C. Guthrie, Baker Brown, Prescott Hewett, George Pollock, C. Babington, A. T. H. Waters, and Mr. Holthouse.

Two of our general Hospitals—one of the oldest and most richly endowed, and one of the youngest, and entirely dependent on public support—have been compelled, by the railway invasion of the metropolis, to seek new sites. St. Thomas's, temporarily located in the Surrey-gardens, has, after protracted delay, caused, apparently, by an *embarras de richesses*, chosen a site, to be called into existence by the end of 1865, on the most fashionable verge of the quarter it was intended to benefit. We believe, however, its choice is to be disputed yet in the Court of Chancery.

The Great Northern has found a habitation near the New Cattle-market, in the very heart of the northern districts, to which it supplies Hospital accommodation.

Of the mental activity of Medical men during the past year the columns of the Journal have contained ample evidence. We have been incessantly busied in accumulating and storing-up observations and facts; and in sifting, comparing, and collating them; with, however, too little of the latter as compared with the former processes—with too much of ingestion and too little of digestion. This last seems too slow a proceeding for us now-a-days, and, when performed at all, is too apt to be performed hastily and crudely; hence, we are always busy also in pulling down or revising old theories and building up new, in their turn to be revised or ruthlessly overthrown. Among the subjects most prominently before the Profession have been—Iridectomy, which, like the British constitution in 1855, is on its trial; the use of the Laryngoscope, the value of which as a means of diagnosis is in many cases indisputable; "Vaccina Syphilitica," about which there has been much discussion, with not very definite results—some, perhaps we may say most, authorities declaring that cases have occurred which are indisputable proofs of the possibility of the transmission of syphilis by vaccination, and others regarding these same cases only as exceptional and accidental—as fortuitous coincidences, in which is to be found no relations of cause and effect; and Ovariectomy, which is fully established in England as a perfectly justifiable operation. It has been successfully performed, also, in Ireland and Scotland, and in France in the provinces. In Paris it is still a fatal operation.

Thanks to the courage and science of the Rev. Dr. Haughton, traumatic tetanus and strychnine poisoning have been successfully treated with nicotine.

Vivisection has been a prominent subject of discussion with the Profession and the public; the abuse of it, chiefly, if not entirely, abroad, having been made a handle for vehement and unreasoning denunciations of its legitimate employment.

In the Académie de Médecine, yellow fever and hydrophobia have been lengthily and wordily discussed, but nothing has been added to our knowledge on either subject.

M. Baudot has published a valuable series of experiments supporting the common-sense, practical view of the use of alcohol, and proving that this hydro-carbon is not exceptionally exempt from submission to the digestive forces, and does not act as a mysterious, incomprehensible agent of evil within

the body, and then escape with wholly undiminished volume and powers.

The meeting of the British Medical Association was highly successful; many valuable papers were read, and admirable addresses were delivered in Medicine, Surgery, Midwifery, and Chemistry; and the meeting was opened with a most scholarly and eloquent address from Dr. Symonds, the President.

At the meetings of the British Association at Newcastle, and the Social Science Association at Edinburgh, Medical men contributed a large share of the intellectual food; a mere list of their contributions would take up more space than we can command. Pre-eminent among the papers at the Social Science meeting was Professor Christison's address, as President of the Public Health Department. However opinions may vary as to the justice and soundness of his conclusions with regard to sanitary matters, and the prevailing theories on the causation of continued fevers, there can be no doubt as to the ability of the address, nor as to the value of such clear and logical questionings. Plausible errors are destroyed by them, but truth is only confirmed.

Of our own labours, it would not be becoming to say much here. Our volumes speak for themselves, and their value would not be increased by any praise of ours. But we may be permitted, without incurring the charge of undue boasting on the one hand, or of mock modesty on the other, to point with satisfaction to our having given to the Profession such series of Lectures as Gulliver's, Huxley's, and Brown-Séquard's; such Clinical Lectures as those by Laycock, Soelberg Wells, Le Gros Clerk, and Holthouse; such Original Communications as those of Professor Haughton, Dr. R. D. Thomson, the Observations in Clinical Midwifery of Ramsbotham, and the Researches in Ethnology by the late Robert Knox. Looking at these, at the stores of Hospital Medical Reports, and at the Editorial Remarks on all the prominent topics of the day, we may hope that we have, at least, kept up the reputation of the Journal, and satisfied the just expectations of our supporters.

We would rather point to the deeds of the past than make promises for the future. Yet we may say, that, whilst the Medical History of England will show the greatness and dignity of our Profession as an element in modern civilisation, the practical contributions which will appear this year will show the advances made in the actual every-day working of our art. Last year, Huxley's and Gulliver's contributions helped to deepen and widen the scientific foundations: this year, Simpson, G. Harley, and Wood, followed by an able band of fellow-labourers, will show the newest additions to our powers of alleviating disease and infirmity.

THE COURT-MARTIAL ON LIEUTENANT-COLONEL CRAWLEY.

LIEUTENANT-COLONEL CRAWLEY has received an honourable acquittal on both the charges brought against him by the authorities of the Horse Guards. Against this result of the court-martial we have nothing to say, for in truth, as those charges were framed, we do not see what other verdict could have been arrived at. But still we are far from satisfied. From the moment that the charges against the prisoner were announced, it became perfectly clear that the real question about which the people of England were most concerned was not that which it was intended to try. It remained, therefore, for those who, with ourselves, were anxious to discover what was the cause of Sergeant-Major Lilley's death, and who (if anybody) was in fault, to scrape together as they could the evidence which the chances of a trial upon other issues brought up, and make the best use of it that under the circumstances they could, for the satisfaction of their own minds. To ourselves, moreover, another grave question arose, namely, how it could be that a man could die under such circumstances as attended the death of Sergeant-Major Lilley

in an army where even a criminal is protected by the regulations from punishment of such severity or duration as might compromise his health or life—in an army where the recommendation of the soldier's friend, the Medical officer, is regarded as paramount. So acute a man as Colonel Crawley was not likely to overlook this weak spot in the case of his adversary, and he availed himself of the opportunity it afforded to shift, not only upon Adjutant Fitzsimons, but upon the Regimental Surgeons also, the blame of what occurred. Well, then, we say, that the questions that interest us are these:—1. The nature of the attack from which Lilley died; 2. The causes of the attack; 3. The conduct of his commanding officers; and 4. That of Surgeon Turnbull and Assistant-Surgeon Barnett in relation to them. This is the aspect in which we, as Medical men, naturally view the whole inquiry. Let us see what light the evidence brought forward throws upon these questions.

1. *The Nature of Lilley's Attack.*—That it was an attack of congestive apoplexy, immediately preceded by that sort of bilious derangement which indicates an accumulation of carbon in the blood, (a) seems to be tolerably clear from the narration of the case and the post-mortem appearances. This, too, was the opinion of the Surgeons; and the measures they adopted for the man's relief were those best adapted for the purpose. No doubt is thrown upon the diagnosis.

2. *What was the Cause of the Attack?*—If we were asked theoretically to lay down directions for bringing about an attack of this kind, we should say,—take a robust man, one inclined to be corpulent being best fitted for the experiment, place him in a heated atmosphere, promote torpidity of the liver, and favour costiveness by reducing the amount of his bodily exercise, enrich his blood by an ample diet, and load it thus enriched with additional carbon by unlimited supplies of beer and spirits; and, when all this has

(a) Detailed Medical case of the late Regimental Sergeant-Major J. Lilley, 6th Dragoons, aged 37 years 4 months.

A strong, healthy, well-developed man, inclined to corpulency, about 17 or 18 stone weight. Had always enjoyed good health. Reported sick when in close arrest on the morning of the 24th of May, about 9 a.m. Was immediately visited by Assistant-Surgeon Barnett at his own quarters. He then complained of colicky pains and flatulent distension of the abdomen, heaviness in the head, feeling of oppression about the chest attended with great depression of spirits, bowels distended and rather confined. A large dose of castor oil was given, and hot fomentations applied to the abdomen. They afforded temporary relief. During the day continued restless, but only referred his restlessness to griping pains and flatulent distension of abdomen. At 6 p.m., the castor oil not having acted sufficiently, and the abdominal distension and griping continuing, 8 grains of calomel were administered, and two hours after he had an anodyne and antispasmodic draught of hyoseyamus, nitrate, ether, and camphor mixture. Was again seen at 11:30 that night, when it was found that free evacuation of the bowels had not supervened since the evening visit. A large cathartic enema was then administered, which afforded immediate relief to the abdominal uneasiness. Soon after this he became restless, moaned a little; eyes dull and heavy, with an anxious expression of countenance. Cold effusion was applied to head and chest. When seen at 2:30 a.m. was insensible and breathing stertorously; pulse rapid and full, face flushed. The temporal artery was opened, and a few ounces of blood drawn. Cold effusion and spirit lotion continued to head and chest; extremities immersed in hot water and rubbed with mustard, etc.; not the slightest reaction was induced. He died comatose about 4 a.m. Had aperient medicine during the period of arrest for bilious derangement. The extreme heat at this season of the year, the constitutional predisposition of the deceased to congestion, the peculiar and painful circumstances of his position, the serious illness of his wife, causing depression of spirits, together with bilious and nervous derangement induced by a sedentary life attendant on close arrest, acted as exciting causes to produce the complaint from which he died. Troop Sergeant-Major Wakefield was admitted into hospital the 20th May, with feverish symptoms and nervous excitement. Remained in hospital. Subsequently re-admitted with slight fever. Is now convalescent. Troop Sergeant-Major Duval admitted June 5th. Suffering from slight fever and headache. Progressing favourably.

Signed, J. TURNBULL, 6th Dragoons.

Report of the post-mortem examination made four hours after death.

Body muscular, very fat, and well-developed. Dark livid patches of ecchymosis on face and neck. Head—On opening calvarium, superficial vessels of dura mater seemed much congested, and on opening it up a large quantity of serous fluid flowed out; arachnoid very opaque; normal amount of fluid in sulci; ventricles contained rather more than a normal quantity of serous fluid. On removing brain a considerable quantity of serous fluid remained in the base of the skull. Thorax—Lungs very much engorged from base to apex, and of a dark purple colour; considerable effusion of blood and mucus into the bronchial tubes; heart, apparently enlarged, and valves hypertrophied. Abdomen—Liver very much engorged, but otherwise healthy; kidneys quite healthy; spleen rather congested; stomach almost quite empty; several spots of ecchymosis on mucous membrane. Other abdominal viscera quite healthy.

(Signed) G. W. TURNBULL, Surgeon to Her Majesty's 6th Dragoons.

been effected, let his affections be harassed by anxiety, his feelings of honour shocked by disgrace, and his mind irritated by a sense of being wronged. And in Sergeant-Major Lilley's case all these conditions were present. Putting the beer and spirits out of the question, it is clear that there was quite enough to produce bilious derangement and apoplexy; but with them no one can wonder at the event. And this, too, seems to have been the opinion of the Surgeons, as expressed in their report of the case. Afterwards, in an addendum, Dr. Turnbull thus expressed himself:—

“In addition to what was stated in my report forwarded yesterday, I have the honour to add that it has been brought to my notice that the deceased was in the habit of drinking a considerable quantity of brandy daily during his arrest, and, on inquiry, I find the above statement to be correct. It is my opinion that this, in connexion with the other exciting causes before related, was calculated to increase the predisposition to an apoplectic seizure, from which he died.”

Admitting that Lilley drank as asserted, this Medical opinion cannot be challenged.

3. *Now what had Colonel Crawley to do with all this?*—That the original arrest was by his orders is not denied. But what about the continuance of close arrest, and this at a period when the heat in India is most intense? What about continuing it without bringing the prisoner to trial for a month, thus breaking through the protection in which English law envelops the liberty of every British subject, whether military or civilian. The 18th Article of War provides that “no officer or soldier who shall be put in arrest or confinement shall continue in such arrest or confinement *more than eight days*, or until such time as a court-martial can be conveniently assembled.” In this instance, Colonel Crawley was informed by the Commander-in-Chief that there was no case to go to a court-martial; and the only excuse which remained for prolonging the arrest was that of preventing communication between Lilley and Paymaster Smales, whose witness he was at a court-martial then sitting. And this ground for continuing the arrest would, as we are told by the prosecutor, have been illegal, inasmuch as it was Paymaster Smales' right to communicate with his witnesses as freely as might be necessary for his defence. That defence was made on May 10. Lilley had been in close arrest then for fourteen days, and yet his arrest was in continuance on May 25, when he died. Now, it appears that Colonel Crawley would have been solely responsible, if the close arrest of Sergeant-Major Lilley had not been first ordered by Major-General Farrell—illegal though it was—sanctioned and approved by Sir William Mansfield, and the “arrest” ordered to be continued by him, until the final adjournment or dissolution of the court-martial upon Paymaster Smales. If this view of the prosecution be adopted, Colonel Crawley was responsible for taking the advantage of the literal reading of these orders, when he ought to have interpreted and applied them, at his own discretion, according to the circumstances of the case. However this might be, the Court appear to have considered Colonel Crawley legally justified in the course he took, and that Sir William Mansfield and the other superior military authorities were every bit as much implicated in anything that might have ensued from the strict and literal interpretation of their orders as was Colonel Crawley, their subordinate. So it has happened—as it always does happen—that this collective blame, when subdivided, was found to leave no one specially and individually liable. We suppose the “system” is again to blame. Again, “close arrest,” we believe, consists in confining the prisoner to the guard-room or his quarters, with a sentry placed outside the door. In this instance, Colonel Crawley ordered the sentry to be placed inside, and not to lose sight of Lilley day or night. The very words of the order were sworn to by competent witnesses, who were present when the order was given. We do not say that this order might not have had some excuse in the circumstances of the season; but if any annoyance was occasioned by it, all the blame is not to be shifted upon the shoulders of

subordinates. An attempt has been made to lay blame on Colonel Crawley in respect of the place in which Lilley was confined. This attempt, we think, has broken down. The first bungalow was large, capacious, and airy enough; the cubic capacity of the largest room was about 5440 feet. He was, with his wife, removed to the second bungalow on May 12. It was the best that could be obtained at the time, and, although much smaller, was still not so small or close as had been represented. The capacity of the larger room was about 3220 cubic feet, and that of the smaller, where the sentry was posted, 980 cubic feet. The real fault was confining Lilley in any place at all on May 12, a time at which, under any circumstances, he should have been at large. It has been said that the place was not unfit for human habitation (as this term is understood in military circles in India), but still it is another question whether it was equally adapted for use as a prison. We are not ourselves astonished that Lilley complained of its closeness and heat, after being confined in it for a week; for it appears that, until he asked for the privilege, he was not even permitted to use the verandah. But against all charges of harshness and undue severity in carrying out the arrest, Colonel Crawley pleads that no indulgence was at any time asked of him that he did not grant. We can only discover two such indulgences that were asked, and they appear to have been granted so ungraciously, that we cannot wonder at any one abstaining from asking more. One of these, and the first, was the request of Surgeon Turnbull that Lilley should be allowed exercise. Now, if the exercise of a man not convicted, and hence legally innocent and unpunishable, (b) is to be of any use, it must partake of something more than mere bodily exertion; it should be to some extent recreation. Even a soldier consists of something more than flesh, bones and internal organs, and unfortunately these organs are influenced for evil by conditions acting on them unremittingly through the mind. When, therefore, we read that, even in his exercise on the parade-ground, Lilley was closely attended by an armed sentry, we are in no way disposed to quarrel with the statement of Surgeon Turnbull, that "the good effect of the exercise was in a great measure nullified by the manner in which it was carried out."

4. *And now for the Surgeons*, Assistant-Surgeon Barnett and Surgeon Turnbull. What had they to do with all this—with the existence of those conditions which led to Lilley's death? We are told that the recommendations of a Surgeon in the army are paramount to all other considerations, and the Surgeons have consequently been blamed, first for ignorance of all the conditions of disease to which Lilley was exposed, and next for permitting them to continue. In his defence, Colonel Crawley absolutely went so far as to impugn the credit which was to be attached to Surgeon Turnbull's evidence, and asked "if it was not plain, beyond all manner of doubt, that there was, on the part of Surgeon Turnbull at least, a deliberate design, by a *suppressio veri* and a *suggestio falsi*, to saddle him with personal responsibility for the death of that unfortunate man?" Now, to this accusation of unworthy conduct and improper motives on the part of these Professional men, the vindication which appeared in our last number, written by one whose acquaintance with military custom and military law is beyond all question, is the reply. It is the addendum to their report, and this only, which has brought them into trouble. Their first report as to the causes of the apoplectic seizure was conscientiously true. It would have been well for them had they been content to stand by their

first report. But when Colonel Crawley informed Mr. Barnett that he had been informed that Lilley drank, and Barnett reported this to Surgeon Turnbull, the latter was obliged to cause inquiries to be made, and to report the result of these inquiries, as a matter of regular duty, to the Colonel, in the form of the "addendum." We do not indeed know, nor shall we probably ever become acquainted with, the truth as to the quantity of liquor which Lilley consumed during his arrest. That he drank at all was bad for a person in his circumstances, whether he drank "considerable" quantities of brandy, etc., or not. We hold the bill delivered by the Parsee merchant valueless as evidence, for there is no proof that all the liquor said to have been supplied between April 26 and May 24 ever reached Lilley's bungalow. It certainly is not fair to attribute neglect of duty to the Surgeons on the ground of their not reporting any anticipated injury to Lilley's health from the confinement to which he was subjected. Surgeon Turnbull's answer upon this head is an ample justification:—"I did not understand," he says, "the nature of the confinement he was undergoing. The circumstances connected with the arrest were so unusual, and, I considered at the time, of so mysterious a nature, that I did not know how exactly to act in the matter, and I never anticipated that Sergeant-Major Lilley's imprisonment would have continued so long: I thought, if he was to be tried, he would have been sent to the Hospital, so as to furnish the commanding officer with a Medical certificate." In fact, any blame on the ground of not reporting and not recommending any necessary relaxation in the arrest must lie at the door of Colonel Crawley, who was the first to break the law of arrest in not sending the prisoner first to the Hospital, for Medical inspection. He failed, in short, to give the unfortunate prisoner the benefit he was entitled to in the inspection by the regimental Surgeon. Assistant-Surgeon Barnett, indeed, saw Lilley daily, but this was not an official inspection. He saw him on visiting Mrs. Lilley, because he could not avoid doing so. At all events, Lilley did not receive the advantage of the inspection he was entitled to. The law upon this subject is sufficiently laid down, we think, in our correspondent's communication of last week, to warrant us in leaving the question as he puts it.

We must confess that it occurs to us that the position of the Surgeons was one of great difficulty, more especially as Mr. Turnbull had been before recommended by General Mansfield to "carry out his sanitary measures in harmony with his commanding officer." At the most, it can only be charged against them that they were unwilling to interfere with what their commanding officer had ordered as necessary to the discipline of the regiment—acts which in themselves were illegal, and which they could not comprehend. They were placed from the first, not only in a difficult, but in a false position; the opportunity of performing their duty was not afforded them, and no explanation given of the neglect. We can understand, too, with such a man as Colonel Crawley appears to be—a strict and uncompromising disciplinarian, to use the mildest possible description of his official character—that they would, on the one hand, strive to direct their own proceedings by the strict letter of the regulations of the service, leaving him to carry out, without remonstrance or inquiry on their part, that which he might regard as the duty which he owed to the service. For aught they knew, both inquiry and remonstrance might have been resented by him as an impertinence; certainly, they found reason to complain of his mode of receiving the only recommendations they felt authorised to offer. His manner to them as well as to other officers does not appear, from the evidence, to have been habitually such as to encourage unnecessary communications. When it is considered, too, that Surgeon Turnbull had already been reprimanded by his military superiors for the performance of his duty in the sanitary arrangements of his regiment, we can well understand the reticence which this was likely to induce. Medical officers know very well, too, that if they are to succeed in the service they have selected they must stand well with the Horse Guards.

(b) The following extract from Colonel Crawley's defence seems to indicate that he took a different view altogether of Lilley's position when in arrest:—"The ease," he said, "had been treated as one of peculiar military barbarity; but, he asked, in what respect the execution of military law differed from that of civil sentences? Did a judge, in passing sentence, take into account the circumstances of an offender's personal position in determining the measure of punishment when inflicted upon him? Did he ask what was his habit of body, or what was the exercise he was used to? Or did he inquire whether he had a wife, and if she was sick? Equality of sentence for similar offences was the rule both of civil and military tribunals. Equality of operation upon the offender was beyond the reach of human justice."—*Report in Daily Telegraph.*

THE WEEK.

REGISTRATION OF BIRTHS AND DEATHS.

At the Meeting of the Metropolitan Association of Medical Officers of Health, on Saturday last, a report was brought up, by Drs. Lankester and Buchanan, upon the present mode of registering births and deaths. It was stated that the subject had been brought under the notice of the Registrar-General, in a conference with that officer, and he had engaged to submit the views of the Association to the Home Secretary. At the same time, he could not fully agree with the opinions of the Committee. The main topics considered in this conference were the compulsory registration of all births, the registration of still-births, and the institution of official inquiry by the coroner, or otherwise, in cases of sudden death, or where any death is not certified by a legally qualified Medical practitioner. Various irregularities were referred to in the course of discussion, such as we propose, at an early period, to bring under the notice of our readers. There is no doubt that the time is not far distant when the whole subject of the Registration Act must be reviewed in Parliament.

CANDLER *v.* PEAT.

THE Court of Queen's Bench has lately furnished another instance of the injustice to which the Medical Profession is exposed by the power which the law gives to any person to bring unfounded and damaging accusations against his Medical attendant, and, without the institution of a previous inquiry into the circumstances of the case, or character of the respective parties, to have the charge investigated at an enormous expense, a large portion of which, whatever be the issue, must of necessity fall on the shoulders of the defendant. Illustrative cases have been so plentiful of late that we ventured to hope that their number would be for a time exhausted. But not so: the indignation raised by the trial of *Symm v. Fraser and Andrews* had not subsided when that of *Candler v. Peat*, an equally unjustifiable one, although lacking some of those points of surprising effrontery which made the former a topic of the day, was reported in the daily papers. The facts of this case are soon recounted. The plaintiff is a bricklayer, living at Manningtree, in Essex. On the 23rd of July, 1862, he fell from a height of ten feet, dislocating the foot backwards, and fracturing the malleolus. The defendant was sent for to attend him. He saw him the same day. He found that the foot had been already reduced by the plaintiff's brother, who, at the time of the accident, to use the plaintiff's words, "had pulled the foot forwards." Mr. Peat had the patient put to bed, placed the foot in a semi-flexed position on a pillow, and, as there was a considerable amount of inflammation, ordered some leeches and an evapoting lotion. He visited the man twice a-day. On the 5th of August, the inflammation and swelling having partially subsided, Mr. Peat put the limb up in a bandage. At that time the limb was perfectly straight, and the joint was in its proper position. Mr. Peat visited the man until the 11th of August, and up to that time everything appeared to be going on well, except that the patient was so impatient and unruly that his wife frequently had to apologise to Mr. Peat for his conduct. Mr. Peat, however, had no idea that Candler was dissatisfied with the course of treatment he pursued. On the 12th the defendant went again to the house, when he was met by the plaintiff's wife, who refused him admittance, saying that "she was very sorry, but her husband had been so obstinate that he had removed the bandage; he had complained of its giving him pain." After this, Mr. Peat never again visited him professionally. He saw him, however, accidentally six weeks later, and found then that the dislocation had returned, and that there was great deformity. Subsequently the defendant gave the plaintiff a note to Mr. Partridge, the senior Surgeon to the Colchester Hospital. The latter recommended the application of bandages, but the plaintiff refused to submit to the prescribed treatment. Mr. Peat assisted

in procuring a subscription to provide a boot for Candler, and on another occasion asked a Professional friend, a Mr. Manning, to look at the foot. After discarding Mr. Peat, the plaintiff came to London and obtained the opinion of several Hospital Surgeons, who seem to have been unanimous in the opinion that nothing could then be done to remedy the deformity. It was not until a twelvemonth after (in July, 1863) that the defendant received notice of the action, and up to that time he had never heard that any blame was attributed to him.

It is clear from the above facts, which were proved at the trial, that the patient, and he alone, was to blame for the unfortunate termination of the case. The jury at once took this view of the matter, and returned a unanimous verdict for the defendant. This, however, is but meagre consolation for Mr. Peat, who, after having been subjected to all the mental anxiety and annoyance inseparable from an action which has been hanging over his head for six months, will now have to pay his own costs, for it is utterly improbable that they can be obtained from a crippled bricklayer. It is reported that Candler has been urged on to the course which he pursued by a personal enemy of Mr. Peat's. If this could be proved, we should be heartily glad to learn that the true culprit had been made to pay for the mischief in which he has aided and abetted.

There is one passage in the opening speech of the counsel for the prosecution on which we congratulate the Profession. Serjeant Parry said:—

"There had been great difficulty in procuring Medical testimony—whether there might be a disinclination in Medical men to come forward against a brother practitioner, or from what other cause, he could not say, but in some instances a fee had been demanded which it was impossible for the plaintiff to bear."

We are heartily glad that the various Medical men who saw the plaintiff, with a single exception, refused to appear on his behalf. We have a right to believe that the disinclination of which Serjeant Parry complained is based upon a growing feeling in the Profession—that no practitioner is justified in criticising publicly the treatment pursued by another legally qualified Practitioner in a case which the former did not himself at the time witness. We think we may fairly take credit to this Journal for having insisted on this principle, and for having placed more clearly before the Profession than had been previously done, the exact conditions under which a Medical man is or is not compelled to appear in the witness-box. The only Medical witness who appeared on the side of the prosecution was Mr. Holmes Coote, of St. Bartholomew's. Although Mr. Coote occupied a singular and unenviable position, we are bound to say that he carefully abstained from offering any opinion as to the treatment adopted by Mr. Peat. His evidence was simply a statement of the condition in which he found the patient when he examined him a short time before the trial. Mr. Manning, Mr. Partridge, of Colchester, and Mr. Bryant, of Guy's Hospital, attended as witnesses for the defence, and their testimony completely confirmed that of the defendant as to the propriety of the course of treatment he had adopted. We only regret that the Medical Profession does not possess a "Defence Fund," which would insure the defendant against pecuniary loss as completely as the result of this trial has left him undamaged in reputation and character.

FROM ABROAD.—PRIZE QUESTIONS OF THE ACADEMY OF MEDICINE.—M. PERRIN ON ALCOHOL.

THE following are the subjects proposed for the prizes of the Académie de Médecine for the years 1864 and 1865:—1. The Academy Prize of 1000 francs for 1864, "Describe, by the aid of clinical observations, the complications which may involve the venous centres and their membranes during the course of acute rheumatism;" for 1865, "Traumatic paralyses." 2. The Portal Prize of 1000 francs for 1864, "The condition of the nerves in local paralyses;" for 1865, "Do there exist any specific characters of cancer, and which are they?" 3. The

Civrieux Prize of 1000 francs for 1864, "The history of ataxie locomotrice progressive;" for 1865, "The relations of general paralysis and insanity." It must be especially stated whether general paralysis is a primary affection, originating in individuals hitherto sane, or whether it often occurs as a complication in the course of simple insanity. 4. The Capuron Prize of 1000 francs for 1864, "Incoercible vomiting during pregnancy;" for 1865, "The pulse during the puerperal condition." 5. The Barbier Prize of 8000 francs for 1864 and 1865. This prize, originally established to recompense the discoverer of complete means of curing diseases hitherto reputed incurable, as hydrophobia and epilepsy, has hitherto given rise only to a crowd of fruitless pretensions, and the Academy has resolved to enlarge the programme. It will in future bestow it also upon any Surgeon who, by means of a bold operation, is enabled to arrest the course of a disease, the issue of which is usually fatal. Surgeons of all parts of the world are invited to compete. 6. The Itard Prize of 3000 francs for 1864. This triennial prize is to be adjudged for the best work or memoir on practical Medicine or applied therapeutics—such work having undergone the ordeal of publication for at least two years. 7. The Amussat Prize of 2000 francs for 1865. This is for the work which realises or prepares the way for important progress in Surgical therapeutics. 8. The Orfila Prize of 6000 francs for 1864, "Poisonous mushrooms." This is the third time that this subject has been proposed without eliciting satisfactory responses. 9. The Godard Prize of 1000 francs for 1864 and 1865, for the best memoir upon a subject in general pathology. The essays competing for these prizes, written in French or Latin, must be forwarded to the Academy by the first of March of the respective years.

M. Perrin, one of the authors of the now famous work on alcohol, has lost no time in replying to the strictures by M. Baudot, referred to in our number for December 12. He maintains that his critic lies under a complete misapprehension with regard to the argument maintained in the work in question. While maintaining that alcohol is eliminated from the economy, and possesses none of the characteristics of an aliment, it was never asserted that the whole of any given amount taken could be recovered and exhibited. This could scarcely occur in a mere chemical apparatus, however carefully prepared, and the economy is no such apparatus. However carefully experiments may be devised, large quantities of the alcohol given off by the skin and lungs (to say nothing of the portion absorbed by different organs) cannot be recovered. The assumption commonly made, that because alcohol was not found in any notable quantity in the blood or the products of secretion, it underwent combustion in the economy, was totally unsupported by the production of the resulting water and carbonic acid; and the numerous experiments set on foot by MM. Lallemand, Perrin, and Duroy, without any preconceived ideas upon the subject, having exhibited an abundance of unchanged alcohol in the excretions, the expired air, the blood, and various organs, its intravascular combustion could no longer be maintained.

The one great principle which has to be borne in mind M. Perrin observes is—that every alimentary substance contributing to nutrition, whether this be ternary or quaternary, subjected to the active forces of the chemistry of life, rapidly loses its identity, and becomes a constituent part of the blood; and never, in the state of health, in either small or large quantity, does it ever appear in an unchanged condition in the products of excretion. On the other hand, non-alimentary substances undergo no transformation, form no constituent part of the blood, and are mere foreign bodies, which the economy does its best to get rid of. With respect, then, to alcohol, the following propositions may be laid down, and are fully elucidated by the various investigations published in the work in question. 1. Alcohol, contrary to what happens with alimentary substances, sojourns in the blood as a foreign body. 2. Unlike them, it is expelled the economy unaltered through the various channels of elimination. This elimination com-

mences almost immediately after the ingestion, is constant, whatever be the quantity absorbed, and continues as long as the blood and organs remain impregnated with alcohol. 3. Alcohol undergoes no transformation within the economy, and furnishes no product of oxidation. 4. It betrays its presence by certain special effects, which are always of the same kind, and may acquire such an intensity as to become very rapidly fatal. 5. It accumulates in certain organs (the nervous centres and the liver), which, for equal weights, constantly contain more of it than does the blood. The following are M. Perrin's final conclusions:—*Alcohol may unreservedly be stated not to be an aliment.* Because—1. It exists unchanged in the blood: 2. No traces of its transformation or destruction can be discovered: 3. It is eliminated unchanged by all the excretory organs: 4. The phenomena which it gives rise to, in whatever dose it is taken, its accumulation in the nervous system, and its well-known toxical and pathogenic action, demonstrate it to be a modifier of nervous force, and negative the alimentary character attributed to it: 5. The objection drawn from the inability to reproduce the total quantity taken cannot be received by physiologists. At most, this shows that some portion becomes lost during the peregrination of the alcohol through the economy; but it in no wise proves that it has been burnt or destroyed.

M. Perrin by no means admits that, because alcohol does not undergo decomposition for the purposes of the economy, its presence is therefore useless or injurious. "In demonstrating that alcohol is no succedaneum to starch or fish-oil, but a kind of dispensator of nervous force, we have not lessened the importance of the part it is called upon to play. On the contrary, we have enlarged, specialised, and I had almost said, ennobled it. Under the new point of view, based upon experiment, all is explained concerning the organic effects and functional disturbances produced by alcoholic drinks. It is by their action on the nervous system that, taken in small quantities, they induce in exhaustion that surprising and immediate restoration of power; and it is by the same action, under the form of generous wines, that they give rise to that reaction and feeling of comfort which will be sought for in vain from the aquatic dinner, however well provided. It is through action on the nervous system that, taken in excessive quantities, they produce true poisoning; and, finally, it is by this same action that they interfere indirectly, yet most actively, in the process of nutrition, of which they appear to us to be the especial regulator and moderator."

REVIEWS.

Practical Lithotomy and Lithotrity. By HENRY THOMPSON, F.R.C.S., of University College Hospital, etc., etc. Pp. 270. London: Churchill and Sons. 1863.

Few departments of practical Surgery have received so large a share of attention from the Surgeons of this country for many generations as the removal of stone from the bladder. It might well be supposed, therefore, that the principles and details of at least the old operation of lithotomy were so far determined as to leave but little for elucidation at the present day. But, in truth, the introduction of lithotrity within the last forty years has effected a great revolution in this branch of Surgery. It has drawn the attention of the Surgeon more closely to the diagnosis of the individual characteristics of each case, so as to enable him to apply to each its most appropriate treatment. And the perpetually recurring question of the choice between lithotomy and lithotrity has reopened this further question, which for many years was shelved in this country, even by Surgeons of the best and largest experience—whether the lateral operation is in reality so far superior to all other forms of lithotomy for all cases of calculus, as the uniform practice seemed to imply? As our author says—

"The conviction has forced itself on the minds of most Surgeons that the difference between a large stone and a small one is so great, both as regards the prognosis of the case and the difficulty to the operator, that it is impossible to regard even all calculous patients, who are to be submitted to the knife, as belonging to one category, and as amenable but to one mode of the remedy."

There were, thus, ample materials for fresh discussion, and the revision of this important subject could scarcely have

fallen into better hands than those of Mr. Thompson. With an extensive practical experience, with a large knowledge of the subject in all its branches, with a calm and dispassionate judgment, and with a liberal appreciation of the experience and opinions of others, he was peculiarly well qualified for his self-imposed task. And it is but the merest justice to say that he has performed that task in a manner beyond all praise; and that he has given to the students of this branch of Surgery a text-book such as they will seek in vain elsewhere—a work which could only be the result of special study over a long series of years, and which will, doubtless, for many years to come, rank as the most authoritative on the subjects of which it treats.

The work is divided into twelve chapters. The first six are devoted to the description of the various operations of lithotomy, with their difficulties and dangers, and the causes of death after operation. The four following describe in great detail the present practice in lithotripsy. The next chapter treats of the choice of operation best adapted to different cases; and the last consists of brief reports of typical cases, illustrative of the main principles of practice.

In the third chapter are described, at full length, the various operations of lithotomy performed in the central portion of the perineum, which have been devised from time to time by various Surgeons with the avowed object of avoiding the serious dangers incidental to any operation in the side of the perineum. Five varieties of central operation are described:—Dupuytren's bilateral; Civiale's medio-bilateral, which Mr. Thompson justly says appears to be utterly unknown in this country; Allarton's median operation, an improvement on the old Marian; Buchanan's, known as the operation with the angular staff, and which approaches most nearly to the ordinary lateral; and the recto-vesical operation. Most, perhaps all, of these operations undoubtedly have their value in particular cases. But the discussion of the anatomical considerations in which they all originated gives occasion to Mr. Thompson to enforce a doctrine of the highest value with reference to all operations on such delicate and sensitive parts as those under discussion—a doctrine, however, which appears to be too often overlooked by those who, in the pride of minute anatomical knowledge, are apt to forget the difference between an operation and a dissection, viz., that supposed anatomical requirements are not to be allowed to override the vital or physiological ones. This truth is of so great importance towards the appreciation of the various points of practice included throughout the volume, that we transcribe our author's own words:—"Unquestionably, it must be agreed by all that the anatomical necessities of the region, *if alone considered*, demand that in the preliminary incisions the operator should avoid the upper and outer parts of the perineal space, and that he should confine the deep ones within the limits of the prostate gland. But there is another necessity, *not an anatomical but a vital one*, less obvious, possibly, to the casual observer, but not a whit less urgent, and with which the former must be reconciled, viz., the important fact, that the internal opening must be sufficiently free to admit the instrument and the stone to pass *without the exercise of so much force as to hazard the destruction of the tissues* at or about the neck of the bladder. It is the clashing of these two opposed considerations, the vital and the anatomical, which will, probably, always maintain a difference of opinion and of practice in lithotomy."

The author belongs to the vital school, and loses no opportunity of enforcing the doctrine, that the vital considerations are to be regarded as at least equal, if not paramount, to the purely anatomical. This is the text, on which the whole work is a practical commentary. On this principle, he insists that the two main points to be attained are—a sufficiently free incision and an avoidance of all violence in manipulation. In speaking of the causes of death after lithotomy in the adult, he places first destructive inflammation of the tissues in consequence of mechanical violence inflicted in the removal of the stone. "From what I have seen," he says, "of the practice of lithotomy, in various hands, I am persuaded that insufficient internal incisions are equally dangerous with those which are too free, and that the tendency of the present day is towards the former extreme. The purely anatomical view of the subject appears just now to be in the ascendant." He considers that the danger of urinary infiltration, *simply as the result of too free incision*, is, to say the least, greatly overrated, if not purely mythical, believing that, whenever it occurs, it is the result of violent bruising and laceration of the connective tissues. "I very much doubt," he says, "if urinary

infiltration *ever* occurs when they (*i. e.* the tissues) are otherwise uninjured, in a person of fair vigorous health." This unorthodox position he fortifies by pointing to two highly significant facts:—first, that while it is certain that the boundaries of the prostate are almost invariably overstepped by the knife in children, infiltration of urine very rarely occurs in their cases; and, secondly, that the most successful operators have been those who advocated sufficient incision as less dangerous than violent extraction. He adds, that in the numerous correspondence he has had with the best lithotomists of the day, he has found that, whatever discrepancies there may be between them on other points, this is the single particular on which all are agreed. The whole argument, which is stated very fully, is well worthy the close study of the Surgeon.

The author draws an important distinction between the causes of death in the adult and in the child, showing that in the latter the usual causes are peritonitis and constitutional exhaustion, and rarely diffuse cellular inflammation.

The portion of the work which treats of lithotripsy has a value of a different kind from that devoted to lithotomy. For lithotripsy is essentially a new operation. For many years after its introduction it was tentative and experimental. Founded on no principles, and regulated by no laws, it was performed in a manner radically bad and wrong, which has only gradually given way to the sound and successful operation of the present day. In the operation as formerly performed, but few precautions were taken against mechanical injury to the parts concerned, either during the operation or, subsequently, from the passage of fragments. Hence arose frequent and serious complications, and the operation fell into unmerited obloquy. Now, such precautions form the basis of every step of the operation, and in the hands of a good operator accidents are comparatively rare. This vast improvement has been effected by attention to innumerable details, each of which, as our author observes, "may be minute in itself—indeed, apparently insignificant at first sight to some minds—but each becomes important when the result of their aggregated influence is regarded." We shall make no attempt to analyse the very full and circumstantial exposition of the principles of the operation given by Mr. Thompson. To give a satisfactory account of it would be to transcribe his four chapters, for, where everything depends on detail, no detail can be omitted without detriment to the whole. Suffice it to say, that this is the only work published in this country which lays down fully and accurately the conditions of success in lithotripsy.

Not the least valuable portion of this most instructive work is the chapter devoted to the discussion of the choice of proceeding in different cases. Mr. Thompson points out that the introduction of new and varied methods of operating has rendered *absolutely necessary* a correct diagnosis of the size, form, and chemical characters of the stone. For want of this accuracy in diagnosis he asserts that lithotripsy at its first introduction "actually increased the fatality from stone operations, and was a positive calamity for many stone patients." Many who might have been saved by lithotomy were destroyed by lithotripsy, which was quite unfitted for their individual cases. He considers it actually safer "uniformly to practise lithotomy in every instance if the Surgeon does not arrive at an accurate diagnosis of the nature of the stone, and select an operation in accordance with it." Great strides are being made every year in our knowledge of the means of forming such a diagnosis, and Mr. Thompson gives an admirable *résumé* of that knowledge. Whether lithotomy will ever be entirely superseded by lithotripsy is a question which it would be premature to attempt to answer; but most assuredly, if so desirable a result is ever to be attained, it can only be by an improved diagnosis enabling us to discover every stone in the earliest stages of its existence. And, in truth, diagnosis is steadily doing its work in this direction. In the large collection of calculi at Norwich, Mr. Thompson "calculated the sizes presented during each consecutive ten years down to the present time, and noted the significant fact, that they are gradually decreasing in size;" in other words, that the stone now is detected in an earlier stage of its existence than formerly.

We have endeavoured briefly to point out the leading features of this, the most complete and trustworthy work in the language on the subjects of which it treats—a work which more than upholds the deservedly high reputation of its author, as second to no living Surgeon in this department of practice.

THE

MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.

Senior Physician to the Royal Infirmary for Diseases of the Chest.

PRELIMINARY WORD.

THE idea of giving to the public and the profession of Medicine a series of facts on the Medical History of the Cities and Towns of England, originated with the senior representative of the eminent publishing firm, the Messrs. Churchill. The labour of carrying out a suggestion so happy and so promisingly useful, has been entrusted to me, the columns of the *Medical Times and Gazette* being the field for my work. That the work, if it be done well, is a great work I know: it is a work that should live for future historians to quote from, elaborate, criticise, and use as historians only can use facts of the past, and pictures drawn at the time when the events depicted were being carried out in very life; and I have undertaken the duty, because it irresistibly suits my fancy. But how far I shall succeed I must leave to fortune and friendship. I know my weakness on the one hand for a task so heavy; but then, I know also, I write for a Profession that of all others is most forgiving; that lives on forgiveness; that knows the human heart so intimately that it looks on all acts, omissive and commissive, with gentleness and hope. For the rest of the world, what need is there for care so long as each line is written faithfully?

I have set before myself certain rules which are few and easy. A first rule, to write with the simplicity of a child, describing what he has seen, during a holiday from home. A second rule, derived from the experience of a man, to put into the foreground those points which are most likely to be of use to other men, also occupied in meeting the daily requirements of Medical practice. Thus, as I pass from one place to another, I shall find some Medical brother practising some new art, which I shall learn, note, and submit it to all brethren. A third rule, to notice everything, as far as I am able, that may seem anywhere to require improvement. And, a last rule, to endeavour, by choosing those localities for description which are most interesting to the Medical world, to seek for information from the best centres of intelligence and active life. Ere this preliminary word is over, I must seize the opportunity of asking the kind aid of other men, who, willing themselves to be recipients of information, are not less willing to offer what they know for the common good. I must ask that any new fact, though it may seem to be trifling to the possessor of it, may be mine for distribution; for, as the great Dr. Rush well said in his eulogy on Cullen:—"There are mites in science as well as in charity; and the ultimate results of each are often alike important and beneficial. Facts are the morality of medicine; they are the same in all ages and throughout all time."

I open this work with the Medical History of Norwich and Lynn.
B. W. R.

THE MEDICAL HISTORY OF NORWICH.

Taking it all in all, there is no city in the United Kingdom that presents more striking features of interest to the Medical man than the city of Norwich. Not that its size gives its unusual importance (it contained 74,865 inhabitants in 1861); not that its public buildings or its commerce give it undue pre-eminence, but that it has had the advantage of possessing for—I had almost said centuries past—Esculapian citizens, who have been singularly active in observation, and singularly successful in special departments of practice. To the stranger, the city is not at first inviting. It is at once straggling and cramped; for the streets, widely distributed, are long and narrow, and the city altogether is constructed without uniformity. It is one of those cities which, having arisen first from a castle and a few surrounding buildings, became, in time, a fortified town. It is reported as having been founded on the ruins of the Venta Icenorum, at Caistor. The castle was built in the reign of Anna, in the year 652. In 878, Alfred the Great, after conquering Guthrum, the Chief of the Danes, gave to him the kingdom of the East Angles and Norwich Castle as his royal residence. The possession held by the Dane was soon cut short; the Saxons again became masters, and continued so to the time of Edward the Martyr. In the reign of Ethelred the castle and city were invaded by Sweyne, King

of Denmark, and both are said to have been entirely destroyed; this event occurred about the year 1004. The legend runs that the present castle was built by Canute, who commenced his reign in 1017; this is inferred from the style of the architecture, which is mainly Danish. At the Norman Conquest the castle was evidently considered of great importance; the Conqueror appointed Roger Bigod constable, and the office remained in the Bigod family for many generations.

There seems reason to believe that at the time of Canute an arm of the sea extended to Norwich, and some historians opine that the sea washed up to the city even when the Conqueror was king. There are two theories extant as to the natural process by which this arm of the sea was cut off. The one theory is, that the river on which Yarmouth has since been built was divided into two channels by a sand bank. In process of time, one of these channels, the lower, became choked up with sand, and the consequence was, that the sea was prevented from finding its way to the marshes below Norwich. A second theory assigns as a cause for the withdrawal of the sea the sinking or depression of the waters of the German Ocean. Any way, at the present time the only bodies of waters near to Norwich are the rivers Wensum and the Yare. The former river (the Wensum) enters the city at the north-west and leaves it at the south-east point. It pursues thus a winding direction, including in its course on the left or northern side about one-fourth of the city. In 1294, the city was surrounded with walls, built of flint. These walls enclosed the whole of the place, except on the south-eastern side and on the northern side, where the river Wensum formed a natural boundary. Remnants of the walls still remain: when in their glory, they were flanked with forty towers, and pierced by twelve gates.

The local chroniclers are proud to tell of the space of ground which their city occupied in the ancient times. "This city," says the editor of the "Norfolk Tour," "chiefly occupies the top and sides of a gentle hill, which runs parallel with the Wensum on its western side, and terminates at a sudden bend of the stream. It is said to stand upon more ground comparatively with its population than any city in the kingdom, the buildings being generally interspersed with gardens, which circumstance has given rise to the appellation of 'a city in an orchard.' The shape or plan is irregular, approaching that of a cornucopia, or bent cone, and has been said, with more truth than elegance, to resemble the outline of a shoulder of mutton. It is rather more than one mile and a half in length, from Conisford-gate on the south to Magdalen-gate on the north; and a mile and a quarter broad, from Bishop-gate on the east to St. Benedict's-gate on the west."

In the history of Norwich, from the time when it was a walled city until now, so many marked and astounding events have occurred, that barely to name them would occupy more space than can possibly be spared; but I must not omit to mention that the city in 1551 was visited with an epidemic of the fifth and final outbreak of the disease known as the "sweating sickness." In this outbreak 960 of the citizens died in a few days. I should also narrate, that in 1558, quartan ague, in a severe and fatal form, appeared in the city, and returned at different times with great vehemence, so that the following are reported as destroyed by it:—667 in the year 1591, 3076 in 1602, 1431 in 1625, and as many as 2251 in 1665. During these times the water supply must have been derived mainly from the marshes, waterworks not having been established until the year 1698. The city was first lighted in 1702.

The general outline of the city remains much as of old, but around the magnificent cathedral there are open places and buildings of very great beauty. The cattle market is a magnificent improvement. This market-place, overlooked by the castle, is nearly equal in size to the market in Copenhagen-fields, London, and is infinitely better arranged. On a fine day the Norwich cattle market is now one of the most remarkable sights in the kingdom; it is a model which the sanitary legislators of our other large towns would do well to follow. The city, for the most part, is now also well drained, the sewage emptying itself into the river. The water supply is derived from the river about a mile above the city. To this point I shall refer in detail at a subsequent page.

The manufactures of Norwich are extensive. At first it is probable the city was merely a centre for soldiery: then it became a market for goods of various kinds. In the early part of the reign of Elizabeth its trade declined; but in 1655 nearly three hundred Hollanders, flying from the Low Countries after the persecution of the Duke of Alva, settled in

Norwich, and introduced the weaving trade, and especially the manufacture of bombazine and crape. Queen Elizabeth, always alive to the interests of commerce, fostered these fugitives, and their families rapidly increased, so that at the close of her eventful reign they numbered nearly five thousand. They stamped the commerce of the city in its main branches.

Proceeding from these general facts relative to the city, I pass now to matters more purely of professional interest, taking up those charities which present points most worthy of our attention. In this direction I naturally commence with

THE NORFOLK AND NORWICH HOSPITAL.

The Norfolk and Norwich Hospital was founded in the year 1770. It would seem that for some years previous to the foundation the want of such an institution had been keenly felt by the inhabitants. The then Bishop of Norwich had specially fostered the idea, if he were not the actual author of it. In his recommendations he was warmly supported by Mr. Benjamin Gooch, a chirurgeon whom we shall see by-and-by as one of the celebrities of Norfolk. At the instance of the Bishop, Mr. Gooch visited London, and inspected all the Hospitals of the metropolis, with a view to learn every fact in regard to construction, and the various Hospital necessities. The site of the Hospital was determined on the 30th of August, 1770. It was a piece of ground without St. Stephen's-gates, belonging to the Corporation. The lease of the ground was obtained for five hundred years, at a rental of £6 per annum.

The Hospital was originally built in the form of the letter H, and great care was taken to give sufficient space for each patient, and to secure good ventilation. For these provisions, the Hospital managers, and hundreds of sick patients since, are indebted to the care and foresight of Benjamin Gooch, of Halesworth. In speaking of these provisions, Gooch, in his account of "the rise and progress of the Norfolk and Norwich Hospital," refers with special emphasis to the "particular regard that has been paid to a point of the utmost consequence, which is, having the wards lofty and airy." "The wards," he adds, "are of different sizes, and all fifteen feet high; they are kept very neat and clean, not crowded with beds, and well ventilated by having the convenience of letting down the upper parts of the sashes occasionally in the wards and in the galleries communicating with them, which is done every day for a due time, when the weather will admit of it; and it is observed by all people who enter these wards, that there is not the least offensiveness, particular care having also been taken in respect to the adjacent necessaries, which has effectually obviated any complaint on that account." As illustrating the reason why he attached so much importance to space and ventilation, he says: "In a conversation which I formerly had with my worthy friend, Dr. Hunter, Consulting Physician to the Brownlow-street Hospital, he told me there were two wards of equal length and breadth, one directly over the other, but the upper some feet lower than the other, in which the same number of patients were lodged in similar circumstances, and that it was observed more died in the upper than in the lower. This difference of success could not at first be accounted for, but, upon further consideration, it was apprehended it might arise from the greater impurity of the air they breathed; consequently, the number of patients was lessened in the upper ward, and then they did as well in that as in the other."

I have dwelt on this fact, because, to my mind, it is an explanation of an important result. We shall learn, when the practice of the Hospital at Norwich comes under discussion, that certain operations have been performed there with a success that is almost without a parallel. The reason of this is, I think, that in the Norwich Hospital the great experiment of treatment after operation, by fresh air and plenty of it, has been going on systematically from the first.

To return to the building: it was so far completed as to be ready for the reception of patients on Saturday, July 11, 1772. On that day three out-patients were admitted, and in the following month there was accommodation for thirty in-patients. The Medical Staff was complete, consisting of Mr. Benjamin Gooch, as Consulting Surgeon; Drs. Beevor, Manning, Murray, and Hook, as Physicians; Messrs. Maltby, Rogers, and Donne, Surgeons; and Messrs. Alderson, Rigby, and Palgrave, as Assistant Surgeons. An Apothecary was also elected, and drugs were ordered from "Apothecaries' Hall" and "Corbyn's."

Dr. Copeman, at this time one of the well-known Physicians to the Hospital, in a very valuable treatise on the History of the Institution, shows that, at first, there was a misunder-

standing between the acting Surgical Staff and the Governors, in reference to the appointment of Gooch as Consulting Surgeon. The three acting Surgeons, in fact, issued a memorial, drawn up not in the best taste, inquiring what duties the Consulting Surgeon would have to perform, and stating that such appointment was not common in other Hospitals. Gooch was then ill, and the memorial might well have been spared, for the office was intended to be purely honorary, and a compliment to one who had taken so active a part in the foundation. Some curious communications also took place, as Dr. Copeman shows, between the Medical Staff, at various times, in regard to the Assistant Surgeons. Finally, the number of Physicians was fixed at three, Surgeons at three, and the Assistant Surgeon at one. It was also determined "that it was not necessary, in the election of a Surgeon, that he should previously have been an Assistant Surgeon."

Notwithstanding occasional differences of opinion between the Faculty and the Board of Management, it is certain that of the English county Hospitals, of which this was the fifteenth, none have been better officered than the Norwich Hospital, from the day of its opening until now;—when Drs. Ranking, Copeman, and Eade, are the Physicians; Messrs. Nichols, Firth, and Cadge, the Surgeons; Mr. Crosse, the Surgeon-Assistant; and Mr. Williams, the Resident Surgeon. The Hospital was originally intended as a house of charity, and nothing more: but soon after the opening, in 1774, a precedent was set for allowing patients to enter on payment of a certain moderate sum to the funds of the charity.

A resolution, that all infectious disorders should be excluded from the Hospital and from any building in the grounds, was passed in 1780, at the instance of the Medical Staff, and this rule has remained in force. A regulation was also made in 1801, to the effect that patients should be discharged at the end of two months, unless the Staff, on consultation, think there is a probability of cure or of considerable relief.

In the years 1802, 1825, and 1848-9, additional wards were constructed, on the last occasion two very large ones being added. These buildings have caused a modification in the original plans of the Hospital, but have enabled the Governors to enlarge their charity in proportion to the demands made upon them. The Hospital, at the time of my visit during December of the year just passed, contained 148 beds.

The last great improvement in the Norwich Hospital consisted in the formation of the museum. So far back as May 15, 1773, owing to the great number of stone cases in the Hospital, an order was passed, that the Apothecary "provide a nest of drawers to deposit the stones extracted in this house, that they may be carefully preserved and shown to strangers." A museum was thus commenced,—at all events, its nucleus was formed. With additions, the nest of drawers continued, but without a companion, until the year 1843, when the late Mr. John Dalrymple presented to the Hospital his father's museum. Afterwards, the late Mr. Crosse contributed his museum; and on September 10, 1845, a new museum was formally opened, Mr. Crosse delivering one of the most interesting and learned addresses that ever graced such an occasion. The corner-stone of the Hospital, as a school of practical science and charity, was thus completed.

As the Hospital at present stands, it is less imposing from without than most other buildings of its class. Its architecture is of the plainest, essentially "modern-age English." Within, there is the same simplicity and want of art, but the air in every part is peculiarly free from offensive odour. I was never in a Hospital where this fact was so well marked. The purity of the air is due to the simple and effective means of ventilation that has from the first been carried out. There is no elaborate artificial system of ventilation adopted, but a natural system, by which, through the windows of the ward, a free current of air is allowed to pass regularly and freely from one side to the other. In this respect, the plan used, and so much boasted of, at the Hospital of Bordeaux, is presented—not so elaborately, perhaps, but as effectively. Here it has been at work ninety years; and while millions of money have meantime been spent in inventing and carrying out artificial plans of ventilation, the inexpensive natural plan has been going on at Norwich with perfect success, and at scarcely the cost of a penny. So successful is this mode of ventilation, that since the foundation there has not been a single epidemic of either pyæmia or erysipelas in the Institution. No wonder that the Surgeons can show an admirable balance-sheet in favour of life after capital operations. The Surgeons of Norwich not only acknowledge nature, but take her in as the senior partner in their firm. In addition, ample space is

given to each bed—1215 cubic feet being the average. Another custom worthy of remark in the management is, that from the first straw mattresses have been used in the wards, the straw being destroyed after use, and a new mattress made for a new patient. Under present circumstances, there can be no doubt that this method is the best; but it is essentially inartistic, and open to improvement. What is wanted in sick Hospitals is a bed that can be steamed through every fibre, and yet not be destroyed.

The floors of the Hospital, of white pine, are washed and scrubbed with soap and water; dry scrubbing has never been tried; I doubt, in fact, the possibility of cleaning white pine by the dry process, however desirable it may be when it is admissible.

As in most English Hospitals, there is an absence of any uniformity in the classes of patients. On the male side, the Medical cases are separated from the Surgical; but on the female side they are mixed. One ward is set apart for compound fractures, one for accidents, and one for operations. The beds in every ward are severally loaded with blue chequered curtains: the tester certainly is removed, but on each side there are two or three yards of surface of curtain; so that if the curtains are drawn closely round the bed, as is not uncommon, and you look at the patient from the foot of his bed, he resembles one of the images in the side-slips of the cave of Elephanta; while, from either end of the ward, the enormous surface of blue sheeting presented to the eye, conjures up droll ideas of intoxicated Dutch crafts in full sail. Irrespectively altogether of the uselessness of these appendages to beds, especially in the Hospital ward, they are objectionable from the slovenly appearance they impart: some are tucked-up, others are half drawn, others are drawn in full—disorder at every point, with nothing for the eye of the sick man to rest on but blue curtain and dead-white wall. Not a picture, not a flower. These are the thoughts that occur to the mind of a stranger, and I hope my Norwich friends will take them, as they are given, all in good part.

The Museum, to the inauguration of which reference has already been made, is a fine room with a surrounding gallery, and excellent and well-stocked cabinets. It is ornamented with four paintings, of uniform size, and representing Gooch, Caius, Rigby, and Dalrymple. There is also a very fine bust of the late Mr. Crosse.

In some respects the museum of the Norwich and Norfolk Hospital is unique; but in all its parts it is excellent, and it reflects the greatest credit on its founders and curators. I must not attempt, even, to describe it in full; but there are a few specimens I cannot pass over. Amongst these, John Dalrymple's cabinet of anatomical and morbid preparations of the eye hold a first place. Changed less than such specimens usually change from preservation, they present a series, from which a volume might be written and illustrated—a volume such as no student in Ophthalmic science at present possesses. I wonder, indeed, that some one of the able representatives of Physic in Norwich does not undertake a task so interesting and profitable.

In another cabinet there is a singular, and, as far as I know, unique, specimen of fracture of the odontoid process of the axis. The patient in whom this accident occurred lived for a whole year afterwards, and died of cholera. He pursued, up to his fatal illness, his usual avocations, without experiencing any inconvenience. There is also another rare specimen in the museum, of dislocation forwards of the last dorsal vertebra, *without fracture*.

Near to the last-named specimen is the skull of a boy; in this skull the breech piece of a gun was lodged in the frontal sinus. After receiving the accident, this boy walked to the Hospital, with the iron piece in his forehead. There were no serious symptoms, until an operation was performed for removing the foreign body. The attempt was followed by hæmorrhage, and death as the consequence. Amongst these relics of bones, the skull of Sir Thomas Browne, author of the "Religio Medici," figures prominently. The skull is in an excellent state of preservation, and is a kernel for the Phrenologists. It is somewhat beyond the ordinary size; but the shape is not altogether Jovian. The forehead is very retreating, and the animal part, if the head-feelers are right, is rather too prominent for so good a man. Probably an explanation of these difficulties may be supplied, on the theory of the "balance of power"—a theory which is as useful to the followers of Gall as it is to the disciples of Machiavelli. Independently of the bumps and the balances, the skull conveys to the mind that its owner was a perceptive, rather than a

profoundly reflective, man. I shall refer again to this relic, when treating of the celebrities of Norwich.

A specimen of ligature of the common carotid is of interest, as being the dead representative of a case in which Mr. Dalrymple performed the then unique operation of tying the carotid, for aneurism of the orbit by anastomosis.

The skeleton of a dwarf named Pycroft, who was executed at Norwich for murder some years ago, is preserved as a pathological feature. The skeleton, like that of almost all murderers, proclaims that the body it supported during life was more than usual of the earth, earthy. It is that of a miserable, semi-witted deformity, who in charity should have been put into an asylum as beneath revenge, and as utterly incapable of exciting so grand a passion in wise men.

(To be continued.)

GENERAL CORRESPONDENCE.

THE EXHIBITIONERS' COMMITTEE v. THE COUNCIL OF THE ROYAL MEDICAL BENEVOLENT COLLEGE.

LETTER FROM MR. H. BURFORD NORMAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—As a constant reader for many years past of your valuable Journal, I have been very often highly gratified with the tone and spirit of your Leaders when they have touched upon those questions which affect the dignity, character, and welfare of our Profession. But never have I been more pleased than by that of this week's number, in which, with uncommon clearness and vigour, combined with a most gentlemanly tone and spirit, you have exposed the facts of the case of the Exhibitioners' Committee v. The Treasurer and Council of the Royal Medical Benevolent College. The time is come when all who subscribe towards the funds of that noble Institution must, like you, throw aside all needless delicacy, and seeing that the promises of the founders have not yet been fulfilled, and that one of the most important of the original purposes of the school remains unaccomplished, so that the poorer members of our body cannot obtain for their sons that good and cheap education there which they have a right to expect, must fearlessly lay the blame, as you do, on the right shoulders, and steadfastly combine to obtain redress.

The grievance is no small one; and, judging by the past, it will not be one easily got rid of. Taking the cost of a boy's maintenance on plain, good, and substantial food, such as we should give our own boys at home, we know that that can offer no reason why an Exhibitioner should not get his board and education at Epsom at £26 per annum. No boy in a large establishment eats, drinks, and wears out goods to that amount; and every master of an establishment or father of a family is well aware that these items do not absorb anything like that proportion of his yearly expenditure. Yet, if I understand the constitution of the College and of the class of Exhibitioners, this is all, or nearly so, that can be demanded or expected of the Exhibitioners. The subscriptions and donations to the College make up an income which will meet the other expenses. To say that each Exhibitioner is at present costing the Institution £40 1s. 9d. per annum, as the Secretary of the College in his letter to Mr. Kesteven asserts, is, we all know, an utter fallacy. No honest calculation could have produced those figures, unless there is fearful extravagance in the management of the College. Twenty pounds per annum would be much nearer the truth, if the funds are rightly managed. I do hope, Sir, that you will continue to lend a hand, as heartily as you do this week, in aid of the efforts of the Exhibitioners' Committee. That is a Committee of men, *sans peur et sans reproche*, well worthy of our fullest confidence. At a great cost of time, labour, and money, they have been, for years past, seeking justice at the hands of the Treasurer and Council, and, with great forbearance, have waited to see if they could get it. All has been, thus far, in vain; but it is not possible that efforts such as theirs can fail, eventually. They are intent on a good business; they have honour, justice, truth, and charity on their side. They must succeed, and earn the thanks of the Profession, as well as my old friend the Treasurer has already earned them for his original conception of the College, and for the marvellous zeal, energy, and cost of all sorts to himself and family, with which he gained for it the ear and heart of the public and the Profession. I

know something of these, and never wish them to be forgotten or lost sight of for a moment. But I say, without hesitation, that the idea had better have never entered his head—the zeal, energy, and cost of its promulgation had better have been all spared, than that the College should fail to be the blessing which it was intended to be to the poorer members of the Profession, and its managers lie under the stigma of bad faith with the public. I shall be exceedingly glad if the Exhibitioners' Committee will add my name to their number, if, whilst living at a distance from town, I can help them: they shall also have my hearty co-operation in the matter of funds.—I am, &c.,

H. BURFORD NORMAN.

Portland Lodge, Southsea, Dec. 23, 1863.

MR. SYME'S DISPARAGEMENT OF EDINBURGH MEDICAL GRADUATES.

[To the Editor of the Medical Times and Gazette.]

SIR,—As the opinions lately expressed in Edinburgh by Professor Syme, upon modern Medical education, have now received the utmost publicity by their publication in the *Times*, I think it right to come forward and defend the Medical graduates and students of my University from the consequences that certain erroneous statements will necessarily entail, if uncontradicted.

Mr. Syme proposes to reform the whole system of training for the Medical Profession. He tells us that his qualifications for this office consist in his "having been engaged in teaching Anatomy or Surgery during the long period of forty years, together with the nature of his clinical duties, which, by establishing an intimate relation with students, has enabled him to become well acquainted with their feelings and difficulties."

With all deference to these qualifications, I would merely remark, that Surgical students are, of all others, the most imbued with veneration for the practical parts of the Profession, and that they come in contact with Mr. Syme, as an Edinburgh University teacher, at a period of their curriculum antecedent to that in which they study the application of scientific principles in the practice of Medicine. Hence, I consider it vain to gather data as to the effects of Medical education from such a class of students, and it is of these alone that he has had experience as a teacher for forty years.

Mr. Syme, speaking from his own knowledge, of which he only can speak, describes the Edinburgh student as "listless in his demeanour, and brooding over his impending fate" at examinations, and that he thus passes through his studies to undergo examinations which are no test of his Professional attainment, "with a no less loaded memory than unfurnished mind, to join the ranks of mediocrity, beyond which it is difficult to aspire with success under the present system of Medical education" at the University, of which he has personal knowledge.

As a recent graduate, I have read this with no less indignation than surprise.

According to my experience of Edinburgh students, the statement is not true in fact as to the average of students, and can only apply to those whose powers of acquiring knowledge are already below mediocrity. Moreover, it is incredible that the Medical faculty of the University of Edinburgh should year after year issue documents to the effect, that after careful examination of candidates they have found them qualified, and empower them to teach and practise Medicine, and call upon students to appear before them, and announce that their merit has been great in the examinations.

Mr. Syme can speak as to his own conduct as an examiner and the effect of his examinations; but I must protest against the imputation which he throws upon the merits of the examiners and examinations in general as an unjust disparagement of the graduates of Edinburgh.

Further, Mr. Syme insinuates, if he does not distinctly affirm, that this degraded academic condition of the Edinburgh student and graduate is due to the present defective methods of teaching there. He states that he "approaches the subject of teaching with the consciousness of being about to tread on tender ground, but, knowing that his opinions on this subject are the mature result of long and careful observation, he feels no scruple in freely expressing them." What, then, is the result of his observation of his colleagues?

That "some of them, making the duties of instruction subservient to the gratification of their own self-esteem, or the

indulgence of peculiar fancies, not only misspend the time of their pupils, but withdraw their attention from the true path that leads to eminence."

Having had more experience than Mr. Syme of the teaching of his colleagues, as he has probably heard few of them lecture, and I have heard them all, I can positively affirm that this, also, is contrary to fact; and I can appeal to the experience of hundreds of my fellow-students and graduates whether they have ever heard one word of homœopathy fall from the lips of the Professor of Pathology, whose personal preferences for that narrow system of Medicine are no secret.

Nor does the statement, true enough in itself, as to the great extension of every branch of Medical science, warrant the assertion, that the mind of the Edinburgh student is loaded with details; on the contrary, as Mr. Syme must be well aware, their attention is directed to principles even in examinations, and this necessarily from the fact, that the development of a science renders the study of it more feasible and valuable by reason of the generalising principles of classification which become available to teaching. (a)

Even in the teaching of the Practice of Medicine, the last to benefit by generalisation, this is the case; therefore I need hardly say that Mr. Syme's assertion, that "the Professor of the Practice of Medicine has placed in the hands of his pupils a printed list of no fewer than 800 fevers!" is utterly unfounded on fact, as all Dr. Laycock's students must know. The printed list referred to is an etiological nosology of both fevers and inflammations, corresponding to the "pyrexia" of Cullen, but strikingly more simple, brief, and comprehensive. (b)

By this syllabus, Dr. Laycock has rendered the study of fevers and inflammations less difficult in spite of the extended knowledge of the subject which we now possess. It is a singularly happy instance of the benefits to be derived from the employment of generalising principles. Thus, by placing such a syllabus in the hands of his class, Professor Laycock used to dispose of the whole subject of fevers and inflammations in the course of some ten or twelve lectures; whereas, one of his predecessors in the chair, Professor James Gregory, occupied an entire winter session in lecturing upon fevers.

All these lamentable mistakes and misrepresentations, so disparaging to the Edinburgh school and Edinburgh graduates, evidently arise from the peculiarities of Mr. Syme's own mental character.

Eminent in his art as a Surgical *artisan*, it would be ludicrous to compare him, as to scientific research and attainments, with Surgeons like John Hunter, Charles Bell, Benjamin Brodie, or James Paget. To these Mr. Syme makes no pretence. He ignores the use of the stethoscope; and if the practice of ovariectomy, iridectomy, excision of the knee-joint, acupressure, and similar operative procedures, be taught to the students of Edinburgh, they are not indebted to Professor Syme.

When, therefore, he attempts to set all the world right on Medical education, there can be no harm in reminding him of the sage maxim—"Ne sutor supra erepidam."

I am, &c.,

AN EDINBURGH GRADUATE.

London, December 23, 1863.

PROFESSOR TAYLOR'S EVIDENCE IN THE CASE OF ELIZABETH WATERER.

[To the Editor of the Medical Times and Gazette.]

SIR,—As an old lecturer on Forensic Medicine, I cannot help thinking that Dr. Taylor owes to his Medical brethren some more precise explanation of his views, concerning the cause of the death of Elizabeth Waterer, than he gave to the jury who found Joseph Mahaig guilty of her murder at Guildford.

Every one who has had ever so little experience in the

(a) As is shown by the directions issued in the *University Calendar* by the Medical Faculty to undergraduates: thus, the subjects of Chemistry, Botany, and Natural History are restricted as follows (p. 115, *University Calendar*, 1863):—1. *Chemistry*.—A knowledge of the general laws of affinity and equivalents will be required. There must be a general acquaintance with the chief chemical properties of the more common elementary bodies and their compounds, etc., etc. 2. *Botany*.—Organography, the physiology of the reproductive organs of plants, the natural system of classification of De Candolle, and the natural orders of Calycifloral Dicotyledons, etc., etc. 3. *Natural History*.—The general principles of zoological classification, the general morphology of all the primary groups of the animal kingdom, etc., etc.

(b) This list is now open to public criticism, since Dr. Laycock has lately published it in the second edition of his "Principles of Medical Observation and Research," under the head of "Pyroctic Diseases."

courts of law will have learned, that the "marvellous accuracy" with which it is usual to credit the reporters for the daily press, does not characterise the ordinary reports of scientific evidence. It may, therefore, well be that we do not possess a trustworthy account of Dr. Taylor's evidence. In this event the Profession will be glad to have the deficiency supplied from the only authentic source. As the case stands, we are to assume that Dr. Taylor did not concur in the testimony of the two "local Surgeons"—as they are styled—which favoured the hypothesis, that the woman's death was due to strangulation; but pronounced a positive opinion that her death was due to poisoning by strychnine. Now, I will not dwell upon the evidence of Messrs. Phillips and Sells, the "local Surgeons," strong as it is, if not quite conclusive, in favour of the strangulation theory, further than to observe that these gentlemen spoke from examination of the body in a recent state, which Dr. Taylor did not. Why Dr. Taylor rejects the idea of death by strangulation is not the question; but how does he come to the conclusion that death was caused by strychnine? We have usually three sources of information as to the action of poisons. These are—1, the symptoms manifested during life; 2, the appearances left in the tissues and fluids of the body after death; 3, the detection of the poison by chemical analysis. Upon which of these does Dr. Taylor rely? He admits that he could not detect the strychnine by chemical tests; he tells us nothing of any characteristic alteration of tissue or fluid; no one saw the woman in her last moments. Where, then, is the evidence of poisoning by strychnine? The case differs entirely from that of Cook, in whom the physiological action of the poison was clearly observed. The failures of the post-mortem chemical analysis in that instance was of little moment. The reaction of the living body under the influence of strychnine is a test which, for certainty, cannot be rivalled in the laboratory. But where we have neither physiological nor chemical evidence of the presence of strychnine, from what other quarter can evidence come? I mean, of course, evidence of a scientific character, such as may properly be expected from a Medical jurist. That the woman bought strychnine, and had written letters expressing her intention to commit suicide, may be very good facts for a jury, but they are quite beyond the pale of Medical reasoning.

If Dr. Taylor possesses any means of a scientific character, yielding proof of poisoning by strychnine, other than the physiological test, or the chemical detection of the poison, the Profession will look for his exposition of them with all the interest which a discovery so important cannot fail to excite.

DUBITANS.

December, 1863.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, December 24, 1863:—

Alfred Square Cooke, Gloucester; Paulin Martin, Abingdon, Berks; Thomas Theodore Steward, Wolverhampton; William Hanks, Snaith, Yorkshire; Samuel Edward Walker, Warwick; John Robert Ruddock, Leeds; William Henry Disen Meuce, Cambridge; Nathaniel Levett, Grosvenor-place School; Philip John Simpson, Gower-street, Bedford-sq.

The following gentlemen also on the same day passed their First Examination:—

David Webster Tomlinson, St. Mary's Hospital; Josiah Paull, St. Bartholomew's Hospital; Charles Edward Martin Shaw, St. Bartholomew's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CHAMBERS, T., M.R.C.S. Eng., has been elected Assistant-Surgeon to the London Surgical Home, Stanley-terrace, Notting-hill.

HAYWARD, SIDNEY, M.D., has been appointed House-Surgeon to the Huntingdon County Hospital.

JORDAN, ROBERT C. R., M.D. Lond., has been appointed additional Honorary Medical Officer to the Birmingham and Midland Free Hospital for Sick Children.

OLDMAN, JOHN, M.R.C.S. Eng., has been appointed Honorary Surgeon to the Huntingdon County Hospital.

ROBERTS, E., M.R.C.S. Eng., has been elected House-Surgeon and Dispenser to the West Kent General Hospital, Maidstone.

SMITH, J. W. F., M.D., has been elected Physician to the Royal Infirmary, Aberdeen.

THURSTON, E. WHITEFIELD, L.R.C.P. Lond., has been appointed House-Surgeon to Guy's Hospital.

DEATHS.

BOOTT, FRANCIS, M.D. Edin., at 24, Gower-street, Bedford-square, W.C., on December 25, aged 72.

BOWEN, SIMON S., M.D. St. And., at High-street, Tewkesbury, on December 7, aged 37.

FRESHFIELD, PHILIP W., M.R.C.S. Eng., at West-street, Harwich, on November 30, aged 67.

GRIFFITH, J., M.R.C.S. Eng., at Bangor, North Wales, on December 13, aged 29.

POW, ANDREW, M.D. Edin., at Dundas-street, Edinburgh, on December 16.

SMYTHAN, GEORGE, M.D., at Canaan-park, Edinburgh, on December 25, late of the Bombay Medical Board.

WHEELER, CHARLES W., Surgeon, at Shirley Lodge, Hants, on December 26, aged 72.

A NEW MEDICAL SOCIETY.—A society has been formed by the students and resident staff of the London Hospital for the purpose of discussing Professional subjects. The meetings are to take place weekly.

THE PARIS FACULTY OF MEDICINE.—M. Pajot has been nominated Professor of Midwifery.

SIR RODERICK MURCHISON.—The Cuvier Prize of the Academy of Sciences has been decreed this year to our distinguished countryman.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

A paper on "Rupture," by Mr. J. Wood, of King's College, is unavoidably postponed until our next number.

A *Constant Reader*.—We believe he would be liable to a criminal prosecution. G. H. K.—Consult any respectable Physician or Surgeon.

Tyro.—A solution of 1 to 2 per cent. of chromic acid in water is a very good and cheap preservative solution for anatomical or pathological specimens.

Dr. M.—Mr. Collis was the operator in the recent case of ovariectomy at the Meath Hospital, Dublin. We regret to learn that a low form of diffuse peritonitis set in, and proved fatal.

Oculist may learn from Mr. Wilde's last report that "the greatest number of blind in Ireland was in Munster, where the proportion was 1 in every 596 persons; next in Leinster, where it was 1 in 872; then in Ulster, 1 in 1052; and least in Connaught, where it was only 1 in every 1078 persons. Amongst the cities, the largest proportion existed in Limerick and Waterford; in the former it amounted to 1 in 371, and in the latter 1 in 416."

Rusticus.—The Léporide is said to be a real cross between rabbit and hare. It was obtained by M. Lépél-Corictet, who gave it that name. The animal is said to be of remarkable fecundity, and its flesh to be like that of rabbit, with a slight flavour of hare. If the existence of such a cross should seem to our correspondent to be an absurdity—"contrary to established laws regulating the properties of species"—we can only regret the fact, but cannot alter it. We would merely ask our correspondent, in all humility, when he talks with such precision about *lais*, where do such laws exist?—and who found them out? If there were a revelation from heaven to the effect that the offspring of no several species could be prolific, and that if a cross were prolific it could not be between different *species*, there would be something in it; but the so-called *law* is only a human inference from imperfectly-ascertained facts. Our correspondent should write to M. Rufiz de Lavison, Director of the Garden of the Society of Acclimation, Bois de Boulogne, Paris.

Questionable Advertisement of University College Hospital.—A correspondent calls our attention to the following. It is a remarkable document as illustrating the financial position of the Hospital, and is certainly in questionable taste; though we are bound to add that it is very improbable that the Medical officers have any share in the offence:—

"SPECIAL APPEAL.—The Committee of the University College Hospital make an urgent Appeal to the public for increased funds. They spend annually about £7000, and they receive in annual subscriptions less than £1000. In spite of strenuous special efforts there is a large annual deficit. Already the relief afforded is considerably below the capacity of the Hospital, and the Committee are most anxious that its usefulness shall not be still further impaired by want of public support. They appeal to the benevolent for a share of the gifts which distinguish the season, for several reasons.

- "1. Their great need of aid.
- "2. The great comfort of the sick wards (!)
- "3. The excellence of the nursing (!)
- "4. The eminence of the Medical officers (!)
- "5. The immense population which surrounds the Hospital.
- "6. The danger of depriving the poor of that population of some of the

relief now afforded. A subscription to a Hospital is not only an act of benevolence, but the payment of a debt, as the eminent skill of the Physicians and Surgeons of the wealthy is due in very large measure to the opportunities of thorough study which these institutions have afforded."

LITHOTOMY AT ST. BARTHOLOMEW'S.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It is stated that the sum of £120 a-year is paid to the Surgeons of St. Bartholomew's Hospital specially for the performance of the operation of lithotomy. Many years ago it is said that the Surgeons took it by turns, for a season, to do all cases of lithotomy *while their hands were in*. Is this correct? And might it not be a good thing for Hospital patients and for students if certain operations were confined to a few Surgeons?

Hull, December 26.

I am, &c.

IGNORAMUS.

THE CRAWLEY COURT-MARTIAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—So it appears, by a short notice in the *Times* of the result of this court-martial, that Colonel Crawley is acquitted, but that, as John Bull must have some victim to appease his indignation at the death by slow torture of poor Lilley, some officers (who had nothing to do with Lilley's death) are to be sacrificed on account of the way in which they gave evidence! Of course, on the principle of the weakest to the wall, the Medical witnesses may be expected to be made tubs to the popular whale.

All the Profession is indebted for the masterly articles in defence of Surgeons Turnbull and Barnett that have appeared in the *Medical Times and Gazette*. Doubtless you will not let it drop. Just please to ask how the alleged misconduct of a witness in December can have to do with a death last May; and how an erasure of an entry about Sergeant Wakofield can be made an apology for the death of Sergeant Lilley?

I am, &c.

ALPHA.

THE PLEA OF INSANITY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If Townley is let off on the plea of insanity, I hope an equal measure of justice will be accorded to John Green, the unfortunate man who lies under sentence of death at Cambridge for murdering Elizabeth Brown. Observe the parallelism of the two cases. Each has insanity in some remote collateral ancestor; who has not? I defy you to find any one without a mad great or great-great uncle, if he have such a relation. Each acted without premeditation. Neither would have murdered his victim if she had yielded to his wishes. The impulse to kill was not inherent, like a maniacal furor, but contingent. Townley was the worst, for death resulted from a blow that could only murder. Green did not intend murder, but injured his victim in a struggle, without intent. As for after conduct, I see nothing to choose between a man who tries to burn a dead woman and one who drinks tea with her grandfather. However, Townley's relations are people of consideration; Green's are poor devils, and, therefore, it serves them right.

December 29.

F.

EDUCATION FOR THE SONS OF MEDICAL MEN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your editorial article on the "Royal Medical Benevolent College" in your last number must meet the approval of a large portion of those who have contributed to the existence of that well designed and noble institution. My present purpose is not to criticise the management of the College, but simply to inform my brethren who may be in quest of a school in which they can have their sons conscientiously and thoroughly grounded, efficiently prepared for active life or for the higher colleges, well fed, kindly treated, and gently trained, for £30 per annum, that I shall be happy to give them the address of the establishment at which two of my sons are now placed to my entire satisfaction.

A note addressed to M.D., North Brixton Post-office, shall meet with an immediate response.

December 23.

I am, &c.

MEDICUS.

SYMM v. FRASER AND ANDREWS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Profession has so unequivocally and handsomely expressed its sentiments respecting the above iniquitous prosecution, that I most unwillingly trouble you with any reference to it; but, in justice to my co-defendant and myself, I cannot allow to pass unnoticed a letter which appeared in your last number from Dr. Tunstall, of Bath, in which he states that the evidence he gave theoretically was confirmed practically by the defendants. This is certainly "the unkindest cut of all," making it appear that we confirmed evidence which I have not heard spoken of, in or out of the Profession, except in terms of ridicule and grave censure.

Dr. Tunstall stated in evidence that he first visited the patient on January 24, 1862, at 10 p.m.; that he found her in a very nervous, excited condition, complaining of pain in her leg, and oppression of the chest; he stated that at first he had a suspicion in his own mind that the excitement he saw might have been produced by drink, but that, on inquiring whether she had taken any, she said—"No." Dr. Tunstall further stated in evidence,—"I then proceeded in my investigation, and I am perfectly of opinion that all the symptoms I saw might have arisen from *travelling gout*." Dr. Tunstall added that he saw her at 10 a.m. on the following morning, when she was much better, and left Bath. Now, Sir, this theory of "travelling gout" was one of the strongest points which Mr. M. Chambers dwelt on in his address to the jury, whom he endeavoured to make believe that the state of drunken, ungovernable excitement in which the patient was, during my sixty hours' attendance on her, was produced by "travelling gout." So far, therefore, from confirming Dr. Tunstall's hypothesis, I believe it to be as visionary and hasless as any ever invented by counsel, to "make the worse appear the better cause;" and I cannot help designating his conduct as most cruel, in bringing forward a wild theory, and thereby aiding a weak-minded, vindictive, and ill-advised woman in her endeavour to injure those who had humanely befriended her. The "very nervous, excited condition" in which Mrs. Symm was when Dr. Tunstall saw her, is fully accounted for by the evidence of numerous trustworthy witnesses, who deposed to her suffering from delirium tremens, and being intoxicated for days together during the latter part of December, 1861; also by the evidence of Dr. Barnes, who, on his last visit in January, found her "in a state of helpless intoxication." Mr. Barrett, who attended the patient in Bath from January 12 to 21, and who appeared as a witness for her, somewhat reluctantly, but candidly said he was bound to state his impression as

to her being in liquor, and as to his directions respecting her refraining from drinking being unattended to.

On January 22, Mr. Bond, inspector and clerk of the police at Bath, visited the plaintiff, and found her, as he more graphically than elegantly described, "looking like a woman who had been on the spree for a week, her memory gone, talking incoherently," and as this was on the next day but one preceding Dr. Tunstall's visit, it would be somewhat surprising if he found her otherwise than in "a very nervous, excited condition."

As to Dr. Tunstall's account of his morning visitor with a £5 note and subpoena, I could find a plausible theory on the circumstance, but shall refrain, merely remarking that it is an unusual occurrence for a Medical witness to be called on to give evidence, without the individual in whose favour he is to appear first ascertaining what that evidence is likely to be. It is, moreover, a remarkable fact, that from the commencement of the recent proceedings my solicitor has repeatedly told me that there were to be two Medical witnesses from Bath, on whose evidence the plaintiff principally depended for a verdict in her favour: who those witnesses were, we could not ascertain until we saw them in the witness-box. Apologising for trespassing so much on your valuable space.

I am, &c.

D. FRASER, M.D.

15, Harrington-square, N.W., December 29.

BOOKS RECEIVED.

The Sanitary Condition of Gloucester and its Vicinity. By Dr. Washburn. 1863.

* * This report is entirely devoted to points of local sanitary interest, which would prove of the highest value in a comparative survey. The writer, however, takes occasion to show that "lavish expenditure" upon matters relating to public health, means, likewise, a diminished amount of illness, and, by consequence, a diminished amount of taxation in the garb of poor-rates.

Coxeter's Catalogue of Surgical Instruments and Apparatus. London. 1863.

* * An excellent compendium, containing not only the usual appliances for operative Surgery, but information as to splints, bandages, and the necessary conveniences for the sick room. The woodcuts are particularly neat and comprehensible.

The Useful Knowledge Society's Family Atlas. Parts I. and II. London: E. Stanford. 1863. To be completed in twenty Parts, at 2s. 6d. each.

* * Remarkably cheap. For 50s. we are promised eighty good maps, corrected to the present date; amongst them, geological maps of England and Wales, revised by Sir R. Murchison, and of the stars by Sir John Lubbock. Whoever does not possess a good family atlas should think of this one.

Military Surgery. By George Williamson, M.D., Surgeon-Major 64th Regiment. London: John Churchill and Sons. 1863.

APPOINTMENTS FOR THE WEEK.

January 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

4. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. F. W. Mackenzie, M.D., "On Retroflexion of the Gravid Uterus, with especial Reference to its Occurrence in the latter Months of Pregnancy."

ODONTOLOGICAL SOCIETY. Anniversary Meeting.

5. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 4 p.m. General Anniversary Meeting.

PATHOLOGICAL SOCIETY, 8 p.m. General Meeting for Election of Officers.

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.

OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Annual Meeting for Election of Officers, &c.; Papers by Dr. Day and Dr. Graily Hewitt.

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Anniversary, President's Address, Election of Officers, and Conversazione.

8. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN,

By J. Y. SIMPSON, M.D., F.R.S.E.,

Professor of Medicine and Midwifery in the University of Edinburgh.

ON ACUPRESSURE.

(Continued from page 4.)

WHEN SHOULD THE NEEDLES BE WITHDRAWN?

Much more investigation and practice are requisite before this and some other questions regarding acupressure can be definitely answered. We want, for example, a series of proper experiments and observations as to the actual pathological mechanism by which acupressure occludes the mouths and tubes of arteries before we attain fixed ideas as to its progress and completion. But we know from clinical experience that a comparatively short time usually suffices, the period being varied by the size of the vessel. The largest arteries divided have been found closed within fifty hours; those of medium size in twenty or thirty hours; and those of small size sometimes within a couple of hours.

The largest artery opened in operative wounds is the femoral. In several instances of amputation of the thigh, the femoral has been closed by acupressure needles. Dr. Struthers was the first Surgeon who had the boldness to apply acupressure to the femoral in an amputation of the thigh. The case—a very dangerous instance of traumatic spreading gangrene following a machinery accident—succeeded perfectly. Dr. Struthers did not remove the needle from the femoral till the fourth day, or about ninety-eight hours. In a successful amputation of the thigh, also for traumatic spreading gangrene, Dr. Handyside removed the needle over the femoral in forty-nine hours.

In the following instance of amputation of the thigh for chronic pathological disease, performed by Mr. Crompton, Senior Surgeon to the General Hospital, Birmingham, the needles were left for fifty-two hours:—

Case 1.—Amputation of the Thigh for Scrofulous Disease.—Needles Removed in Fifty-two Hours.—On February 29, 1860, Mr. D. Crompton amputated a young man's thigh, for strumous disease in the femur, and consequent degeneration of the cartilages of the knee-joint. Two acupressure needles sufficed to arrest the bleeding, one of them pressing on the femoral artery, and the other pressing upon two small muscular branches. After fifty-two hours, the needles were all withdrawn. On March 29, or exactly four weeks after the operation, Mr. Crompton sent me a cast of the stump, with a note, stating that the young man was then quite well. In this case no rollers or plasters, nor, indeed, dressings of any kind, were applied to the stump.

In the following case, reported to me by my friend and former pupil, Dr. Hamilton, the needle was removed from the femoral artery after forty-eight hours. The case occurred in the practice of a very able young Surgeon—Mr. Brown, of Carlisle.

Case 2.—Thigh Amputation and Primary Union—Needles Removed in Forty-eight Hours.—The patient was a man of 50 years of age, and had suffered for two years from ulceration of the cartilages of his left knee-joint. Two sinuses connected with the joint were discharging profusely pus of a very offensive character. The poor man was reduced to such a state of emaciation and debility, that when he came down from near Carlisle to Edinburgh for the purpose of undergoing amputation, one of our most distinguished Surgeons refused to undertake the responsibility of operating. He, therefore, returned to Carlisle, where amputation was performed by Mr. Brown, after Teale's method, at the lower third of the thigh, and five bleeding vessels were acupressed. Forty-eight hours after the operation all the needles were withdrawn. Primary union took place throughout, except at a single spot where one of the sinuses, already alluded to, had been cut across. The patient was able to be dressed and down-stairs within four weeks, and in six weeks he was driving out alone in his gig daily; his general health good, and his strength rapidly returning.

VOL. I. 1864. No. 706.

The preceding case is taken from an interesting series of nine or ten examples of the use of acupressure in the larger amputations, &c., kindly drawn up at my request by Dr. Hamilton, House-Surgeon to the Carlisle Hospital. Out of the amputations which he details in his report, let me cite another instance of healing by the first intention.

Case 3.—Primary Union after Amputation below the Knee.—Needle Removed in Forty-eight Hours.—A boy, of eleven years of age, was brought into the Carlisle Infirmary with compound comminuted fracture of the tibia and fibula, from two railway waggons having passed over his leg. Amputation was performed below the knee by Mr. Page, and the anterior tibial artery—the only vessel requiring interference—was secured by an acupressure needle. It was withdrawn after forty-eight hours. The flaps adhered by first intention from end to end, and the boy made a very speedy recovery.

Perhaps, in this instance, the needle might have been safely removed earlier than it was; but it is of still more importance to remark that its continuance did not prevent primary union. In a case of amputation of the arm, in a girl of fifteen or sixteen years of age, which I witnessed some time ago, the needles were all withdrawn within twenty-two hours. The operation was done by Mr. Edwards, who has tried acupressure in more instances, I believe, than any other Surgeon. But let me quote to you Mr. Edwards' own account of the case, which, to my view at least, at first looked a most unpromising case for recovery at all:—

Case 4.—Amputation of the Left Arm, and Needles Removed in Twenty-two Hours.—The patient had been suffering for two years under scrofulous disease of the elbow-joint, apparently set up by an injury. "Latterly (says Mr. Edwards) she had suffered severe pain, and moving the limb was scarcely possible. When I saw it, the elbow was packed in large, heavy poultices, the weight of which had, during some moment when the arm was left unsupported, broken the humerus about two inches above the joint. The fractured ends threatened to pierce the skin. The joint was evidently disorganised. She was not a favourable subject, being thin and feeble; a large swelling, apparently a chronic abscess, over the left side of the thorax; but she was suffering so acutely from the fractured arm, that I thought it my duty to amputate, which I accordingly did the next day, having to go close under the tuberosities, so as to secure tolerably healthy soft parts. All the vessels, including the brachial, were secured with needles and wires by Professor Simpson; they effectually prevented hæmorrhage, and were all removed in twenty-two hours; the flaps adhered, and, except a little pouting at the skin margins, the stump was healed in five days; on the fourth she was out of bed, and was able to walk to my house on the eighth day."—(See *Medical Times and Gazette*, April 11, 1863.)

I have mentioned, in the three preceding instances, three cases of amputation wounds where the vessels were acupressed, and healing of the stump, followed by primary union. The three cases in question were instances of amputation of the thigh, of the leg, and of the arm. As another instance of union by the first intention, let me select an example of amputation of the forearm, from the practice of Dr. Greig, of Dundee, who was among the first Surgeons that used acupressure:

Case 5.—Amputation of the Forearm.—In a case of injury Dr. Greig preferred amputation at the middle of the right forearm, and secured the bleeding vessels with ease and success by acupressure. Little or no local irritation followed, and the wound healed entirely by the first intention. This was the second case of amputation in which he employed acupressure. He removed the needles early, I believe; but I have no note of the exact hour. Dr. Greig, as one of the Surgeons selected and sent out to the East during the Crimean war, as a diligent observer when a student, and as Surgeon to the Dundee Hospital, has necessarily seen many amputations; but latterly he wrote me that this case formed the first amputation wound which he had ever really seen close entirely by union by the first intention. The patient—a stonemason—was soon back to his work, and had the mallet so fitted as to enable him to go on perfectly with his trade.

Wounds of smaller arteries may, as I have already said, be successfully occluded by pressure of still shorter duration. And, perhaps, as I have often ventured to suggest, the time may come when, in minor operations and amputations, the Surgeon will wait six or twelve hours before closing the lips of his wound by metallic sutures, and be able to withdraw, before he does so, most, if not all, of the acupressure

needles which he has employed. If so, he would be able to close the sides of his wound without any foreign body whatever being left between them. In the following instance, my friend and former assistant, Dr. Coghill, now of Shanghae, acted successfully upon this principle.

Case 6.—Excision of the Mamma—Needles Removed in Two Hours.—The patient was a very stout and bulky Highland woman. There was a large cancerous tumour in one of the mammae. In removing it Dr. Coghill was obliged to make a wound of eleven inches in length. Three or four vessels bled, and were occluded by acupressure needles. Dr. Coghill left the wound open for about two hours. Before closing it he removed the needles, without there following any appearance of hæmorrhage. He then, very carefully and accurately, brought together the lips of the wound with stitches of iron-thread. Complete and entire union by the first intention ensued.

In his treatise on "Diseases of the Breast," M. Velpeau has made, in reference to primary union of the wound after excision of the mamma, a few remarks, which are not perhaps uninteresting in regard to such a result as the above. In one part of his masterly work, he speaks of having excised the mamma for cancer alone (independently of other non-malignant tumours) in about 130 instances. These all occurred in Hospital practice; and of course he has often operated in private practice also. Yet in only four or five instances has he observed the resulting wound to heal by the first intention; and in these few exceptional cases *no ligatures* happened to be required. Their accidental absence permitted, as it were, primary union to occur. "Should (to use Velpeau's own words) immediate re-union and complete cicatrization by the first intention occur, so that the wound closes without suppuration, we have every reason to be delighted; but this circumstance is so rare, that I have only witnessed it on four or five occasions, twice in men, three times in women; in all instances, after the removal of small tumours, and in patients who were somewhat thin, where there had been *no necessity for ligatures*, and where the wounds were perfectly even and of small extent. Except under these circumstances, I have usually found the wound to suppurate, so that it almost always required from three to five weeks before cicatrization was complete."—(See "Velpeau on Diseases of the Breast," Sydenham Soc. Edit., p. 528.) In these four or five instances of apparently small mammary wounds, primary union was the result, probably, as I have already suggested, merely because it happened as a matter of accident that no arterial ligatures were necessary. In Dr. Coghill's case, the mammary wound was unusually long and large, and yet primary union was the result, because it was regulated as a matter of art that no ligatures were used, and that the wound was in a short period after its infliction closed, without any foreign body whatever being left lodged within its cavity or between its walls.

LOCAL REQUISITES FOR THE PRIMARY UNION OF WOUNDS.

Such cases as I have latterly cited might possibly lead some of you to imagine that, in the way of the local management of wounds, acupressure was all that was requisite to ensure that desirable object. Any such inference, however, would be most erroneous. The closure of extensive wounds in which acupressure is used to arrest the attendant hæmorrhage, is still the exception and not the rule. It is one of the elements, and, as I believe, a very important and very necessary element, in our attempts to effect primary union; but there are other elements and circumstances which must also be most carefully attended to. The sides or flaps of the wound must, if we expect primary union of them, never be of a kind to require pulling and tension, either to bring them together or to keep them in apposition. If they are too small and short for this purpose, or if the stitches holding them require to be put or kept on the stretch, then union by the first intention becomes scarcely possible. Surgeons will probably come yet to shape their wounds and flaps more systematically than they do even at present, so that the sides and edges of their resulting wounds lie fully and easily in contact. If the sutures, whether metallic or silken, be placed upon the strain, they will cut through the lips of the wound by ulceration to the extent necessary to relieve the strain. When the lips of the wound are ultimately adjusted, and accurately and carefully fitted to each other, no one of the sutures must be found on the stretch and deeply indenting the points on which it rests and presses; for, if so, those points will soon become irritated and ulcerated, and the act of primary union will be more or less

interfered with. But still more, when we strive for primary union, we must beware of leaving any foreign and dead materials—however small and almost molecular they may be—on the sides or in the cavity of the wound. In an amputation wound, when the saw divides the bones, the resulting dead particles of bone-dust are freely scattered all around. Any of these particles left on the surface of the wound would infallibly prevent primary adhesion at the points where they were lodged; nay, they would sooner or later set up suppurative inflammation ere they were finally discharged. They must all be carefully removed by sponging, or, still better, by a stream of water allowed to fall upon the wound; for even our sponges sometimes leave flakes and fragments of their tissue upon the surface of the wound, which, though they be minute, are still dead foreign bodies. Of course, it is needless to close up a wound and expect it to heal by primary union if you allow coagula of blood to remain lodged within it. These coagula act again as foreign bodies, both inevitably preventing present adhesion, and inevitably producing future suppuration. The wound must not be shut up till all bleeding has ceased; and to prevent the mischance of any coagula forming for the next few hours, some Surgeons do not close their wounds till six or eight hours have elapsed. In closing large wounds, particularly large amputation wounds, it is further, I am inclined to believe, a matter of great moment to bring the flaps most carefully together from below upwards, so as to preclude the possibility of a small collection or collections of atmospheric air being left in the depths or between the approximated sides of the wound. I fancy that I have seen the flaps brought together first, and chiefly along their edges, so that a quantity or quantities of air were left lodged within. Like any other foreign body which keeps the opposed walls of the wound from approximating and touching perfectly, air, even in small quantities and bubbles, will as effectually prevent primary adhesion at the parts or points at which it is located as the same bulk of dead solid materials would. Whilst it is thus a great and indispensable indication to free the surfaces of the wound from all foreign matters that can possibly prevent them coming everywhere into close and accurate contact, it is sometimes necessary, also, by the position of the wounded part—by the use, if necessary, of slight bandages, and by supporting sponges or light pads placed externally—to retain the opposed surfaces in the same close contact till they are glued together in sufficient strength by the reparative process. In other words, it is necessary, not only to place the sides of wounds in accurate contact, but it is necessary also to *keep* them thus in accurate apposition. The mere shallow cutaneous edges only of large wounds are usually brought together by the superficial stitches that are used; but if the stitches be made by metallic sutures planted so deep as to embrace the sides of the wound to a considerable extent, bandages, plasters, and dressings are very seldom required. The mere atmospheric pressure keeps the sides of a wound in contact when once its lips are accurately closed and sealed up with an adequate number of metallic sutures. And certainly the fewer local dressings and applications we require to place about a wound, the greater, perhaps, is the chance of its successful repair and reunion. I believe, in other words, that, after the sides and edges of a wound are properly approximated and adjusted with its metallic stitches, the best dressing, as a general rule, is—nothing, absolutely nothing. I have seen full and testing proof of this in the large wounds left by excision of the mamma, and by ovariectomy. We have not easily the power of applying any dressings, or ointments, or lotions to cases of vesico-vaginal fistulæ immediately after they are operated upon; and it is, perhaps, fortunate that it is so; for, probably, these vesico-vaginal wounds close by primary union with the comparative certainty, and in the large proportion which we see in practice, greatly because we are shut out from intermeddling with them, therapeutically or surgically, after they are once stitched up. We cannot overload and overheat them, as was too often done in former times, in "dressing" external wounds with complex layers of ointments, pledgets, straps, rollers, etc. Even a dressing of charpie and cold water to a recent wound is, perhaps, more hurtful than useful. It busily unmakes what nature is busily making—a crust along the edges of the closed wound. If the lips of it become red and irritated or inflamed, apply to them cold air, and you will find, as I have found, that a stream of it directed upon the wound or its vicinity from a pair of bellows will prove both beneficial locally, and most grateful to the feelings of the patient.

IS NOT THE ACUPRESSURE MORE DIFFICULT THAN THE DELIGATION OF ARTERIES ?

Every new practice in the hands of the Surgeon is more or less difficult merely because it is new, and because he is not yet familiarised in the employment of it. The practical difficulties connected with the deligation of arteries, according to the somewhat clumsy modes in which it was first proposed by Paré, formed in themselves early obstacles to its introduction. But, in the course of time, the process of deligation has been much improved and simplified; and the same will probably hold true of acupressure. Other and simpler means of applying the needle than any which I have proposed will very probably be suggested by others, and consequently the process be rendered even still simpler and safer than it is at present.

In its present condition, however, the Surgeons who have tried it have found it as easy, at least, as the ligature. After using acupressure in two cases of amputation of the fore-arm, Dr. Greig, of Dundee, wrote me that he found the needles "applied quite as easily as the ligature." "The process (says he) so far as I have tried it, is the simplest that one can imagine. . . . It is really surprising how very little pressure is required to stop bleeding from an artery." "In giving directions for securing the vessel, you advise the Surgeon to place the forefinger over its bleeding mouth, etc. Now, you will find it much better, when you have a flap, to keep the forefinger of the left hand on the skin side, and use the thumb. You feel the vessel beating between the thumb and the forefinger, and you can introduce the needle in the dark."

In the first case of amputation in which Dr. Handyside used acupressure, he had to undertake the operation at a distance in the country, and improvised some long "darning" needles into acupressure implements for the occasion. He fixed knobs of red sealing-wax upon the heads of them to facilitate their introduction. At that time the two easier modes of effecting acupressure by common short sewing needles had not yet been thought of. But, in order to show you that Dr. Handyside found no difficulties in the application of acupressure even with the long needles, let me state in a few words his case, which was a very interesting one, and then quote the comments which he has himself published on it in reference to the question of the relative facility or difficulty of acupressure.

Case 7.—Amputation of the Upper Third of the Thigh for Traumatic Spreading Gangrene.—The patient received a very severe lacerated wound of the leg, with compound fracture of both bones, from a loaded waggon running against him down a steep incline. Gangrene supervened, and in five days afterwards, when Dr. Handyside was summoned from town to see him, he was delirious and prostrated; the mortification had reached the knee, and was spreading upwards; the inguinal glands were much enlarged, and the lymphatics of the limb tense; the pulse rapid, weak, and irregular; and the skin cold and clammy. Dr. Handyside performed amputation of the thigh immediately below the trochanters, and arrested the bleeding from four divided vessels by as many needles. Two of the vessels were relieved from acupressure at the twenty-fourth hour, and the other two—one of them being the femoral artery at its giving off of the profunda branch—at the forty-ninth hour. The swollen glands in the groin supplicated, it would seem, and the pus was partly discharged from the centre of the cicatrix, which formed at the line of union of the flaps, and partly from two incisions made through the recent adhesions by Dr. Todd. Notwithstanding all the unfavourable circumstances of this case, "the line of cicatrization of the flaps," to use the words of Dr. Todd, "was healed by first intention," and in twenty-one days the patient was in excellent health, and had a cast of his stump taken in plaster.

The woodcut (Fig. 8) shows the shape of the resulting stump, and the directions in which the needles passed to secure the four arteries, which were the femoral (F), and, apparently, the obturator (O), and two ischiatic branches (I, I).

This, as I have said, was the first time Dr. Handyside had ever used acupressure, and yet, in his interesting published account of the case, he states:—"The performance of acupressure seems to me to be free from all difficulty." "The hæmorrhage," he adds, "from the divided vessels was arrested with greater expedition in this way than by the ligature; for, in closing the bleeding orifices by needles, I wholly dispensed with an assistant; and, in employing needles, I further effected a saving of blood, as well as of time. We may, hence, reasonably conclude that the shock to this patient's system was thereby very probably lessened, and his

recovery promoted."—(See *Edinburgh Medical Journal*, for December, 1860.)

FIG. 8.

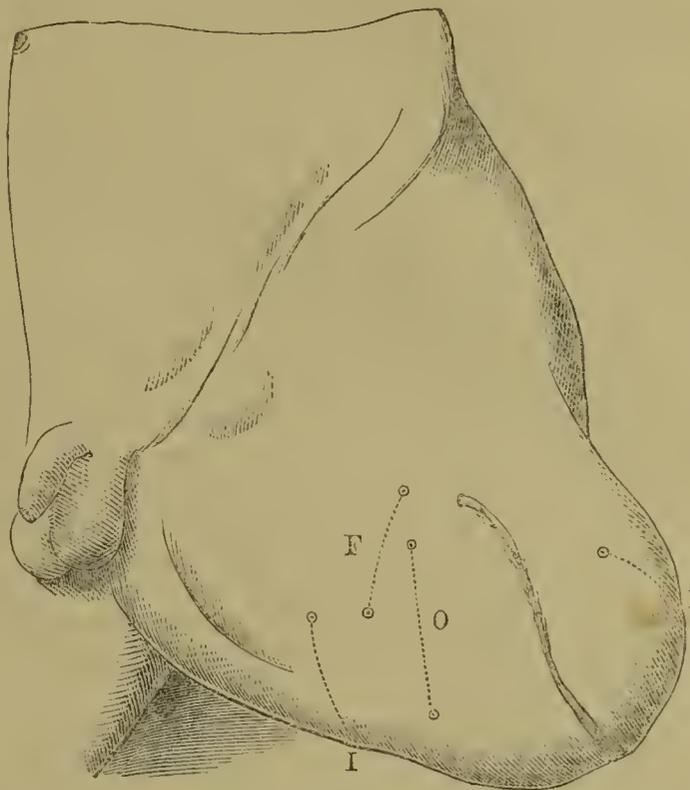

FIG. 8.—Stump after Amputation of the Thigh below the Trochanters (Handyside.)

An accomplished country Surgeon, Dr. Turner, of Leith, has had an opportunity of using acupressure in two or three amputations. "I consider (he writes me three years ago) acupressure as at once efficient, *easy of application*, and conservative; and I will never again employ the ligature where this method can be adopted." "In addition (Dr. Turner more lately writes me) to its chief recommendation, your method has other and not unimportant advantages over the ligature,—it is most easy of application, and admits of being quickly applied. It thereby saves blood to the patient, and to the operator—especially if his light be bad, as it often is with us Gideon Grays—pokings with the hot sponge, slackenings and tightenings of the tourniquet, and even exploratory cuttings with the scalpel for the source of the river, to say nothing of the loss of temper liable to occur in the course of the search with the assistant, with or without cause. I have always applied the needle in the way you first proposed, introducing it from without, passing it over the artery, and bringing it out on the other side. I was acquainted with your later mode of adjusting it before my last operation, but I had only the long needles at hand, and, to say the truth, I have found this method *so simple and efficient*, that I should hesitate to adopt the other instead."

Speaking of the two later methods of applying the acupressure needles, Mr. Edwards has observed,—“Soon after this, Professor Simpson substituted sewing needles for the long pins, threading them with wire, and applying them on the raw surface of the wound. He thus arrested the bleeding in a case where I removed a man's arm above its middle third, and after a similar operation on an infant. The adult stump healed by first intention entirely; the other almost entirely. . . . Since, Dr. Simpson has further modified the method of application by adding a wire-loop to the needle; the latter can be adjusted with *very great ease and rapidity*.”—(*Medical Times and Gazette*, February 14, 1863.)

[The third part of this lecture on Acupressure is in type, and will appear in our number for January 16.]

PHARMACEUTICAL SOCIETY.—A pharmaceutical meeting took place last Wednesday evening, the 6th inst. The following papers were read:—"Note on the Root-bark of Calisaya," by John Eliot Howard, F.L.S.; "Note on *Cassia moschata*," by Daniel Hanbury, F.L.S.; "On Goa Powder," by David S. Kemp; "Note on the Recovery of Essential Oils from their Watery Solution," by Mr. T. B. Groves. Thompson's patent bottles, and Thonger's patent label for the prevention of accidental poisoning, were exhibited at the meeting.

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University
College Hospital.

(Continued from page 5.)

As it is with the diseases of man alone that we have to do, we must now direct our attention specially to

HUMAN URINE.

The most readily observable properties of the human urine are—its colour, smell, taste, reaction, and specific gravity.

The Colour of the Human Urine.—The colour may be said to be quite characteristic, as no other animal liquid possesses a similar one. In health, it fluctuates between a pale straw and a brownish-yellow tint. It is due to the existence of a peculiar pigment—urohæmatin—and upon the relative proportion of this colouring matter and the water do all the varying tints of the healthy urine depend. Consequently, you now observe that I artificially produce from this intensely coloured urine each of the different normal shades by the simple addition of pure water. Hence, we find that, so long as the body remains in health, the larger the quantity of urine daily excreted, the paler the tint; the less the amount, the higher the colour.

Although, as I shall afterwards have occasion to show you, normally coloured urine does not necessarily exclude the possibility of disease, yet it is in general the presence of orange, red, brown, black, green, or blue urine that indicates the existence of the graver maladies. Still, even the presence of high-coloured urine, when an average amount is passed, is a sign which ought never to be lost sight of, as it invariably indicates the existence of a pathological condition of system. The import of this, like that of the other tints, will afterwards occupy our attention; meanwhile we must pass on to the consideration of the next physical condition of normal urine, namely:—

The Smell of the Urine.—Immediately after being passed from the bladder human urine has a mawkish aromatic odour. The smell of the urine is in general quite characteristic of the species of animal. All of you are acquainted with the smell of cat's urine, and I daresay most of you are equally familiar with the peculiar odour of the urine of the horse and cow. The urine in general smells like the fat of the animal; sheep's urine, for example, smells exactly like mutton suet. Many foods and drinks transmit to the urine their peculiar odour. To such an extent, too, may this be the case, that one is occasionally able, from the smell of the urine alone, to tell the kind of solid or liquid of which the patient has partaken. Thus, turpentine, copaiba, garlic, and many other aromatic substances, may be recognised in the urine. All of you must have observed what a strong odour asparagus imparts to the renal secretion. It not unfrequently happens that the mere breathing of odoriferous substances communicates their characteristic aroma to the urine, and the more delicate the individual, the more marked is this effect. The abnormal odours of the urine, such as we meet with in jaundice, Bright's disease, diabetes, etc., will each occupy our attention in its appropriate place.

The Taste of the Urine.—The taste of normal urine is saltish bitter, but the flavour varies very much in disease, being sometimes as sweet as honey—in diabetes; and at other times as bitter as gall—in icterus. In cases of urgent necessity, where the urine has been used as drink, it is said greatly to increase the thirst. Holwell, when confined in the black-hole at Calcutta, found the thirst, which proved so fatal to many, relieved by sucking his perspiration, but not by drinking his urine.

The Reaction of Human Urine.—When freshly passed the urine is slightly acid, the acidity becoming more marked during the first hour or two. According to Dr. Bennet Jones it is neutral, or even alkaline, immediately after taking food, again gradually becoming more and more acid up to the time of the next meal. Although I have been unable to verify this statement on perfectly healthy individuals, I see nothing improbable in it, if the person experimented upon has partaken

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

largely of vegetable food. The urine of dogs fed on flesh is acid, but if the animals are fed for several days on vegetable diet it becomes alkaline. The urine of rabbits, on the other hand, is normally alkaline, but if animal food be forced upon them, or better still, if for a time they receive no food at all, and are consequently obliged to live upon their own tissues, the urine becomes acid, and at the same time assumes many of the other characteristics of the carnivorous animal. It is, therefore, highly probable that diet will, in a similar way, influence the reaction of the human urine. It may be laid down as a rule, however, that if the urine of a person living on mixed diet becomes alkaline in less than twenty-four hours after being passed, there exists some disease, either of the general system or of the urinary organs, which demands immediate attention.

It must not be forgotten that many medicines—alkaline carbonates, for example—as well as alkaline citrates, tartrates, and acetates, which are converted, in their passage through the body, into carbonates, cause even the urine of healthy individuals to become for a time alkaline.

The acidity of normal urine depends on the united presence of acid phosphate of soda, uric, (b) hippuric, and lactic acids. Neither the hydrochloric nor sulphuric acids, which, as will afterwards be seen, are always present in normal urine, have any share in producing the acidity, for they are both combined with bases in the form of neutral salts. After standing for a greater or lesser time, all urines become alkaline. This arises from the urea being decomposed into the carbonate of ammonia, in consequence of a putrefactive fermentation being induced by the presence of such animal matters as mucus from the bladder and urinary passages. The carbonate of ammonia is a strongly alkaline salt; so alkaline, indeed, that putrid urine was at one time in great request for the purpose of removing grease from cloth. This property the urine entirely owes to the presence of the carbonate of ammonia, which unites with the fatty matters of the cloth, and forms an alkaline soap, readily removable by washing. The peculiar odour, so characteristic of putrid urine, is also chiefly due to the carbonate of ammonia derived from the decomposed urea.

It occasionally happens that this decomposition occurs within the frame; and hence in certain diseased states of the bladder and urinary passages the urine is alkaline at the moment of being voided, while in certain others of the general system it becomes so very shortly after being passed.

The reaction of the urine is most readily ascertained with litmus paper. Some recommend neutral paper for this purpose, as one kind does for both acid and alkaline urine; but, as you now see, the change produced in the neutral paper is very slight, whereas with the more intensely coloured papers, one of which, as you perceive, is of a distinct blue, while the other is as evidently red, no difficulty can possibly arise. The blue paper I dip into this dog's urine, the acidity of which instantly turns it red; while the red paper I dip into the alkaline urine of the horse, and, as you observe, it is as rapidly changed to blue. Soft papers are usually more sensitive than hard.

When it is deemed desirable to ascertain the exact amount of free acid daily excreted, a standard solution of caustic soda is employed of such strength, that one cubic centimetre neutralises ten milligrammes of dry oxalic acid. This solution is gradually added to a given quantity of urine until the acid reaction disappears, and the calculation for the whole quantity passed in the twenty-four hours made accordingly. (c) It has been ascertained that healthy adults daily pass, on an average, an amount of free acid equal to about 1.7 grammes (27 grains) of dry oxalic acid.

This mode of estimating the amount of free acid present in urine is unfortunately too troublesome to admit of its being generally employed at the bedside, so that we are forced to guess at the acidity of the secretion from the intensity of the stain it produces on litmus paper.

It occasionally happens that the urine is recognised as being abnormally acid from the presence of brownish-red crystals of uric acid on the bottom and sides of the chamber-vessel; for free uric acid never crystallises spontaneously, except in cases where the urine contains an excess of acid, as, for example, in febrile and inflammatory affections, especially those in which the liver, heart, or lungs are implicated.

(b) Some have thought that all the uric acid is united with part of the soda, of what would otherwise have been the neutral phosphate of soda; but this is an error, as is seen by the fact, that in the most naturally acid urines the uric acid is invariably found in a free state, as is proved by its spontaneously crystallising when the urine cools.

(c) The mode of preparing and employing this solution will occupy our attention on a future occasion.

ORIGINAL COMMUNICATIONS.

ON RUPTURE.

By JOHN WOOD, F.R.C.S.,

Demonstrator of Anatomy, King's College, London, and Assistant-Surgeon to the Hospital.

ALTHOUGH the word "rupture" conveys, in some respects, a meaning which does not exactly explain the origin of the condition which it expresses, yet its cognate and more scientific term "hernia," having a wider application to somewhat similar conditions in the head and thorax, hardly suits so usefully the pathological state of protrusion of the viscera of the abdomen through its retaining walls. The use of the former word also has received the sanction of popular usage, and the recognition of some of our most eminent Surgical authorities. If we guard against the implication, that the protrusion is caused by any tearing of the tissues, and confine the word to its other meaning, of a separation of parts by force or a bursting forth, it becomes sufficiently appropriate and distinctive for all practical purposes.

In the abdomen, a visceral protrusion may occur either through a normal opening left from the transmission of other parts, or through an opening accidentally or unavoidably made, or produced by disease. Of these two ways, the former is much the most common, and the rupture is named after the opening through which it protrudes. If through the openings left for the passage of the spermatic cord in the male, or round ligament in the female, it is called *inguinal*. If through the opening left for the passage of the lymphatics of the leg into the abdomen, it is *crural* or *femoral*. If through the opening of the navel, where the vessels of the funis pass to and from the viscera of the fœtus, it is *umbilical*. To the same class belong the less common varieties, such as the *obturator* protrusion—through the hole for the obturator vessels and nerve; the *sciatic*—through the greater sacro-sciatic foramen; and most *diaphragmic* ruptures, which take place through the aperture for the œsophagus, or that for the superficial lymphatics of the liver, close to the xiphoid cartilage.

The class of protrusions which pass through abnormal openings are mainly included in the term *ventral*. Some forms of *diaphragmic* rupture, and also the *vaginal* and *perineal* varieties, are also included in this class. To all these varieties, certain conditions of the internal parts, as well as of the containing walls, will predispose, and such predisposition may result from hereditary peculiarities, or may be induced by certain occupations and habits.

The conditions of the internal structures which predispose to rupture affect chiefly the lining serous membrane of the cavity, the peritoneum and its processes, especially the greater and lesser omenta, which cover and connect the viscera; and the mesentery and mesocola, which retain respectively the small and great intestines. These tissues, in a certain proportion of hernia cases, exhibit, on a post-mortem examination, a degree of hypertrophy in length and width, giving to the viscera which they attach a lower position in the abdomen, and a degree of play in the cavity, which, in case the containing walls are also deficient, will result in a hernial protrusion. In most of these cases, also, there is a tendency to the formation of abdominal fat in the subserous areolar tissue. This fat is usually most abundant in the great omentum, which is much enlarged. In the folds of the superior false ligament of the bladder it is also found in greater quantities than usual. The presence of fat in these structures, however, is not in itself a cause of their hypertrophy. An omentum or mesentery loaded with fat is often coexistent with a degree of firmness, from a healthy development of fibrous tissue, which holds the viscera well in position. In many hernial cases there is, in addition, a laxity and looseness of the peritoneal connexions. The layers of the great omentum slide readily over each other, and may often be easily separated into four distinct folds. The pancreas, kidneys, and duodenum are more movable than natural; the root of the mesentery is depressed towards the sacral promontory; the anterior parietal layer of peritoneum is separated from the fascia transversalis and iliaca by a layer of loose fat, variable in thickness, giving to the superior and other false ligaments of the bladder a greater play than usual. By a minute dissection, the pellets of fat are found to encroach upon the tissue of the serous membrane itself, rendering it very thin

and transparent in many parts, and giving it the appearance of a reticulated membrane. In the great omentum this condition sometimes attains to a cribriform structure. In the sac of a hernia formed under these circumstances, the microscope shows an openness of texture resulting from the spreading out of the fibres of the areolar base of the serous membrane, and giving the appearance of a paucity of the yellow fibrous element.

The above condition in these subjects is shown by a looseness and bagginess of the abdomen, a hypertrophy of the folds of fat in the groin, by a general flaccidity of the muscles of the limbs, and great play during their action. Frequently the genital organs and groins show a resemblance to the fœtal outline—a long prepuce, a short, rounded scrotum, and a soft, short cord, thickened by fat deposit. The tendency to hernia in such a condition is increased by hypertrophy of any of the viscera, as the liver or stomach, and by a perpetual state of distension of the intestines by flatulence. The form of rupture which results is usually inguinal or umbilical, which take place at the normal apertures most exposed to the increased pressure from within, and most liable to be opened out by distension of the abdominal walls. They are very apt to follow a sudden absorption of the accumulated fat from illness or starvation. The removal of the adipose tissue leaves the areolar meshes wide and weak, and ready to give way to pressure. In many of such cases I have seen the openings in the aponeurotic walls of the abdomen for the passage of small vessels and nerves enlarged by the interposition of pellets of fat. At the internal ring and the umbilical cicatrix, the peritoneum, instead of being closely adherent to the margins of the opening, is loose, lax, and movable, and often bulged into a digital impression, or even a distinct pouch, without any absolute protrusion through an opening in the abdominal wall.

A much more decided predisposing cause of rupture is, however, to be found in a preternaturally weak or patulous condition of the openings in the walls of the abdominal cavity. This weakness is, in the male, most frequently to be found in the inguinal canal. It results from the course followed by the testicle in its descent, and from the presence of the spermatic cord. This weakness tells chiefly, in hernia cases, in three distinct parts of the inguinal canal, viz., at the deep abdominal ring, in some part of the canal between the rings, and at the superficial ring. In the cases just described as accompanied by a change in the peritoneal structures, the connexion of the peritoneum to the fascia transversalis at the deep abdominal ring, is weakened by an elongated and loose condition of the process of tough areolar tissue, which results from the closure or atrophy of the canal of Nuck, or channel of communication between the peritoneum and tunica vaginalis. In a normal condition the peritoneum is closely adherent round the margins of the deep ring, and this adhesion prevents the first tendency to protrusion through the ring. In many subjects I have found an elongated mass of fat growing from the subserous structure, and protruding into the ring among the elements of the cord. In one which I lately examined, such a ball of fat had opened up the ring considerably. In many cases, without any hernial protrusion, the ring itself is placed internal to, and below, its usual position above the middle of Poupart's ligament. By this approximation to the site of the superficial ring, the canal is shortened and opened up, and predisposed to the reception of a hernia. In this case, the sharp internal falciform border of the ring is usually thickened and rendered more prominent. In one, a distinct band of condensed fibres was visible, curving under the spermatic duct, and connected below with the deep crural arch. A general laxity in the attachments, and a mobility of the fascia transversalis, is evident in these cases. The elementary parts of the cord itself are also very mobile.

In a great proportion of the subjects affected by oblique inguinal rupture, and in many in whom no rupture has occurred, but in whom a weak, bulgy state of the groins was evident, I have observed a deficiency in the development of the lower fibres of the internal oblique muscle. In the normal condition the lower arched fibres of this muscle are continued downwards and inwards along Poupart's ligament, arising from at least two-thirds of its length, and covering very decidedly, in front, the aperture of the deep ring, which is normally placed about half an inch above the centre of the ligament. In muscular subjects a decided thickening of the fibres of the muscle is observable over the ring itself, giving an increased safeguard against protrusion. In all, a distinct cellular interval is observable between this oblique muscle and the cremaster. Some of the fibres of the latter can,

moreover, be seen to pass behind the internal oblique, to become connected with the transversalis muscle. On account of the looped arrangement of the cremasteric fibres, they can exert but little influence in retaining a rupture, even though they may be stronger than usual at their origin from Poupart's ligament, which is sometimes the case when the lower fibres of the internal oblique are not well developed. The transversalis muscle in these cases does not come so low down as usual. With this condition of the muscular fibres is also observed a thinned and atrophied state of the conjoined tendon of the internal oblique and transversalis muscles. Instead of being implanted for a couple of inches along the pectineal line, this structure cannot be traced much beyond the pubic spine, leaving a considerable interval between its outer edge and the epigastric vessels. The transversalis fascia can often be stripped easily from the hinder surface of the tendon instead of being more or less firmly blended with it. The tendon is arranged as distinct fibres, with connective tissue of a weaker sort passing between the intervals which separate them. The muscular fibres implanted upon its anterior surface are feeble and scattered. The false ligament of the bladder placed behind it is filled with a loose fat, in which the obliterated hypogastric artery plays freely. The fibres of the so-called triangular aponeurosis are feeble or absent. This condition predisposes to a direct inguinal rupture.

In a certain proportion of cases, and those in which inguinal rupture, when once formed, makes the most rapid progress, the superficial ring is so patulous as to receive the point of the finger. Sometimes this condition is unattended by rupture. There is no bulging at the deep ring, and the canal may be well embraced by the internal oblique and its tendon. In many cases, on the other hand, in which a bubo-nocoele may be present, the superficial ring is well closed up by the intercolumnar fibres. Sometimes these resist the progress of the rupture so firmly, and for so long a time, that a considerable external tumour may be apparent above the ring, and a still larger cavity be hollowed out in the canal. At last, under some great effort, the rupture shoots through the narrow opening, and the tumour will assume an hour-glass shape, with the contracted part at the superficial ring.

Like the deep ring, the superficial may be opened up by the growth of a small fatty tumour. A specimen of this kind in my possession is connected above, in the canal, with the sac of a small hernia admitting the point of the finger. The tumour projects about an inch through the superficial ring, is elongated, and connected above with the subserous areolar tissue of the small hernial sac. It is placed in front of the spermatic vessels and duct, and is covered by all the coverings of the cord.

Many of these cases of a patulous state of the inguinal openings have been doubtless consequent upon a later descent of the testicle than normal. This may possibly have also resulted from the muscular apparatus effecting the descent participating in the vice of defective development. In a certain proportion of cases, congenital hernia is the result, the bowel following close upon the gland, and preventing, by its frequent presence, the progressive closure of the canal. In others, the serous canal becomes closed, and the deep ring sealed by adhesion of the serous membrane to its margins; but the patulous condition of the tendinous canal and superficial ring remains ready for the reception of a hernial sac in after life. Some of the most rapidly-progressive cases I have met with have been of this kind.

They have been usually characterised by the persistence in adult life of some of the peculiarities of foetal conformation such as those before mentioned—of a long prepuce, rounded scrotum, short and plump cord. The mous veneris and folds of the groin are usually loaded with fat, and the pubic hair scanty. The pelvis has often a degree of obliquity which, with the protuberant belly, brings the lower abdominal walls more directly under the pressure of the weight of the abdominal viscera, and so increases the tendency to rupture. The pillars of the superficial ring are thin, weak, and yielding, and the groins bulgy.

In another class of cases, the tendinous parts of the abdominal walls are extensively developed, but are wanting in tenacity and resistance. The pillars of the superficial ring are strong and resisting, but often widely separated. The intercolumnar fascia, which binds them together, is thick and dense, but loosely held or collected into a band, which imperfectly closes the opening. The conjoined tendon is thick, but apt to yield before pressure, from inherent weakness. The muscular portions of the groin are not developed well down towards the

pubis, and, though the cremasteric fibres may be large and strong, they are not closely bound to the lower borders of the internal oblique and transversalis muscles, nor well implanted upon the conjoined tendon. The wings of the ilia are wide-spreading, and the flanks consequently large, and Poupart's ligament longer than is usual in the male, though strongly developed. The recti muscles are broad towards the thorax, but taper considerably towards the pubis, leaving a large aponeurotic space in the groins.

The peritoneal structures in these cases are usually thick and opaque, but yield somewhat readily to pressure. The scrotum is often long, lax, and heavy, and the testes pendulous. The individual is of a sinewy, rather than a muscular build, with a long body, and often large limbed and bony. The ruptures in such cases are of slow growth, and generally of unmarked origin, and, when fully formed, increase to a large size. They are usually of the inguinal variety, often on both sides. Crural hernia may also co-exist, and pouches may be seen at both the inguinal and crural openings.

A third class of cases of inguinal hernia is marked by great muscular development, but with a want of corresponding balance in that of the tendinous structures. The pillars of the superficial ring are firm, but thin, and are apt to split and part asunder between the fibres. The same peculiarity marks the conjoined tendon. The flanks are narrow, and the inguinal and crural openings small. The peritoneum is translucent, and healthily elastic and resisting, and the subserous structures tough and adherent.

Rupture in these cases comes suddenly and with great pain, after some violent muscular effort. It is often direct, and is effected more by a forcible splitting of the fibres of the conjoined tendon, than by a gradual yielding of the tissues. It is more liable to be affected, while still of small size and recent formation, by immediate and violent symptoms of strangulation, than either of the other varieties. This is also more influenced by spasm of the internal oblique muscle, of which the lower fibres are strong and well developed, and closely embrace the neck of the sac.

The importance of an early recognition of these tendencies to rupture—a disease in which, pre-eminently, prevention is better than cure, and the means thereof easily applied, but requiring a proper discrimination withal of each individual case—will justify a close scrutiny into the conditions which favour or retard its production.

RECORDS OF A CASE OF PROPTOSIS, GOITRE, PALPITATION, ETC., WITH REMARKS.

By C. HANDFIELD JONES, M.B., F.R.S.,
Physician to St. Mary's Hospital.

(Concluded from page 7.)

The goitre may, with great probability, be ascribed to a paretic condition of the vasomotor nerves of the thyroidal vessels. Malarious influence, which acts so evidently in an enfeebling manner on nervous structure, produces the well-known enlargements of the spleen and thyroid gland, which again are reduced or diminished by means of an invigorating character. Dr. Mirney has recently recorded some instances of the successful treatment of goitre by strychnia (*vide Dublin Hospital Gazette*, June 1, 1860). If we suppose the supply of blood to the spleen and thyroid to be increased by dilatation of their arteries, and their cell elements to have their nutritive actions increased by the loss of controlling nerve influence, hypertrophy must clearly result. The thyroid, inasmuch as it normally secretes into closed cavities, seems especially liable to hypertrophic enlargement.

The palpitation may also reasonably be ascribed to a semi-paralysis of the vagi nerves, or their cardiac branches. Section of the vagi is well known to accelerate materially the movements of the heart. In a case on which I operated the contractions of the heart were 200 in the minute after both vagi had been divided; when the left only was divided, 110. The occurrence of the palpitation in *accès* indicates its neurotic character.

The cough was evidently a neurosis from its peculiar intermittent character, its violence, and the absence of sputa in any commensurate amount, or of physical signs in the chest. The same may be said of the vomiting, which appeared to be a precisely analogous phenomenon on the side of the stomach.

On the first occasion tonics were of no avail to quiet these disturbances, but sedatives, argenti nitras, and hydrocyanic acid succeeded well. On the second occasion strychnia had excellent success in arresting the vomiting and in improving the general status. I can be confident that the condition of the gastric mucous membrane was not one of chronic inflammation in either of the attacks. Admitting the cough and vomiting to be neuroses of the pneumo-gastrics, can we rank them in the same class as the two preceding affections, which we have ascribed to paresis of the vaso-motor nerves? It appears to me that they may be regarded as closely similar, though not identical states; for we are continually meeting with instances where a state of extreme hyper- or dysæsthesia of some part coexists with most marked debility, and can only be cured by replacing the debility by vigour. It is evident that the debility is the root-malady, without which the hyper- or dysæsthesia would cease. Now, in some of these cases we can cure the two states by one and the same means, as in many cases of so-called scrofulous ophthalmia; but in others of the same disease, tonics entirely fail to relieve the dysæsthesia, and we are obliged to employ sedatives at first, till some ground has been gained in reducing the irritability, and then tonics come in with advantage. In scrofulous ophthalmia there is no doubt that the state of the retina is but a part of a general condition of debility, which takes the form in one particular nervous apparatus of hyper-æsthesia. The latter pathological condition is, in fact, but a modification of the former, and results probably from the debility reducing the power of the nervous expansion to endure even ordinary stimuli without being injuriously affected. The same is true of a multitude of other pains, and dysæsthesiæ, which are notoriously intimately connected with debility, and spring, as it were, out of it. Not unfrequently the dependence of the pain on nervous exhaustion is strongly marked by its being reproduced by slight exertion, after it had ceased to be felt during quietude. On these grounds I think it may be affirmed that the cough and vomiting were intimately connected with a state of paresis of the pneumo-gastric nerves.

The peculiar and extreme debility requires some remark. It was indeed extreme, so much so, that on both occasions there was no small risk that it would prove fatal. Yet, there was no obvious cause for it, no organic disease of any vital part, no drain by suppuration, or persistent diarrhœa. Her history on both occasions is, that she fatigues herself for a length of time by overwork, prostrates her nervous power, and then falls into a state of great debility, attended with a train of peculiar symptoms, and not removed by absolute rest. The administration of iodine on the first occasion might have contributed to increase her debility, but not on the second, when her state was even more perilous. It had then considerable resemblance to delirium tremens, but I am positive that alcoholic poisoning had nothing to do with its causation. To such conditions I think the term *neurolysis* is very appropriate, implying not mere common debility, such as might exist after a fever or other severe illness, but especially debility of the nervous system, which is continually manifesting itself in some form or other, either in the cerebro-spinal or sympathetic department. The recognition of this state is important, because it leads the practitioner to be on the look-out for a variety of disorders, all of which are *au fond* of the same character, and require the same treatment, although their outward manifestations are very different. Sometimes it is a neuralgia, sometimes a paralysis; sometimes a head affection with threatening coma or hemiplegia; again, some inflammatory or congestive state, with more or less exudation, often a diarrhœa. To call this condition hysterical, as is sometimes done, I hold to be an injustice, at least if hysteria be conceived to imply a mental state characterised by exaggeration, deception, and want of earnest desire to recover. The functional nervous disorder is not so palpable and clear as a broken limb, or inflamed lung, but it is not less real, and is often not less remediable by judicious management. I would that those who are sceptical of the reality of this pathological state had some experience of it themselves, that they might learn how much heroism it requires to endure a constant struggle against such crippling and weakening infirmity.

During the height of the disorder, in the first attack, the condition of the urine indicated a considerable destruction of red globules to be going on by its deep red colour. When improvement had commenced this was exchanged for extreme pallor, showing that the waste was reduced even lower than the normal amount. It seems difficult not to refer the former state to a loss of the controlling power of the vaso-motor

nerves, which regulate no doubt the nutritive actions taking place in the blood itself, as well as those in the tissues. The blood cells hurried through their period of life more rapidly than they would have in health, and decayed, yielding up their pigment to the urine; while, from the great emaciation, it is fair matter of inference that the same was the case with the various extra-vascular tissues. All this took place, be it remarked, under, and apparently in consequence of, a condition characterised by extreme failure of nervous power.

A few remarks with respect to the remedies employed may not be out of place. The efficacy of argenti nitras has been doubted, chiefly from the circumstance that it seems impossible it should not be immediately converted on entering the stomach into the insoluble and inert chloride. Admitting this, and, consequently, the difficulty of explaining its *modus operandi*, it yet seems to me quite undeniable that it is a most useful remedy in gastric disorder characterised mainly by undue sensibility of the mucous lining. To decided gastrodynia, or gastric catarrh, it does not seem appropriate,—at least, such is my experience of it. Dr. Fleming, however, thinks it efficacious in chronic inflammation of the stomach when administered so as to form an internal lotion to the empty viscus.

The amount of opium given on the second occasion was large,—varying from eight to twelve grains in twenty-four hours for several days—yet no narcotism was produced, and the effect was evidently beneficial. I can have no doubt that it procured sleep, without which she must have sunk. This has a bearing upon its use in delirium tremens.

Strychnine succeeded admirably in this case, as it often has in my hands, in arresting vomiting and in raising the general tone. It must clearly do this by its action on the spinal cord and sympathetic ganglia, increasing the functional energy of their nerve cells. It is probably just in the same way that it proves sometimes so serviceable in chorea, diminishing the mobility as it raises the power of the nervous structure. These two properties seem almost always to vary inversely, the tendency to action on slight excitement being mostly proportionate to the debility.

The effects of change to country air were always remarkable in this case. There can be no doubt that the atmosphere of large towns does often tend most notably to lower the power of the nervous system, and to generate a state of morbid irritability, which subsides when this chronic poisoning is at an end. My friend, Mr. White Cooper, has mentioned to me a case in which a lady, who has suffered from ague, is apt to have relapses while residing in London (in one of the most aristocratic squares), which she can only shake off by going to Brighton. Her system can resist the malarious impregnation it has received in the purer, but not in the more vitiated atmosphere.

CASES OF UNUSUAL SLOWNESS OF PULSE, WITH REMARKS.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,

Physician to St. Thomas's Hospital, and to the Hospital for Diseases of the Chest, Victoria-park.

(Read before the Hunterian Medical Society, December 2, 1863.)

(Continued from page 8.)

I have myself seen several instances of unusual slowness of pulse in persons labouring under disease of the heart. When I was at the Edinburgh Infirmary, a patient was under the care of Dr. Craigie who, six months before death, had only a pulse of 44 to 50 in a minute, and during the last portions of his life of 30 to 33. After death he was found to have a circumscribed aneurism of the septum of the ventricles, which had produced obstruction to the circulation on the right side of the heart, and was combined with great hypertrophy and dilatation of the left ventricle. Some years ago I was shown, by Dr. Barker, at St. Thomas's Hospital, a man labouring under disease of the heart, whose pulse beat regularly about 36. The two following cases afford examples of the same condition:—

Case 1.—Unusual Slowness of Pulse—Signs of Disease of the Aortic Valves—Occasional Fits of a Syncopic or Epileptic Character.

The man who is the subject of this case is a labourer in the Victualling Yard at Deptford. He first came under my notice six years ago, when he was fifty-three years of age. He informed me that in June, 1857, he was taken with a sudden feeling of

eramp in the calves of the legs, which gradually travelled up towards the heart, when he became faint, and remained so for two or three days. After experiencing these symptoms for a day or two, he fell down, while walking, in a state of unconsciousness, from which, however, he immediately recovered. The faintness continued and he had attacks of syncope every few minutes for several days, and he was laid by and incapable of doing any work for seven weeks. At the end of that period he got tolerably well, and was able to resume his occupation for fifteen months. In November, 1858, he was again taken with a similar attack, and continued to suffer for about three weeks, when he was sent by Dr. Cregeen to see me at St. Thomas's Hospital.

He was at that time still suffering from the synepic attacks which he experienced at all times, both in the day and night, but especially during the day. He complained of constant sense of sinking, aggravated on taking food, and had great difficulty of breathing on making any slight exertion, with palpitation, and a slight cough and expectoration. The pulse at the wrist was extremely slow, and the action of the heart corresponded with it, beating steadily from 28 to 30 times in the minute; the respirations were from 20 to 24. The slowness of the beat of the heart consisted in the prolongation of the interval of rest, and the sounds of the heart, though flat, were free from murmur. He stated that he had suffered from rheumatic fever about twelve years before, and had also had occasionally gouty symptoms. He had always been what he considered temperate in his habits, though he regularly took porter, and occasionally spirit. He had not latterly been addicted to smoking. After I first saw him in December, 1858, he was, for a time, an in-patient at St. Thomas's, and afterwards continued to attend at intervals for about three years as an out-patient. During this time his pulse continued slow; its ordinary rate was from 28 to 32, but occasionally it rose to 40, and, under excitement or active exertion, to between 50 and 60. He did not in this period suffer from the synepic attacks, but was always feeble, and capable of only slight exertion. In August, 1862, after having felt unusually languid and sickly for two or three days, he was suddenly attacked while walking, and fell down entirely without consciousness; and, though he soon recovered, he continued to suffer from a feeling of faintness for several days. Shortly after the attack, I saw him, and found his pulse beating regularly from 30 to 34, and detected a slight systolic murmur at the base of the heart. He was not able to return to work for six weeks, and then was again laid by in November with a fit of the gout. After this his health was better, and he was able to go on with his usual occupation till August of the present year, when he had another synepic attack. Like the former, it commenced with cramps in the calves of the legs, pains extending up towards the heart, and sickness and faintness, but it never proceeded to the production of complete unconsciousness.

December 1, 1863.—He has now been able to resume his employment for the last three months, but can only do light work; the slightest pulling or lifting of heavy weights, rapid walking, or ascending stairs or any slight elevation, at once gives rise to shortness of breath, pain in the region of the heart, and sense of sickness and faintness. He does not complain of palpitation under ordinary circumstances, and he has no cough or expectoration. His appetite is generally good, but he suffers much from flatulency after taking food, and the cardiac symptoms are often so aggravated. His bowels are regular, and he passes water fully and freely.

The pulse beats steadily 32 to 34 in the minute. It is somewhat large, and rises suddenly under the finger, but is soft and compressible. It corresponds entirely with the impulse of the heart, though the interval between the two is rather prolonged. The cardiac dulness on percussion is somewhat greater than natural; the sounds of the heart are feeble; and there is a slight, soft murmur with the systole, the diastolic sound being flat. He complains of a constant whizzing noise in the left ear. There are some enlarged veins on the upper part of the thorax, and he holds his head in a constrained position forwards, so as to produce some flattening of the upper mammary regions on both sides. The resonance on percussion is good; the respiratory movements slight, but natural as to frequency; the respiratory sounds feeble. He counts aloud, without drawing a fresh breath, to 10 or 12.

The following case, which was the first I met with, and which has been before referred to, differs from that just related in not having presented any decisive signs of disease of the heart, though there could be little doubt the organ had undergone some structural change—

Case 2.—Remarkable Slowness of Pulse, continuing for several Years—Occasional Apoplectic or Synepic Attacks—No obvious Signs of Cardiac Disease.

The subject of this case was a gentleman, 70 years of age, who enjoyed fair health for the age, except that he had a remarkable slowness of his pulse. He stated that he had attained the age of 60 without suffering from any serious indisposition, and had led a most active life, having been thirty-eight years in the army, and during a considerable portion of that time a non-commissioned officer in one of the regiments of Guards, in which he performed the campaigns of the Peninsula, and was present at Waterloo. Since leaving the army he had spent much of his time in the quieter kind of field sports. About six years before the date of my seeing him, he was seized with an attack which was regarded as apoplectic by his Medical attendant, for which he was bled with advantage, but which was not followed by any paralytic symptoms. After the attack his pulse was small, and quicker than it had been, and he suffered from palpitation and uneasiness in the region of the heart, and a sensation described as a feeling of something rushing to the head. About two years after the first appearance of these symptoms, he suddenly became faint while engaged in making some slight exertion, and fell down in a state of insensibility; and, on recovering his recollection, the feeling of faintness and languor was still felt, and continued some time, and he found his pulse beating only 25 to 30 times in the minute, a rate which with little variation it had retained for the last four years. I counted his pulse, and it beat steadily and with perfect regularity 28 times in the minute, and this, he informed me, he regarded as the healthy standard. Occasionally, under the operation of depressing causes, as over fatigue by muscular exertion, it fell below that point, being only 20, and, on one occasion, only 18 in the minute. Under these circumstances, the languor and feeling of rushing to the head and of faintness came on. On the other hand, excitement of any kind, unusual bodily exertion, taking one or two glasses of wine, or more frequently mental excitement, occasioned increased frequency of the pulse, when it would beat 32 or 34, and this was uniformly attended with a feeling of oppression and feverishness.

For three years after the change in the rate of his pulse he was liable to occasional attacks of syncope; for the last twelve months, he had, however, been free from them, and during the whole time had been in a pretty good state of health, and capable of taking an ordinary amount of exercise. His general appearance was that of a person of greater strength and activity than most at the same period of life; and, though upwards of six feet in height, so far from being in any degree bent by age, his gait was remarkably erect.

On examination, the impulses of the heart were found to correspond with the pulsations of the radial artery. The sounds of the heart did not present anything unusual, and were heard most distinctly between the sixth and seventh ribs. The first sound was short, and was terminated abruptly by the second; the action of the heart was perfectly regular, its impulse rather powerful, and the pulse at the wrist not deficient in strength. Percussion did not indicate material increase in the size of the organ, and was good over the rest of the chest, except at the lower part of the right side, where the liver was found to advance considerably into the cavity. The respiration was natural as to frequency, and was performed with ease, except when he was engaged in unusual bodily exertion. No indications of cerebral disease existed. In consequence of his absence from home I did not again see him for two years. During the interval he had suffered from an attack of faintness, after which he was left languid and oppressed, and incapable of much exertion for some time. With this exception, his health had been good, and he had been able to follow his usual occupations. His pulse I now found somewhat slower than before, beating only 26 times in the minute. The sounds of the heart were still natural, or nearly so, and there were evidences of some degree of hypertrophy and dilatation, but no signs of valvular disease.

On the occasion of our first interview I had recommended the adoption of a moderately stimulating diet. Latterly, however, he informed me he had abstained almost entirely from fermented liquors, and he imagined with advantage. During his whole life he had indeed been very temperate. He continued in his usual health till the following year, when he was suddenly seized with an attack of syncope and expired,—seven years after the remarkable slowness of pulse had first manifested itself. He was at this time residing at a distance, and no examination of the body took place.

The facts brought forward sufficiently illustrate the frequent co-existence of slowness of pulse with valvular or other form of disease of the heart, and, together with the case mentioned by Dr. Addison, and one of those reported by Dr. Stokes, show that syncope or epileptic paroxysms are of common occurrence in such cases. It remains to inquire whether the infrequency of the pulse is connected with any special form of cardiac disease, or may, on the contrary, occur in different organic affections.

Mr. Mayo supposed that slowness of pulse especially occurred in cases of "ossification of the coronary arteries, and atrophy with or without passive dilatation." It appears, however, more in accordance with experience to find a weak and irregular pulse in cases of atrophy and dilatation; and in the only case of slowness of pulse which I have had the opportunity of examining after death—that under the care of Dr. Craigie—the heart was in the very opposite condition, the left ventricle, though large, being very greatly hypertrophied.

Dr. Stokes (a) and Dr. Quain (b) have pointed out that slowness of pulse frequently accompanies fatty degeneration of the walls of the heart, and suppose that the alteration in the structure of the organ occasions the diminution in the rate. Of the frequency of the coincidence there can be no doubt. In addition to the cases related by Dr. Stokes, and that referred to by Dr. Quain, the former gentleman quotes instances from Adams, Cheyne, and Law; and in one of the cases related by Mr. Worthington the heart is reported to have been loaded with fat, and from the description given of the appearance of its substance its structure was probably also degenerated. On the other hand, Dr. Bence Jones (c) and Dr. Ogle (d) have related cases in which the heart had undergone the fibrinous degeneration, and the pulse during life had been remarkably slow, and they ascribe the slowness to the state of the structure of the heart. These views are, however, open to very grave objections. We know that the occurrence of slowness of pulse in cases of fatty degeneration is only exceptional, the most usual character being weakness and irregularity. Dr. Quain, in the table which he gives of the state of the pulse in cases of fatty degeneration, reports only eight cases of slowness in the fifty-one which he refers to. Dr. Stokes also relates several cases of fatty degeneration in which the pulse was not slow. We have, indeed, all met with cases of the most marked fatty degeneration in which the pulse has not been below the healthy standard. Ossification of the coronary arteries very often coexists with fatty degeneration, and, if occasionally found in cases where the pulse has been slow, is much more frequently associated with a weak and irregular pulse.

In the communication of Dr. Ogle two cases of fibrinous degeneration are recorded, and in one only was the pulse slow; while other examples of the same condition of the heart are reported in the *Pathological Transactions*, which equally show that there is no necessary connexion between slowness of pulse and this form of degeneration. Both forms of transformation must materially impair the power of the left ventricle, and the blood being thus only feebly impelled into the aorta, the pulse at the wrist will ordinarily be weak, and frequently also irregular and small.

Two of Dr. Stokes' cases are instances of aortic valvular disease, and in one of those which I have related the same condition existed; but, though the pulse in chronic aortic valvular disease is often slow, or, at least, not materially accelerated, this affords no explanation of the slowness of pulse. In some of the most remarkable cases of slowness on record there was no evidence of any valvular disease of the heart, as is illustrated by the second of my own cases. I may remark incidentally, that the coexistence of slowness of pulse and aortic valvular disease is entirely opposed to Mr. Mayo's supposition, that the heart was atrophied in cases of slowness; for we well know that with any considerable obstruction at the aortic orifice the left ventricle necessarily becomes hypertrophied.

2. It has been already stated that Mr. Mayo supposed slowness of pulse to depend in some cases on "general depression, exhaustion, and reduction of strength." In support of this view he quoted two cases. In one of them, a young lady, in consequence of suffering from a neuralgic affection of the face and throat, was advised by her Medical attendant to abstain from taking food by the mouth, and was supported by

nutritive enemata exhibited two or three times daily. In four days symptoms of fever supervened; in a month the catamenia, which had been suppressed for nine months, returned, and two weeks after, the pulse suddenly sunk from between 70 and 80 to 35. In the other case, a Medical student, after having sat up for six nights in attendance upon a patient, found his pulse rapidly fall to 35, and, though it rose again to 40 in a few days, several years elapsed before it reached the healthy standard.

It is by no means uncommon, in convalescence from acute febrile diseases, for the pulse to fall below the natural rate, and remain remarkably slow for some time. This is especially the case in convalescence from severe uncomplicated typhus. The pulse, which, during the active period of the disease, may have ranged from 112 to 120 or upwards, falls, as convalescence advances, to 70, 65, 60, 50, and even 45 and 40. This slow rate it will retain for some time, and then, as the patient uses more exertion, it often again rises to 110 or 100 or 112, and, in the upright position, even to 120, and, lastly, sinks gradually to the healthy standard. These changes I have noticed so often, that I have long been in the practice of pointing them out to the students in the wards of St. Thomas's as being the natural process of recovery in typhus, provided no serious local complication occur to interfere with the ordinary course of the disease. Dr. Stokes has referred to a case in which he observed a similar remarkable diminution in the rate of the pulse in a case of typhus. Similar changes may be observed during convalescence from other acute diseases. I may particularly instance diphtheria.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

ANEURISM OF THE ARCH OF THE AORTA COMPRESSING THE VAGUS AND RECURRENT NERVES, AND CAUSING SYMPTOMS OF LARYNGITIS. DIAGNOSIS BY AID OF THE LARYNGOSCOPE.

(Under the care of Dr. GEORGE JOHNSON.)

THIS case is a good illustration of the occurrence of laryngeal symptoms in thoracic aneurism from pressure on the recurrent laryngeal. It shows, too, the great practical value of the laryngoscope in affording the negative evidence that there was no actual disease in the larynx. In all cases of laryngeal dyspnoea, especially when the dyspnoea is paroxysmal, the chest should be carefully examined; and, indeed, when there are merely symptoms of laryngitis, or even altered pitch of voice, it should not be omitted. "It cannot," says Dr. Gairdner, "be too strongly insisted on, that a physical examination of the chest should take place in all cases of supposed laryngeal disease." But sometimes an examination of the chest does not give us definite information, as in Dr. Johnson's case. To quote again from Dr. Gairdner's paper—"The absence of the physical signs of aneurism or tumour should not suffice to remove completely the suspicion that they may be concerned in the affection of the larynx." In such cases the laryngoscope supplies a real want. Aneurisms which are likely to involve the recurrent nerves are, on the right side, those of the right subclavian and the innominate artery, and, on the left, the arch of the aorta. We have, however, seen one case in which this nerve was involved, and yet there had been no laryngeal symptoms. The nerve was found, at the autopsy, to be "flattened out," and yet the patient's voice had been clear to the last. This case is, of course, quite an exceptional one. It may be that the pressure had affected the nerve very gradually, as we know that there is a remarkable difference in the effect of gradual and of sudden pressure on nervous tissue. In Mr. Canton's case of subclavian aneurism, which we published last week, there was a remarkable change in the voice. It was shrill and childlike.

J. H., aged 31, a hawker, of intemperate habits, was admitted, under the care of Dr. George Johnson, into King's College Hospital, July 16, 1863. About seven weeks before his admission, after being out drinking all night for five nights in succession, he first experienced a sensation of a "stoppage in the throat," and lost his voice. The throat symptoms con-

(d) *Ibid.*, vol. viii., 1856-57.

tinued more or less until the time of his admission. For eight days prior to admission he had experienced difficulty in swallowing solids. For five days the voice had become more husky; he had cough and difficulty of breathing, and the breathing was attended with a loud noise in the throat.

The symptoms on admission were cough, with dyspnoea and noisy laryngeal breathing, hoarseness, and difficulty in swallowing solids. He states that sometimes the noise in his throat entirely ceases, and he partly regains his voice, but the noise is usually louder while he is asleep.

On laryngoscopic examination by sun-light the mucous membrane of the larynx was seen to be slightly congested, but there was no swelling; the arytenoid cartilages were freely movable, and the glottis opened wide during inspiration. At the time of the examination the breathing was not stridulous.

It was evident (Dr. Johnson remarked) from this examination, that the laryngeal symptoms were not the result of laryngitis or other structural disease in the larynx. Aneurism of the aorta or other source of pressure on the recurrent nerve was suspected and carefully sought for, but there was no physical sign of aneurism, no dulness on percussion, and no pulsation or morbid sound; the pulse was equal in the two wrists.

On the 18th, two days after his admission, he spat up a few mouthfuls of florid blood, and felt rather faint at the time.

On the 20th, at 1.15 p.m., he suddenly became faint, and brought up, apparently by vomiting, about three-quarters of a pint of florid blood. When Dr. Johnson saw him, at 1.45, he was still pale and faint, as if from internal hæmorrhage. No more blood had been brought up, but on percussion over the stomach there was marked dulness, and it seemed probable that the stomach was becoming filled with blood. He was directed to swallow constantly small pieces of ice. He continued to sink gradually, and died at 5 p.m.

On examination twenty-three hours after death, an aneurism about the size of a small orange was found at the back of the transverse portion of the arch of the aorta. The aneurism had opened backwards into the œsophagus by an oval aperture three-quarters of an inch long and half an inch wide, the opening being partly covered by coagula. The stomach was full of blood. The left pneumogastric nerve passed in front of the aneurism, and was somewhat flattened in doing so. The recurrent nerve passed behind the tumour in its course upwards to the larynx. Both the pneumogastric and its recurrent branch had evidently been stretched and compressed by the aneurism.

LONDON HOSPITAL.

DYSPHONIA, CAUSED BY SPASM OF THE LEFT TRUE VOCAL CORD—LARYNGOSCOPIC EXAMINATION—PAIN IN THE LEFT EAR—ANEURISM OF THE ARCH OF THE AORTA (‡)

THOMAS D., aged 30, well-nourished, and of considerable muscular development, but having large arcus seniles, applied at the Hospital, December 1, on account of a burning pain in the chest. On inquiry it was found that lately he had several times spat up a few tea-spoonfuls of blood, altogether about a cupful. His appetite was good, and there was nothing to indicate disease of the digestive system. A careful examination of the chest failed to detect any signs of cardiac or lung disease, nor could any aneurismal tumour or abnormal bruit be detected, and there were no signs of venous obstruction (from pressure on the large trunks).

The pain had come on quite suddenly about a fortnight before he came under notice, and he compared it to a feeling "as though he had swallowed something too hot." At the time that he first felt the pain, his voice became suddenly very hoarse and weak, and it has since become shrill and feeble. He continued his work for a day or two after he first felt the "burning;" but his occupation (that of a dock labourer) aggravated the pain so much, whilst it caused him at the same time to make "a crowing noise in his throat," that he was obliged to desist from all labour.

A laryngoscopic examination was made by Dr. Morell Mackenzie, who gave the following report:—

"The larynx is quite free from structural disease, and there is not the slightest congestion of the mucous membrane. On inspiration, there is a very slight difference in the position of the vocal cords,—the left being a little nearer to the median line than the right. On the left side also, the

capitulum Santorini is a little nearer to the median line, and on a rather higher level than its fellow, and the same observation applies to the left aryteno-epiglottidean fold and its contained cartilage. This condition of the left side of the larynx is not so marked as in other cases of unilateral spasm of a vocal cord that have come under my notice; but it must be remarked that, in this instance, neither of the vocal cords is so much drawn aside in inspiration as is commonly the case: this fact would account for relative differences between the two sides being less marked than is usual. On gentle phonation, the left vocal cord is observed to remain fixed, whilst the right advances well to the median line: a small space remains between the vocal cords. On forced phonation, the right vocal cord crosses over the middle line, so that its inner edge touches the left cord. When the vocal cords are approximated in this way, the whole of the right cord, but only about one-third of the breadth of the left true cord, can be seen. It was carefully noted that this appearance was not due to any difference in the size of the false cords,—that is to say, the left true cord was not at all eclipsed by the false cord on the same side. The patient can only speak in a high-pitched squeaking voice, of a somewhat falsetto character.

"It may not be out of place to observe that the long recognised relation between aneurism of the arch of the aorta and an altered tone of voice was first proved with the laryngoscope to depend on paralysis of the left vocal cord, by Professor Traube, of Berlin. Cases also have since been observed by Drs. Semeleder, Smyly, and others. In Traube's case, besides an immobile condition of the left vocal cord, there was hyperæmia of the false cords and epiglottis, and of the mucous membrane over the arytenoid cartilages."

Subsequent to this report the patient has become worse, and now the left pulse is decidedly fuller than the right, and there is a very slight systolic murmur, but only to be heard at the apex of the heart. The chest has been examined very many times, but no physical signs of aneurism have been found. There has never been the least difference in the pupils. Taking into consideration all the circumstances of the case, the spasm of the left vocal cord may not unreasonably be thought to depend on pressure of the left recurrent nerve by a thoracic tumour: that the thoracic tumour is an aneurism of the arch of the aorta is very probable.

This patient's voice has gradually altered from hoarse to squeaky and shrill, and resembles that of Mr. Canton's patient. Is it that irritation has passed into paralysis?

We may draw attention, too, to the pain in the ear, which, we have heard Dr. Gull remark, is a symptom not uncommon in thoracic aneurism. The patient, at his last visit, complained bitterly of the pain. He said that it "ran up" from the left side of his chest to the ear. The pneumogastric gives off an auricular branch, but it is distributed to the prima, in which part the patient has no pain; it is "a piercing pain right inside," and he tries to enforce his remark by sticking his finger in the meatus. It will be well then simply to record the fact. It may be a coincidence. There is not the least deafness. This patient also has very frequent retching, which is probably due to pressure on the trunk of the pneumogastric where the recurrent nerve is given off. Death by pneumonia from implication of this nerve occurs also in thoracic aneurism. We lately saw an autopsy at Guy's on a patient who had died with aneurism in the thorax implicating the right pneumogastric. The right lung was pneumonic. The pneumonia was ascribed by Dr. Habershon, under whose care the patient had been, to pressure on the pneumogastric. Cancer of the œsophagus often terminates by pneumonia, and the pneumonia here, too, is supposed to be due to implication of the pneumogastric. It may be said, if this reasoning be correct, that pneumonia ought to be common in aneurism; but probably it chiefly depends on the general health of the patient whose lung is enervated, as in animals, section of the pneumogastric does not produce pneumonia so long as the animal is well fed and cared for. Absence of nervous power alone does not produce inflammation, but renders parts liable to it.

Thus we have in thoracic aneurism symptoms referred to the wide distribution of the pneumogastric—to the larynx, as evidenced by the laryngeal symptoms—to the lung, as shown by the pneumonia—the stomach, by the sickness. We have sometimes also pain in the ear, although the explanation of this symptom is not very clear, but probably in some way it also is due to the pressure on the pneumogastric. Pain in the course of less important nerves is also common in thoracic aneurism. In Mr. Canton's patient, the pain in the shoulder

was, before the operation, very severe. The whole arm was weakened, and his grasp feeble; but it is very remarkable that there did not seem to be loss of sensation in the arm. He could feel touching, pinching, and could tell two points of compasses at a normal distance, so that, to rough and scientific tests, his feeling was normal. He said it felt numb, but the defect must have been trifling. Pain shooting in the course of nerves is very characteristic of pressure, and this patient had also well marked pathognomonic signs of nervous pain—"pins and needles," to use his expression, "as if it were asleep." This regional kind of pain may often help us to locate an aneurism, and often does so, when pains shoot in the course of one or more intercostal nerves on the left side. Dr. Gairdner has also drawn the attention of the Profession to another valuable symptom in the diagnosis of aneurism, viz., contraction of the pupil, attended with slight ptosis, from paralysis of the cervical sympathetic. We shall speak of this symptom in reporting a case of sweating on one side of the face.

CANCER OF THE CERVIX UTERI—SYSTEMIC INFECTION—(SECONDARY CANCER?)—DISTANT VASCULAR AND LYMPHATIC OBSTRUCTIONS AND PHLEGMASIÆ.

(Under the care of Dr. BARNES.)

Case 1.—Cancer of Cervix Uteri—Systemic Infection—Vomiting—Glandular Swellings—Phlegmasia Dolens.—P., aged 45, admitted August 19, 1863. Has had nine children, the last six years ago. Menstruation has been regular, but during the last nine months she has had repeated floodings. Is now very anæmic; deep straw complexion. For the last four days has been distressed with vomiting. The cervix uteri was found far gone in scirrhus degeneration, but the mass was still slightly movable. There is some swelling of a tense character of the right leg. This began within the last few days. She had always had venectasis during pregnancy, and persisting more or less since, but the affection had diminished considerably since the floodings. She was ordered bismuth and cyanide of potassium to relieve the sickness, with good effect. Irritative cough followed; the cervical glands became a little enlarged; the left elbow became swollen, shiny, and a little red; she was unable to extend the arm fully, and had a burning sensation in it. She was ordered cod liver oil and hydrochloric acid. In a week the swelling in the arm had gone down; she complained of expulsive uterine pains as being very distressing; otherwise she was much stronger and better.

Case 2.—Cancer of Cervix Uteri—Vomiting—Distant Glandular Tumours.—D., aged 55, admitted April 13, 1862. Has had twelve children, the last fourteen years ago. No menstruation after the last labour; but floodings began to appear two years ago, and leucorrhœa of an offensive odour and staining her linen; had a very severe flooding seven months ago, and more or less hæmorrhagic discharge continuously since. She is much emaciated; has no appetite; for some months troubled by frequent vomiting. Has shooting and pricking pains in the pelvis. The cervix uteri and the upper part of the vagina were confounded in an extensive mass of cancerous degeneration. During the last six weeks she has noticed the growth of several lobulated tumours. There is one on the right ham; one in the left arm-pit; numerous others on the hips and thighs. These swellings are hard, varying in size from that of a pea to that of a walnut; they are painful on pressure, so much so that she finds it difficult to lay down without suffering from one or more. They consist of lymphatic glands, enlarged and inflamed by cancerous matter (?) passing through and partially arrested in them, and of inflammation and induration of the surrounding cellular tissues. It does not appear that any of the tumours have supplicated. This patient was under observation some months. The offensiveness of the vaginal discharge was moderated by injections of Condy's fluid; and the general health supported by cod-liver oil. The condition of the lymphatic nodules remained without much alteration.

Case 3.—Cancer of Cervix Uteri—Venectasis—Thrombi—Phlegmasia of Left Leg.—C., admitted April 15, 1863, aged 57. Has had six children, the last nineteen years ago. Menstruation had ceased for twelve years. Hæmorrhagic discharges began a year ago. At times has floodings, and passes clots; leucorrhœa; lumbar, sacral and abdominal pains very severe; sense of bearing down. Difficult defecation. Has had phlebectasis of left leg for several years. On the 12th inst., a phlegmon appeared on the left calf; it did not break. The saphena vein was varicose, raised in knotty points; induration round

these points, indicating thrombi in the veins, and inflammation of the cellular tissues around. The patient was put upon cod-liver oil. In a month the veins were much less swollen and less painful, and she had gained strength, and the hæmorrhage had been diminished. In the course of the next three months, however, she had three smart attacks of flooding. The condition of the veins has not become worse.

Case 4.—Cancer of Cervix Uteri—Swellings of Glands of Arms and Legs.—E., aged 54, admitted July 17, 1862. Has had two children, the last twenty-four years ago; has had an abortion since. Menstruated regularly until eight years ago. Has had menorrhagia for the last fifteen months, and constant dragging pains in the hips. The cervix uteri is converted into a cancerous mass; there is extension of the disease to the surrounding tissues, so that the uterus is set fast. She has lately noticed nodular swellings in the forearms and calves. She was ordered quinine and hydrochloric acid, and after a time cod-liver oil. On August 28, the tumours in the arms and legs had quite dispersed, and at the end of September the floodings had much diminished, and altogether the patient's condition had much improved.

These cases (Dr. Barnes observes) are not very uncommon. They may appear to prove that cancerous matter—either the cells, granules, or the cancer-fluid—find their way into the circulation from the primary uterine cancer, by absorption into the veins and lymphatics, or perhaps by direct entry into veins, where ulceration is present. The offending matter, not always cancerous, thus carried into the blood, in the form of emboli or septic fluid, may—1st, give rise to minute peripheral thromboses; 2ndly, in like manner carried as emboli, or irritating ichor, may cause larger thrombi in the larger veins, as the saphena, setting up local phlegmasiæ, or causing œdema from obstruction—even phlegmasia alba dolens—of which a remarkable instance occurred in the London Hospital a year ago; 3rdly, the cells, granules, or ichor taken into the lymphatics, and arrested in the lymphatic glands, cause the knots and tumours described in the above cases. It is remarkable, as evidence of the great share which general degradation of the blood bears in this process of thrombosis and lymphatic tumefaction—how marked is the improvement sometimes effected by cod-liver oil, and other tonics. The excellent effect of cod-liver oil especially, in arresting the break-down of the system, the extension of the primary local cancer, and in diminishing the exhausting hæmorrhages, is a fact of which Dr. Barnes' clinique affords numerous and most satisfactory proofs. These cases bear a striking analogy to certain forms of puerperal fever, in which septic matter is absorbed from the uterus injured by labour.

SATURDAY, JANUARY 9.

THE EDINBURGH MEDICAL EDUCATION SCHEME.

WITHIN the last few days the Medical authorities of Edinburgh have put before the world their views on the subject of Professional Education. The position of Professors Syme and Christison within their own University, as well as their possession of seats in the General Medical Council of Great Britain, gives their opinions great weight; and were other reasons necessary for discussing here the doctrines they have put forth, we might add, that these doctrines have been

recently published, but not discussed, in the columns of the most widely-circulated of our non-professional contemporaries.

The Edinburgh programme, dealing with the two chief agencies employed in Medical education—compulsory attendance, to wit, upon lectures and examinations, is mainly and briefly this:—Compulsory attendance upon at least certain courses of lectures the Edinburgh Professors advocate; examinations—at least what are in England understood by the name—they consider a great evil; and, finally, they propose, not a substitution of the one system for the other, but a combination and modification of the two.

That something would be found to object to in every solution, by whomsoever attempted, of such a question as that of Medical education, we were prepared to expect. What has surprised us is, that we have found so little to approve of in a scheme endorsed by such names as those we have mentioned.

First, as to the system of examinations. The arguments of Professors Syme and Christison lead directly to the doing away with all examinations whatever; and, though the Professors themselves stop short of the conclusions to which their premises lead, we will not hesitate to say that this would be a most desirable end, if only mankind were possessed of omniscience, and could, by merely looking at a would-be Doctor, look also through and into his mental and moral constitution. Being, however, merely mortals, we are constrained to employ mundane means; and, for the particular purpose in question, examinations in one form or other are the only means we can employ in the present condition of things. The Edinburgh system of examination seems to us, upon the showing of the Edinburgh Professors themselves, to be as bad as anything can be, except the substitute they propose for it; but in a discussion as to the principle upon which trade marks are to be impressed upon particular goods, it is beside the purpose to say, that the imperfection of the machinery employed in a particular place for the purpose, proves anything as to the inexpediency of the practice generally, or "*calls for*" anything but an improvement of the processes. We may, it is true, discard the name, "examination," but so long as we are but men we shall have to retain the thing. In the thing, call it what we will, as in all human systems, there will be an intermixture of good with evil, of bitter with sweet, of drawback with advantage; but it is a fuller statement of the truth to say, that examinations are a mixed evil to the good student, and an unmixed good to the bad one. They hamper and impede the good student a little; they are the sole agency by which the indifferent student is made to work at all. But in drawing up schemes of education, as of all legislation whatever, it is not the excellent few, but the ordinary and indifferent many, whom we ought to have in view. Legislation is intended for the majority in numbers; and in every class of mankind, persons of mediocre abilities, mediocre aims, and mediocre perseverance, the very persons least injured and most benefited by examinations even of the worst kind, make up that majority. If example goes for anything in proving expediency, we would add, that it is their excellent system of examinations, and well-nigh that alone, which has enabled our mediæval English Universities to maintain what hold they have on the respect of the country, and to escape, so far as they have as yet escaped, from the hands of the Radical Reformer.

Compulsory attendance upon Professional lectures has been done away with at the elder of those venerable institutions to which we have just alluded, except in the case of the theological professors, to whom, indeed, protection is extended, not by the University, which has wisely adopted the principles of free trade, but by the bench of bishops. But there is no need to refer to the example of Oxford for the condemnation of the system of compulsory attendance upon lectures. The old proverb, "One man can take a horse to the water, but ten men cannot make him drink," contains in sufficiently plain language all that need be said upon the matter.

The third point is the combination of this system with that

of examinations; and with reference to it, it seems to us that, if examinations are well conducted, as we know some are, at all events, in London, they render the question, "Whence did the examinee get his knowledge?" superfluous; and secondly, that, if the system of lecture attendance were as all-sufficient as we believe it to be all-fallacious, we might dispense with examinations as needless and supererogatory. The Edinburgh Professors, it may be said, are not fairly dealt with by proposing this dilemma to them. Their own scheme, however, violates many other laws besides those of logic. In accordance with it, the professor would at once compel his pupils to attend his lectures, and would subsequently himself conduct their examination. Of all possible plans, this seems to us to be the most objectionable; and we hope that it is but put forward provisionally. Its demerits are too numerous and too obvious to be pointed out here. We will only say that, if an attempt should unfortunately be made to carry it into practical working, it will succeed in proving a snare to the professor and a mockery to his pupils, whilst it fails to obtain either security for, or confidence from, the public.

It is obvious that the remarks made at Edinburgh are levelled at the system inaugurated by the London University. But we believe that the Medical Profession feels that it owes a very large debt to that system; and we have good hope that our Medical Council will resolutely refuse its sanction and endorsement to all retrograde movements set on foot against it.

COUNSELS AGAINST COLD.

WE must not forget that the clear, frosty weather which has set in is sure to be followed by a large increase in the number of deaths. Without doubt, frost is good for the whole population in the long run. It kills vermin, and breaks up the soil, and renders it more fertile; it gives the power of taking brisk, exhilarating exercise, and it keeps up in the active and vigorous part of our race the power of bearing hardships generally. Healthy people find their spirits, appetite, and strength the better for it. Yet there is a heavy fine to pay for these advantages in the sickness and death of the infant, and aged, and feeble amongst us. The question comes before us—Ought we not, with increase of physical and physiological knowledge, to be able to reap the benefits and escape the penalty?

Amongst deaths which occur in cold weather, let us consider, first, those due to improper exposure. A short time ago, Dr. Lankester held an inquest on an aged gentleman who had gone out fasting to partake of the holy communion, early in the morning, at one of the churches in Marylebone. He died suddenly in the church. During the hard winter of 1860-61, we noticed in this Journal similar cases of sudden death amongst the aged. When the power of rapidly producing heat is lost, a worn-out heart or lungs may easily be paralysed by too low a temperature. For one, however, who dies suddenly out of doors, there are hundreds who die slowly at home: the venous blood, whose heat has been lost and its chemical changes deranged, stagnates in the lungs—hence the congestion and bronchitis which so largely swell the registrar's returns. With the aged, then, as well as with children too young or too feeble to take active exercise, if there be a doubt as to the power of withstanding cold, the patient should have the benefit of the doubt, and be kept at home.

Much has been said, and well said, about the necessity of warm clothing, more especially for keeping the limbs of young children warm as well as the trunk. It should never be forgotten that blood, thoroughly chilled, is poison to the lungs. But something more besides clothing is needed. This preserves warmth, but does not create it or distribute it. Feet cold as frogs, and quite as damp and flabby from cold perspiration, may be muffled hopelessly in the thickest stockings and boots. But take off these wrappings, which shut out the

air, and use soap and water and a good rubbing, and they become warm at once. The custom of *dressing* for dinner, *i.e.*, removing the warm, out-of-door garments, and substituting something lighter, after a good polish with soap and towels, is pre-eminently conducive to health. The colder the weather, the more does the skin require the warm or cold souse and the hearty rubbing.

But here we are met with difficulties arising from an odious piece of stinginess. Young people must not "dress," we are told, lest they should catch cold in their bed-rooms; and they must be excused if they cut short their morning toilette, because it is so cold. Of course. But why not give them a fire in their bed-room? Ought not we to be ashamed of squandering money on delicacies for the belly and finery for the back, and denying our poor children the comforts necessary for cleanliness and health? How we wish that, instead of buying a Christmas "half-dozen hampers" of gin, some people would treat themselves to an extra ton of coals! In a warm room, by a good fire, with a nice hot, dry towel to polish off, a wash with cold water would be felt to be a luxury by any one. But, instead of this, we fear the rule in many middle-class families is to have no bed-room fires, and to rely for warmth on close animal heat and frowsy vapour. Doors and windows are listed up, and chimneys, unconscious of fire, are choked with boards or bags of straw. Well roasted by the parlour fire, and warmed with hot spirits and water, people rush with chattering teeth into their bed-rooms, huddle off their clothes, and jump unwashed into bed. There they get the warmth of blankets and of their own anything-but-perfumed atmosphere, and in the morning rush down to the fire with as little washing as possible. The water jug is frozen and the towels are frozen, and we forgive any one who demurs to a frozen towel.

Cold weather proves to us how deficient our houses are as habitations for really civilised beings. We may warm our rooms with blazing fires; but the draught that feeds the fire chills the people that cower round it, because we have no means of warming the house as a whole. There is a phenomenon, too, known as *back smoke*, which shows that in two rooms out of three we depend for fresh air upon the supply that comes down the chimney. The last thing we think of is, where does our air supply come from?

When we add to the want of fresh air the defective supply of water, caused by freezing of the service pipes, owing to the wilful stupidity of plumbers, who always will arrange those pipes in a manner which makes them most exposed to frost; and when we superadd the impossibility there sometimes is of getting rid of slops and liquid refuse, through the freezing of sinks and closets, we say enough to show why very cold weather is by no means always a healthy time in-doors. But things are not mended when a thaw comes. Then the warm outer air comes into the cold house, and deposits wet upon every wall. Then leaks made in the pipes during the frost begin to show themselves; and when the high pressure service is turned on early in the morning, the house may be deluged with water, running down-stairs, soaking carpets, going through floors and washing down ceilings, leaving it as badly off as if it had been next door to a fire. In order to avert this crowning calamity, every householder should know where the tap is by which to turn off the water at a minute's notice. But as this is a part of household furniture not wanted, perhaps, once in a lifetime, we suspect that few persons know of its existence.

In fine, our counsels against cold are, to keep the delicate in-doors; to warm houses, taking care that there shall be no lack of fresh air; to allow bedroom fires liberally, and keep them all night in the chambers of the aged and young; to clothe warmly, and yet to give the skin an extra share of oxygenation by washing and rubbing; to give abundant diet, and yet to avoid indigestibles; to drink cold drinks rather than hot; and, above all, to eschew hot spirits and water.

THE WEEK.

THE NEW PRESIDENT OF THE MEDICAL COUNCIL.

It appears that Dr. Watson is unwilling to accept the Presidency of the General Council, and to add thereby to the great amount of Professional and administrative work which is already incumbent on him. Under these circumstances, there is little doubt that Dr. George Burrows will be nominated, and if nominated, that he will be elected. The manly and spirited tone of Dr. Burrows' remarks at the London meeting of the British Medical Association pointed him out as the right man to take the helm. A vacancy will thus be created amongst the Councillors, which the College of Physicians will have to fill up.

HOSPITAL ADVERTISING.

In the last number of this Journal we deemed it our duty to call attention to a very questionable advertisement on behalf of University College Hospital, which has lately been circulated in almost every newspaper. We are now informed, on the best authority, that the advertisement in question was not published or authorised by any of the officers of the Hospital, and that it was not signed either by the Secretary or the Clerk, which, had it emanated from the Council or Committee, would have been the case. The advertisement, it seems, was the production of a person who has just been appointed to collect money for the Hospital; and we are also informed that the only Hospital authority in town at the time took measures to suppress it before the notice appeared in this Journal. We are glad to give publicity to this statement. Of course, neither our Professional readers nor ourselves supposed that the Medical Officers attached to the Hospital could ever have given their sanction to such a reprehensible mode of gaining support for their charity. But as the advertisement has been very widely circulated both in the weekly and daily papers, we are sure that the Medical staff will be grateful to us for bringing the affair under their notice, and enabling us to prove what we before asserted, that they had no share in the matter.

FITZGERALD *v.* FITZGERALD.

If we wanted a text to discourse on the manner in which a professional reputation may be talked away in mere wantonness by unprincipled or interested persons, we should find it in the details of the action of *Fitzgerald v. Fitzgerald*, which has lately occupied the Divorce Court. As the particulars of this most creditable case have been widely published and commented on, we need not reproduce them. The accusations against Mr. Perry in which the Major and Mrs. Fitzgerald indulged, were proved to have been made on the testimony of so many witnesses, that we are bound to believe that they were not all under an illusion, in spite even of *her* denial. Mr. Perry, a Fellow of the Royal College of Surgeons, and a Practitioner of thirty years' standing, was called to attend Mrs. Fitzgerald two or three days after one of those matrimonial misunderstandings in which the lady was so frequently and so unhappily engaged. She was at that time in the eighth month of her pregnancy, and Mr. Perry had no hesitation in asserting the child was dead. He simply made a slight manual examination. The theory which the lady appears to have entertained was, that the husband had killed the child by his violence, whilst his friends seem to have believed that the cause of its death was the ungovernable fury into which Mrs. Fitzgerald had allowed herself to be betrayed. However, it does not seem that either of these theories at first suited Mrs. Fitzgerald or the Major, so the suggestion of a third party, and that the unfortunate Doctor, being the cause of the catastrophe, was started and adopted. We just extract from the evidence one or two instances of the charitable and kind manner in which Mr. Perry's reputation was made a scapegoat by this attached couple:—

"Lady Ann Maria Sherson: I am the wife of Captain

Sherson. I knew Mrs. Fitzgerald slightly before her marriage, and I renewed my acquaintance with her in 1858 or 1859. I called on her in Chester-street before and after her confinement. About a month after her confinement she told me that Dr. Perry had examined her so roughly that he had caused the death of the child. She spoke of her husband in most affectionate terms. She called on me in the middle of March, 1862, and talked about the Major's conduct to her: I said very little. Three of my children were seriously ill, and I told her that Dr. Perry was attending them, and that he intended to call in some one else. She said something to the effect that she was glad of it, for she had no opinion of him after his treatment of her.

"Caroline Temple: Major and Mrs. Fitzgerald lodged with me at 4, Charles-street, Lowndes-square, in 1859 and 1860. They came on November 28, 1859, and stayed till April 23, 1860. The Major's conduct towards his wife was most kind. I have frequently conversed with her about her being in the family way. She said that Dr. Perry had caused the child's death. I said it was a cruel thing to say of a gentleman in practice, and in my opinion she would never have a child on account of the violence of her temper. I had frequently seen her violent."

Of course, we all know that Medical men, of all professional grades, are liable to this kind of thing. But the naïveté and apparent absence of any misgiving with which the charge was invented and promulgated in this case, is not a little curious. At all events, it is not often that such a revelation of the amiable scandal of the *boudoir* is given to the world.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH
—MEAT FROM DISEASED ANIMALS.

The Metropolitan Association of Medical Officers of Health, having undertaken the investigation of the effect of diseased meat upon the health of those who consume it, are desirous of collecting all the facts upon the subject that are in any way obtainable. They feel convinced that such facts must be in the possession of many Practitioners, and, consequently, they ask their assistance in their endeavour to determine this,—one of the most important questions which can engage the attention of a sanitary association. Some kinds of diseased meat may be injurious, others not; some at one stage and not at another of the disease in the animal; it may be injurious if long kept, and not if eaten immediately it is killed; or to a person out of health, and not to one that is healthy; when badly cooked, and not when thoroughly cooked, etc., etc. The Association will feel greatly obliged if such Practitioners as are in a position to do so would forward to the President or Secretaries any information which they can give upon the subject. It is desirable to obtain negative as well as positive facts. They would further add, that even when diseased meat fails immediately to damage health by setting up an acute ailment, its prolonged use may yet operate injuriously. It is possible that gentlemen having charge of large establishments supplied by contract may be in the way of giving the fullest information on this branch of the inquiry.

In the detail of any cases that may be kindly forwarded, the Association begs that as many of the following particulars as possible may be included:—

1. The nature and stage of the disease in the animal.
2. The physical characters of the meat.
3. The degree of cooking it had undergone.
4. Whether kept several days after cooking, and under what circumstances.
5. The effects on persons consuming the meat.
6. Any post-mortem appearances where death has resulted.
7. Any experiments undertaken to establish the connection between the use of the meat and the disorders supposed to be its result.

R. D. THOMSON, *President*.
G. BUCHANAN, } *Secretaries*.
J. N. VINEN, }

December 26, 1863.

Communications to be addressed—Court House, Marylebone, London.

POPULAR MEDICAL BOOKS.

POPULAR Medical books always deserve notice. To be written well they require such good sense and good taste as may fairly be commended. If ill done, they bewray our Profession most unpleasantly, and we have a right to rebuke one who comes forward unasked as our spokesman, and does us discredit. To make a good popular book, the Medical writer should take matter on which the Profession is agreed, and should earn distinction by the clearness with which he expounds physiological doctrines already acknowledged by us, and by the force with which he urges the habits or practice that should follow. Above all, self should be kept out of sight. The public should be taught what we as a body believe and know; and the lecture should not be made a vehicle of the peculiar opinions or practice of its author. If he has anything new or rare, let him tell it to his brethren; and, when we have all sifted and tested it, the public may be told of it with probability of usefulness to them, and of the preservation of self-respect and decorum amongst ourselves. We are led to these remarks by a discourse on consumption,^(a) by Dr. Shepherd Fletcher, which was delivered at the request of the Manchester and Salford Sanitary Association, and is now published in a separate form. It contains a great deal of useful information clearly put, but yet it scarcely comes up to our ideal, nor earns for the author the credit which it might have done. He describes himself in the Preface as holding "views as to the early changes in consumption which are not those held by the majority of the Profession," and adopting "many points in the preventive treatment" which are not generally advised. We can assure him, on the contrary, that there is nothing which he tells us of real value which is not pretty universally known and acted upon. He speaks with great good sense and clearness on the necessity for pure air, the advantage of an open-air life, of abundant exercise, nourishing food, clean skin, etc.; but in all this there is nothing new. The only special point which he seems to us to claim for his own is the necessity of adopting measures for promoting the expansion of the upper part of the chest. But his means to his end are not new in principle, and seem singularly uncomfortable in practice. To tell a man with consumptive tendencies to stand with his back against a wall "for at least five to ten minutes every morning, without once failing, before fully dressing, and for the same time at night," and during these minutes to inhale forcibly through the nose, so as thoroughly to expand the chest, and hold the breath for a short time to keep up the distension—this, we say, is to give a direction which is irksome, tedious, and, we suspect, impracticable to most people. Why not tell him to take a good run, or to fence, or to sing, or play the flute? Who can doubt the expansion of the chest during a good bout of *sol-fa-ing*? We notice several of the littlenesses which infest most books of the sort. For instance, "pork, veal, and ham" are not to be eaten. Why not? If patients are to use "fat and animal oils" freely, why not pork? And why not that delicious fat of a loin of veal in which nestles the kidney? As for ham—there may be some tough as hickory wood, from which any stomach may pray to be delivered—but a nice, juicy, well-flavoured, tender, home-cured ham—why not allow a slice of both fat and lean at breakfast? When shall we hear the last of that dismal talk about "young ladies, who have been clad in woollen and furs all day," and who "go with the upper half of the chest free from all covering, or, at most, covered with only thin gauze, to crowded ball-rooms at night," etc., etc., etc. Let the popular sanitarian or the puritan say what he will, we defend the denuded full-dress costume of young women on every ground of health, as well as of beauty. It is infinitely good to dress for the evening; it involves *petits soins* of the toilette which must conduce to purity of complexion, and,

(a) Consumption: its Causes, Prevention, and Cure. A Popular Discourse. By Shepherd Fletcher, M.D., late Lecturer on Anatomy at the Chatham-street School of Anatomy, Manchester. Pp. 78.

consequently, to health. Many a girl, chilly and crouching over a fire all day, derives warmth and cheerfulness from the exchange of high furs and flannels for free exposure to the warm air of the *salon*; and we suspect that no man will honestly say that he does not like to look at the "upper half of the chest" of a handsome woman. Dr. Fletcher's reader will be left in a state of puzzle between theoretical views, which at one time describe vital changes as abnormally active, and requiring to be repressed by alcohol, and at another enforce the necessity of promoting the acts of oxidation and excretion of urea. A diet scale is given for infants, which is pure starvation. Luckily, any child so attempted to be reared would yell so frightfully as to compel its nurse to give it more food. Were it not for this lucky provision of Nature, the slaughter of babies brought up by rules such as Dr. Fletcher's and those of the Ladies' Sanitary Association would be prodigious. We likewise demur to our author's dictum, that "consumption finds its victims mainly amongst the sweetest and most beautiful." If he had said that many consumptive girls are *pretty*, we should agree with him; but true beauty is inconsistent with the precocious prettiness and fragile conformation of the phthisical; whilst the disease selects far more numerous victims amongst the dusky and stunted.

FROM ABROAD.—ILL-TREATMENT OF PRISONERS BY THE CONFEDERATES—POOR-LAW MEDICAL OFFICERS IN FRANCE—ANNUAL MEETING OF THE ACADEMIE DES SCIENCES, AND DISTRIBUTION OF PRIZES.

AUTHENTIC accounts have now been brought concerning the condition of the Federal prisoners at Richmond, by several Surgeons who have been recently liberated. This seems to be most deplorable, both as regards the state of the prisons in which they are confined, and the deficiency in the amount and bad character of the food supplied. In and near Richmond, there are stated to be about 10,000 prisoners, of which number 1000 are treated as sick, with a daily mortality of 5 per 1000, or 1825 per 1000 per annum. The prevalent diseases are diarrhoea, dysentery, and typhoid, produced by overcrowding in unventilated rooms, and semi-starvation. Men have been brought to the Hospital literally starving to death; and were it not for supplies sent through the agency of the United States Sanitary Commission none would have escaped the pangs of hunger. It is to be feared that this condition of things cannot be entirely explained by the scarcity of food and clothing which prevails at Richmond, as there is good evidence to prove that much of the cruelty has been deliberately inflicted. This treatment of prisoners is strikingly in contrast with that pursued by the Federal Government with respect to Confederate prisoners, who are treated with every care and consideration. Unfortunately, matters are more likely to become worse than otherwise; for the resolution to exchange no more prisoners, until black soldiers are placed upon the same footing as white ones, will lead to an indefinite prolongation of the captivity of the Federals; while a determination on the part of the South to allow no more supplies to be sent to them by the agency of the United States Sanitary Commission, will add greatly to the horrors of their situation.

The French Medical officers of the poor seem to be suffering from inadequate payment, like those of our own country, but they have the advantage of us in the possession of a more prompt remedy. It is some satisfaction to find that the system of arbitrary decrees which at present constitutes the *regime* in France, is sometimes turned to so beneficial a purpose. One of the little viceroys of the country, the *Préfet du Nord*, has just addressed a letter to the mayors and members of the *bureaux de bienfaisance* of his department to the following effect:—

"My attention has been drawn to the ill-remunerated condition of the Medical officers of the *bureaux de bienfaisance*. The services which the Doctors of the poor render in the rural districts are of too great an importance, and these Practitioners

are, as a general rule, too devoted to their duties, for it not to be desirable and just that a remuneration more proportionate than it is at present to the services they render, and to the resources of the charitable establishments, should be allowed them. I therefore beg of you, when the budgets of the *bureaux* are arranged, that you should examine into what can be done in this matter; and, if the resources at your disposal are defective, I shall look upon the intervention of the municipal councils with pleasure, and will hasten to make the advances which may be asked for."

The Academy of Sciences of France held its public annual meeting for the distribution of prizes, and the delivery of orations to the memory of departed members, on December 28. M. Flourens delivered one of his exquisite sketches, taking Duméril for his subject, but really devoting the greater portion of his address to the glorification of his illustrious master, Cuvier. In his discourse, Cuvier's great antagonists, Geoffroy St. Hilaire and De Blainville, were, perhaps, somewhat unjustly treated; but the entire oration was one of great interest, and we hope to return to it. In the mean time, we will enumerate the prize-holders.

First, we have the Montyon prize in Experimental Physiology, which has been decreed to M. Armand Moreau for his memoir on the "Swimming-bladder of fish." Humboldt and Biot had found by analysis, at the beginning of the present century, that the oxygen and nitrogen contained in the swimming-bladder of fish exhibited most remarkable changes in their proportion, varying from 90 per cent. of oxygen to 90 per cent. of nitrogen. M. Moreau has shown experimentally that, in proportion as the air is removed from the bladder, it is replaced by oxygen, so that the oftener the air is removed, the greater becomes the proportion of this gas when the fish is again set at liberty. If, however, the animal be not in full health, the amount of oxygen diminishes; and when a fish is asphyxiated, and can no longer obtain a supply of oxygen from the surrounding medium, he obtains it from the gas of his swimming-bladder until the supply there is entirely exhausted. Another prize has also been adjudged this year to MM. Philipeaux and Vulpian for two memoirs on the physiology of the nervous system. One of these is entitled, "Researches on the union, end to end, of sensitive nervous fibres with motory nervous fibres;" and the other, "On a physiological modification which is induced in the lingual nerve in consequence of the temporary abolition of the motricity of the hypoglossal of the same side." An "honourable mention" was also decreed to M. Bataille for his researches on the human voice by the aid of the laryngoscope. M. Haeckel's magnificent work on the "Radiaria of the Mediterranean" was also referred to with commendation, but it was not considered to fall within the conditions of the competition. The prize in Medicine and Surgery has been decreed to M. Chassaignac for his mode of treatment, termed *ecrasement linéaire*—a somewhat tardy recognition of what must be considered, in spite of the exaggerated value and extensibility attributed to it by its inventor, as a great Surgical improvement. "Honourable mentions" were decreed to M. Debout for his memoir on "Vicious conformations produced by the arrest of the development of the limbs;" to M. Gallois for his memoir on "Inosuria," i.e., the passage of *inosite* into the urine; to M. Bourdon for having discovered the anatomical lesion in "*ataxie locomotrice progressive*," this consisting essentially in a degeneration, with atrophy of the nervous tubes, of the posterior spinal roots and the posterior columns of the spinal cord, and in an analogous alteration of the nervous cells of the grey substance; and to M. Cahen, for a remarkable monograph on "Vaso-motory neuroses and their treatment." Prizes for memoirs on the insalubrious arts have been decreed to M. Grimaux de Caux for his work on the "Water-supply of large towns and rural localities;" to M. Guignet for the preparation of an innocuous chrome green, suited for the dyeing of tissues and the manufacture of wall-papers; and to M. Bouffé, for having substituted for arsenical greens in the colouring of artificial flowers, a green resulting

from a combination of picric acid with Guignet's green. The Cuvier prize, as we have already noticed, has been presented to Sir Roderick Murchison, this being the first instance of its having been conferred on a geologist. A Bordin prize—subject, "The vessels of the latex of plants"—has been divided between Dr. Leopold Dippel, of Idar, Oldenburgh, and Dr. John Hanstein, of Berlin; and another Bordin prize—subject, "The anatomy and physiology of coral, and other zoophytes of the same family"—has been awarded to M. Lacaze-Duthiers. The Chemical Section has decreed the Jecker prize of 5000 francs to Dr. Hoffmann, of London, for his works on organic chemistry, and especially for those relating to the artificial inorganic alkalies. The Barbier prize, in relation to medicinal plants, has been divided between M. Lepine, for his work on the Indian *Materia Medica*, and M. Viellard, on the medicinal and alimentary plants peculiar to New Caledonia.

The following are the subjects for future prizes:—1. The Great prize (a gold medal value 3000 francs) in the physical sciences for 1864—"The comparative anatomy of the nervous system in fishes." Essays to be sent in by September 2, 1864. Another prize for 1866, "The production of hybrid animals by artificial fecundation." The prize for 1865 is to be given for the "osteographic work which shall have most contributed to the advance of French palæontology." 2. The Montyon prize in experimental physiology, a gold medal of 800 francs, for 1864, 1865, and 1866, will be adjudged to the author of the work, whether printed or manuscript, which has most contributed to the progress of experimental physiology. Works or essays to be delivered before April 1 of each year. 3. The prize in Medicine and Surgery. According to the provisions of M. Montyon's will, the Academy will annually adjudge one or more prizes to the authors of the best works on "The art of healing, or to those who may discover the means of rendering an art or occupation less unhealthy." Works to be sent in by April 1 of each year. For the year 1864 the subject of the prize in Medicine of 5000 francs will be "The history of Pellagra;" and for 1866, "The application of electricity to therapeutics." For the prize in Surgery of 20,000 francs, the subject is "The preservation of the limbs by the preservation of the periosteum." 4. The Cuvier prize of 1866, a gold medal of 1500 francs in value, will be given to the author of the most remarkable work upon the animal kingdom or geology that may be published since January 1, 1863. 5. The Bordin prize for 1865, of a gold medal, 3000 francs in value, will be given for the best essay on the following subject:—"Exhibit experimentally the causes of the inequality of absorption by different plants of the saline solutions of various nature contained in the soil, and demonstrate, by an anatomical study of the roots, the relations which may exist between the tissues which constitute them and the matters which they absorb or excrete." For 1866, the subject is—"Determine by anatomical investigation whether there exist in the stems of plants characters proper to the great natural families, and in accordance with those derived from the organs of reproduction." 6. The Bréant prize, of 100,000 francs, awaits the discoverer of the causes or the cure of cholera; and, in the meantime, the interest of this sum is to be made payable to whoever may be considered to have advanced the study of this or other epidemic disease, or who may discover the cure of "darts." 7. The Jecker prize for 1864 will be decreed to whoever may be considered to have most advanced the progress of organic chemistry. 8. The Barbier prize for 1864 will be accorded for the best work on chemistry or Medical botany forwarded to the Academy by April 1. 9. The Godard prize for 1865 is to be given for the best memoir on "The anatomy, physiology, and pathology of the genito-urinary organs."

GUY'S HOSPITAL.—The Right Hon. Sir Lawrence Peel, Bart., has been unanimously elected President of the Hospital in the vacancy occasioned by the decease of Mr. Bonamy Dobree.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

(Continued from page 21.)

RESUMING the history of the museum of the Norfolk and Norwich Hospital, I would lead the reader to a very interesting cabinet of old Surgical instruments. Blunt gorgets and sharp gorgets, and "lithotomies" of every kind, shine here. There is a mysterious pair of bellows with a wooden collar, evidently intended for artificial respiration, but which the prince of the power of the air himself could not comprehend, if he were not told by its inventor. By its side there is another instrument which no one could mistake at first sight for a small hurdy-gurdy with the strings off, the handles, the wheels, and the outlines altogether, are so complete. What is it? On further acquaintance it turns out to be an uterine speculum. How it was used is better imagined than described. I would prefer to leave the description of it to Dr. Robert Lee, who alone is capable of treating such an instrument as it deserves.

I could linger longer over this cabinet, and I must stay to describe one other old-new instrument. In a quiet corner there hangs a harmless looking weapon; surely an old-fashioned boot-hook, with the handle in the wrong axis for the purpose of accommodating Hessians and pantaloon legs. We take it out, and, lo! it is no boot-hook (shame on the unpremeditated suspicion!) but a veritable rectangular staff, with side groove and all else like the modern staff. The only difference between it and the instrument invented by Dr. Buchanan is, that at the angle there is a gentle curve, and that the instrument is mounted with a handle, which stands transversely across the stem. From the character of this staff, as a work of mechanical art, I should judge that it is at least from seventy to a hundred years old; or it may have been of local construction, perhaps a trial instrument,—but its intention is clear enough. No history attaches to it, and I cannot offer any opinion as to who may have been its inventor. I could not ascertain that it had ever been used in the practice of the Hospital in modern times, or that it was ever considered otherwise than a Surgical curiosity.

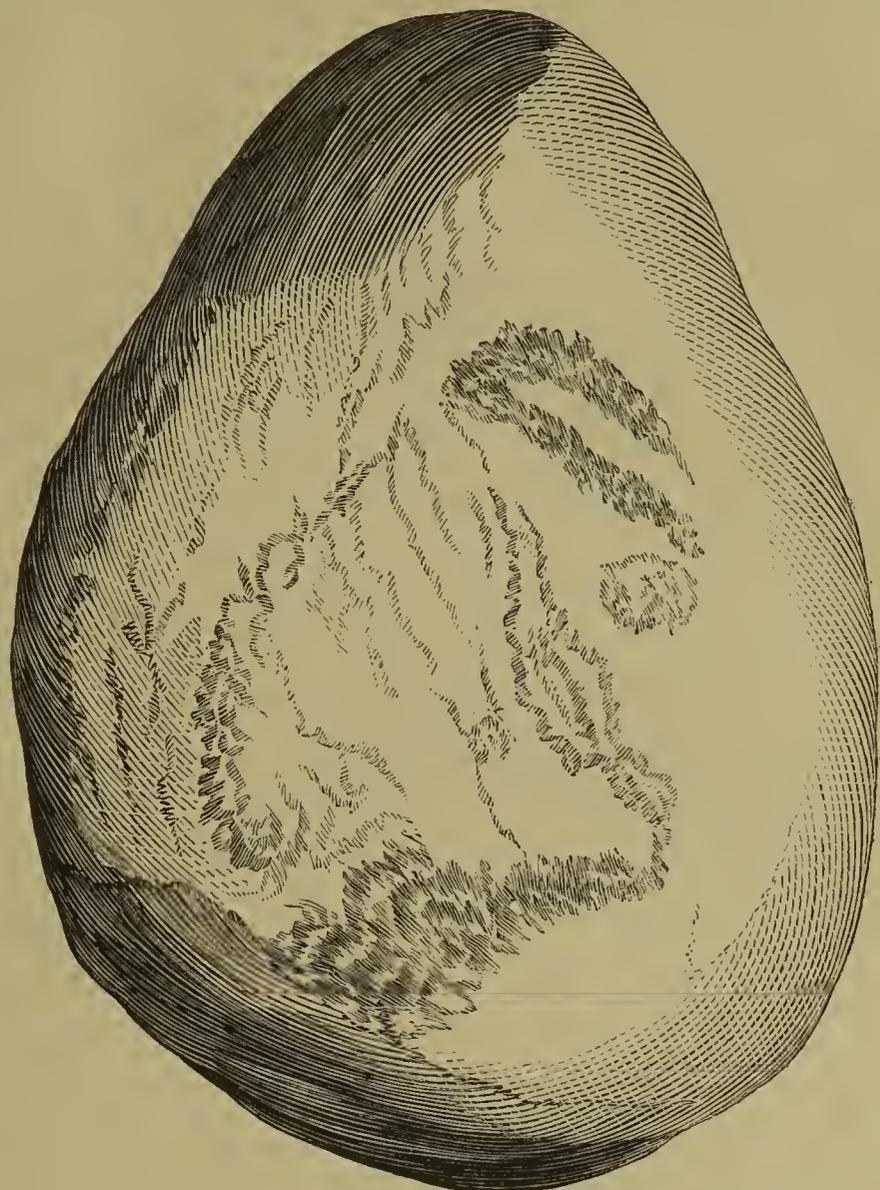

But the most valuable cabinets in the museum of the Norwich Hospital are those containing the calculi. The pathologist who wishes to see every variety of calculus, and to learn the largest number of facts in relation to lithotomy, should begin to study here. He will find collected for him, arranged, and classified, *one thousand six hundred and forty specimens*; each specimen mounted with a ticket stating the age of the patient from whom the calculus was removed, the exact weight of the stone, the date of the extraction, and the result of the operation. He will also find an analysis of 663 of the specimens, and will only regret, that since the time of Dr. Yelloly this mode of examination has not been continued.

Amongst so many forms of calculus one would expect to discover certain points of great interest, pathologically and surgically. It is so. Thus we look in vain through the whole collection for one single illustration either of the xanthic or cystic oxide calculus. Indeed, these varieties are unknown in the county of Norfolk. There is one very perfect specimen—the most perfect I have ever seen—of mulberry calculus, and a large phosphatic calculus weighing eight ounces and a-half, respecting which there is an interesting history. The patient from whom this calculus was removed was a youth of 18. On May 18, 1836, he was put on the table, to be operated upon by Mr. Dalrymple. The famous Surgeon, Liston, was present, watching the operation. Mr. Dalrymple cut into the bladder, reached the stone, but could not extract. Liston took a turn, and failed also. The patient, therefore, was replaced in bed without having the stone extracted. Afterwards it was removed in segments, but the case terminated fatally.

There is another large calculus, weight six ounces, which was spontaneously extruded from the bladder of a female.

The most famous calculus, however,—the most famous of this, and perhaps of any museum,—is one which weighs nearly fifteen ounces, and which was removed from the human subject by Mr. Harmer, of Norwich. Gooch has preserved for us the account of this singular instance of calculus. The patient was a man forty-eight years of age, who had been subject to stone from infancy, and who ought to have been cut at eight years of age. He was a robust man, but intemperate. He was operated on on the 8th of June, 1746, by Mr. Harmer, Gooch being present,—the operation known as the Marian, a

median operation named after Marianus Sanctus, but really the invention of Johannes de Romanis, his master. After getting into the bladder through a wound of the common size, Mr. Harmer found it impossible to extract, neither could he break the stone; Gooch, therefore, at his desire, gradually enlarged the wound with a knife, while he (Harmer) kept up a gentle extraction. By this means the stone was removed. The man recovered without a dangerous symptom, but the wound did not heal. "On the contrary, it remained," says the narrator, "in a foul and bad condition, and was made worse by being constantly wetted with urine, which prevented all applications from taking their proper effect. These circumstances induced the man to endeavour to tempt a little favourite dog to lick the parts; and in a short time he was so well instructed in his business, that whenever his master laid down and uncovered them, he immediately went to work with his tongue, which afforded a pleasing sensation; and then the application of soft dry linen cloths gave him more ease than any applications his Surgeon furnished him with. As long as he lived his dog was his surgeon, and kept the wound tolerably clean and easy, to his great comfort and satisfaction, as he often told me." Gooch adds to this account a remark by Belloste, on the "balsamic virtues of a dog's tongue"—virtues believed in to the present day by residents in rural places of England. The patient who yielded the fifteen-ounce calculus lived until April, 1751, and walked abroad until a few days before his death. To give the reader an idea of this calculus, Mr. Churchill has had it engraved, from a rare print by Gooch. The accompanying woodcut represents the exact size and outline.

The calculus was held by Gooch until his death, and then for a time was lost. At last it was regained by the late Mr. Crosse, and deposited in the museum. The appearance of the calculus is precisely the same as in the drawing. Gooch described it as "of hard texture," with "a substance like spar, to a considerable thickness, upon many parts of its surface." Somewhat recently it has been divided into two segments, and an analysis has been made of a part of it by an eminent local analyst, Mr. Sutton, who has kindly favoured me with the particulars. These are rendered in the table subjoined:

COMPLETE ANALYSIS OF LARGE CALCULUS IN THE NORFOLK AND NORWICH HOSPITAL MUSEUM.

The calculus consisted of three distinct layers.

<i>Nucleus.</i>		Per cent.
Oxalate of lime		31.08
Uric acid		65.66
Silica, animal matter, and loss		3.26
	100.00	
<i>Inner Ring.</i>		
Uric acid		81.52
Phosphate of magnesia and ammonia		2.34
Animal matter		13.90
Insoluble matter, silica, and loss		2.24
	100.00	
<i>Outer Ring.</i>		
Phosphate of magnesia and ammonia		57.20
Carbonate of Lime		16.67
Uric acid82
Animal matter		24.37
Insoluble matter, silica, and loss94
	100.00	

A notice of the calculi of the Norwich Hospital museum would not be complete unless an accurate description of their composition was supplied. I have already said that analyses had been made of 663 specimens by Dr. Yelloly (excluding the analysis of the large calculus). My friend Mr. Williams, the Resident-Surgeon of the Hospital, whom, for all his kindness and research, I cannot thank too much—has been good enough to tabulate for me the result of Dr. Yelloly's inquiries. The facts are taken from a paper published in 1838:

CALCULI IN THE MUSEUM OF THE NORFOLK AND NORWICH HOSPITAL.

ANALYSED BY DR. YELLOLY.

First Group.—Calculi consisting principally of One Deposit.

Lithic acid	164
Lithate of ammonia	55
Oxalate of lime	21
Phosphate of lime	5
Mixed phosphates	35

Second Group.—Calculi consisting of Two Deposits.

I would invite special attention to these tables, as bearing on a question to be discussed ultimately, relative to the prevalence of calculous diseases in Norfolk, and of the causes of calculus in general.

PRACTICE OF THE HOSPITAL—LITHOTOMY.

From the museum we may pass to the consideration of certain of the points of practice in the Norfolk and Norwich Hospital. And, first, we may turn with advantage to an operation for which the Surgeons of this Hospital have become most famous—I mean *lithotomy*.

During the ninety years in which the institution has been in existence, lithotomy has been performed—I am writing up to the present moment—917 times. Seven cases, however, are so recent that, in estimating the results of the practice, it is fair to exclude them from the list. We have left, therefore, 910 cases, of which perfect records have been kept. Mr. Williams has been kind enough to carry out for me an analysis of the facts yielded, which analysis is herewith appended:—

LITHOTOMY STATISTICS OF THE NORFOLK AND NORWICH HOSPITAL.

Time included.—Ninety years (1773-1863).

Operators.—Messrs. Maltby, Rogers, Donne, Jonathan Matchett, Alderson, Rigby, Palgrave, Philip Martineau, William Dalrymple, Colman, Bond, Scott, Thomas Martineau,

John Green Crosse, Carter, Norgate, Johnson, A. Dalrymple, Firth, Nichols, Cadge, and Thomas William Crosse.

Number of Cases.—910.

Sexes.—Males, 869; Females, 41.

Total Results.—Cures, 792; Deaths, 118.

Median Operations.—41.

Deaths after Median Operation.—11.

Deaths after all Operations, according to the Sexes.—Males, 108; Females, 2.

Deaths at Decennial Periods of Life.

Age.	1800-1809				1810-1819				1820-1829				1830-1839				1840-1849

With the exception of a series of operations for stone performed by Mr. Stedman at Aden, these are probably the most successful statistics of lithotomy that have ever been presented to the world. On two occasions, Dr. Copeman states that forty cases of stone were operated on without a single death. In the first of these periods the forty operations were all performed by one Surgeon, Mr. Martineau; in the second by three Surgeons, Messrs. Dalrymple, Crosse, and Norgate, in successive operations.

It must be a useful study to inquire into the reason or the probable reason of this immense success—a success which, by the side of the practice of many other Hospitals, stands as four to one. If the same number of operations had, for instance, been performed in Metropolitan Hospitals, the deaths would, on the modern average, have been 472 instead of 118. Why? Some will tell us that all turns on the selection of cases. The statement will not hold good, for in the Norwich Hospital, the Surgeons, emboldened by their success, have perhaps been less cautious in their selections than others; they have all been bold operators, and it would be false to suspect them of any attempt to make out a strong case by selection; or, indeed, of having premeditated any of the results which they have obtained. Others will tell us that it is the superior skill of the Surgeons. Can it be so? Norwich has always had first-class Surgeons we know; but London believes, and very correctly, that she has had fine Surgeons also, and fine lithotomists especially. A third class may tell us that the mode in which the operation has been performed—I mean, of course, the kind of operation—has determined the results; and, in fact, some countenance is given to this view by the mortality following the forty-one median operations as compared with the mortality following the remainder of the operations, all of which I believe have been lateral. For it will be observed that the mortality after the median operation is not less than 1 in 3.72, while the mortality from all the other operations, the medians excluded, is only 1 in 8.13. These facts certainly tell largely in favour of the lateral operation; and when put by the side of those of Mr. Stedman, who operated over seventy times without a death, and of Cheselden, who operated, by his own lateral method, on twenty-seven patients in succession without a death (a result unknown as following on the median operation of Marianus Sanctus), we are bound, I think, to admit that the median operation by the side of the lateral does not contrast favourably.

At the same time, these comparisons do not really affect the question, because, in truth, the median operation has not, for the past ninety years, been *the* operation for stone anywhere. But the lateral operation—Cheselden's operation, as it should be called—has been *the* operation everywhere; while, again, the median itself—the most fatal of all in Norwich—has been more successful there, in forty-one cases, than any kind of

cutting operation for stone performed, perhaps, in this century in the London Hospitals; since the deaths, after the median at Norwich, are, at most, but 1 in 3.72, or nearly 1 in 4, instead of 1 in 2, or even 1 in 1.88, as is common in London.

But if neither the selection of cases, nor the skill of the Surgeons, nor the character of the operations, have given to the Profession of Norwich such a magnificent harvest, and thrown around their Hospital so bright a fame, what is the directing cause? Good luck? There is no such thing below the surface of fact. Good luck simply means, in all cases, that some unappreciated cause has been at work doing what has been done; and in the Norwich Hospital there has been no mythical subtlety, but one great and ever-pervading element of success,—not good luck, but *good air*. When Benjamin Gooch absorbed from Dr. Hunter that simple lesson, told in my last paper, about the necessity of having free ventilation, and plenty of cubic space for each patient, he achieved half the success that was to come; when he applied the lesson, he, seconded by his able followers, achieved the rest.

The modern student who would be not only the most skilful but the most successful Surgeon of the future, will do well to study the great lesson which has been rendered to science by the statistics of the Norwich Hospital. He will look in vain for any information of a profitable kind in his treatises on Surgery. He will find in them line upon line, and page upon page, respecting needles, and knives, and sutures, and ligatures, and saws, and flaps, as though such details were the essentials, the guiding principles, instead of the mere tools or plans of the Surgeon: about the surroundings of the patient operated on, how little mental food will he gather! But in the history supplied by the Norwich Hospital respecting lithotomy, a fact is given him which is worth a hundred books, and a museum of instruments. It is a fact which, well understood, shows that a Liston himself will be an unsuccessful Surgeon, in comparison with other Surgeons, if his patients be placed in conditions which, however apparently good, are incompatible with restoration of tissue. There is that case in which a man of intemperate habits had a stone of fifteen ounces dragged out of his bladder after the median operation, and yet lived. Is it to be supposed for a moment that he would have lived in a crowded Hospital? There is the whole practice of a small and ventilated Hospital, exhibiting for ninety years a success almost unexampled. Let the student remember these things, and let me conclude for him the narration of those seventy successful cases of Mr. Stedman at Aden. Why were they so successful? For this reason: the patients were treated, virtually, in the *open air*.

RESPIRE OF TOWNLEY.

(From a Correspondent.)

VICTOR GEORGE TOWNLEY, condemned to be hung for wilful murder, "has been respited during Her Majesty's pleasure on account of insanity." That is to say, on account of the alleged insanity of the criminal, the Home Secretary has set aside the verdict of the jury and the sentence of the judge. Your readers will very naturally expect that you will criticise, or at least set forth, the grounds on which this decision has been formed; but this no one can do, for the Solomon of the Home Office is above the weakness of giving reasons for his judgments. He announces a decision, *pure et simple*, and we, the public, have only to bow the head in silence, unless, indeed, we have the greater grace to utter forth our thankfulness that a Solomon *has* come to judgment, and to the rescue of a victim to the foolishness of trial by jury. Still, though I am precluded from considering this case in its purely Medical aspects, and in spite of the awe and wonder, if not precisely the reverence, excited in me by the autocrat of the Home Office Court of Criminal Appeal, I must venture to remark on some points in which the case of Townley touches all Englishmen in common.

There is no one, however convinced he may be of the expediency and the righteousness of capital punishment for wilful murder, who would not recoil from meting out such punishment to the criminal who is indisputably insane,—no matter whether insanity began before or after the commission of the crime. The mere fact, then, that Townley has been respited on account of insanity will not explain the excitement—I had almost said the alarm—it has caused. The reasons for this wide-spread feeling must be sought elsewhere, and they are not far to seek. Publicity of trial, and equality of rich and poor before every criminal tribunal, lie at the very root of an

Englishman's ideas of law and justice; and in this case both these ideas have been outraged. Townley has been rejudged by a secret tribunal, moved to action by means beyond the reach of the poor. After public trial, he was found guilty of wilful murder by a jury of his "fellows;" the verdict was entirely concurred in by the judge, and he was sentenced to death. No one can doubt, that had he been a poor man he had been hopelessly left to his fate as a condemned murderer. But he is a man of position and education, and possesses relatives and friends sufficiently wealthy and influential to force the attention and sympathies of the Secretary of the Home Office, who sends men of his own choosing to examine the criminal in private, and on their report, which is kept secret, the criminal is judged insane and respited. It may be perfectly right and just that he should be respited. There is, as I said before, no means of questioning it; but if so, the mode in which justice has been obtained for him is the height of injustice to every poor friendless man who may have to pray for "a good deliverance" before the tribunals of his country. There has so often arisen occasion to point out the imperfections of our legal system in cases where scientific evidence is needed for the defence to a trial, that no one will regret that so glaring an instance of the inequality this need creates between man and man has occurred,—an instance which so forcibly and loudly proclaims, that the result is determined by private influence and depth of purse, not by the real merits of the case. In all trials where insanity is pleaded as a defence, the prisoner should be examined by public officers, whose report should be public; not by men appointed at the will, and selected at the pleasure of the Home Secretary for the time being, and whose report is kept secret. Till some such change in our system of justice is made, trial by jury is a farce, and our boasted equality of rich and poor is a cruel mockery and pretence.

REVIEWS.

The Quarterly Journal of Science. No. 1. January, 1864. London: Churchill and Sons. Pp. 212. Price 6s.

THIS new quarterly appears to us to be calculated both to form a medium of communication and *répertoire* of memoirs for purely scientific men, each in his special pursuit, and likewise to give the educated portion of the community a broad, general insight into the progress of the different branches of science. The combination of the purely scientific with the popular character is very happily carried out. The introduction gives a capital survey of the present relations of science to agriculture, to our manufacturing and mining interests, to geographical research, aerostation, photography and spectrum analysis, the acclimation of plants and animals, and to the higher branches of natural history, including anthropology, and to theology. It is really curious, however, to notice one slip which the very able editor has made. He justly deprecates any interference with "the free discussion of scientific topics on the ground that the views enunciated might give offence to the believers in some particular *theological* doctrine." Alas! substitute the word "political" for "theological," and we find him railing at the holders of certain scientific theories which run counter to his own politics as vehemently as the Pope himself might. Surely the question, whether or not the negro is a distinct species, and an inferior species, and, if a distinct species, a more ape-like one than the European, might be discussed on its own merits or demerits, without dragging in the American war, and adopting the insinuation of a country newspaper, that the men who held the affirmative were "tools of the Southern Confederacy." How can a man pretend to banish the *odium theologicum*, if he himself does not scruple to use a most malignant bit of political *odium* to damage the holder of a theory adverse to his own? Saving, however, this little escapade, the introductory survey is as temperate as it is interesting. Mr. Hull follows with a consolatory article on the Coal Resources of Great Britain, which he shows to be greater than Sir W. Armstrong would lead us to believe. Two articles on Oceanic Telegraphy come next; and these fairly make us blush at the mismanagement of the Atlantic cable. A paper on Earthquakes by Mr. Mallet is an intelligible introduction to the new science of Seismology. Dr. Gladstone gives a History of Lighthouse Illumination by magneto-electricity. Dr. Carpenter treats of the correlation of physical and vital force, showing that the organising power of the vegetable world is as fair an equiva-

lent of heat as motion is. Professor William King deals with the reputed Fossil Man of the Neanderthal, and makes him out no man, but an ape. An abundant chronicle of the existing state and progress of all the leading branches of science, including agriculture, astronomy, botany, etc., with reviews and news, completes the volume. We repeat that it is not an exclusively technical work, but one which every gentleman may read with interest.

Practical Treatise on the Diseases and Infirmities of Advanced Age. By DANIEL MACLACHLAN, M.D., Fellow of the Royal College of Physicians, late Physician and Principal Medical Officer to Chelsea Hospital. John Churchill and Sons. 8vo, pp. 718.

DR. MACLACHLAN, having been for more than twenty years Physician and Senior Medical officer to Chelsea Hospital, has enjoyed unusual opportunities of studying the diseases and infirmities of old age, and he gives us the results of his experience in the above volume. It is by far the fullest and most important treatise that has appeared on the subject in the English language. Valuable as are the various essays and articles on the diseases of old age, by Sir Henry Hallford, Sir Henry Holland, and Drs. Roget, Symonds, and Copland, especially those by the last-named Physician, they treat of the subject in but a fragmentary and imperfect manner, and they lie scattered in several different works. The monographs of Sir Anthony Carlisle and Dr. Van-Oven are chiefly concerned with the modes of attaining and preserving a green old age; and the work of Dr. Day, "On the Domestic Management and most Important Diseases of Advanced Life," published in 1849, treats all its subjects very briefly, and altogether omits many important ones, and may, perhaps, be considered as intended more for the public than the Profession. On the Continent, the subject has been written on much more fully and adequately, and we have often wondered that neither Constatt's valuable work, "Die Krankheiten des Höheren Alters, und ihre Heilung," nor the pith of Durand-Fardel's "Traité Clinique et Pratique des Vieillards," have ever been reproduced in an English dress. Certainly, we are either wanting in the industry of our contemporaries the playwrights, or we are more easily satisfied with the worth and sufficiency of our home manufactures than they are. Any productions of equal relative value in their *métier* with the above-named works, would speedily have been "adapted" for the English market. Be the reasons what they may, however, up to this time English Medical literature has been without any standard work on the diseases of old age, and Dr. Maclachlan has ably supplied this want. In the first, or "Introductory," part of his work, he treats of the "Anatomy, Physiology, and Psychology of Advanced Life," the diseases incidental to it, the general principles of treatment, remedial and preventive, and of climacteric disease. At the very outset he has of course to meet the difficulty of fixing the age at which "advanced life," anatomically, physiologically, and psychologically considered, begins. We all know what we mean by an "aged man," but one man is as "aged" at 40 as another is at 60 or even 70; yet, for the purposes of scientific description and examination, we must divide life into fixed periods. The Chinese, our author informs us on the authority of Sir John Bowring, divide life into decennial periods, each distinguished by a special designation; thus, 20 is "youth expired;" 30, "strength and marriage;" 40, "officially apt;" 50, "error-knowing;" 60, "cycle-closing;" 70, "rare bird of age;" 80, "rusty-visaged;" 90, "delayed;" 100, "age's extremity." It sounds a sufficiently wise and shrewd, as well as poetically-named, system of division, but does not afford much help for our purpose. The Greeks regarded forty-nine as the turning-point of human strength and vigour. Flourens does not allow that decadence begins till seventy. Dr. Maclachlan, after noticing the various divisions of the later periods of life adopted by systematic writers and physiologists, observes—"In speaking of advanced life in the following pages, I wish to be understood as meaning a period commencing at fifty or fifty-five, which I propose extending to sixty or sixty-five. By mature or confirmed old age, I mean the period extending from sixty-five to seventy-five or eighty; and by decrepitude, or second infancy, the period onwards from eighty to the grave." It would be easy enough, of course, to quote plenty of living refutations of the exactness of this division, from my Lords Brougham and Palmerston downwards; still, we have no doubt it will be allowed as generally correct, and quite sufficiently so for its purpose.

Having thus determined the limits at which the periods of life of which he means to treat begin, the author then gives sections on the changes, bodily and mental, to be observed in advanced life, and on the duration of human life, and the rarity of death from old age.

In the second chapter of this introductory part he gives sound and valuable warning and advice on the special difficulties of diagnosis, arising partly "from the complicated nature of disease at this period—several diseases of more or less importance, and of longer or shorter duration, frequently coexisting, and blending their respective symptoms or masking them. The gradual failure and modification of the different functions also vary the phenomena of disease. Thus, the declining irritability of the nervous system hinders the development of some local symptoms, and influences the character of the constitutional reaction, if it does not entirely prevent it. Those remarkable sympathies between distant or contiguous organs that interest the observer and aid the Practitioner in forming a correct diagnosis, cease altogether, or are much less constant and intense, particularly in extreme old age. Vomiting is less generally present in disease of the brain, liver, or kidneys, than in the adult; it is even often entirely absent in organic diseases of the stomach itself. . . . The kidneys are also frequently extensively diseased with little urinary distress; and the bladder, deprived of its former irritability, is sometimes distended to bursting without the usual agony. Nosology is at fault, and typical examples of disease are exceptional. Inflammation seems to paralyse sensation, and pain is often entirely wanting in many diseases which at other periods of life are accompanied with it in a high degree. Pleuritis, and still more frequently pericarditis, even when associated with that disease, again and again proceed to a fatal termination without it; and yet, on post-mortem examination, we find indubitable evidence of the inflammation having been of the most intense form. The isolation of the different organs in disease is one of the most remarkable phenomena in the pathology of advanced life, and the frequency of latent maladies of the most dangerous character ought never to be lost sight of. . . . On more than one occasion I have known old men sitting at the fireside or moving about, apparently in their usual health, with acute pneumonic consolidation, and even suppuration of the lung. . . . In another instance, occurring on the verge of sixty, empyema existed to such an extent as to displace the heart to the opposite side; and yet the man was following his vocation as groom and coachman, though the disease had existed several weeks. . . . These sufferers frequently die unexpectedly, and, as it were, accidentally, from rapid exhaustion, and their deaths appear in public returns as 'sudden,' or more commonly as caused by 'old age,' whilst, in truth, death, "as purely and simply the result of old age, is amongst the rarest of deaths."

Chapter III. is devoted to the description and consideration of "Climacteric Disease," first described by Sir Henry Hallford, and since treated of by many Physicians,—by none more fully and ably than by Dr. Henry Kennedy, of Dublin. Our author remarks:—"My own opinion is, that the disease is early met with as an idiopathic or distinct affection. Many years ago, imbued by the description given of it by Sir H. Hallford, I imagined that I had met with it in numerous instances; but I soon found that, in those cases terminating fatally, and which I had set down in my own mind as climacteric decay or disease, death was the result of some latent affection of long standing, hidden from observation by the absence of its ordinary symptoms, the most frequent being tubercular disease of the lungs, organic disease of the liver, or cancer of one or more of the internal organs. . . . I am satisfied that, until of late years, granular degeneration of the kidney, occurring in elderly people, without anasarca, must have frequently been put down as climacteric decay." Still, he allows that the disease does occur. "The best examples occur in our own trying, laborious, and anxious profession, in literary persons, clergymen, lawyers, and also in elderly spinsters who devote themselves to visiting the sick and poor." It is principally met with between the ages of fifty and sixty, though it may occur before or after that. "At this age men are busily engaged in the affairs of life, still struggling with its cares and anxieties, and exposed to disappointments and reverses which wound the feelings and lacerate the heart. Later, in the succeeding decennial periods, they have either reached the summit of their hopes and ambition, or they have failed in their aspirations and fallen behind in the race, and now calmly resign themselves to their fate." Dr. Maclachlan's remarks on the causes, duration, and treatment of the affec-

tion are sound and practical. In the succeeding parts of the book he treats of the diseases of the nervous system, of the respiratory organs, of the organs of circulation, of the digestive, the biliary, and the urinary organs, of the skin and its diseases, and of constitutional or blood diseases. Each part is prefaced with a description of the anatomical characteristics of the organs in old age; and then the most frequent and important diseases are treated of under the heads of history, causes, diagnosis, prognosis, anatomical appearances, and treatment. Dr. Maclachlan handles all these topics with ability and learning, showing that he is a close and judicious observer at the bedside, as well as a careful student of all writings, foreign as well as English, that bear on the subject he deals with.

We had marked out many parts for quotation, but our space will only allow us further to strongly recommend the work to our readers. We will not say that "it is a work which ought to be in every (Medical) gentleman's library," because, to our mind, that phrase indicates rather a book to be looked at than one to be looked into; and we are sure that this will be found very valuable for consultation and reference. It is, we repeat, a valuable addition to Medical literature. We will only add that it is provided with a table of contents and a good index, and that as to paper and print it is worthy of the publisher.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

DECEMBER 21, 1863.

SINCE my last letter appeared in your columns there has been no very marked change in the general health of the town. The number of deaths from fever continues to be above the average, and we have only the negative satisfaction of knowing that we are not so badly off in this respect as we were this time last year. The workhouse continues very full, both with sick and healthy paupers, but their number is no accurate gauge of the condition of the poor of this town, inasmuch as many of them come, especially into the Hospital wards, from distant places. As far as I know, there is not now any more distress than that which always haunts such a population as ours.

It is somewhat singular that I should this month have to record another death from hydrophobia. The case was that of a boy, who was bitten above the eye by a dog. He had imprudently interposed on behalf of a small dog who was being worried by a larger one, and thus became himself the next object of attack. Nothing was thought of the injury at the time, the amount of laceration of the skin being very slight; but, about five weeks afterwards, he complained first of a "queer" feeling in the side of the head on which he had been bitten; then of a burning pain in the same part; and then the usual laryngeal symptoms, impossibility of swallowing, harsh cough, etc., came on. He was attended by Dr. Rice and Dr. Brabazon, of the South Dispensary, but all means proved unavailing to avert the fatal issue of the case.

The proceedings of the Medical Society have recently included much interesting matter. At the meeting of November 12, a paper was read by Mr. Lowndes on "the diet suitable after childbirth." He was inclined to believe that the tendency of recent writers upon this subject was towards the severe regimen of olden times, and that such a retrogression was most undesirable. He usually gave a little wine or beer immediately after delivery. Then, for the succeeding twenty-four hours, he kept his patient without animal food, allowing tea, toast, and gruel; the next day, a breakfast-cupful of strong broth for dinner; on the third day, a little chop or chicken; and after this period he permitted the patient to return to her usual diet, and take a little wine or ale. He found that with this treatment patients suffered far less from those affections of the breast and nipple, where the pain is out of all proportion to the actual lesion, and less also from those muscular pains so often complained of when the patient begins to sit up. On November 26, Dr. Nottingham showed a large "cauliflower excrescence of the uterus" removed from a patient aged 33. It appeared to have commenced about eighteen months before the operation, and had gained such a size that it filled the vagina. By means of blunt hooks the uterus was brought slowly and completely down,

so that the chain of a curved ecraseur could be passed around the cervix above the disease. The division was accomplished in a quarter of an hour, without the loss of any blood; though there was some bleeding half an hour afterwards. The further progress of the case I am not yet able to give.

At the same meeting, Dr. Imlach read a case of disease of the supra-renal capsules, characterised by the bronzed skin, constantly increasing anæmia and dyspeptic symptoms, such as acid vomiting, &c. She had taken pepsin with great advantage. In this case there were a number of little black pimples, apparently outgrowths from the epidermis.

Dr. Vose referred to a case which had been under his own treatment, in which the variegated colour described by Dr. Addison existed, along with the constitutional symptoms usually allied with disease of the capsules, and yet no morbid change was found in these bodies.

Dr. Cameron mentioned a case of phthisis, unaccompanied by any peculiar tint of skin, in which tubercle was found in both capsules.

A case of internal uterine hæmorrhage, presenting some important points, was read by Dr. Whittle. The patient, aged 35, had had five children, the last five years since. She was of a hæmorrhagic diathesis. On September 21, she complained of slight pains all day, and when sitting at tea she was seized with great abdominal pain, and fainted away. Dr. Whittle found her collapsed, pale, covered with cold sweat, and her pulse just perceptibly beating about fifty per minute.

The abdomen was tense and hard; no uterine action, but soreness over the region of the bladder. The os was about the size of a crown piece, the membranes ruptured, and the head presenting. Tinct. opii, η xx., were given at once, and brandy from time to time. She rallied satisfactorily; at ten p.m. the pulse was 84; but by two o'clock the next morning it was evident that the uterine efforts were insufficient; the pulse had risen to 120, and the woman was getting low. The child (a very large one, which had been dead some time) was delivered with the forceps, and was followed by a clot very like, in size and shape, to the liver, and which Dr. Whittle thought would represent about four pints of blood. The placenta came away without any trouble, and there was no further bleeding. The patient recovered after a tedious convalescence.

At the meeting of December 10, several specimens of more than ordinary interest were shown. Two cases of fracture of the spine were presented by Dr. Nottingham. In the first, the fracture had occurred in the lower portion of the back, and there was separation of the posterior fragments, whereas in the second there was just the reverse. This latter specimen was from the body of a strong man, who fell thirty feet, and alighted on the top of his head. There was found a long scalp wound, no fracture of the skull; his faculties were entire, his pupils contracted, and his sight not much interfered with. There was some difficulty of breathing and paralysis of the bladder, but not of the legs. He was found to have sustained a fracture of the spine about the fourth dorsal vertebra, and a fracture of the sternum about the same level. There was great separation of the anterior parts of the spine at the site of fracture, and a transverse process was broken off, but there was little visible injury to the cord itself.

Dr. Nottingham's third case was still more remarkable. It was that of a boy who fell from a pile of timber, injuring his head, fracturing a thigh, causing a fracture into one elbow joint, and a wound in the perineum as large as that made in lithotomy. Some severe head symptoms, which he had at first, passed off, and he went on quite well, complaining only of indigestion, until rather more than two months after the accident, when he was seized with symptoms of perforation of the stomach, and died in about half an hour. A post-mortem examination showed that the stomach, very much dilated, has passed into the left pleural cavity, and had ruptured; so that the cavity was filled with a mixture of meat and potatoes. The left lung was flattened, and the heart of course compressed. The edge of the aperture in the diaphragm was so smooth as to suggest the idea of there having been some congenital deficiency, rather than that of the diaphragm having been torn at the time of the accident. The edge of the aperture in the stomach was rough and vascular. The extreme rapidity of his death was not extraordinary, considering the way in which the left lung and heart were interfered with.

Mr. Higginson showed a portion of the skull of a man who had fallen from the rigging of a ship. He was found to have sustained a large scalp-wound, and depression of a portion of the skull was distinctly felt. When the flaps of skin were

turned back, there was seen to be a hole in the skull, looking just as if the man had previously been trephined. Around this there were several fractures. A small circle of bone was removed by the trephine; but the patient, who was of intemperate habits, unfortunately was attacked with inflammation of the membrane of the brain, and died. In the portion of the skull shown to the Society, there were, besides the hole just mentioned, two other perforations of the skull, apparently due, either to non-development, or to absorption of the bone over some of the Pacchionian bodies. Two other parts were so thin as to be diaphanous. Another pathological specimen, of quite a different order, was shown by Dr. Rawdon, House Surgeon to the Royal Infirmary—a soft calculus from a child's bladder. The patient had prolapsus ani, and pain before micturition, but not after; and there was pus in the urine. The child had been sounded four times before the operation; twice some indications of the presence of a stone were obtained, and twice nothing could be felt. The stone was removed; but the child sunk, its death being ascribable, at least in part, to the diseased condition of the kidneys. The stone was about the shape and size of an olive, its central, solid, calcareous portion being surrounded by a thick, soft coating, composed of a series of concentric layers. I remember seeing, some years since, a stone, removed by Mr. Bickersteth, of much larger size than this, but invested, in like manner, with a thick coating of soft material, composed, probably, of the tenacious material of the vesical mucus with some of the salts of the urine, which also caused some difficulty in obtaining certain proof of the presence of the stone.

Among miscellaneous matters I may mention a case which recently came under my notice, which illustrates the practice sometimes pursued by the "herbalists," with whom, I think, we are more infested in the north than you are further south. One of these worthies had, it seemed, been in regular attendance on a young gentleman who suffered from constant cough, increasing weakness, and loss of flesh. His treatment mainly consisted in the administration of frequent emetics, warm "packs" to the chest to encourage perspiration, and exhortations to the parents to get the patient up. Of course, a favourable result was confidently predicted. On Medical advice being at last sought, it was found that the poor lad was in the last stage of phthisis.

It is difficult to know which is the wiser course, in cases thus maltreated, whether to pass them unnoticed, or, where any legal proceedings are possible, to run the risk of converting the quack into what the public may consider a victim to Professional jealousy, and a martyr in the cause of the "Medical liberty of the subject."

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

DECEMBER 15, 1863.

Mr. PRESCOTT HEWETT in the Chair.

Mr. PARTRIDGE brought forward a man, the subject of
MALFORMATION OF THE GENITALS.

The individual had been christened Thomas, but doubts had been raised as to his sex. There was, however, no doubt that he was a male. The penis was small, but it was too large for a clitoris. It was grooved, and at its base was an opening which led into the bladder. He had had erections, and had made futile attempts at intercourse.

Mr. SIBLEY showed a specimen of

RUPTURE OF THE AORTA.

The patient, a man fifty-two years of age, was considered to be in good health until the day of his death. He went out to wait at dinner, and complained of flatulence, for which brandy was given. Soon afterwards he died suddenly. The transverse part of the aorta was ruptured, and blood had escaped external to the pericardium. The aorta was dilated, but not diseased. There was an appearance in the left carotid as if a dissecting aneurism were forming, and this had no apparent connexion with the disease of the aorta, as the intervening parts were quite sound.

Dr. BROADBENT showed a specimen of

HEMORRHAGE INTO ONE HEMISPHERE OF THE CEREBELLUM.

A girl, sixteen years of age, was found leaning against a wall,

and complaining of being sick. She was brought to the Hospital, and was then unconscious, although she could move her limbs, and died an hour later. At the autopsy a large clot was found in one of the hemispheres of the cerebellum. Dr. Broadbent also exhibited the uterus. There was extravasation of blood on the external surface of the uterus, but not on the internal. Dr. Broadbent referred to a specimen of hæmorrhage in the cerebellum which he had exhibited in a former session.

Mr. COOPER FORSTER brought forward a specimen showing an

APPENDIX EPILOICA IN THE SAC OF A HERNIA.

It looked so like a testis, that at first glance it might have misled an operator, but an examination readily detected its real nature.

Mr. COOPER FORSTER also alluded to the practice of leaving cases of strangulated hernia too long before they were sent to the Hospital for operation.

Mr. SOLLY said not only was the operation thus delayed, but the parts were often very much bruised by manipulation before they came under the notice of the operator.

Mr. CALLENDER exhibited parts removed by amputation ten months after

EXCISION OF THE ELBOW-JOINT.

The patient was twenty years of age. Twelve months ago, the elbow-joint was excised at a large Provincial Hospital for strumous disease. Seven months later, the arm was cold, shrivelled, and useless, and there was loss of sensation in the region supplied by the ulnar nerve. All the fingers were useless, the thumb being the only part of the hand in which power of motion remained. Mr. Callender thought that there ought to be a clearer understanding among Surgeons as to the time when passive movement should be begun. He thought that the joint should be kept at rest, and that, when the swelling had subsided, a splint should be kept on.

Mr. HOLMES thought that movement was generally not commenced soon enough; and in this opinion Mr. Hulke coincided.

Mr. WOOD thought that too early movement would prevent union of the ulnar nerve, which he believed was divided oftener than was supposed. He had known it divided, but a perfect union of the nerve occurred.

The PRESIDENT said that, in Mr. Callender's case, the division of the ulnar nerve would not account for the paralysis of the whole hand, as this nerve supplied two muscles only.

Dr. GIBB showed a diagram of the larynx in a case of

FUNCTIONAL APHONIA, OF TEN YEARS' DURATION,

occurring in a married lady, aged fifty-two, arising gradually, in the first instance, from emotional causes. She had undergone various plans of treatment, without any result, except on one occasion, for about three weeks in the early part of 1862, when a harsh, rough, masculine sound appeared, and then went away. This was about eighteen months before Dr. Gibb saw her. He found paralysis of the vocal cords present, with complete immobility, both cords running perfectly parallel for the greater part of their length, and then meeting at their point of origin. This parallelism and the form of the glottis were accurately represented in the diagram from a sketch made at the time of examination. The width of the glottis was about two lines, and respiration was performed without in any way altering it. As almost every thing had been tried in vain, including galvanism to the cords, reliance was placed chiefly upon showers of powdered nitrate of silver to the larynx, with the best results; for the natural voice returned in good power and compass in the course of a few days, and has continued after a ten years' absence.

Dr. WILKS showed a specimen of

FIBROUS TUMOUR ATTACHED TO THE KIDNEY.

He brought the specimen to the Society as an example of a fact which he thought was scarcely sufficiently recognised, that the internal organs of the body are liable to the same class of affections as are described as new growths or tumours when occurring on the exterior of the body. He said that the Surgeon had discriminated between various forms of external tumours, as regarded their structure or malignancy, and he thought that the same could be done with respect to the affections of internal organs. For instance, many of the diseases of the stomach, formerly called cancerous or fungoid, consisted of various kinds of growth as described by the Surgeon as fibrous, recurrent fibroid, etc. So also the so-called intra-thoracic cancer often consists of growths which, on the external part of the body, would be styled the firmer and softer varieties of recurrent fibroid; and the same might

be said of the kidney, uterus, ovaries, and other structures of the body.

Dr. WILKS also showed

PLASTIC LYMPH LINING THE LATERAL VENTRICLE OF THE BRAIN.

A man, aged forty, was admitted into Guy's Hospital, under Mr. Birkett, for fracture of the skull and injury to the brain, which he survived a fortnight. The orbital plate was comminuted, and the dura mater torn. At the anterior lobe there was an abscess, and this was closely contiguous to the cornu of the ventricle. On opening the latter it was found to be lined by a tough layer of lymph, which formed a complete cast of the cavity. The roof, floor, and descending cornu were covered, and thus a hollow sac or cast of the ventricle was constituted. It resembled a croupous membrane, as seen in an inflamed trachea, and could be moved entire. It contained some purulent matter. Dr. Wilks said that he had never met with a similar case before in which the ventricle had poured out a plastic lymph of this kind.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 2, 1863.

Dr. OLDHAM, President.

The following gentlemen were elected Fellows:—Drs. Davis, Savage, and Swyer; Messrs. Bryant, Chisholm, Griffiths, Morgan, and Sequiera.

Dr. Gervis and Mr. Ray were appointed auditors.

Dr. BARNES exhibited and described a new

CRANIOTOMY FORCEPS.

It combined the advantages of the instruments of Professors Simpson and Murphy, and by a further contrivance added by Dr. Barnes was rendered much more effective than any other instrument with which he was acquainted. The elbow on the inner blade, allowing free room for any fold of scalp at the point of perforation, permitted the duck-bill-toothed portions of the blades to be pushed high up to secure a firm hold of the cranium, without the danger of straining the lock. By this means the blades were always kept in perfect parallelism, ensuring a widely-diffused grasp of the cranium, and avoiding the risk of tearing away. Having properly seized the cranium, it became a point of great importance to secure the hold in a manner to save the operator the fatigue and muscular strain of pressing the handles together, whilst at the same time considerable extracting power is required. For this purpose he had adapted a powerful screw, which united the extremities of the handles, setting the blades fast at any interval required. Another advantage provided for was the fitting the blades with a modification of the French forceps-lock, so that the instrument could either be used as one piece, or the two blades could be applied separately. The entire length of the instrument was fifteen inches. Dr. Barnes said he had used the instrument several times, and that its grasp and action were so perfect that he had never been obliged to take a fresh hold. It was made by Weiss.

Mr. BAKER BROWN read a case of

OVARIAN DROPSY,

which had three years and a-half ago been treated by him with tapping and pressure, with apparent recovery for three years and a-half. The cyst, however, began at the end of that date to enlarge, and the patient, being in good health, was recommended by Mr. Brown to submit to ovariectomy, which was performed by him at the London Surgical Home in the usual way, with a very small incision. The cyst was nearly unilocular, but was not of the ovary, which was healthy and free, but in the broad ligament; the pedicle was broad. She recovered without a bad symptom, and is now well. Mr. Brown considered the case of especial interest just now, proving that no adhesions were produced by the previous tapping and pressure.

The report of the committee (Dr. Tyler Smith and Dr. Braxton Hicks) appointed to examine a specimen of Extra-Uterine Fœtation, in which two fœtuses were found in connexion with the same Fallopian tube, was read. They considered that the smaller fœtus was the result of a former conception, and was attached to the fimbriated portion of Fallopian tube in such a manner as not to impede a subsequent conception, which also remained extra-uterine about the middle of the tube, from the bursting of which the patient had died.

Dr. J. BRAXTON HICKS read a short appendix to his paper on

COMBINED EXTERNAL AND INTERNAL VERSION,

in which he stated that, in consequence of not having seen Wigand's memoir, he was unable at the last meeting to reply to the statement made by Dr. Barnes, that he had *fully* described internal and external version. Since that time he (Dr. Hicks) had been able to go over the work, and took exception to the above statement as far as regards internal version. In comparing this memoir with his own paper, he pointed out that, although in regard to cephalic version, there was much similarity in the two plans, still that Wigand had no knowledge of the pushing on the child from within, in the direction of its head, so as to produce podalic version; that he had never adopted complete podalic version, and he makes no mention of the way to convert a more or less cephalic version into podalic. Wigand's plan was to bring that part to present which was nearest the orifice of the uterus. Therefore he applied it only to the rectification of *abnormal* presentations. Consequently, on comparing the two methods, it would readily be seen that very many of the conditions to which Dr. Hicks applied his plan were contra-indicated in the other as mentioned by Wigand himself. It was shown that the only use he makes of the internal hand is to first determine the presentation, and to receive the part as it is pressed down from above, and guide it to the os uteri. Dr. Hicks again pointed out that it was by combining the two powers, within and without, that made the plan he had brought forward much more complete and available than either employed separately.

Dr. GERVIS exhibited the body of a child, in whose birth, after the passage of the head, extreme difficulty was experienced in completing the delivery, owing to a great enlargement of the abdomen. It was, however, accomplished by simple traction. On dissection, this enlargement was found to be due to an enormously distended uterus, presenting two distinct cornua, and with an imperfect septum dividing its cavity. It was filled with a turbid serum containing white flocculi. The os uteri was impervious. There was no indication of an anus, and the rectum terminated in a cul-de-sac attached to the posterior part of the uterus.

The PRESIDENT remarked that it was a most interesting specimen, and suggested that Dr. Gervis should, jointly with Dr. Hicks, furnish a further report upon it.

Dr. J. BRAXTON HICKS read three cases of

ABNORMAL CONDITION OF FŒTUS

which had caused impediment to labour. One in which there was found three quarts of ascitic fluid, in combination with cystic enlargement of the pelvis of both kidneys, in consequence of occlusion of the ureters. Another, in which the abdomen of a female fœtus was distended by the bladder, which reached to the ribs, and which was full of fluid. No obstruction existed in the urethra. Both were delivered readily after puncture by the crotchet. In the third there was dropsy of the amnion to an enormous extent, coupled with a very peculiar enlargement of the forepart of the neck of the fœtus, which had to be ruptured before labour could be completed. It was partly filled with serous fluid. The mothers in all the cases recovered.

Dr. GRAILY HEWITT remarked, that the occurrence of cases such as those brought before the Society by Dr. Hicks favoured the idea, that normally a secretion and excretion of urine from the fœtus was going on during intra-uterine life. He alluded to cases recorded by Mauriceau and Depaul similar to Dr. Hicks' case.

Dr. Hicks was invited to report further on the tumour, conjointly with Dr. Gervis.

Dr. LUMLEY EARLE (Obstetric Surgeon to the Queen's Hospital, Birmingham) read a paper

ON DISTENSION OF THE BLADDER CONSIDERED AS A CAUSE OF POST-PARTUM HEMORRHAGE.

The author pointed out this condition as one of the many causes of post-partum hemorrhage; and called attention to the propinquity of the bladder to the lower portion of the uterus, so that when the former was distended the latter was not only displaced, but prevented from contracting completely. He pointed out the usual symptoms which would lead to the discovery of the accumulation of urine; and gave three cases in illustration that the removal of urine caused the subsidence of the flooding.

Mr. RICHARD MARLEY read a paper

ON PERTUSSIS: ITS PRACTICAL TREATMENT AND MORE RAPID CURE.

After alluding to the history and symptomatology of this com-

plaint, the author analysed the various modes of treatment. He laid stress upon the value, in the second stage, of conium, belladonna, and hydrocyanic acid taken internally; and also the careful inhalation of chloroform at the commencement of the attack, whereby the fit was invariably mitigated or stopped. Although he had by the use of the above treatment been led to think very favourably of it, yet he did not urge it to the exclusion of all others. As in all other diseases, the treatment must be modified by the special features of each case. He advocated warmth during the first stage, and change of air in the third.

Dr. DAY thought it was scarcely safe to leave chloroform in the hands of nurses. He considered that the disease should be treated on general principles. Bromide of ammonium had been latterly much recommended, but in the few cases in which he had tried it he had not found it to possess much influence on the disease.

Dr. HOLT DUNN thought that the treatment in whooping-cough was uncertain, and that we should hail with pleasure any plan which gave more satisfactory results. He had tried the last-named drug, and thought he had found more success with it than with any other.

Dr. GRAILY HEWITT had some years ago examined carefully into the causes of death from whooping-cough. In the cases he had examined, which were for the most part children badly fed, ill-nourished, and in other respects diseased, death had occurred from collapse of the lung—a condition formerly described as lobular pneumonia. It was useless to attempt to treat such cases by specifics. In all cases of whooping-cough he had found the greatest benefit from a treatment mainly consisting of hygiene—good food, exercise, warmth, ventilation, etc. Antispasmodics and sedatives were frequently required, and were not seldom of great use; but the primary object of the treatment should be to maintain the general health of the child.

MEDICAL NEWS.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CLARKE, WILLIAM FAIRLIE, M.A. Oxon, F.R.C.S., has been elected Junior Surgeon to the West London Hospital.

ILIFFE, FRANK, M.R.C.S. Eng., has been appointed House-Surgeon to the Coventry and Warwickshire Hospital.

MAHOOD, GEORGE, M.D. Glasg., has been elected Medical Officer of the Workhouse and Fever Hospital of the Enniskillen Union.

MAUDE, FREDERICK W., M.R.C.S. Eng., has been appointed Resident Surgeon to the Royal Sea-bathing Infirmary, Margate.

PARKER, THEOPHILUS, M.D., to H.M. Coast-guard Station, Burton, Bridport, Dorset.

TULLOCH, J. STEWART, M.D. Edin., has been elected one of the Assistant-Surgeons to the London Surgical Home for Diseases of Women.

DEATHS.

BADGLEY, FRANCIS, M.D. Edin., at Holyrood House, Great Malvern, on December 24, aged 56.

BETSON, GEORGE, at Auckland-villa, Southsea, on January 2, late Superintending Surgeon Madras Army.

BULMAN, DARNELL, M.D. Edin., at Newcastle-on-Tyne, on December 24, aged 68.

DAVIS, JOHN FORD, M.D., at 13, Royal-crescent, Bath, on January 1, aged 91.

DERBISHIRE, JOHN, Surgeon, at 58, Upper Marylebone-street, Portland-place, on December 31, aged 72.

HUTSON, JOHN R. F., M.D., at Demerara, on October 13, aged 67.

JONES, THOMAS, F.R.C.S. Eng., at Chesterfield, on December 18, aged 46.

LEWIS, DAVID, M.D., at Ryde, Isle of Wight, on December 28, aged 65.

SINCLAIR, ALEXANDER, M.D., Staff-Surgeon, at Southsea, Hants, on December 26.

SLEIGH, WILLIAM W., M.D., at Brixton, on December 30, aged 67.

STATTER, RICHARD D., M.R.C.S. Eng., at Mount Pleasant, Liverpool, on December 28, aged 38.

WARD, FRANCIS, M.R.C.S. Eng., at 4, Angel-terrace, Stockwell, S., on December 31, aged 57, late of Balham-hill.

PROPRIETARY MEDICINES.—At a recent meeting of the owners of proprietary medicines, held at Anderton's Hotel, for the purpose of adopting measures for opposing, in the ensuing session of Parliament, the insertion of clause 57 in the Medical Act, Mr. Barclay, who occupied the chair, stated, that if the General Council of Medical Education succeeded in engrafting

upon their present Act the contemplated clause, its effect would be to render valueless some two millions of invested property, now regarded as a sort of copyright, and which, in fact, was the sole maintenance of some thousands of persons. A committee was appointed, armed with the necessary powers for resisting the passing of the proposed Bill, and nearly £3000 was subscribed towards raising a fund for defraying the expenses.

THE RESPITE OF TOWNLEY.—It has been publicly stated that Sir George Grey, in sending a commission to inquire into Townley's state of mind, acted under the 3rd and 4th Vic., chapter 54, which provides that any person, even if under sentence of death, may, if shown to be insane by the certificate of the magistrates and two Medical men, be removed to a lunatic asylum. Sir George Grey, therefore, had no choice in the matter. The real grievance is, that a similar commission is not issued in every case, rich or poor. The Derbyshire county magistrates have memorialised the Home Secretary on the subject of Townley's respite, which they consider to be an infraction of justice.

COLLEGIATE ELECTIONS.—The Council of the Royal College of Surgeons of England will assemble on Thursday next, when the death of their late universally-esteemed colleague, Mr. Joseph Henry Green, will be officially announced, and an early day, probably the following Thursday, fixed for the election of his successor as an Examiner. With the exception of the memorable contest between Mr. Kierman and Mr. Partridge, perhaps few collegiate elections have created so much sensation in the College and amongst the Profession generally as the present; for a rumour has been some time floating about Guy's and King's College Hospitals that the Council in whom the election rests are about to imitate the example adopted some time since by the Fellows, and break through or cut the red-tape of seniority. From the published list it would appear that Mr. Gulliver is the senior candidate, who will be opposed by Mr. Partridge, and the latter also will meet with an antagonist in Mr. Hilton. Perhaps neither of the candidates are more deservedly popular than Professor Gulliver, who, as a Fellow of the Royal Society, and of other learned and scientific institutions, has contributed largely to the advancement of anatomical, physiological, and zoological science; his researches having been, for the most part, prosecuted, not when surrounded by the pleasant facilities and encouragements of this great metropolis, but amid the inconveniences and distractions of a military life, and without a sacrifice of any of his regimental duties. For many years he had charge of the Surgical division of the General Hospital at Fort Pitt, Chatham, and for more than twenty years afterwards was not without charge of some military Hospital. Professor Partridge, who is also a Fellow of the Royal Society, President of the Royal Medical and Chirurgical Society, and Surgeon to King's College Hospital, has been for many years a teacher of Anatomy, and of this branch of the Profession he is the Professor at the Royal Academy, having succeeded Professor Green. Professor Hilton, F.R.S., is Surgeon to Guy's Hospital, and well known by his admirable and philosophical course of lectures on the Influence of Rest in the Treatment of Surgical Diseases, and is, moreover, one of the Examiners at the University of London, an appointment which he will have to resign on becoming an Examiner at the College of Surgeons. It is stated that Mr. South will be Mr. Green's successor at the Dental Board.

AUTHORITY OF MEDICAL SUBORDINATES.—An opinion has lately been given by the Judge Advocate General of the Bombay Army, which may be interesting to those connected with the Army Medical Department. It appears that, at Nusseerabad, Apothecary Lawrence, a warrant officer, ordered a sergeant into arrest in a matter arising out of Hospital discipline, when the sergeant refused to obey. The following is the legal opinion on the case:—"It would appear that Sergeant Piggins was attached to the Hospital, and that it was in a matter connected with the discipline of the Hospital that he was ordered into arrest by Apothecary Lawrence, who, being a warrant officer, was not only superior in rank to Sergeant Piggins, but clearly his superior officer in matters connected with the discipline of the Hospital, and therefore, in my opinion, a lawful authority when he ordered the sergeant under arrest." And it is gratifying to add, that the Judge Advocate-General of the British Army, in his reply, states that he fully concurs in thinking that any apothecary or Hospital steward in the Indian forces may lawfully order a

Hospital sergeant into arrest for an offence directly connected with Hospital duties.

GENERAL PRACTITIONERS IN INDIA.—Mr. John C. Harper, a Surgeon practising in Moulmain, having lodged a complaint against Apothecary S. Sausman, of the General Hospital, for indulging in private practice to the injury of the former, the court dismissed the complaint in the following terms:—"With regard to the competition complained of by petitioner, the court believes that the Government, either in this country or in England, have no objection to their servants in the Medical department having private practice as long as it does not interfere in any way with their public duties, or that the knowledge they possess should not be made available for the benefit of the community as well as the personal advantage of their servants themselves; they further consider that the community of Moulmain can be very safely left to make their own selection of Medical advisers, whether such may be in the Government service or not, without any interference from the court."

A MODERN ADONIS.—A poor fellow named Seeds, a cowman, in the employ of Mr. Howard, of Greystoke Castle, has recently met with his death in a manner that recalls one of the most famous stories of old time. He was not hunting a wild boar, but attempting to drive one of the domestic breed, and struck it with a stick, when the animal suddenly turned, reared itself on its hind legs, and gored the poor fellow in the thigh with its tusks.

Μηρόν ὀδόντι
Λευκῆ λευκὸν ὀδόντι τυπεῖς,

The poor fellow called out for help, and Cytherea, in the earthly guise of a dairymaid, came unavailingly to his help. She heard the poor fellow call out—"I'm dying," and saw blood gushing from his leg.

Τὸ δὲ οἱ μέλαν ἔιβετο αἷμα
Χιονέας κατὰ σαρκὸς ὑπ' ὀφρῖσι δ' ὄμματα ἰαρκῆ,
Καὶ τὸ ρόδον φεύγει τῷ χεῖλεος

Ere he had gone a dozen paces, he fell down and died. A post-mortem showed that the femoral artery had been severed by the boar's tusk. We are sorry that the prevalent knowledge of common things does not include the mode of checking hæmorrhage by putting the finger into the wound so as to check the issue of blood from the artery.

FRENCH AND ENGLISH IDEAS OF A NAVAL SANITARY COMMISSION.—A correspondent of the *Times*, referring to the present defective ventilation of ships of war, writes:—"To illustrate how differently things are done in France, the French Admiralty, having found it necessary to reorganise the sanitary department of the navy, have just created a commission, composed of Admiral Jurien de la Gravière, one commissary, and six Medical officers. When our Admiralty, about three years ago, in order to satisfy the public that something was being done towards endeavouring to improve the ventilation of our ships, peculiarly a question which scientific Medical men, conversant with all the details of their internal arrangements and requirements, are most fitted to decide on, yet their lordships appointed a commission composed of one captain, one engineer, and a shipwright. Something is urgently required to be done in our new iron and iron-clad ships. I agree with 'Observer' that a fearful amount of preventable disease and deterioration of the health of seamen is now due to defective ventilation and other insanitary arrangements. We have no ship afloat properly and scientifically ventilated."

THE CINCHONA PLANT IN JAMAICA.—The annual report of the island botanist, presented to the Jamaica House of Assembly, contains some interesting information relative to the experiment of cultivating the cinchona plant in that island. In the autumn of 1860 a quantity of the seeds of this valuable plant was received, and by the month of October of the following year the island botanist had succeeded in rearing over 400 healthy plants, quite ready for planting out. This was in the low lands, where the climate proved too warm for the cinchona, and one half of the plants perished. Subsequently they were removed to the mountain region, at an elevation of about 4000 feet above the level of the sea, and placed under artificial treatment, with the happiest results. "In 12 months after, a plant of the red bark (*Cinchona succirubra*) had attained to the height of 44 inches, with leaves measuring 13½ inches long, by 8¼ inches broad. The same plant, now two years old, measures six feet in height, with ten branches, having a circumference of stem at base of 4½ inches. The *Cinchona micrantha* (grey barks), being of more slender habit of growth, have not made so rapid progress; the highest

has attained to five feet, with three branches. The leaves, however, are larger, and measure 14 inches by 10 inches." Thus far the experiment had proved eminently successful, and, if only properly followed up, will, no doubt, lead to important results for the island, where there is an abundance of land possessing all the conditions favourable to the growth of the cinchona.—*West India Letter Times*, December 31, 1863.

THE GLASGOW ROYAL INFIRMARY.—At the last meeting of the governors of this institution, a question arose as to the propriety of adding to this already gigantic Hospital. The late prevalence of small-pox has turned the attention of the authorities to the necessity of providing separate accommodation for variolous patients, and from this the present proposal for the further extension of the Hospital has arisen. The report submitted to the governors referred to the subject as follows:—"It may be necessary during this year to extend the accommodation, and the managers request the requisite powers from this court to enable them to do so. This measure is almost forced upon the managers by the great desirability of treating small-pox patients, on account of the highly contagious nature of the disease, in a building apart. This separation is strongly recommended to the managers by their Medical officers, and experience has shown the managers that it is desirable to relieve the fever-house of the small-pox patients, in order to leave more room for the fever cases themselves. A motion will therefore be submitted to the meeting, authorising the managers to lay out the necessary expenditure to accomplish the object in view." The proposal to extend Hospital accommodation in the part of the town occupied by the Infirmary was opposed by Dr. Fleming and other speakers, on the ground that, were the Hospital, which now numbers 650 beds, enlarged, it would become unmanageable, and also because its site is not within easy reach of large portions of the town which have sprung up since it was chosen. The original proposition to extend the accommodation by raising additional buildings in the immediate vicinity of the Infirmary was carried, on a division, by the casting vote of the chairman. This balance of opinion shows, at least, that there is much to be urged against the original proposition. It seems more reasonable that such a city as Glasgow should possess several moderate-sized Hospitals, placed in different districts, than one huge one at a distance of three or four miles from its outskirts.

BOOKS RECEIVED.

Thirty-sixth Annual Report by the Directors of James Murray's Royal Asylum for Lunatics, near Perth. June, 1863.

** The most minute and elaborate work of its class which has come under our notice. The body of the document consists of 74 pages, and an appendix of 31 gives statistical information in tabular form. Among the many topics enumerated in a contents of five pages long, we may mention the preference expressed for the "modern plan of securing the services of scientific experts in cases of difficulty, over the old system of fixed and salaried Consulting Physicians or Surgeons." It is stated to be more economical and satisfactory. The subject of diet is considered at much length, and excellent comparative tables are furnished of poorhouse, prison, and asylum dietaries. The principal bulk of the report is composed of these valuable inquiries. In the Appendix is a good obituary table, showing symptoms and autopsy in parallel columns. To this are added others of industrial occupations among the patients, and the diet-tables to which allusion has been made.

Excelsior: the Literary Gazette of the Inmates of Murray's Royal Institution for the Insane, Perth. Nos. 16 and 17. 1863.

** This publication forms an appropriate pendant to the able Report above noticed. It is stated to be occasional and irregular in its issue, and its profits devoted to multiply the means of instructing and amusing the inmates of the asylum. A list is given in the present number of the newspapers and serials circulated among them; and a chronicle of drives, concerts, lectures, microscopic demonstrations, picnics, and balls, show how actively this desirable object is carried out.

Requirements for the Proper Study of Medicine; being the Introductory Address delivered at the opening of the Medical School. By Dr. J. Warburton Begbie. Edinburgh: Oliver and Boyd. 1863.

** A scholarly and thoughtful essay, such as might be expected from its able author. It takes for its text one of the same grand works of antiquity which furnished this Journal with the remarks to students in the Students' Number for the current year—the "Nomos, or Law of Hippocrates," a composition which, in conjunction with the oath, may still stand for the Medical man's profession of faith and rule of conduct.

A Handbook of Practical Telegraphy. By R. S. Culley, etc. Published with the sanction of the Chairman and Directors of the Electric and International Telegraph Company. Svo. London: Longman and Co. 1863.

** This work is adopted as a text-book by the Company under whose sanction it appears. After a short summary of electrical laws, the space is devoted to the practical management of apparatus, the detection of faults, and the construction of a line of telegraph. Much of this matter was previously only attainable by verbal instruction or actual experience. The language is divested of technicalities as much as possible, with the view of rendering the work more acceptable to practical men. On these grounds it may deserve the attention of our readers.

The Glasgow Medical Journal. No. xlv. January, 1864. Mackenzie, Glasgow.

* * Contains articles on Diphtheria in Campbellton; on Certain Abuses of Caustics; cases of Tracheotomy in Croup and Diphtheria; also of Inversio Uteri; Death from Placenta Prævia; and an essay on the Mechanism of Parturition, by the editor, Dr. Leishman. Reviews and general news complete the number.

On the Calabar Bean: its Action, Preparations, and Use. By T. Nunneley, F.R.C.S.E., etc., etc. London: Longman. 8vo, pp. 38.

* * This paper, reprinted from the *Lancet*, contains the substance of the author's communications to the British Medical Association and the British Association for the Advancement of Science. It contains: 1. The internal effect of the bean alone, or in combination with strychnia. 2. The best solvent for its active principle. 3. Its local effect on the eye, and its most convenient form for use in practice. The subject is one of the highest importance, well summed up in the memoir.

Metropolitan Board of Works. Account in Abstract, showing the Receipt and Expenditure from March 26, 1862, to March 25, 1863. Also, Summary Statement of all Contracts entered into during such period, etc., etc.

* * Gives pecuniary details as to new streets, and the important main drainage of the metropolis.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Amor Proprie.—Jarvis, "Duties of Coroners," 10s. 6d. Stevens, Bell-yard, Fleet-street.

Medicus.—A soldier absent from duty on "furlough" is not entitled to Medical aid at the public expense, unless a military Surgeon happens to be stationed at the place where he may be residing. So that a private Practitioner, affording aid to a soldier so circumstanced, has no claim against the Government, and would not be allowed any remuneration, the man being on leave, and therefore a private individual.

New Jaw-bones!—The Abbeville jaw-bone, which raised such a storm a few months ago among geologists, has suddenly received an important reinforcement from a new quarter, M.M. Gassigou, Martin, and Trutat having last week announced to the Academy of Sciences the discovery of two new fragments of human jaw-bones, discovered in the cavern of Bruniquel (Tarn-et-Garonne), under circumstances clearly pointing to the coexistence of man with some of the extinct species of carnivora, ruminants, and birds. The cavern lies in a mass of Jurassic limestone, and open towards the east at an altitude of about seven metres above the level of the Aveyron. Its floor consist of several successive strata—viz., a stratum of stalagmite, 22 centimetres deep; a pudding-stone, interspersed with bones, to a depth of 150 centimetres; and several black argillaceous strata, to a depth of 120 centimetres, interspersed with a quantity of flint implements and weapons, bones of various quadrupeds and birds, and a quantity of round pebbles, comprising garnets, gneiss, quartz, syenite, serpentine, etc. Lines of charcoal separate some of these layers; and the bones of the ruminants bear marks of having been fractured for the purpose of getting at the marrow, or making them into instruments or weapons; the extremities alone are still perfect, and have enabled the above-mentioned gentlemen to ascertain the species of *Cervus elephas*, *Bos primigenius*, *Rhinoceros tichorhinus*, and several birds, one of these being very large. But the reindeer is the animal which characterises the age of the cavern of Bruniquel. It belongs to M. Lartet's third palæontological period of the quaternary epoch. The existence of flint implements here would alone be sufficient to prove the existence of man in those distant ages; but this existence is placed beyond a doubt by the discovery of the two fragments of human jaw-bones, one of the right side and the other of the left, but belonging to different individuals. They are both in a bad state of preservation. Among the other fragments of bone there is the humerus of a bird, on which the body of a fish is roughly carved. This seems to have been an amulet or ornament. Ten witnesses were present at the finding of these relics. Hence, it appears that three human jaw-bones belonging to the same type (the brachycephalous one) date from three perfectly distinct periods, viz., that of Aurignac, found in company with the *Ursus spelæus*; that of Moulin-Quignon, accompanied by the *Elephas primigenius*; and that of Bruniquel, found among the bones of the rein-deer.—*Galignani*.

Pisciculture in the Thames.—Mr. Frank Buckland, in a letter to the *Times* of January 1st, gives the following account of the effort made during the past year to restock the Thames with fish:—

"We let loose on the shallows in the neighbourhood of Hampton, Sunbury, Walton, etc., 22,000 English trout, 6000 Rhine salmon, 2000 French trout, 3000 ombre chevalier (charr), and 2000 grayling, in all 35,000 fish, being when let loose about the size of minnows. Should there be any doubt as to whether these fish are doing well in the Thames, let me beg the reader to take a boat some warm morning next spring, and paddle gently along the shallows above Hampton, and I shall be much mistaken if he does not see a considerable number of our little silver-scaled beauties darting away like water swallows from the bank side. Last year, several skeggers—what a delightful sound to hear the word! (the local name for young salmon)—were caught with the fly at Sunbury, and to Mr. Charles' shop in Pinlücke were brought three specimens of young salmon (nearly the size of herrings) which had been caught by a fisherman in his smelt nets at the mouth of the Thames. We have every reason to believe these were some of our hatching at Hampton. We are often told that it is no use putting salmon into the Thames, 'they will not be able to come back again.' My answer is, 'Of course they will never come back again if they are never put into the river.' We are in great hopes that they certainly will come back again when the main drainage works are complete; anyhow, we intend to persist in the experiment, be the result success or failure, and it will be a grand thing to restore the salmon to our noble river. A salmon is 'no fool,' he will not come up through the dirty water between bridges when the water is low, but will wait for a rush of comparatively pure water, and then up he goes. The English trout eggs hatched at Hampton we obtained with our own hands from various parts of England by the kind permission of the proprietors of the fisheries, and we have now just begun to stock our hatching boxes for this season. These boxes have already a considerable number of ova in them, and I here invite all those who are interested in the beautiful process of hatching fish by artificial means to call at Mr. Ponder's at Hampton, and examine the apparatus for themselves. The Acclimatisation Society (of which I have the honour to be one of the secretaries) have also erected a large apparatus on the premises of Mr. Francis Francis, at Twickenham, and the list of applicants for ova and young fish will show how many gentlemen there are who are anxious to obtain them for their fisheries. This apparatus is under the entire charge and management of Mr. Francis Francis."

The Health of Salisbury.—Mr. A. B. Middleton, in a letter to the *Times* of the 5th inst., thus notifies the continued low death-rate which has followed the sanitary improvements at Salisbury:—

"Some weeks since, public attention was called to the extraordinary death-rate in the city of Salisbury for the quarter ending September 30,—in a population above 9000, only 20 deaths having occurred, less than one-half of the average number, that average having been 45. The past quarter shows a number actually a little greater, but relatively much less when compared with corresponding quarters for many years, the deaths having been 24, in place of the old average of 60.

"This number of 24 deserves a special note, as by itself remarkable; and although inferences as to sanitary laws cannot be drawn from the returns of one quarter, nor even of the two quarters together, yet when it is seen that in 1863, generally an unhealthy year, only 133 deaths have happened in a town population of about 9200—a fraction over 14 in 1000—in place of the usual average, before drainage and waterworks, of 259, or 28 in 1000—a reduction of 126, or very nearly one-half of the whole number for an entire year—certainly such figures denote a sanitary fact the importance of which will be evident when viewed in conjunction with a few established of mortality. The average annual number of deaths in each 1000 of population over the whole kingdom being, for cities and large towns, nearly 25; for London, one of the healthiest cities, 22; for country districts and small towns, 19 (which figures will doubtless be exceeded in the returns for last year, an unhealthy one in London and the country), Salisbury, with only 14 deaths in 1000, will stand out prominently as furnishing one of the most favourable sanitary returns ever registered."

Erratum.—In the pass-list of the Apothecaries' Hall, published last week, for "William Henry Disen Meuce," read "William Henry Dison Mence."

UNION OF FRACTURED PATELLA IN A PATIENT AGED 80.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following case is interesting on account of the advanced age of the patient and its satisfactory termination:—

November 26.—I was sent for to visit Mrs. W., aged 80, and was informed that she had fallen down a flight of stairs. I found her suffering from several severe contusions on different parts of the body, but the chief source of complaint was the left knee, which was much ecchymosed. I also detected a complete transverse fracture of the patella, the fractured portion being separated to the extent of three-fourths of an inch. I placed them in close apposition, and applied a long splint to the posterior part of the limb, and a calico bandage. A considerable degree of inflammation set in, for which I directed the constant application of cloths wet with cold water. She suffered much pain for the first week after the injury, which was relieved by occasional small doses of morphia.

It was not until the expiration of a fortnight that the swelling was sufficiently reduced to allow me to apply a strong leather plaster around the joint, a strong wooden splint to the posterior, and a pasteboard splint to the anterior aspect of the joint.

On the 18th inst. I removed the applications, and found the fractured portions in complete adaptation, and firmly united by ligamentous union. She has now very good use of the limb, considering the short time which has elapsed since the occurrence of the accident.

I am, &c.

EDMUND GRUNDY, M.R.C.S.E. and L.S.A.
Bury, Lancashire, December 27.

IRIDECTOMY IN GLAUCOMA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As regards the interesting case of acute glaucoma, reported in your last by Mr. Hildige, of Dublin, will you allow me to observe, that I differ very considerably from that gentleman in his estimate of the value of iridectomy as preferable to "the simple evacuation of the aqueous humour?" Nor is Mr. Hildige so candid as he ought to be. He cannot be so ignorant of Mr. Hancock's operation for the division of the ciliary muscle as might otherwise be inferred from the absence of all mention of it in the letter referred to. But it is too much the custom, in the interest of iridectomy, to ignore the importance of this latter operation, and to class it merely as another method of evacuating the contents of the

aqueous chamber of the eye; though, as this is a consequence and not the object of the incision made, which is to divide the fibres of the ciliary muscle, I do not see why it should be so described any more than iridectomy itself, in which there is the very same escape of the fluid. There must also be division of the ciliary muscle; and when only the same benefits are obtained, it becomes a serious consideration, if we reflect upon the serious consequences of non-success in iridectomy, how far even the most practised oculist is justified in performing it, when the simple operation of Mr. Hancock (well described in Hogg's "Ophthalmoscopic Surgery") is available in every case, and everywhere, where the Surgeon knows how to hold a lancet as in ordinary venesection. So much, perhaps, it is admissible for me to say, in the interests of humanity, without being included among those "fierce opponents of iridectomy" alluded to by Mr. Hildige; and I may add, however right and graceful it may be to break a lance in defence of his old teacher, Von Graefe, it seems to me a very remarkable way of proceeding to stigmatise legitimate progress—the substitution of a safe and very simple practice for one exceedingly difficult and dangerous—as having originated in a spirit of partisanship, and just for the sake, as it were, of opposition. I am, &c.

Barnstable, January 3.

ALPHA.

THE CASE OF SYMM v. FRASER AND ANOTHER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to correct a misimpression in your remarks on my letter. The subject of proceedings against Dr. Fraser and Mr. Andrews was not discussed during my professional intercourse with Mrs. Symm; it was about a year after my attendance that I first heard from her that she intended proceedings, and then and subsequently I advised her against them; and, if my memory does not fail me, the first intimation I had that I was to be mixed up in the case was when both Dr. Tunstall and myself were subpoenaed. It is, therefore, impossible that I could have, as you say, "lent myself" to the purpose of the plaintiff.

There is another point of more importance on which I must ask you to allow me to put myself right with your readers. I certainly did not write "Amicus Socrates, amicus Plato, sed magis amica veritas" as verse, though you have made me do so, but as prose. Whatever may be my sins, I was not guilty of this grammatical one. I must apologise for my delay in sending this, which has been from circumstances I could not control. I am, &c.

Bath, Dec. 29, 1863.

JOHN BARRETT, F.R.C.S. (Exam.)

** With regard to the first portion of Mr. Barrett's letter, we are sorry if we misunderstood the following sentence:—"It was no business of mine to sit in judgment on them, yet I did strongly urge on the plaintiff, when she called on me, in the first place not to bring, and afterwards not to persist in, the action, though I then feared, from what little I heard, that they had rendered themselves liable to it." As to the second portion of his letter, which Mr. Barrett regards of most importance, we are sorry to have to correct him as to the meaning of the terms he uses. The mistake was a *typographical*, clearly not a *grammatical* one.

THE EFFECTS OF VACCINATION IN MODIFYING SMALL-POX.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following cases may be interesting to your readers, as proving the modifying effects of vaccination in subsequent contraction of small-pox, and also the difficulty of recognising cases thus modified from those of variella.

On November 23 I was requested to visit Mrs. T., the mother of a large family, residing in a detached house some distance from any other dwelling. I found her very feverish; she had had a severe rigor; there was considerable stomacic disturbance, and inflamed conjunctiva. She complained of pain all over, but more particularly about the back. I inquired whether the family had been vaccinated, and was told—yes; that all had taken very effectually except the youngest child, a girl five years old, in whom, to use the mother's own language, "there was only one small pimple hardly to be seen."

On the third day of visiting my patient, I found her covered with a papular eruption, which on the day succeeding was secreting serum. About the sixth or seventh day the vesicles began rapidly to disappear, and after two or three days more had elapsed she was quite well. During the first five days of her illness, the pain, fever, and general derangement were considerable.

On the 8th of December following, and the two succeeding days, the father and three daughters, including the youngest before-mentioned, were similarly attacked, although from the commencement they suffered less from functional disturbance, except the latter, who, from the first, was exceedingly ill. The tongue became quickly and densely covered; there was great tumefaction of the whole body; the eyes closed, and there was scarcely a feature discernible. In short, the disease assumed the character of severe confluent variola, beneath which the little patient succumbed on the seventh day.

I deeply regret not having re-vaccinated the child on the first occasion of seeing the mother, thinking it probable that the attack might have been mitigated, if not prevented, had I done so. I shall not let the regret be to useless purpose as regards any future case, should I be similarly circumstanced. I am, &c.

Horsey-road, December 31, 1863.

EDWARD COTTEW.

SYMM v. FRASER AND ANDREWS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I sincerely regret that Dr. Fraser should have been so ill-advised as to publish a personal attack on me, and still more that he should attempt in his letter to you to hold me up to the reprobatum of my Professional brethren.

The evidence I gave was impartial; and surely I was the only person who could give a professional description of Mrs. Symm's condition on the night of the 24th of January. Dr. Fraser could not do so, because a month had elapsed since he had seen her; his friends, "professional and otherwise," who, he says, condemn my evidence, could not do so, because they never saw the patient at all. The policeman who saw her two days before could not do so, his business being to find the whereabouts of a tenant of Dr. Fraser's, who in a presumed state of intoxication had left her house unprotected from depredation. With regard to my cross-examination, this was confined to the nature, causes, and treatment of delirium tremens; this evidence was confirmed in every important particular by that subsequently adduced by the defence.

I again repeat "my account of my morning visitor, with his £5 note and subpoena," and will not allow "any plausible theory" that Dr. Fraser may "invent to account for it," to make me swerve from the plain truth, that I knew nothing whatever of the action, nothing of the presumed facts of the case, and nothing whatever of the evidence expected from me until I arrived in London in obedience to subpoena, unusual as the occurrence may be in Dr. Fraser's experience.

Surely, I cannot be held responsible for Mr. Chambers' speech; he was leader for the plaintiff, and his only duty was, if possible, to obtain a verdict for his client. Dr. Fraser has every reason to congratulate himself that the course of justice was not affected by his forcible advocacy of a bad case—a fact clearly shown in the admirable charge of the Lord Chief Justice, and the instantaneous verdict of the jury.

I have nothing whatever to do with Dr. Fraser and his solicitor's ignorance with regard to the names of Mrs. Symm's Medical attendants in Bath. The same means employed to find the runaway tenant would easily have discovered this; but no one but the plaintiff could have told them what Medical men were to appear at the trial, because these gentlemen were not asked to appear, but compelled by subpoena when the case was set down for trial.

Although I can most heartily and sincerely congratulate my Profession on the failure of this action, I must claim a small modicum of their sympathy for those members of their Profession who are compelled, as I was in this case, to appear as evidence for plaintiff in actions against Medical men, without being asked whether they can give evidence or not, who, in addition to browbeating from counsel, and reports of their skilled evidence given in newspapers by non-medical reporters, become the innocent victims of Professional misrepresentation.

The great fact is this—Dr. Fraser attended her in December, and swore to her state *then*. I saw her in January, and swore to her state *then*. Why should we quarrel? I am, &c.

Bath, January 5.

JAMES TUNSTALL, M.D.

ALCOHOLIC STIMULANTS IN FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As I have but just been watching the progress of a case of typhus of a very severe character (in fact, the case is still under my observation), and as I have been much impressed by the success of the alcoholic plan of treatment, I was astonished indeed to read the opposite plan of treatment (*viz.*, "natural tonics," consisting of "food, air, and cleanliness," which no one with natural intelligence would neglect) laid down as the only correct treatment of this disease.

I am but young in practice compared with the gentleman whose opinions appeared in your last impression on this subject; but I have seen many of these cases, have watched them eagerly, and have been convinced of the efficacy of the alcoholic treatment of this malady, which, in all the cases of typhus which have come under my observation, has never failed. May I, then, claim your indulgence for the insertion of the following particulars?—

A gentleman, aged 28, tall, dark, of nervous and irritable disposition, and studious habits, had complained for several days of the usual pre-moultures,—chills, languor, congestive pains, and general *malaise*; and, as he was a Medical man, with fever around him, he often expressed the conviction that he had caught the fever.

On November 30 I saw him *et time* in the morning. He was then in a state of active delirium, struggling violently, and attempting to jump from his bed, though he had occasional intervals of consciousness. He was much purged, and very weak. Three other Medical men were present, and he was then ordered to have one drachm of the compound chalk powder immediately, and half an ounce of wine every two hours, with the following mixture:—℞. Tr. hyoscyam., ʒss.; tr. aurant., ʒij.; aq. camph., ʒvj. Misc. suvat eoch. amp., ij.; tertiis horis. At eleven, as the purging continued, the powder was repeated, with the addition of five grains of Dover's powder. At five, the delirium was still more fierce, though great prostration succeeded each outburst. Pulse 140. To take the following draught immediately:—℞. Tr. hyoscyam., ℥x.; aq., ʒiiss. Misc. At twelve, he slept quietly; the breathing natural; pulse 130. Has not been purged since the administration of last powder.

On Monday, at 1.30 a.m., he awoke with a shriek, and, on joining him hastily, I found his head thrown back, his jaw fallen, dyspnoea urgent, pulse almost imperceptible, and remitting. Brandy was immediately in requisition, and he could swallow it; but, at 2 a.m., that chance was gone, and hope also. At 5.45, to every one's astonishment, he was observed to swallow the brandy which had been continually applied to his lips with a quill. From this time brandy was diligently supplied to him, and, at 11 o'clock, his pulse was fuller, though still 140. Countenance haggard, eyes glazed, and pupils dilated. 12 p.m.—He was decidedly improved; has taken brandy and beef-tea continually since last visit. Being very restless, he was ordered to take the following draught:—℞. Liq. opii. sedativ., ℥v.; aqua, ʒiiss. Misc. ft. haust.

Tuesday, 10 a.m.—Has passed a tranquil night. Pulse 130, and fuller. A blister was applied to the back of the neck. 10 p.m.—Has taken his wine and beef-tea eagerly since last visit (when it was substituted for the stronger stimulant); occasionally recognising his attendants.

Wednesday, 10 a.m.—He has been quiet during the night, though he has never slept. 8 p.m.—He was more sensible, though uttering delirium is often present. Repeat the opiate.

Thursday, 10.30.—The opiate has been twice repeated, and a tranquil night resulted. At 12 p.m. he was quite conscious, and passed a tolerably quiet night.

On Friday he took ox-tail soup and two glasses of wine daily, in addition to sherry with his jelly.

Since this time he has gone on very favourably, with no symptom of relapse, and to-day he has walked half-a-dozen yards.

I have brought this case forward simply for the sake of an additional proof—if such are wanting—of the efficacy of the plan I espouse in the treatment of these diseases.

Apologising for the intrusion on your valuable space, and hoping that my Professional brethren will come forward to support this my view of the case, I am, &c.

December 15, 1863.

H. R. S.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am very much obliged to those gentlemen who have thought my letter worthy of their notice, and especially to Mr. Bayley, for his elaborate explanation, which I shall now proceed to examine in detail.

It is quite clear that I have not cast any unfair imputation upon Mr. Bayley, as he corroborates the correctness of my description of the particular case referred to, and accepts the position that wine is not neces-

sary in the treatment of diseases characterised by prostration, and even attributes the death of the patient to the mistaken kindness of the friends in administering wine. During the last two or three days of the poor man's existence, vomiting occurred immediately upon taking food. No attempt was made to administer nourishment by the rectum, and thus, for two or three days, this man, exhausted by the depressing effect of the fever poison, and incapable of assimilating nourishment, was deprived of wine, a substance requiring no digestion, but capable of being absorbed by the blood-vessels, and of conveying to the heart the stimulus required to keep it in action. The manner of death in this case was exactly what may be anticipated from the history, viz., death beginning at the heart, or cardiac syncope. Further allusion to this particular case is unnecessary, as it is not my wish to fix the attention of the Profession upon one instance of bad management, but rather to draw attention to the mistaken principles that guided the treatment.

The first part of Mr. Bayley's letter consists of quotations from a variety of authors, for the purpose of showing that alcohol is not a food; and Dr. Beaumont adds, that alcohol taken in the form of wine or brandy is exhaled from the lungs and skin, and is therefore not nutritious. By a fortunate coincidence, the same number of your Journal contains an article, or rather a review of a work, on the "destruction of alcohol within the economy," by M. Baudot, who proves, by a series of most carefully-conducted experiments, that alcohol is not eliminated by the skin and kidneys, and that it is destroyed in the economy. Assuming, however, that alcohol is eliminated, such a fact has no bearing upon the action of alcohol as a medicine, since its absorption by the blood-vessels and transmission through the circulatory system is incontestably proved, and it is obvious that its presence in the blood may exert a direct and powerful influence upon the nervous system, and, through the nerves, upon the heart itself. That it has such an effect all writers concur in testifying; and anybody may prove it upon his own person by counting the pulse immediately before and after taking a glass or two of wine.

In addition to the assertion, that alcohol is not an alimentary substance, Mr. Bayley reiterates the expression, that alcohol is a pernicious poison, that it is the most pernicious substance received into the stomach, and that toxicologists agree in defining it as a narcotic. Conscious that all this has no bearing upon the question at issue—viz., the medicinal employment of wine in exhaustive diseases—he (Mr. Bayley) connects the argument by the following curious specimen of reasoning:—Thus, he says, "If these facts be true with regard to health—viz., that alcohol is a pernicious poison, etc.—they apply with double force to states of disease, especially of an adynamic character." The utter absurdity of this argument will be best exhibited by applying it generally. Thus, arsenic is a pernicious poison in health, therefore it is doubly injurious in disease, and so on with all medicinal agents; so that we arrive at the startling conclusion, that all medicines being pernicious in health are doubly injurious in disease. It is almost unnecessary to add, except for Mr. Bayley's information, that virulent poisons may be most useful medicines—as opium, strychnine, belladonna, etc., etc.—and that it is generally true that the most active and powerful poisons are the most useful medicines in the hands of the skilful Physician.

And now let us examine Mr. Bayley's assertion, that alcohol is not a stimulant; and here I shall point out that his friends, Mr. Mudge and Dr. Beaumont, appear to differ with him, as they both employ the term "alcoholic stimulants." "Toxicologists," Mr. Bayley says, "regard alcohol as a narcotic." Toxicologists are those who treat of the action of poisons in poisonous doses; with this we have no concern. The medicinal dose of alcohol is small, and exerts a stimulant action on the circulation through the nervous system. All writers that I have been able to consult regard wine and brandy as diffusible stimulants; and I would ask, what is the effect of brandy when administered to parturients exhausted by very rapid and violent hæmorrhage, when fainting occurs and the heart ceases to act? Do we not immediately administer brandy in addition to the proper means for restraining further loss, and is it not usually successful? Would the theorists who deny the stimulant properties of alcohol remain consistent with their opinions, and withhold the use of brandy in such an extremity?

The principal authority adduced by Mr. Bayley in support of his views is Mr. Higginbottom, of Nottingham, who himself confesses that his method of treatment is "contrary to the received opinion and practice of the Profession," and who also regards wine as an artificial stimulus. It is quite possible that the type of fever which came under Mr. Higginbottom's notice was inflammatory, and not requiring stimulants; but admitting to the full the statement of Mr. Higginbottom, is admitting that he advocates the treatment of true typhus without wine: surely the experience of one man ought not to counterbalance that of the most eminent Physicians throughout the empire, the general testimony of the Profession, and also of those whose connexion with Fever Hospitals has afforded them the fullest possible opportunity of observing the effect of wine in the treatment of fever. A few quotations will prove that these latter are unanimous in their approval of the employment of wine.

Dr. Stokes, of Dublin, directs our particular attention to the phenomena of the heart's action as an index for the administration of wine. It is sufficient for the purposes of this discussion to quote these words:—"I believe that in the diminished impulse, and in the feebleness or extinction of the first sound of the heart, we have a direct and important indication for the use of wine in typhus."

Dr. Bennett, of Edinburgh, says:—"Among all the agents at your command there are none which will enable you to conduct a case of fever to a favourable termination more successfully than stimulants, when properly managed."

Dr. Barlow, of Guy's, says:—"As wine is a direct stimulant to the heart and large vessels, it is highly desirable to delay its use till the fever has subsided, etc.; when this is the case, although the tongue be brown, the patient almost unconscious, and in the most abject state of prostration, we may confidently expect the greatest benefit from wine freely administered." And he further says, that "in cases of extreme prostration brandy must be given in addition to wine."

To these authorities I could add the names of Drs. Watson, Tweedie, Murchison, *cum multis aliis*. I will only cite one other authority—Professor Miller, of Edinburgh, himself a total abstainer. In a little work entitled "Alcohol: its Place and Power," written especially for teetotallers, he commences the article "On Alcohol as a Medicine" thus:—"From amongst the fiercest poisons come some of our most valued medicines." (I commend this sentence to Mr. Bayley.) And he also says:—"In certain fevers, such as typhus, there is marked and dangerous depression. Practitioners have, in consequence, learnt to anticipate and oppose the evil by an early and judicious use of stimulants."

These quotations are sufficient to prove that Medical men of the greatest

experience advocate the employment of wine in fever. I will conclude with my own opinions respecting the general question—viz., the treatment of fever. In the commencement of fever, if the arterial system be excited, the pulse full and strong, the face flushed, and tongue white and furred, an emetic may be given with advantage, and followed up by salines with antimony. This type of fever is, however, very rare in the present day, and the usefulness of emetics is confined to fever of this type. In fevers, as now seen, the nervous element predominates; excitement is rapidly followed by exhaustion, and it is better to anticipate, and, if possible, prevent sinking, by the timely administration of wine. With regard to quantity, no law can be laid down: the quantity of wine must be measured only by the effect upon the heart and arterial system; and whereas, the stomach in certain cases of fever is unable to digest or assimilate food, wine is then invaluable, as it requires no conversion, is absorbed immediately, and is sufficient in itself to keep the heart in action, and so gain time for the elimination of the fever poison by the natural channels.

I am, &c. THOS. MASSEY HARDING.

Stourbridge, December 21, 1863.

APPOINTMENTS FOR THE WEEK.

January 9. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

11. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Dr. Palfrey, "A Case of Uterine Polypus, unaccompanied by Hæmorrhage." Mr. W. Miller, "On Two peculiar Properties of Chloroform independent of Anaesthesia." Dr. Habershon, "Abscess of the Liver."

12. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. Rev. G. R. Hall, "On the British god, Mogan, and the Religion of the Northumbrian Celts." C. R. Markham, Hon. Sec. Geog. Soc., "On the Tribes inhabiting the Valley of the Amazon and its Tributaries."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Holmes Coote, "Case of Left Ovary Found in the Sac of an Inguinal Hernia." Dr. Habershon, "Effects of the Implication of Branches of the Pneumogastric Nerve in Aneurismal Tumours." Dr. John Harley, "On the Endemic Hæmaturia of the Cape of Good Hope."

13. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.

HUNTERIAN SOCIETY, 8 p.m. Dr. Daldy, "On the Influence of Feeble Heart upon Disease."

14. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

15. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN,

By J. Y. SIMPSON, M.D., F.R.S.E.,

Professor of Medicine and Midwifery in the University of Edinburgh.

ON ACUPRESSURE.

(Continued from page 27.)

SECONDARY HÆMORRHAGE—IS IT MORE LIABLE TO OCCUR WITH ACUPRESSURE OR WITH DELIGATION?

Any one who has been in the habit of witnessing the closure of vessels against hæmorrhage by the ligature is liable to fall, against his better judgment, into the mistake of supposing that some strong force is necessary to secure arteries against the mischances of primary and secondary bleeding. The mistake originates in the fact that, in seeing the ligature applied, he sees much force employed—so much as will sometimes break a strong thread. But the force here used is, of course, not the force required to stop successfully the flow of blood along the artery, but the force required to divide and tear through the two inner coats of the vessel—an effect which is necessary to allow of the strangulated external coat being eaten through by ulceration, as speedily as possible. How small, however, and delicate an amount of pressure is necessary to close the mouth of an artery against the escape of blood we know theoretically from physiological experiments upon the force of the current; and we daily ascertain it practically by witnessing how very slight a touch of the finger will close temporarily, in operations, the bleeding mouth of any large artery. In acupressed vessels we find in the same way a comparatively small amount of pressure sufficient to occlude their canals, provided the pressure is applied as directly as possible to the vessel, and without (as, indeed, I have already stated) the intervention of a cushion of elastic tissues between the vessel and the needle. When thus used, the compression of the needle is as effectual in preventing primary hæmorrhage as the laceration and tightening of the thread. But will acupressure prevent *secondary* hæmorrhage as effectually as deligation?

The common local causes of secondary hæmorrhage in deligation consist of ulceration or sloughing of the arterial walls—either too rapid in point of time, or too great in point of degree—by which the cavity of the artery is opened before the internal plug of blood and fibrine, formed above the ligature, has completely occluded its canal. Mr. John Bell tells us that “secondary hæmorrhage arises from ulceration of the artery more frequently than from any other cause.”—(“Principles of Surgery,” vol. i., p. 321.) Secondary hæmorrhage “may occur (observes Dr. Druitt) from *sloughing* or from *ulceration* of an artery; or from imperfect closure of an artery when a ligature separates.” Or, according to Mr. Syme (“Principles of Surgery,” page 89), “if a ligature has been applied, the ulceration by which it is separated, if too rapid or extensive, may cause a bleeding from three days to as many weeks after the infliction of the injury.”

In every case of deligation there is more or less ulceration and sloughing as an unavoidable consequence of the use of the ligature. It is when one or other, or both, of these processes go to a morbid excess and depth, that secondary hæmorrhage from the opened arterial tube follows. But, in acupressure, there is no required ulceration or sloughing at all of the arterial tube; its cavity is obliterated merely by laying its internal surfaces in contact by the pressure of the needle. And hence, secondary hæmorrhage as the result of its two common causes—viz., ulceration and sloughing—should be almost or altogether unknown when acupressure is resorted to.

But in the present limited state of our knowledge regarding the mode or mechanism of the occlusion of arteries by acupressure, and the time required for it, acupressure has been followed by secondary hæmorrhage in two amputations out of the pretty long list in which the vessels in stumps have been acupressed. These cases and their causes are, therefore, considerations of no small moment. In the first of the two, probably the needle was withdrawn too early, and before the sealing up of the arterial tube was fully accomplished. In the second case, the process of internal closure of the tube by an internal plug and cohesion was probably delayed much

beyond the usual time by the state of impaired health and impaired blood of the patient. The first has been reported by Dr. Hamilton in his Carlisle list of cases:

Case 8.—Amputation of the Thigh, with Acupressure and Secondary Hæmorrhage.—A boy, aged five and a-half years, underwent primary amputation of the thigh, at its lower third, for a railway accident, which had mangled the leg. Twenty-four hours after the amputation, Mr. Page withdrew the only two acupressure needles that had been required, when bleeding immediately occurred to the extent of two ounces. The dressings were at once removed and the stump raised, when the hæmorrhage ceased. There was no tension or redness of the flaps. The blood escaped by the opening left by the wires of the acupressure needles. Except at this point, there was union by the first intention along the whole line of incision. For the next two days, the pulse, as on the first day, was high, with vomiting and much tossing. After a fit of restlessness, hæmorrhage recurred from the wound forty-one hours after the withdrawal of the needles. It ceased under manual compression of the femoral and raising of the stump. “Having,” says Dr. Hamilton, “adjusted a tourniquet over the vessel high up, I forcibly tore asunder the flaps, which were adherent from end to end, except at the small orifice by which the blood escaped on the 26th; then clearing out some newly-formed clots, exposed the bleeding orifice, which proved to be that of the popliteal. I then passed a needle under it, and secured it in the usual manner. The hæmorrhage being completely checked, the flaps were approximated by four points of wire suture. On this occasion it was calculated that between four and five ounces of blood were lost.” There was no recurrence of hæmorrhage. Sixty-nine hours after the introduction of the needle, it was withdrawn; and within five weeks after the amputation, the wound from it was quite closed and healed.

Perhaps, in this instance, the needles were withdrawn too early—that is, within twenty-four hours after amputation of the thigh. More evidence, however, as I have already argued, and more experience are required on this point before any very fixed principles can be laid down. I will betimes have occasion to speak of a case of thigh-amputation, where the needles were withdrawn in a young child within twenty-four hours, and without bleeding following. In conversation upon the preceding case, Dr. Hamilton informed me that he was inclined greatly to attribute the second attack of hæmorrhage to the little patient’s great restlessness.

Perhaps I may also be allowed to add here, that in Dr. Hamilton’s report of amputations at the Carlisle Hospital, there are given eleven cases where the ligature was used, and eleven where acupressure was employed. Among the latter eleven there was only the preceding case of secondary hæmorrhage. Among the former eleven, where the ligature was used, there were four cases of secondary hæmorrhage, and two of these were cases of fatal secondary hæmorrhage. In other words, there happened in that institution four times more cases of secondary hæmorrhage from the ligature than from acupressure.

Case 9.—Amputation of the Thigh—Secondary Hæmorrhage after Acupressure.—In the case of a phthisical young man, of twenty years of age, Mr. Crompton performed circular amputation in the lower third of the thigh, on account of severe compound comminuted fracture of both tibia and fibula,—the result of an engine-tender having passed over his leg. The femoral artery was secured by an acupressure needle, and two small muscular arteries were twisted. After seventy hours the stump was in great measure united, but there was still pulsation over the needle near its point of exit. Mr. Crompton, therefore, hesitated about withdrawing the needle, but, as there was considerable inflammation and suppuration in its track, he ventured to remove it. No hæmorrhage took place at the time, but two days afterwards Mr. Crompton found four or five ounces of coagulated arterial blood on the bed, and more blood still oozing from the depending part of the incision. He at once reintroduced the acupressure needle a little higher up, and thus arrested the bleeding completely. The hæmorrhage was attributed to the patient having made use of the bed-pan about half-an-hour before. That same day slight symptoms of phlebitis had been noticed. Shivering and vomiting soon followed, and the patient became delirious at times, and died of pyæmia on the tenth day after the operation. On examining the body, “the external iliac,” to use Mr. Crompton’s words, “and the common and superficial femoral arteries on the right side, were found quite empty, even down to the position of the needle, and the lining coat was of its natural colour, except at the point of pressure,

where there was a line of blue discoloration. The external iliac and common and superficial femoral veins were filled with decomposed clots and sero-purulent fluid. This state did not extend into the common iliac vein or the vena cava." The apex of the left lung was "adherent," says Mr. Crompton, "containing several small cavities. Around them, for two or three inches, the tissue of the lung was filled with tubercular matter."

In this patient, it would appear that the internal consolidation and organisation of blood or fibrine necessary for the permanent occlusion of the injured artery had never properly taken place. Whether this deficient action was owing to the previous low state of the young man's health, as testified by the tubercular disease in his lungs, or to the depression resulting from the injury and the operation, or to some other cause, it is not, perhaps, possible to determine. It possibly would have occurred equally with the ligature. But an important lesson in acupressure practice is surely read to us by this interesting case; for, according to the very sagacious observation of Mr. Crompton, the pulsation could be felt going on along the artery down to the very point of compression by the needle; and the lesson, I take it, is this—that so long as the arterial pulsation in any case may be felt close to the needle, as can always be done immediately after its insertion, we may regard it in any doubtful case as an indication that perfect consolidation and permanent occlusion have not yet taken place, and that the time for the withdrawal of the needle has not yet arrived.

No improvement in our Profession has ever, perhaps, succeeded without, in the first instance, being more or less strongly and strenuously opposed. In consonance with this common and healthy law, there have been adduced, since I first suggested it, a variety both of special and of

GENERAL ARGUMENTS AGAINST ACUPRESSURE.

Some of the earliest general objections urged consisted, of course, of the two old standard objections, which are always ready to be adduced against every proposed innovation in practice, namely—*First*, that the proposed practice is not new; and, *Secondly*, that it is not true, or, in other words, will not be found to have the power claimed for it—that power being in this instance the power of arresting hæmorrhage.

Before I first brought the subject of acupressure under the notice of the Royal Society of Edinburgh in December, 1859, I took occasion to look over a great number of chirurgical treatises, both ancient and modern, with the expectation of finding some notice of such a practice in the past records and suggestions of Surgical science. But I met nowhere with any hint as to the *needle alone* being ever employed as a hæmostatic agent. M. Velpeau, in some experiments upon dogs, had, with a view to the cure of aneurism, tried to obliterate the femoral and other arteries, by transfixing or piercing the cavity of the vessel, and leaving the portion of needle which traversed the cavity of the vessel as a foreign body, around which a coagulum might form. In one or two instances, the late Mr. Phillips, of London, introduced into the sacs of aneurisms in the human subject the ends of needles, with the same views, namely, with the hope of producing retardation and coagulation of blood in the aneurismal cavities. But these proposed operations were on quite a different principle from needle compression. They were instances of the acupuncture of vessels, and not of the acupressure of them. The plan of using a *needle and wire* in conjunction together, as in the third method of acupressure which I have already described, has been long used to some extent as an indirect hæmostatic means in harelips, and occasionally in other affections where twisted sutures are employed, as in the cure of varices and of nævi and other vascular tumours; and Velpeau suggested, but apparently never yet tried, whether the plan could not be extended from veins to arteries supplying aneurisms. But I am not aware of any previous proposal to use it as a means of closing up the ends of arteries laid open in a Surgical wound.

The second argument, that the needles would not produce the effects theoretically claimed for them, has now been fully set aside by the experience of their employment in many operations—in several amputations of the thigh, and other amputations of the limbs, in excisions of the mamma, and of tumours, etc. That the needles can and do arrest Surgical hæmorrhage as certainly as the ligature, is now well known to all who have seen them employed. Acupressure, however, is still in its infancy; and the history of the deligation of arteries, and of other similar innovations in Surgery, does not offer strong hopes for any very speedy and general introduction

of it into practice. At the present time it is passing through many of the same ordeals of objection to which the ligature itself, as a means of arresting Surgical hæmorrhage, was very long subjected.

The want of a simple and efficient means of arresting Surgical hæmorrhage long retarded the progress of Surgery. The ancient and mediæval Surgeons seared the raw surfaces of their wounds with red-hot irons, or besmeared them with boiling oils and pitch, or applied potential cauteries, as they were termed, to the bleeding orifices. In order that the tide of flowing blood might be stemmed as speedily as possible, the old Surgeons recommended the red-hot cautery-iron to be pressed strongly and rapidly against the bleeding surface—"fortiter admoventum est"; and Hildanus further urges that the Surgeon should, if possible, be "ambidexter;" for, holding a heated cautery in each hand, he was thus able to apply them both at once, so as to grill and char the whole raw wound with duly artistic expedition. "The horrors of the patient," truly observes Mr. John Bell, "and his ungovernable cries, the hurry of the operator and assistants, the sparkling of the irons, and the hissing of the blood against them, must have made terrible scenes, and Surgery must in those days have been a horrid trade." Just 300 years ago, or in 1564, Ambrose Paré, declaring the application of cauteries and caustics to Surgical wounds to be "a thing which cannot be spoken or but thought upon but with great horror, much lesse acted," and seeing further that "combust wounds difficultly come to cicatrisation," ventured to propose in their stead the ligature of the bleeding vessels in amputations. But this beautiful and simple suggestion of Paré excited little, except the ire and the persecution of most of his contemporaries. They petitioned the French Parliament to prevent the dissemination of his doctrines. His contemporary, M. Gourmelen, Professor of Surgery to the Faculty of Medicine at Paris, bitterly denounced Paré and his invention in a work on the principles of Surgery which he published in 1566. He and other Surgeons had been so long accustomed to their caustics, and were so satisfied—so perfectly satisfied—with *their* power and effects, that they wanted no such disturbing innovation as this ligature. "It was then," writes Gourmelen, "very forward, rash and presumptuous in a certain person to venture upon condemning the cauterising of vessels (after cutting off a mortified limb)—a method so highly and continually commended and approved of by all the Ancients; teaching, in opposition to that, without any authority, without knowledge, without experience, without good sense, some new method of his own, of tying arteries and veins."—(See John Bell's "Principles of Surgery," vol. i.) This same argument of the old Parisian Professor—and in nearly the same words, too—was employed two or three years ago in the Medico-Chirurgical Society of London, when the subject of acupressure happened to be discussed.—See *Medical Times* for April, 1860, pages 425 and 459, and *Lancet* for May, 1860, page 446.) Paré's proposal spread very, very slowly. Even his favourite pupil, Guillemeau, to whose evidence in favour of the ligature Paré himself had directly appealed, and who translated Paré's works into Latin, declared his preference for the old orthodox cauteries in some forms of amputation. We know, from Dionis, that the Surgeons at the great Hospital of the Hôtel Dieu of Paris—the city in which Paré lived and practised—continued still, a century and a half after Paré's time, to apply to the open arteries vitriol buttons instead of ligatures in all their amputations. The same distinguished Surgeon, Dionis, in his "Course of Chirurgical Operations" (the first edition of which was published in Paris in 1707), tells us that, after removing cancerous mammae, he himself had now "given over the use of the searing irons called fire-buttons, and that of the red-hot flat-iron," because, when approached to the raw and bleeding wounds, "these hot irons," says he, "make the patients tremble;" and no wonder. He recommends the hæmorrhage attendant on that operation to be restrained by the application of chemical caustics and the use of astringent powders. I copy these expressions from a second English edition of Dionis' work, published in London in 1736. In the most popular English Surgical work of the last years of the seventeenth century, Mr. Cooke, when treating of that "dreadful operation," the amputation of limbs, tells us that it is done "with the dismembering-knife, which some use red-hot;" and for staunching the resulting hæmorrhage you may employ three modes—first, potential caustics; or secondly, "actual cauteries," which are (he says) to be applied to the mouth of the vessels, being cleansed from clotted blood once or twice at most. "The third way (he

contemptuously adds) is by stitching, which is almost *wholly rejected*. See Paræus for the manner."—(“Cooke’s Marrow of Chirurgery,” fourth edition, 1693, p. 203.) Toward the middle of the last century the knowledge of the “stitching” after ligation of vessels was still in such a condition in our own country, that Mr. Sharpe, Surgeon to Guy’s Hospital, when he published in 1761 his well-known work, entitled, “A Critical Inquiry into the Present State of Surgery in England,” found it necessary formally to advocate the employment of the ligation for the arrest of Surgical hæmorrhage in preference to styptics and the cautery, because “it was not yet universally practised among Surgeons residing in the more distant counties of our kingdom.”

The history of the ligation in Surgery powerfully and painfully teaches us how very hard and very difficult it is for the Professional mind to give up ideas and practices to which we have been long trained by education and by experience. “Porro,” exclaims Fabricius Hildanus, when discoursing of the grand properties (“*egregiæ virtutes*”) of his red-hot cautery-knife—“*porro excellentiam hujus cauterii non satis extollere possum.*” Formerly he and other Surgeons scornfully rejected the ligation, because they were completely satisfied and contented with their cauteries, and declared that they required on change. Now-a-days, Surgeons reject acupressure on the same argument, because they are quite satisfied and contented with the ligation, and declare they require no innovation. In discussing this question, I have both read and heard of leading and eminent Surgeons stating that the ligation was “one of the grandest things in Surgery,” “*excellentiam non satis extollere possum.*” What! one of the “grandest things” in Surgery to bury and implant in the depths of every wound which it inflicts as many sloughs of dead decomposing arterial tissue as there are arteries tied, and expect primary union to follow! Surely English Surgeons in the latter half of the nineteenth century ought to be able to boast of something better than a practice which thus bids utter defiance to all the fundamental principles of true English Surgery.

Besides the general arguments which I have noted, there have been brought forward by different Surgeons several individual or

SPECIAL OBJECTIONS TO ACUPRESSURE.

It is necessary for us to consider the chief of these special objections in detail, however tedious and disagreeable the process may be; and in doing so, perhaps we may find that most of these so-called objections turn out as arguments in favour of acupressure rather than against it.

First Objection.—Compression of the Attendant Veins and Nerves.

“In acupressure,” observes Professor Miller, “it appeared to him impossible to limit the needle to the bleeding point, so as to avoid including along with it the vein, and probably also the nerve. But it was well known,” he continues, “that veins were extremely intolerant of pressure, and could not be subjected to it without the most hazardous consequences.” (*Edinburgh Medical Journal*, 1860-61, p. 568.) The simple and direct answer to this objection consists in the fact, that acupressure has now been used in a considerable number of amputations and other operations without any such evil consequences as those suggested by Professor Miller having ever been produced. And even *a priori*, one would scarcely, I think, expect that the mere compression of the tube of a vein, for twenty, forty, or fifty hours at most, would be liable to excite deleterious results. In his “Principles of Surgery,” Professor Miller recommends for the cure of varix, that a series of needles and threads, in the form of twisted sutures, should be placed around the dilated vein, so as to compress and obstruct its canal, not for a few hours, as in acupressure, but for “some days.” And he speaks of this as a “simpler and safer mode of treatment” than any other. If a diseased vein can stand such prolonged and strong pressure with comparative impunity, surely a sound vein may do it still more safely when both much less in degree and much shorter in duration. After venesection, and wherever, in fact, there is venous hæmorrhage, we compress the sides of the vein together with a pad or otherwise, and, I think, usually without dreaming that any evil consequences are apt to follow the temporary obliteration of the venous tube by compression.

But, further, I am inclined to hold that the closure of the vein along with the artery is, perhaps, a gain from acupressure, instead of an objection to it—Dr. Watson, Lecturer on Surgery, has adduced the opinion, that one great cause of the non-union of amputation wounds by primary adhesion was

the circumstance, that after the wounds were closed, “oozing ensuing afterwards, the cut surfaces were kept apart by a coagulum, which, acting like a foreign body, induced supuration.”—(See *Edinburgh Medical Journal*, 1860-61, page 569.) Surely this deleterious coagulum of blood is much more likely to be mainly, if not entirely, venous than arterial in its origin; for every careful and conscientious Surgeon takes due pains to close all the arterial orifices that are bleeding upon the surface of his wound. He diligently ties these arterial orifices, though he usually avoids tying any venous orifices. Sometimes, however, though not very often, the veins in a stump wound, as described by Chelius, Velpeau, Fergusson, Skey and others, do bleed so profusely as to require to have their orifices occluded. If these orifices are tied with a ligation, the tissues of the vein are lacerated; and such physical injury may be apt occasionally to terminate in phlebitis. If, on the contrary, these venous orifices are closed by acupressure, they escape any direct physical injury to their tissues; and further, perhaps it may be yet found that the closure of the venous orifices in stumps, where acupressure is used, is a prophylactic measure of great importance in this respect—that hereby we prevent, to a certain extent, the introduction or absorption by these gaping venous orifices of deleterious and ichorous fluids existing upon the surface of the wound itself.

The supposed deleterious effects of compression of the attendant nerves in acupressure are, I believe, equally groundless and hypothetical. Patients whose wounds are acupressed have certainly, in truth, not more pain than those which are ligatured. I have seen the central artery of the sciatic nerve, and, consequently, the mass of the nerve itself, compressed by an acupressure needle without any bad effects; and here the nerve compressed was the largest that can be met with in Surgical wounds. The case in which this occurred was in the practice of Dr. Handyside, and was, in various other respects, interesting in reference to our subject.

Case 10.—Amputation of the Thigh at its Upper Fourth.—The patient was a strumous man, aged forty-one, emaciated and debilitated to the last degree, and labouring under high irritative fever, in consequence of an extensive ulcer from a burn. The ulcer was of several years’ duration, and involved the right thigh, knee, and leg. Dr. Handyside amputated the thigh at its upper fourth. The vessels which bled were acupressed with short needles. As the wound was about to be closed, a projecting portion of the sciatic nerve was clipped off, and its central artery began to bleed freely. To avoid the removal of the stitches which had been already introduced, a needle, five inches long, was brought down between the sciatic nerve and the os femoris, through the skin of the region of the hip, and made to emerge between five and six inches from its point of entrance. The effect of this acupressure was instantaneously seen in the bleeding being arrested. This long needle was removed from under the sciatic nerve twenty-five hours after the operation. The stump yielded a discharge of pus not great in quantity. Two months after the operation, both the stump and the entire body of the patient had become stout; and his pulse, which, long before the operation, had been extremely rapid and intermittent, was now seventy-two, and regular. On the night of the operation the patient had severe pain in the back,—an effect produced more probably by cold, wetting, and exposure on the operating table, than by the acupressure of the sciatic nerve; for the withdrawal of the needle had no effect in lessening the pain; it increased subsequently, and was relieved, at his own suggestion, by the application of a strengthening plaster,—a remedy which he had used successfully in similar attacks.

Perhaps it is not uninteresting to stop and remark, that almost all the leading arguments and objections which in olden times were adduced against the introduction of the ligation, and for the perpetuation of the heated iron, have been reproduced, perhaps unwittingly, against the introduction of acupressure, and for the perpetuation of the ligation. Names, and men, and times, and things change, but the spirit of opposition always continues wonderfully the same in all ages. In the observations of Professor Miller, from which I have cited his objection regarding the deleterious compression of the veins by acupressure, he argues that, in Surgery, innovations are not necessarily improvements. M. Gourmelen, Professor of Surgery in Paris, uses the same argument, in nearly the same words, against Paré’s “*new way to tie the vessels,*” and its “*farre greater perills.*” He maintained that the drawing out of the vessel for deligation would “bring no less pain than the cauterizing irons do,” and he adduced Pro-

fessor Miller's objection regarding veins and arteries,—“for if the needle shall prick any nervous part, yea, the nerve itself, when he shall by this new and unaccustomed way constraîne the vein by binding it, there must necessarily follow a new inflammation; from an inflammation a convulsion; from a convulsion death.”—(See Translation of Professor Gouremelen's Objections in the English edition of Paré's works, page 1134). No one, I fear, has any great respect now for these arguments in favour of the “burning and ution of the vessells,” “much praised and commended, and always approved by the Ancients.” Perhaps the same argument, as applied against acupressure, is destined ere long to meet the same fate.

[The fourth part of this lecture on Acupressure is in type, and will appear in our number for January 23.]

ORIGINAL COMMUNICATIONS.

CASES OF UNUSUAL SLOWNESS OF PULSE, WITH REMARKS.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,

Physician to St. Thomas's Hospital, and to the Hospital for Diseases of the Chest, Victoria-park.

(Read before the Hunterian Medical Society, December 2, 1863.)

(Continued from page 33.)

The following instance affords an example of slowness of pulse coming on with the cessation of the fibrile symptoms in acute rheumatism—an affection in which I do not remember to have previously noticed the peculiarity. It is, however, possible that the patient's pulse may always have been below the ordinary standard, and, if so, the case should rather be placed with the first class of cases described by Mr. Mayo:—

Case 3.—Remarkable Slowness of Pulse coming on during Convalescence from Rheumatic Fever, with a Murmur at the Base of the Heart, regarded as Anæmic.

Sarah H., aged 21, a servant, residing in Kennington-lane, was admitted into Elizabeth's Ward, October 15, 1863, labouring under symptoms of rheumatic fever. She states that her father is living, but her mother died in early life, with symptoms of rheumatism, terminating in decline. Of the family of eight, two only are living besides herself, and those who are dead all died in early life. She is of a fair complexion, very anæmic in appearance, and obviously strumous, and states that she has been all her life subject to rheumatic pains, but has never before had rheumatic fever. About a month ago, being somewhat out of health, she left her situation, and went into the country; was away about a week, and on her return began to feel poorly,—suffering from sore throat and pains in the limbs; and about three days before her admission she had pains and swelling in the limbs, and was not able to get about. On admission, she had a draught and a purgative powder, and has since taken a scruple of carbonate of potash and half a drachm of bicarbonate of potash thrice daily.

On the 18th she had two grains of calomel and ten grains of Dover's powder at night.

October 19.—She is not at present materially better. Her tongue is somewhat dry and furred; her pulse is sharp, 100; her skin is hot, and she perspires profusely; she complains of pain and stiffness at the back of the neck, left shoulder and wrist, and left ankle, and the latter is considerably swollen and somewhat red, and very tender. There is a copious eruption of small papular and partly vesicular spots upon the thorax; the heart's sounds are somewhat flat, without murmur; a sibilant rhonchus is heard over all parts of the chest. She says she has not got any rest at night since her admission. To have one grain of calomel and six grains of Dover's powder each night. Her bowels are acted upon regularly, and she passes a considerable quantity of water, which is slightly alkaline, and has a specific gravity of 1032.

22nd.—She appears better, and expresses herself as freer from pain; she does not sleep at night, but dozes, chiefly during the day; she complains of pains in the left arm and ankle, but the pains are better in the arm, and she can move it more freely; the ankle still continues red, swollen, tender, and painful. The back of the neck is easier, and she can open her mouth more freely than before. Tongue somewhat dry, red at the tip and edges, slightly furred on the dorsum; pulse slow, 60; skin warm, profusely perspiring;

perspiration somewhat sour and offensive; heart sounds flat, without murmur; sibilant rhonchus in all parts of the chest; the bowels have been acted on five times in twenty-four hours; she is passing water freely, but the quantity cannot be ascertained; to omit the calomel, and take the mixture every four hours instead of every six hours; urine, specific gravity 1020, alkaline; quantity, Oiss. daily, besides that passed in the motions.

26th.—She appears much better, and expresses herself as feeling so; she still has slight pain in the left arm, but can move the joints quite freely. The left hip, knee, and ankle are still painful, and the left ankle is still somewhat swollen, but less tender. Tongue moist, slightly brown on the dorsum; pulse 42. The bowels have been relaxed about four times in twenty-four hours since the last visit. The first sound of the heart is somewhat prolonged, and she complains of some pain in the region of the heart. To have a mustard poultice over the heart, and three ounces of wine daily. There is still some slight sibilant rhonchus. To take the mixture only thrice daily.

29th.—She has continued to improve, but still complains of some pain in the region of the heart; she has less cough than before, and no difficulty of breathing. The pains in the limbs have almost entirely gone. Pulse slow, 36. The rhonchus in the chest much less; there is a somewhat harsh but low systolic murmur heard most intensely in the course of the pulmonary artery and for some distance round, but very indistinctly. She complains of pain on the left side, but it is apparently surface tenderness. There is a systolic but no continuous murmur in the neck. Tongue still somewhat dry and furred. Bowels not relaxed. To take the mixture only twice daily, and a quinine and iron pill also twice.

November 2.—Her appearance is very much improved, and she is nearly free from pain. Tongue clean, somewhat dry; pulse 36. The systolic murmur is still audible to the left of the sternum at the level of the third cartilage; the intensity diminishes very rapidly, as you remove the stethoscope from one point. Bowels regular without the pills. To have slice of fish; to discontinue the mixture, and take the pill thrice daily. She passes about two and a-half pints of water in twenty-four hours.

5th.—Pulse 68, still sharp. She complains of some pain over the heart; the systolic murmur continues most intense at the base, but it is somewhat more diffused than before. There is a harsh systolic murmur audible in each carotid, but no continuous murmur. Tongue clean.

16th.—Her general appearance is much improved, Tongue clean and moist; pulse quiet, 64. She complains of having a troublesome cough, and expectorates a considerable quantity of colourless, glairy, and somewhat viscid fluid containing small air-bells. There is some little sibilant rhonchus in the front of the chest, and more posteriorly at the lower part of each lung. The systolic murmur is still audible in the precordia, and is apparently most intense in the course of the pulmonary artery; it is very soft in its character. She takes her food well, is improving in appearance, and gaining strength.

24th.—She is now up, and is much improved in general appearance, but is still anæmic-looking. Pulse somewhat sharp, 48 per minute. The bowels still continue acted upon three or four times daily. To have the quinine and iron mixture, with five minims of tincture of opium thrice daily. The systolic murmur is still audible at the base and in the course of the pulmonary artery, not at the apex, nor to the right of the upper part of the sternum.

25th.—Presented cured, but to continue the quinine and iron pills.

December 1.—She came to the Hospital to-day to see me. I found her stronger and quite free from rheumatic pains, but complaining of a troublesome cough and some expectoration. The pulse, in the erect position, beat steadily 48 in the minute. There was a very slight systolic murmur still audible at the base of the heart.

I cannot concur with Mr. Mayo that slowness of pulse may be dependent on general exhaustion. Such a state ordinarily is attended with the very opposite character of pulse; under such circumstances, indeed, the left ventricle acts feebly, irritably, and rapidly, and the pulse is quick, small, sharp, and generally feeble. In cases in which the rate of the pulse is unusually low during convalescence from severe disease, it is not during the stage of greatest exhaustion that the rate begins to fall, but during the period of recovery, and the diminution often continues and increases, while the patient is steadily progressing towards cure, taking more food and gaining strength. There is also no just relation as to the degree

of prostration between the cases in which the pulse becomes slow and those in which it continues to beat considerably above the healthy standard. Certainly, in the instance which I have related, the rheumatic symptoms were slighter, the prostration less, and the recovery more rapid than in another case in a neighbouring bed, though the pulse of the latter patient long continued to beat upwards of 100 in the minute.

3. Closely allied to the class of cases last named are those in which the pulse is slower than in health, and sometimes much slower during the active stages of acute febrile diseases. I have seen cases of fever in which the pulse never exceeded 52, and a case of pneumonia in which it ranged between 50 and 60, without in either case there being any marked cerebral disorder, and in which, unlike the last cases, the pulse rose with the progress towards recovery.

4. It will thus be seen that slowness of pulse occurs under very different circumstances: in some cases in which the heart is extensively diseased, and in others where there is no reason to suppose that there is any defect in the structure of the organ. It must also be evident that none of the causes hitherto assigned for the peculiarity—applicable as they are only to particular classes of cases, and not to the whole of those in which it obtains—can be accepted as affording adequate explanations of the occurrence of the condition. As, also, it has been further shown, that when the slowness of pulse is combined with decided disease of the heart the structural changes are of very different characters, it follows that such changes can only be regarded as coincident, and not as essential to the production of the peculiarity, the defect being evidently one of function.

It would appear, therefore, that the undue slowness of pulse must result either from a want of proper muscular irritability or from a defect in the special nervous endowment of the heart. Whichever view we adopt, it will explain the occurrence of the peculiarity, for such defect may, and is indeed very likely to, coexist with any form of structural change in the heart, and yet may occur when the organ is entirely healthy. It would also be a condition very likely to ensue during convalescence from acute febrile diseases; for it is a well-ascertained law of the animal economy, that no organ can be the seat of prolonged over-action without its power being exhausted, and a state of debility or defective action being induced. In the cases in which the pulse is slow during the active stages of febrile diseases, the morbid cause may be supposed to act specifically upon the part in the same way as certain sedatives (I may especially instance aconite and the cinchona alkaloids, given in full and frequently repeated doses) depress the power of the organ, and greatly reduce its rate of pulsation. The condition of the blood probably affects the rate of the pulse in some cases, a slow pulse being not very uncommon in cases of chlorosis and anæmia.

That this view, which affords a probable solution of the occurrence of slowness of pulse in the different circumstances described, is further supported by the very little effect which, in some of the cases in which the condition supervenes during convalescence from acute diseases, is produced upon the rate by the exhibition of stimulants. Indeed, sometimes the condition is very persistent, continuing after the patient has gained both flesh and strength, and is able to make a considerable amount of muscular exertion. In such cases, indeed, it only subsides under the prolonged use of iron and other remedies which may act directly on the muscular structure or nerves of the heart. The young woman who was recently in St. Thomas's Hospital has at present only a pulse of 64, though she has recovered strength to such an extent as to be able to resume her usual occupations.

28th.—I have again seen this young woman; her pulse beats 60 in the minute. The murmur has entirely disappeared, but she is still chlorotic-looking.

The intermittent pulse bears a very close analogy to the slow pulse, and occurs under very similar circumstances. It may accompany different forms of valvular and other diseases of the heart, yet may be present when the organ is entirely free from disease. The explanation which has been given of the cause of the former condition is equally applicable to the latter.

GERMAN LADY-SURGEONS.—Frau Josepha Fey has just received a license to practise "lesser Surgery" in the Cologne district, on the condition that she should always act under the direction of a received Practitioner. This is the first example of such a concession being made to a woman in Germany.

MULTILOCLULAR OVARIAN TUMOUR— OVARIOTOMY—OMENTAL AND UTERINE ADHESIONS—REMOVAL OF A LARGE PIECE OF OMENTUM—RECOVERY.

By JOHN CLAY, M.R.C.S.,

Professor of Midwifery, Queen's College, and formerly Obstetric Surgeon to the Queen's Hospital, Birmingham.

I WAS consulted by Mrs. C. on July 24, 1863, respecting an abdominal enlargement from which she had been suffering for several months. Dr. McVeagh, her Medical attendant, kindly furnished me with the following history of the case:—

"Mrs. C., now in her thirty-ninth year, was first attended by me on September 9, 1861, in her third confinement. Hitherto, I was told, there had been alarming post partum hæmorrhage, so I took the precaution of giving a strong dose of freshly-powdered ergot when the head was on the perineum, followed up the contraction of the uterus during the extrusion of the child, and kept the organ firmly grasped in my hand for some twenty minutes afterwards. I was gratified to find that no flooding occurred. No symptoms of a grave nature interfered with the recovery, but convalescence was tedious. Hæmorrhoids were very troublesome, and a dull sense of weight and uneasiness in the left iliac region was seldom absent for long together. She occasionally consulted me between this period and last March, when she bespoke my services, supposing herself four months pregnant. Hearing some days afterwards that 'a slight show' had appeared, and that some of the feelings were very different from those experienced in former times, I wished to institute an examination, which I did on March 22. The abdominal enlargement then corresponded with what might be expected; but from the fact of the navel not being at all prominent, the breasts being small and flabby, and especially as the most careful stethoscopic application failed to elicit either foetal movements or placental sounds, I confessed my doubts in the matter, and proposed waiting another month before committing myself to any opinion. On April 18 I again examined her, but with no positive result. The abdominal tumour was uniform and equable, but no further evidence of pregnancy. I could discover no change in the state of the cervix uteri to indicate such a condition. My next visit was on May 16, when I detected a firm substance, like a child's head, to the left of the navel; she said she was sure she felt movements there. I could hear only a loud friction sound; fluctuation was now very distinct over the lower belly; could it be pregnancy of a later date than she supposed, complicated with dropsy of the amnion? Possibly, I thought; but the state of the navel, mammae, cervix uteri, and a return of 'the show,' disproved the probability. On June 8 Mr. Bicknell (my colleague) saw her with me, but we could not satisfy ourselves that pregnancy existed. I again visited her on June 23, when she had a free, sanguineous discharge, to all appearance menstrual. Fluctuation now was general over every part of the abdomen; friction sounds audible over the situation of 'the firm substance,' which felt larger and more lobulated; it had, moreover, risen rather higher up, while the finger could detect no appreciable alteration of the cervix uteri either in shape or position. I now expressed my own firm conviction that she was not with child, but suffering from ovarian disease. The patient herself admitted that she long expected as much, as her mother had died of 'dropsy of the womb.' At my request she consulted Mr. John Clay, of Birmingham, during the following week, who, without hesitation, diagnosed ovarian dropsy, for the relief of which he advised speedy operation; with what a happy result the sequel of the case will show."

The above concise detail of the phenomena manifested by the patient sufficiently describes her condition at the time I saw her. I may add that there was a small quantity of ascitic fluid in the peritoneal cavity. The os uteri was drawn up towards the symphysis pubis, but no tumour was perceptible in the recto-vaginal cul-de-sac, and it was found impossible to introduce the sound or a bougie into the uterine cavity. I had no difficulty in coming to a conclusion that the patient was suffering from a multilocular ovarian tumour, with a mass of solid matter situated at its left extremity, and I advised its speedy removal, to which the patient eventually consented. During the seven weeks previous to the operation, at intervals of ten days, she had severe attacks of menorrhagia. The last attack came on about a week before the operation.

The operation was performed in Birmingham, on Friday,

August 28, at one o'clock p.m. Drs. Dewes and McVeagh, Messrs. Bicknell, Ebbage, Smith, Troughton, Waters, etc., being present.

The patient was speedily brought under the influence of chloroform. An incision of two and a-half inches in length was then made in the median line, and the cyst exposed. The patient was turned on her side, the cyst was seized with vulsellum forceps, tapped, and drawn gently forwards. It now became apparent that a mass, consisting of several small cysts, interfered with the extraction of the tumour. The incision was enlarged about an inch and a-half, and the cysts punctured as they came into view, and the mass was eventually brought externally. A severe hæmorrhage was now taking place from one of the punctures of one of the small cysts. The bleeding vessel could not readily be found; a clamp was, therefore, promptly placed around the pedicle of the tumour, by which the hæmorrhage was immediately and effectually arrested. An adhesion containing several large vessels, between the omentum and the cyst, was then discovered, and a portion of omentum, measuring two and a-half inches by five, was removed by means of my adhesion clam,^(a) and the tumour excised above the clamp. The pedicle was about three inches broad, and united by a cartilaginous adhesion to the fundus of the uterus. The adhesion contained several large vessels; three of these were ligatured with silk, the pedicle and adhesions then transfixed and tied in four portions; the stump was left in the cavity of the abdomen, the ends of the ligatures being brought out at the lower angle of the wound. The incision was closed by three sutures of silver wire, transfixing the peritoneum, and by three superficial ones. The patient was removed to bed, and a linseed-meal poultice applied to the abdomen. The tumour proved to be a multilocular one of the left ovary, with a solid mass of four and a-half pounds, which, together with the contents of the large cyst, weighed about eighteen pounds. Reaction was established in about three quarters of an hour, and four hours after the operation the patient had an anodyne injection.

On the morning of the 29th she suffered from sickness, flatulence, and great depression of spirits. Pulse 119. These symptoms were considered to be due to an empty condition of the stomach, and she was ordered a teaspoonful of milk alternately with the same quantity of thin custard every quarter of an hour. This was well borne, and the quantity increased to two teaspoonfuls at the same intervals, and towards evening she felt much better, when she was ordered three teaspoonfuls of the same kind of food every half-hour. An anodyne injection was administered on the evening of the second day. The urine was drawn off with the catheter three times, but she passed it voluntarily twenty-eight hours after the operation. The bowels were relieved by means of injections on September 1, and all the sutures were removed on or before that time. On September 3 there was a slight sero-sanguineous and rather fetid discharge from the wound. The patient was much depressed; pulse 120; skin hot, and covered with clammy perspirations. Her condition appeared very critical, and Dr. Blunt kindly saw the patient with me. The patient was turned on her left side, and gentle pressure made over the abdomen, when several ounces of fetid purulent matter, mixed with bloody serum, were discharged through the wound, and afforded her much relief. The pulse diminished in frequency during the day, and the skin became cool. The perspirations did not recur, and she was in every respect much better, and continued to improve until the morning of the 5th of September, when she was attacked with diarrhœa. The tongue was then red and fissured, and the fauces were covered with aphthæ. There was also a good deal of tympanitis, with abdominal tenderness. Dr. Blunt kindly saw the patient again with me, and we were of opinion that the symptoms arose from too generous a diet, which, however, had been well borne. The quantity of nourishment was consequently diminished, and she was ordered bismuth, magnesia, and calumba, from which she found great benefit. From this time she improved rapidly. Two of the silk ligatures came away on the seventh and ninth days, and the ligatures of the pedicle on the twelfth, seventeenth, nineteenth, and twenty-seventh days respectively. One silk ligature remained. She left Birmingham for Kenilworth on September 24; but the last silk ligature did not come away until seven weeks after the operation. Since that time she has continued to improve in condition, and she is now stouter than she has been for many years, and in robust health.

(a) For description, see *Medical Times and Gazette*, June 21, 1862, p. 640.

Remarks.—The most notable features of this interesting case are,—

1. *The Mode of Dividing the Extensive Omental Adhesion.*—The absence of hæmorrhage from the small vessels renders this method the safest and most expeditious yet devised for dividing adhesions connected with ovarian tumours. I have used and superintended the use of the instrument in five cases, and in each instance the object has been effected with great facility, and without the slightest hæmorrhage taking place.

2. *The Stump of the Pedicle was left in the Cavity of the Abdomen.*—I am decidedly of opinion that it is much better, in the majority of cases, to adopt this procedure than to fix the pedicle between the lips of the wound: we thus avoid the dragging of the pelvic viscera, which, I have no doubt, increases the risk of peritonitis.

3. The beneficial effect of the careful administration of nourishment was well marked, and the propriety of the usual advice to give no nourishment during the first few days may, I think, be very seriously questioned.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

REPORT OF A CLINICAL LECTURE ON CASES OF TUMOURS UNDER MOLES.

(By Mr. PAGET, Surgeon to the Hospital.)

THE occurrence of melanotic cancers under or in moles or pigmentary nævi has been long known. Among the cases of this disease, having their primary seat in or near the skin, more than half have thus grown in close relation with moles. There can, therefore, be no doubt that these congenitally defective or diseased parts offer some conditions peculiarly apt for the growth of melanotic cancers. What these conditions are we cannot tell, any more than we can what those are which are sometimes induced in a part by injury. Their reality and influence are, nevertheless, certain. And with the knowledge of these facts some useful points in practice may be connected. For example, if a patient have a tumour growing in or beneath a mole, it must be considered as most likely a melanotic cancer; or, if we have an increasing outgrowth from a mole, epithelial cancer must be suspected. And if in any one, especially an elderly person, a mole begins to grow prominent, or to become more vascular or more irritable, it had better be forthwith cut out or destroyed with caustic. I have known cases in which, when moles were quickly increasing, and changing just like those that have afterwards become seats of melanotic cancers, their total destruction has been the end of all mischief. Of course, I cannot be sure that these would have become cancerous if they had been left; but I believe that, at least, some of them would, and that the rule for the destruction of all growing like them is a good one. If the formation of cancer be not quite averted by it, it may be deferred, as it seemed to be in a case I have lately seen. A patient had many pigmentary moles in his back. Five years ago one of them began to grow, and Sir Benjamin Brodie destroyed it with caustic. The scar remained sound till a few months ago, when an epithelial warty cancer began to spring up from it.

Hitherto, I believe that the only tumours for the growth of which moles have been known as offering peculiarly favourable conditions, are melanotic and, much more rarely, epithelial cancers.

But the tumour removed last Saturday is an instance of another kind, of which I have now met with three examples. The patient from whom this tumour was removed was sixty years old, healthy all his life, and very temperate, and in the site of the tumour there had been a mole as long as he could remember, and like one which he has on the back of the neck. This, however, never gave him any trouble until about nine months ago, when, with some tingling, etc., it began to enlarge, and had gradually increased in size up to the time of his admission into the Hospital.

A second case, which came under my notice a few years ago, was in a gentleman, who was unhealthy from repeated fever and other less serious maladies. He had noticed the tumour for at least four years, and it might have existed much longer, and have been overlooked, till, during these years, it

had increased more quickly than before. In this, as in the last case, there had always been a mole at the place; but it was uncertain when the change and increase took place in it.

The third case was a woman, aged fifty-nine, who was admitted into St. Bartholomew's Hospital in 1850. She was a rather feeble-looking, poor woman, high-coloured, but not robust. She had always (she said) been feeble and ailing; but in the three years before her admission into the Hospital her general health had been better than usual. Since childhood she had had several sebaceous or epidermal cysts of the scalp, but nothing of the present tumour over the sacrum had been noticed till between six and twelve months before admission.

The cutis over this tumour had, after, as well as before the removal, a distinctly brown hue, which gave it the appearance of a mole—a mere pigmentary mark, not raised above the surrounding skin.

In these three cases the tumours were so alike, that, with few additions, one description may suffice for all. Growing on the back of the trunk, they lie imbedded in the subcutaneous fat. They are roundly oval, moderately well-defined to the touch, closely connected with the structures round them, very firm, heavy, dully elastic, feeling like fibrous tumours. The skin over them is raised and thinned by their growth; adherent, but not confused with their surface; and, in addition to the dark tint of the mole spread over part of the surface, the skin has a dusky, or ruddy and glossy, tint of diffused vascularity; and enlarged veins ramify over it, or away from it. The skin, or the tumour beneath it, has been in two cases the frequent seat of hot, burning pain; in the third there was no pain.

The section of the tumour has a lowly nodular or tuberous outline, easily separable by dissection from the surrounding skin and subcutaneous tissue. The cut surface appears divided by whitish tissue into lobes and minuter lobules, much like those of secreting conglomerate glands. It is very pale, greyish white, with tinges of yellow or pale purple, smooth on its section, and glistening. It may have minute cavities filled with fluid, or one or more larger cysts, containing serous fluid or grumous matter. The substance is firm, but brittle, easily breaking into small fragments, yielding on pressure or scraping only some yellowish clear fluid, and no turbid fluid like cancer-juice even after it begins to decay.

The microscopic appearances are too various and indefinite for any useful minute description. There are appearances of glandular arrangement in minute acini, or in groups of cells of similar form. The cell structures, of which nearly the whole mass is composed, are some of them very like epithelial cancer-cells of various shapes; some, like those cells withered, or rolled up, or very small, or abortive, and without nuclei; some, more like elongated and very small cylinder-epithelium cells; some like small, thin gland-cells. With these are granular matter, bodies like free nuclei, appearances of fragments of membrane; but no more traces of fibrous or other such structures than may be referred to the partitions between the lobes, into which the whole substance of the tumour appears divided. In none of the cases has there appeared any pigment matter indicating relation to the melanotic growths more commonly found under moles.

There is sufficient in these structural characters to prove the occurrence of a form of tumour which, so far as I know, has not hitherto been described; but there is not enough of what is definite to justify the giving of a new name. More specimens must be examined before this can be safely done. Meantime, it may be held that moles are, even more than has been supposed, apt to be the seats of the growth of tumours, and that among the tumours likely to be found in or beneath them are some which are neither epithelial nor melanoid cancers, and which, probably, are not cancers at all.

One of the cases, indeed—the second—has now remained well, without any recurrence, for more than four years after the removal of the tumour—a period much longer, almost certainly, than that which would have elapsed after the removal of a deep-seated epithelial or a melanotic cancer.

THE SOUTH DEVON HOSPITAL, PLYMOUTH.

A CASE OF FEMORAL ANEURISM CURED BY COMPRESSION.

(Under the care of Mr. WHIPPLE.)

[Reported by Mr. W. RICKARD.]

HENRY P., aged thirty-two, residing at Stonehouse, was

admitted into the Crimean Ward, under the care of Mr. Whipple, on July 13, 1863.

The man has a cachectic appearance, though tolerably muscular.

History.—Was a sailor for thirteen years; now a waterman. No hereditary diathesis. States that he has always enjoyed good health. Has contracted syphilis on three separate occasions, though not followed by secondary symptoms; has taken mercury at these times, but never to salivation. Has a stricture of urethra of ten years' duration, but passes a good stream of water at the present time. Three months ago he perceived a small lump, the size of a filbert, at the upper part of his thigh; had met with no blow or violent strain to account for its appearance. He continued at work for some weeks subsequently, though he noticed it gradually increasing in size. Five weeks before admission, he began to suffer pain in the thigh, running down to the knee; and this has been so severe for the last fortnight that he has been obliged to keep in bed.

On Admission.—A tumour, about the size of an orange, but of rather an ovoid shape, lies in Scarpa's space, about four inches below Poupart's ligament, in the course of the femoral vessel. Pulsation and bruit most distinct. A good deal of neuralgia extends from upper part of thigh to knee, and follows the course of the anterior crural nerves. The femoral vessels on both sides, just below Poupart's ligament, feel cordy and inelastic. Heart's sounds feeble; no murmur. Respiratory system normal.

July 15.—Mr. Whipple fixed a horse-shoe tourniquet over the femoral vessel, about two inches above the tumour, and a conical pad (composed of squares of adhesive plaster spread on thick leather) was adjusted to the seat of pressure. The instrument to be kept on for the space of one hour three times a-day, and as much pressure to be employed as the man can conveniently bear. To have the ordinary meat diet of the Hospital, with one pint of beer.

16th.—The neuralgia of the limb has increased since the application of the tourniquet, so that the sleep at night is much impaired. Half a grain of morphia.

22nd.—The limb is much swollen from thigh to knee, tense, œdematous, and tender to manipulation. No redness. Ordered to discontinue application of tourniquet for a few days. To have cold water cloths, kept continually moist, to the limb, and to take an anodyne draught when necessary. During the application of the instrument, the pressure exerted has been sufficient to diminish the pulsation and bruit in the tumour, and now, when the instrument is off, both pulsation and bruit are notably less.

29th.—The swelling and pain in the limb nearly gone. To resume the application of tourniquet.

August 1.—Since the 29th ult., the tourniquet has been applied seven or eight hours a-day, for an hour at a time; and, for the last two days, no pulsation has been perceptible while the instrument was on the limb, but it has returned on withdrawing the pressure. A bladder of ice ordered to be applied to the tumour, and the pressure to be continued.

2nd.—After the instrument was taken off last night, no pulsation or bruit was detected in the tumour, though a slight pulsation returned a few hours afterwards. There is no beat to be felt to-day, though the instrument has been off for some hours.

3rd.—No pulsation or bruit. Tumour getting more solid, but still rather soft and elastic. To leave off the pressure, and continue the ice. The latter is applied for about eight hours a-day.

6th.—No pulsation; more solidity. Continues the ice.

12th.—Tumour becomes gradually more solid; neuralgia and œdema of limb quite gone. To discontinue the ice.

31st.—General health much improved; has gained flesh since admission; sits up in the afternoon. Tumour diminishing in size; feels harder, and its oval form less definable. Limb of same appearance as opposite one. Posterior and anterior tibials of aneurismal limb can just be felt beating; those of sound limb beat rather feebly. The temperature of each limb is the same.

September 2.—Feels quite well, and has left the Hospital to-day cured.

Remarks.—In this case, the man's occupation as a sailor and waterman, where sudden and violent action of the heart, with pressure on the arterial system, takes place, and super-added to which was a deteriorated state of the tissues from syphilitic poison and mercury, gave ample cause for aneurismal disease. With regard to the treatment, the pressure exerted was sufficiently great, while the instrument was on, to

diminish the pulsation and bruit in the aneurism, but not such as to give any great amount of pain; and when neuralgia came on severely, the tourniquet was slightly slackened. The pad employed throughout was useful, inasmuch as it prevented the pressure from causing the slightest abrasion of the skin. The duration, from the commencement of the treatment to the permanent cessation of pulsation in the tumour, occupied a period of nineteen days. The instrument was adjusted for the first time on July 15, and left off permanently on August 2, during which time seven days elapsed without any pressure being applied: probably, the obstruction to the circulation in the limb which gave rise to the œdema, and which necessitated a suspension of the treatment, did not interrupt the progress of the case, but favoured the deposit of fibrin in the walls of the aneurism, for the pulsation and bruit did not, at any rate, increase by the compression being suspended for this interval. The only disadvantage that seemed to attend the treatment by compression was the increased neuralgia of the limb occasioned, but this was to a great extent alleviated by anodynes. The advantage gained was, that a speedy cure was effected without any of the risks which occasionally attend the application of the ligature.

In Mr. Whipple's last case of femoral aneurism treated by compression, the cure was effected in thirty days.

HOSPITAL NOTES.

DIGITALIS IN CARDIAC DISEASE.

As to the action of digitalis in cardiac disease there is a great diversity of opinion. In the *Medical Times and Gazette* of December 13, 1862, we published two cases in the practice of Dr. Handfield Jones, at St. Mary's Hospital, giving his experience of the action of the drug in cases of "dilatation and enfeeblement of the heart." He remarked that digitalis acts as a "cardiac tonic." Dr. Sutton, in order to test the value of this conclusion, has prescribed tincture of digitalis in several forms of heart disease occurring amongst the out-patients of the Metropolitan Free Hospital. The following are the results of his observations:—

1. In cases of mitral regurgitation, with dilated hypertrophy and enfeebled condition of the heart, digitalis gives great relief, as in the following case:—A woman, aged 38, was so weak that she was led into the out-patients' room. Her feet and ankles were œdematous. Her pulse was very feeble and quick, but regular, and the heart's visible impulse was diffused and indistinct, and the apex was felt over the seventh rib. The first sound was inaudible at the base, and the second was of a very high pitch. There was a faint systolic bruit at the apex. Her complaint was, in her own words, "I feel so very faint." Fifteen drops of the tincture of digitalis, with the like quantity of tincture of the sesquichloride of iron, was given in an ounce of water three times a-day. Four days later she walked into the room without help, and said she felt much better. The bruit was more audible. She continued to do well.

2. In a case of chronic pericarditis, with very great effusion into the bag of the pericardium. A man, aged 30, complained of shortness of breath and great faintness. He was unable to move in bed without feeling very faint; his lower extremities were œdematous; his pulse was very feeble and quick. The only sound of the heart that could be heard was the very faint, distant-like click of the second sound at the base. *R.* Tinct. digitalis, $\mathfrak{m}\text{xxv}$.; *eth. chlor.*, $\mathfrak{m}\text{xxv}$.; *tinct. ferri mur.*, $\mathfrak{m}\text{x}$.; *ter. die. s.* Five days afterwards he expressed himself relieved. Pulse regular and stronger; no perceptible difference in the extent of dulness on percussion. The urine was not increased. The digitalis was continued for six weeks. He recovered so far that he could walk about the house, but he had a relapse, and died four months later. A post-mortem confirmed the diagnosis.

3. In aortic regurgitant disease it requires to be given with great caution. In one case, while taking digitalis, the patient's pulse became irregular, increased in frequency, and he died, with well-marked symptoms of intra-cardiac blood concretion.

4. In heart disease, with dropsy, it exercises no well-marked influence over the secretion of the urine.

5. In one case of aortic obstruction, with simple hypertrophy, and a strong, heaving impulse, digitalis was given in fifteen-drop doses three times a-day for fourteen days, when the patient remarked, "I feel the action of my heart much more troublesome when I take the mixture."

6. That in a case of aortic regurgitant disease, complicated with angina pectoris, the patient having an atheromatous physiognomy, digitalis was given for fourteen days. No relief to the pain; pulse irregular.

7. Digitalis is very beneficial in cases of the following class:—Men of middle age, of the sanguine temperament, and of the neuro-vascular diathesis, as described by Professor Laycock; (a) complaining of dyspnoea on exertion; very weak; appetite normal; pulse rather quick, easily excited, and soft; heart's impulse seen in the epigastrium, feeble to the hand; first sound inaudible at the base; second sound, high pitch; at the apex, first sound faintly heard. In one such case there was albuminuria; in two, arcus senilis. All these cases improved quickly while taking tincture of digitalis and iron. That it was not the effects of the iron was proved by the fact that they all had improved after taking the mixture three or four days.

8. It may be given cautiously for six or eight weeks in fifteen-drop doses in cases of enfeebled heart with mitral disease, without producing any irregularity of the pulse, but the reverse in aortic disease.

It will be seen from the above conclusions, that Dr. Sutton confirms Dr. Handfield Jones' remarks, that the most suitable cases for the administration of digitalis are those of enfeebled heart; that digitalis "seems to be injurious in sthenic, and beneficial in asthenic cases." The same with respect to Dr. Corrigan's statement (to which Dr. Leared called the attention of the Profession), that in cases of aortic disease the effects of digitalis are injurious.

In a future number we shall report a series of cases from Dr. Sutton's practice, in further illustration of the above remarks.

We will now give the experience of another Hospital Physician, Dr. Wilks. Going round with him a few days ago, we saw at least a dozen cases of heart disease which had their origin in a former attack of rheumatism. When there was dropsy, the ordinary treatment was adopted; and when the heart was weak and irritable, iron and digitalis appeared to be Dr. Wilks' favourite combination. He said that, as no medicine could alter the changes which had occurred in the valves, the only remedies which can be of use are those which tend to preserve the power of the muscular tissue, and, therefore, the great benefit of iron in weak heart. As regarded digitalis, he had always acted on the principle, that this remedy is efficacious in proportion to the weakness and irritability of the organ, and hence the reason why some had called it a tonic. Owing, however, to the prostration produced by its long continuance, a very prevalent opinion existed that it was a remedy not available in a depressed state of the system; whereas the opposite is the fact when the heart is concerned, a reduced frequency of the pulse being a more correct test of the influence of the medicine on the circulation than the force of the arterial action. Dr. Wilks mentioned an instance where a patient was literally restored to life by its use. The case was that of a woman, who, having long suffered from disease of the heart, had a severe flooding after labour. She was apparently *in articulo mortis*; her limbs were cold; the body in a state of deathly clammy sweat; the face livid; no pulse to be felt at the wrist, and a mere fluttering to be heard when the ear was placed over the region of the heart. Brandy and ether had been given without any good effect, and, as dissolution was every moment expected, it was determined to try the effect of digitalis. Half-drachm doses of the tincture were given every hour, and after four doses a reaction had taken place, and after seven doses complete recovery had occurred. The heart, though irregular, was beating with a defined action, and the pulse could again be felt. From this time recovery took place.

It must be remembered, however, that, as Dr. Dickenson has shown, digitalis in large doses checks uterine hæmorrhage; but even if the improvement in Dr. Wilks' case were due to this, the principle is probably the same, that digitalis is a tonic, not to the heart alone, but to the (organic) muscular system generally. In Dr. Fuller's recent work on "Disease of the Chest" will be found some interesting remarks on the action of digitalis. He writes:—"It is a most valuable remedy when given in the treatment of dilatation, and is dangerous only in hypertrophy. Whenever the pulse is feeble and irregular, and more especially when, from any cause, its feebleness and irritability are temporarily increased, digitalis is, of all known remedies, the most useful."

(a) See *Medical Times and Gazette*, February 1 and 15, 1862, Lectures III. and IV.

The above views of Dr. Handfield Jones, Dr. Wilks, Dr. Sutton, and Dr. Fuller are not yet generally received by the Profession. The exact reverse is generally held—that digitalis is valuable in hypertrophy and dangerous in dilatation. One of our most distinguished authorities on diseases of the heart, Dr. Walshe, writes:—"If the power of the ventricles be seriously impaired, digitalis cannot be given without excessive risk, and had better be altogether avoided."

We require an extensive series of cases with careful observations as to the valves damaged, and as to the result, as regards regurgitation and obstruction (as aortic obstruction, for instance, is of infinitely less consequence than aortic regurgitation), but, more than all, as to the condition of the heart itself as regards hypertrophy, dilatation, and muscular power.

IBERIS AMARA, A NEW PURGATIVE.

We observed Dr. Wilks use a purgative which was new to us, the *Iberis amara*, or candy tuft-seed. He had been recommended to its use by Mr. Stillwell, of Epsom, who said that it had been a favourite purgative medicine with him during the whole of a long practice, given either alone or combined with jalap powder. The seeds when bruised are oily and acrid, and, when made into a pill of four or five grains, act as a good purge. Dr. Wilks said he had found it answer its intended purpose; but as there was no want of aperient medicines in the Pharmacopœia, he saw no reason to adopt it in preference to those in ordinary use. A strong Irishman took three grains with no effect, but ten grains purged him two or three times. A man who was habitually constipated, and who had been taking magnesia mixture daily with only slight effect, was ordered three grains three times a-day; he took five pills, and was purged violently several times. A lad with cardiac dropsy took five grains, and in a few hours it acted twice. In some cases it produced sickness. In the case of a man with renal dropsy ten grains were given. In two hours he was sick, and in seven hours he was well purged. It was repeated, but without the sickness. In all about twenty cases were treated, and its purgative action well tested.

THE CALABAR BEAN—ITS INTERNAL ADMINISTRATION.

The Calabar Bean, for the introduction of which into Medical practice we are indebted to Dr. Fraser and Dr. Robertson, is now much used as a local application to the eye. It is antagonistic to atropine, not only in its effects on the iris, but also on the ciliary muscle; and it is its power over the latter—its power of restoring accommodation when it has been lost by any cause—as, for instance, from paralysis, or from the previous use of atropine for ophthalmoscopic examination—which renders it so useful to ophthalmic Surgeons. It has now also found its way into our general Hospitals, as a remedy in certain nervous affections. There is a very interesting case of chorea, in a girl aged 11 years, now being treated in University College Hospital by this drug. Dr. Harley, under whose care the patient is, began by giving one grain of the powdered bean for a dose, which was gradually increased to three grains three times a-day—(nine grains in the twenty-four hours). It was then further increased to four and a-half grains for a dose; and latterly the patient has been actually taking six grains at one time, but in this case only once a-day. Careful notes have been kept by the Physician's assistant; and, as we purpose giving them in detail, we may at present merely mention that the patient has much improved under the treatment. The only disagreeable effects that have followed the use of this remedy have been the occasional occurrence of brief attacks of colic, and once or twice slight vomiting. At first the remedy caused contraction of the pupils, and greatly accelerated the heart's action. The pulse was often 144, and on a few occasions 160 per minute. These effects, however, gradually became less apparent, as the patient gained in strength, and the system got accustomed to the remedy. The powdered bean, as employed by Dr. Harley, forms an elegant preparation, and has the great advantage of being almost tasteless. The dose for an adult, Dr. Harley says, is from three to six grains.

SYRUPUS RHAMNI IN CONSTIPATION.

At one time buckthorn was much used as a cathartic, but it has lately been chiefly used as a purgative for dogs by Veterinary Surgeons. Dr. Neligan says that the operation of the juice of the berries is very severe, and that it is "frequently accompanied by severe tormina, thirst, and distressing nausea." But Dr. Handfield Jones says that he has used

it recently, and finds it an excellent purgative, and he states that it has none of the faults above mentioned in any marked degree. He gives, to adults, one or two drachms of the syrup, and a drachm of the potassio-tartrate of soda. This is, he thinks, quite as good a combination as black draught, and is not nasty; this is a great gain, as black draught is to most people a horrible mess. The syrup is the only official preparation, and the dose is stated by Neligan to be ʒss. to ʒj. The dose prescribed by Dr. Jones is much smaller, but he finds it quite effectual in obstinate constipation, especially in habitual constipation.

THE TERCHLORIDE OF CARBON.

Mr. Bryant informs us that at Guy's Hospital the terchloride of carbon has been employed for many years, and that it was a very favourite remedy of the late Mr. Aston Key, tracing its employment back, therefore, at least fifteen years. As a lotion, it has acquired considerable value, and may be looked upon as a stimulant, and in a measure as a disinfectant. In sloughing and fetid ulcers it is of great use. It may be used in the indolent and weak ulcer with general advantage. The usual strength of the lotion is from ʒxxx. to ʒss. of the drug to an ounce of water. It has an agreeable odour and rapid effect. In cases of gangrene, and in sloughing phagedena, it may be employed in its concentrated form with some confidence, a wound thus affected rapidly taking on a more healthy aspect. Upon the whole, it is a very valuable local stimulant, and in Mr. Bryant's estimation ranks above most of the drugs of that class now in use.

SATURDAY, JANUARY 16.

CONFIDENCE.

THIS is a phrase much more often in the mouth of patients and their friends than in that of Medical men. The very frequency of its iteration leads us sometimes into slight irritation on its occurrence. And yet there can be no doubt that it represents a real and important element in our Professional responsibilities; for without it, our art is shorn of half its power, and our very drugs seem treacherously to lose their force. Here, however, we do not intend to dilate upon the influence of mind on body, of imagination on structure and function, but to say a word or two such as may be supplemented by our reader's own experience and reflection.

Our standing as an aggregate and corporate body in public esteem and confidence must obviously control to a degree that of each single man. It is unnecessary to show that this varies with every day; rising on the news of some great discovery or some noble act of devotion, and falling again with the publication of some erroneous opinion, with some instance of dogmatic, unpractical theorising, or with the scandal of some damaging exposure before a legal tribunal.

But our duties being essentially personal, it is usually in a private and informal manner that we are canvassed; and hence the attribute of confidence, while it is withheld from one, is freely granted to another purely as a result of special circumstances and individual appreciation. Many elements go to form

the desirable result: mere age is with a large, though probably not the more intellectual portion of the community, of itself a ground of trust. Into this wide and delicate subject it would require time to enter. Medicine is undeniably an art which takes long to learn from its very magnitude; but familiarity is not necessarily experience, and modern diagnosis is not always to be fulfilled by the dimmed eye, the dull ear, and the trembling hand. Social respectability has a strong and legitimate influence, especially in this country, though, perhaps, it may be in some quarters exaggerated, and a kind of tyranny established which obliges its victims to live a life of shams, of expense, and of consequent worldly anxiety. But after these and a few similar postulates, much lies in our own hands; and for this reason it is well now and then to give a deliberate moment of thought to the subject, and by putting ourselves in the position of our own friends, relatives and patients, to neutralise the self-concentration which must needs follow earnest labour in one field of occupation. Each man may seek his own models. Not long ago we ourselves drew attention to the vast power and confidence attained by Father Mathew in a direction not alien from the Physician's function, and parallel cases will occur to every one.

Or, in a lighter mood, we may turn to the stage, and there behold ourselves *veluti in speculo*. The stage undoubtedly "holds the mirror up to nature" in the relations of Doctor and patient, as well as in other circumstances of life. It is true, and probably satisfactory, that Professional men do not act in the demonstrative melo-dramatic manner with which they are credited in fiction, any more than they are open to the gross sarcasms with which they were assailed by Molière. But it is instructive to see ourselves reflected, even in the sketchy and limited picture of a representative microcosm; and we may gain a hint in conduct from one who, like the dramatist, must needs approximate his fabrications to truth and probability. As a rule, we there figure in an honourable manner. Perhaps popular prejudice as to law and lawyers shares with the fitness of their business for sensational treatment, in producing the frequent scenes of villainy or violation of duty, brought about by their agency. The family Doctor may witness the will, and know its contents, but he can hardly have so active an interest in them as to falsify, conceal, or substitute; and among many contrivances for wronging legitimate heirs, a fraudulent accoucheur has not often been turned to account, though the scene from which he is inseparable has long figured to the ear, if not to the eye, in the drama of Terence, so dear to old Westminsters and their friends.

As a rule, the stage Doctor is upright, calm, shrewd, observant, and despotic; even kings tremble before him, and no one shares a tittle of his authority. He speaks in a judicial tone, proceeds to tremendous operative measures on the spot, and directs potent remedies with the accuracy of the Armstrong gun. His diagnosis is instant, his prognosis is so precise and far-seeing as slightly to discourage less-gifted brethren in the audience; but whatever happens, he usually comes well out of the affair. It is past denial that all the virtues here exhibited are just those which, in real life, gain confidence; and as they honourably ensure success, so they should be sedulously cultivated.

There is another aspect in which the same character has been represented by the greatest of dramatists, to us infinitely more touching and instructive. When Lady Macbeth comes on the stage asleep, but brooding over her crime; torn with remorse for an evil deed beyond remedy, the physician is powerless; and, making no attempt at display of useless learning, or at meddling interference, he calmly, but sadly, watches out the working of retribution. Little as he contributes to the action of the play, he seems to us a peculiarly fit audience for the dreadful spectacle of crime self-punished.

We hope it may be our lot to see on the stage few characters taken from among ourselves, and marked by vanity, self-interest, or charlatanism; still less do we desire to meet

with such hindrances to confidence in ordinary life. Many of the rubs which gall men in practice may really be due to these and like causes. On the other hand, how could his influence, and the confidence reposed in him, fail to be increased, who should justify the trust by a spirit like that of old Ambrose Paré? This great Surgeon, when his friends congratulated him on a cure, answered—"Je le pansai; Dieu le guérit."

RAILWAY SURGEONS.

A TRIAL has lately been compromised, to the deep regret of the lawyers. It would have afforded them materials for many an argument on the rights of "infants," and plenty of fun withal. A Medical man would have been put into the witness-box, and his cross-examination would have been a treat. Do you ask why? Was it a case of unset fracture or of unreduced dislocation? Was it about some poor woman who had died after delivery of some disease sworn to have followed upon something which the accoucheur either did or did not? Was it that a widow, who loved to drown grief and travelling gout in brandy, had been hindered from throwing herself out of window? or that a half-mad tradesman had been restrained from beating his wife? No! there was luckily no question of Medical theory or practice at stake: the fun would have been got, and the odium affixed, through transactions out of and beyond the duty of the Medical man, which we would entreat our brethren to leave alone for the future.

As we are concerned only with principles, we need not give names or dates, and may tell the story thus:—After a certain notorious railway smash, the company, as usual, employed their own Surgeon to attend the sufferers. (We may say, by-the-by, as a bit of Professional etiquette, that no sufferer ought to be debarred the services of any other Medical man whom he chooses to see;—certainly, the railway Surgeon should see the case on behalf of the company, but his functions need go no further, unless the patient choose; otherwise, he would have undue advantages over his brethren.) One sufferer there was, a girl of eighteen, who seemed not to have sustained any serious hurt, and (so the story is told us), at the end of a fortnight or three weeks, the Surgeon employed by the railway company said to her father, "Well, now the patient is so nearly well, suppose we settle." Whereupon, a calculation was made: a silk dress was valued at so much, a bonnet and parasol, and other articles of feminine attire, at so much more, and a certain sum added for the bodily injury. It amounted to £25, which was paid on the spot; and (as we are told) a most elaborate receipt was drawn up by the Surgeon and signed by the father, acknowledging the receipt of the money of and from the railway company in full of all demands from himself his heirs executors administrators and assigns to all eternity. So the thing seemed to be settled. But the poor girl after a few weeks became more ill, and signs of inward mischief began to show themselves. In fact, two eminent Professors of Medicine have pronounced her to be labouring under aneurism of the aorta, and she, who once was a lively, active girl, who could swim twice round a large swimming-bath, is now condemned to a life of inaction, with the fear or almost certainty of early death. The father, finding the real state of the case, began to think that he had been somewhat hasty in his settlement with the railway company; so he applied to an attorney, who was not in the least dismayed by the elaborate receipt in full which had been procured by the Surgeon, but fired off a writ, and brought an action for damages £2000, and, when the case was ready for trial, accepted £700 with costs, which the company were glad to pay by way of compromise.

Now, we have not a word to say against the Surgeon, so far as he acted surgically. Not only no question was raised of his Surgical conduct, but it is admitted that he acted as a man of skill and humanity in his Profession. Doubtless, also, whilst

eager to settle the case on behalf of his clients, the company, he was not conscious of anything unfair to the girl or her father, nor ought he to be accused of it. The injury was slight, and £25 would probably have appeared sufficient to any one at the time. Still, we hold that a Surgeon ought, for the sake of his own Profession, when employed surgically, to keep out of transactions which belong to the attorney or agent. If he meddle with them, he is sure to commit himself, and our entire fraternity with him. Medical witnesses seldom do us credit, even when speaking on Medical matters; we shiver at Medical trials; but what will become of us if railway Surgeons are to get themselves, and drag us, into false positions like this?

Suppose the case had gone to trial, and that the company had set up the receipt in full, procured by the Surgeon, and on this ground had resisted any further claim? What lawyers say is this: the case would have been pre-eminently a sensation case. A sensation sergeant (since gone to a better place) is said to have been retained. With a cambric handkerchief to wipe the forensic tears from his eyes, and with a voice faltering with emotion, how he would have pointed to the plaintiff—said to be a remarkably pretty girl, who of course would be sitting, in half-mourning, in court with her pretty sisters—how he would have described her young life nipped in the bud,—her girlish aspirations blighted,—the seeds of the fell destroyer planted in her palpitating bosom, and all her affectionate family watching her every movement with breathless excitement, awaiting the moment when her fragile structure should give way, and a sudden, horrible fate carry her almost alive into the tomb! And, the learned sergeant might continue, whence came the mean and insulting proposition to barter the life of this exquisite creature for £25? Can it be that a member of an honourable, a learned, a humane Profession can have so far forgotten himself as to frame, with cold and selfish fingers, this miserable receipt in full, and that, after gaining the confidence of this afflicted family by a specious performance of the duties of his benevolent Profession, he, *concealing the worst and hidden injury*, could extort a signature to such a document from the unsuspecting and unhappy father? We will not stop to speculate what effect such venomous eloquence might have had on a British jury, nor what amount of obloquy might have been affixed on the Surgeon. We only hear that the plaintiff's attorney, in looking back on the case, thinks the company got off too cheaply; whilst we feel more strongly than ever the expediency of keeping members of our Profession out of money transactions, which are no business of theirs, and which are sure, some day, to get them into false positions, and taint them with the most odious and undeserved imputations.

THE WEEK.

CONFINEMENT OF H.R.H. THE PRINCESS OF WALES.—BIRTH OF A PRINCE.

OF course, we must not, even to gratify the loyal curiosity of our readers, trespass on the sanctity of that privacy to which such events are entitled in any station of life. Yet we may be allowed to mention the following particulars, which may be relied on as authentic.

Her Royal Highness's confinement was expected to take place early in March, and every arrangement had been made for its taking place in London.

Two or three days before the event the Princess had suffered from a slight cold, for which she was attended by Mr. Brown, of Windsor.

Early in the afternoon of the 8th she was slightly indisposed, but the signs of approaching labour were not then evident. As soon, however, as Her Royal Highness became more indisposed, Mr. Brown, of Windsor, was sent for, and Dr. Sieveking, the Prince's Physician, from London. Soon afterwards, it being then evident that the symptoms indicated an approach-

ing confinement, a telegram was dispatched to Dr. Arthur Farre, who immediately started by a special train for Frogmore. So rapid, however, had been the labour, that on his arrival the infant was already born.

The confinement, though so speedy, was of the most favourable description, and both mother and child have been going on without a shade of illness or discomfort.

The statement, in the newspapers, that the baby, although a seven months' child, weighs nine pounds, our readers will take for what it is worth. For the information of any of the gentler sex who may honour our columns, we may add, that the baby is pretty, and like its father, *and has never yet been weighed*.

The size corresponds very accurately with the calculation made by the Princess's Physicians as to the period of gestation.

Sir C. Locock and Dr. Gream were also summoned. The first bulletin was signed by Dr. Sieveking and Mr. Brown; the subsequent ones by Dr. Arthur Farre.

Were politics within the scope of this Journal, we might find enough matter for rejoicing in a comparison between existing circumstances and those under which the children of the two last Princes of Wales of the Hanoverian line have been ushered into the world. But we will content ourselves with the reflection that, although history furnishes numerous examples of royal personages cradled in the ease and luxury of a court, surrounded with all that can procure happiness or excite admiration, belying early promise, and living lives which end in premature physical and mental decay, no such fate is to be feared for the Prince of Wales. The deplorable loss which his family and the nation sustained so lately has devolved on him such duties and obligations—the care and support of the Sovereign—the promotion of all those great objects of public good which his father had at heart—and the responsibilities and happiness of an early marriage of affection—that there is little fear that the long life which he is, we hope, destined to spend in the second place in this great Empire, will be passed in ignoble sloth, or sacrificed to enervating or trifling pursuits. The Prince and Princess have already won golden opinions from all. In them the nation sees the representatives of the virtues and good sense of Victoria and Albert, and it hails the birth of their son as a pledge vouchsafed by Heaven, that its blessings descend to the third and fourth generation. In the present aspect of political affairs, it is, perhaps, too much to hope that the birth of the infant now cradled at Frogmore, representing, as he does by blood and lineage, the two contending European interests on whom all eyes are turned, may be received abroad as a signal for peaceful counsels and mutual concessions. But, at least, we may congratulate ourselves, that in our own nation, in our Royal Family, in our people, in our institutions, the two ethnic elements—the Norse and the Teuton—which have played the first part in modern history, which have eclipsed all others in government, in arts, in sciences, are indissolubly united, and can never be opposed. To us belongs the Norman, from whom the ruling classes, not only of England, but of nearly the whole of Europe, are derived. Ours, also, is the Saxon, whose race appears destined to repeople and to regenerate the world. This last born of our princes is, by lineage as well as by birth, a true representative of the English people!

THE NEW PRESIDENT OF THE COUNCIL.

PURSUANT to notice, the General Medical Council assembled at the Registration-office, Soho-square, on the 13th inst., for the election of a president in the room of the late much-lamented Mr. Green. Dr. Stokes, on the unanimous request of the members present, took the chair. The newly-appointed members—Dr. Parkes, Dr. Quain, and Mr. Romsey, nominated by the Queen in Council, and Dr. Paget, representing the University of Cambridge—were introduced, and took their seats. A vote of sympathy and condolence with the family of the late President was adopted. A lengthened discussion

took place as to whether it was desirable or not to elect as president some distinguished non-Medical gentleman who had taken a greater or less interest in Medical politics, and whose rank and position in relation to Government might promote the objects of the Council in connexion with legislation, etc.; and, secondly, as to whether it was necessary that the president should be resident in London. We learn that the conclusions of the Council amounted to this, that, if it were desirable to select a non-Medical president, this was not at the present moment practicable; and secondly, that, if it were practicable to elect a non-resident Medical president, it was not desirable in connection with the business details of the Council. Dr. Burrows was then nominated, and, as we anticipated last week, was elected President for the usual period. Of Dr. Burrows' election we can but say that it will please all who wished for the best possible man. The election of Dr. Burrows will require the College of Physicians to send a representative to the Council. Several names have been already mentioned. The office of joint treasurer to the Council (with Dr. Sharpey), also vacated by Dr. Burrows' election as President, was filled up by the appointment of Dr. Quain. The Council, having reappointed the Executive Committee, adjourned until April.

ELECTION OF EXAMINER TO THE ROYAL COLLEGE OF SURGEONS.

WE learn that a special meeting of the Council of the College of Surgeons is to be holden, on Monday, the 25th inst., to elect a successor to the late Mr. Green in the Court of Examiners of the College. As we have already stated, there are said to be three parties, each with a favourite candidate. No. 1 supports Mr. Gulliver, the senior candidate; No. 2, asserting that no one save a London Hospital Surgeon is worthy of the post, proposes Professor Partridge; No. 3 also affirms the necessity of electing a London Hospital Surgeon, but proposes to run Mr. Hilton, of Guy's Hospital, against Mr. Partridge.

Now, we need scarcely say that we have not one word to allege against the competency of either of the two latter gentlemen. Mr. Partridge's admirable method of teaching anatomy, and his long experience as a Professor, and Mr. Hilton's sterling common sense and practical knowledge of Surgery, as shown by his unique and valuable lectures on Rest and Pain, stamp each of these gentlemen, in his turn, with the seal of Professional approbation. But, in the present instance, to elect either of them would be a gross injustice to Mr. Gulliver, the senior candidate, and a heavy blow at the best interests of our Profession in its tenderest point. Mr. Gulliver has earned a world-wide reputation not only as a physiologist, but as an original thinker and worker at the history, the facts, and the philosophy of physiology. His lectures show John Hunter in by far a truer light than did those of his predecessors. Without dimming his great reputation, he vindicated the merits of others whose labours were not less meritorious, so far as they went, though they have attracted less Professional idolatry. If Mr. Gulliver be not elected, it will be a sign which the rising generation will not be slow to interpret. It will say to them,—“Do not waste your time on science; do not spend your days and nights in researches which ennoble us as philosophers, and which will have their fruits in improved practice for generations to come: but play a close game; win tricks when you can; get a snug Hospital appointment; seek practice and money, and let science go to the winds.” Mr. Gulliver, besides, has not lived the life of a hermit or closet philosopher,—he has been an Army Surgeon in most parts of the world, and has been for many years in Surgical charge of the General Hospital at Fort Pitt. We are sure that the friends of the junior candidates would decline to assert that Surgery cannot flourish out of London, nor yet deny that it is highly desirable to have in the Court of Examiners representatives of every branch of science and practice. Students ought to be tested by the ablest phy-

siologists, the most dexterous anatomists, the most brilliant operators, and by the most shrewd and successful practitioner in maladies that require *unbloody* treatment only; more especially is it right that one who is versed in all the modifications of Surgery requisite for military practice should have a share in the examination. To pass over Mr. Gulliver will be a contumely to the whole body of Surgeons and physiologists who do not live in London, and will add a last bit of degradation to the Army Medical Department.

ST. BARTHOLOMEW'S HOSPITAL.

THE Governors of St. Bartholomew's Hospital have, at their last court, elected Dr. Burrows, Honorary Consulting-Physician, in recognition of his thirty years' service as Physician and Assistant-Physician to the Hospital. This election is the more complimentary, inasmuch as no previous Physician on his retirement has had such a gratifying mark of approbation conferred upon him.

THE RESPIRE OF TOWNLEY.

THE letter of Sir George Grey to the protesting magistrates of the county of Derby will have been so generally read that we need not reproduce it. It clearly shows that, however justly the Home Secretary's antecedents had laid him open to the suspicion of having abused, or at least weakly consented to exercise, the Royal prerogative of mercy, in this instance at any rate he had no alternative but to carry out an existing statute. That there should be an Act of Parliament which places the power of setting aside the verdict of a jury in the hands of any two justices of the peace and any two Medical men, constituting them a secret tribunal whose authority overrides that of the Law and the Crown, has excited as much indignation as surprise; but, as such an Act does exist, Sir George Grey had only a formal and executive voice in the matter; and, however the certificate of Townley's insanity may have been obtained, being obtained, he was legally and of necessity respited.

The bright spot in the letter is the information, that a poor and undefended prisoner, convicted of wilful murder and sentenced to death in 1862, obtained the benefit of the same Act at the instance of the judge who tried him.

We think, however, that it will cause no little astonishment and animadversion that, since the existence of this most preposterous enactment was known to Her Majesty's advisers in 1862, no attempt was made to amend it during the last session of Parliament.

GOVERNMENT TREATMENT OF THE MEDICAL OFFICERS OF THE BOMBAY MARINE.

ASSERTION of personal claims to position and social precedence is always a disagreeable thing; and most men would rather waive their right to a trifling distinction, than condescend to demand it from persons who concede it with reluctance. But there are cases when the assertion of social right, even in trifles, becomes a duty; and in such a category must be placed the instance of a man who, in a public position, represents a Profession, and whose social rank and status are adjudged to him solely on Professional, and not on personal, grounds. In such a case it becomes his duty to see that the dignity of his calling suffers no dishonour in his person, and at whatever sacrifice of personal considerations to maintain his claim on those punctilios of respect which he might willingly forego were his own honour alone concerned. The representatives of Medicine in the public services have no alternative but to be guided by this rule, and they would be wanting in loyalty to their calling did they tamely put up with affronts and indignities offered to them as Medical officers, which personally they could well afford to despise. Our attention has lately been called to a correspondence between the uncovenanted Surgeons of the Bombay Medical Service serving on board vessels of the Bombay Marine and the Government authorities, which we think tells very much:

to the honour of the former, and very much to the disgrace of the latter. It is first to be observed, that the vessels of the Bombay Marine are to all intents and purposes Government passenger vessels, and that their officers are not military or naval officers in the ordinary sense of the latter term, but simply civilians. It is the duty of the Medical officers of these ships to render Professional services to the passengers, and it is impossible that a proper relation can subsist between them if the patient find his Medical attendant systematically placed in an inferior position, and denied the right of social intercourse with him on a footing of perfect equality. The correspondence referred to commences with a memorial to Sir Bartle Frere, the Governor of Bombay, signed by three of the uncovenanted Surgeons of the Bombay Marine. The memorial shows that on board the ships of this service there are two messes, in the first of which the commander of the ship and the passengers are associated, and in the second the inferior officers, and it is to the second that the Medical officers have been informed they belong. We have not space to state categorically the reasons which the memorialists urge against this piece of petty insult. It is sufficient to say that the memorialists show, that in the packets of the Indian navy, in the army, and in various other services, no such degradation is put upon the Profession of Medicine, and that the class of inferior officers who assemble at the second mess is not such as would allow the Medical officer to introduce his friends to their society. As the vessels of the Bombay Marine are constantly employed in carrying military officers, there is frequently the anomaly of the army Surgeon dining at the commander's table, whilst the Surgeon of the ship is degraded to the second. The remainder of the correspondence, which we publish *in extenso*, will put our readers in possession of the fate of the memorial and of the subsequent conduct of the Medical officers. The latter will command the full approval of the Profession, who will know how to appreciate the choice made by these gentlemen between emolument and the honour of their calling. We only regret that it is deemed inexpedient that the names of these gentlemen should be at present made public.

“Messing.

“Surgeons, Bombay Marine.

“Marine Department,
No. 1111.

“Bombay Castle,
21st October, 1863.

“Letter from the Superintendent of Marine, No. 286, dated 8th September, 1863, submits a memorial from the Surgeons of the Bombay Marine, praying that they may be allowed to mess with commanders on board. Captain Young considers that, for the maintenance of discipline, the commanders should live apart from the rest of their officers.

“Resolution.—Although his Excellency in Council does not fully share Captain Young's objection, yet he thinks it best to leave the matter to be decided according to the judgment of the Superintendent of Marine.

(Signed) “W. F. MARRIOTT,
Lieutenant-Colonel, Secretary to Government.

“To the Superintendent of Marine.”

“Memo., “Superintendent's Office, Bombay,
No. 1935 of 1863. 22nd October, 1863.

“Forwarded to the commanders of the steam-vessels *Zenobia*, *Coromandel*, and *Berenice*, for communication to the Surgeons of their respective vessels, with reference to their memorial, dated 1st September last.

(Signed) “J. W. YOUNG,
Superintendent of Marine.”

“From Uncovenanted Surgeons, &c., &c.,

“To Lieutenant-Colonel W. F. Marriott, Secretary to Government.

“Bombay, 24th October, 1863.

“Sir,—We have the honour to request the favour of your bringing to the notice of Government, in connection with its Resolution No. 1111 of 1863 in the Marine Department, dated 21st October, 1863, signed by you, which was communicated to us yesterday by order of Captain Young, C.B., late I.N., Superintendent of Marine, an unintentional error in the wording of the preamble to that resolution, which causes us to appear to have put a slight on the Medical Profession. The

words to which we refer are these:—‘Memorial from the Surgeons of the Bombay Marine, praying that they may be allowed to mess with commanders on board.’ The object of the memorial referred to was, not to pray that we might be allowed to mess with the commanders, but to state our belief in the right of members of the Medical Profession, as such, to perfect equality in all social relations with the commanders, which relations are as prominent as any other in a civil service, and to pray his Excellency the Governor in Council to order that right to be acknowledged and conceded.

“2. Did this matter affect us only personally, the deep sense we have of our own unworthiness would deter us from taking any notice of it; but as it refers to us in our professional and official capacity, we feel bound, by regard for the honour of our Profession, to call attention to it. When we are soliciting a favour from Government we trust we show, and shall always show, the humility which becomes us; but we feel that any exhibition of false humility, when speaking of our Profession, for which we will not accept a secondary position, would deserve to be treated with contempt, as an evidence of pusillanimity. “We have, &c.

(Signed) “———, ——, &c., &c.”

“From Uncovenanted Surgeon ——, Bombay
Medical Service, &c., &c.,

“To Captain J. W. Young, C.B., late Indian Navy,
Superintendent of Marine.

“Bombay Marine Steamer *Zenobia*, 23rd October, 1863.

“Sir,—I deeply regret that the decision of the Government of Bombay, as conveyed in Resolution No. 1111 of 1863 in the Marine Department, under date October 21, 1863, with reference to the memorial presented by the Medical Officers of the Bombay Marine on the subject of their position in that service, leaves me no alternative, consistent with the honour of my profession, but to request the favour of being relieved from further service in that department.

“2. In that memorial, the view taken by the Medical officers serving in the Bombay Marine of the subject in question is so fully detailed, that I need not do more than state, that the reasons assigned in paras. 8, 9, 11, 12, and 14 of that document are those which chiefly influence, and, indeed, compel me to take the present step, which, under other circumstances, I should be most unwilling to do at present.

“3. It will hardly be considered out of place for me to reiterate what is already implied in the memorial, that I consider that were I, as a member of the Medical Profession, to permit myself to be consigned, in a civil service, to a position inferior to that of any of my equals, but more especially of my patients, I should be allowing that honourable Profession to be degraded in my person.

“4. As this is my only reason for asking to be relieved from the Bombay Marine, and as I believe such an one to exist in that department only of all the departments under the Bombay Government, I am perfectly ready to accept thankfully an appointment in any other department to which an uncovenanted Surgeon of the Bombay Medical service is eligible.

“5. Since, under existing circumstances, my position in the Bombay Marine is anomalous and peculiarly disagreeable, it will probably not be considered an unreasonable request that as early an answer as possible may be made to this application.

“6. May I solicit the favour of this letter being submitted *verbatim* to Government? “I have, &c.

(Signed) “———, &c., &c.”

“Squadron Order, No. 518.

“Office of the Superintendent of Marine,
Bombay, 7th November, 1863.

“Surgeons ——, of the *Zenobia*, and ——, of the *Coromandel*, having been permitted to resign the service, are to be discharged to the shore from this date.

(Signed) “J. W. YOUNG,
Superintendent of Marine.”

FROM ABROAD—REVACCINATION IN THE PRUSSIAN ARMY IN 1862—PROFESSOR VIRCHOW'S EDITORIAL DIFFICULTIES—THE ACADEMIE DE MÉDECINE—RETIREMENT OF M. RAYER.

The Prussian Government has published its report on the results of revaccination in the army during 1862. From this it appears that 19,545 individuals were vaccinated or revaccinated during the year. Of these, 16,669 exhibited distinct cicatrices from former vaccinations, 1852 indistinct traces, and 1024 no traces at all. The present vaccination pursued a

regular course in 12,272 of the 19,669 soldiers vaccinated, and an irregular course in 2738, while in 4534 it was followed by no results. On these last being again vaccinated, success attended it in 1324. Among all the soldiers of the Prussian army on whom revaccination had been successfully performed, either during or before 1862, 4 became the subjects of varicella, 10 of varioloid, and 1 of true variola. Besides these 15 cases, there occurred also 2 cases of varicella and 3 of varioloid among soldiers who had not been revaccinated, and the same number in others who had been revaccinated without result, making altogether 25 cases, viz., 8 of varicella, 16 of varioloid, and 1 of variola. The case of variola occurred in an artilleryman, aged 57, and proved fatal, being the only example which has been met with in the Prussian army of fatal variola after successful revaccination.

In the last number of his *Archiv*. Professor Virchow pours forth some editorial groans, with which all those engaged in the conduct of periodical publications cannot but sympathise. The number and the extent of the contributions sent to his journal are, he says, ever on the increase, and, notwithstanding that its size has been augmented for their reception, room cannot be found. Manuscripts delivered a year since have not yet found their way to the printer's hands, notwithstanding that the editor has postponed his own contributions in their favour. To enlarge the journal still further would be to put it beyond the purse of many of its present subscribers, and the remedy for the evil complained of must be sought at the hands of the contributors themselves. The necessity is, therefore, urged upon them of compressing their articles as much as possible, by the omission of all details that can be dispensed with. This, says the Professor, is a more reasonable request than it would have been some years since. Then, it seemed indispensable, that as many cases and experiments should be furnished as possible, as the only means of proving that a satisfactory method of observation and investigation was being pursued; but, at the present day, when the better methods of the new school have become firmly established and widely spread, it is, in the face of the colossal accumulations of material which take place, of pressing necessity that a more compressed form of exposition should be adopted. Not content with this complimentary reason for brevity, the editor threatens the authors of lengthy contributions with the priority of their more concise competitors; while, if their communications go beyond what many may think the excessive length of three sheets, these must take their chance of delay, piecemeal production, or even exclusion. Professor Virchow has done a good deal in the reform way as regards Medical doctrines, and is trying his hand in political life; but we venture to think, that if he can succeed in bringing the above injunctions into fashion, many a perplexed editor and wearied reader will regard this as one of his principal claims to admiration.

M. Grisolle, the new President of the Academy of Medicine, opened the new session of this body with some observations which apply to learned societies and academies in general:

"Continually inspired," he says, "by that idea of progress which created scientific academies, you always give to rigorous observation and the experimental method, the philosophy of facts (to employ the happy expression of Fontanelle), that pre-eminence which has for ever rendered impossible the return of the scholastic system and sterile discussions, and has imparted to contemporary science that progressive course which it has uninterruptedly pursued since Bichat, and which no effort can in future even slacken. Assured may we be of the future when we see around us that vigorous and valiant band of labourers animated by one common ardour, and penetrated by the same desire—the necessity, if anything durable is to be established, of maintaining the rigorous observation of facts as the base of reasoning. This Academy has well understood her mission, which, indeed, is that of all learned bodies. Their function, it has been well said, is not to make discoveries, but to recognise and consecrate them, and to sometimes avert and direct the spirit of innovation, in order to preserve it from its vagaries, and thus redouble its energies by hindering its wan-

dering and preventing those violent shocks and sudden invasions of systems, which, if not always useless, it must be admitted, most frequently, nevertheless, retard regular progress by the ruins which they accumulate around them. Besides this great guardianship which you exercise, you also powerfully aid in the advancement of science by the distinctions you confer, and the number of which you are endeavouring to increase, penetrated as you are by that idea of Cuvier, that nothing is so suited to the multiplication of labours as the public marks of esteem which they receive."

At this meeting of the Academy, Professor Stromeier, of Hanover, was elected a Foreign Associate, his competitors being Professor Porta, of Pavia, and Professor Chelius, of Heidelberg. The discussion on the Origin of the Vaccine Virus was also resumed, in an able discourse, by M. Guerin, in refutation of the paradoxical statements made by M. Depaul, who, it will be recollected (*Medical Times and Gazette*, Dec. 12, p. 620), led away by the similarity of variola as observed in the horse and man, and its communicability to the cow, came to the conclusion, that it and vaccinia being the same disease, the vaccine virus, as a separate entity, really has no existence, and that variolous inoculation is a justifiable procedure. M. Guerin exposes the fallacies of such views, and arrives at these conclusions—1. The various affections (of the horse), considered up to the present time as capable of engendering the cow-pox, may be all resolved into one and the same disease, variola, which, transmitted from the horse to the cow, and from the cow to man, constitutes the true cow-pox—the vaccine virus. 2. That although the vaccine virus emanates originally from the variola of the horse, and preserves something of its origin, it acquires, by its passage through the cow and its installation in man, elements of a different nature and new properties, which prevent its being longer considered as identical with the variolous virus. 3. That inoculation of variola ought not, and cannot on any ground, or under any pretext, be substituted for vaccination, which remains endowed with all its properties as a preservative from variola.

M. Rayer, unable longer to withstand the unmitigated opposition which he has met with on the part of the students and some of his colleagues, has just resigned the post of Dean of the Faculty of Medicine. The arbitrary manner in which his appointment was made was the chief cause of the opposition it met with; for the late Dean seems to have administered his high office with very enlightened views, and to have introduced notable improvements into the courses of teaching and the facilities for the acquisition of knowledge. However this may be, M. Rayer's fame is European, based upon the approved labours of half a century; and we are glad to find it recognised by his elevation to the rank of Grand Officer of the Legion of Honour—the highest degree of this honour ever accorded to a Medical man.

MEDICAL OFFICER OF HEALTH FOR BIRKENHEAD.—At the last monthly meeting of the Birkenhead Commissioners, it was resolved to appoint a Medical officer of health—a situation which was rendered necessary in consequence of the rapid increase of population in the township. The matter was left in the hands of the Health Committee, and, after carefully considering the testimonials of forty applicants, they decided upon recommending the appointment of Dr. Baylis, who was a commissioner for several years, but who has for a year or two resided in Douglas, Isle of Man. The recommendation was confirmed by the board at their meeting on January 6. Whilst a commissioner, Dr. Baylis took great interest in the sanitary condition of Birkenhead, and the township is indebted to him for many improvements. The salary is £250 per annum.

EFFECTS OF EATING MEASLY PORK AND SAUSAGES IN PRUSSIA.—If all the accounts which reach us be correct, there is an alarming prevalence of trichina disease in Prussia, in consequence of eating raw or badly cooked bacon and sausages. The last we have seen is from Hettstädt, in the Government of Marseburg, which states that after a feast, at which fresh sausages formed a prominent dish, ninety persons became affected with trichina, of whom twenty soon died. The local governments of Cologne and Erfurt have issued proclamations on the subject, calling attention to the danger of eating this description of food.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF NORWICH.

(Continued from page 43.)

SURGICAL MORTALITY OF THE NORFOLK AND NORWICH HOSPITAL.

In my last communication I dwelt on the operations for stone, and on the probable reasons for the low mortality by which that operation has been signalised in the Norwich Hospital. From this special point I propose to glance briefly at the mortality of the Surgical practice altogether. No test of the salubrity of any Hospital approaches that rendered by the results of the Surgical practice. The Medical cases cannot easily be calculated upon; they may yield a very high or a very low mortality in different years, because the diseases may vary greatly in kind and intensity; but when a series of deaths occur in a given time, within one building, upon Surgical practice, and especially upon operative practice, we may predicate almost with absolute certainty as to the condition of the Hospital. Unfortunately, the records of the Norwich Hospital do not supply us with accurate information respecting deaths after operation for longer than three years; but I have before me the whole mortality of the institution per year for seven years, viz., from 1856 to 1862, both years inclusive; and from these details I am enabled to calculate the percentage of deaths from all causes, and also the percentage on the Surgical side as a whole for these seven years. To this I am prepared to add the percentage *after operation* for three years, viz., for 1860, '61, and '62.

Mortality for the Year 1856.

Total of cases in Hospital	870
Total of deaths per cent.	5.51
Total of deaths per cent. on Surgical side	3.98

Number of operations—Capital, 102; minor, 23: total, 125.

In the course of this year there were eleven deaths from burns and scalds, and four deaths from fractures of the thorax,—cases which were brought to the Hospital, we may say, to die.

Mortality for the Year 1857.

Total of cases in Hospital	885
Total of deaths per cent.	4.63
Total of deaths per cent. on Surgical side	3.16
Number of operations—Capital, 81; minor, 12: total, 93.	

Mortality for the Year 1858.

Total of cases in Hospital	910
Total of deaths per cent.	4.83
Total of deaths per cent. on Surgical side	2.52
Number of operations—Capital, 135; minor, 12: total, 147.	

Mortality for the Year 1859.

Total of cases in Hospital	1007
Total of deaths per cent.	3.77
Total of deaths per cent. on Surgical side	2.28
Number of operations—Capital, 122; minor, 27: total, 149.	

Mortality for the Year 1860.

Total of cases in the year	930
Total of deaths per cent.	5.59
Total of deaths per cent. on Surgical side	3.01
Number of operations—Capital, 155; minor, 44: total, 199.	
Deaths per cent. after operations, 4.02.	

Mortality for the Year 1861.

Total of cases in the year	1011
Total of deaths per cent.	4.64
Total of deaths per cent. on Surgical side	2.86
Number of operations—Capital, 198; minor, 85: total, 283.	
Mortality per cent. after operations, 6.00.	

In this year (1861), while the number of operations performed in the Hospital increased to 283, the mortality after operations rose to 6.00 per cent. The whole Surgical practice, however, showed only a mortality of 2.86 per cent., so that there must, obviously, have been special causes at work to produce so high a rate of mortality after operation. At first sight, the greater number of operations performed might seem to account for the results; but on turning to the table of cases, we trace the increase to *one* operation alone—I mean the median operation for stone. That operation added 2.12 per cent. to the mortality after operations.

Mortality for the Year 1862.

Total of cases in the year	1040
Total of deaths per cent.	5.09
Total of deaths per cent. on Surgical side	2.50

Number of operations—Capital, 171; minor, 138: total, 309.

Mortality per cent. after operations, 3.55; or 1 in 28.09 patients.

We gather from these details that the total mortality in the Norwich Hospital for the past seven years, at least, has been remarkably low, being not more than 4.85 per cent.; while the mortality of the Surgical practice has been .01 under 3 per cent. This mortality, which is a little below the average—the mean for ninety years being 5.52 per cent. per annum—might compare with that of many towns and villages where the people are supposed to be in health and in work, instead of suffering from the most painful and fatal maladies, as in Hospital. The key to this success is to be found in the fact, that two of the most mortal maladies after operations are scarcely known in the Hospital. Looking over the list of deaths for the seven years, the word *pyemia* occurs but once, and *crispelas* not once. Five times in the seven years tetanus has appeared, every case proving fatal; and hernia seems to me to rank high as a cause of death, the proportion being, in the seven years, nearly 25 per cent.; but the cause of this high mortality from hernia arises from the circumstance, that the patients are too frequently brought under the operator long after the first symptoms of strangulation have set in.

I may add, while treating on operations for hernia, that it is the custom with the Norwich Surgeons to open the hernial sac. Whether this adds to the mortality or not can only be settled by reference to the statistics of other country Hospitals, where a different method prevails. I shall call attention, in the future, to this point of inquiry.

DAYS OF OPERATION, AND OPERATIONS.

Friday is the operating day at the Norwich Hospital. The theatre is large, and excellently lighted from above, and the gallery for lookers-on is well arranged. I was so fortunate as to be present on a Friday, when four capital operations were performed—viz., two median operations for stone, and one amputation of the thigh, by Mr. Cadge; and an amputation of the thigh by Mr. Firth. The style of operating by both these gentlemen—the precision, the dexterity—were simply perfect. There was no hurry, no attempt at brilliancy, but a practical mastery, which I have nowhere seen surpassed. The operators were most efficiently seconded by the Assistant-Surgeon, Mr. Crosse.

Mr. Cadge, as I have said, performed two median operations: in the first, the stone being small, extraction was very easy and rapid; in the second, after the stone was grasped, it was extracted with considerable difficulty, for it was very large.

There is a point of practice followed by Mr. Cadge in these and in all lithotomy operations, which is new, and which, in the hands of a skilful operator, probably possesses its advantages. Mr. Cadge invariably has the staff withdrawn so soon as he cuts into the bladder, never using the staff as the guide for his finger. He tells me, that even in children he has no difficulty whatever in passing his finger into the bladder, after the withdrawal of the staff.

CHLOROFORM AND ITS ADMINISTRATION.

Chloroform at the Norwich Hospital is entrusted to one responsible administrator, viz., the House-Surgeon. In some cases one of the Physicians also takes part in watching the symptoms produced. The mode of administration is of the most simple kind. A piece of linen is folded into the shape of a funnel, and chloroform is poured on the inner surface. The quantity of chloroform is not measured, but at first abundance of air is allowed to enter the lungs, so that the process of narcotisation progresses with moderate slowness. The patients are invariably prepared for inhalation by being kept from eating a meal for some hours previously; but half an hour before the inhalation a glass of wine is allowed. The results of these methods of administration and preparation have been exceedingly good. Chloroform has been administered in the Hospital at least one hundred and fifty times per annum since its introduction in 1848. This would give a total of two thousand two hundred and fifty administrations, and there has not been *one* death. Indeed, the only death that has ever occurred from chloroform in the city of Norwich was one in which a homœopath, acting, of course, on the rule of *similia similibus curantur*, tried to stop pain in a suffering patient by subjecting the patient to the excruciating tortures

of anæsthesia from chloroform. In the hands of this philosopher, the agony excited by the narcotic was mortal, so that he succeeded in his intention even beyond his own expectations, and the homœopathic dogma was amply, though rather unhappily, vindicated. It may be noted, that in the Hospital practice at Norwich vomiting after chloroform is extremely rare. This arises from the preparation of the patient. The freedom from any accident of a fatal kind is due unquestionably to the skill and unremitting attention paid to the sleeper during the administration. The administrator here looks on his duty, not as a measure simply for assisting the Surgeon, but as a process to which he must subject the patient. Consequently, he feels his own responsibility equally with the Surgeon, and acts with the discretion of an independent operator.

PREVAILING DISEASES IN THE HOSPITAL.

The prevailing diseases admitted into the Hospital, excluding accidents and injuries, are seven in number, and arranged in order, according to their prevalence, run thus:—Ulcers; diseases of joints; phthisis pulmonalis; rheumatism, acute and chronic; cancer; stone in the bladder; struma and tuberculosis. In the years 1861-62, out of 2051 cases of all kinds, the diseases named presented the following percentages:—

1. Ulcers 5.60
2. Diseases of joints 5.41
3. Phthisis pulmonalis 4.58
4. Rheumatic fever and chronic rheumatism 4.09
5. Cancer 3.07
6. Stone 2.58
7. Struma and tuberculosis 2.28

The relative proportion of cancer in this list is greater than I have ever seen it in any comparative table of disease derived from a given locality; and the fact will stand out more remarkably when I state, that twenty-two cases of lupus, and all tumours about which there could be any doubt, are excluded. In order to render the analysis of cancer clearer, I would ask attention to the following tables, showing the varieties of cancerous disease, the organs affected, and the sexes. I am once more indebted to Mr. Williams for the facts supplied.

Cases of Cancer observed at the Norfolk and Norwich Hospital from October 1, 1860, to October 1, 1862.

The seven diseases which have been thus noticed furnish in the gross no less than 28.13 per cent. of all the maladies, for the treatment of which the Norfolk and Norwich Hospital has been built. I cannot dwell on a fact of so important an order as this is with too much force. The pathologist, as he lets his eye follow the line of diseases, grasps the fact, that they are one and all connected, and are dependent for their development on conditions bearing on the social state of the sufferers; and that what is simple ulcer in one man is cancer, or phthisis, or joint disease in another. Thus led on, through the causes back to the maladies, he is brought to the sure and certain conviction, that if the benevolent friends who support this Hospital were to pay more attention to the homes and comforts of the poor who come to the Hospital, 28 per cent. of the persons there treated at great expense, and at the best with much suffering, need never go there at all, but might be working as perfectly healthy men always work, with spirit, alacrity, and little care.

ON THE USE OF ALCOHOL IN THE HOSPITAL, AND ON BLOOD-LETTING.

Before leaving the Norwich Hospital and the lessons it communicates, I was anxious to make out whether any relationship existed between the quantity of alcohol taken, or the amount of blood withdrawn from the patients, and the mortality. In respect to venesection I could gain no accurate facts; but Mr. Williams has extracted from the books of the Hospital the quantities of alcohol consumed per patient from the year 1823 to 1836, and from the year 1849 to 1862. He has also made out the cost of leeches from 1831 to 1836, and from 1849 to 1862, and to each year he has added the number of patients in the house, and the mortality. We are thus enabled, from Mr. Williams' calculations herewith subjoined, to estimate absolutely, over a long period, the relation of alcohol to the mortality; and, inasmuch as of late years the leech has almost entirely taken the place of the lancet, we may arrive at an approximative idea as to the effects of loss of blood:

Year.	Number of Patients.	Deaths.	Ounces of Alcohol per Patient.	Cost of Leeches.
1823	688	35	oz. dr.	Not given.
1824	645	27	12 3	„
1825	712	37	11 6	„
1826	760	34	12	„
1827	773	65	11 3	„
1828	841	42	15 6	„
1829	774	59	16 2	„
1830	801	28	6 4	„
1831	838	26	15 4	£38
1832	816	36	6	£20
1833	822	38	6	£14
1834	851	35	10 5	£23
1835	869	46	11 3	£25
1836	792	48	7 3	£26
1849	783	37	8 6	£15
1850	836	46	13	£8
1851	847	38	17	£9
1852	859	45	18 3	£5
1853	895	37	11 4	Unknown.
1854	883	44	12 6	£13
1855	868	46	22	£12
1856	870	48	18 6	£13
1857	885	41	17 5	£7
1858	910	44	12	£9
1859	1007	38	18 6	£6
1860	930	52	14 5	£3
1861	1011	47	18 2	£4
1862	1040	53	21	£3

We glean from this table a fact which might well be anticipated, that of late years the quantities of alcohol that have been administered have increased, while the abstraction of blood has decreased almost to *nil*. But beyond this the calculations furnish us with no data that run in a line indicating any precise order of phenomena. To be accurate, I have worked out the mortality per cent. of each year from 1831, and I find that in the year 1831, when not less than £38 was spent on leeches, when unquestionably the lancet and cupping-glass were also freely used, and when, at the same time, the amount of alcohol was liberal—15 oz. 4 drs. per patient—the mortality was lowest, being only 3.10 per cent. It was next lowest in 1859,—when 18 oz. 6 drs. of alcohol were supplied, when only £6 were spent in leeches, and when a lancet scarcely ever was seen,—being at that time only at the rate of 3.76 per cent. On the other hand, the mortality was highest in 1836, when but 7 ozs. of alcohol were allowed, and when the abstraction of blood was nearly a fourth less than in 1831, the year in which the mortality was lowest.

I can extract only two practical conclusions from the above table, and these are—1st. That at the Norwich Hospital alcohol has never been pushed to such an extreme as to cause a large increase of the mortality; 2nd. That the reduction of blood-letting in that Hospital has not given rise to any decrease in the mortality.

Those members of the Profession who remember Dr. Patrick

Fraser's able researches and deductions relative to the influence of alcohol and of blood-letting in the London Hospital, will refer to the statistics I have given above with much interest. Dr. Fraser's results show the effects of extreme measures of stimulation and depression, and yield a bad column to each extreme. Mine show a middle measure, and no great harm at any point.

"Diet Table of the Norfolk and Norwich Hospital.

I.—FULL DIET.

II.—MIDDLE DIET.

	MEN.			WOMEN.			MEN.			WOMEN.

III.—MILK DIET.—MEN AND WOMEN.

IV.—LOW DIET.—MEN AND WOMEN.

	Breakfast.	Dinner.	Supper.	Breakfast.	Dinner.	Supper.
Daily . . .	Bread 5 oz. Milk 1 pint.	Milk pottage 1 1/2 pint. Bread 4 oz.	Bread 5 oz. Milk 1 pint. Arrowroot 1/2 oz., or rice 1 oz. Sugar 2/3 oz.	Bread 3 oz. Tea 1 pint. Butter 1/2 oz.	Bread 2 oz. Broth 1 1/4 pint. Vegetables.	Bread 3 oz. Gruel 1 1/2 pint. Sugar 2/3 oz.

"Every patient, when admitted, is to be put upon middle diet, unless otherwise prescribed for by the Physician or Surgeon. Toast and water to be always ready in each ward, and barley water when required.

"The following modifications of the above table are to be made for patients of various ages:—Patients above 15 are to be considered adult as to diet. Patients from 12 to 15 to have the allowance of women for full diet. Patients from 8 to 12 to have women's middle diet for full diet. (Both these classes to have half the men's full diet for middle diet.) Patients under 8 are to have half the men's full and middle diet for their full and middle diet respectively. All patients under 12 to have the breakfast of milk diet. In milk diet, for patients under 12, 10 oz. of bread daily, and 8 oz. for those under 8 years.

"N.B.—Vegetables mean potatoes."

In quoting this table, we detect in it the same faults as in all diet scales, viz., the three days per week of everlasting slop. There is, however, one great improvement in this table which deserves to be copied into all tables—twice weekly, on alternate days, in the male and female wards, roasted animal food takes the place of boiled.

In the facts now recorded I have supplied, I believe, all that is most noteworthy from the Norwich Hospital. There are certain inquiries progressing which will bear fruit: thus, the alkaline treatment of diabetes is undergoing careful observation, and, as we have seen, the median operation for lithotomy is fairly on its trial. But the data are as yet insufficient on these points to permit of any correct inferences being drawn from them.

THE NORWICH DISPENSARY.

The Norwich Dispensary, or, as it is called by the poor, the "County Dispensary," was established in 1804. The Dispensary was first situated at Elm-hill. Later, it was removed to Pottergate-street; and finally, in 1856, it was removed to a convenient house in St. John's Madder-market, where it still remains. The number of patients relieved

amount to two thousand annually; more than five hundred of these are visited at their own houses.

Patients are admitted on the recommendation of a Governor only.

The Dispensary is managed by a Committee of Governors, which includes, as *ex officio* members, the Patron (the Lord Bishop of Norwich); the President, the Treasurer, and the Physicians.

Henry Brown, Esq., is, and has been for many years, its excellent Honorary Secretary, as well as Treasurer.

The Medical Staff consists of two Physicians and a qualified resident Medical officer.

The Physicians attend at the Dispensary on four days in each week.

Since the foundation of the Institution, in 1804, the following Physicians have successively held office in it:—Drs. Wright, Evans, Barrett, Johnson, Tawke, Wharton, and Eade.

The present Medical Staff consists of—Dr. James Johnson, M.D., and Dr. Peter Eade, M.D., M.R.C.P., as Physicians; and Hugh Taylor, Esq., M.R.C.S. and L.S.A., as resident Medical officer.

POINTS OF PRACTICE.

Prevailing Diseases.—Dr. Eade, one of the able Physicians to the Dispensary, has been good enough to report to me his observations on the practice of the Dispensary. "The condition of the patients is," says my learned friend, "essentially adynamic, often combined with the presence, to a greater or lesser degree, of the oxalic diathesis, and of more or less marked nervous symptoms,—either actually manifest, or readily induced by any treatment which is in the slightest degree depressing. This condition has been generally benefited by the mineral acids, steel, nux vomica, and other such specially nervine tonics, in contradistinction to ammonia, gentian, and the more ordinary forms of tonic remedies.

"The presence of oxalates, in quantity, in the urine, with more or less of the general constitutional phenomena which

usually coexist with this condition, is a very common form of disorder in Norwich.

"A large experience of this morbid condition," continues Dr. Eade, "enables me to speak of it with some confidence, and to express an opinion with regard to it very much in corroboration of that of Dr. Prout, and in opposition to that of other writers, who have considered the presence of oxalates in the urine of no special significance. It is quite true that a few crystals of oxalate of lime may be, and are, found in the urine of a very large number of patients. It is also true that oxalates, in large numbers, may be found in the urine of patients suffering from full-blooded, plethoric, irritative dyspepsia; but in these cases there will also be present, in large quantity, the amorphous lithates, lithic acid, and an excess of nearly every other urinary constituent. But in the true oxaluria seen here, oxalates are the only crystalline deposit often seen under the microscope. The urine, too, is peculiar. It is of high specific gravity, containing a large proportion of earthy salts, often an excess of urea; it is very pale in colour, depositing a faint mucoid cloud after repose; and, when the diathesis is very pronounced, the patients will report that it is always bright and clear, and never turbid or thick (with lithates) after standing to cool,—a fact which they often mention as proof of its necessarily healthy condition.

"The constitutional accompaniments of this state I have not found very constant, but they are generally referable to a varying amount of general debility, flatulent and slow digestion, irregular action of heart, pain in the loins, uneasiness or weight at the vertex of head, depression of spirits, loss of sexual power, and occasionally, also, of some muscular power in the legs.

"The treatment I have found most successful is the use of the mineral acids, with the addition of a little tincture of steel, tincture of nux vomica, sulphate of magnesia, etc., according to the peculiarities of the case; the avoidance of malt liquors, and the daily use of cold salt-spongings of the skin, followed by active friction. It is noticeable that these patients, though they feel so weak and languid, yet will say that they generally are the better after any vigorous exertion of the body, such as shall have actively excited their circulation, and thereby increased the cutaneous transpiration.

"Another very common disease in Norwich is anæmia, or, more properly, spanæmia, with its allies, hysteria and neuralgia, and more or less derangement of the uterine functions. This, perhaps, is only what might be expected where a considerable proportion of the female population is employed in factory work, or in the sedentary occupation of binding shoes, the boot and shoe trade being now a large and increasing industry in this city.

"The features of this disorder are, simple pallor, or otherwise sallowness of skin, pain below one or both breasts, generally the left, tenderness (nearly always) in dorsal spine, a sensation of painful weight over the forehead, pains in ovarian or other abdominal regions, dyspnœa and palpitation on exertion, anæmic vascular murmurs, and generally scanty or colourless or deferred menstruation.

"Cold bathing is nearly always useful, but steel is not the only remedy required in many cases for cure. Where there is struma also present, quinine and cod-liver oil are most useful; but I have found that many cases which have resisted all these have at once and speedily recovered when a little iodide of potassium has been added to a steel mixture. This remedy is doubtless a powerful emmenagogue, as well as regulator of the glandular system; and I assume that it is by virtue of this power of re-establishing a normal secretion that it is so useful in these cases. Even when administered alone, I have found it of great use in correcting uterine and ovarian irregularity.

"Bronchocele is comparatively common; diabetes occurs rather often; and strumous debility and phthisis form a very numerous class of cases."

On the Hypophosphites in Phthisis.—On this point Dr. Eade reports as follows:—"In 1856, when Dr. Churchill first recommended the administration of the hypophosphites as a remedy for phthisis, I prescribed the hypophosphite of soda in five-grain doses, thrice daily, to eight successive and non-selected cases, and carefully observed its effects. In several of these patients, some of the more urgent symptoms, such as the cough, expectoration, and sweating, did undoubtedly appear to be relieved at first, and soon after commencing the treatment, and for a time the patients expressed their belief that the medicine was doing them good; but as they soon began to fail again, in spite of the continuance of the remedy,

the conclusion was forced upon me that its efficacy, if any, was but slight and temporary, that it was insufficient to arrest the progress of phthisis, and that the temporary amendment was rather to be attributed to the sanguine temperament peculiar to the disease, which would be more particularly called into play by the knowledge that a new remedy was being tried upon them, and by the livelier state of their general system, which would be excited by the greater and closer attention they were receiving.

"*Discoloration of the Gums in Phthisis.*—Some rather numerous observations have also been made at the Dispensary with reference to the presence and significance of a red or bluish-red discoloration of the free edge of the gums in phthisical patients. The presence of a well-defined line was found, as a rule, to indicate the existence of phthisis, or of some other form of scrofulous disease: on the other hand, it was found to be rare, indeed, for a well-developed case of phthisis not to present this discoloration in one or both jaws. The general conclusions arrived at as to the significance of this mark were, on the whole, confirmatory of those enunciated by Dr. Theophilus Thompson, as the result of his observations on the subject, and went far to indicate this as a most valuable sign of present or threatened tubercular disease.

THE JENNY LIND INFIRMARY FOR SICK CHILDREN.

The Jenny Lind Infirmary for Sick Children, founded in 1853, is another institution deserving notice. It is a small, comfortable house, with playground attached. Sick children are received on recommendation of a Governor.

Boys between the ages of two and nine years, and girls between the ages of two and eleven years, suffering from any disease not contagious or infectious, are admissible as in-patients; and children of both sexes, from birth to the age of twelve years, are admissible as out-patients of the Infirmary. Under special circumstances, a child under two years of age may be admitted into the Hospital, and, if requisite, with the mother. In cases of great urgency the admission may be immediate.

All in-patients are discharged at the end of two months after their admission, unless the Physician or Surgeon certify to the Committee of Management that there is a probability of their being cured, or of receiving considerable relief.

Children suffering from accidents or external injuries, or their immediate effects, are not at present generally admissible as in-patients. Such children may, however, be treated as out-patients, and may also, under special circumstances, be received into the Infirmary.

Every in-patient affected subsequently to admission with epidemic or endemic disease, is placed in a separate department of the Infirmary, and remains there during the whole time of residence in the Infirmary, being strictly secluded from any kind of intercourse with the patients or nurses in the other parts of the house.

All children removed to this part of the Infirmary are at once, and during the whole period of their stay in the Infirmary, furnished with needful clothing. The clothes, which the child wore on its removal are washed, exposed to the air, and returned to the child on its discharge.

From sixty to seventy patients are admitted to this Institution annually as in-patients, and nearly four hundred attend as out-patients. The diseases subjected to treatment are mainly ophthalmia, dental irritation, convulsions, scrofula, eruptions of the scalp and skin, club feet, curvature of the spine, atrophy, nœvus, hydrocephalus, abscess, diseases of the ear, diseases of the lungs, diseases of the hip and knee joints, burns and rickets.

The arrangements of the Hospital seemed to me very simple and effective. The wards are ventilated by the insertion of one large sheet of perforated glass plate in the lower sash of the window. I have not seen the same method carried out on so large a scale in any Hospital previously. It seemed to me that it must necessarily lead to draught; but Mr. Hutchison, one of the Surgeons, who was so courteous as to explain to me every fact, stated that the objection had not, practically, been felt. Certainly, where an old house has to be turned to a new purpose, this plan of ventilating is as simple as it is cheap; but I should think that the *upper*, not the *lower* sash, should be the half of the window to receive the perforated plate.

In 1856, Jenny Lind Goldschmidt, after whom the Infirmary is named, and who contributed largely to the foundation, paid a visit to the charity, and left in the visitors' book the follow-

ing characteristic note, which is now framed and placed in the Board-room :—
 “February 8, 1856.

“Jenny Lind Goldschmidt, having succeeded in inspecting the institution herself, feels happy to confirm the words of satisfaction which her husband expressed for her, in regard to this lovely institution, two days ago.”

The Medical officers to the Jenny Lind Infirmary are—Physician—Dr. Copeman; Surgeons—T. W. Crosse, Esq. and G. S. Hutcheson, Esq.; Assistant-Surgeon—C. E. Muriel, Esq.

Medical pupils are admitted to the practice of the Jenny Lind Infirmary.

NORWICH LYING-IN CHARITY.

This Lying-in Charity is held at the same building as the Jenny Lind Infirmary, but the two charities are quite distinct. The Medical officers of the Charity are—Dr. Copeman, Physician; T. W. Crosse, Esq., and W. H. Day, Esq., Surgeons, with C. E. Muriel, Esq., Assistant-Surgeon. The object of the Charity is to supply to poor women, at their own homes, attendance in childbirth, by midwives, who act under the direction of the Medical staff, and who refer to some member of the staff in all cases of difficulty. Nine midwives are appointed to the Charity, and each one receives four shillings for every ease she attends; their services are required in at least 400 cases annually. Recommendation has to come from a Governor, who, for a guinea, is allowed three tickets a-year.

Every poor woman who has the benefit of the Charity, receives, in addition to attendance, the loan of a bag containing double suits of requisite clothing, and a box of anodyne aperient pills; the whole costing the institution six shillings and twopence each time. She also receives as a gratuity three pints of oatmeal or groats, one pound and a-half of sugar, two ounces of tea, and three-quarters of a pound of soap.

I was anxious to enquire as to the competency of the midwives in their attendance on the parturient cases; and I received the most unmistakable report in their favour. Carefully selected at first, and acting at all times under the superintendence of a competent Medical direction, they perform their duties with signal success. There does not seem to have been a single fatal error ever committed by them since the Institution was founded—nor, indeed, any error whatever. It would be a great boon if in every other town where there is an excess of poor, and where a proper Medical fee cannot be paid for midwifery, the Medical men were to organise a similar charity. It would ensure for the poverty-stricken qualified assistance at an hour of great need, and would prevent that gross imposition to which they are constantly subjected by midwives who act under no responsibility, and rely only on their own impudence and love of self.

While alive to all the social advantages arising from the Norwich Lying-in Charity, I cannot avoid pointing out one particular and grievous error—I refer to the donation of soap and of so-called food to the parturient women. No objection can be made to the soap—that is equally suggestive as useful: but oatmeal, sugar, and tea—think of those articles as flesh and blood makers! Where can we find in them either flesh or blood, or milk for the infant at the breast? The same money's worth, spent in soup or solid animal food, would be of real use to mother and child; that which is given is worse than thrown away.

NORFOLK AND NORWICH INFIRMARY FOR THE CURE OF DISEASES OF THE EYE.

The Norfolk and Norwich Infirmary for the Cure of Diseases of the Eye was established in 1822, and ten years ago was placed on a permanent footing. The present Infirmary house was originally an old-fashioned mansion; it is in a good central position, is roomy and spacious, and, though not surpassingly elegant, it answers its purpose. Only two floors are occupied as yet. The Medical staff consists of Dr. Copeman, Physician, and G. W. Firth and G. Goodwin, Esqs., Surgeons. From forty to fifty operations are performed annually.

POINTS OF PRACTICE.

Airing Grounds for the Blind.—The most noteworthy, because a novel and important point of practice in this Infirmary, is the formation of an airing-ground, so arranged that patients who cannot see can walk out, in warm or suitable weather, and enjoy themselves without guides or attendants. The exercise-ground, which adjoins the institution, is marked off into paths by firm, smooth railings, high enough to be felt comfortably by the hand, and to direct the patient the way in which he may walk safely. The advan-

tages of this simple plan are so obvious, that I cannot doubt but that it will be followed out in every similar institution, when it is generally known. The Profession, and the public not less than the Profession, are indebted for this thoughtful advancement in the humanities of Surgical art, to Mr. Firth.

Iridectomy.—The operation of iridectomy has not yet been largely tried. Mr. Firth has had five cases. In one case of intense glaucoma, the operation, performed as a forlorn hope, caused recovery of sight; but in a little time cataract followed, for which disease Mr. Firth operated by extraction. The patient recovered, and the restoration of sight was again perfect, and this time permanent.

Operations for Cataract.—The operation by extraction is mainly carried out. The results of the operations are thus given :—

Restoration of sight in 50 per cent. of cases.	
Guiding sight	25 " "
Failures	25 " "

Chloroform.—Chloroform is not used in adults, in operations on the eye, except in very rare instances.

Firth's New Canular Forceps.—I cannot close this notice without referring to a new canular forceps which has proved of great use to the operating Surgeons. Ten years ago, Mr. Firth observed that the ordinary canular forceps was inconvenient. It was necessary to press down the lever to close the blades during their passage through the opening in the cornea, and a good hold was not retained on the capsule. The capsule itself was also wont to give way. To obviate these difficulties, Mr. Firth had a catch adapted to hold down the lever, and allow, after grasping it at one point, a portion of the capsule to be twisted round, rope-like, until it was strong enough to be completely extracted. This instrument did not quite answer, for it was difficult to release the catch so as to allow the expansion of the forceps within the aqueous chamber. He, therefore, had constructed, by Messrs. Weiss, in 1858, a canular forceps which was expanded by pressure upon a lever, and closed by recoil of the spring. The instrument was perfected by Mr. Weiss, who adjusted to it a carved double-lever, which can conveniently be pressed by the thumb at either end, so as to close or open the forceps at pleasure. Those ophthalmic Surgeons who have not yet seen or used this canular forceps will find the instrument worth their attention, and worthy of their skill.

REPORT OF THE COUNCIL OF THE PATHOLOGICAL SOCIETY, JANUARY, 1864.—The Report stated that the total receipts for the past year have amounted to £353 14s., of which £12 8s. 1d. have been realised by the sale of *Transactions*, and £5 14s. 3d. as dividend from stock, leaving as the amount of subscriptions the sum of £334 19s. Of this, £45 3s. have been received as life fees and as composition fees from non-resident members, and will, in accordance with previous practice, be invested in Three per Cent. Consols. Besides this, there is a balance of £190 18s. 5½d. from the preceding year, making a total of £543 19s. 9½d. Of this, £119 19s. have been added, by order of the Council, to the Society's funded property. The total expenditure amounts to £329 3s. 3d., leaving in the treasurer's hands a balance of £78 2s. 6½d. to be carried forward to the account of the current year. The amount of stock in Consols held by the trustees for the Pathological Society is now £259 13s. 5d. Next, in relation to numerical strength, it should be stated that the Society is at this moment constituted by a larger number of members than at any previous period of its existence. The average attendance at its meetings is also higher—a fact which demonstrates the increasing interest which attaches to the operations of the Society. The supply of pathological specimens has been more than ample, and on most evenings more than sufficient for examination, to say nothing of discussion. If any ground of complaint could possibly be alleged, it arises from an absolute superabundance of valuable examples of morbid product. The often imposing list, the reading of which commences the proceedings of each meeting, sometimes suggests such a reflection as the following :—“It is true that each of these preparations is intrinsically valuable and interesting; that it is necessarily so to the exhibitor, who has watched narrowly the phenomena which have marked its development; but has it been considered whether the specimen subserves also that purpose which is, after all, the higher one, viz., to afford interest, and perhaps instruction, to many of the hundred members whose time will be occupied by its examination, or of the four hundred who pay for its record in their annual volume?”

REVIEWS.

Shanghai Hygiene: or, Hints for the Preservation of Health in China. By J. HENDERSON, M.D.

THERE can be no doubt of the value attaching to any attempt at lessening the mortality of Europeans in China. From whatever cause it arises, the decimation of our countrymen by disease soon after their arrival in that climate should be attentively studied, and, if possible, prevented. The writer of a memoir bearing the name given above, does not only address himself to his Professional brethren, but aims at instructing the general reader. "It is always safe," he says, "and frequently successful, to appeal to the reason and common sense of an Englishman, and to place the real facts or the truth before him, and let him judge for himself." Dr. Henderson, as a resident at Shanghai, is undoubtedly competent to form a trustworthy opinion of the climate, and we rejoice to find his testimony so clear and decided. He is of opinion "that an European with a tolerably good constitution has his health almost entirely in his own keeping on arriving in Shanghai; and if he is careful in regard to his diet, drink, exercise, and clothing, he need not fear the climate."

In the first place, Europeans appear to eat too much. "They come off the P. and O. steamer," says the doctor, "bordering on a state of disease from over repletion." And on landing they continue the dangerous excess, leading him to add that "much dyspepsia, languor, and a feeling of being generally out of sorts, requiring changed climate, and also troublesome diarrhœas, are produced by rich food in too great variety and too large quantity during the hot season."

Especially are residents warned against excesses in fruit and vegetables, which Dr. Henderson holds to be distinct causes of diarrhœa and dysentery. He affirms, that during the preceding year he could trace all such cases, as well as those of cholera, to indulgence in Chinese fruit or vegetables; and he adds in a note a shrewd comment, which is worthy of the attention of our theorists for utilising town sewage: "May not this," he says, "be owing, in some measure, to the peculiar kind of manure used here, and all over China, in raising vegetables?" He is, however, quite alive to the fact, that hot climates do differ from more temperate regions in the violence of the disorders caused by slight indiscretions, that "that which produces uneasiness, indigestion, or slight inconvenience in England, will, in Shanghai, during the summer months, induce diarrhœa or dysentery."

The author repeats the same caution respecting alcoholic drinks, and gives some lamentable information as to the habits of many residents. He insists on regular exercise, and warns his readers against the sudden coldness of the nights in September. A little pleasantry directed against "griffinish sticklers for decorum," who persist in retaining their European costume in a tropical climate, seems fairly deserved; and his high opinion of the Turkish bath as a hygienic precaution carries conviction on its face.

The latter part of the work is devoted more especially to the requirements of his fellow colonists, and, therefore, beyond our present scope; but we strongly recommend it to all who are called by the necessities of business into a climate which has, perhaps, been too hastily condemned. Dr. Henderson's memoir bears in every page the stamp of practical good sense and impartial observation.

From Matter to Spirit. The Result of Ten Years' Experience in Spirit Manifestations. Intended as a Guide to Enquirers.

By C. D. With a Preface, by A. B. London: 1863. Longmans.

OF this very unequal book, the only portion which requires detailed notice is the preface. It is true that neither preface nor substance can prefer an equitable claim to authenticity, from their studious affectation of an anonymous character. We cannot but demur strenuously to the very opening paragraph, where it is stated, that "for obvious reasons names are suppressed and initials changed." It is an attempt to substitute general rumour and vague conversation for personal evidence; and, even if it be granted that social considerations justify withholding the author's name—a fact which is open to grave doubt—the same argument should have led to the suppression of the work itself. Such a document, to be valid evidence in a *bonâ fide* enquiry, should be duly signed and attested. If, on the other hand, the *ineognito* be, as we

shrewdly suspect, more simulated than real, the duplicity, patent on the very title-page, cannot but invalidate all that follows. What weight can be given to the allegation, that—"I have neither exaggerated the marvellous features of any case, nor omitted to mention circumstances by which its marvellousness might seem to be lessened? For the truth and accuracy of all incidents given without names, or with initials, I hold myself responsible." Such testimony, in an obscure case, would be accepted with suspicion from a familiar and unimpeachable authority; but when proffered by an unknown and impersonal "C. D.," it becomes, not only ludicrous, but impertinent. On the same "responsibility," we learn, in the next page, that the narratives of Mr. Home's book are perfectly trustworthy; and soon after, under the same guidance, are expected to acquiesce in Phrenology, Mesmerism, and, perhaps we may add, Swedenborgianism. Incidentally, however—from the phrase, "my husband's family"—we discover that the unknown is a woman. On the value of the "experiments" which follow, we offer no opinion, except that they seem, like all other of the class, self-convicted by their inconclusiveness and triviality. Every one will, doubtless, concur with the author, when she candidly admits, that—"I know not how to secure anything like a belief in the trustworthiness of a narrator who is not at liberty to authenticate the truth of any one narrative by the names of those concerned."

The preface stands on somewhat different ground. Although written in a style at times painfully jaunty, and all but irreverent, it is undeniably more able and profound than its bulky better half. By its very presence an accessory before the fact, and, moreover, masked by similar initials, it opens with a declaration that its writer "will not stand committed either for or against the conclusions of the book. I am perfectly convinced," says A. B., "that I have both seen and heard, in a manner which should make unbelief impossible, things called spiritual which cannot be taken by a rational being to be capable of explanation by imposture, coincidence, or mistake. So far I feel the ground firm under me."

The writer then proceeds to urge with force the common intolerance of unexplained facts, and the readiness to class all who "have seen faith-staggering occurrences" as either impostors or dupes. The distinction is drawn between truth and credibility, and an amusing onslaught is directed at the positive way in which many topics are conversationally pronounced on by superficial thinkers. The incompetence of coincidence as an explanation leads to discussion of evidence generally. It is unlucky that all the illustrations of this should be drawn from forensic sources, and so necessarily complicated with technical rules invalid in science, however essential for the administration of law.

Some depreciation of Bacon's philosophy leads to a good explanation of the hypothetic element present even in such discoveries as that of gravitation; and then the "spirit-hypothesis" is set before us to show that it is not less improbable than many admitted facts. "Four courts of the mind," for dealing with the different forms of evidence, have a strong savour of the Baconian method, in spite of his disesteem. The "fourth court," unlike its Cambridge namesake, presides over "principles which are presented as more or less obvious, but not capable of the absolute demonstration of logic or mathematics." Five short narratives follow, good, indeed, as stories, but whose argumentative force is beyond our perception.

And then at length we reach the evidence of spiritualism. This is well summed up in Aristotle's words. We translate them in simple astonishment at our author's pretended inability. "It is obvious, that actual occurrences must be possible," says that clear thinker and concise writer, "for they would not have occurred if they had been impossible." The facts in this instance are that a certain Mrs. Hayden, a "well-known American medium," convinced our anonymous preface writer of the truth of spirit-rapping, and also "that the sounds were made *amosgepotically*," a word proposed by him as convenient, but to us utterly mysterious and incomprehensible. It is to be hoped that the Greek translation given above may avert the impeachment of ignorance; and possibly this grand compound may belong to the obscure dialect which produced "Aneroid," "Kalos Genesis sauce," and "Anaxyridian trousers."

In conclusion, it is just to thank so smart a writer, not only for a new etymological sensation, but also for a neat little essay. The work, as a whole, like the fruit at a stall, carries its finest sample on the top. In what we have read there has been nothing to shake the judicious and logical

conclusion of a recent writer in the *Quarterly Review*: Whether spiritualism be true or false, we are as yet justified in suspending our opinion till more decisive evidence is forthcoming.

A System of Instruction in Qualitative Chemical Analysis.
By Dr. C. REMIGIUS FRESENIUS, Director of the Chemical Laboratory at Wiesbaden, Privy Aulic Councillor of the Duke of Nassau. Sixth Edition. Edited by J. LLOYD BULLOCK, F.C.S. London: Churchill and Sons. 1864. Pp. 355.

WE were well acquainted with the first edition of Fresenius when, some years since, we went through a course of laboratory instruction, and took it for our text-book; and the thin, well-fingered volume, scored with pencil-notes, which stands on our shelves, is a memento of its practical usefulness. By its side we are glad to place the new and plumper sixth edition, which has just appeared. The character of the work is established, and we need only say that every new process in *qualitative* analysis is added to it. Whereas the earlier editions left out the rarer elements, this includes every known element, although such parts as treat of the rarer ones are put into smaller type. The subject of spectrum analysis, which, as the editor observes, marks a new era, is fully described, and illustrated with a coloured map of the spectrum and the bands produced by various elements.

FOREIGN CORRESPONDENCE.

AMERICA.

NEAR RAPPAHANNOCK STATION, VA.,
December 17, 1863.

TIME has sped rapidly since I wrote you last. Continual marching, and the excitement engendered by an occasional skirmish, have given one no opportunity to observe its flight. Yet among all the varied occurrences that have been coursing pell-mell after each other during the past autumn, comparatively little can be found worthy of narration in the pages of a Medical journal. All the interest of the fall campaign is concentrated in its military manœuvres. My last communication was written while the troops were resting in summer quarters, along the line of the Orange and Alexandria Railroad, with the Rappahannock between them and the enemy. Here they enjoyed a month of much-required repose. Here it was that the army was reinforced by the drafted men or their substitutes, whose advent gave the Medical Officers in the field an opportunity of observing a class of diseases to which, for a long time previous, they had been strangers. A large percentage of the embryo heroes, lugged forward by Columbia to fight her battles, spent the first part of their stay in Virginia in Division Hospital, under treatment for one or other of the forms of venereal disease. I mentioned before, that, while here, regimental Surgeons had no duties whatever to perform; that their sick were removed from their charge, and, having been aggregated at one point, those of a division were placed in the care of a Surgeon and one or two assistants. After a short time, it seemed to strike the heads of the Medical Department that this arrangement left the officers in charge of regiments with no work on hand other than the not very onerous task of sending for an ambulance now and again, in which to dispatch their sick to the newly-formed Hospital; and an order was issued which kept them busy for a few days. For the furtherance of statistics, it was required that a report be handed in, as soon as possible, giving the former occupation, age, height, and circumference of chest of every enlisted man in the command, and of conscripts as they joined. Every one had to measure his men at the same time, and for a few days tape lines, etc., were much above par. However, the thing was speedily accomplished, and a mass of statistical information was added to the immense amount heretofore accumulated in the Surgeon-General's office.

This over, a copy of Hammond's "Military Hygiene" was issued to each regiment upon requisition, and no movements taking place for a week or so thereafter, time was afforded us to scan the contents of the work. A treatise on hygiene was very much required by the Surgeons of this Army. Habituated, before volunteering into the military service, to inattention to the hygienic conditions combining to prevention, great,

but unintentional, neglect of duty was in many cases the consequence. They had considered that they had done their duty in prescribing for disease as it presented itself, until the appearance of the Surgeon-General's volume brought them a reminder that prevention is better than cure, and as much their duty.

Here it was, too, that the indefatigable curator of the Army Medical Museum gave a fresh proof of his anxiety for its increase, and his fear lest the excitement and onerous duties consequent on an engagement should cause his institution and himself to be forgotten by some of the operators. He caused vessels of tinned-iron to be issued to the Surgeons-in-Chief of the divisions of the army, who are to be held accountable for their safe keeping. These vessels, each half filled with antiseptic solution, each provided with a padlock and key, and with the name of the division to which it belongs painted upon it, accompany the ambulance trains of the army, when, should a fight occur, their presence would keep alive in the minds of the operative staff the existence of the museum, and would mutely petition for specimens to enrich it. A general order issuing from Medical head-quarters was promulgated at the same time, earnestly impressing upon army Surgeons the necessity of taking advantage of the many opportunities they at present have of collecting and contributing valuable specimens. This, I believe, is the first and only time that the institution has been officially brought before the notice of the Surgeons in the field. Many were unaware of its existence until this order was circulated.

September had fairly begun; the hottest of the hot season in this part of the world had passed away, when the fall campaign was commenced. We broke camp, and, crossing the Rappahannock, marched in the direction of Culpepper Court-house. The march of the first two days was, in a Medical point of view, the most important of any that has since occurred. The weather, notwithstanding the lateness of the season, was most oppressively hot, and the energies of the men rapidly gave way, laden as they were with eight days' rations, in addition to knapsack, woollen and rubber blankets, shelter tent, arms, and sixty rounds of ammunition. Cases of insolation were of very common occurrence; but a heavy thunderstorm swept across the face of the country, leaving behind it an invigorating coolness, which banished sun-stroke from the ranks of the army for the remainder of the season.

Massed in the neighbourhood of Culpepper, the main body of the army, with good soil, water and weather, passed a few pleasant weeks, during which the sight of a sick man was a rarity. But it was otherwise with the advance. The troops forming it lay in the woods which beset the low-lying grounds forming the north bank of the Rapidan, near Rapidan Station. Every circumstance affecting them was of a nature tending to engender disease; and disease was soon rife amongst them. For military reasons it was, I presume, that the different brigades were huddled so closely together. No regular camp was formed. The spot on which the sinks of one regiment ought to have been, was occupied by the camp of another command. The ground was low-lying, and its surface covered more than ankle deep with the leaves which autumn had already thrown from the trees. A smart shower of an hour's duration would yield for two or three successive days six or more inches of a mud formed from vegetable decay, by wading through which the soldiers' feet were kept continually damp, and from which the exhalations of a morning could be seen in the form of a grey vapour, hanging among the branches overhead. Large fires in this location were unfortunately contraindicated, lest by day the curl of their smoke above the tree tops, or by night their lurid glare, should reveal the position to an enemy—so near that his bugle calls and music were plainly audible—and so draw upon it a fire of a less agreeable nature than that which had drawn it. Remaining, however, a few days undisturbed in this position, and hence feeling a sense of security in it, the men braved the danger of the rebel artillery, and made themselves comfortable during the remainder of their stay, at least so far as huge fires could contribute to comfort. Water was scarce, and, what was worse, the little that could be obtained was bad. In addition to this, the mind was kept continually in a state of tension. Scarcely a day passed without some cavalry skirmish, or picket firing on the part of the infantry. Every evening it was set down by the men that to-morrow would be the eventful day—the day on which the passage of the Rapidan would be effected; but as constantly were they deceived. The consequence of all this was, that large squads of sick had every few days to be sent to the rear, to Hospitals established in Culpepper, where like-

wise the wounded in the various skirmishes were being treated. Most of those sent away sick were affected with the same complaint—an insidious and fatal form of fever. The man feels out of sorts for a week or ten days before he takes to bed. He is weak, and has no appetite. His tongue is not dry, but it has a bluish colour, and a grey film is spread over it. His skin is dry, but there is little alteration in the pulse—a little less full and more frequent, perhaps, if diarrhoea be present, or with a slightly marked feverish throb if the bowels be constipated. In this state he may continue for six or eight weeks, feeling at intervals, for a day or two at a time, well, but weak; and then he gradually recovers, or sinks exhausted. But it often runs to a fatal termination more speedily, the pulse never altering much from the natural standard of frequency until life's last hours have arrived, when also, for the first time, the tongue becomes decidedly dry, and the delirium of exhaustion sets in.

The forced retreat from the Rapidan to the vicinity of Centreville, the subsequent advance on Orange Court-house, and the late retrograde move to the Rappahannock, present nothing of interest, nor do the various skirmishes we have had offer me anything worthy of writing about. The wounded at the battle of Bristow, the passage of the Rappahannock, and at the recent affair at Robertson's Tavern, were comparatively few, and of these few the majority were immediately transported for treatment to Alexandria and Washington by rail.

At present we are lying on the south bank of the Rappahannock; and, although no orders have been issued relative to the construction of winter quarters, every man is busily engaged in the erection of a log shanty, in which he fondly hopes to spend in comfort the dreary months of January, February, and March.

GENERAL CORRESPONDENCE.

MORTALITY AFTER LITHOTOMY IN THE METROPOLITAN HOSPITALS.

LETTER FROM MR. HENRY THOMPSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have read with pleasure the papers of Dr. Richardson, relating to Norwich and its Hospital. Interesting as the subject is, all must feel that the interest is increased by Dr. Richardson's graphic style.

There is a statement of alleged fact, however—and a most grave statement, too—which I am compelled to deny—viz., that which Dr. Richardson makes, respecting the mortality from lithotomy in the metropolitan Hospitals. He has assumed it to be, "one death in two cases, or even one in 1.88."

This is a subject respecting which I have made large enquiry, and possess, lying before me at this moment, extensive records. The evidence of this may be seen at pages 223 to 229, and at page 269 of my work on "Lithotomy and Lithotripsy," reviewed in your Journal of last week. These there proved—and I am prepared to fully substantiate, if need be—that the average mortality from lithotomy in the male subject at all ages, in the practice of the London Hospitals where reliable records exist, does not exceed one in seven cases, while the Norwich experience is about one in seven and a-half to seven and three-quarters.

In this inquiry, as every one knows who understands the value of figures, it is necessary to deal with numbers as large as possible, and not to be satisfied with the result of a few cases, or of those observed during any short period of time. The result given above is that of the entire experience of the last twenty to thirty years at Guy's, St. Thomas's, and the University College Hospitals, and amounting to 520 cases. If it were right to select two or three years only, I could find some recent years in which the results were better still. No one can be more ready than myself to admit the excellence of the Norwich results. Thanks to the kind courtesy of my Professional brethren there, I have long been familiar with their successful practice, and with that magnificent collection; and I have learned much from their experience. But, gladly and freely yielding all this, a fair comparison must be made between Norwich and London; and this only, I am certain, is desired by my Norwich friends. Nothing less than an accurate statement on so important a point as the metropolitan rate of mortality in lithotomy can be permitted to emanate from so widely-circulated and influential a Journal as the *Medical Times and Gazette*. The superiority of our results in

this matter are already admitted in Paris, and no error can be permitted to shake any fairly-earned credit we may possess, either on the Continent or in the provinces.

I am, &c.,
HENRY THOMPSON.

35, Wimpole-street, Jan. 11.

TOWN AND COUNTRY HOSPITALS.

LETTER FROM MR. T. HOLMES.

[To the Editor of the Medical Times and Gazette.]

SIR,—My attention has been drawn to a paper by Dr. Richardson, in your number of January 9, on the subject of the Norwich Hospital, in which Dr. Richardson lays down the startling proposition (at least he seems to do so), that if the patients with stone at that Hospital had been treated in metropolitan Hospitals, the mortality after lithotomy in their cases would have been increased fourfold. The enormous error on which this assertion rests will be exposed, I believe, by Mr. H. Thompson, the person whose authority will carry most weight on this point. A study of Mr. Thompson's recent work on lithotomy and lithotripsy would have preserved Dr. Richardson from falling into the mistake of taking the number of deaths in a few cases of adults in London Hospitals to represent the rate of mortality over all cases of lithotomy in those Hospitals. I need not spend words on so obvious a fallacy; but what struck me even more forcibly in Dr. Richardson's paper, was the exaggerated idea of the difference in salubrity between a town and a country Hospital, which could alone make any writer imagine it possible that a mere change from the country to the town should multiply the deaths after a given operation fourfold. Other circumstances, such as Hospital arrangements, Surgical skill, the constitution of the patients, etc., being assumed to be the same, I should be disposed to draw a very different inference from the real state of the facts which Dr. Richardson has so strangely mistaken, and to argue, that if the difference in the rate of mortality between town and country is so slight as Mr. Thompson's table (*op. cit.*, p. 226) shows it to be, while there is good reason to think that the patients of country Hospitals are in a more healthy general condition than those in the metropolis, the benefits of country situation must, if they exist at all, be only slight. The reality of the advantage of the "fresh air" which is always assumed to surround a Hospital which is called a "country Hospital," over the air, assumed not to be "fresh," in which a London Hospital is placed, is one of the most difficult questions connected with Hospital construction. I have lately had occasion to think carefully on this subject, and have come to conclusions far less positive and far less striking than Dr. Richardson's, but, I venture to hope, supported by more solid foundations. These conclusions have been formed by the examination of most of the Hospitals in Paris and the United Kingdom, and I hope will soon be placed before the Profession. Meanwhile, let me merely say this much,—that it is in my opinion a delusion to believe that the mere situation of a Hospital (unless that situation is decidedly malarious or unhealthy) will have much effect on the general rate of mortality of diseases, injuries, or operations; that the success of Hospital operations depends principally upon the selection of the case (*i.e.*, the constitution of the patient and nature of the disease) and the proper performance of the operation; next, upon the proper ventilation, spaciousness, and cleanliness of the Hospital. Every Hospital Surgeon must know that the success of cases of lithotomy depends principally on the age of the patient, his state of health, and the size of the stone; and that a healthy child, with small stone, will have a far better chance of recovery, though the operation be done in the worst kennel of St. Giles', than a broken-down old man, with a large stone, though it were done in a palace, or on a mountain-top, if that is thought more healthy. The fact that operations succeed better in the country than they do in town, has never been proved; inasmuch as those who have published tables bearing on the subject have never taken the pains to analyse the cases, or, perhaps, have not had the data from which to do so. But until this is done, such statistics are useless, or, as in the case before us, worse than useless—misleading. The differences of mortality between the town and country Hospitals in Mr. Thompson's tables, are not more than exist between Hospitals in the same town which admit patients of a different class, and which, therefore, get patients in different states of disease—as happens in the cases of hernia, admitted into Guy's and the London Hospital at one end of London,

and St. George's at the other. Nor do the tables published in Mr. Teale's book on "Amputation," show any remarkable advantages on the side of country Hospitals in that operation. That cases do better in well-constructed and well-ventilated Hospitals than in those of an opposite character, is a fact which I believe to be capable of proof; and there can be little doubt that the construction of a Hospital is a matter of far more importance than its situation. Now I think that few Surgeons could visit, on successive days, the Norwich Hospital and one of our great London Hospitals (say St. Bartholomew's), and come away with any doubt which is the most eligible place for the treatment of disease. That metropolitan Hospitals are, as a rule, far better adapted for the reception of cases of acute disease than the provincial Hospitals, is a fact which is hardly a matter of opinion, but rather of observation. If, under such circumstances, the practice of the Norwich Hospital were more successful than that of the metropolitan Hospitals, irrespective of the cases they admit, and the patients on whom they practise, it would be a *presumption* (but only a presumption) that this better success was due to the rural situation. But, as far as present evidence goes, this does not seem to be so.

The Medical public appears to be under a very mistaken impression as to the unhealthiness of the London Hospitals. There is nothing to show that the air of London is in the least degree unfavourable to recovery, apart from previous unhealthiness in the patient. Thus, in this very matter of stone, can it be shown that the mortality of lithotomy in *children* is affected by their being operated on in the atmosphere of London? I can only say, that during the fourteen years I have attended the practice of St. George's Hospital, I have never witnessed a death after lithotomy in a child. Would this be so if the atmosphere had so depressing an effect as is surmised? The fact is, that the Hospitals of London receive a different, and a far more acute class of cases from those of country towns, and treat these cases with a success very little inferior to that obtained in the milder cases treated in country Hospitals.

I agree with Dr. Richardson, that good air, and plenty of it, is a good thing for a Hospital; but I think that nothing but harm can be done by rash and exaggerated conclusions from imaginary facts. I am, &c.,

22, Queen-street, Mayfair, Jan. 13.

T. HOLMES.

SILVER SHOWERS.

LETTER FROM DR. GEORGE D. GIBB.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the report of my case of functional aphonia, brought before the Pathological Society, in your last number, is an error of importance to be rectified. The expression is used of "*showers of powdered nitrate of silver to the larynx.*" This I did not make use of, but employed the phrase "silver showers," which signifies the application of a solution of nitrate of silver in the form of spray. The mischievous results that might ensue if the *powdered* nitrate were employed in the manner attributed to me, is my excuse for troubling you with this letter. I am, &c.

Portman-street, January 11. GEORGE D. GIBB, M.D.

CASE OF COMPOUND FRACTURE OF THE TIBIA AND FIBULA, WITH FRACTURE OF THE PUBES AND PERFORATION OF THE BLADDER—RECOVERY.

LETTER FROM MR. WILLIAM TOWNSEND.

[To the Editor of the Medical Times and Gazette.]

SIR,—I consider the following case well worthy of insertion in your journal:—On June 20, 1857, a boy aged 17 was caught in some machinery at a paper mill. He had sustained a very severe compound fracture of the middle third of the right tibia and fibula. The tibia was protruding to the extent of several inches; he had also fracture of the pubes with perforation of the bladder. On first seeing the case, my predecessor, Mr. Goodlad, wished to remove the limb; I considered him in too great a state of prostration—in fact, collapse; I therefore placed the limb as in an ordinary case of compound fracture. The following morning I found the boy so comfortable that I considered it only right to give him a chance of saving his leg. I was requested to take sole charge of the case. The catheter was passed twice daily for seven-

teen days, and then the leg was dressed and put upon a swing splint: for eight days more the catheter was passed twice daily. On September 1, 1857, rather more than ten weeks after the injury, a spicula of bone three quarters of an inch long came away per urethram, after the discharge of about a pint of blood. On September 1, 1859, I removed three and a-half inches of the tibia. In February, 1859, he walked with a stick, and in March, 1859, without either stick or crutch. At the present time the leg is about one-third of an inch shorter than the other, but equally strong.

Remarks.—I attribute the freedom from peritonitis in this case to the fact of the patient being kept on his back and the catheter frequently applied. I should be glad to hear of some similar cases.

I am, &c.

WILLIAM TOWNSEND, M.R.C.S. Eng.,
and L.S.A. Lond.

36, Bolton-street, Bury, Lancashire.

LARYNGOSCOPY IN CASES OF TUMOUR INVOLVING THE RECURRENT LARYNGEAL NERVE.

LETTER FROM DR. GAIRDNER.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have just perused in your Journal of this day, the interesting records of two cases of aneurismal disease, detected mainly by laryngoscopic examination. I am able to add to them a brief statement, not, indeed, of a case of aneurism, but one of tumour, in which this modern addition to our means of diagnosis was of great service. Some months ago, I was consulted in the case of a lady, who for ten years or more had had a moderate-sized goitre-like swelling, closely applied to the lower part of the trachea, and extending into the anterior mediastinum.

As the neck was very short and thick, owing to the obesity of the patient, the diagnosis was rather difficult; and, as a suspicion had formerly existed of disease of the heart, on account of which she had at one time consulted Sir James Clark, there was a further uncertainty as to the cause of her symptoms. These were—1. A degree of difficulty of breathing and cough, almost equally divided as to characters, between thoracic and laryngeal. 2. An alteration in the tone of the voice, and a slightly stridulous inspiration. 3. Expectoration of frothy mucus, just tinged, on one or two occasions, with blood. These symptoms were, for the most part, recent, the goitre having for many years caused her no inconvenience.

I have fully discussed the importance of these symptoms as indicating aneurism, in my "Clinical Medicine," referred to by your reporter. In this instance, no clear evidence of thoracic disease could be detected, except a slight prolongation of the first sound of the heart, which might very well be regarded as functional. I, therefore, viewed the symptoms as probably dependent upon the implication of the recurrent, on one or both sides, in the goitre, or in the surrounding thickening of the cellular tissue. The nature of the goitrous swelling being obscure, and the influence of remedies upon it uncertain, the prognosis was grave and anxious. I need say nothing about the treatment. The sudden death of the patient some time afterwards fully justified the prognosis, and a post-mortem examination rather hastily conducted, but still practically complete and satisfactory, showed that an apparently carcinomatous degeneration of the thyroid gland was the true cause of the symptoms.

The case occurred during Dr. Czermak's visit to Glasgow, and he had an opportunity of examining the larynx during the life of the patient. The parts brought into view by the laryngoscope were all perfectly sound as regards structure and anatomical relations. But the left vocal cord was absolutely motionless in inspiration, and in the formation of the voice. This observation was regarded both by Dr. Czermak and the physicians primarily engaged, as affording complete confirmation to the diagnosis of a tumour implicating the recurrent nerve.

I have for many years habitually employed a rather long forefinger in the exploration of the larynx down to the glottis, and by the method of touch have usually found it easy to acquire valuable information in regard to the state of the vocal cords and arytenoid cartilages in doubtful cases of this kind. I have rarely, if ever, found an exception to the rule, that well-marked laryngeal stridor or cough, with imperfectly closed glottis, indicates a tumour pressing on the recurrent, if the epiglottis and glottis are normal. It is partly

by giving us greater assurance on this point, and partly by developing the positive proof of inequality of movement on the two sides of the glottis, that laryngoscopy may be expected to assist our diagnosis of a difficult and doubtful class of cases.

I am, &c. W. T. GAIRDNER.

Glasgow, January 9.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 5.

Mr. PRESCOTT HEWETT in the Chair.

THIS was the annual meeting of the Society. Mr. Henry Thompson, the Financial Secretary, read the report, from which it appeared that in number of members in average attendance at its meetings, and in supply of important material for its investigation, the Society had never been in so prosperous a state as during the past year. As regards the supply of specimens, the supply had indeed been, if anything, too abundant; and the report extended to the members a gentle caution that they should be careful that the cases brought forward should be not only of interest to the exhibitor, but should be such as to legitimately claim the time of the meeting and the expense of subsequently printing their narratives. In respect to finances, the report stated that during the year a considerable addition had been made to the funded property of the Society.

The adoption of the report was moved by Dr. Johnson, seconded by Dr. Murchison, and unanimously carried.

Mr. CURLING next, in appropriate terms, moved the thanks of the Society to the retiring officers.

Dr. WILKS seconded the motion, which was unanimously carried.

The PRESIDENT next adverted to the fact, that the Society would this year lose the services of one of its highly valued secretaries; and, with a warm eulogium on his long-sustained efficiency in the post he was about to vacate, proposed a special vote of thanks to Mr. Henry Thompson.

This vote having been carried by acclamation, Mr. Thompson replied.

Dr. DICKENSON brought forward specimens from a case of SUDDEN DEATH FROM OBSTRUCTION OF THE PULMONARY ARTERY.

A young woman was admitted into St. George's Hospital, suffering from ailments supposed to be hysterical. Under ordinary measures she improved, and was about to be discharged, when it was observed that one leg was somewhat swollen. On the same day that this latter symptom was noticed she had a fainting fit whilst in the water-closet, and died before she could be got back to bed. At the autopsy, all the various viscera were carefully inspected and found healthy. On laying open the pulmonary arteries, however, they were found occupied by fibrinous clots, evidently of considerable age, which adhered to the coats of the vessel at parts, and extended even into the smallest ramifications. The femoral vein of the limb which during life had shown slight swelling, was found plugged by a long clot of old fibrin, which extended downwards into the smaller veins. The femoral artery of this limb was also closely plugged for a like extent. It was not easy to assign any cause for the occurrence of these clots. The patient had not sustained any injury; she was unmarried, and her uterus was quite healthy. There was no inflammation of the iliac veins. In explanation of the immediate cause of death, Dr. Dickenson suggested that probably the clots had for long nearly closed the vessel, and that some accidental displacement occurred, and was sufficient to cause complete occlusion. The patient had throughout complained of pain in the chest.

Dr. BRISTOWE mentioned a very similar case which had occurred some years ago under his care in St. Thomas's Hospital. In it, also, the death was quite unexpected. He thought Dr. Dickenson's explanation probably correct.

Dr. GRAILY HEWITT adverted to similar cases occurring after parturition, and inquired as to the state of the uterine veins.

Dr. MURCHISON exhibited specimens from a case of PYÆMIA WITH NECROSIS. The patient, a lad, had been admitted into the Fever Hospital

with all the symptoms of enteric fever, excepting that there was no rash. He had been ill for ten days previously, and was brought from a neighbourhood where typhus fever was prevalent. Whilst under treatment, abscesses formed with great rapidity in several different parts. One of these was connected with periostitis of one acromion process and necrosis of a small fragment. An acute abscess formed over the middle of the sternum, which had pulsation, and also filled on coughing. After this had been opened, it was found that the sternum was ulcerated and perforated. There was, however, no empyema. The boy died about a month after the commencement of his illness. Throughout there had been no rigors. At the autopsy, the sternum was found, as supposed, perforated, and quite movable at the site of disease. It was roughened over a considerable extent on both surfaces. The left sacro-iliac synchondrosis was also the seat of disease. Its cartilage was ulcerated, and the adjacent bones extensively bare of periosteum. A large abscess existed here both within and without the pelvis. In one lung was a small encysted abscess. In both kidneys were numerous small purulent deposits, but the liver and other viscera were free. Dr. Murchison suggested two hypotheses as to the primary disease: either that the lad had suffered from typhus before his admission, and that the pyæmia was, as is not very unusual, secondary to it, or possibly that the case was one of pyæmia consequent on acute periostitis. Peyer's patches were found quite healthy, so that the hypothesis of enteric fever was quite negatived.

Mr. T. HOLMES showed a specimen of

CONGENITAL TUMOUR REMOVED FROM THE NECK.

The patient, a boy, of eight years of age, came under care at the Children's Hospital. The tumour, which was of considerable size, was situated below the ear, and behind the edge of the sterno-mastoid. It had existed from birth, but had latterly begun to grow rather rapidly. It consisted in part of cysts, but chiefly of solid tissue. The fact that it was growing determined Mr. Holmes to remove it, in spite of the deep attachments which it possessed. Its excision was safely accomplished. Mr. Holmes gave the particulars of two other cases, in which congenital tumours of a similar kind had come under his notice. In one the tumour was considered to be too large for safe removal, and the child died. In the other, the position of the tumour, occupying the upper part of the neck and projecting upwards under the tongue, forbade any attempt at excision, and in this also death ensued. He referred to a paper by Mr. Cæsar Hawkins on these tumours, published in the *Medico-Chirurgical Transactions*, and stated that Mr. Hawkins seemed to consider these tumours of less serious moment than, judging from the cases now brought forward, he (Mr. Holmes) was inclined to do.

The PRESIDENT mentioned a case which had been under his care, in conjunction with the late Mr. Keate, some years ago. The tumour was congenital, and occupied the neck of a little girl, extending deeply. It was excised with the exception of one lobe, which, as it adhered to the subclavian vessels, could not be got away. The wound healed well, but some years later the small part which had been left enlarged, and constituted a cyst of great size. This cyst was treated by a seton, and afterwards suppurated. He warned Mr. Holmes that, if in his case any portion had been left, subsequent redevelopment must be expected.

EMPLOYMENT OF VERATRUM VIRIDE IN DIAGNOSIS.—Dr. Percy, in a recent lecture, detailed the great advantage he had derived for some years from the employment of the *veratrum viride* in aid of the diagnosis of diseases of the heart and chest. By preparing patients by means of small doses of this substance, functional disturbances which mask and render obscure the suspected disease are removed or suspended, so as to allow of the characteristic signs becoming discoverable. In this way he has been enabled readily to diagnose cases of incipient phthisis, pleurisy, pneumonia, diseases of the heart, etc., which he never could have had any certainty respecting without this preliminary. The *veratrum* quiets the functional disturbances, lessens the rapidity of the circulation, tranquillises the respiration, and so moderates the activity of these functions that the mind can readily define and arrange the sounds that are communicated to the ear. Dr. Percy thinks that this means will be found of great use to the officers of life insurance companies in cases of doubtful diseases of the chest.—*American Med. Times*, July 11.

OBITUARY.

FRANCIS BOOTT, M.D. Edin., L.R.C.P.L., V.P.L.S., etc.

THOUGH taking no part latterly in Professional practice, Dr. Boott's death is one which will be severely felt, not only amongst a large society of Medical men, but in the ranks of science generally. Few men were more accomplished and well-informed; fewer still more beloved and esteemed, whether for the power and will to serve or to please, or for the sterling qualities of his mind.

Dr. Boott was born in the year 1792, in Boston, Massachusetts, of British parents, his father being an Englishman and his mother a Scotch lady. His parents being in good circumstances, young Boott, after completing his classical education at Harvard College, was sent over at seventeen to England, that being then, as now, the grand tour to many young Americans. Here his studious habits and literary talents soon led him to form intimacies only with persons of like pursuits; and his habits were thus early copied from models so judiciously chosen, that he ever after regarded these counsellors of his youth as types of refinement and moral worth. For several years he voyaged backwards and forwards between England and America, making life-long friendships in both countries, but especially in this, when Sir Joseph Banks' house offered great attractions to young men, whether of literary or scientific tastes; and where Sir James Smith, President of the Linnean Society, and Mr. (now Sir William) Hooker keenly encouraged his botanical tastes.

In about 1820, when upwards of twenty-eight, already married, he determined upon studying Medicine, and placed himself under the tutelage of Dr. John Armstrong, in London. Thence he removed to Edinburgh, where he finished his education, and took his Doctor's degree in 1824.

On his return to London, he commenced practice, and accepted the lectureship on botany in the Webb-street School of Medicine; this chair, however, though admirably conducted, he did not long hold. He also published his lectures on *Materia Medica*; and more lately, at the dying request of his friend Dr. Armstrong, he edited his life, and published with it a treatise of his own on "Marsh Fevers," illustrative of Dr. Armstrong's views. This latter part of the work is one of considerable eruditive merit; it treats largely of the fevers of the United States and of Europe, and of the plague, under the several aspects of that disease, which he traced from Egypt and Syria, through Italy, France, and Holland, to England, showing that its type was always that of a periodic fever, but that its symptoms varied according to the climate of the several countries mentioned.

For seven years Dr. Boott practised very successfully in London, being especially noted for his treatment of fevers, in which he followed the practice of Dr. Armstrong in giving abundance of air, etc., to the patient,—a course which, at that time, was vehemently objected to by the Profession at large. In other respects, too, he was a judicious innovator, being one of the first to discard the black coat, white neckcloth, knee-breeches, and black silk stockings, for the ordinary costume of the day. This was then a blue coat, with brass buttons, and yellow waistcoat, which he continued to wear to the last; and thus, by outliving the fashion, as he had forestalled it, he came to be as well known in 1860 as he had been in 1830.

Dr. Boott early retired from practice, and, having inherited a competency, he devoted himself for the last thirty-five years to the cultivation of his literary and classical tastes, to the study of botany, and to the duties of a Member of the Council of University College, and Secretary and Treasurer of the Linnean Society. In the latter capacities, especially, he was most highly respected,—conducting the business of the College and of the Linnean Society with singular tact, skill, and judgment; neither giving nor taking offence; and winning the esteem and cordial support of his brethren in office during a very long period of active and gratuitous services. Of the Linnean Society especially he seems to have been a distinguished member, no less for the disinterested zeal with which, as a personal friend of its founder, Sir James Smith, he devoted himself to its financial welfare, or as a cordial friend of science and scientific men, interested like himself in its meetings and publications. His portrait hangs on the Society's walls, and his blue coat and bright buttons are with many inseparably connected with its meetings.

Dr. Boott's botanical labours were entirely confined to the study of the great genus *Carex*, of which upwards of 600

species are known, and in which he took the keenest interest, spending many hours daily in analysing them, and laying out large sums of money on their illustrations. Much of his labours have seen the light in a large folio work, in two volumes, containing upwards of 400 plates and descriptions of *Carex*, all produced at his own expense, and distributed with a lavish hand amongst English, European, and American botanists. This is, indeed, a magnificent work, and will immortalise its author. To it, however, we regret to add, the curtailment of his life is in some measure undoubtedly due, the close application necessary for its successful elaboration having materially tended to enfeeble his never very vigorous frame. The immediate cause of his death was disease of the right lung, induced by pneumonia, of which he had two severe attacks, one in 1839, which permanently injured his health, and prevented his undertaking any very laborious exertion thereafter, the other in June of the past year, from which he never rallied, and of which he died on Christmas-day, at the age of seventy-one years.

In person, Dr. Boott was very tall and thin. His manners were singularly pleasing, and his expression refined in the highest degree. His countenance was, indeed, very much a reflex of his mind, which was singularly polished, cultivated, and sensitive. Nothing delighted him so much as companionship with the young, to whom his kindly manners, generous sympathies, and considerate conduct much endeared him. His love of art was no less strong than of literature and science. His house was full of excellent and always-pleasing pictures, and his large library was as select as possible. In connexion with literature, a most characteristic act of his was to erect a tablet to the memory of Henry Kirke White, of whom and whose family he knew nothing personally, but whose life and poems he ardently admired, and to whose memory no tribute of the kind had been paid.

Such is a meagre record of the life of a man whose death is felt by a large circle as a personal loss, and who was, in every sense, an ornament to the Profession of Medicine.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, January 7, 1864:—

Joseph Morris, Birmingham; Joseph Smith, Lozells, Birmingham; Henry McKenzie Parkes, Guy's Hospital; George Elkington, jun., Birmingham.

The following gentleman also, on December 31, 1863, passed his First Examination:—

Richard Rothwell Daglish, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BURKE, WILLIAM M., M.D., has been appointed Medical Registrar for Ireland.

CLELLAND, JOHN, M.D., has been appointed Professor of Anatomy in Queen's College, Galway.

EADE, PETER, M.D. Lond., has been appointed Physician to the Jenny Lind Infirmary for Sick Children, Norwich.

FERNANDES, A. L., M.R.C.S. Eng., has been appointed Resident Medical Officer to the Sheffield General Infirmary.

GIBSON, R. E., M.R.C.S. Eng., has been appointed Surgeon to the Jenny Lind Infirmary for Sick Children, Norwich.

OWLES, JAMES A., M.D. St. And., has been appointed House-Surgeon to the Hospital for Women, Soho-square, W.

PATERSON, WILLIAM, M.D., has been elected House-Surgeon to the Chorley Dispensary.

RITCHIE, ROBERT P., M.D. Edin., has been elected Physician to the Hospital for Sick Children, Edinburgh.

SEABROOKE, WILLIAM, M.R.C.S. Eng., has been appointed Resident House-Surgeon to the Brighton and Hove Lying-in Institution.

WHITE, CHARLES, M.R.C.S. Eng., has been appointed Surgeon in Ordinary to the Dispensary, Warrington.

DEATHS.

CORY, SAMUEL S., M.R.C.S. Eng., at Bridport, Dorset, on December 17.

CROW, J. W., M.R.C.S. Eng., Staff Assistant-Surgeon, Army, at Madeira, on December 2.

EVANS, WILLIAM, F.R.C.S. Eng., at Broomfield-house, Herne, Kent, on December 30, aged 47.

FOSTER, SAMUEL, L.R.C.S. Edin., at Northwich, Cheshire, on December 16.
 HANNAH, JAMES LEE, M.D., at Pavilion-parade, Brighton, on January 10.
 HARMAN, EDWARD B., M.D. Edin., at Weeting Rectory, on January 6, aged 62, late of Pembridge-place, Bayswater.
 HASLEWOOD, GEORGE D., M.R.C.S. Eng., at Cradley-heath, Stourbridge, on December 30, aged 64.
 HOBART, S. HEMRY, M.B., T.C.D., at Marlborough-street, Cork, on January 9.
 JAMES, JOSEPH W. W., L.R.C.P. Edin., at 25, Nelson-terrace, Stoke Newington, on January 9, aged 37.
 NEWBIGGING, PATRICK S. K., Surgeon, at 29, Heriot-row, Edinburgh, on January 10.
 O'MULLANE, A., M.D., at Bourke-street West, Australia, on October 21, aged 51.
 PENBERTHY, JOHN, jun., M.R.C.S. Eng., at Redruth, Cornwall, on December 17, aged 29.
 SARGINT, RICHARD, M.B. T.C.D., at Clonmel, Ireland, on January 4.
 STAIG, JAMES A., late Surgeon, Bengal Medical Staff, H.M.E.I.C.S., at 6, Clifton-terrace, Maida-hill, W., on January 8, aged 52.
 THOMSON, D., M.D., at Abbotsford-place, Glasgow, on December 27, aged 82.
 WILSON, ROBERT, M.D. St. And., at Elmbank, Dunoon, Argyleshire, on January 3.

WEST LONDON HOSPITAL.—Several changes have occurred at this Hospital during the past few months. Dr. Gibb and Mr. Christopher Heath, who were appointed to the Westminster Hospital, have been succeeded by Dr. Logan and Mr. W. F. Teevan; whilst the offices of Junior Physician and Junior Surgeon, vacated by these last-named gentlemen, are now filled by Dr. Maudsley and Mr. Fairlie Clark.

NEW TERMS.—The rapid progress of science naturally compels the frequent coinage of new terms; but this procedure becomes somewhat ridiculous when applied for the unnecessary multiplying of designations. The last specimen of this kind which we have observed is "Puericulture," employed by M. Caron, at the Medical Congress at Rouen, to designate "the science which teaches the mode of bringing up children."

THE PRUSSIAN UNIVERSITIES.—In the summer of 1863, the following were the number of Medical Professors and Students in the Prussian Universities:—Griefswald Professors and Privat-Doctores, 14; Students, 190; Halle Prof. and Priv. Doc., 15; Students, 83; Breslau Prof. and Priv. Doc., 22; Students, 130; Königsburg Prof. and Priv. Doc., 14; Students, 116; Berlin Prof. and Priv. Doc., 49; Students, 357; Bonn Prof. and Priv. Doc., 18; Students, 122. The entire number of the Teachers was 132, 50 being Ordinary Professors, 20 Extraordinary Professors, and 62 Privat-Doctores. The Medical Students were 998, 907 being natives, and 91 foreigners. The entire number of the students of these Universities amounted to 6309 (829 of this number being foreigners), so that the Medical Students constitute 15.8 per cent. of the whole.

RABIES IN BERLIN.—The Berlin police has published a statement in order to show the great efficacy which the plan of muzzling dogs exerts in the prevention of the spread of rabies. This plan was commenced being carried out at the end of 1853, since when the number of cases coming under the cognizance of the police has vastly diminished. Thus, in 1852, the number of cases of rabies reached 107, and in 1853, 94; while, since this latter year, they have occurred in the following numbers:—1854, 1; 1855, 3; 1856, none; 1857, 2; 1858-60, none; 1861, 5; 1862, 2; and 1863, 10. It is, however, to be feared that epidemic influences have been here, in some part, overlooked; for in the years 1846-51 there were nearly as few cases observed, although police interference did not then exist.—*Preuss. Med. Zeit.*, No. 48.

BONE-SETTER V. DOCTOR.—The Committee of the Newport (Ireland) Dispensary met, last week, to investigate a charge of malpraxis, preferred by Mr. Twiss, one of the committee, against Dr. Harris, one of the Medical Staff. The charge was, that Dr. Harris had said that a boy's "arm was neither broken nor dislocated;" and, further, that the Doctor had entered the case in the Medical Registry as a "contusion of the elbow." Mr. Twiss' "witnesses" were—Mr. Webster—his dictionary—brought to prove somehow, we suppose, that the injury could not have been a contusion, and to "show the committee the meaning of the word;" the lad's father, "a respectable farmer," who had "found the spindle of the elbow out of place;" and Delany, who "had been a bone-setter since he was born, and his generation before him." He had spurned the Doctor's lotion, as being as useless as "so much ditch-water;" "he got some soft water" (in this country ditch-water generally is soft water), "and laid the inflamma-

tion in two minutes, and set the bone (by aid, we suppose, of the soft water) in three." The committee declined to receive Mr. Webster's evidence altogether, and would only hear the bone-setter at the request of Dr. Harris, who, probably, thought it would be a pity to lose the fun of it. The boy's mother gave evidence of the Doctor's "careful examination" of the case, and his attention to it. The committee declared that they would not take the opinion of fifty quacks against the Doctor's opinion, and resolved that his statement was most satisfactory and conclusive. We are happy to compliment the committee on their intelligent and strenuous support of their officer. Such conduct on the part of a managing committee is, unfortunately, somewhat rare, and redounds to their honour.

ADVERTISING QUACKS.—A GOOD JOKE.—The following has been sent us by a correspondent, who assures us that it is literally true. The "Dr." is a well-known advertising quack:—"Some little time since the *pseudo* 'Dr.' sent his filthy pamphlet, entitled 'Spermatorrhœa,' etc., to the private residence of a friend of mine, himself a Medical man. Of course the quack pretends to detect spermatorrhœa by an examination of the urine, and this is one of his directions:—'Those having doubts as to their state of health are invited to enclose twelve postage stamps, when a phial, fitted in a box, will be sent (prepaid), in order that the same may be filled with fasting urine, and returned to the author, who will make the usual microscopical and chemical tests, and transmit his opinion of the case free of cost.' My friend forwarded the required stamps, and he received a 'phial,' which he returned filled with horse's urine, and in a few days he received the following most impudent letter, signed by the 'private secretary':—'Having microscopically and chemically examined your urine, and also well considered your case, I am decidedly of opinion that your health is critical, and, unless immediately attended to, impotency and its concomitant evils must ensue. At the same time I am glad to state that your health (mental and physical) can be restored, provided you adopt the means which I have found so eminently successful in similar cases. The treatment required in your case will be 'local and constitutional,' therefore a curative instrument is most essential. If the means are applied as directed I can guarantee a cure.—Yours, etc.'—The 'curative instrument' is, of course, an 'American machine' for the cure of spermatorrhœa, price three guineas."

A SUPERNUMERARY EYELID.—In the normal condition the conjunctiva forms at the large angle of the eye a semilunar fold representing a kind of rudimentary eyelid; and in certain subjects a supernumerary eyelid has been found at the smaller angle of the eye, formed by a thin, triangular fold of the conjunctiva. M. Dubois has figured such a case in the *Annales d'Oculistique*, vol. xxxiv., and at the external angle of the eyelids a fold of the conjunctiva, which extended half a centimetre in front of the conjunctiva, to which it did not adhere, constituting a fourth eyelid. M. Fano presented a somewhat similar case at the recent Ophthalmological Congress, occurring in a child four months old. No other anomaly was observed either in the visual or other organs. On the right side, in front of the external half of the sclerotic, there was observed a semilunar fold, with its concavity turned inwards, which projected much more when the lower eyelid was depressed. When the eye was rolled inwards, the fold rolled with the globe; but as it never reached so far as the circumference of the cornea, it did not interfere with vision.—*Ann. d'Oculistique*, 1863, No. 1.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Fraser and Andrews' Fund.—The following subscriptions have been received at the office of the *Medical Times and Gazette*:—Messrs. Churchill, £3 3s.; Dr. Dyer, £1 1s.; Dr. Tunaley, £1 1s.; Mr. Pearse, £1 1s.; Mr. Dingley, £1 1s.; Dr. Bissett Hawkins, £2.

Mary Nothing should go to another gin-shop, or else turn teetotaler.

R. H.—Degrees of Ph.D. are granted by the Philosophical Faculties of all German Universities. The Tübingen degree is easiest to procure, and the fee for it is only about £9. The most valuable is the Berlin degree, which is only granted to candidates after having written an essay of merit on some philosophical subject in Latin, and after a rigorous examination in the different branches of philosophy, both *viva voce* and in writing, also in Latin. The fee for the latter degree is about £25.

"The Eight Hundred Fevers!"—Mr. Syme was evidently duped by a student into making this absurd statement regarding Dr. Laycock's nosology. He now has corrected the error, and "understands there are only 600." He is still wide of the mark, and only exposes himself to damaging criticism, by adopting such wild, second-hand information.

A Constant Reader.—The Act states that the carman is not bound to weigh any quantity of coals less than 560 lbs., and that the distance at which the coals are delivered must not be more than 25 miles from the Post-office, St. Martin's-le-Grand. In provincial towns beyond this radius the carman is not bound to weigh.

Medical Advertising.—The following is from the *Liverpool Mercury* of the 9th inst. We do not find Mr. J. Pearson, of 66, Great Howard-street, in the Register or in the Directory. For the credit of the diplomas appended to the name, we hope that one of the "oldest Practitioners" in Liverpool is as mythical a personage as the "oldest inhabitant":—

"THE KNOWLEDGE OF A DISEASE IS HALF ITS CURE!—Consult J. Pearson, Surgeon, M.R.C.S.L., L.A.C., one of the oldest Practitioners in Liverpool, at the Medical Hall, 66, Great Howard-street. Advice gratis between the hours of ten and twelve a.m. and six and eight p.m. Resident Surgeon.—Proprietor, J. Bebbington."

Erratum.—In Professor Simpson's lecture on Acupressure, p. 27, for "Dr. Turner, of Leith," read "Dr. Turner, of Keith."

A CAUTION.—CAVEAT EMPTOR.

Is there a devil? 'Tis supposed there is,
And men believe in the hypothesis;
Most will emphatically answer—"Yes."
How true those words which whining school-boys learn by
Rote—*Descensus facilis Averni,*—
Sed revocare gradum, labor est, (a)
Say visitants, and they, of course, know best!
May Pluto's shades, grim, gloomy Tartarus,
Never be visited by one of us!
Perhaps his majesty satanic can
Claim as his own that diabolic man,
The shameless, advertising charlatan.
Though devil's work he *now* does well and fast,
Satan, ungrateful, may forget the past,
And turn against his *quondam* friend at last.
Those advertising quacks who live by gammon,
And, both by day and night, hunt after Mammon,
May be requited for their deeds of evil,
And be consigned to their dear friend, the devil.
Many there are who, failing to repent,
May find themselves in this predicament.
Quacks, by the aid of many a decent journal,
Disseminate obscenity infernal.
Such journals aid, unwittingly, those scamps
Who advertise their filth for "postage stamps."
The stamps are sent by hypochondriacs,—
Most pitiable men,—half maniacs,—
The best of patients for designing quacks;
And nerveless valetudinarians
Become the dupes of these barbarians.
No sooner is the filthy trash received
Than it is read, and—worse than read—believed.
A medley 'tis of filth, mendacity,
Pledging—not much—the quack's *veracity*,
His *honour*, ay, and e'en his *reputation*,
To effect a speedy, perfect restoration.
His honour, truth, and reputation! pooh!
Where is the pawnbroker, I wonder, who
Would on such merchandise advance a *sou*?
Of course, the reader finds *his* case recorded,
But overlooks this fact, that quacks are sordid;
And thinking their *one* statement is sincere,
Namely, that they possess a panacea,
He sends his fancied case—he sends a fee—
"M.A.," factotum, answers *pro* "M.D."(b)
Thus he begins his cant, by way of preface—
"I've well considered your distressing case
(In phrases stereotyped he writes to all)—
Your case, indeed, is very critical;
And, failing to adopt my means of cure,
I fear, in your case, what you dread is sure.
Still, there is hope if you adopt my means—
Buy one of my '*American machines*,'—
A means, as curative, the most potential,
And, I may add, in your case, most essential.
Adopt this plan, then; on my reputation,
I guarantee your speedy restoration."
His other machinations would, if told,
Prove that he has an "itching palm" for gold.
O, heaven! that such companions thou'ldst unfold,
And put in every honest hand a whip—
(Their "withers are unwrung" by censorship)—
"To lash the rascals naked through the world,"
That they to infamy might all be hurled!
Need it be said, if men will trust such scamps,
They'll rue the day they sent their "postage stamps?"
'Tis better far to bear the ills they have
Than be the dupes of a designing knave.
Ab uno disce omnes, anglicised,
Means, men will by one and all be victimised;
And he who does become these fellows' dupe,
Will be a most egregious nincompoop.

ANTI-QUACKERY.

(a) *Facilis descensus Averni, sed revocare gradum, hoc opus, hic labor est.* The fiction may be realised in its application to every mortal soul.

(b) These "honourable men" all style themselves "M.D." and they also keep a "private secretary," generally a "M.A.," whose letters are unquestionably true, as he is undoubtedly a Master of Arts.

LIME IN SUGAR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me a little space to say a few words on the subject of lime in all sugars, refined and raw? In the colonies, no juice is boiled without so much temper lime. Such can never be thoroughly extracted. (The more one studies chemistry, the more will this fact be found true.) A young chemist here urges the scooping out the pith of the cane before squeezing. Such would require a process of first splitting the cane in two or three; then vacuum-pans of fireclay would be a great additional improvement to aid the boiling and concentration of juice. Sugar consumers get tartar on their teeth, and calculus shows itself at times in urine, etc.; and more from lime in sugar than from most other sources.

I am, &c.

Butc-road, Cardiff. C. M. DICK, late Sugar Planter in Trinidad.

THE MEDICAL REGISTRATION ASSOCIATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—May I request a small space in your paper once more to call the attention of the Profession to what I cannot help considering a great stain upon our honour and liberality? I allude to the debts still remaining on account of the Medical Registration Association. These debts, it must be remembered, were incurred in a laudable attempt to render the Medical Act of some *real* use to the Profession generally, and not for the advantage of the Committee. It does seem hard, therefore, that those who took an active part (especially our respected treasurer) should be subjected to the annoyance of receiving writs, summonses, etc., on account of these outstanding liabilities. The appeal made some time since was so feebly responded to, that at a meeting of the Committee last evening it was determined to endeavour once more to urge upon every member of the Profession the necessity of giving as freely as possible, in order that this stigma may no longer rest upon us. I trust we may also hope for the great benefit of your powerful advocacy, for in a matter of this kind we must depend in a great measure upon the kind and liberal support of the Medical press.

I am, &c.

20, Cross-street, Islington, Jan. 9. N. H. CLIFTON.
Subscriptions may be sent to J. Lavies, Esq., 5, Great George-street, Westminster.

SYMM v. FRASER AND ANDREWS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am sorry to find that Dr. Tunstall has written you another letter necessitating a reply from me, which, however, I shall endeavour to make as brief as I can. He says, the business of the police inspector at Bath "was to find the whereabouts of a tenant of Dr. Fraser's," and further on he adds, "the same means employed to find the runaway tenant would easily have discovered the names of Mrs. Symm's Medical attendants at Bath." The inference from these observations is, that I either employed, or knew of the employment of, the means alluded to. I therefore wish to state, that such an insinuation has no more foundation in fact than that "travelling gout," or moonshine, was the cause of Mrs. Symm's illness. I employed no means to discover Mrs. Symm's "whereabouts." I could have had no motive for doing so: she was no "runaway tenant" of mine, having always paid her rent punctually, and when she went to Bath left her house full of furniture; but as it was not securely fastened up, and strange rumours were circulated in the neighbourhood respecting Mrs. Symm's disappearance, the London police took the matter up, and communicated with Mrs. Symm through the police at Bath. But neither my solicitor nor myself knew anything of this until the second day of the trial, on the afternoon of which day we received a telegram from Bath, describing the sad condition in which Mr. Bond, the inspector of the Bath police, had found Mrs. Symm on January 22, 1862, two days before Dr. Tunstall saw her; and from the details of what passed when Mr. Bond saw the plaintiff, I have no hesitation in saying, that I have far more confidence in the correctness of his etiology and diagnosis on the 22nd than in that of Dr. Tunstall on the 24th, especially as, since the trial, I have heard the opinion of another Medical Practitioner, under whose care Mrs. Symm was after consulting Dr. Tunstall, but whom she very prudently did not subpoena to give evidence.

Dr. Tunstall says, "I knew nothing of the presumed facts of the case until I arrived in London, in obedience to subpoena." Such being the case, it is very surprising that, when Mrs. Symm called on me in February, 1862, more than twelve months before the subpoena was served, she told me she had consulted "two Doctors in Bath," and narrated to them the particulars of her illness, etc., in London, and that they said she had been most improperly treated,—that her illness had not arisen from drink, but was occasioned by gout.

I am fully aware of the many obscure symptoms presenting themselves in a patient with a gouty diathesis. I also know that, when such a diathesis exists, many symptoms, the cause of which is difficult to ascertain, are ascribed to suppressed gout; but I have yet to learn that the usual condition of a person after an attack of delirium tremens, and a subsequent free use of stimulants, may be reasonably mistaken by any experienced Practitioner for "travelling gout;" and when such a purely visionary theory is brought forward in a court of justice, in a case where, if credited, it might injure another professional man, and in the face, moreover, of the most indisputable evidence as to the cause of every symptom under which the patient laboured, I maintain that such conduct is highly reprehensible; and in this opinion I know I am supported by every right-thinking member of the Profession.

In justice to Dr. Tunstall and myself, I wish to point out an evidently unintentional error contained in his letter. He says, "Dr. Fraser has every reason to congratulate himself that the course of justice was not affected by his forcible advocacy of a bad cause." Dr. Tunstall, no doubt, intended the word "his" to apply to Mr. Chambers, whose name is mentioned in the immediately preceding lines.

I am, &c.

D. FRASER, M.D.

"AUDI ALTERAM PARTEM."—THE CASE OF CANDLER v. PEAT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Had it not been for the interposition of numerous friends I should not have condescended to notice the attempts made in newspapers to lead the Profession and the public to believe that I was a party to the institution of this action, in which I have always studiously avoided interfering.

Having put myself in communication with Mr. Bennett, my former assistant, I received the accompanying letter, which fully explains the facts, and which, I think, should satisfy the Profession and the public

that I had no wish to appear in the case, but did everything in my power to keep out of the contention.

Regarding the letter I wrote to Mr. Bryant on March 27, 1863, I have merely to state that, in doing this, I was solely actuated by pure motives for the benefit of suffering humanity; that my only object was to ascertain if he could suggest any further mechanical contrivance for Candler's relief; and that the communication was a confidential one to Mr. Bryant as a consulting Surgeon, which, I understand, was demanded from him previous to the trial, although not produced in court, and published, not only without Mr. Bryant's sanction, but after such had been asked and refused. This, the accompanying note from Mr. Bryant, will sufficiently prove.

Having said thus much in order that I might free myself from the imputation attempted to be impressed on the minds of my Professional brethren and the public, I have merely to add that I shall not enter into any further correspondence on the subject, having now given, once and for all, an emphatic denial to the unwarrantable charge against me.

Trusting you will find a space for these communications in your Journal,
I am, &c.

Manningtree, Essex, January 12. JAMES HENRY SMITH, Surgeon.

(Copy of Mr. Bennett's letter.)

"Chesham, Bucks, January 11, 1864.

"My dear Mr. Smith,—I was very sorry to see this morning that it is attempted to impress on the minds of the Profession and the public that you were the instigator of the trial of Candler *versus* Peat. Being your assistant at the time, and as I happened to be the person who answered Candler's summons to attend him, I must be allowed to have a knowledge of the facts of the case. Now, I think it right that I should explain to the Profession that you always expressed your unwillingness to have anything whatever to do with Candler's case, and, when you heard that an action was pending, you at once expressed your determination not to have any concern in the matter. More than this, you repeatedly sent me to tell Candler that you would neither appear in the case nor have anything whatever to do with it. On my first visit to Candler, he told me that he accidentally met a legal gentleman, who had occasion to come to Mistle, who asked him why he was lame, and on Candler telling him of his case, he (the lawyer) asked him why he did not make the Surgeon pay for it, as he was sure he could recover damages. This, I believe, was the first instigation of the action. I am also aware that you did not fully examine Candler's foot, but referred him to several other Surgeons. The above ought, I think, to prove to the public that you endeavoured in every way to keep out of the matter, as I am confident you did.

"Your frequent visits to Candler's house in attendance on his son might possibly lead the people in the neighbourhood to suspect that you were encouraging Candler to bring this action, of which I know you to be perfectly innocent. I send you this letter, and you can use it if you think proper. With kind regards,
I remain, yours faithfully,
"J. H. Smith, Esq." "HUGH BENNETT.

(Copy of Mr. Bryant's letter.)

"2, Finsbury-square, January 11, 1864.

"Dear Sir,—Your partner, Dr. Cook, has just called on me respecting the publication in some papers of a private letter I received from you on March 27, 1863. I have no hesitation in stating that such a thing has been done without my sanction. Yours truly,
THOMAS BRYANT.

"J. H. Smith, Esq."

COMMUNICATIONS have been received from—

A CONSTANT SUBSCRIBER; JOHN FOSTER, Esq.; T. RULE, Esq.; Dr. J. F. MINER; Dr. CHARLES KIDD; Dr. TURNER; ANTHROPOLOGICAL SOCIETY; C. M. DICK, Esq.; T. J. WALKER, Esq.; Dr. ALTHAUS; THE YORK STAR; Dr. CHARLES SMART; APOTHECARIES' HALL; Mr. H. STANLEY GALE; Mr. J. RICHES; Mr. W. RIDDELL; Dr. E. G. WAKE; Dr. E. ROBERTS; MESSRS. ROBINSON and KNIGHT; Dr. W. T. GAIRDNER; ROYAL INSTITUTION; T. HOLMES, Esq.; HARVEIAN SOCIETY; A CONSTANT READER; THE ANTI-TRANSPORTATION LEAGUE; HENRY THOMPSON, Esq.; Mr. BATTERSLEY; Mr. R. L. BENGLEY; Dr. J. DEANE; Mr. F. H. JERVIS; THE JUNIOR MEDICAL SOCIETY; Dr. J. RATRAY; Mr. T. J. STARLING; Dr. R. ADAMS; Dr. R. LEYS; Mr. R. CRAVEN; Mr. R. W. MARTYN; Mr. T. S. BOURNE; Mr. T. NICOLL; Mr. J. J. CLAPCOTT; Mr. C. DANDY; Mr. J. W. GREENWOOD; Mr. J. H. LAMBRICK; Dr. GRIGOR; Dr. J. R. THOMSON.

BOOKS RECEIVED.

Edinburgh Veterinary Review. January, 1864. Edinburgh: Maclachlan and Co.

* * * Contains, as usual, much to interest the general Medical students as well as those engaged in the Veterinary branch of our art.

Homes without Hands. By the Rev. J. G. Wood, M.A. Part I. London: Longman and Co.

* * * An interesting account of the habitations and the life and manners of moles, rabbits, prairie dogs, and other animal-builders.

A Manual on Extracting Teeth, etc., etc. By Abraham Robertson, D.D.S., M.D. Philadelphia: Lindsay and Blakiston. 1863.

* * * This is a sensible and practical little work on a branch of dentistry usually rather hurried over by systematic writers.

Transactions of the Odontological Society. Vol. III. London: 1863.

* * * A bulky volume, exceedingly well got up, and containing, besides woodcuts, some beautiful engravings by Bagg, apparently on steel. It embraces the years 1861-2 and 1863, and consists of communications on most important subjects in connection with dental pathology and Surgery.

The Social Science Review. New Series. No. I. January, 1864.

* * * This, the first number of a new periodical, edited by Dr. Richardson, whose powers of literary labour seem perfectly superhuman, is of considerable interest, and we cordially recommend it to our readers. Its contents are not strictly Medical in character.

A Manual of Phonography, or Writing by Sound. By Isaac Pitman. Eleventh Edition. London: F. Pitman, 20, Paternoster-row.

* * * The English language has some sounds with no simple letter to match, and more than one letter to some sounds. Mr. Pitman will show how to adapt to each sound some letter or sign of so simple a character that the pen may trace them as fast as the mouth can utter them.

The Half-Yearly Abstract of the Medical Sciences. Vol. XXXVIII., July to December, 1863. London: Churchill and Sons, New Burlington-street.

* * * On comparing together Ranking's and Braithwaite's well-known half-yearly abstracts, we are puzzled as to which deserves preference. Ranking's is rather fuller, Braithwaite's possibly a little clearer; but both are good, and if the Practitioner be in any doubt, he should buy both.

Edinburgh Medical Journal. January, 1864. Edinburgh: Oliver and Boyd.

* * * Mr. Syme's recent Observations on Medical Education; a good series of notes as to *Veratrum Viride*, "*Tinct. Boleti Laracis Canadensis*," *Sarracenia Purpurea*, and *Carbolic Acid*, showing the small value of the three former drugs, by Dr. J. Watson; a valuable paper on the Source of *Hæmorrhage* in a Case of Fibrous Tumour of the Uterus, by Dr. Matthews Duncan; and some reports as to *Acupressure*; with Reviews and general news, make up a capital number.

The American Journal of Ophthalmology. Vol. I. New York: Baillière Brothers. 1863.

* * * The Editor, Dr. Homberger, remarks, that "the publication of a new journal, in the midst of a great civil war, devoted to a specialty neglected in a country where hitherto the names of specialist and empiric were identical, by an editor who is not entirely master of the language in which he publishes his journal, and independent enough, from the very outset, not to stoop to advancing the interests of the journal by placing it under the protection and influence of a clique, was certainly, from the beginning, not a very promising enterprise." It appears that the periodical has hitherto been irregular in its issue, but will, for the future, be regularly brought out trimestrially.

Observations on the Present State of Medical Education, with Suggestions for its Improvement. By James Syme, F.R.S.E. Edinburgh: Edmonston and Douglas. 1864.

Consumption: its Causes, Prevention, and Cure. By Shepherd Fletcher, M.D. Manchester: D. Kelly. 1864.

Pharmaceutical Journal. January, 1864. London: John Churchill and Sons.

APPOINTMENTS FOR THE WEEK.

January 16. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

18. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.
MEDICAL SOCIETY OF LONDON, 8½ p.m. Meeting.

19. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. R. Lee, Esq., B.A., M.R.C.S., and T. Bendyshe, Esq., M.A., "On the Extinction of Races."
JUNIOR MEDICAL SOCIETY OF LONDON (King's College, Strand), 8 p.m. Mr. Fowler, "On Pyæmia."
PATHOLOGICAL SOCIETY, 8 p.m. Meeting.
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, "On Experimental Optics."

20. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.

21. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, "On Experimental Optics."

22. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 8 p.m. W. R. Grove, Esq., Q.C., "On Boiling Water."

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN,

By J. Y. SIMPSON, M.D., F.R.S.E.,

Professor of Medicine and Midwifery in the University of Edinburgh.

ON ACUPRESSURE.

(Continued from page 56.)

Second Objection.—Acupressure only Adapted for Occlusion of Small Arteries.

Professor Erichsen, in his admirable treatise on "The Science and Art of Surgery," states that, though acupressure is, in the case of small arteries, "unquestionably a safe as well as a convenient and easy method of suppressing bleeding," but "for arteries of large size, as the femoral, it yet remains to be shown that acupressure can be depended upon as a mode of restraining hæmorrhage equally safe with the ligature." Already, however, acupressure has been repeatedly employed in stopping hæmorrhage from the largest vessels ever opened in wounds, and that as readily, and as successfully, as from the smallest bleeding arteries. It has been used repeatedly in all the larger amputations. I know of at least ten cases of amputation of the thigh in which the femoral and all the other arteries of the stump were secured by acupressure.

Third Objection.—Great Number of Needles sometimes Required.

I have heard it urged that some wounds, as amputation wounds, and especially where the operation has been performed for some pathological disease, the number of bleeding arterial orifices is sometimes too great to allow of acupressure being employed. Loder, Cloquet, and others have described cases where sixteen, and even twenty, ligatures have been found necessary after amputation. Sixteen or twenty points in which the Surgeon voluntarily set up a process of local strangulation and sphacelation, of ulceration and suppuration; and twenty ligature or seton threads tied to these points! What chances are there of such a wound going on prosperously and successfully? If sixteen or twenty needles were ever requisite, their use, at all events, would be followed by no such unfortunate local lesions as the ligature inevitably produces. But, in such cases, acupressure further presents advantages that can scarcely be claimed for the ligature, for one needle is occasionally capable of staunching the flow of blood from two or more separate orifices. In proof of this, I might refer to Case 1; or let me adduce another instance from the practice of a most able and accomplished provincial Surgeon, Mr. Dix, of Hull.

Case 11.—Amputation of the Arm.—The operation was necessary to save the patient's life, on account of severe and old-standing disease of the elbow-joint, etc. The patient was himself a very unhealthy, ill-conditioned subject, and prone to suppuration. Eight vessels were secured by the acupressure needles. One of the needles was made to compress two vessels in the posterior flap, at some distance apart. The two needles placed in the anterior flap closed three arteries. The last of the needles was not withdrawn till five days after the operation. During the healing of the wound the whole amount of purulent discharge did not exceed two drachms, and this came exclusively from the tracks of the retained needles. There never was any from the surfaces of the flaps. (*Medical Times and Gazette*, 1860, vol. i., p. 547.)

In reference to the objection we are considering, let me here add, that possibly the day may come when in some amputations an acupressure needle or needles will yet be passed—immediately before the operation—half-an-inch, or an inch or more, above the proposed line of the wound, so as to shut the principal artery or arteries of the limb, and render the whole operation comparatively bloodless. If so, these needles would serve, at one and the same time, the double uses for which the tourniquet and arterial ligatures are employed, and would, at the same time, leave the wound free from the presence of any hæmostatic foreign body whatever. In weak subjects, incapable of standing any loss of blood, "a suggestion has been made," says M. Velpeau, "to place a ligature upon the principal artery of the limb before commencing the incision of the soft parts. M. Blandin," he adds, "gives an example of this practice, which is still followed at the Hospital of Beaujon by M. Marjolin."—(*Médecine Opératoire*, vol. ii.) The deliga-

Vol. I. 1864. No. 708.

tion of the principal artery of a limb, as of the femoral, is an operation which itself is attended with considerable risk to life; but the acupressure of it is probably, on the contrary, alike comparatively free from difficulty and danger.

Fourth Objection.—Death of the End of the Bone.

As an objection not so much against acupressure as against the probability of union by the first intention following its use in amputation, Mr. Spence—one of our most careful and successful Surgeons—has argued that the "difference of textures in the stump was the principal cause of the suppuration; the end of the bone had to be rounded off; in this process portions died, and it often happened that, long after the ligatures had come away, discharge was kept up by the presence of little bits of dead bone."—(*Edinburgh Medical Journal*, January, 1864, p. 666.) Now, that the end of the amputated bone does not offer anything like an insuperable obstacle to the primary union of stump wounds, is proved by the admitted fact, that such wounds, when ligatures are employed, do sometimes, however rarely, heal at all points except where the ligatures are found. I have already, in this lecture, further adduced cases of amputation wounds, treated not by ligature but by acupressure, where the wounds *did* heal entirely by *primary union*. I selected as illustrations four cases—(see Cases 2, 3, 4, and 5)—of amputation of the thigh, of the leg, of the arm, and of the forearm, in which the vessels were acupressed, and entire union by the first intention followed. These are instances of the four largest sets of bones divided in amputation, and in none could have "portions died" of the extremities of these bones; for, in that case, primary union would have been utterly impossible. But perhaps there are few conceivable conditions more likely to lead to the death of portions of a divided bone, than having in their neighbourhood, or in contact with their surface, for a succession of days, as happens under deligation, irritating foreign bodies, such as the ligature threads, and portions of strangulated and sloughing tissue. Bone is a tissue relatively of so feeble a type of organisation, that it cannot withstand the same amount of irritation as the more soft and vitalised textures. Hence, "in a majority," says Dr. Wilks, "of our cases of pyæmia the bone was involved, being, in the case of stumps, necrosed, and involved in a suppurating or sloughing process."—("Guy's Hospital Reports," 1861, p. 121.) Surely, to save the bone, therefore, we should carefully avoid forming sloughs and suppuration in the wound. We do form them by using ligatures. We so far avoid forming them by using acupressure. Besides, according to Cruveilhier and other pathologists, pus and sanies in contact with the cut ends of bones is specially dangerous, on account of the liability of the osseous veins (which do not readily close) to easily absorb such morbid materials. General pyæmia, in short, often, in the opinion of these pathologists, originates in pus formed in, or entering into, the unclosed osseous veins exposed in the cut ends of the amputated bones.

With the exception of bone, the tissues entering into the composition of the walls of a vesico-vaginal fistula—which usually, when operated upon, easily closes by primary union—are as complex as those of a stump, for they include the muscular walls of the vagina, the muscular walls of the bladder, two mucous surfaces—the vaginal and cystic; arteries, veins, absorbents, and nerves, and quantities of connective tissue.

The most eminent of living operators, a celebrated metropolitan Surgeon, has suggested what may be regarded as two other arguments against acupressure.—(See *Lancet* for January 24, 1863, p. 94.)

Fifth Objection.—Tracks of Ligature useful as Vents for Pus.

The high Surgical authority to whom I refer seems inclined to hold that deligation was preferable, because "the track of the ligatures acted as vents for the discharge of pus." I think that one great and undoubted source of the suppurations in the interior of wounds is the very presence of the ligatures and of the sloughs and irritation which they produce; and if primary adhesion were far more aimed at, the formation of pus would be a far more rare occurrence. In short, it is better to have no foreign bodies, as ligatures, left in the wound, in order, as far as possible, to avoid the formation of pus, rather than lead the pus off when once formed.

Sixth Objection.—Acupressure might Heal Wounds too rapidly.

This gentleman uses another and, as I look upon it, a still stranger objection. He fancies the advantages of union by the first intention overrated. "Suppose"—to

use his own words—"the stump did heal by the first intention, it could not be used for weeks—for months, as it was, in great measure, new material, which would not bear pressure. In fact, the ligatures were of advantage in this way, that they prevented the patient using his limb too soon." Now, if the mere speed with which a wound was completely healed were any objection to the method by which that speed was accomplished, it would be a strange paradox in Professional ethics. It would be an argument, at all events, that no patient could appreciate or approve of; for it would be difficult, I opine, to persuade him that his wounds should heal slowly under a chronic application of local disturbances, dressings, and discharges, rather than heal rapidly and kindly without any long continuation of pain, or vexation, or trouble whatever. The cure of a Surgical wound, as much as the infliction of it, ought always surely to be accomplished, as Celsus writes it, "*tuto*;" but also as surely wherever it is practicable, "*cito et jucunde*."

Some time ago, one of the most distinguished of our living provincial Surgeons, and himself a Professor of Clinical Surgery, stated to the Medico-Chirurgical Society of London, that he had "three grounds" of objection to acupressure. His three grounds were the following (see *Lancet* for May, 1860, p. 445):—

Seventh Objection.—*The Ligature not Hurtful, but Useful in the Healing of Wounds.*

"The ligature," according to the objector that I refer to, "did not deserve the charges which had been brought against it" in regard to its effect upon the artery and surrounding tissues. On this point I have already cited abundance of authorities, showing that the tied artery does inevitably die, and become a mortified piece of tissue, at the point ligatured. On the present occasion I shall content myself by citing against this old argument by this new opponent one authority more, namely, the high authority of Mr. Syme, as to the state of the end of a ligatured vessel; for, as he correctly states, the ligature "at once deprives the part embraced within its noose of vitality." This devitalised, dead, dying, or gangrenous state—to use the meaning attached by Mr. Travers and other leading Surgical pathologists to this last term—is doubtlessly the general and inevitable effect of every ligature applied to an artery. "It has been further said," argues the objector, "that the ligature causes injurious irritation subversive of the uniting process." Most certainly it does; for any excess of irritation or inflammation subverts adhesion. A ligature in its track is confessedly nought but a small or miniature irritating seton. Would this Surgeon, or any Surgeon, have the hardihood to propose keeping setons, however small, between the lips of wounds to produce adhesion? And surely it is ridiculous to argue that their mechanical presence, and the chemical irritation which they produce in such a position, do not constitute very evident causes of the non-occurrence of adhesion along the course of their tracks and in their immediate vicinity. The neighbouring surfaces have newly-formed, organisable materials effused upon them; and, as Mr. Lawrence correctly tells us, "all newly-formed parts are weaker in vitality than the original structures, and ulcerate more easily." (See his "Lectures on Surgery.") The "*principal obstacle*," the same Surgeon elsewhere observes, to the "*speedy union*" of wounds is the presence in them of the body of the ligature; and hence his well-known proposition to cut the ligatures short (*London Medico-Chirurgical Transactions*, vol. vi., p. 172).

The Surgeon, whose special objections to acupressure we are considering, further observes that, "so far from regarding ligatures as hurtful, he had long looked upon them as useful, by maintaining a connexion between the bottom and surface of wounds, so as to prevent that accumulation of blood in the cavity which is so apt to happen, and substitute an abscess for primary union." Now, in regard to such a novel and very strange reason for using and preferring ligatures, I must be allowed to remark, that if "accumulations of blood" in the cavities of wounds are so frequent as is represented in the sentence quoted, there must assuredly be something very wrong either, first, in the ligature itself as a hæmostatic agent, to allow of any such common secondary escapes and collections of blood between the lips of wounds; or else, secondly, the wounds must have been closed too soon and before all the primary oozing had properly ceased. In the former case the ligature is used to repair its own hæmostatic deficiencies; in the latter it is used to repair the unnecessary haste of the Surgeon. And certainly a very imperfect reparative means it must prove in any way, if

at all. Is it not far more likely, by its presence and by the mere mechanical irritation of the vascular granular surface of the wound, to produce this internal oozing of blood—to create it rather than cure it? For it is difficult to see what curative effect it can possibly exert. If a drain were really required from the depths and cavities of wounds, an actual small drainage tube of the unirritating caoutchouc form used in abscesses, etc., by M. Chassaignac, would surely be preferable to irritating, deleterious ligature-threads. But no Surgeon has ever, as far as I know, dared to propose to place such drainage-tubes for "accumulation of blood" between the lips of wounds; for the simple reason, I suppose, that no such provision is really required. The "accumulation" is a "logical" rather than an actual fact, and is adduced, I believe, because there is a want of other or better arguments against acupressure, rather than because the thing itself is apt to happen. Some large wounds, particularly if shut up too early, are liable to distil from their surface, for a time, a coloured serum, but not "blood." Such reddish serum will always find free enough vent by the tracks of the acupressure needles and wires; and it is usually finished long before these needles or wires require to be withdrawn.

The author of the objection we are considering, and who, in his published observations, so earnestly and ardently objects to acupressure as a substitute for the ligature, would, I doubt not, had he lived two or three centuries ago, have equally earnestly and ardently objected to the ligature as a substitute for the actual cautery. "Whoever," remarks Dr. Henry Marshall, "proposes an alteration of existing usages, will meet from some men with a sort of instinctive opposition, which is influenced by no process of reasoning, and no considerations of propriety or sound policy; which defends the existing system because it exists, and which would have equally defended its opposite if that had been the oldest."—(*On the Abolition of Flogging in the Army*, in his "*Military Miscellany*," p. 182.) Our objector would have probably denounced the proposed ligature of arteries—as it was denounced in 1638, by Alexander Read, in his excellent "*Treatise on Wounds*"—as nothing but "a troublesome and dangerous toy, as he shall find who shall goe about to make triall of it."—"A Treatise of the First Part of Chyrurgerie," p. 12.) Or, possibly, if he did adopt deligation of the arteries, he would (like the Surgeon spoken of by Sprengel) have, in addition to this deligation, carefully frizzled and singed over with the red-hot cautery the remaining surface of the wound, that, in the language of Fallopius, it might be duly dried, purged, and strengthened ("ut exiccetur, evacuetur et corroboretur"). For, according to our objector's professed opinion, if acupressure were used, ligatures also should be duly lodged and fixed in the wound, for ligatures have a mystical beneficial effect upon the wound, just as cauterisation had a similar beneficial effect attributed to it in the olden system of Surgery. These ligatures do not, in the opinion of our objector, "cause injurious irritation subversive of the uniting process." They are not "hurtful," but "useful," as they "prevent that accumulation of blood in the cavity of the wound which is so apt to happen and substitute an abscess for primary union." The old fire-button had analogous profitable properties attributed to it in its day. For example, that famous old Glasgow Surgeon, Peter Lowe, "Scottishman," in his "*Discourse of the Whole Art of Chyrurgerie*," gravely remarks, "The cauter or actual fire draweth into it the virulency and malignitie of the humor which is in that part, and in that point it is more sure and better than knitting [or the ligature]. . . . It hath the virtue to drie and corroborate the same" (page 93). In favour of his pathological and practical views regarding the useful effects of ligatures on the healing of wounds, our objector took the opportunity of appealing to the Medico-Chirurgical Society of London, to whom he went up and stated them; and in favour of his pathological and practical views regarding the useful effects of hot cauteries and other matters, Peter Lowe appealed in an "Epistle General" to "the Worshipfull Companie of Chyrurgians in London and Edenborough, and all such well experimented men in this Kingdome, who are licenced to professe the Divine art of Chyrurgerie." These strange views of our objector regarding the supposed beneficial effects of ligatures on the cure of wounds, how very different in philosophic spirit and wisdom are they from the observations published forty years ago upon the same subject by the distinguished French Surgeon, M. Roux. In the account which he published of his Professional visit to this country in 1814, when treating of the means of promoting union by the first intention,

M. Roux makes the following remarks:—"The ligatures are extraneous bodies, which, as long as they remain in the wound, irritate it, and keep up suppuration. There is certainly no doubt but that their presence is the principal obstacle to an adhesion without any suppuration, in those cases where the immediate union of a wound of greater or less extent is attempted; and," he adds, as if in anticipation of some such method as acupressure, "if there were any means by which a wound that was to be united by the first intention should not be traversed by ligatures, the success of that immediate union would be still more certain." (See his "Narrative of a Journey to London," p. 119.)

But the same Surgeon has, as I have said, two other objections to acupressure.

Eighth Objection.—Torsion, a sufficient Substitute for Ligature.

"But (again he argues) if the ligature were objectionable, its place might be supplied by torsion." In adducing this objection, as he himself terms it, he seems to have utterly forgotten that the observations of Manec, Sanson, Chelius, and others, long ago demonstrated that, when torsion is applied to a large artery, the effect of the twisting and physical laceration of the coats of the artery is generally such, that suppuration and death of some part of the contorted and torn arterial tissues are almost as certain to occur as after ligature. In his first objection he merely betrayed an excess of, perhaps, unblamable Professional prejudice. In this second objection, however, he affects an amount of Professional want of knowledge regarding torsion that is scarcely commendable in an old teacher of Surgery; for most modern text-books for students of Surgery contain the information which—as far as his published observations go—he lacks on this point. I would beg, for example, to refer him to the very masterly text-book on the "Principles of Surgery," which our own Professor of Surgery in the University of Edinburgh has published; and the objector will, I hope, agree with me in believing that I could not defer to a higher authority. When treating of the effects of torsion, Professor Miller tersely and truly remarks—"The twisted portion of the vessel *must slough* and separate; the noose of a ligature is not more truly, or to a greater extent, a foreign body."

Ninth Objection.—Acupressure only very Limited in its Action.

"He was persuaded that the field for using the needle process would be found of the most limited extent, since it could only be adopted in cases where the vessel lay in the integuments or textures adhering to them." This objection merely proves that the gentleman who used it simply and entirely misunderstood the whole subject. Acupressure has been successfully and repeatedly employed in the deepest wounds. Perhaps there may be cases and circumstances, in wounds expected to heal by primary or secondary union, where the ligature would answer and the needle not; but if any, they must be few indeed. On the contrary, I know of several instances where acupressure has at once arrested the hæmorrhage after a fruitless trial of the forceps and ligature. In evidence of this important remark, permit me to adduce four or five

INSTANCES OF ACUPRESSURE PROVING SUCCESSFUL WHERE THE LIGATURE HAD PROVED INAPPLICABLE.

Case 12.—Amputation of the Thigh.—In the last case of this operation at which I was present, the Surgeon—one of our most able and dexterous operators—rapidly secured by acupressure all the arteries exposed except one. This vessel bled most profusely whenever the compression of the femoral artery at the groin was relaxed. The bleeding orifice, which was retracted, appeared to be situated very deep in the angle formed by the flaps of the stump, and apparently at the upper end of the divided apex of a sinus that had run up alongside of the femur. It was, probably, a deep obturator branch. The operator turned to me with the remark, that this was an example of a deep retracted bleeding vessel which only the ligature could arrest. Of course, I made no remark, as the case was his and not mine. He tried to secure the bleeding orifice with the forceps and ligature over and over again, but without success. He then remarked that it would be necessary to dissect up the flap somewhat to reach the bleeding orifice, that it might be properly laid hold of. I then ventured to ask him to try an acupressure needle before doing so. The needle—a long one, of the form Fig. 1—was passed through the skin, and at once and effectually closed the vessel, being so introduced as to compress it against the bone. The needles, six in number, were all removed in twenty-one hours,—perhaps a

date that would have proved too early for freeing such a vessel as the femoral from acupressure, had it not been that the patient was very young,—between seven and eight—and the vessels correspondingly small. The child's recovery was complete before the fourth week.

Case 13.—Amputation below the Knee.—Surgeons know well that in some amputations, and especially in amputations below the knee, the arteries sometimes retract so as to be difficult to catch and secure with the ligature. Both Mr. Guthrie and Mr. Fergusson, in describing amputation below the knee, speak of having seen cases where the divided tibial arteries retracted so much, that the efforts to catch them for ligature ended in a kind of "despair." In a case of this kind, which occurred in the practice of Dr. McKinlay, of Paisley, several attempts were made to seize a bleeding tibial artery, both with forceps and with tenaculum, but without success. In order to reach the retracted artery, Dr. McKinlay then cut off a piece more of the bones, and again attempted deligation, but in vain. At last he procured a long "darning" needle, and immediately and successfully compressed the artery against the bone. Two other vessels were secured by ligature. The needle was withdrawn on the third day, and the patient made a good recovery, the wound healing, in great part, by first intention.

Case 14.—Amputation at the Ankle.—After removing the foot, Dr. Henderson, of Leith, secured the two largest vessels that were open by acupressure. The ligature was applied to two small ones situated close to the cut extremities of the bones. A fifth vessel began to bleed freely when the stump was about to be closed. This vessel could not be secured by the ligature, which always slipped, owing to the dense nature of the tissue. At last a small acupressure needle was used, and easily secured it.—(See *Edinburgh Medical Journal*, 1860-61, p. 698.)

For the following note of a case of retracted fibular artery, where the ligature failed repeatedly, I am indebted to my friend Mr. Edwards:—

Case 15.—Amputation of Ankle—Retracted Fibular Artery.—The patient, a young man aged 22, had chronic disease in the ankle joint. He was much exhausted by the malady. I removed his foot above the ankle. My chief reason for doing so was the exsanguine condition of the patient, and this prevented my attempting the then new method of acupressure. I tied several vessels, therefore; but the fibular artery had retracted, so that I could not seize it without further dissection. Professor Simpson, who was present, took a needle from his case, and secured the artery *at once*. This poor, weak lad rapidly recovered; his stump healed in a great measure by first intention, except where my ligatures hung out; but to my amazement Dr. Simpson's needle healed *in*. Around it there was no suppuration, and when I withdrew it after two weeks, the eye was full of new material, granulation substance, I suppose. The patient left Edinburgh in three weeks, and I saw him recently, well, with a good stump. I would venture to add, that although I could have tied his fibular artery, doing so would have put him in greater danger, while it would have put me to some trouble in the way of additional dissection, and prolonged the operation."

Case 16.—Divided Radial Artery.—A young man of 16 received a wound from an axe in his left forearm immediately above the wrist, and had his radial artery completely divided. He was sent, with the wound and forearm very tightly bandaged, into the Carlisle Infirmary, where Dr. Hamilton easily tied the distal end of the vessel, but failed to secure the cardiac orifice by ligature, owing to its great retraction. Instead, then, of extending the wound upwards with the knife, and exposing the artery so as to be able to place a thread round it, he had recourse to acupressure, which immediately produced the desired hæmostatic effect; and when the needle and wire compress were withdrawn after thirty-four hours, the vessel proved to be quite occluded. (See Dr. Hamilton's "Reports" in *Edinburgh Medical Journal*, January, 1864, p. 630.)

In such instances as the preceding wrist-wound, and in others, acupressure assuredly offers no small advantage over ligatures. Whenever we can obtain our object without applying the knife to the living flesh of our patients, it is, as a general principle, right even for the practised operator to avoid it. The dissection down upon the retracted end of a radial is sometimes not an easy matter, and particularly in country practice, where no proper assistance is at hand. Under such circumstances, it is surely better, and safer, and simpler to use acupressure without any dissection, than deligation with precedent and sometimes difficult dissection.

In the following interesting case, which was under the able care of my friend, Mr. Page, of Carlisle, the needle succeeded ultimately in closing the vessels in an instance where ligatures were followed several times by dangerous secondary hæmorrhage.

Case 17.—Popliteal Aneurism and Amputation, with Repeated Secondary Hæmorrhages.—The patient, aged 30, who had served in the army for nine years, was admitted into the Carlisle Infirmary on account of a double popliteal aneurism. Compression of the femoral artery was tried for a time, but had to be desisted from on account of the severe pain it occasioned, and the artery was tied. The ligature came away on the thirteenth day, and secondary hæmorrhage took place. Both extremities of the artery were then ligatured, but secondary hæmorrhage recurred several times, till at last Mr. Page was driven to amputate the thigh at its upper third. Ligatures were applied to the vessels. They separated in the course of a week. On the ninth day secondary hæmorrhage once more supervened, and after about twelve ounces of blood were lost, the bleeding artery was compressed against the bone by means of a needle, with perfect success. The application of a ligature was at first contemplated, but this project was abandoned on account of the manifest difficulty of seizing the orifice of the vessel in the midst of the mass of exuberant granulations which surrounded it, and the very weak and depressed state of the patient. Five days subsequently, another artery which had taken to bleeding was secured by a second needle. After that, there was no more hæmorrhage, and in three weeks the man was discharged cured. In talking over the case, Mr. Page stated to me that he believed acupressure was the means of saving the man's life.

Sometimes acupressure succeeds where it is difficult to use the ligature with success,—in the instance of small vessels situated in awkward positions, or where there is not enough of the arterial tube projecting to seize with the forceps, as in the following:—

Case 18.—Ovariectomy.—Vessel Bleeding on the Inner Surface of the Abdominal Walls.—In an instance in which I saw Mr. Spencer Wells perform ovariectomy with his usual great skill and dexterity, the ovarian tumour was pretty firmly fixed to the abdominal walls by old adhesions. After these adhesions were severed and the tumour removed, there were two points on the abdominal peritoneum which bled considerably. One of these bleeding orifices was closed by the application of a silk ligature, which was cut short. The other bleeding orifice was so flat that the attempts to seize it with the forceps and ligature failed; but it was readily closed by passing an acupressure pin through the abdominal walls, so as to bridge over and compress the bleeding vessel. This mode of arresting the hæmorrhage had the further merit in such an operation, that the head of the needle being left externally, it could be withdrawn at will; while, if the ligature had been used, it was, of necessity, permanently left within the cavity of the peritoneum.

Occasionally, when the coats of an artery are much diseased or ossified, they are brittle and friable, and will not bear the strain of the common silken ligature. Dupuytren, Roux, and Manec recommend the introduction of a piece of bougie into the ossified artery as a plug in these circumstances, when deligation becomes dangerous or impossible. But in such a grave complication acupressure has been found quite safe and sufficient, as seen in the following instance:—

Case 19.—Acupressure capable of Closing an Ossified Artery.—For mangling of the left foot by a wagon, M. Foucher performed, at the Necker Hospital, Paris, amputation at the lower third of the leg by the double flap method. He acupressed four bleeding arteries. "It was evident," he says, "to me, as well as to the *Internes* of the Hospital present at the operation, that acupressure constitutes a hæmostatic method speedy and easy of application." On the third morning two of the needles were removed; but gangrene spread rapidly up the limb, pyæmia supervened, and the patient ultimately sank. The needles placed over the anterior and posterior tibials were allowed to remain till the patient died. "At the autopsy," says M. Foucher, "we were enabled to satisfy ourselves that the two needles compressed firmly the anterior and posterior tibial arteries, and that, on a level with the needles, the walls of the arteries had not undergone the slightest alteration or destruction. In the interior of the canal was found an obliterating clot, which, in the case of the posterior tibial, was firmly adhering to the extremity of the cut arterial tube. I may add," he continues, "that the two arteries were ossified

for a considerable distance above the wound, and that their walls were rigid and friable. This disposition," he concludes, "or condition of the vessel, which is altogether unfavourable to the employment of the ligature, did not interfere in the slightest degree with the process of acupressure, which up to the last moment gave all we asked of it—to wit, complete arrestment of hæmorrhage."—(*Edinburgh Medical Journal*, 1859-60, p. 1048.)

ACUPRESSURE AS A MEANS OF SAVING LIFE.

Sometimes the Surgeon is, humanly speaking, the arbiter of his patient's fate. Whether the patient live or die may depend entirely on whether the Surgeon operates or not. Nay, the very mode in which he operates may sway and settle the question; for in a case of grave doubt and danger, a mode, for example, of removing a shattered or diseased limb may, when the patient is already much shaken or reduced, make all the difference to him between life and death. A mode by which any unnecessary loss of blood is prevented—by which any unnecessary irritation of the wound is avoided—and by which any unnecessary amount of exhausting, suppurative discharges is averted, may turn his fate when that fate is trembling in the balance.

It would be presumptuous, in the present state of our knowledge, to dogmatise to the extent of averring that in this way the fate of one or more Surgical patients has already been decided by the employment of acupressure instead of deligation in some amputations of the limbs. But I believe acupressure to be a means calculated in this way to save both human suffering and human life. In Case 2 we have already seen an instance where the highest Surgical authority in Scotland refused to amputate the thigh in consequence of the apparently hopeless state of the patient. But when his limb was amputated, and the bleeding vessels acupressed, union of the wound by the first intention took place, and the man was driving out in his own conveyance six weeks after the operation. In Dr. Handyside's case of amputation of the thigh for traumatic gangrene (see above, Case 7), recovery rapidly took place under circumstances which are usually reckoned by our highest Surgical authorities, as by Brodie, Erichsen, and others, to be perfectly desperate. The first case of amputation of the thigh in which acupressure was ever used was an instance of the same kind; and in illustration of the preceding view let me cite some of the particulars of it, as published by my friend, Dr. Struthers, of Leith:—

Case 20.—Amputation at the Middle of the Thigh for Traumatic, Spreading Gangrene.—The patient, aged 40, sustained a compound comminuted fracture of both bones of his leg from a machinery accident. He also had his foot much bruised, as well as the thigh on its posterior aspect, as far up as the hip. Two pieces of the tibia, one of them an inch square, were removed from the wound in the leg, and a McIntyre splint put on. The limb soon became very much swollen, and on the fifth day free incisions were made into it, and several ounces of fetid bloody pus allowed to drain away. By the ninth day the skin was mottled, and the wound blackish and sloughy. The skin around it crepitated on pressure, and the parts were evidently gangrenous. On the day following, "the whole limb," to quote the words of Dr. Struthers, "from the ankle to the knee, crepitated on pressure; the wound and incisions were sloughy, and the tissues there were dead; the skin over the knee was red, and crepitation was perceptible over the inner condyle and in the popliteal space. The patient had slept none for two nights; was very exhausted, occasionally delirious; pulse 130; countenance sallow and sunk. The limb being now gangrenous and the gangrene spreading, the only chance of life lay in amputation." Mr. Spence and Dr. Gillespie were called in consultation, and Dr. Struthers adds, "we were all of opinion that the case was a desperate one, and that the patient would almost certainly sink whatever means were adopted." It was, however, thought right to remove the dead member; and accordingly Dr. Struthers amputated at the middle of the thigh by the circular method. "On the limb being removed" (I quote Dr. Struthers' own narrative) "Dr. Simpson passed a needle from the inner aspect of the thigh over the femoral artery, about an inch from its cut extremity, bringing its point out in front; the needle was passed with great ease, and, to the gratification of all present, completely stopped the flow of blood. The passing of this needle resembled, in rapidity and ease, the passing of an ordinary catheter, and satisfied every one present of the practicability and efficiency of acupressure as a means of arresting hæmorrhage. Five smaller

needles were required to stop the other arteries, the mouths of which did not require to be sought for and pulled out, as it sufficed to pass the needle across the track of the vessel, to which the bleeding point was a guide." After eighty-five hours all the needles were removed except the one over the femoral artery, which was allowed to remain for ninety-eight hours. In his report on the fifth day after the operation, Dr. Struthers says:—"The stump looked well on the anterior aspect, but the posterior edge of the flap, for the space of three inches by one, was sloughing. The whole of the posterior and outer surface of the thigh looked very suspicious, being quite black from ecchymosis (the result of the original injury), but there was no appearance of the gangrene spreading further." From this time the progress was very favourable; the slough on the posterior flap soon separated, and before six weeks from the time of the operation, "the stump," says Dr. Struthers, "which is an excellent one, was entirely healed." (See *Edinburgh Medical Journal*, 1860-61, p. 692.)

I have still to discuss the important question, how the deligation of arteries is liable to prove dangerous to the health and life of the patient.

(To be continued.)

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

(Continued from page 28.)

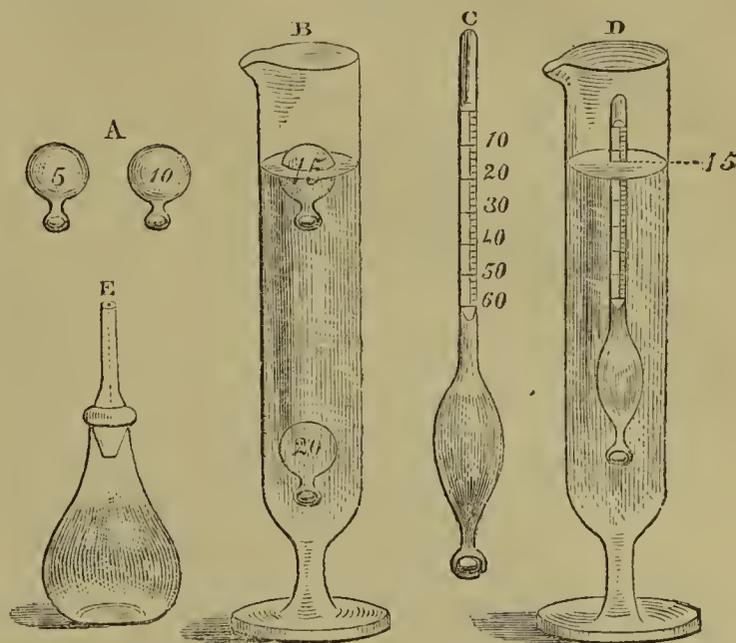

THE SPECIFIC GRAVITY OF HUMAN URINE.

The specific gravity of healthy urine ranges between 1002 (after drinking) and 1030 (after food), pure water being 1000. It is never lighter than water. In disease its density may be as high as 1060. The variations in the specific gravity of the healthy secretion depend upon the quantity of solids it contains, and that again varies with the time of the day, the constitution of the individual, the food and drink, and the amount of exercise taken. The urine that is passed immediately after drinking, and hence called "urina potûs," is pale coloured, faintly acid, and of low specific gravity (1002 to 1015). That passed in the morning, after sleep, and named "urina sanguinis," from being supposed to come directly from the blood, is darker in colour, of a more acid reaction, and a higher specific gravity (1015 to 1020); while that voided some hours after food, and named, accordingly, "urina cibi," although having a still higher specific gravity than the last (1020 to 1030), is neither so dark in colour nor so acid in reaction as the morning's urine.

Seeing that the different urines voided at different times throughout the day vary so much in specific gravity, it is easily understood how dangerous it must be to draw any conclusions from observations made on only one of them, and proves the necessity of collecting the whole urine passed during the twenty-four hours, and estimating the specific gravity therefrom. When such is done, it is found that the average specific gravity varies in health from 1015 to 1025; pregnancy being the only exception to this rule. In it, and more especially during the latter months, the average specific gravity may reach as high as 1033, and yet the individual be in the enjoyment of the most perfect health. I have even noticed that of the urina sanguinis in such cases as much as 1030. Were such changes as these observed in a non-pregnant female, they would infallibly point to an abnormal condition of system, such as the existence of febrile or inflammatory disease. In pneumonia and pleurisy the specific gravity of the urine is often as high as 1035, and in fever it has even been noticed to reach 1038. On the other hand, when the average specific gravity is abnormally low (less than 1015), we may with equal safety suspect the presence of some exhausting non-inflammatory complaint, such, for example, as Bright's disease, in which it may be as low as 1008, or as cholera, where it has been known to fall even to 1006. It may be stated as a rule, that the lower the specific gravity in these affections, the more unfavourable is the prognosis; the

higher the specific gravity, the less dangerous the case. (b) The specific gravity of urine is estimated in three different ways. First, by means of density beads (Fig. 3, A), such as were formerly used in ascertaining the specific gravity of spirit.

FIG. 3.

These beads are gradually dropped into the urine until one sinks to the bottom of the vessel, when, by reading off the number on the last bead that floated, the specific gravity of the liquid is ascertained. In the urine glass (B), bead 20, being too heavy, has sunk to the bottom, while bead 15 is floating at the top. The specific gravity of the liquid is, therefore, 1015. This method is open to two objections:—1st. It does not come nearer than five degrees, for the beads are numbered 5, 10, 15, 20, 25, etc.; and 2nd. It is exceedingly tedious in its mode of employment.

The second method of ascertaining the specific gravity is by what is called a urinometer (Fig. 3, c)—a most convenient little instrument consisting of a blown glass float, a small bulb weighted with mercury, and a graduated stem. All that is required with this instrument is, to pop it into the urine, and read off the number which happens to be on a level with the surface of the liquid. If it chance to be 15 (Fig. 3, D), then the urine has a specific gravity of 1015. If, on the other hand, the instrument is high in the liquid, and the reading is at 30, the urine is proportionally heavy, the density being 1030.

Although this instrument does admirably for clinical purposes, it is not sufficiently exact for scientific research; accordingly, when we desire to make scientific observations, we use a pycnometer (Fig. 3, E), which, as shown in the wood-cut, is a small bottle, with a long stopper perforated by a capillary tube. When the stopper is accurately adjusted, the bottle holds exactly 20 c. c. of distilled water. To ascertain the specific gravity of the urine by its means, the bottle is filled to overflowing with the liquid, accurately stoppered, wiped dry, and weighed; and the difference between its weight when filled with distilled water and with urine indicates the specific gravity. For example, suppose the urine weighs 20.3 grammes, (c) while the distilled water weighed only 20 grammes, the calculation would be to multiply the 20.3 by 1000, and divide by 20.

$$\frac{20.3 \times 1000}{20} = 1015$$

Or, simply multiply the decimal, whatever it may chance to be, by 5, and the result is the last two figures of the specific gravity, $3 \times 5 = 15$.

The Temperature of the Urine.—We frequently hear patients say their urine scalds them, and this has led to the idea that the urine is hot; whereas the temperature of the urine, even at the moment of being passed, is never higher than the temperature of the body. The urine, in reality, receives its heat from the body; and, as the material warmed can in no case be hotter than the material which warms; the urine cannot possibly have a higher temperature than the frame. When patients complain of the urine scalding them, we may be assured of one of two things, either that the canal, or part

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

(b) The exceptions to this rule will afterwards be pointed out.

(c) Calculated in grammes or grains, the result is precisely the same.

of the canal, is in a state of inflammation, and has, consequently, its sensibility increased; or, that the urine possesses more than its usual degree of acrimony. The normal temperature of the freshly-passed urine is 99°F., or thereabouts; but in cases of pneumonia, scarlet fever, and such other diseases as raise abnormally the bodily temperature, the urine also participates in the change, and its temperature may also reach as high as 105° F.

QUANTITY OF URINE.

The amount of water expelled from the body varies exceedingly, not only as regards the relative quantity voided at each micturition, but also as regards the absolute amount passed in the twenty-four hours. From what has been previously said with regard to the different kinds of urine passed in the day, you can easily see the absolute necessity of collecting all the urine made by the patient during twenty-four hours, and analysing a sample taken from the whole. Formerly, the constituents of the urine were reckoned at so much per cent.; but subsequent research has shown that such a mode of analysis gives rise to most erroneous data: it has, therefore, been thrown aside as worse than useless.

Indeed, when we are making a study of any particular disease, the mere calculating the quantity of urine passed in a single day is scarcely sufficient, for, as will be immediately seen, there are very many things which accidentally influence the quantity. In order to arrive at exactitude, the urine should be collected and measured during at least two, if not three, consecutive days, and the average for the twenty-four hours calculated. Some recent writers (Vogel and Neubauer), think it advisable to measure the hourly excretion; but this can scarcely be done except in Hospitals, and fortunately for us there is no absolute necessity for such measurements.

If we merely wish to ascertain the presence or absence of any particular substance, such, for instance, as albumen or sugar, testing any of the urines passed during the twenty-four hours, is in general sufficient for the purpose. You will find it is usually recommended in books to examine the morning's urine (*urina sanguinis*). This recommendation, however, is not unlikely to lead to error, and that, too, in those very cases where it is of the utmost importance to avoid it, namely, in those where the disease is in its early stage, and, consequently, where but little of the abnormal substance is present in the urine. In such cases, it is much better to employ the *urina cibi* (that passed from three to four hours after dinner is the best), as it invariably contains the greatest amount of either of these foreign substances. The reason of this I shall subsequently explain.

(To be continued.)

HIGH DEATH-RATE IN THE METROPOLIS.—In the week that ended Saturday, January 9, the deaths registered were 1798; in the week ending January 16, they were 2427. The average number in the ten corresponding weeks of the years 1854-63 was 1409, which, if raised in proportion to increase of population, becomes 1550. Hence, the deaths of last week exceeded the estimated amount by 877. These persons were killed almost suddenly by the cold wave of the atmosphere. In comparing the present results with those of the previous week, a great increase is apparent in diseases of the respiratory organs. Fatal cases of pneumonia rose from 91 to 156; of phthisis (or consumption), from 194 to 235; of bronchitis, from 326 to 543. Of the 2427 persons who died, 818 were under 20 years of age, 800 were 20 and under 60 years, and 809 were 60 years and upwards. Taking the numbers living at the respective ages into account, it appears that, while persons at all ages have suffered, the severity of the weather has been particularly fatal to persons in advanced life.—*Registrar-General's Weekly Return.*

PROSECUTION FOR INOCULATING.—At the Cashel Petty Sessions, on Wednesday, before John M. Bushe, Esq., chairman, the Hon. Martin Joseph French, R.M., and Captain Graham, the only case of importance was brought by constable Daniel Maguire, of Peake, against a woman of the name of Mary Sullivan, of Gralla, for inoculating the children of John Thornton and Mary Butler, of Ballytarsna, with the small-pox. The parents of the children gave their evidence most unwillingly. Dr. Cormack proved that the children had been cut and inoculated with the small-pox. The woman was sentenced to two months' imprisonment—one month for each offence. The court then adjourned.—*Clonmel Chronicle.*

ORIGINAL COMMUNICATIONS.

CASES OF FRACTURED PATELLA TREATED BY MALGAIGNE'S HOOKS.

By G. E. PYLE,

House-Surgeon, Middlesex Hospital.

THE treatment of fractured patella by Malgaigne's apparatus has not, I believe, been adopted at any Hospital in England, either in town or country, as a recognised plan, or, if so, the cases so treated have never been made public. It may, therefore, be interesting to place before your readers the record of the cases which have been treated in this way at the Middlesex Hospital during the last few years, particularly as the results have been most satisfactory. The advantages gained by this over other methods of treatment are, principally, the easy application of the instrument, the trifling inconvenience to the patient, and the close approximation into which the broken fragments are brought and retained—*i.e.*, the complete union which results. When we consider the complex apparatus which have been devised for fractured patella, the difficulty of their application, and the inefficient results which have followed their use, we are led to wonder at the neglect into which the simple instrument of Malgaigne has fallen. It is not attempted to be shown that complete bony union takes place in all the cases so treated, but there are strong grounds for believing that such is by no means so unfrequent a result as is generally believed; and even in those cases where bony union has not taken place, a much closer ligamentous union is effected than at most times occurs under other plans of treatment. A table is appended containing an equal number of cases treated on the old principle and on the new. It will be seen by this table, and by the cases reported in full, that the time of application varies according to the amount of swelling or bruising which may be present in the injured knee; that the hooks are applied without any bandage or other appliance in addition; that, though the leg is generally kept elevated at first, this is by no means a necessary part of the treatment, and does away with the long-continued maintenance of a position which must be exceedingly irksome to the patient; and, finally, that the introduction of the hooks has in no case given rise to local inflammation or injury to the joint.

I would direct attention to two of the recorded cases especially. The first is that of M. T., who figures in both tables. When admitted she had fracture of both patellæ, with separation of the fragments to the extent of three-quarters of an inch on the right, and half an inch on the left side. The hooks were applied to the right patella, and the left leg was simply elevated on an Earle's bed, and the broken bone kept in position by bandages. When discharged, complete union had taken place on the right side, but on the left there was still a considerable interval between the fragments.

In the second case, that of W. S., the point of interest is this: two years before, he had fractured the other patella, and after treatment, on the old principle, for eight weeks, an interval of about an inch still remained between the fragments. This time he remained in the Hospital less than six weeks, and went out with a closely-united patella.

Case 1.—C. C., aged 39, admitted April 22, 1862, under the care of Mr. de Morgan. Far advanced in pregnancy; transverse fracture of right patella, caused by muscular action; not much swelling of knee or large interval between the fragments; Malgaigne's hooks applied about one hour and a-half after admission; leg not elevated, nor any bandage applied.

25th.—Has suffered little pain from application of hooks; no inflammation around them.

May 2.—Hooks tightened to their fullest extent.

27th.—Hooks removed; complete and satisfactory union has taken place.

On June 2 starch bandage was applied, and the next day she was discharged, able to walk.

Case 2.—A. B., aged 47, admitted October 31, 1862, under the care of Mr. Shaw. Transverse fracture of left patella, from muscular action; considerable effusion into joint; separation of fragments for about three-quarters of an inch; leg elevated, and sal-ammoniac lotion applied constantly to reduce the swelling.

November 6.—Swelling having considerably subsided, Malgaigne's hooks were applied.

7th.—Fragments have been brought to within the eighth of an inch of each other; did not sleep much, but says, as far as pain goes, she is as easy as before the application of the hooks; leg still elevated.

December 9.—Hooks removed; has suffered no more pain during the whole time they were in; joint still rather swollen; line of division between the fragments can be felt, but no appreciable interval.

11th.—Discharged.

Case 3.—P. N., aged 55, admitted May 13, 1862, under the care of Mr. Shaw. Transverse fracture of left patella, from direct violence (a fall on the pavement); separation of fragments fully an inch; considerable effusion into and bruising of knee-joint; leg elevated, and cold lotion applied.

June 6.—Swelling has been very obstinate to reduce, and accompanied with pain; but having now nearly subsided, Malgaigne's hooks were applied.

24th.—Hooks removed; leg still kept elevated.

July 29th.—Discharged. Union good, but not bony.

Synopsis of Sixteen Cases of Fractured Patella—Eight treated by Malgaigne's Hooks, and Eight by other Methods.

No.	Name.	Age.	Sex.	Treatment.	Result.	No. of days in Hospital.	Remarks.
1	M. T.	37	F.	Malgaigne's hooks applied 4th day	Close union (not bony)	78	Hooks applied for 23 days.
2	C. C.	39	F.	Do., 1½ hour	Complete union	42	Do. for 35 days.
3	A. B.	47	F.	Do., 6th day	Line of division can be felt, but no distinct interval	41	Do. for 33 days.
4	R. E.	40	M.	Do.,	Not ascertained	71	
5	P. N.	55	M.	Do., 23rd day	Good union	77	Do. for 19 days.
6	H. D.	40	M.	Do., 7th day	Do.	57	Do. for 21 days.
7	W. S.	37	M.	Do., 2nd day	Complete union	44	Do. for 27 days.
8	A. S.	64	F.	Do., 2nd day	Do.	48	Not ascertained
9	J. Y.	25	M.	Limb elevated upon an inclined plane.	Firm union	50	
10	J. V.	25	M.	Do.	Interval of ¼-inch between fragments	28	
11	M. T.	37	F.	Do.	Interval of slight extent remaining	78	
12	M. C.	60	F.	Do.	Fracture united	49	
13	C. E.	45	F.	Do.	Interval of ¼-inch remaining	72	When nearly well, fell down again, and separated united medium.
14	E. T.	47	F.	Do.	Ligamentous union; ½-inch interval remaining	56	
15	C. N.	23	M.	Do. (back splint)	Not united	49	
16	E. W.	47	F.	Do.	Fracture united	91	

ON DISEASED MEAT,
AND WHAT TO OBSERVE IN CASES OF
SUSPECTED POISONING BY MEAT
OR SAUSAGES.

By EDWARD BALLARD, M.D.,
Medical Officer of Health for Islington etc.

Few beside those who have engaged in such an investigation are aware of the difficulties which surround an inquiry into the injurious effect of diseased meat upon health. The conflicting opinions which have been put forward upon the subject, and the very imperfect histories of cases of disease thus induced recorded in the public journals, sufficiently testify the scanty amount of real knowledge we have at present upon this important subject. In fact, so far as this country is concerned, very little has hitherto been effected towards its elucidation: most of the knowledge we possess is derived from abroad. This is very discreditable to us as scientific men. The only way of explaining the neglect which this inquiry has met with lies in the difficulty which is felt,—first, in tracing out the source of the meat which is believed to have proved injurious; and next, in separating the operation of this from that of other causes of disease which may be combined with it. Partly, too, it may be explained by an incomplete notion of the points which it is necessary to ascertain before we can establish with any certainty an etiological relation of this nature.

The Metropolitan Association of Medical Officers of Health have done well, therefore, in taking up this question, and it is to be hoped that they will receive from the Profession in the United Kingdom all the assistance which it can bestow. In no other way that I know of is it possible to arrive at a satisfactory result. The enquiries to which they have requested replies are few and simple enough. What I wish to do now is to point out the real extent of the inquiry. In a certain degree this has been done in a recent leading article; but possibly it may not be amiss at the present time to place before your readers more fully the points which it is of importance to notice. No one can expect that any case forwarded to the Association shall embrace a detail anything nearly as full as the following programme would seem to indicate; but, at the same time, some good may be done by showing what a complete case would embrace. Although perfection may be unattainable, we may still advantageously reach towards it.

I. PARTICULARS RELATING TO THE ANIMAL WHILE LIVING.

Health of animal [stating whether facts were observed by reporter, or from whom derived].—Diseased? in what way—*e. g.*, typhous disease, pleuro-pneumonia, carbuncular disease, braxy, splenic apoplexy, inflammatory or febrile diseases, diseases after parturition; parasitic disease, such as liver-fluke, measles, etc. (stating the grounds on which the diagnosis was based, and any post-mortem appearances).

Duration of disease—its stage at death?

Died during or after parturition? Immediate cause of death: exhaustion, injury from manual interference, metritis, fever, etc.? Any effect on the person assisting in the delivery of the animal?

Mode of killing?

Poisoned? by what means?

Circumstances immediately preceding death or killing: hunted, coursed, over-driven, etc.? crushed, drowned, suffocated, and how?

Any medicines given? what, in what doses, and how long?

II. PARTICULARS RELATING TO THE MEAT, ETC.

Temperature of the atmosphere when killed, and during period that elapsed before cooking? Other meteorological conditions—*e. g.*, electrical phenomena, weather muggy, etc.?

Meat, etc.—salted, dried, smoked, preserved? made into sausages? how long after killing? Condition and physical appearances of meat prior to any of such modes of preparation? (See *infra*.)

Physical characters of meat, etc.—Presence or absence of subcutaneous, inter-muscular, and internal fat? its amount, its colour, firm or loose? unusual predominance of filamentous tissue or oil vesicles? fat between muscular bundles? Marrow of long bones loose? deficient in fat? watery? bloody?

Muscular flesh plump or wasted? Its colour—unnaturally dark or dingy, bloody (oozing or dripping with blood)? presenting the appearance of circumscribed effusions of blood? Pale, looking macerated? watery-looking (*wet*)? Inter-muscular tissue watery, jelly-like, exuding drops of watery fluid? Odour—natural, sour, sickening, putrid, or tainted? Consistence to the touch—firm, hard, soft, readily broken down? viscid or sticky?

Presence of parasitic animals in the flesh, liver, brain, etc.? measles, fluke, etc.?

Cancer or other organic disease?

Heart, kidneys, or liver.—Appearances denoting fatty degeneration?

Sausages.—Colour: unusually pale? unusually red? apparent proportion of flesh, fat, and bread? odour, etc.

Microscopical examination.—Condition of muscular fibre, heart, kidneys, liver, used as food? fatty or other degeneration?

Chemical examination.—Mineral poisons or medicines discoverable: antimony, arsenic, mercury, lead, etc.?

III. COOKING OF MEAT, ETC.

Time that elapsed between killing or death and cooking.

Mode of cooking.—Broiled, fried in fat (what fat?)—roasted, boiled, stewed (with what?)—made into soup or meat-pie or pudding (with what additional, and with what was crust made?) etc.

Perfection of cookery.—Any part red (underdone)? did red gravy run out on meat being cut into?

Re-cooked? in what way?

IV. KEEPING OF COOKED MEAT.

How long kept after being cooked? where kept? was meat kept in contact with other food, and what? with potatoes or

other vegetables? with bread, flour, fat, etc.? In what vessel? its material?

Temperature at which kept. Character of the weather.

Apparent changes undergone by keeping.—Had it become damp or "muddled?" tainted? mouldy? sour? etc., changed in taste?

V. DISORDERS CONSEQUENT ON EATING MEAT, ETC.

Full details of circumstances connected with eating the meat, etc.

Did all who ate of meat, etc., suffer? Did those who abstained suffer? Did all who suffered eat an equal amount?

Did supposed sufferers eat anything else or drink anything at meal, and what? Did they in this differ from those who did not suffer?

How often was meat, etc. (the supposed cause of disorder), partaken of? Was diseased meat, etc., habitually used? for what period?

Habitual state of health of sufferers? had a similar attack been suffered before, and under what circumstances?

How soon after eating meat, etc., did disorder commence?

Describe attack. Symptoms in order of occurrence. Phenomena in order of the systems affected. Cutaneous system, nervous system, mouth, throat, and digestive system, heart and circulating system, respiratory system, muscular system, etc. General symptoms: shivering, debility, *malaise*, fever, etc.

Duration of illness.—Result, recovery, death?

VI. POST-MORTEM EXAMINATION.

Detailed under the following heads:—

General external appearances. Nervous system. Digestive system and peritoneum. Respiratory system and pleura. Circulating system: pericardium, heart, vessels, and blood. Urinary system. Muscular system: parasites.

Contents of stomach and intestines. Their physical characters: entozoa?

Microscopical characters of contents of stomach.

Chemical characters of contents of stomach: mineral poisons? etc.

VII. EXPERIMENTS WITH MEAT, ETC.

Effects of feeding dogs, cats, etc., with suspected meat, uncooked and cooked.

N.B.—Negative facts should be observed and recorded, as well as positive ones.

[It may not be amiss to add, that any communications with which the Profession may favour the Association should be directed to Dr. R. D. Thomson, the President, at the Court-house, Marylebone.]

REMOVAL OF A FIBROUS TUMOUR FROM THE UTERUS.

By MICHAEL T. SADLER, M.D. Lond.

THE patient, Mrs. H., the wife of a farmer, is about forty years of age, a tolerably robust-looking brunette, who has had no children. She has enjoyed good health, with the exception of pains at the commencement of menstruation. In April, 1861, she had an unusually painful period, with a sensation of cutting pains on passing the motions; this was followed by leucorrhœa, which, however, did not continue long, though the pain on defecation was still occasionally felt.

About November, 1862, these symptoms became more troublesome, though not so severe as to induce her to seek Medical advice.

In February, 1863, after exposure to wet at the menstrual period, she had an unusually large amount of discharge, with severe pain; from this time at each period the discharge and pain were excessive, continuing for ten or eleven days, with leucorrhœa during the intervals, and by May the coloured discharge was continuous, with frequent attacks of severe hæmorrhage, and expulsion of clots of blood. Finding that complete rest, perchloride of iron, mineral acids, and other remedies gave only partial and temporary relief, on May 29 I made a vaginal examination, and found the uterus enlarged, and apparently tilted forwards, with the os uteri small, and not easily reached. I diagnosed a fibrous tumour or polypus within the cavity of the uterus, as yet inaccessible. Occasional doses of ergot were given at intervals, with the hope of dilating the os, but for some time without much effect. The appetite, which had hitherto been good, began to fail, whilst the pain and discharge increased, frequently being so severe as

to cause fainting. The patient's strength and spirits began to fail seriously, and I feared that it would become necessary to dilate the os uteri by sponge tents, or other means.

On July 4, however, when Mr. Teale, of Leeds, saw the case with me, the os began, for the first time, to show signs of yielding to the internal pressure, and a continuance of the same plan of treatment was advised.

On July 12 the pain was unusually violent, and, on examination, I found the os distinctly dilating, and could reach the tumour within it. On the 15th, the pains continuing very severe, the tumour began to descend into the vagina, and by 8 a.m. on the 16th it had got so low as to press on the urethra and prevent micturition. As it now seemed fairly within reach, and the patient was suffering extremely, I determined to attempt to remove it. I accordingly emptied the bladder, put the patient under the influence of chloroform, and, finding no kind of forceps of any use, on account of the yielding nature of the tumour, and the small proportion of it which was as yet extruded from the uterus, I passed my hand (not without considerable difficulty, the patient never having had a child) alongside of the tumour into the uterus until I reached its base; then with my fingers separated it from its attachments—enucleated it, in fact, as there was no pedicle, and the rounded base of the tumour seemed to be imbedded in the substance of the uterus. This being done, the whole tumour came away without much more difficulty.

There was no hæmorrhage of any consequence; but the patient was rather slow in recovering from the effects of the chloroform, and about twenty minutes after she had ceased to inhale it fell into a rather alarming state of syncope, in which respiration was with some difficulty maintained. By degrees, however, this passed off, but she long continued very sick and faint. From this time she gradually, though slowly, recovered, regaining flesh much more rapidly than strength. She has just returned from a visit to Scarborough, looks almost as well as ever, but complains of slight pains in her back and legs. Menstruation is re-established, and is now attended with less pain than she has had for some years.

The tumour was egg-shaped, the smaller end having passed first through the os uteri. It was about ten inches long, and six or seven inches wide at the broadest part, and it weighed one pound two ounces avoirdupois. On section, it displayed an areolated fibrous structure, with numerous large vessels. There is a figure in Cruveilhier's "Anatomie Pathologique," 13th livraison, planche 6, fig. 2, which gives an excellent idea of its appearance. The microscope showed nothing but fibrous tissue without any cells.

Barnsley, Yorkshire.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

LIVERPOOL SOUTHERN HOSPITAL.

CASE OF INTESTINAL OBSTRUCTION—FAILURE OF ALL MEDICAL TREATMENT—ABDOMINAL INCISION—DEATH.

(Under the care of Mr. HAMILTON.)

[Reported by GULSTON WOLLASTON, M.D.]

C. B. was admitted into the Liverpool Southern Hospital, October 23, 1863, under the care of Mr. Hamilton. She is a short, stout, florid Irishwoman, aged 48 years, and is the mother of nine children, and states she has always enjoyed good health. Six or eight months ago, she says, she began to suffer from general swelling of the abdomen, which, though varying in extent, has never disappeared entirely, and about the same time attacks of pain, referred to the umbilical region. She also describes a pain of a persistent character, which she refers to the left iliac region. Accompanying these symptoms was a tendency to constipation, but the bowels at this period yielded readily to the action of purgatives, and the general health does not seem to have been impaired. About three or four months before admission she suffered from an attack of English cholera (was "purged up and down"), accompanied by severe abdominal pain, but leaving her, after its subsidence, in much the same state as previous to its occurrence.

In September, the "attacks" of abdominal pain became more frequent, and increased in severity, but she did not state

clearly as to whether the "fixed" pain in the left iliac region underwent any change. The constipation became more marked, but still the bowels acted with the assistance of strong purgatives. The appetite has continued good, and there has been no loss of flesh or strength.

On admission, the abdomen was found to be considerably distended, and, when the patient was examined lying on her back, generally tympanitic, except in the hypogastric region, where the sound on percussion was somewhat dull. By turning her, first on one side and then on the other, and then making her assume the upright position, the depending region of the lower abdomen became dull on percussion, and communicated to the hand a well-marked sense of resistance, but no fluctuation could be detected, nor could any tumour be discovered. (She had been told that she was suffering from ovarian dropsy.) The stomach rejected all food, and the bowels had not been moved for four days.

On the day after admission (October 24), the bowels were acted upon three times by medicine taken by the patient the day before (castor oil and jalap), but the evacuations were not seen by any one. After this date there was complete obstruction, neither fæces nor flatus passing.

It will be tedious to detail the treatment; everything was done that could be suggested, but without effect; injections were given through a tube passed twenty-three and a-half inches into the bowel; purgatives were administered, but only added to the distressing vomiting; hot baths, fomentations of poppy, tobacco, etc., were tried, calomel and opium were resorted to, galvanism, etc., etc., but without avail.

On the 30th, seven days after admission, the vomiting became decidedly stercoraceous; and, at a consultation held the following day, the question arose, shall the patient be left to die, or shall Surgical means be resorted to?—as it was quite evident that nature could do no more. The case was fully explained to herself and friends, and that Surgical interference gave her a chance, however remote, of life. The suggestion was gladly grasped at, and it was resolved to open the abdomen. This was accordingly done the same day by Mr. Hamilton: an incision sufficiently large to admit the finger was made between the umbilicus and pubes; on the finger being inserted nothing abnormal could be felt, the incision was therefore extended so as to allow the introduction of the hand. On the left side (the side to which all the symptoms pointed) everything appeared perfectly natural; on the right, a hard body, evidently blended with the intestinal parietes, was discovered. A portion of intestine immediately above this was drawn forward, and an artificial anus made in the usual manner, and a large quantity of thin, light-brown feculent matter poured from the opening. She never rallied after the operation, and gradually sank and died in sixteen hours.

At an examination made next day, it was found that a scirrhus tumour, about the size of a large walnut, completely encircled the intestine at a distance of three and a-half inches below the ileo-caecal valve, the constriction admitting only the tip of the little finger. All the organs were healthy, and there was only a slight inflammatory change in the vicinity of the wound.

MIDDLESEX HOSPITAL.

DOUBLE STRICTURE OF THE URETHRA TREATED BY FORCIBLE DILATATION WITH HOLT'S DILATOR.

(Under the care of Mr. GEORGE LAWSON.)

W. H., age 26, was admitted into the Middlesex Hospital on July 3. He had two strictures, one just in front of the bulb, and the other one and a-half or two inches from the meatus. He had been previously an in-patient in the Hospital on this account; and, although benefited at the time he left, yet the strictures had again contracted, and now caused him considerable inconvenience. It was with great difficulty that a No. 2 catheter could be introduced into the bladder. The urethra was excessively irritable, and after each introduction of the instrument he suffered from severe rigors.

After his admission into the Hospital, he was kept in bed; and after a few days' perfect quiet, and abstinence from stimulating drinks, a No. 4 catheter was passed. In anticipation of the rigors which had always followed after the catheter had been used, quinae gr. ij., opii gr. $\frac{1}{2}$, was given immediately after each introduction of the instrument, and succeeded in warding them off.

July 8.—To-day the man was brought into the theatre, and

Mr. Lawson, having introduced Holt's staff, rapidly split up the two strictures, and immediately introduced a No. 9 catheter, which was fastened in the bladder in the usual manner. The man was returned to bed, and a pill of quinine and opium given to him.

9th.—Has passed a good night; had no rigors, and suffers no inconvenience from the presence of the catheter.

Three days afterwards the catheter was removed, and in ten days he was discharged from the Hospital quite well, never having had a single untoward symptom since the operation.

ST. GEORGE'S HOSPITAL.

EXOPHTHALMIC GOITRE—SLOUGHING OF THE CORNEA FROM EXPOSURE.

(Under the care of Mr. TATUM.)

THE notes of the following case are imperfect. It occurred some time ago. We give it as illustrating one result of this remarkable disease, recently the subject of an admirable paper by Dr. Handfield Jones.

Mary Ann E., aged 18, was admitted into St. George's Hospital under the care of Mr. Tatum, Nov. 26, 1851, on account of protrusion of the eyeballs. She was of a very pale, strumous aspect, with red hair and very light complexion. The eyes were so prominent, that when she closed the eyelids as far as possible, a portion of the cornea was still left uncovered. The protrusion had only been noticed about eight months, and enlargement of the thyroid body had been observed during the same period. The catamenia had never appeared. She complained of pain in the head. Sight was unaffected.

Treatment was commenced with preparations of iron, which had proved extremely successful in a similar case of exophthalmia, also occurring simultaneously with goitre in a young woman, who had been in Hospital under Mr. Tatum's care a short time previously. But this patient happened to take alarm at the sight of a woman in the next bed to herself attacked by erysipelas, and insisted on leaving the house a week after her admission.

She returned on Jan. 2, 1852, on account of inflammation of the left eye. This had been going on for about a week. She could not assign any cause for it. During the last two days sight had been entirely lost in the eye. On examination the conjunctiva was seen in a state of serous chemosis. There was a very deep and extensive ulcer, involving almost all that part of the cornea which corresponds to the upper segment of the iris, and the inner part of its surface was sloughy. The sclerotic vessels could be seen in some parts, and were injected. There was much circumorbital pain.

The treatment consisted of slight local depletion (by means of a few leeches to the temple and blisters behind the ear), combined with tonics internally; but it was quite ineffectual. The whole cornea became opaque, and gradually scaled away, sight being entirely lost. A copious discharge of pus came on, and the eyeball withered. A few days after her admission, lachrymation, circumorbital pain, sclerotic and conjunctival redness came on in the other eye, and on examination, a small transparent ulcer was seen on the cornea. The progress of the disease in this eye has not been noted; but it is believed that (though the symptoms yielded for the time to the treatment employed) this eye ultimately followed in the same course as the other, and that vision was entirely lost.

HOSPITAL NOTES.

BRIGHT'S DISEASE—HYPERTROPHY OF THE LEFT VENTRICLE—APOPLEXY.

THE concurrence of chronic Bright's disease (the granular kidney), hypertrophy of the left ventricle, inelastic, tortuous arteries, and sanguineous apoplexy, is a recognised clinical fact. It was strikingly illustrated recently by two cases at Guy's. In both the patients had been, until the rupture of the vessel in the brain, well, in the conventional sense of the word; yet, as people are doing every day, they went about, although particularly ill nowhere, in a state of general disease. They were seized with apoplexy, and died in a few hours. In one, the corpus striatum was torn up, and blood had escaped into the ventricles; in the other, the clot was in the pons Varolii. In such cases, as a rule, there is no attendant dropsy to point prominently to renal disease. Nor is this symptom gene-

rally to be found in the slighter kind of apoplexy, apoplexy of the retinae.

Besides the obvious practical importance, this association is most interesting as illustrating the clinical study of disease. Nothing could show better that it is to constitutional conditions, rather than to local damages, that we should devote our attention. Of course some diseases, especially in young people, must be thought of as damages to organs, although often brought about by constitutional affections, and although they produce secondary results in the greater part of the body. Thus, the mitral valve is damaged in acute rheumatism, and the organ is permanently defective. There is a good instance of local damage in Stephen's Ward, Guy's Hospital, under the care of Dr. Wilks—aortic disease, allowing regurgitation, following overwork in a young and very healthy man. In this case the heart's mechanism is deranged, but its tissue is good or healthily hypertrophied. But in the hypertrophy attending Bright's disease, and where there is a movable pulse, and perhaps an arcus senilis, we have quite a different kind of disease. In one, the symptoms are general, because the organ damaged is a central one; in the other, the symptoms are general, because the tissue changes are universal.

Before the sanguineous effusion we may do good to the patient, but our efforts are generally useless when blood has been effused in the pons Varolii, and unfavourable when in a part less important to life, as when hemiplegia results from rupture in the corpus striatum, or blindness occurs from retinal apoplexy. The place of rupture is, comparatively speaking, an accident, and in some instances of apoplexy of the retina, it is of less importance to the individual than the attendant hypertrophy of the left ventricle and the renal disease. Nay, sometimes the effects of rupture are insignificant, from the comparatively unimportant function of the organ in which it occurs, as in epistaxis, which now and then precedes retinal or cerebral apoplexy. But though the damage is slight, the symptom may have a very ominous significance if associated with the other conditions referred to, and scarcely any if these are not present.

To show still further how general is the constitutional condition which often ends so suddenly, so dramatically, we may mention the now-well-known condition of the retina, by which alone granular kidney may be, and often is, confidently diagnosed. But as we have already published a series of cases of this kind, with remarks by Mr. Hulke, we need not now dwell on it, except to repeat that it is often associated with apoplexy of the retina. Cases of this kind are not uncommon. A patient of middle age becomes suddenly "blind;" apoplexies are found at the yellow spot; the urine contains albumen. He gradually "recovers" from the blindness, and, indeed, sometimes to a surprising extent, and insists that he is well; and yet, still having no dropsy nor any œdema, his urine continues loaded with albumen, and he dies a few months later of rupture in a more vital part of the nervous system.

In another case, a patient has first an attack of hemiplegia and albuminous urine. He "recovers" from the hemiplegia, but a few months later has apoplexies of both retinae, then paralysis of part of the face, and a few days later dies suddenly.

The first of these cases refers to a patient under the care of Mr. Wordsworth, at the Royal London Ophthalmic, and the other to one under the care of Dr. Hughlings Jackson, at the Hospital for Epilepsy and Paralysis. There is now also attending at the latter Hospital, under his care, a case of hemiplegia in a woman, forty years of age, who has the peculiar retinal degeneration alluded to and albuminous urine; and, although her sight is still good, and although, except for the hemiplegia, she would be said to be, speaking popularly, healthy, she must be considered to be in constant danger of further rupture in some other part, perhaps more important than the one lesion of which now produces the hemiplegia.

One great practical point in reference to such association of diseased conditions, is as to the value of certain premonitory symptoms in individual cases. For instance, as Dr. Gull remarked in a recent lecture at Guy's Hospital, a symptom like giddiness may have comparatively little significance, or be of very evil import. A very slight cerebral symptom should lead us to examine the heart and kidneys. If we found no evidence of disease in them, we might hope that the giddiness was not a warning of any grave evil; but if we found hypertrophy of the left ventricle, and if the urine were albuminous, the least giddiness would lead us to give a most cautious prognosis.

The same kind of reasoning applies to other diseases. A young man who has cardiac disease and sudden hemiplegia from plugging of the middle cerebral artery, or a patient who has hemiplegia following an attack of unilateral convulsions associated with a deposit of syphilitic lymph in the pia mater on the surface of the opposite hemisphere, have really, for treatment, diseases quite different to the hemiplegia in a patient past fifty, who has chronic Bright's disease, rigid arteries, a movable pulse, hypertrophy of the left ventricle, and an arcus senilis, although the same physiological system is damaged in all three cases. In fact, and this is most prominently true of hemiplegia, many diseases of the nervous system are rather diseases *in it*. Hemiplegia is generally due to rupture of a vessel rather than to primary disease of nervous tissue. It may be confidently asserted that it is, in cerebral disease, of just as much importance to examine the heart and the urine as it is to enter into a scrutiny of the symptoms of the actual disease for which the patient comes to us. Probably the treatment will not vary, whether the blood be effused in the retina, in one hemisphere, pons Varolii, or spinal cord. The physiology would be exceedingly different, but the pathology—effusion of blood in nervous tissue—would be just the same. In cerebral disease it is, therefore, of far greater importance, at least in a utilitarian point of view (and ours is a utilitarian Profession), to ascertain the state of the patient's circulation and viscera, than to get to know the exact position of the disease. We do not wish by any means to underrate the physiological study of diseases of the nervous system, but the clinical study of these diseases ought to be carried on *pari passu*. Sometimes the physiological fact and the clinical fact will point to the same conclusion. For instance, paralysis of *part* of the face shows *central* disease [paralysis of the whole of the face would indicate disease of a *nerve trunk* outside the central nervous system], and this coinciding with evidence of renal degeneration, shows that not only is the patient's condition dangerous, but that danger is at hand.

Whilst, then, in cerebral cases, whether slight giddiness, paralysis, or apoplexy, we diagnose, when we can, the exact seat of the disease, we should examine the heart, the urine, the radial and temporal arteries, the eye for arcus senilis, and we may, too, look at the retina for further evidence of tissue-change. In a word, when we study diseases as defects of organs, we must attend carefully also to the general signs of degenerations of tissues. As a final illustration of this principle we may instance syphilitic affections. Here a node on the tibia, in the liver, a nodule of lymph on the iris, or a mass of lowly-organised material on the surface of the brain, are pathologically one, although, as damages of different organs, they produce the most diverse symptoms. Yet the treatment of syphilitic inflammation of the choroid, iris, or pia mater, is the same, although the organ in which the syphilitically-diseased tissue exists is so very different. It is the development of such principles that gives so high a practical value to the teachings of Laycock, tending to substitute a rational treatment of the patient for a kind of artillery practice at the diseased point where his special ailment is localised when he consults us.

FORMIATE OF AMMONIA AND FORMIC ACID IN DISEASES OF THE NERVOUS SYSTEM.

If chemical homologies had corresponding therapeutical relations, we should not expect to find great energy in formiate of ammonia. Of course, identity of composition does not in any way imply identity of properties either of form or of chemical relations, but identity of type is pretty certain evidence that the difference of chemical properties is simply one of degree and not of kind. Formiate of ammonia is the homologue of acetate of ammonia, formic acid being the acid from methyl alcohol, and acetic acid from common alcohol; and the difference in composition in these two acids, as betwixt each, in the series, is two equivalents of carbon and two of hydrogen. This gradual increment of carbon and hydrogen in this series is attended by a corresponding increment of properties, greater solidity, and a higher boiling point (19 centigrade). Now, it has been suggested that, as there is, with some discrepancies, however, a gradual ascent of physical and chemical properties, so there may be a corresponding one of therapeutical power. Such schemes of thought may be useful to suggest remedies, but not to decide on them. The following observations, gathered from the practice of Dr. Ramskill at the Hospital for Epilepsy and Paralysis, show that such reasoning cannot be trusted in the instance of formiate of ammonia. Although lower in the scale, chemically

it seems to have far more energetic properties than we are in the habit of ascribing to acetate of ammonia, our common saline. Probably the action of formic acid on the skin is strictly analogous to that of acetic acid. Formic acid is the acid found in ants, and also in the juice of the common nettle.

Formiate of ammonia is used chiefly for internal administration; it is especially applicable to cases of chronic paralytic disease, accompanied by general torpor.

It is contra-indicated wherever there is reason to suppose activity in or about the seat of the original lesion in the nervous centres: irritable stomach also, whether the result of cerebral mischief or not, excludes its use. On the contrary, cases of reflex paralysis are most benefited; next, those cases where, from disuse, the muscles and nerves have become unable to convey commands of the will, or to execute movements. It is equally useful in paralysis of sensation as of motion. The dose is five grains. Given in larger doses than five grains, it produces vomiting. When it agrees, patients experience an epigastric glow, and it appears to act as a general stimulant.

Applied externally, we find in formic acid, diluted with an equal quantity of water (or less), the best local application for paralysed limbs. It restores circulation, and frequently produces the sensation of being stung with nettles, and occasions an erythematous eruption. As we have remarked, this acid is contained in the juice of the common stinging-nettle, and in ants. Just as burnt sponge had been used long before it was known to contain iodine, so ants have been used empirically. We do not attach much importance to the authority, but we may mention that De Leuw, the notorious quack oculist, almost always prescribed, in anæmic cases, an ointment, composed of ants of the larger kind mixed with lard, to be rubbed over the branches of the fifth and seventh nerves in the neighbourhood of the eye. There is a considerable quantity of formic acid in the bodies of these insects.

In some forms of epilepsy the internal administration both of the acid and its salt of ammonia has done great good; in others, apparently harm. We shall recur to the subject hereafter.

USE AND ABUSE OF STIMULANTS IN FEVER— OCCASIONAL ANTIPHLOGISTIC TREATMENT.

A few days ago we saw at Guy's several patients convalescent from fever. In reference to them, Dr. Wilks remarked on the treatment of fever by stimulants. A young man, who had had typhus fever, and who had been covered with the ordinary mulberry rash, had recovered without any. As there appeared no need to give any, Dr. Wilks wished to prove to his class that alcohol was not always necessary in fever, and that he did not by any means consider alcohol as an antidote to fever, for he found the disease always ran its course under every form of treatment. He considered the rule laid down by many of the older Physicians to be the correct one with regard to the treatment of all fevers; that in very many cases supervision was alone required, and that in others a stimulant plan was necessary; the only question being the quantity of alcohol required and the time when it was needed. He thought, therefore, that those who spoke of their success by the universal treatment by alcohol in all cases of fever, were adopting (to say the least) a very unscientific method, which was, in reality, one founded on such a reasoning as this:—That severe cases of fever are benefited by alcohol, and mild ones are not killed by it, and, therefore, it is safer to give it to all. The same may be said of those who declare carbonate of ammonia to be *the remedy* for all cases of scarlatina. It is, no doubt, of great value in severe cases, and in mild ones it certainly will not kill the patient. Dr. Wilks would not say, however, that wine and spirits did no harm, for in some cases he believed they were decidedly injurious, especially in young persons with typhus fever and violent delirium. He had such a case under his care, in which he ordered cupping to the back of the neck, and which was followed by quiet and sleep. He was a total disbeliever in the change of type theory; for such a case as this, and two others which he had seen bled, and yet did well, entirely refuted such an opinion. Although he believed the present plan of treatment by support saved more lives, he was quite sure, that if no stimulants were given, and that if patients were bled, that the greater number would recover as heretofore.

FACULTY OF MEDICINE OF PARIS.—The Minister of Public Instruction has just made the appointment (which is likely to be popular with both Professors and pupils) of M. Tardieu as Dean of the Faculty, in place of M. Rayer, resigned.

Medical Times and Gazette.

SATURDAY, JANUARY 23.

THE INFLUENCE OF THE SOCIAL POSITION OF THE MEDICAL PROFESSION ON MEDICAL EDUCATION.

THE plea for the dunces of the Edinburgh Medical School, lately published, has created a warm sympathy for those of other schools. The London teachers lament the number of young men who come to town and enter to lectures, but never go through with their studies, nor pass their examinations. Some become actors, or literary hacks, photographers, dentists, or tradesmen, or take situations as dispensers in shops and surgeries, or as "unqualified" assistants, or emigrate, or otherwise disappear. The causes of these failures are not to be sought, as at Edinburgh, in excruciating examinations at Hall or College, but in the conditions of the students themselves. A few of these wasters are without means to continue their studies, more are idle, and still more are deficient in the mental training and capacity required to master the multiplicity of subjects put before them. With little Latin and no Greek, Celsus and Gregory were always awful phantoms to the illiterate candidate at "the Hall," not to be as easily laid by "grinding" as the Professional requirements of examiners. And now that the screw of the preliminary examinations is being tightened, a cry of anguish arises from this class. At Edinburgh this must be even more keenly felt than in London, for, until lately, men occasionally "got through their Latin" there, to whom the grammar and *delectus* were unapproachable mysteries.—*Hinc illic lachrymæ* of the Edinburgh Jeremiad. It must, however, be considered a matter of congratulation for both the public and the Profession, that examinations thus serve their purpose, and so many unfit lads are repelled from it to more congenial pursuits, inasmuch as the evils worked by those who just squeeze through the examinations and register are clamant enough. Without capital to purchase a connexion, or to decorously bide their time until they make one, they must get practice at any sacrifice of labour, character, and dignity. They would rather not; but, like the Apothecary in "Romeo and Juliet," their poverty and not their will consents to unprofessional and degrading courses. If the evil went no further, they alone would suffer; but unhappily, the whole body suffers with them. The great public judges of the Profession generally by the conduct of these notorious few. Practitioners of capital and gentlemanlike feeling get disgusted with the unseemly competition they are exposed to, and betake themselves to other pursuits; or, if they remain, lose all *esprit de corps* in discovering that the presumptuous, boasting, pushing quack, whether in or out of it, is too often preferred to the scrupulous and honest practitioner. Thus, the moral force of the Profession is wasted away by the zymosis of a moral *materies morbi*.

The common and obvious remedy proposed for these acknow-

ledged evils is, that the candidate shall be required to have the education of a gentleman. If to this be added a knowledge of the elements of the natural sciences, as botany, natural history, natural philosophy, chemistry, and the like, before the student commences his Professional studies proper, he can then be finished off as a Professional man,—well-taught and well-trained, a scholar and a gentleman. Doubtless, if such candidates can be got, the remedy is certain; but will they come? What is there in the Medical Profession to attract such a class? These would be men of capital in every sense of the word. The very requisites imply good natural powers of mind, time to cultivate them, and money to pay the teachers and maintain the unproductive learner while being taught,—requisites which would ensure success in any other calling or profession whatever. It is not an unbusiness-like proceeding, therefore, if the parents of a youth so endowed inquire what returns, as compared with others, the Medical Profession will afford for the capital invested. And certainly these are at a minimum. Wealth is attainable, but by no means in proportion to some other professions or to commercial or manufacturing enterprises. Social position is money's worth; it follows upon wealth, when got in any department of business, provided there be moral worth and tact also; but in all the great professions except the Medical, it goes with the profession. High offices in Church and State, and military and naval rank and consideration, are prizes in the other professions; but snubbing and degradation pervade all ranks of office in the Medical Profession, from the army and navy down to the Poor-law service. A poor curate or ensign is looked down upon by the wealthy because he is poor; but he is, nevertheless, socially a gentleman. Even in the novels favourable to the Profession, the assistant to the village Doctor marries the poor governess at the rectory, while the curate or young officer of the army weds with the rector's sister or daughter. Then, further—the rank which titles afford in other professions is unattainable in ours. A knighthood is rare in the Medical Profession; a baronetcy rarer; a peerage unheard of; and, lastly, to the ordinary mind, looking at the Profession as an industrial occupation and not as a scientific pursuit, it is more repulsive than attractive. There is, therefore, no reason whatever why the sons of the nobility and gentry, or of the more ambitious of the commercial and professional classes, should enter it in preference to other professions, in the absence of any suitable return for the capital invested in the form of intellectual power, time, connexions, and pecuniary outlay. Now, as the mere addition to the Profession of a considerable number of men possessing these requisites would suffice to raise it in every way, it follows that all reforms in Medical education to be effectual must have as their ultimate object this end in view.

Tested by these principles, some of the educational schemes current appear to be worse than useless. That which has lately emanated from Edinburgh is, perhaps, the weakest and the worst. One of the evils to be obviated is undue competition by poverty-stricken, ill-bred, and ill-taught practitioners. Mr. Syme would legislate in favour of the class of students which supplies this class of practitioners. They have naturally a horror of strict examinations; he would therefore have examinations entirely abandoned, and revert to the old and corrupt system of examinations by the teachers individually. And, in deference to the same dull mediocrity, he would destroy the liberty of teaching. "The most brilliant eloquence and the profoundest science" are of no use in teaching, he argues, for they may inculcate "doctrines positively injurious in the practice of our Profession." He would have the teacher called upon from time to time by his colleagues, to "produce a syllabus of his course;" and if he "taught doctrines not conducive to sound practice," or "allowed an unruly hobby to carry him away," Mr. Syme would have his colleagues to censure, and, if necessary, depose him! In this way, those teachers who disturbed the dull souls amongst the professors and students by new principles in science and new methods in practice, could be held in salutary check or got rid of. And,

since the Medical sciences have been so greatly developed of late years that they cannot now be properly taken in by the poor dull souls aforesaid, he would not extend the period of professional study at all (for that demands capital), but rather hints at a diminution—"less than three years with a winter and summer session would certainly prove insufficient," but three might serve.

Mr. Syme's scheme is obviously calculated to keep up and increase the number of candidates defective in the capital requisites we have indicated; anything more stringent as to mental qualifications, time, and power of paying for teaching; would diminish the number in proportion to the stringency. But it is equally obvious that such stringency would seriously influence the prosperity of the Scottish Universities. They, Mr. Syme observes, "are the great Medical seminaries of the country;" they "at present educate more students than all the schools in London put together;" in them teaching is a profession, and not "merely a step to something better." The conclusion, therefore, naturally follows, that the number of students must be kept up in the interests of the teachers. And to this end teachers and taught must be kept at a low level of attainments.

It is true that Mr. Syme proposes that no youth should be allowed to commence Medical studies until he is eighteen years of age; but this is just as much in favour of dull mediocrity as his other propositions. Some youths of fifteen have more intellectual power and capacity than others of twenty. These he would repress from the ranks, because power and time are correlatives; while the dull souls would spend the years between school and Medical classes in a half apprenticeship, if not in more menial occupations, hoping to "grind" through the preliminary examinations.

Audacity quite as often marks imbecility and ignorance as wisdom. Mr. Syme has (happily, we hope) so mooted the question of Medical education, that men must take either the side of scientific progress or barbarous retrocession. His propositions are too absurd, it is true, for adoption; but they should serve to stimulate the Universities of Oxford, Cambridge, London, and Dublin to a more solicitous education of the general practitioner. As for Edinburgh, we can only hope that Mr. Syme does not represent the opinions of the University.

The Medical Council will doubtless nip this attempt at a Dutch auction system in the bud; but more may be expected than this. It is within the province of the body, in the interests of the public and of Medical education, to submit to the Government, and through this to British statesmen generally, that there is an imperative necessity for giving due rank and remuneration to at least all public Medical officers, whether civil or military, as one means of attracting a better class of candidates for entrance into the Profession and the public Medical service. Nor would it be amiss to add, that the higher appointments in the State in which Medical knowledge is useful, should be filled by Physicians and Surgeons, and not by officers in the army or members of the Bar as heretofore. The Medical Profession have a right to expect that as to these it should be placed on a level with at least the Church and the Bar, if not with the military profession. If such were now the state of things, we should not have had members of the Medical Council so forgetful of their own dignity and of that of the Profession to which they belong, as to seek out of their body and out of the Profession for a person sufficiently high-bred and distinguished to preside over their deliberations.

THE BRITISH PHARMACOPEIA.

WE may congratulate the Council on the appearance of the first British Pharmacopœia. Doubtless, the work has been difficult, tedious, and expensive; but so it is when you build a new house, if there are old ruins to be cleared away, and the interests and tastes of many proprietors to gratify. Now that we have one Pharmacopœia, the task of future revisions will be easy. The present work has just the defects which

are unavoidable in all literary works which are joint products of more than one head. It is difficult to hit the mean between too great diffuseness and too great exclusiveness; and it is more easy to keep out what displeases every one than to include what shall please all. We think the list both of *Materia Medica* and of pharmaceutical compounds might have been larger.

A pharmacopœia is to Medical Practitioners what a regular system of coinage is to the merchant. For every man to be compelled to write out all the ingredients of every remedy, would be like going back to the times when the great Bedouin sheik, El Khalil, weighed out his silver to pay for the cave wherein he buried his wife. It cannot contain *all* the drugs used by *all* Practitioners, but it may contain most of those used by men of repute, and it may give a public authoritative description of the quality which should belong to each drug or compound. Every man is conscious of the amount of labour saved when he writes *Tinct. opii*, instead of defining the ingredients and strength of the preparation; and the same rule holds good with regard to such combinations as chalk mixture, steel mixture, and the like. It would have been a convenience both to prescribers and to dispensers, if the number of the latter class of formulæ had been greater. Why should there not be off-hand formulæ for many medicines in daily use, such as the black draught of senna and salts, the red draught of infusion of roses and salts, the white draught of sulphate and carbonate of magnesia, black-wash, saline draught, and the like? Gregory's Powder may now be prescribed as *Pulv. Rhei Comp.*, and it would have been well had set formulæ been given for other combinations in common use. The new *Pil. Plumbi Comp.* is an example.

We may regard the "British Pharmacopœia" as a great improvement upon any of its predecessors, which have now coalesced and become extinguished by it. It is a gain to have one instead of three. There is a vein of common sense and practical usefulness throughout. The language is English, which need not be regretted, since it is impossible to make classical Latin comport with the description of things, processes, and notions, of which Latin writers and speakers never dreamed. The book is handsomely and clearly printed, and we notice only one error, viz., page 317, where "Resin of Jalap" is given as the translation of "*Scammonia Resina*." The Index, an important thing for hurried readers, is not so full by one-half as it should have been; and the nomenclature and arrangements have just that small amount of inconsistency which is a hindrance to rapid reference. For example, a man who wants Resin of Jalap will look in vain under "Resin," or "Resina." If he wants Tincture of Opium, he will not find it under "Opium." A larger Index would have been a great boon. Yet, after all, this is a mere *macula*.

One thing which will please the practical reader is the return to old definite empirical names, which will hold good in all times; whilst names derived from the idea of the chemical composition and the symbol of a drug, may, and must, vary according to the views entertained by philosophers from time to time of the "essential nature of things." So now, an apothecary, who was in practice before 1815, may rub his eyes and dream that he is young again, and quite up to the present day, when he finds the name "Calomelas" restored, with the synonym Subchloride of Mercury, and the symbol Hg 2 Cl. ; whilst the name "Corrosive Sublimate" is restored to the sister compound with the synonym Chloride of Mercury and symbol Hg. Cl. Woe to the patient whose Physician should now hastily write "R. Hyd. Chlor., gr. v." We would suggest that in any future pharmacopœia the plan be carried further. Why not perpetuate the names of the good working men who gave us our most valuable formulæ? Can no niche be found for Galen? Why should not Hofmann's name still be associated with some soothing preparation of ether, even though the familiar *Spiritus Ætheris Sulphurici Comp.*, or Hofmann's Anodyne, have lost its place on the roll, and is

omitted in this new Pharmacopœia? Why not give that little reward for services rendered to mankind, which would cost no more than keeping up the names of James's Powder, Dover's Powder, Griffith's Steel Mixture, Marshall Hall's Aloes Pill, Huxham's Tincture of Bark, Fowler's Solution of Arsenic, Plummer's Pill, Battley's Liquor Opii and Liquor Cinchonæ, Gregory's Powder, Henry's Magnesia, Ward's Paste, Goulard's Extract, and the like? Paris's name should have been associated with the Lead Pill, and Prout's with the Phosphate of Iron? We possess the labours of these men, why not pay their *manes* this slight compliment? Here we have spoken only of the departed, but we know that there is many a man still amongst us who has been labouring hard for years at the improvement of the drugs in daily use,—we need mention only the names of Squire and Lloyd Bullock,—and without whom many of the preparations in the first British Pharmacopœia would never have seen the light. But a severe and frigid etiquette has caused the names—not only of bygone worthies to whom we owe our best formulæ, but even of the working committees and real authors—to be suppressed, although those of the Council appear at full length.

The book will shortly be in the hands of our readers, who will besides have the advantage of reading a series of lectures which will be delivered immediately at the Royal College of Physicians, and reported in this Journal. We need not, therefore, add more at present than a very few comments on the points which have excited our own curiosity in cutting open the pages, and which probably are those which most of us look at first.

Of the weights and measures everybody knows the history, as we gave it in *Medical Times and Gazette*, 1862, Vol. I., p. 562. We have now only the imperial pound of 7000 grains, the ounce, one-sixteenth of the pound = 437.5 grains, and the grain. All the barbarous and confusing old symbols— ʒss. , ʒj. , ʒij. , ʒiij. , etc.—may now go to the cemetery whither their astrological colleagues— ⊕ ℥ —have gone before them. The ounce even is superfluous and mischievous. The ounce, half ounce, quarter of an ounce, etc., have no definite relation to round numbers of grains. It were far better to write so many grains at once. If any one who consults the formula for Tincture of Opium, for example, could see at a glance how many grains to the pint, he could soon calculate the dose of the tincture. The old tincture contained the soluble pint of one grain in 13.33 minims, or 720 grains to the pint. The new contains 656.25 grains to the pint, or about one grain to 11.3 minims. Surely, an even number of grains per pint would have been more convenient.

Some remedies are added that did not appear in the last London Pharmacopœia, as Sulphurous Acid, Benzoate and Phosphate of Ammonia, Solution of Terchloride of Antimony, Oxide of Silver, Arnica, Bebeerine, Bael, Precipitated Carbonate and Phosphate of Lime, Indian Hemp, Chiretta, Coccus Indicus, Collodion, Kouso, Digitalin, Arseniate of Iron, the Citrates of Iron, and of Iron and Quinine, Magnetic Oxyde, Perchloride and Pernitrate of Iron, Phosphate, Granulated Sulphate, and Iron reduced by Hydrogen, Glycerine, Hemidesmus, Acid Nitrate of Mercury, Kamela, Cherry Laurel Water, Carbonate and Citrate of Lithia, Heavy Magnesia, Matico, Podophyllin, Permanganate of Potass, Sugar of Milk, Santonin, Arseniate of Soda, Pyroxylic Spirit, Valerianate of Zinc. We are glad to see the Aromatic Sulphuric Acid, but miss the *Liq. Arsenici Chloridi*, in which many skin Doctors put great faith.

It is a curious thing to compare the list of new remedies admitted into the Pharmacopœia, with a list of those which are advertised by zealous pharmaceutical chemists, and used by Physicians of repute even, without including some whose good effects are only predicted *à priori* by credulous rationalistic Physicians. It takes a long time for even a good remedy to take decided rank. Some few are, perhaps, admitted by favour of some influential prescriber, only to linger till they shall be ignominiously expelled at the next

revision. There are even some in the above list which have a suspicious look,—as the Phosphate of Ammonia, Oxide of Silver, Arnica, and some others. Meanwhile, there are some highly fashionable remedies left out. What is prescribed more often and more confidently than pepsine? We miss the Oxalate of Cerium, Chloride of Gold, *Actæa Racemosa*, the *Cotyledon*, *Galium*, Bromide of Ammonium, and many others much in request. How much, too, has been written to show that preparations of manganese *must* do good? But admission to the Pharmacopœia is a sort of canonisation, which every drug cannot attain to. They must bide a further test of experience. All are glad to see, by the way, that cod-liver oil ought to be *pale*, and extracted from the fresh liver, and with a *bland* fishy taste. We are certainly astonished to find so little use made of *glycerine* for external applications. Our decided impression is, that the principle of exclusion has been carried too far; and that the Council would have acted wisely had they given recognised place and formula for more preparations, and if a larger number of prescribers and pharmacutists had been represented.

Some notice ought to have been taken of the concentrated infusions which are very largely used by Surgeons and chemists, in order to avoid the waste and trouble of preparing fresh infusions from time to time. The new Pharmacopœia has an "Extractum *Cinchonæ Liquidum*" identical with the former "Infusum *Cinchonæ Spissatum*," and it has analogous preparations of Ergot, and a few others. But "Concentrated Infusions" of Senna, Gentian, *Calumba*, etc., are in constant use, as a means of making common infusions by dilution. Are they perfect substitutes? Certainly, they are not so agreeable. But if they answer the purpose, the Pharmacopœia should adopt them, and give them the stamp of authority.

The work comprises—First, a list of the *Materia Medica*; secondly, of the preparations and compounds; and, thirdly, of substances used in manufacturing or testing. Suppose we glance at the *Narcotics*. Part I. gives full details as to Opium, which is described in its best form, and with a lime-process for its quantitative analysis. Eleven internal and four other preparations are then enumerated, and may be found in Part II. Hydrochlorate of Morphia heads the list. A process for the extraction of this salt is given, in addition to the tests for purity, which alone figured in the former London Pharmacopœia. Acetate of Morphia is omitted. Besides this, we have the extract—a new liquid extract—(*Liq. Op. Sed.*), and a *Pilula Opii*, replacing the old Compound Soap and Storax Pills. There is also a formula for *Pil. Plumbi cum Opio*, with gr. iij. of the former, and gr. ss. of the latter, in a four-grain dose. The *Pulvis Cretæ Aromat. c. Opio* contains, as before, one-fortieth of opium. *Pulv. Ipecac. c. Opio* replaces the old Dover's Powder, but retains the proportion of 1 in 10. *Pulv. Kino c. Opio*, with different quantities, preserves the former proportion of 1 in 20. *Tinctura Opii* is exactly the same in words, but is weaker in the proportion of 437.5 to 480. *Tinct. Camphoræ c. Opio* takes the place of Paregoric, and contains a very minute excess of camphor, with an unimportant increase in the quantity of both opium and benzoic acid. *Vinum Opii* slightly increases the quantity of the opium, containing 656.25 grains to the pint, instead of 600, and omits the cinnamon and cloves, which kept up its alliance with Sydenham's Laudanum. The *Enema Opii* retains the mxxx. of laudanum, with half the quantity (2 oz.) of its starchy vehicle. The *Liquor Morphiæ Hydrochlor.* is of half the strength of the present London preparation.

Among the other narcotics we find *Aconitia* with a process for its manufacture, and *Digitalium* with the same addition, both absent in the last London Pharmacopœia. *Atropia* is directed to be made by a percolation tincture treated with chloroform. Its sulphate is omitted altogether. From *Aconitia* an ointment is prepared, and the same from *Atropia*; a "liquor" containing gr. iv. to the ounce is given as the common formula of alkaloids. The roots and leaves of the plants, with their officinal formulæ, are for the most part retained.

The old *Pilulæ Conii Co.* is expunged, but *Conium* appears as a fruit, from which the tincture is made, and the plant itself, in the form of fresh leaves and branches, dried at a heat not exceeding 120°. From these, the *Cataplasma Extractum* and *Succus* are to be manufactured. In a similar way directions are given for the Extract and Tincture of *Hyoscyamus*.

Dulcamara appears as the young branches dried, from indigenous plants which have shed their leaves, an infusion of which appears identical with the old decoction. Tobacco, and the Enema, its only preparation, are not materially changed. *Lactuca* and its extract are not mentioned, neither is the *Extractum Papaveris*, which was very useful as an external application. The Extract of *Stramonium* continues much as before, and a tincture is added, which is directed to be made from the seeds.

Ferrum.—Iron is first represented by a new preparation—the Arseniate; also by the Citrate of Iron and Ammonia, as well as the Citrate of Iron and Quinia. The *Ferri Iodidum* is added to the Syrup of the same, and the *Ferri Oxidum Magneticum* appears for the first time, as well as the Peroxide of Iron, in addition to the former Hydrated Peroxide, which remains, though with some change in the process of manufacture. The *Liquor Ferri Perchloridi* is directed to be used in the preparation of the Tincture *Ferri Perchloridi*, apparently replacing the old tincture of the Sesquichloride, but differing principally in nomenclature. A *Liquor Ferri Pernitratidis* does not occur in the last London publication; and the same remark applies to the *Ferri Phosphas*, the *Ferri Sulphas Granulata*, and the *Ferrum Redactum*. *Ferrum Tartaratum* takes the place of *Ferri Potassio Tartrat*. *Ferri Ammonio-Chloridum*, and its Tincture, are expunged from the list, probably with reason.

Expectorants.—*Ipecacuanha* is introduced into the *Pulv. Ipecac. c. Opio*, *Trochisci Morphiæ c. Ipecac.*, and appears alone in the *Vinum Ipecac.* Squills are retained in the form of the *Pil. Scillæ Co.*, and as a Syrup not previously officinal, which represents the *Oxymel minus* the honey. The Tincture also remains. Balsam of Peru forms no compounds; that of Tolu remains as Syrup, Tincture, and as an ingredient in the *Tinct. Benzoini Comp.* *Ammoniacum*, as an internal remedy, is still used in the simple form of *Mistura*, and also in the *Pil. Scillæ Comp.* The other expectorants, with some few omissions, do not appear to be materially changed.

Iodine.—Iodum is to be resublimed, and from it a Liment, Tincture, and Unguentum Comp. are made, the first two differing only in strength from one another, the last preparation practically identical with that now in use. The *Liquor Potassii Iodid. Comp.* is not inserted. Iodide of Potash, for the manufacture of which a process is given, concurs in forming the three preparations above, and its own simple ointment also. *Potassii Bromidum* figures for the first time, but without any accessory formulæ.

This may suffice for the present about the new British Pharmacopœia.

THE WEEK.

RECOVERY OF H.R.H. THE PRINCESS OF WALES.

HAPPY, as is the kingdom with no annals, must be the confinement, followed by no event save uninterrupted recovery. Bulletins have ceased to be issued, and Dr. Arthur Farre is no longer a guest at Frogmore. Dr. Jenner visited the Princess during the temporary illness of Dr. Sieveking.

Dr. Arthur Farre and Dr. Gream have been gazetted as Physician-Accoucheurs to her Royal Highness. It is no disparagement to either gentleman, if we add that there are other men of University education and profound knowledge of natural science, who have worked hard at teaching, at original research, and in the composition of books received as authorities on obstetric subjects, all over the world, to whose names the Professional mind reverted when contemplating the possibility of new appointments of this kind. It is not possible to make

all Court Physicians who are worthy of it. But the Profession may congratulate itself that the Prince's advisers had so large and unexceptionable a set of men to choose from—that the number of eligible men far outweighed the number who could possibly be chosen. In the present instance, both the suffrages of the Profession and of the aristocratic female world are well represented. If we may say of the one that his scientific repute is above praise, we must record it of the other, that the fact of obtaining the confidence of the most refined, sensitive, critical, and fastidious community on earth, shows the possession of powers much to be envied. "*Principibus placuisse viris,*" or "*fæminis,*" is not the work of a fool; and he may well be vain, for whom the highest women of England fought so earnestly in every *salon*, and so successfully as they did for Dr. Gream, about the appointment of Physician-Accoucheur to H.R.H. the Princess of Wales.

THE NATIONAL REGISTRATION ASSOCIATION.

DR. HENRY G. WRIGHT, of 23, Somerset-street, has consented to be treasurer of an Indemnity Fund, for the purpose of relieving Mr. Lavies from the pecuniary claims which are allowed to fall upon him, through the failure of the members to pay up their subscriptions. We must return to this matter next week, hoping meanwhile that such a blot on the *esprit de corps* of our Profession will soon be wiped out.

THE CRAWLEY COURT-MARTIAL AND ITS RESULTS.

THE proceedings in the Crawley court-martial have been summed up by some remarks from H.R.H. the Commander-in-Chief. The accused colonel is almost the only person who has escaped scatheless, and he returns to the command of his regiment with a few words of advice from the Horse Guards. Not so, however, the witnesses. Major Swindley, Adjutant Fitzsimon, and Surgeon Turnbull have, in reality, undergone their trial, and received a sentence of dismissal from their regiment. In future cases witnesses will do well to remember the facts supplied by the few courts-martial of late years. Into Surgeon Turnbull's conduct a court of inquiry is held. The president of that court is, we understand, Major-General Eyre, and the members are Medical officers of rank. We have neither ratified nor entirely supported the course pursued by the Surgeon of the 6th Dragoons, but we have stated what might and ought to be urged in vindication of his conduct and that of our Profession. One point, however, cannot be too strongly dwelt upon. This court of inquiry is held upon the Medical records of the regiment, and has ostensibly arisen from the discrepancies (real or supposed) in the case of a Sergeant-Major Wakefield. Now, putting aside every question of the proper or improper conduct of the Medical officers, this matter was totally and entirely irrelevant to what was the subject of the late court-martial. This was not about Sergeant-Major Wakefield, but about the arrest, illness, and death of Regimental Sergeant-Major Lilley, and no one else. The Horse Guards, apparently, have seized upon this distinct and irrelevant subject for saddling one of the Medical officers, who was a witness for the prosecution, with a large amount of discredit and opprobrium. On the proceedings or finding of this court of inquiry we can have no right to enter or venture an opinion. No doubt the conclusions arrived at will be just and fair; but we only desire to call attention to the fact, that a Medical officer's conduct is called in question upon a case which had nothing whatever to do with the subject for which he was a witness.

And here let us advert to another subject. All cannot be right in the Army Medical Department, or we should not read of the resignation of Assistant-Surgeons of many years' standing, and two such appeared only the other day. It is contrary to common sense to believe that such resignations would take place—it is contrary to all the ordinary experience of life to find men voluntarily disconnecting themselves from a certain means of livelihood for the more precarious chances of success

in civil life—if some grave defects did not exist in the department which they quit. The fact is, that the Army not only offers no chances of speedy success to good Medical men, but it holds out so little probability of promotion within a reasonable time, that really good students refrain from entering it. The discontent is widely spread. In some cases the grounds on which it is urged are substantial enough, such as the above, and the degrading duties of branding soldiers, etc.; in others the reasons are more indefinite, but the discontent undeniably exists.

There are rumours in abundance about changes in the department, but they rest on no other foundation than the necessity which is supposed to exist for supplying the ranks of the Army with Medical material. So long as Government can get Medical candidates, so long will there be no changes. That is our opinion, and we commend the lesson which flows out of it to the attention of Medical aspirants for Army honours.

SURGEON TURNBULL AND THE HORSE GUARDS.

SINCE the above was in type we have been informed that Surgeon Turnbull has been entirely exonerated by the Court of Enquiry from the charge of interpolating the Medical cases in the Hospital Registers of the 6th Dragoons. We learn that this matter had already been fully investigated by Colonel Crawley, in India, and that his bringing it before the Aldershot Court-martial was an adroit means of diverting attention from the charges against himself, by damaging Surgeon Turnbull in the eyes of the Court. Notwithstanding the failure of the attempt to get up a charge against Mr. Turnbull about the books, it is said that he is about to be placed on half-pay by the Commander-in-Chief on account of the *animus* which he is alleged to have shown in giving his evidence. This may be a warning to Medical officers for the future not to give any evidence that is not palatable to the Horse Guards.

THE REPRIEVE OF TOWNLEY.

WE are much indebted to the magistrates of Derbyshire. Their memorial to the Home Secretary, though up to the present time powerless to affect the fate of George Victor Townley, has been productive of two very notable results. It has made public the startling fact, that by the unremarked introduction of the two words, "or death," into an Act of Parliament providing for the maintenance of criminal lunatics—a re-enactment, introducing these two words (3 and 4 Vict. c. 54), of an existing law (9 Geo. IV., c. 40)—the power of abolishing the punishment of death is given to "any two justices of the peace, and any two Medical men;" and it has procured the publication of the Report of the Commissioners of Lunacy on Townley's case.

The first of these two matters will doubtless be amply discussed and commented on elsewhere; it is not exactly suited to these pages; but probably not even the most sentimental advocates of "the deep cry of humanity's voice"—that is, of a sympathy with the "poor murderer," not with his victim—can wish to see the power and majesty of the law, so masked and juggled away—the brightest and purest prerogative of the Crown transferred to such hands.

We are more concerned with the Medical part of the case. The Report of the Commissioners of Lunacy is highly creditable to them. We must own that the publication of all the documents concerning the case has wholly freed Sir George Grey from the suspicions of almost criminal weakness and sentimentality which had been raised against him—suspicions entirely and very naturally due, however, to his conduct in some other cases; but, after Mr. Baron Martin's two letters, he could not do otherwise than direct an inquiry into the prisoner's state of mind, and for this purpose he could not have employed better machinery than the Commissioners of Lunacy. Their Report is a very careful and well-considered document. They state that they found the prisoner always

"remarkably calm, quiet, and self-possessed;" that "his views of right and wrong, false as they are, appear to have been coherently acted upon, and with a full sense of what they involved;" and that "what his mental condition is now, it had been throughout the entire period of his imprisonment;" they give weight to his "extravagant opinions;" "his extraordinarily perverted moral sense;" and "the hereditary taint alleged, and apparently proved, to have existed in the family of his grandmother;" but they conclude in these words:—

"Being of opinion, therefore, that the prisoner continues to be now in the same mental state as when he committed the murder and underwent his trial, we think that, applying the law as laid down by Mr. Baron Martin to this case, the prisoner, George Victor Townley, was justly convicted."

It cannot be imagined, then, that this report would have saved Townley; and Sir George Grey had already expressed an opinion that the report of the trial "did not appear by any means conclusive" as to the alleged insanity of the prisoner. But now stepped in the *Deus ex Machina*, in shape of the certificate signed by "any two justices of the peace and any two Medical men," and bore the murderer triumphantly away. The jury, the judge, the Home Secretary, and the Commissioners all seem to have done their duty, and to have done it well; but law and justice were eventually taken out of their hands: whether finally remains to be seen.

Of the part played in the affair by the Surgeon of the gaol it is not pleasant to speak. A more naïve and more pitiable confession of vacillation and confusion of mind than his letter has perhaps never been read. Townley became his prisoner, August 24. October 6 he states in his journal—"Townley, good health, mind and body." He thought "his mind was weak, and he was ill-educated," but "was impressed, as the public were, that he was sound in mind and body." The grammar equals the logic: the Surgeon seems to think that the public had the same opportunity for judging of the mental state of a man, then in gaol for six weeks, as he had. When the time of the assize was settled, it occurred to him "that the judge might ask his opinion" as to the prisoner's mental condition, so "for seven or eight weeks" he held repeated discussions with him—resulting in "sore perplexity." "Sometimes I thought he was insane. Again I thought he was sane." He consulted with Dr. Hitchman, "and our joint opinion was that no case of legal insanity could be established, and that an intelligent jury would be certain to find him guilty." One hopes he has now found rest; but, alas! for him, the great psychologist comes down, and all is again doubt and confusion; but after carefully reading Dr. Winslow's opinion, and after "putting all the varied and accumulated facts, opinions, etc., together," he comes "to the conclusion, through the portals of doubt, that Townley was of 'unsound mind.'" And then he illustrates in a most curious way the difficulty of diagnosing insanity; "like a broken leg or a dislocated shoulder, it often needs close, protracted, and repeated investigation to fathom it." What will Surgeons in general say to this? It may, perhaps, in rare cases, be difficult to state the precise nature of the injury to a limb, but surely not whether it is unsound or no? But even now there was hesitation. "Almost till going into the witness-box I was undecided as to the opinion I should give. I told Mr. Leech (the prisoner's attorney) I should be guided much by what transpired in court." Mr. Gisborne talks about "bigots and cowards adhering to an opinion once entertained," "whereas men of good sense and honesty pursue a more meritorious course." We do not doubt for a moment his "honesty;" but when we find his opinion taking hue, chameleon-like, from the mind he is last in contact with, we must take leave to doubt his "good sense." That his motives were throughout "honourable" and "creditable" to his feelings, if not to his judgment, no one questions; but we must venture to entreat that, for his own credit and the credit of the Profession at large, whatever he may do or not do, determine or doubt, about any future case, he will never again rush into print.

FROM ABROAD. — MASTURBATION IN GIRLS—ANIMAL MAGNETISM IN SAXONY — SPONTANEOUS GENERATION — THE ASSUMED PHYSICAL DEGENERATION IN FRANCE.

M. BROCA, at the last meeting of the Paris Surgical Society, related the case of a girl, aged only 5 years, who, together with great precocity of mental power, exhibited excessive genetic excitement in the shape of the most uncontrollable masturbation. The most assiduous watching and various mechanical means had been resorted to in vain, until at last the child became excessively emaciated, and delirium with hallucinations ensued. After various means had been tried in vain, the amputation of the clitoris was proposed; but, before resorting to so extreme a measure, M. Broca determined to try a modification of the ancient practice of *infibulation*. Having scarified the labia and brought them together by means of a suture, he succeeded in producing union by first intention; so that the clitoris and labia minora are now protected from contact by means of a bridge or barrier of about half a centimetre in thickness. There only exists a small aperture for the passage of the urine at the lower part of the vulva scarcely large enough to admit the point of the little finger. As this operation had only been performed a few days, its result remains to be proved; and we should not have noticed the case now, had not its relation to the Society called forth an account from several of its members of their experience in this distressing affection. MM. Morel Lavallé and Deguise, indeed, stated that they had no expectation of success following the procedure followed by M. Broca, as masturbation will still be practised beneath the sort of bridge which has been constructed. M. Deguise would have preferred cauterising the genitals, recollecting the great benefit which followed this practice, continued for a year, in the case of an insane youth violently addicted to masturbation. M. Richet maintained that it is not in this or that portion of the female genitals that the sensations consequent on masturbation are capable of being excited, any portion of them, whether the clitoris, walls of the vagina, cervix of the uterus, etc., being liable to be so stimulated. Some years since he removed the entire clitoris in a girl, aged 17, who, by excessive masturbation, had reduced herself to a mere skeleton. The patient recovered her flesh and strength, and for a considerable time lost her bad habits. Eventually she relapsed, suffering as before, the seat of excitement now being the neck of the bladder, the walls of the vagina, and the cervix uteri. In answer to a question, M. Richet stated that he had tried the bromide of potassium in vain, but that the sulphuret of carbon seemed to have been of some temporary benefit. M. Guerin did not consider the bromide of potassium a merely inoffensive remedy, as it has given rise, in his hands, to nervous accidents, resembling epilepsy. He does not admit the exclusive importance generally attached to the clitoris as the organ of pleasure in women, the bulb of the vagina and the vaginal glands being of great importance in this point of view. M. Giraldès cited cases of children of from 3 to 6 years of age, who gave themselves up to excessive masturbation, even after so serious an operation as amputation of the thigh. M. Guersant has frequently employed circumcision in the case of boys, and has cured in this way, at all events for a time, a certain number of cases, the means operating to a certain extent by terrorism. In little girls, he either excises the glans of the clitoris, or touches that organ with the extremity of a probe heated to a white heat. M. Marjolin reprehends this as a very dangerous practice, while in most cases it proves quite useless. For his own part, he has little confidence in any local remedy, believing that the real seat of the evil is at least as often in the nervous centres as in the genital organs. M. Broca, in reply, observed that two descriptions of masturbation may be distinguished, the one cerebral or cerebro-spinal, depending upon affections of the nervous centres which may give rise to a perversion of the genetic instincts and propensities; the other, genital, having

its source in the external organs of generation. The one is central, and the other peripheric; and the two species are not very easily distinguished from each other. A special condition of the genital organs may induce masturbation, as is the case in phimosis in young boys. The irritation or pruritus gives rise to rubbing, which may induce a voluptuous sensation, which, once experienced, is instinctively sought to be reproduced; and in little girls born with a large clitoris masturbation often occurs. Against the masturbation due to affections of the nervous centre we have no means of direct action; but when this has its seat in the genital organs, an operation, by its physical or its moral effect, may be of avail. The operation he has performed in this case preserves the sensitive parts concerned from contact; and if it does not succeed altogether in preventing masturbation, may much diminish the frequency with which it is resorted to, and thus also diminish the severity of the consequences.

The last number of Dr. Kürchenmeister's *Zeitschrift* contains a curious example of the manner in which quackery is officially coquetted with in Saxony. In its official section it records a decree, issued by the Minister of the Interior, as so much a matter of course as to call forth neither remark nor reprobation. One J. G. Unger, a peasant, of Zobnitz, near Lobau, having sought permission from the Ministry of the Interior to practise animal magnetism, and no objection thereto having been made by the official Medical authorities, such permission is accorded to him, providing he does not carry his procedures far enough to induce magnetic sleep, but confines himself to simple passes and imposing of hands upon the parts affected. Should Unger, however, during his manipulations, unintentionally induce magnetic sleep, he is at once to send for the district Medical officer, and leave all further dealing with the case in his hands. This functionary is also directed to keep a constant eye upon Unger, so as to restrain his activity within the limits indicated by this decree. A noble function, truly, for an educated Medical Practitioner!

The question of "spontaneous generation," which has been so long and keenly debated at the Academy of Sciences, is now put into a train for settlement as far as this is possible. M. Pasteur on the one hand, and M. Pouchet on the other, have agreed to repeat their experiments before a committee of the Academy, and to take its interpretation of the results as final. The following members of the Academy constitute the committee:—MM. Flourens, Dumas, Bronghiart, Milne-Edwards, and Balard.

Alarmists having spread the report, that for some years past the population of France has been undergoing a physical degeneration, M. Legoyt, Chief of the Statistical Bureau, has just published a statement which contains a pretty decisive answer to the assertion. M. Legoyt attributes the origin of this opinion to observers having confined their attention to the period 1854-59, which was really a critical one for the French population. A devastating epidemic of cholera, an unusual series of deficient harvests, and two great wars, sufficiently explain, however, any temporary arrest of the development of the population which may then have been observed. Examining the mortality returns for the present century, M. Legoyt finds that the proportion has diminished from one death in 40.59 to one death in 42.30 inhabitants; and in the progress of such diminution France occupies the ninth rank of twenty-five countries. The mean duration of life has also notably increased since the commencement of the present century. Among other proofs of this is the larger number of young men born in given years who reach their twentieth year, as seen by the conscription returns. For the forty years 1820-59, there were 11,919,254 names inscribed, being the survivors of a total of 19,586,931 boys born twenty years before, *i.e.*, 60.85 survivors in 100 births. This proportion has oscillated in the eight subperiods of five years each into which the period may be subdivided; but the general conclusion is that, from 58.22 for 1820-24, it has risen to 61.59 for 1855-59. Another test of the condition of the population of the country is its degree of

military aptitude, as measured by the number of exemptions on account of insufficient height and diseases or infirmities. The number of exemptions on account of defective height (the standard being 1.560 metre) has diminished from 875 in 10,008 conscripts in 1831-35, to 613 in 1856-60. Again, the exemptions on account of infirmities and diseases have progressively diminished from 3.055 in 10,000 for 1836-40, to 2.677 for 1856-60; and that notwithstanding that much more rigorous care has been exerted during the latter periods in excluding all men except those of sound constitutions. In part consequent upon this more rigorous examination, it results that the mortality of the army is not now greater than that of the civil population of the same ages. The great improvement which has taken place in this respect is, however, also greatly due to the improvement in the hygienic condition of the army. Finally, one other fact, which has been advanced in proof of increased physical degeneration, M. Legoyt is not able to reply to so satisfactorily, *viz.*, the proportion of children born dead. Thus, while in 1851-55 there were but 3.91 per cent. in 100 births, these rose in 1856-60 to 4.30. It is true, that of late years the numbers have been more exactly recorded. Moreover, a similar increase is observable throughout Europe.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF NORWICH.

(Continued from page 71.)

ASYLUMS FOR THE INSANE.

There are three asylums for the insane in Norwich. One is entirely private; the second is a charity; and the third is for the parochial patients of unsound mind.

HEIGHAM HALL PRIVATE ASYLUM FOR THE INSANE.

This asylum, situated a little distance from the city, is capable of receiving sixty patients. The Hall is most commodious and commanding, and the grounds are very extensive and excellently arranged. I had the pleasure of visiting this asylum, and of being conducted through every part of it. The care that has been taken in securing the most modern sanitary improvements reflects the greatest credit on the managers, and with all these arrangements there is an artistic decoration which I have rarely seen equalled. The reports of the Commissioners in Lunacy have been unusually favourable to the Institution; and this is not to be wondered at, for all that is said is richly earned. J. F. Watson, Esq., is the Resident Medical Superintendent of Heigham Hall; Dr. Ranking, whose abstracts of the Medical Sciences adorn all our shelves, is the Visiting Physician; and W. P. Nichols, Esq., Senior Surgeon to the Norwich Hospital, is the Visiting Surgeon. I believe the Hall was transformed into an asylum by Mr. Nichols, and that the improvements to which I have referred have been carried out under his direction and on his suggestions.

THE BETHEL ASYLUM.

The institution known as the Bethel Asylum was founded in the year 1713 by Mrs. Mary Chapman. She, the daughter of one John Mann, Esq., once Mayor of Norwich, married the Rev. Samuel Chapman, of Thorpe. Her husband dying, she determined to raise an asylum for the insane, and at first she entrusted the management to a governor; but, hearing that the business of the institution was not progressing as it should, she went down one day, turned out her servants, and at once took the control into her own hands. A portrait of this lady hangs in the board-room of the asylum; it represents a lady with a fine Saxon face, and a gentleness and charity which both win and govern. She died in 1724. Her will, which was lent me for perusal, is a curious document. Originally, the number of patients admitted were very small; but at this time from seventy to eighty are housed and fed, and there is at least one attendant for every twenty patients. The income of the asylum amounts to about £400 per annum, and each patient adds to the sum by a payment of from two to six shillings weekly.

Some little time ago fault was found with the management

of the asylum, the great objection being that there was not sufficient space in the airing-grounds. Situated as the asylum is, in the heart of the city, it is true, and necessarily true, that the grounds are small for the number of patients who move in them. It also struck me that the separate rooms of the inmates were unusually small, and that the corridors, owing to the old style of building, were low and cramped; but the greatest comfort prevailed throughout, and such objections as have been raised were not warranted by the actual facts.

Before leaving this Asylum, I would draw special attention to an important lesson taught here in relation to the dieting of the inmates of establishments of this kind. In our workhouses and in many of our public charities, the system is carried out of weighing every particle of food at every meal for every person. The act, in itself, is disgustingly offensive to the feelings of any right-minded man, who considers poverty no crime; nor is there any justification for it but one, that it is economical. The question then comes,—Is such justification founded on truth and experience, or is it the blurted hypothesis of some individual who had himself more determinate gastric machinery than heart? We have the question solved at the Norwich Bethel Asylum. There the inmates take what amount of food they like that is at table, and, in reason, what they like. Nothing is weighed. The result is, that an actual saving, instead of loss, is effected; and, while everything is good and plentiful, eleven shillings per head proves ample for support and maintenance through each week. The reason for the result named is very simple, and was explained to me practically by Mr. Nichols, the visiting Surgeon. In providing food for a large number of persons daily, it invariably happens that both tastes and appetites differ. Hence, if eighty people at a given meal receive each one pound of food of the same kind and quality, cut up previously, and dished and placed to hand, with "this or nothing" written upon it, scarcely one is really satisfied, and much is lost. Some hardly touch their food, but send it away picked over and rendered useless; others eat heartily, and want more; any way, eighty pounds of food are lost for good. But place eighty pounds of food before eighty persons, and feed all according as they ask, and one wishes for but a little, and another for plenty; one for more potatoes and less bread; another for more bread and less potatoes; one for fat meat, another for lean without fat, and so on, the grand result being, as is proved, that something always remains in the central dishes which no one has touched, which is not lost, and which, however small the saving per day, becomes in the year an important item. If I could reach, with a true argument like this, the ears of the so-called guardians of the poor of England, and they would act on the experience, what an improvement would soon be effected in the moral, not less than the physical, life of the workhouse inmate, by insult "pauper!" To see old men and old women toddling up to a hole in a partition, carrying plate or basin in both their hands, like an Egyptian slave going before the great king, to ask for so much measured victuals, is, to my mind, one of the most degrading spectacles that could be witnessed in any community, savage or "civilised." And all for what? Economy! We have seen about that. No, not for economy, but to add penance to poverty, and to transform charity into chastisement.

W. P. Nichols, Esq., is the Visiting Surgeon; C. M. Gibson, Esq., the Resident Surgeon; and Mr. E. D. Dodd, the Superintendent of the Bethel Asylum.

PAUPER LUNATIC ASYLUM.

The Pauper Lunatic Asylum of Norwich was originally a lazaret-house. It is a dull, low, old-fashioned building, situated at some distance from the city, and having accommodation for about eighty patients, thirty-seven of whom, at this time, are men, and forty-five women. The diet scale is liberal, and the men and women dine together in one large room. Objections have also been made of late to this Asylum, to the effect that the grounds are not sufficiently large, and that out-door labour is not obtainable for the patients. The grounds, nevertheless, are moderately extensive; they contain conservatories, which have been built by the patients, and a variety of amusements of an active kind are freely encouraged. The patients, moreover, being mainly, on the male side, weavers and shoemakers, are not accustomed to out-door work, and would not be competent to perform much manual labour if it were there for them to do. The arrangements of the Asylum, which I carefully inspected, were as good as they could be made under the circumstances; there was no overcrowding, ventilation was free, and the inmates had a clean and healthy appearance. By this

time the institution is transformed into a Borough Asylum. To make a perfect modern Asylum, this old place, which covers a great deal of ground unnecessarily, should come down, and be replaced by a new and improved building. G. W. Firth, Esq., is the visiting Surgeon.

OTHER INSTITUTIONS CHARITABLE AND PAROCHIAL—THE BOYS' HOME.

In addition to the above, Norwich is well provided with other charities and parochial institutions. *The Workhouse*, a very fine building on the Dereham-road, accommodates from 600 to 700 inmates. *The Doughty Hospital*, founded in 1687, receives twenty-eight men and sixteen women, who are allowed 5s. 6d. per week, with coals and clothing, and who are attended in sickness by Mr. Cadge. *The Infirmary for the Indigent Blind* is a Hospital for the aged blind, and a school for the instruction of blind children. There is one other institution to which I would direct special notice, because it develops a new principle—I refer to a house situated in St. Faith's-lane, called the *Boys' Home*. This charity was organised in 1846. It is parochial in character, but in principle there is nothing elsewhere like it in England. It receives in the course of the year some sixty boys, who come from the Workhouse, and who are divided into two classes, the *school* and the *home* class. Boys nine years old are first placed in the school class; when they are old enough they are allowed to go out and work; some go as clerks, others as handicrafts, and others as labourers or messengers. While thus working and learning the world, they still find for a long time a residence at the Home, and are thus kept during the most critical period of their lives under good and gentle discipline. The wages earned by the boys go towards their maintenance, but they are allowed threepence a-week for themselves. The working boys average sixteen a-year, and their earnings in eight years have brought in no less a sum than £969 sterling. The diet is on the Poor-law scale, and is, therefore, insufficient as a whole; but for the working boys it allows animal food five days in the week. Mr. Hutchison, the able Surgeon to this establishment, spoke to me enthusiastically on the great good that was effected by this simple measure. Every domestic comfort was supplied in the house. I found the wards large, clean, and airy; the bedding and clothing were unexceptionable, there were facilities for the bath, and the schoolroom was of good size. Mr. Hutchison supplied me with the facts relating to the health of these boys. By strict attention to cleanliness epidemics had been kept away nearly altogether, and only four deaths had occurred in nine years. When disease appeared, it was usually in the forms of struma and anæmia.

I hope those members of the Profession who act as Surgeons to the workhouses of this kingdom, and who are always ready to assist the poor, socially not less than professionally, will not forget the Boys' Home at Norwich. They may be the means in their districts of forming similar homes, and of conferring immense benefits on that almost outcast youthful community which the workhouse pours into the streets, homeless and hopeless.

THE CITY GAOL.

The Gaol at Norwich receives about eighty-eight prisoners yearly. The average of sickness is 2.50 daily. Such cases of disease as occur are low fever; but the mortality is exceedingly small. There is a very indifferent infirmary, which is now only occupied by female prisoners; the wards are dark and low. Once both males and females were admitted during sickness, but at last it was found that in one instance the patients succeeded in talking to each other by means of a chimney common to a male and female ward. Since then, the males have been prohibited the infirmary, and, when sick, have been treated in small cells within the gaol, which cells are utterly unfitted for such a purpose. They are scarcely better than large rabbit-hutches, with little light and less air. This state of matters is fortunately about to be remedied, by the construction of appropriate accommodation for the sick. The prisoners are kept well occupied; those on the treadmill are allowed five minutes' rest at short intervals, and the wheel is regulated. Others are occupied in hair-picking, mat-making, carpenters' work, shoe-making, e-log-making, and other useful arts. To the credit of the Norwich authorities, torture has not been practised in the gaol for seven years; neither has any human being been executed for a long period. The last execution took place in 1830.

THE SANITARY CONDITION OF NORWICH.

Apart from the Hospital, the sanitary condition of Norwich is not satisfactory, in many points. Great improvements have,

however, been made of late by the authorities, and what remains to be done is, to a large extent, in the matter of private hygiene.

Ventilation.—Ventilation is defective both in the public and private dwellings; and, in fact, it seems to be little thought of. The construction of the houses, especially in the old parts of the town, is against any effective system, and some excuse may be made for the occupants of such houses. But in public places neglect is less pardonable. What, indeed, can be said in extenuation of the condition of things which I am about faithfully to describe?

At two o'clock on Saturday, the 19th of December of last year, I went into the cathedral, by the western door. On entering the magnificent building, I was conscious of a cloud of vapour, somewhat dense and peculiar. Proceeding towards the organ, for the purpose of looking into the choir, I found myself giddy and nauseated, precisely as from breathing a narcotic gas. I soon returned, and found the attendant, a woman, speaking to Mr. Nichols, near the door; she was very pale, and also suffering from the air of the place, which always was so bad, she said, after lighting the coke fires in the side aisle on the right. On inspecting these, I found that warming was effected by means of great furnaces—I can call them nothing else—holding smouldering coke. These furnaces were open at the side, but at the top they were covered by a sort of huge funnel, having one ridiculous escape pipe, probably of two inches in diameter. Of course, the air of the cathedral was charged with carbonic acid, and, probably, with carbonic oxide; and but for the size of the building, it would be fatally poisonous when fires, so laid, are burning. If the worthy Dean and Chapter would read a lesson from Dr. John Davy's admirable description of the case of coke-poisoning in the church at Ambleside, they would, perhaps, see the propriety of attending to the physical, not less than the spiritual, welfare of their congregations.

Water Supply.—The water supply is by pumps, and by the reservoirs of the Norwich Waterworks Company. That derived from the pumps is of doubtful character for consumption, as will be seen by the following analysis made by Mr. Sutton:—

Partial Analyses of the Waters taken from the various Public Pumps in the City of Norwich during the Autumn of 1861, and reported to the Board of Health.

Parish of		Grains per imperial gallon.		
		Inorganic.	Organic.	Total.
St. Michael at Plea		52.24	9.01	= 61.25
„ St. Peter's, Hungate		61.99	9.88	= 71.87
„ St. George's, Tombland		69.16	8.76	= 77.92
„ St. Peter's, Mancroft		61.59	5.96	= 77.55
„ St. John's, Maddermarket		37.54	6.91	= 44.45
„ St. Lawrence (deep well)		37.03	2.98	= 40.01
„ St. Augustine's		39.47	4.98	= 44.45
„ St. John's, Timberhill		68.66	10.37	= 79.03
„ St. Peter, Mountergate		71.25	6.79	= 78.04

All the above-mentioned pumps are situated near churchyards, and the bulk of the waters contain considerable quantities both of ammonia and nitrates.

The supply from the waterworks is derived from the Wensum, at a distance of about a mile from the town. The works were reconstructed, and, indeed, I may say constructed, in 1850. The following analysis of the company's water was also made by Mr. Sutton; it shows a fair quality:—

Complete Analysis of the Water supplied to the City by the Norwich Water Company. Sample drawn October 3, 1861.

	Grs. per imperial gal.
Carbonates of lime and magnesia	13.71
Sulphate of lime	2.36
Chlorides of sodium and potassium	2.47
Oxides of iron, alumina, and silica	0.59
Organic matter	1.86
Total solid matter	20.99

Drainage.—The drainage of Norwich is now very complete; the river is the recipient of the sewage, but the sewage is as yet unutilised. There is little surface drainage, and the air generally is free from effluvia from drains. I observed, however, that the open refuse heap was still a prominent object in the lower parts of the city, but this nuisance is less than it was formerly. There are no manufactures that are specially injurious to the health of the city.

Climate and Meteorology.—Norwich bears the character of being both cold and damp. The statement is scarcely just.

The city stands thirty feet above the sea level, and in latitude 52°37' N. A well-known meteorologist, Mr. Brown, has kept faithful records of the weather, which have been forwarded to, and registered by Mr. Glaisher. I have looked over the whole of the results as epitomised by Mr. Glaisher, and the following, representing the year 1856, seems to be a fair mean:

Barometer—Mean monthly range of readings	1.091
Thermometer—Mean, monthly, of highest readings	66.0
„ „ „ of lowest readings	30.0
Air, mean temperature of the	48.7
Dew point do. do.	44.1
Humidity, mean degree of	84.0
Ozone, mean amount of	1.6
Cloud do. do.	6.8
Rain, number of days of	154.0
„ amount collected	25.4

Easterly winds are prevalent, but I have no daily record of prevailing winds.

Dwellings of the Poor.—The dwellings of the poorer classes in and about Norwich are revolting. In October last, the proprietors of the *Norfolk News*, one of the most ably-conducted of the provincial papers, opened, at great trouble and cost, a commission of inquiry on the homes of the poor. I must not enter into details, which would be but a repetition of the narrations in Godwin's late work, "Another Blow for Life," but I must mention a report made by Mr. Samuel Clarke, the energetic Inspector of Nuisances for the City. Amongst many examples given by Mr. Clarke is one in which a man, his wife, his son (21), his eldest daughter (29), and another daughter (15), all slept in one close room 12 ft. by 7 ft. 9 in. The woman was ill with typhus, so was the son. The son died on a Sunday, and was kept in the bedroom until the next Tuesday, the father and mother sleeping there all the time. This is even a scant illustration. The whole state of things is so bad that, in a foot note to an article on October 31, the Editor of the *Norfolk News* almost apologises for his narrative on the grounds that he must justify the public in believing that he is dealing with matters of fact, and not of imagination or romance.

Diet of the People.—If the dwellings of the poor of Norwich are very, very bad, the diet is even worse. The Norfolk dumpling—flour and water—is the prevailing dish. Solid animal food and soups are sparingly used, and even bacon and cheese are consumed in smaller quantities than in most of the other rural districts of England. Norfolk dumpling, weak tea, potatoes, heavy bread, and an occasional spare plate of animal food—and that more frequently salted than fresh—make up the daily meal of the Norfolk labourer. It is a sad lot. What wonder that vice prevails, and its twin sister, disease? What wonder that the Physicians call out for supporting measures so early in the course of disease?

Epidemics.—We have seen that in its early history the city of Norwich was frequently subjected to epidemic plagues, and until a recent date the communicable disorders have run their course too often triumphantly. But since the recent improvements in drainage and water supply, these diseases have declined to a considerable extent. In the year 1819, small-pox invaded the city, and carried off no less than 530 persons. The history of this epidemic was written with great power by the late Mr. Crosse. In 1861 there was another severe epidemic; and Mr. Samuel Clarke, the sanitary inspector, reports to me that no less than 3000 cases of the disease occurred. Respecting the other epidemics, Mr. Clarke states—"We are rarely now visited with any epidemic of scarlet fever or of typhus, although we were noted for these diseases in Crook's-place and Peafield before the drainage was laid down. Again, in Magpie-road, St. Augustine, we had typhus periodically until the drainage was completed, when the disease vanished. This was eight years ago." Cholera visited Norwich in 1849 and 1854. In 1849 it destroyed 38 persons; in 1854 it destroyed 193 persons. In the same years, respectively, diarrhoea carried off 99 and 184. These figures in 1854 are very high. In the eastern counties there was no town that suffered so severely in that year.

Mortality in Norwich.—The mortality of Norwich is above the average, the deaths of children being very numerous. In the year 1841 the population numbered 61,846, in 1851 it reached 68,195, and in 1861 it reached 74,865. In the ten years ending December, 1851, the mortality from all causes was 15,865. Through the kindness of Mr. Clarke, I am enabled to give the details of the quarterly and yearly mortality from 1837 to 1861:

Deaths from January, 1850, to September 30, 1861.

Years.	Totals.	Years.	Totals.	Years.	Totals.	Years.	Totals.
1850	496	1853	465	1856	340	1859	424

I had partly analysed, with a view to publication, the deaths of infants as compared with adults, and of males as compared with females. It is, however, impossible for me to find space for the results. I must, therefore, content myself with taking an example from one year presenting a fair average, when no epidemic specially prevails. The year 1856, the meteorology of which has already been given, is the best year I can select :

Males and Females.

Total births of males, 1146; deaths, 691. Total births of females, 1113; deaths, 713.

Deaths at Different Ages.

Males.—Under 1 year, 207; under 5 years, 279; at 15 years, 35; at 25 years, 40; at 35 years, 38; at 55 years, 77; at 65 years, 67; at 75 years, 52; and at 85 years, 13.

Females.—Under 1 year, 148; under 5 years, 219; at 15 years, 42; at 25 years, 57; at 35 years, 49; at 45 years, 58; at 55 years, 56; at 65 years, 88; at 75 years, 86; at 85 years, 20.

Causes of Death.—The causes of death in Norwich have been classified with great care for thirteen diseases, for some years past, and have been epitomised in the yearly returns of the Registrar-General, but sufficient care is not paid, I fear, to the minutiae of diseases to render an account of every fatal disease possible. The following abstract is, nevertheless, interesting: The rate of mortality, annually, to 1100 persons living is 24.25. The disease highest in the list of fatal causes is phthisis pulmonalis; this disease carries off 11.76 per cent. of all who die; next to it come diseases of the respiratory organs,—these destroy 11.70 per cent; diarrhoea takes 6.41 per cent.; typhus, 4.34 per cent.; violent deaths stand as 3.20 per cent.; scarlet fever takes 1.98 per cent; pertussis takes 1.14 per cent. Following in proportions of less than 0.49 per cent. come erysipelas, small-pox, measles, cholera, and puerperal fever. The malignant diseases have not been classified for accurate computation.

ETIOLOGY OF NORWICH.

The causes of the most fatal diseases of Norwich are obvious: bad ventilation, indifferent food, confinement indoors, and uncleanness. Phthisis, struma, joint disease, anæmia, cancer, and even calculus—these run together, and, when read deeply, are seen to be of common local origin. All our great cities and

towns, in fact, are grand experimental fields for the production of disease, and Norwich stands very high in the scale of disease-making communities. Much attention has been paid to the cause of the frequency of calculus. Dr. Yelloly was most particular in his investigations on this subject. He showed, from the practice of Mr. Martineau, one of the most eminent of lithotomists, that operations for calculus was required in *one* of the better classes of patients to *eleven* of the poor. He also showed that the calculus tendency was nearly double in the city to the county at large, and that the proportion of males to females was *twenty to one*. Our calculations to the present date are—males, 869; females, 41. We have thus evidently three disposing influences, viz., poverty, city life, and male sex. In respect to direct causes, there have been assigned hereditary tendency, the farinaceous diet, and the character of the water supplied. The first of these direct causes is scarcely tenable, because the tendency from the parent should pass alike to male and female child. The second cause is also not tenable, as sufficient to account for the phenomenon altogether, because the women live on the same kind of farinaceous diet as the men; and the third cause is out of the question entirely, because the women have the same water to drink as the men, and there is nothing special in the water to produce disease, as Mr. Sutton's analyses will show. There is, therefore, some other explanation of the fact; and the best explanation I have heard is one by Mr. Williams, which is, that exposure to cold and rheumatic disease, not necessarily acute, but chronic and diathetical, is the main cause. This is probably sustained by peculiarities of diet; but it is clear that there must have existed, before the actual formation of calculus, a febrile condition, in which the formation of lithates and phosphates in excess has been the leading fact. The relapses of calculus are 44 in 920 persons.

MEDICAL LIBRARY OF NORWICH.

There is a Medical library in Norwich, the rooms of which, two in number, are in the Literary Institute. The library is small, and the books are not up to the requirements of the time. There are some good classical works, and, indeed, the nucleus of an excellent library. Books circulate amongst the members. The annual subscription to the library is £1 1s.

MEDICAL SOCIETIES OF NORWICH.

There are two Medical societies of Norwich, the "Pathological" and the "Medical."

The "Pathological" meets in the museum of the Hospital every other month, for the reading and discussion of papers and the exhibition of specimens. Mr. Crosse is the honorary secretary.

The "Medical" is a society recently organised. The members meet at each other's houses for discussion and reading of papers. Dr. Copeman is the honorary secretary.

The societies named have not as yet published any volume of transactions. It would be a great point for Medical science if they did, for not only is Norwich a fine field for Medical observation and research, but the Practitioners there, at this moment, have but to say that they *will* use their advantages, to use them with singular success. "The Medical Transactions of Norwich" for the year 1865. That is the book wanted.

THE MEDICAL BIOGRAPHY OF NORWICH.

I cannot conclude this notice of the Medical history of Norwich more appropriately than by giving a brief summary of the lives of the eminent Medical men who have in past times flourished in this city. I will take them alphabetically.

Sir Thomas Browne, M.D., Oxon., the well-known author of the "Religio Medici," resided and practised in Norwich from the year 1636 to his death, on October 19, 1682. Sir Thomas had a very large practice, although, as we all know, he held his own opinions, and was subjected to much literary criticism. In 1641 he married a widow lady of good Norfolk family, named Mrs. Milham. The marriage, says one of his biographers, brought down upon him great railery, inasmuch as he had shortly before written "that we ought to multiply our species like trees, who by themselves throw out young suckers;" and "that the whole world was made for man, but only a twelfth part of a man for woman," and "that man is the whole world, but woman only the rib, or twelfth part of a man." Sir Thomas was knighted by Charles the Second, in 1671; he was also the author of a book entitled "Pseudo Doxiæ Epidemix; or, a Treatise on Vulgar Errors;" of another work called "Hydriotaphia; or, Urn

Burial;" and of the "Garden of Cyrus." The true character of Sir Thomas Browne has yet to be written. He was either one of the profoundest satirists we have had, or he was a learned twaddler; but all agree that he was an amiable and benevolent man. He was buried in the church of St. Peter Mancroft. Recently, his tomb has been opened, and his skull, which was in good preservation, has been removed to the museum of the Norwich Hospital, where, as I have already said, it still remains. On his coffin-plate was a curious and almost enigmatical Latin inscription, a rubbing of which was obtained by Mr. Firth. I am sure I am not asking too much of my friend in requesting him to send to the column of "Notes and Queries" of the *Medical Times and Gazette* his copy, and his very ingenious translation of this inscription.

Dr. Edward Browne, M.D., F.R.S.—Dr. Edward Browne was the son of Sir Thomas, and was born at Norwich, probably in the close of the year 1642. He was educated at the Norwich Free school, and thence went to Cambridge, and afterwards to Oxford, where he graduated in Medicine in 1667. It is not certain that he ever practised for any length of time in Norwich. He was fond of travel, and in 1673 published an account of his travels in Hungary, Austria, Macedonia, and other countries and provinces. He afterwards practised in London, succeeded Sir John Mickelthwait as Physician to St. Bartholomew's, was made a Fellow of the Royal Society, was some time Physician to Charles II., and was summoned to a consultation during one of the illnesses of William III. In 1705 he was made President of the Royal College of Physicians. He was the friend of Dryden, the poet, and wrote the life of Themistocles for the English translation of "Plutarch." He also wrote the life of Sartorius.

Dr. John Caius, M.D.—Dr. Caius, or, in correct English, John Kaye, known as the founder of Caius College, Cambridge, and as the Caius of the "Merry Wives of Windsor" was born at Norwich in 1510, and was educated at the Free School. He afterwards went to Gonville Hall, Cambridge, and became a Fellow of it. Later in life he practised in London, and was made Physician to Edward VI. On the accession of Mary, despite differences in politics and religion, he was appointed "Physician to the Queen," and on the death of that monarch he was retained by Elizabeth. As he rose into wealth and fame, he was specially anxious to benefit his old college, Gonville Hall; he therefore refounded it, and endowed it liberally, so that its name was changed to Caius College. He was the author of several learned works—"On the English Breed of Dogs," "On Rare Plants and Animals," "On the Hot Springs of England," and "De Medendi Methodo." But he is known especially by his work entitled "A Boke or Counsell against the Sweat" (1552), from which Hecker has borrowed largely, and on which Dr. Francis C. Webb has mainly founded his historical essay "On the Sweating Sickness in England." Dr. Caius died at Cambridge in July, 1573.

Dr. John Greene Crosse, M.D., F.R.S., one of the most eminent and most estimable Surgeons of Norwich, was born at Finsborough, in Suffolk, on the 6th of September, 1790. At twelve years of age he went to a grammar-school at Stowmarket; and on the 18th of August, 1806, he began to study Medicine as a pupil of Mr. Bayly, of Stowmarket, having chosen that profession instead of the Law, for which he was intended. Dr. Copeman has ably collated some of the parts of a diary kept by Mr. Crosse from very early life, and in which there are passages which would do honour to Franklin or Defoe. In 1811 Mr. Crosse reached London, and became the pupil of Sir Charles Bell; and in 1813 he was dresser to Sir Everard Home, at St. George's. Leaving London in October, 1813, he crossed to Dublin, and became Demonstrator of Anatomy under Dr. Macartney; and in December, 1814, after a brief visit to Suffolk, during which he was introduced to the late Dr. Rigby, of Norwich, he went to Paris, and stayed several months. Returning to London, he published his "Sketches of the Medical Schools of Paris," and took a house in St. Giles', where he remained some years. On the nineteenth day of the year 1823 he was elected Assistant-Surgeon of the Norfolk and Norwich Hospital; but the election cost him a serious illness, to remove which he took a trip to Holland. He had not long to wait in Norwich for practice, for his practical skill was soon known everywhere, and appreciated. In 1826 he was made full Surgeon to the Hospital, on the death of Mr. Bond. In 1829 he commenced to give courses of clinical lectures on Surgery at the Hospital, and he took an active part in the formation of the present Norwich Hospital Museum. As a writer, as a teacher, as a Practitioner, Mr. Crosse excelled equally. I have risen from

the perusal of his works with a sorrow, not easily expressed, that I had not read them more carefully before. The style is most simple, yet perfect; the argument clear; the narrative true, easy, and natural. His chief works are, "A History of the Variolous Epidemic of Norwich," "Memoirs of the Life of the late Dr. Rigby," "A Memoir of the Life of Philip Martineau," and a Jacksonian Prize Essay on "The Formation, Constituents, and Extraction of the Urinary Calculus." Mr. Crosse was elected F.R.S. in 1836; M.D. of Heidelberg (honorary) in 1835; and M.D. St. Andrews (honorary) in 1845. He was also a Fellow of the College of Surgeons, and a member of numerous learned societies at home and abroad. He died at the age of 60, of disease of the vessels of the brain, on Saturday, June 8, 1850, and was buried in the cloisters of the old Cathedral on Friday, June 14, amidst general sorrow. His son, the present Mr. Crosse, of Norwich, follows him, and not less worthily.

William Dalrymple, Surgeon, was born in Norwich, in 1772, and was educated at the grammar-school at Aylsham, and at the free school of his native city. He studied at Guy's and St. Thomas's Hospital, under Cline and Astley Cooper. He commenced practice in Norwich in 1793, and in 1812 was elected Assistant-Surgeon to the Norwich Hospital. In 1814 he was elected full Surgeon, and filled the post for the period of twenty-five years. He is not celebrated for any written works, but his learning, modesty, and amiability, won for him the affections of all his friends and patients. He was the founder of the Hospital Museum, to which he also largely contributed; and he was the father of the learned oculist and anatomist, John Dalrymple, whose memory is still retained in the London Professional world. Mr. Dalrymple in 1839 resigned his Surgeoncy of the Norwich Hospital, and in 1844 left practice altogether. He died in London, on December 5, 1848.

William Donne, Surgeon, deserves notice as an eminent lithotomist, and as one of the first Surgeons to the Norwich Hospital. He was, perhaps, the largest contributor in his time to the cabinet of urinary calculi, to which reference has before been made. He died in 1805.

Benjamin Gooch, Surgeon.—Gooch, who may be considered the founder of the Norwich Hospital, was a Surgeon living at Shottisham, near by Norwich. He is known as a writer by his two admirable volumes of "Cases and Practical Remarks on Surgery." They are the purest and most classical of the contributions to Surgical literature of their day. In style, though brief and abrupt, Gooch is superior to Pott, and he gives suggestions which are still of great value. A far-seeing man, he looked beyond the surface of things, and projected his thoughts onwards many ages. He lived to see the Norwich Hospital completed, and, having raised that monument to his own memory, sank quietly to his rest in the little village where he had been so long a resident. His death occurred in 1773.

Dr. Richard Lubbock, M.D., was born in Norwich, in 1759, and was educated at the free school. He commenced his Medical life under Dr. Rigby, and graduated in Edinburgh. He was one of the first pupils of the Norwich Hospital, and was Physician to it from the year 1790 to 1808. He died in 1808, and was considered one of the most accomplished of the Norwich Esculapians. He placed on record, in a short essay, the history of a case of catalepsy, and published one or two minor papers.

Philip Meadows Martineau, Surgeon, son of David Martineau, a Surgeon, was born in Norwich, on November 9, 1752. He was educated partly at Norwich and partly at Macclesfield. In 1769 he went to Mr. Webster, Surgeon, of Dereham, as pupil, and in 1770 to Mr. Donne, of Norwich; thence to Edinburgh in 1773, where he studied under Cullen and Horne, and in 1775 passed to London for a turn there of twelve months. After a visit to Geneva he returned to Norwich, and entered into a partnership with Mr. Donne, which lasted ten years. In 1777 Mr. Martineau was elected Assistant-Surgeon to the Norwich Hospital; in 1784 he founded the Public Library of the city, and in 1793 he was elected the Principal Surgeon to the Hospital. Having built a beautiful mansion at Bracondale, Mr. Martineau continued to practise with great success and position, and in 1824 he took an active part in inaugurating the now famous Norwich Musical Festival; he took an active part also as a Unitarian in the celebration of the repeal of the Test and Corporation Act. Mr. Martineau was considered during his life, and still is considered, as one of the best operating Surgeons who has lived and practised in Norwich. His literary contributions

are but two in number; the one is on an "Extraordinary Case of Dropsy of the Ovarium," submitted by John Hunter to the Royal Society in 1784; and the other is the famous paper on "Lithotomy," published in the eleventh volume of the "Transactions of the Medico-Chirurgical Society of London." In this paper are detailed the results of eighty-four operations for stone by the lateral method, in which there were only two deaths. After filling the office of Surgeon to his Hospital for half a century, Mr. Martineau resigned in November, 1828, and was elected Honorary Consulting Surgeon. He died on the evening of the 1st of January, 1829, and was buried in Thorpe Church, hard by Norwich.

Dr. John Murray, M.D., a philanthropist and Physician, was born in the year 1720, at Unthank, Eskdale, and settled in Norwich in 1768. He is recollected as the founder of the Scots Society, for the assistance of such of the Scottish in Norwich who could claim no parochial relief. He was also a staunch slave abolitionist. He died on September 26, 1792.

Dr. Edward Rigby, M.D., one of the great Medical celebrities at Norwich, was born on December 9, 1747, at Chowbent. He was placed early in life under the tuition of the immortal Priestly, and remained under him at Warrington until 1762, when he was apprenticed to Mr. David Martineau, Surgeon, of Norwich. He studied in London under the Brothers Hunter, and was admitted a member of the Corporation of Surgeons on May 4, 1769. In the same year he married, and commenced practice in Norwich, and soon rose to the first place. By the year 1789, he was sufficiently rich to take his yoke easily, and he, therefore, visited the Continent, was in Paris during the Revolution, and saw the head of the Governor of the Bastille carried on a pole. On his return to Norwich, he took an active part in social and political matters, and introduced amongst the weavers the Lancashire improvement known as the flying shuttle. In 1803, he married a second time, and had twelve children by this union. Four of these children—three of them boys and one a girl—were born at one birth; the membranes in which they were enclosed is still in the museum of the Norwich Hospital. The late Dr. Rigby, of London, was one of the children of this marriage. In connection with the Hospital itself, Dr. Rigby was Assistant-Surgeon for nineteen years, Surgeon twenty-four years, and Physician seven years, in all fifty years. He made many contributions to Medical and general Literature, viz., "An Essay on Peruvian Bark in the Cure of Intermittents," "On the Theory of Animal Heat," "Chemical Observations on Sugar," "Tracts on the Management of the Poor," "The Cultivation of Mangel Wurzel," "Framingham and its Agriculture, with the Economy of a Small Farm," and others. But the Professional work on which his fame rests is his "Essay on the Uterine Hæmorrhage which precedes the Delivery of the Fœtus," in which such hæmorrhage is divided into the accidental and unavoidable, and in which the true principles of treatment are laid down with a precision which leaves nothing to be desired. Dr. Rigby was a member of the Medical Society of London, and of the Linnean; an Alderman for Norwich, Sheriff in 1803, and Mayor in 1805. He was also one of the founders of the Norfolk Benevolent Society for the relief of the widows and orphans of Medical men, of which he was treasurer until his death. He died on the 27th of October, 1821, his friend and admirer, Mr. Crosse, pronouncing on him, on December 13, a eulogy which in itself is one of the most interesting and warm-hearted pages in British biography.

Dr. Frank Sayers, M.D., an accomplished scholar, and a schoolfellow of Lord Nelson, was also a Norwich celebrity in his time, so much so, that one of his biographers speaks of him as "the first gentleman of Norwich." He was the author of various poems and works on antiquarian and learned subjects. He was born in London, in March, 1793, and died in Norwich on August 16, 1817.

Sir James Edward Smith, M.D., F.R.S., the eminent botanist, was a Norwich man. He was born in the city on December 2, 1759, and died on March 17, 1828. He did not pursue the active duties of practice, but, as President of the Linnean Society, the friend of Sir Humphrey Davy, and the author of the "English Flora," he ranks amongst the first, in his chosen walk of scientific life.

Sir Benjamin Wrench, was a Physician who practised in Norwich for sixty years, viz., from 1687 to 1747. A painting of him is still retained. He was of the school of Mead, one of the old princes of physic, who held by his prerogatives, and made his position, on a small scale, ministerial. He was

accustomed to drive into the city in a chariot and four, with outriders and all else; and if he did not cure the more on this account, a great many more came to him to be cured. He died in 1747.

Dr. John Yelloly, M.D., F.R.S., is the last name on my list of Norwich Medical worthies. A long list, which began with a good name, and ends with one as good: I have been able to glean but few facts of the life of Yelloly; but he practised in Norwich from 1821 to 1833, and he is known for his admirable contribution to the *Philosophical Transactions*, "On the Tendency to Calculous Diseases, and on the Concretions to which these Diseases give rise." It remains yet for some Practitioner in Norfolk to take up the mantle of this Physician, and, beginning where he ended, to bring the problem he so carefully investigated to a satisfactory solution.

And now I close this first Medical History of an English city. It was but for me to write as I found, and that is done. If the facts shall stand for the manner, and the intentions for the deed,—enough: I shall rest and be thankful.

REVIEWS.

On Rupture: Inguinal, Crural, and Umbilical. With New Methods of effecting a Radical and Permanent Cure. With Illustrations. By JOHN WOOD, F.R.C.S. Eng., Exam., Demonstrator of Anatomy at King's College, Assistant-Surgeon King's College Hospital, &c., &c. Pp. 326. London: John W. Davies, 54, Princes-street. 1863.

RUPTURE has probably been one of the most important Surgical subjects since men were doomed to earn their bread by the sweat of the brow. In the earlier writers we constantly find allusions to it, and directions for its cure. They do not seem to have ventured, as a rule, on operating after the gut was strangulated; they merely endeavoured by methods more or less barbarous to prevent such an occurrence taking place. From Celsus to Heister we read of boys being castrated. "In such a bad state was Physic and Surgery at that time (1700), that not a person in so considerable a city as Frankfort knew how to cure an enterocele without the loss of the testicle." This proceeding was not limited to boys, as we find, in 1712, a tailor operated upon near Attdorf, who died from the combined effects of the operation, which deprived him of one testicle, and brandy, which was forced upon him by the itinerant quack who performed it. The history of this proceeding has been so thoroughly worked out of late, that it is needless to occupy space by describing the ligature of the sac, the royal stitch, the punctum aureum, and other methods of compressing the neck of the sac; the caustics, both actual and chemical; setons of the most varied material; or how Belmas operated on the Parisian bitches with his bags of gold-beaters' leaf. Then we come to the pluggers, Signoroni, Gerdy, and others. If any one wishes to follow out the subject, is it not written in the chronicles of our Profession?—and in Houston especially he will find quaint descriptions.

One who commenced his studies twelve or fourteen years ago merely heard of operations for the radical cure of hernia as historical facts; and he would as soon have expected to see his pastors and masters tattoo a patient, as operate when there was no strangulation. He was forced to learn with painful minuteness the "anatomy of the parts of hernia," but he learned them as weapons of defence from certain demons who came forth by night in Lincoln's-inn-fields, *retiarii* whom he knew some day might catch him in the eribriform fascia. Then, after all, he was informed this knowledge is of no use in operating—you must cut through these layers, without heeding their names or number, and never operate as a rule, except where there is absolute necessity. If he asked why, the answer was, "Wounding the peritoneum under any circumstances is generally fatal." But a few years ago matters took a different turn. Wurtzer, of Bonn; Rothmund, in Munich; Sigmund, in Vienna, and others, revived the old subject of radical cure; but in this country we undoubtedly owe to the active and practical mind of Mr. Spencer Wells that the attention of English Surgeons once more was directed to it; they were encouraged by his success, and many workers entered this old Roman camp, and ploughed up with profit the buried relics of the past.

Among these was the *punctum aureum*, which had for its object narrowing the passage for the escape of the gut, but not entirely preventing the passage of blood down the cord. It is obvious that this could hardly be done except by acci-

dent very often, but it suggested the operation now called, and justly so, Wood's. He starts with this proposition—"To effect a radical cure of inguinal hernia in a satisfactory manner it is necessary to adopt a plan to shut up *permanently* the inguinal openings and canal, by drawing together and producing adhesion of its tendinous walls as far up as the internal opening. If we succeed in doing so much as to restore the valve-like action of its oblique sides, we shall *restore* the part to its normal power of resistance to dilatation and hernial protrusion."—Cap. v., p. 88.

"To ensure success, complete union must be established along the *whole* length of the canal." . . . "Simple closure of the pillars of the superficial ring will not afford this requisite amount of resistance." "The conjoined tendon may be taken up by a needle without difficulty, if the forefinger be first passed along the canal, and placed fairly behind the lower border of the internal oblique muscle, and then made to hook it forward towards the surface, so as to raise the tendon to which it is attached in salient relief."—P. 89.

We presume that this manœuvre is executed when the patient is deeply anæsthetised, as but few are so flaccid as to let their internal oblique be hooked up into salient relief. But Mr. Wood thinks it can be accomplished in most hernial cases. "Let us now consider this operation.

The instruments are—a needle in a handle, much curved near the shaft, less so near the point.—P. 95. There is also a needle provided with a sliding guard for those unaccustomed to points and edges;—(when *will* these "Surgery made easy" things find rest in the rag and bottle shops?) A "knife like a tenotomy knife . . . for the scrotal incision, and separating the fascia from the skin." A "pad of boxwood, glass, or porcelain, long and broad enough to cover the hernial canal . . . with a hole or groove about the middle to fasten the threads upon"—strong thread or wire.

Mr. Wood gives a clear and full description of his operation, which may be summed up shortly, thus:—A cut is made an inch and a-half below the spine of the pubis, long enough to admit the tip of the finger and the needle; the knife is carried round between skin and fascia; the loose connections of the scrotal fascia are then detached with the handle. The detached fascia is pushed by the forefinger into the inguinal canal from as low a point as possible, and pushed up as high as possible. Then the forefinger, hooked forwards, will raise the lower border of the internal oblique. The needle, unthreaded and well oiled, is now pushed along the thumb side of the finger through the tendon at its most salient part, so as to take up a considerable portion of it; then through the internal pillar of the superficial ring obliquely upwards and inwards; then one end of the thread is connected with the needle, and the latter withdrawn, leaving the other end in the puncture. The needle is then passed with the ligature through Poupart's ligament. When its point is seen to raise the skin, the latter is drawn outwards until the former can be pushed a second time through the puncture before made. A loop of thread is now left in the puncture, and the needle withdrawn, carrying the free end. The needle is then passed through the triangular aponeurosis, and again, the third time, through the first aperture. The wires or threads are attached to the compress, pledgets of dry lint applied, and a spica bandage. These were removed from the third or fourth day to the seventh. The operation was generally followed by serous and, occasionally, purulent discharge. Mr. Wood has modified his operation in several ways, and especially we would draw attention to, at p. 135, his operation by pins—a most ingenious form of *trussing* in culinary and chiralurgical senses.

But how is this a permanent cure?—does it kill patients? Let our author answer at p. 161. The average duration of the cases in bed has been about twenty-one days. Of sixty cases (one being operated on both sides) the number of failures is eleven: one being a woman, and one went to very heavy work as a sailor too soon, and without a truss. So did the others. The skewers we alluded to only failed *twice*.

Our space does not allow us to say more than that the chapters on the Anatomy of the "parts of hernia" are admirable; the statements frank, and evidently those of one who thinks more of the credit of Surgery than his own glory; and the Appendix of Cases valuable subjects of meditation for those who contemplate performing the operation.

Mr. Wood's experience has now been very extensive; if there be danger in the operation, he has reduced it to a minimum consistent with its efficiency. He has already sent many men back to useful labour, who might have died under the

taxis. (Who gave that sarcastic appellation to bruising a piece of gut to death?) And last, but not least, he has shown that learning the "parts of hernia" may be of some use after all.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 12.

MR. PARTRIDGE, President.

A CASE by Mr. HOLMES COOTE was related,
IN WHICH THE LEFT OVARY WAS FOUND IN THE SAC OF AN
OBLIQUE INGUINAL HERNIA, OCCURRING IN A YOUNG WOMAN;
WITH REMARKS.

A young woman was brought into St. Bartholomew's Hospital with a swelling in the left groin, and suffering from the symptoms of strangulated hernia. In the course of a few hours the usual operation was performed, when the ovary and the Fallopian tube were found in the sac. A similar malposition of parts was subsequently noticed on the opposite side of the body. The left ovary was removed, some thickened omentum cut away, and the patient was put to bed; but the sickness and constipation continued, and she died four days after the operation. The cause of the sickness, etc., was displacement of the stomach and transverse arch of the colon. Mr. Coote raises two questions:—1. Was the displacement of the ovaries congenital, or the consequence of the hernia? He inclines to the former opinion. 2. The woman stated that she had always menstruated regularly. Now, on the examination of the body, it was found that both ovaries were well developed, and that the formation of the Graafian vesicles was going on naturally; but the Fallopian tubes were quite impervious, the uterus was completely absent, and the vagina was a short canal—an inch and a half in length, and terminating in a thin membrane. She said that she had been menstruating the week before her admission; and some of the female attendants at the Hospital noticed the usual marks, though faint, upon her dress. Are we to admit the possibility of menstruation under this abnormal condition of parts?

Mr. PARTRIDGE said it was a very interesting question to decide whether menstruation occurred, as was stated, under such circumstances as obtained in Mr. Coote's case, or whether it was merely a vicarious action. There was another question, of great importance in a moral point of view, which presented itself to Surgeons in such cases. Were they justified in emasculating, as it were, a woman in whom the ovaries were thus involved? A case had lately come under his care in which a difficulty of this kind existed. The patient was a male child, with the parts of generation so imperfectly developed that it was mistaken for a female, and christened and educated as such. It was discussed whether the testicles should be removed. The Surgeon in attendance thought that they should, as their removal would be advantageous to the child in assisting it to keep up its assumed sex. Mr. Partridge decided, however, that the operation was not justifiable, and it was not resorted to. Mr. Partridge then referred to two cases in which the uterus was absent; the one was an unmarried, the other a married woman. In each the vagina was short, but the clitoris, ovaries, and breasts were fully developed. In neither of these cases had there been any menstruation.

Mr. CÆSAR HAWKINS observed that the paper before the Society opened two interesting questions—one in relation to the operation of hernia, and one of physiological importance. Now, in hernia scarcely two operations were found to be precisely similar. He had met with two cases in which the ovary was found in the hernial sac. In one of these the patient was an elderly woman, and died of peritonitis. The Fallopian tube and ovary had been for many years in the hernial sac, and by their position had produced an elongation of the greater portion of the uterus, which with the Fallopian tube formed a canal of about fourteen inches in length. The other was a case of inguinal hernia in a lady. In the sac the Fallopian tube and ovary were found shrivelled up. In these cases he thought the better practice was to leave the ovary in the sac, as its removal was attended with danger. With regard to the statement of Mr. Coote's patient, that she had regularly menstruated, he (Mr. Hawkins) was sceptical. Cases were re-

corded in which there was no uterus, and no true menstruation, and he thought this was the invariable rule. Mr. Hawkins then referred to the case of a lady without a uterus who had consulted him; and he mentioned, by way of caution, that she had been operated upon twice by different Surgeons, under the impression that there was some mechanical obstruction to the catamenial discharge. Something was cut through on these occasions, but of course without beneficial result.

Dr. GRAILY HEWITT considered the case related by Mr. Holmes Coote to be one of very great interest. It was a most unusual circumstance for a menstrual-like discharge to be noticed in cases of absence of the uterus; and, so far as he was aware, there was not a single instance of the same kind on record. Admitting the correctness of the statements made in the paper, the case was unique. He did not consider it absolutely impossible for a menstrual-like discharge to be noticed periodically in cases where the ovaries were carrying on their function; but the discharge would be in such a case, as the President had suggested, a "vicarious" one. That menstruation, in the proper sense of the word, was dependent on ovulation, physiological facts had long ago proved; and in cases of absence of the uterus, the ovaries often, as in Mr. Holmes Coote's patient, went on exercising their function. It was interesting to find that positive evidence of ovulation was present in Mr. Coote's case—viz., the cyst-like cavities in the ovary distended with a grumous-like fluid. These cases were very rare. He was consulted about three years ago respecting a young lady, a governess, who was about to be married; but there never having been any menstruation, it was thought right to obtain a professional opinion on the matter. He found the vagina merely a cul-de-sac, only admitting a probe a short distance, and no uterus could be found on very careful examination. In this case there had been on two or three occasions a menstrual nusus, showing that the ovaries were in a certain state of activity; but not the slightest appearance of menstruation had ever been observed. It was needless to add that, in this instance, any kind of operation was out of the question.

Mr. HULKE inquired what signs or symptoms had induced Mr. Coote to operate in his case, and to suspect that the ovary was present in the hernial sac? He (Mr. Hulke) had seen an instance in which Mr. Lawson had removed the ovary from the right groin of a servant girl; this at every menstrual period became inflamed and tender, and caused her much suffering. The removal was effected without difficulty, and the patient made a good recovery.

Mr. SPENCER WELLS said that the question raised by Mr. Hulke, as to the means of recognising an ovary when it formed part of a hernial tumour, had once come before him (Mr. Wells) in consultation. An old lady had a large labial hernia on the left side, irreducible, consisting chiefly of omentum, but containing a hard body, which was supposed to be the ovary, as there was a clear history of pain and swelling several years before at every menstrual period. All doubt was set at rest by the fact, that when the uterus, which was in its natural situation, was moved, the movements of the uterus were communicated to the displaced ovary. On the right side there was no hernia; but a hard body, like an atrophied ovary, could be felt in the labium. Cruveilhier had noticed the not unfrequent presence of the ovaries in the inguinal canal or labia of old women; and when they were found on both sides, the malposition might, probably, often be congenital.

Mr. SAVORY, in the absence of Mr. Coote, said, that in the case under discussion, the symptoms of strangulation were of a constitutional rather than of a local character—such as vomiting, constipation, prostration, etc. The tumour resembled a testicle; but as this was, of course, impossible, it was concluded that it was the ovary; and this was found to be correct.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 6.

Dr. OLDHAM, President.

THE following gentlemen were elected Fellows:—Alfred G. Brown, Esq., Woolwich; Dr. Fleetwood Buckle, Royal Mint; William Gilbee, Esq., Melbourne, Australia; Edward Head, M.B., Harley-street; L. J. Martin, M.D., Melbourne, Australia; Dr. Playfair, London; Dr. Pugh, Melbourne, Australia;

Dr. Ritchie, London; B. M. Walton, Esq., Hurstpierpoint; Dr. W. M. Whitmarsh, Hounslow.

Dr. MADGE gave a short account of a case of

LESION (RUPTURE?) OF THE PLACENTA, occurring in a patient who aborted two or three days after falling downstairs. She was four months and a-half pregnant. She was carrying a pitcher of water upstairs, and fell forwards, the bone of her stays coming with great force against the lower part of the abdomen. The placenta contained a clot of blood, which Dr. Madge was inclined to believe was the result of rupture of the placenta at the time of the accident.

Dr. OLDHAM and Dr. DRUITT doubted the correctness of the view expressed by Dr. Madge.

Dr. E. DAY read a paper on

EXTRA-UTERINE FŒTATION, AND INDUCTION OF PREMATURE LABOUR.

A specimen was exhibited, consisting of the uterus of a woman in whom premature labour had been induced, together with an old extra-uterine fœtation. She was attended at King's College Hospital in her sixth labour in 1859, when a tumour was felt behind the uterus; this was pushed up, and labour proceeded well. In January, 1861, Dr. A. Farre induced premature labour at the eighth month, the tumour still existing. In August, 1862, she was delivered of a seven months' child, the tumour being still present. She became pregnant in January following, and came again under notice in May. Labour was induced at seven months and a-half by an air caoutchouc dilator. The membranes were subsequently ruptured, turning performed, and a dead child extracted. The woman died two days after from flooding. The post-mortem examination showed that the tumour felt behind the uterus in the recto-vaginal pouch, and which was during life the size of a goose-egg, consisted of a fœtus of the size of one from three to four months old, enclosed in a thin cyst, attached to the peritoneum on the right side of the rectum. The right Fallopian tube contained a tumour, apparently the remains of an organised clot, and remains of decidual membrane.

Mr. S. NEWHAM introduced

THE GUIDE-HOOK: A NEW OBSTETRIC INSTRUMENT.

The instrument is simply a blunt hook, with the addition of a prow or guide on the convex side. The addition of the guide is to favour the adjustment of the hook into many positions in which a hook is required, to assist in breaking up the base of the skull, and in sundry other manipulations.

Dr. DAY exhibited a specimen of

ADHESIONS BETWEEN THE UTERUS AND THE RECTUM, DRAGGING DOWN THE FUNDUS.

and inquired of the Society as to the possibility of stretching such adhesions by treatment.

Dr. OLDHAM and Dr. GRAILY HEWITT made some remarks.

ANNUAL MEETING.

The Report of the Auditors of the Accounts of the Society was first read. The balance-sheet showed a balance in the hands of the treasurer of £255 12s. 3d.; while, in addition to this, there was invested in consols the sum of £550, of which latter sum £150 had been invested in the course of the last year. The amount of subscriptions received during the year was £474 12s. The sale of the "Transactions" during the year had realised £55 17s. 1d.

It was moved by Dr. ROUTH, seconded by Dr. CLEVELAND, and carried,—That the Report of the Auditors be received and entered in the Minutes. Dr. Routh alluded in terms of very congratulatory character to the exceedingly satisfactory financial position of the Society, which he considered reflected the greatest credit on the management.

Mr. BRYANT and Dr. TILBURY FOX moved and seconded a vote of thanks to the President and Officers of the Society for their valuable services during the past year.

Dr. OLDHAM and Dr. GRAILY HEWITT returned thanks.

The list of "Donations" during the year having been read, the President announced the result of the ballot for Officers for 1864 to be as follows:—Hon. President.—Sir Charles Locoek, Bart., M.D. President.—Dr. Oldham. Vice-Presidents.—Dr. Druitt, Dr. Gream, Dr. Greenhalgh, Mr. Hardey (Hull), Dr. Swayne (Bristol), Dr. Tanner. Treasurer.—Dr. Barnes. Hon. Secretaries.—Dr. Graily Hewitt and Dr. Hicks. Other Members of Council.—Dr. Clay (Manchester), Dr. Cleveland, Dr. Hall Davis, Dr. Drage (Hatfield), Dr. Gervis, Dr. Hall (Brighton), Mr. Harrinson (Reading), Dr. Langmore, Dr. Meadows, Dr. Madge, Mr. Mitchell, Dr. Murray, Mr. Ray,

Dr. Richards, Dr. Tyler Smith, Mr. Symonds (Oxford), Dr. Tapson, Dr. Wilson (Glasgow).

The PRESIDENT then delivered the

ANNUAL ADDRESS.

He remarked that the task before him was of a pleasing character. He had nothing to recount but progressive prosperity on the part of the Society. During the past year not a jar or discord had occurred. 41 new Fellows had joined the Society, making the present number of Fellows 535. Amongst these were gentlemen from our most distant colonies, as proof of which he might mention that this very evening three members of the Profession residing at Melbourne had been elected Fellows. In Constantinople, in India, in New Zealand, Jamaica, New South Wales, the Society had extended its ramifications. The character of the debates, the authority of its judgment on disputed points, the large sale of the Society's "Transactions,"—all these facts showed its popularity, and the estimation in which it was held by the Profession. He doubted whether those who still withheld their presence from the Society rightly measured the great interest felt by Practitioners in all relating to obstetric practice. That interest he believed to be even stronger than that felt in the other great divisions of our Profession. The independent and efficient organisation of this Society was required to do for obstetrics what the previously existing societies had failed to effect. The financial state of the Society was highly satisfactory. £550 invested in the funds, and a balance of £255 at the banker's, also ready to be invested, was the financial expression of the condition of the Society at the end of the fifth year of its existence. The Society possessed nearly nine hundred volumes of works relating to obstetrics. During the past year the Council had considered the possibility of making this library available for use by the Fellows. On the whole, it was considered advisable to wait, more especially as there had been reason to think that accommodation might be had in the present location of the Society. The matter was still *sub judice*, and the Council would carry out the idea at the earliest possible moment. Six additional Honorary Fellows had been elected during the year—Professors Faye (Christiana), Braun (Vienna), Depaul (Paris), Martin (Berlin), Dr. Beatty (Dublin), and Dr. Pagan (Glasgow). From Prof. Scanzoni, one of the first Honorary Fellows, the Society had received the gratifying compliment of the dedication of his work "On Chronic Metritis," in recognition of the manner in which it had advanced gynaecology. Four volumes of "Transactions" had been published, and a fifth would appear in the course of a few weeks. It was quite unnecessary for him (the President) to remark on the value of the contents of these volumes. They formed an important part of existing obstetric literature. To certain of the papers therein contained the Profession was indebted, amongst other things, for the establishment of the operation of ovariectomy as rational and legitimate. He had often wished that the discussions before the Society had embraced a revision of the precepts for the management of the puerperal state. No subject was more important, involving as it did the comfort and health of thousands. It involved another point of interest: What was the length of attendance included in the midwifery fee? In a court of justice he had recently been asked this question, and his reply was that a week was enough for ordinary convalescence. He had found that many still acquiesced in the old notion of a puerperal "month," during which attendance was, they considered, obligatory. There should be some uniformity on this point. He contended that the limit should be, not a puerperal month, but a puerperal week. He could only understand the need of Medical care for a month on the supposition that the precepts which are laid down in some of our midwifery books, steadily induce a debility in the first fortnight, which requires a drawing convalescence in the next two weeks to overcome. Parturition and its immediate effects should be divorced from disease, and not made to wear its likeness. A puerperal month, under the guidance of a monthly nurse, was easily drawn out. He knew no reason why, if a woman was confined early in the morning, she should not have her breakfast of tea and toast at nine, luncheon of some digestible meat at one, her cup of tea at five, her dinner, with chicken, at seven, and her tea at nine; or the equivalent, according to her habits of living. Common sense must guide in the selection of articles of food. Excess and stimulants must be avoided; so also gruel and slops. Such had been his practice for the last twenty years, and by it he could affirm that the process of involution was greatly assisted,

and various disorders prevented. The patient should be removed to her sofa in two or three days. He would not now pursue the subject further. In conclusion, the President stated, that during the year three Fellows had been lost to the Society by death. He begged to congratulate the Society on its present prosperity, and trusted it would increase.

A vote of thanks to the President for his interesting address, proposed by Dr. Druitt, and seconded by Dr. Greenhalgh, was carried by acclamation. The Society then adjourned.

EPIDEMIOLOGICAL SOCIETY.

MONDAY, DECEMBER 7, 1863.

DR. BABINGTON, F.R.S., in the Chair.

A COMMUNICATION by Dr. Bryson, R.N., Inspector-General of Hospitals and Fleets, was read, on

EPIDEMIC PLEURO-PNEUMONIA IN SOME SHIPS OF THE MEDITERRANEAN FLEET.

The disease was of a low, asthenic or typhoid type, accompanied with great congestion usually of the lower lobes of the lungs, and in many of the cases in the ship chiefly affected, the *St. Jean d'Aere*, with scorbutic symptoms, although the diet of the crew was in every respect as good as in the other vessels of the squadron. In the *Cressy*, too, there was an unusual prevalence of lung disease, often of an obscure and anomalous character, which was not easy to designate. The evidences of the pulmonary tissue being congested or even consolidated in different parts of the chest, associated with pleurisy or pleurodynia, and with such a cachectic condition of the system as might probably lead on to tubercular degeneration in chronic cases, were the most conspicuous features of the malady. Effusion into the chest was discovered in a few instances. Diarrhoeal and dysenteric attacks were common both in the early and late stage. The following table shows how very differently different ships of the squadron were affected with diseases of the lungs in the course of the year, and also with other diseases, the extent of whose prevalence is usually regarded as a fair test of the healthiness, or otherwise, of a ship's crew. Attention should be paid to the number of the crew in each vessel, to estimate aright the marked difference in respect of the number of case under each head in the different ships. The reader can easily calculate the ratio of attacks to the crew for himself:—

	No. of Crew.	Cases of sickness in year.	Diseases of lungs, etc.	Dis-eases of bowels.	Fevers continued and re-mittent.	Ulcers.
<i>Marlborough</i>	1145	937	129	64	10	75
<i>Agamemnon</i>	840	881	241	58	17	30
<i>St. Jean d'Aere</i>	815	1601	401	171	136	115
<i>Cressy</i>	720	1483	298	254	12	102

The deaths from disease in the *St. Jean d'Aere* and in the *Cressy* were twice as numerous as in the *Marlborough*, notwithstanding the much smaller crews of the former vessels; and the number invalided from the first ship was fourfold as numerous. As to the chief cause of this enormous disproportion in the sickness and mortality, &c., in two ships of the same fleet and similarly exposed, it was clearly shown that this lay in the excessive overcrowding of the men at night in the *St. Jean d'Aere* on the lower deck, while in the *Marlborough* the men were more distributed on the different decks, and greater attention was paid to ventilation of the between-decks. Only fourteen inches space was allowed to each hammock in the former ship; and so thoroughly was fresh, cool air excluded from the men while asleep, that the air above the hammocks was found to be from eight to ten degrees hotter than the air below the hammocks, and so offensively impure as to cause nausea to any one going down from the open air. With such a state of things, it is not wonderful that the health of the ship was so bad during the two years while on the station, that it was at last found necessary to send her to England to be paid off. Besides several features of resemblance in the symptoms of the pleuro-pneumony in the *St. Jean d'Aere* and *Cressy* to the lung disease in cattle, it is to be noted that there are good grounds for suspecting that the affection was communicated by the sick landed from the vessels to other patients in Malta Hospital.

An animated discussion, in which Drs. Babington, Bryson, Dickson, R.N., Stratton, R.N., Murchison, Milroy, and Mr. Burge took part, followed the reading of the paper.

OBITUARY.

SIR JAMES GRANT, M.D.

ON Monday, the 18th inst., the mortal remains of the late Sir James Robert Grant, C.B., K.H., formerly of the Hill, Cumberland, were interred in the small burial-ground at the west end of St. Mary's Church, in Carlisle, leave having been obtained from the Secretary of State to reopen the family vault for that purpose. Sir James died on the 10th inst., at Basford, near Nottingham, where he had been staying for some time. He was born at Forres, in the county of Moray, in 1773, and if he had survived another month would have attained the great age of 91 years. His father's family consisted of nine sons and three daughters. Seven of Sir James' brothers died fighting the battles of their country, or from diseases contracted while on foreign service, and the deceased and his brother Lewis were knighted. Sir James served as a Medical officer of the army throughout the whole of the Peninsular war, and was the chief of the Medical department at the battle of Waterloo. He was one of the few who served in the first and last campaigns of the war—namely, that of 1793 and that of 1815. In the year 1814, while Earl Bathurst was at the head of the War department, he was appointed Inspector-General of Army Hospitals, and in that capacity he rendered such signal services to the Russian army in France, under Count Woronzow, in preventing the spread of an epidemic, that in the year 1815, at the meeting of crowned heads in Paris, he received the order of St. Anne of Russia from the Emperor Alexander in person. It is a fact worthy of mention, as showing his robust constitution, that, during thirty years in which he served his country abroad, he never had a day's leave of absence. For several years after his retirement from the service, Sir James resided at the Hill, near Carlisle, and was placed upon the commission of the peace for Cumberland, but a few years ago he went into the south of England, and died while staying near Nottingham. The funeral service was performed by the Chancellor of the diocese, and his remains were followed to their last resting-place by most of the gentry of the city and neighbourhood, including several of the leading members of the Medical Profession.

JOSIAH SMYLY, ESQ., VICE-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

We regret to have to announce the death, after ten days' illness, of Mr. Smyly, the senior of the six Surgeons of the Meath Hospital and County Dublin Infirmary, which occurred on the morning of the 19th instant, at his residence in Merrion-square. Mr. Smyly was son of the late John Smyly, Esq., K.C., and on his mother's side was nephew of the late Sir Philip Crampton, Bart., under whose guidance he commenced his Professional career. Having graduated in arts in the University of Dublin, young Mr. Smyly proceeded to Paris; and during his stay in that metropolis he received, under the ministry of the Rev. Lewis Way, in the English Church in the Champs Elysées, those religious impressions which so strongly characterised him during the remainder of his life, as an earnest and devoted Christian. On the death of the late Mr. Hewson, in 1831, he was elected one of the Surgeons to the Meath Hospital; and in June last he was chosen Vice-President of the Royal College of Surgeons in Ireland. Mr. Smyly was not an extensive writer: his principal contributions to Surgical Science are to be found in the *Dublin Quarterly Journal*, and consist of essays on "Lithotripsy," on "Compound Fractures of the Patella," and on "Thoracentesis in Empyema." Respected for his Professional attainments, esteemed in private life, and distinguished by active zeal in every plan of Christian usefulness, his loss will be long and deeply felt by a wide circle of friends in every rank in society.

THE LATE DR. WEBSTER, OF DUNDEE.

(From the *Dundee Advertiser*.)

Dr. Webster was a native of the parish of Inverarity, in which his father was an extensive tenant farmer. He was born in 1799, and, after receiving such an education as the parish school could give, he went to the High School in Forfar. On the completion of his school education, he selected the Medical Profession, and was apprenticed to Dr. Hull, of Forfar. At its close he went to the University of Edinburgh; and, having passed through the usual curriculum of study, took out his degree of M.D. in 1822. In a few

months thereafter he went a voyage in the capacity of Surgeon in an East Indiaman, bound to Calcutta. In May, 1825, he commenced the practice of his Profession in Dundee, and his frank manners and good-humoured disposition soon gained for him a numerous circle of friends. In 1832 he was appointed by the Governors of the Infirmary to fill the office of Dispensary Surgeon; and during the dreadful epidemic of cholera which burst out in that year he was appointed Secretary to the Board of Health, and many will no doubt retain a vivid recollection of the morning bulletins he then issued, announcing the number of cases and deaths occurring on the previous day. In 1833, the office of Police Surgeon having become vacant by the death of Dr. Stephen, he was appointed by the Commissioners as that gentleman's successor. Being a good practical chemist, the Doctor was in the frequent habit of giving lectures on chemistry in the Watt Institution; and in 1835 he was appointed by the magistrates to analyse water procured from various sources, with the view of finding the quality best suited for the use of the inhabitants, and the same year he was called before a Committee of the House of Commons to give his evidence on the question. In 1839 he was appointed by the Directors of the Infirmary one of the daily Visiting Physicians, which situation he filled to the satisfaction of all for about twenty years, and, on resigning a few years ago, he was appointed Senior Consulting Physician. In 1840 he took an active interest in the formation of a Statistical Society, but, though supported by many gentlemen well qualified for such investigations, and warmly encouraged by the late eminent and enthusiastic statistician, Dr. Cleland, of Glasgow, it appears never to have come into practical operation. The office of daily Visiting Physician to the Infirmary afforded the Doctor a large field for statistically observing diseases; and in fevers and other prevailing epidemics he took great interest in tracing their origin and in studying their mode of propagation, ratio of mortality, etc., and we believe he succeeded in collecting a great number of valuable facts and observations on such matters, some of which are to be found recorded in the annual reports of the Infirmary. To Medical friends accompanying him in his rounds through the wards in the Infirmary he had always something new to impart on his favourite subject of study, fever; and it was but the other day we noticed, in a pamphlet by Dr. Steel, of Forfar, "on the changes of the type of typhus, etc.," that his attention was first drawn to the peculiar eruption in typhus by his friend, Dr. Webster, of Dundee, about twenty-five years ago, in the Dundee Infirmary. The Doctor never took any active part in our local politics, but always showed great interest in all matters tending to local improvement. To mark the plan and watch the progress of any public building in the course of erection was a great treat to him; and often have we been amused by seeing him in wet and in cold inspecting such with an earnestness as intense as if it had been his own. Unless with one exception, we do not remember of Dr. Webster ever taking part in any of our public meetings or discussions, however much opinions might be advanced jarring with his own. Indeed, in the company of strangers, he appeared to be, if not diffident, at least silent and reserved. A singular exception to his usual diffidence was the Doctor appearing on the stage of our theatre in the character of Captain Thornton, in the play of "Rob Roy." The exchequer of the Infirmary being exhausted, it became a serious question, in a time of much public distress, how it could be most readily replenished. The Doctor, as an important office-bearer, naturally felt an interest in it, and having at the time Medical charge of the soldiers stationed in the barracks, and, of course, frequently coming in contact with the officers, the thought occurred to him that the novelty of some scenic entertainment, performed by amateurs in the art, might draw together a respectable audience. On making this known to the officers, and to other young gentlemen in the town whom he thought likely to enter into his views, they readily agreed to give their services, but on one condition—that the Doctor himself should take a part. The Doctor, rather than it should fail, reluctantly agreed to do so, and a sufficient staff of amateur actors was soon mustered for the occasion. The affair turned out what, in histrionic language, is called a "great success,"—that is to say, it procured what was much wanted, funds to meet the exigencies of the Infirmary. A few months after, it was followed by an oratorio, presided over by the late Earl of Airlie, by which a handsome sum was realised, and handed over to the treasurer of the Infirmary. It is but due to the memory of Dr. Webster to state that this mode of raising

funds in behoof of the Infirmary originated with himself; and if his modesty in placing himself before a public audience was for once overcome, it was only so by one of the noblest motives that could influence the human heart—that of affording the wealthy a few hours of rational and innocent entertainment, to receive in return a small portion of their riches to sustain and keep alive those less blessed with earthly treasures. For some months before his death, which took place on December 8, Dr. Webster had been the subject of pulmonary disease. He survived for many years a wife and three sons, the eldest of whom, a student of law, residing in Edinburgh—a young gentleman, we understand, of great promise—was drowned some twelve years ago while bathing at Portobello. An only daughter, who is married, survives him.

LEGAL INTELLIGENCE.

DUBLIN ROLLS COURT.

THE Attorney-General, at the relation of the Provost and Fellows of Trinity College, petitioners; the King and Queen's College of Physicians, respondents.

The hearing of this important case, which is to decide the right of the Irish College of Physicians to confer the title of Doctor of Medicine, was commenced on Saturday, January 16.

The Solicitor-General, with whom were the Attorney-General, Messrs. Brewster, Q.C., Lloyd, Q.C., Dames, and Waters, instructed by Mr. John H. Nunn, appeared for the petitioners, and stated their case; and

Sergeant Sullivan, Mr. J. E. Walsh, Q.C., and Mr. Wm. Smith, with Messrs. Smith and Whitestone, as solicitors, appeared for the respondents.

The petitioners prayed for a declaration, that the respondents are not legally authorised to admit any person to the degree of Doctor of Medicine, or to grant or issue any license or diploma purporting to admit to the degree of Doctor of Medicine, or certifying by such license that such persons are, by virtue thereof, entitled to the degree of Doctor of Medicine, or implying that such license has conferred the degree of Doctor of Medicine, or in any other form purporting to confer the title of Doctor of Medicine, or give the persons to whom such testimonial is granted the right or privilege thereof to use the title of Doctor of Medicine, or the initial letters M.D.; and that the respondents may be restrained by injunction from admitting any person to the degree of Doctor of Medicine, or granting, or issuing any license, diploma, or letters testimonial, purporting to admit to the degree of Doctor of Medicine, or confer the rights or privileges of that degree, or the privilege of using the initial letters M.D. The petition set forth the letters patent granted by Queen Elizabeth in 1592, incorporating Trinity College, and establishing that institution as the "mother of an university," and ordaining that no one should in any other place make public profession of or teach the liberal arts within the kingdom of Ireland without special license from the Crown, and that students should have the privilege of obtaining the degrees of Bachelor, Master, and Doctor, after suitable periods, in all the arts and faculties. By letters patent of Charles I. in the year 1637, the previous letters patent of Elizabeth were ratified and confirmed, and from that period to the present the corporation of Trinity College, Dublin, have enjoyed the privilege thereby conferred of granting degrees in the arts and faculties, and, amongst others, have granted degrees in the Faculty of Medicine to candidates complying with the rules and regulations of the College, the graduates obtaining such degrees being entitled to use the initial letters; that the said College was the only body in Ireland who, from the date of its charter, possessed the privilege of granting degrees in said arts and faculties until 1850, when the Queen's University in Ireland was established, with the power of granting degrees in the arts and faculties, and that among the qualifications required by the Provost and Fellows and Scholars of Trinity College was one (still in force) that the candidate for the degree of Doctor of Medicine should have previously attained an university degree in arts. The petition further stated that the College of Physicians owes its foundation as a college to one John Stearne, M.D., and one of the Fellows of Trinity College, Dublin, who, in the 17th century, induced the Provost, Fellows, and Scholars of the College to grant certain premises, called Trinity Hall, then near Dublin, for the sole and proper use of the Physicians; and, by letters of King Charles II., the said John Stearne and others were, on August 8th, 1667, incorporated

as "the President and Fellows of the College of Physicians in Dublin," and John Stearne was appointed the first president; and it was provided, that (in consideration of the gift of Trinity Hall) the Provost, Fellows, and Scholars of Trinity College, Dublin, should, after Dr. Stearne's death, from time to time elect, from the College of Physicians, some one to be president thereof, and should have the privilege of admitting to the membership or fellowship of such College of Physicians such persons as were deemed fit, and practised in Medicine; and, that within Dublin, or within seven miles thereof, no person should practise the faculty of Medicine without having been admitted thereto by letters testimonial under the seal of the College of Physicians. These letters patent were, however, surrendered in the fourth year of the reign of King William III. and Queen Mary, and fresh letters patent were granted, incorporating the "King and Queen's College of Physicians in Ireland," and Dr. Patrick Dun and thirteen others—seven of whom were the surviving Fellows of the previous College of Physicians—were constituted the first President and Fellows, and the election powers and authorities of the said Fellows and College, etc., were duly provided for, but their ordinances, orders, acts, etc., were to be in accordance with the laws, statutes, rights, and customs of the kingdom. Provision was also made for the examination and licensing of persons desirous of practising Physic, and the King and Queen's College of Physicians were authorised to give testimonials to such persons. Those letters patent likewise provided that no person, save graduates of the Universities of Dublin, etc., should practise Physic in Ireland until he should have been examined and received a testimonial from the said King and Queen's College of Physicians, under a penalty of £5; but it was specially enacted that all graduates in Physic of the University of Dublin should, on application, be immediately admitted into the College of Physicians without further examination, on paying the usual fees; but this last-mentioned provision was repealed by the 40th George III., cap. 84. Three years after the granting of those letters patent, the College of Physicians, in October, 1695, ordered that whoever was to be a Fellow of the King and Queen's College of Physicians was first to be a Doctor of Physic of the University of Dublin, because there was entered in the registry of the University an order, that whoever took a Degree in the Faculty of Physic should give timely notice to the President and Fellows of the College of Physicians to be present at the performances of the exercise and arts, to give judgment whether the candidates be duly qualified. It was contended by the petitioners that this fact was strong evidence that the King and Queen's College of Physicians did not then claim any privilege of granting degrees or of admitting to the title of M.D. independently of the University of Dublin. The petitioners relied on the 25th George III., cap. 42, secs. 15 and 16, and the 40th George III., cap., 84, secs. 19 and 42, as showing that no power of conferring Medical degrees was conferred on the College of Physicians. From the date of the charter of William and Mary down to 1860, the College of Physicians have held public examinations of students in physic, and have granted letters testimonial licensing such persons to practise physic; but such letters testimonial did not purport to confer on the person any degree or right to use the title "Doctor," or append M.D. to his name, but merely constituted him a licentiate of the College of Physicians. However, in the year 1860 the College of Physicians conceived the design of assuming the right to confer degrees in medicine, and announced, by public advertisements in the daily papers in 1861, that they had the opinion of the Attorney-General for Ireland and the Solicitor-General for England to the effect that their fellows and licentiates were entitled to the degrees and title of M.D., and to embody such in their diploma, and adopted a form for granting the degree, title, and qualification of "Doctor of Medicine," and have since professed to confer degrees in medicine in that form. It was submitted by the petitioners that the granting of such testimonials was and is a distinct excess and violation of their charter and authorities, especially having regard to the fact, that in all cases where degrees are authorised to be conferred by universities certain oaths are by law required to be administered to the candidates; whereas there is no officer of the College of Physicians empowered to administer the oaths by law enjoined on all persons obtaining degrees in any of the arts or faculties in an university. By the published regulations, dated 1862, of the College of Physicians, the form in which the President admits to the Licentiate and Doctorate in Medicine was given, and also the form of their diploma was alleged to be a

mere colourable attempt to avoid the use of the word "degree," by employing the phrase "entitled to the title of Doctor of Medicine;" while in effect the diploma purported to confer a title and a degree in medicine, which those persons only who have obtained the degree of M.D. in an University are entitled to assume and enjoy. The granting of diplomas, in this last mentioned form, it was submitted, is an act in excess and violation of the powers vested in the College of Physicians by their charter, and the right to grant degrees is vested in such bodies only to whom the Crown expressly grants such power, and the power to confer such degrees is not given to the College of Physicians by charter or otherwise; and it would be mischievous and dangerous, and tend to lower the standard of attainments in the arts and faculties, to permit any public body not duly authorised to grant certificates, purporting to give the holders the right to assume the titles which, by law and usage, are recognised as belonging to the Graduates of an University; and by doing so the College of Physicians are arrogating to themselves the exercise of the prerogative of the Crown to grant degrees, and the right to do so in Ireland has been delegated by the Crown only to Trinity College and the Queen's University; and unless the College of Physicians be restrained injury will result to the public, inasmuch as many persons who otherwise would enter a University, and there obtain a University education, with the ultimate object of obtaining degrees in medicine, may no longer do so, and thereby the Practitioners in Medicine will no longer enjoy the advantage of liberal education in a University. Also, the emoluments of Trinity College from fees from candidates for degrees in medicine will be greatly diminished if the College of Physicians be any longer suffered to grant titles purporting to be degrees, without requiring candidates previously to have a University education, or obtain a degree in arts. Besides, there is a School of Medicine in Trinity College, Dublin (under Professors of great eminence), enjoying high reputation and character, which would likewise be injured if the College of Physicians persist in the course they have adopted, and which they announce they will do, in the *Medical Times*, *Lancet*, and other Medical journals. They are still granting testimonials and admissions in the form mentioned to persons who have not obtained the degree of M.D. in any University, and, having been applied to on the subject, declined to enter into any correspondence with the petitioners in relation to the assumed power to grant such licenses and certificates, etc.

Mr. Lombe Atthill, M.D., the Registrar of the King and Queen's College of Physicians, filed an affidavit in sustenance of the respondent's view of the case, and relied on the charters granted to that Corporation by King Charles the Second and by King William and Queen Mary, and the statutes and by-laws of the College of Physicians. He denied that the first charter was, as alleged, surrendered, but insisted on its remaining in full force, so far as the second charter is not repugnant thereto, and stated that it was currently reported, that for 200 years the persons who from time to time received the diploma authorising them to practise Physic generally have been publicly known or designated as Doctors of Medicine or of Physic, and are so recognised by several Acts of Parliament. He set forth the form of diploma or license exclusively used in the College since January 1, 1862, and deposed that they had not purported to confer any degree of Doctor of Physic or Doctor of Medicine to any person, nor do they intend to do so; but, independent of the question whether they have power to confer degrees, he submitted that they had full authority to grant licenses or diplomas in the form set forth, stating that the party was thereby entitled to the title of Doctor of Medicine, and the persons to whom such shall have been granted have a right to practise Physic and assume the title of Doctor of Medicine, although they may not have obtained any degree from Trinity College, Dublin, or any other university. He denied that the title of Doctor was exclusively attached to persons who have obtained degrees of the rank of Doctors of Medicine in Trinity College, Dublin, or other universities, but is, on the contrary, by usage, and even since the granting of its charters, used by and attached to all persons who obtained the license or diploma of the College of Physicians. Dr. Atthill denied that the order of October 2, 1695 (above referred to) afforded any such evidence or proof as the petitioners attributed thereto, and submitted that it applied only to the admission of Fellows, and not Licentiates, of said College of Physicians, and was subsequently rescinded by another order, and could not have operated to prevent the admission of a Licentiate or any person who had obtained the degree of Bachelor of

Medicine, although he had not obtained the University degree of Doctor of Physic; and further, that the said order, and one by the Provost and Fellows of Trinity College, Dublin (dated June 25, 1701), were matters of arrangement between the parties, and determinable by either of the said Colleges at discretion. Dr. Atthill denied that the granting of the testimonial was in excess or violation of the charters or the powers or authorities of the College of Physicians, nor do they profess to have granted the degree of Doctor of Medicine. He denied that the certificate was a colourable attempt to avoid the use of the word "degree," or that it purported to grant a degree as a "University degree," but submitted that it purported to grant the "title of Doctor in, or of Medicine of the said College of Physicians only." He denied many of the allegations of the petition, such, for instance, as the alleged assumption of the prerogative of the Crown; or of the likelihood of injury to the public as alleged; or that a person wishing to practise Medicine would think it unnecessary previously to obtain an university degree. He thought that the alleged standard of education required by the College of Physicians was as high, if not higher, than that required by Trinity College, Dublin, or its School of Medicine, and that several persons who had become graduates in Medicine in Trinity College, Dublin, had, at examinations, been subsequently rejected by the College of Physicians, and stated that they relied on 40th Geo. III., cap. 84, sec. 45; 1st Geo. III., cap. 14; and 25th Vic., cap. 15. He submitted that it was immaterial whether the number of students in Trinity College, Dublin, was diminished by the conferring of such testimonials by the College of Physicians, or that Trinity College, Dublin, would in any degree be injured thereby; and that, without doubt, the College of Physicians is more competent to judge of the qualifications of Physicians than the Universities. He submitted that persons possessing the diploma of the College of Physicians in the form set forth are entitled to use the name or title of Doctor of Medicine, although they have no university degree, and are not liable to a prosecution under the Medical Act, 1858, sec. 40; and he submitted generally that the petitioners have submitted no case to entitle them to the relief they prayed.

Dr. Toleken, Senior Fellow and Registrar of Trinity College, Dublin, filed an answering affidavit to that of Dr. Atthill. Dr. John Hughes, Mr. William M. Burke, and Dr. Aquilla Smith, likewise filed affidavits in support of the respondents' view of the case, and deposed that it was the usage and custom of persons who had received the diploma of the College of Physicians to receive same without a previous university degree, and to assume the title Doctor of Medicine, and that it was the general repute that for a period of 200 years such a custom had prevailed.

The hearing of the case has not concluded.

BENNETT v. HICKSON.—COURT OF EXCHEQUER, Jan. 15.—(Before the Lord Chief Baron, and Barons Martin, Channell, and Pigott.)—It will be remembered that this action was brought by the plaintiff, a Surgeon practising at Worksop, in Nottinghamshire, against the executors of Mr. Thomas Beardsall, a Surgeon, formerly practising in the same place, for breach of agreement. Mr. Bennett was the purchaser from the executors of Mr. Thomas Beardsall's practice. The breaches complained of were—first, that Mr. William Beardsall, Surgeon, brother and executor to Mr. Thomas Beardsall, had said of the plaintiff that his charges were too high, and had thereby induced a patient of the plaintiff, named Smith, who had also been a patient of the testator, to leave him; second, that William Beardsall had competed with the plaintiff for, and had obtained the post of Medical officer to a lodge of Odd Fellows, which had been held by the testator in his lifetime; and, third, that W. Beardsall had competed with the plaintiff for, and had obtained, the post of Medical officer to a sick club; which, however, had not been enjoyed by the testator. The cause was tried at Nottingham, at the last Spring Assizes, before Mr. Justice Williams, when a verdict was found for the plaintiff, with £100 damages. Mr. Sergeant O'Brien and Mr. Beasley now showed cause against a rule which had been obtained to set aside this verdict on the grounds that it was against evidence and that the damages were excessive. They contended that by the strict construction of the agreement W. Beardsall was bound to abstain from the acts complained of, which were all of a nature to injure the plaintiff in his practice. Mr. Boden, Q.C., and Mr. Cave, who appeared in support of the rule, contended that the agreement had only reference to the testator's practice, and was complied with

when the defendant had issued the circulars and had introduced the plaintiff to the testator's patients. W. Beardsall was not bound to give up practice, and at any rate was free to compete with the plaintiff for any patient not belonging to the testator. They also submitted that the damages were excessive. The Court adopted the latter view, and made the rule for a new trial absolute, unless the plaintiff consented to reduce the damages to £50, and to accept that sum in full satisfaction of all claims under the agreement.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 19th inst., and, when eligible, will be admitted to the Pass Examination :—

G. H. Hills, T. E. D. Hayes, W. T. G. Hicks, R. J. Andrews, J. C. Roberts, and C. E. Blair, students of Guy's Hospital; P. C. F. Kilroy, A. E. Conolly, R. F. Allen, and E. P. Davies, of the Dublin School; J. H. Wraith, E. Child, D. M. Williams, and E. Horne, of the Charing-cross Hospital; G. Shannon and J. G. Coulter, both holding the qualification of M.D. Queen's University, Aberdeen, and H. C. Mauley, of the Belfast School; W. B. Stirling and W. Powles, of the London Hospital; R. Brennan and H. G. B. Harris, of St. George's Hospital; J. C. Leach and E. R. Woodford, of University College; J. Hope, of Newcastle; J. B. Blanchet, M.D., and Master in Surgery of Montreal, of St. Bartholomew's Hospital; T. H. Morris, of St. Thomas's Hospital; J. C. Macaulay, of Birmingham; W. A. S. Dykes, of Hull; and F. Argles, of King's College.

Also, on the 20th inst. :—

W. H. Harding, H. Hyde, F. Flint, and C. G. Leacock, Students of King's College; T. Warren, J. F. H. Richardson, W. May, and W. H. Bryant, of St. Bartholomew's Hospital; W. R. Goodfellow, B. Blewitt, J. Todd, and J. Rogerson, of the London Hospital; F. Chabot, A. Kisch, W. H. Strange, and J. Carless, of St. Thomas's Hospital; T. Cuppage, W. L. White, and R. N. Macpherson, of Edinburgh; C. Broom and R. Orme, of Guy's Hospital; E. O'Leary and W. McConnell, of Dublin; W. Pogson, of Leeds; W. Skinner, of Sheffield; H. Jones, M.D., Heidelberg; T. Hora, of St. Mary's Hospital; R. Z. Miller, of the Middlesex Hospital.

The following gentlemen have just passed their Preliminary Examinations at this College, viz. :—

G. Abbott, G. Andrews, J. Bartlett, J. J. Benyon, J. G. Beasley, H. M. Briggs, R. B. Boswell, J. W. Burman, H. Case, R. M. Cole, G. J. Chadwick, J. W. Carr, W. Davies, T. V. de Donne, T. B. Dyer, W. Drinkwater, W. H. Edwards, H. F. Elliot, J. T. Evans, J. Evans, C. Fitzgerald, J. T. Fox, J. Foster, T. W. W. Fay, T. B. Furner, A. S. Gatty, E. Gill, J. H. O. Goulden, J. T. Green, A. F. Greenhill, C. Gadson, W. H. Gregory, A. Hallam, S. L. Herbert, H. E. Hestling, C. E. Hobbes, J. G. Huxford, W. D. Hutehins, C. Higgins, J. S. Jarvis, J. Jenkins, R. W. Jones, H. E. Juler, E. J. Kirkman, T. W. Lee, C. W. Latham, A. Morton, C. G. Newington, R. B. Nowell, E. Peacock, J. E. Peirce, R. H. Prior, J. W. Pindes, J. Reynolds, G. M. Roberts, G. Salt, J. P. Smith, R. H. Stevens, E. E. Tarleton, G. E. Terry, A. Wall, G. E. Walker, C. Wells and T. E. Webb.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, January 14, 1864 :—

James Bredin Beresford Ryley, Myshal, County Carlow, Ireland; Frederick Joseph Keene, Holbrook, Ipswich.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- ALINGHAM, JAMES H., M.R.C.S. Eng., has been elected Honorary Dental Surgeon to the Asylum for Female Orphans, Westminster-road.
- BURROWS, GEORGE, M.D. Cantab., F.R.S., has been elected President of the Medical Council.
- GUY, TOM, M.D., has been appointed Deputy Coroner for Doncaster.
- LAPRAIK, THOMAS, M.D. Glasg., has been re-elected Physician to the Glasgow Asylum for the Blind.
- MALCOLM, ROBERT B., M.D. Edin., has been appointed Physieian to the Fettes College, Edinburgh.
- O'NEILL, WILLIAM, M.D. Aberd., has been elected Physician to the Lincoln Lunatic Hospital.
- PAGET, GEORGE E., M.D. Cantab., has been appointed Physician to Addenbrooke's Hospital, Cambridge.
- PAUL, JAMES T., M.R.C.S. Eng., has been elected Surgeon to the Hunter-street section of the E Division, Metropolitan Police.

DEATHS.

- BAYNE, JOHN, L.F.P.S. Glasg., at Dumbarton, Scotland, on January 10.
- CRAIGIE, JOHN L., F.R.C.S. Eng., at the Woodlands, Chigwell, Essex, and of Finsbury-square, on January 14, aged 50.
- DUNCAN, ALEXANDER, L.R.C.S. Edin., at 11, Ladbroke-villas, Notting-hill, W., formerly in H.E.I.C.S., on January 13.

- GRANT, SIR JAMES ROBERT, M.D., C.B., K.H., at Basford, Nottingham, on January 10, aged 90.
- HARDWICK, ROBERT G., M.D. Lond., at 7, Park-square, Leeds, on January 19, aged 30.
- LOCKWOOD, JOSEPH, M.R.C.S. Eng., at Honley, near Huddersfield, on December 15, aged 29.
- SMITH, JOHN, M.R.C.S. Eng., of the Royal Hospital Schools, in Greenwich Hospital, on January 17.
- SMYLY, JOSIAH, F.R.C.S.I., Vice-President of the Royal College of Surgeons, Ireland, at Merrion-square North, Dublin, on January 19.
- VINCENT, CYRIL JOHN, M.R.C.S. Eng., at High-street, Oxford, on January 14, aged 34.
- WHITTLE, EDWARD H., M.R.C.S. Eng., at Brenchly, Kent, on January 15, aged 44.

ROYAL COLLEGE OF PHYSICIANS.—The lectures of the present year will be delivered at the College, Pall-mall East, at five o'clock on each of the following Wednesdays and Fridays :—Dr. Garrod—January 27, 29, February 3, 5, 10—“The British Pharmacopœia : its Construction, its Comparison with the London Pharmacopœia, and the Value of its New Remedies in the Treatment of Disease.” *Gulstonian Lectures*.—Dr. Markham—February 12, 17, 19—“The Uses of Blood-letting in Disease.” *Croonian Lectures*.—Dr. Basham, February 24, 26, March 2—“On Dropsy : its Significance as a Symptom in Renal, Cardiac, and Hepatic Diseases.” *Lunleian Lectures*.—Dr. Barclay—March 4, 9, 11—“Fallacies in the Application of the Inductive Method of Reasoning to the Science of Medicine.”

* * * Dr. Garrod's lectures on the “British Pharmacopœia,” revised and corrected by himself, will be published regularly in this Journal.

THE COLLEGE LECTURES.—The Course of Lectures for the present year will be commenced in the Theatre of the College on Tuesday, the 2nd proximo, by Professor Huxley, F.R.S., who will deliver twenty-four lectures “On the Structure and Classification of the Mammalia;” at the conclusion of which, Professor Fergusson, F.R.S., will commence his Course. There will not be any Hunterian Oration this year; it is only now delivered biennially.

ROYAL INSTITUTION.—Tuesday, January 26, at 3, Professor Tyndall, F.R.S., “On Experimental Optics.” Thursday, January 28, at 3, Professor Tyndall, “On Experimental Optics.” Friday, January 29, at 8, Professor Frankland, “On the Glacial Epoch.” Saturday, January 30, at 3, John Lubbock, Esq., “On the Antiquity of Man.”

THE PARIS SOCIETY OF SURGERY.—This body, at its first meeting for this year, elected Dr. Robert Adams, of Dublin, and Messrs. Hodgson and Paget, of London, as foreign associates; and MM. Melchiori, Gamgee, Bruns, and Gherini, have been elected as foreign correspondents.

THE QUEEN'S COLLEGE, BIRMINGHAM.—Mr. William Sands Cox, the Treasurer of the Queen's College, Birmingham, has issued a financial report to the patrons and friends of the College, which he prefaces with the following letter :—“Birmingham, December 12, 1863.—My Lords and Gentlemen,—It is with great pleasure and much thankfulness that I place in your hands the report, from which it will be seen that the trade liabilities which I took upon myself have, through your liberality, been discharged; and I have no hesitation in stating, that from the experience of three years as Treasurer *pro tem.*, the College, provided all the departments be consolidated under one roof, may be made self-supporting. The past year has been one of difficulty, but yet of progress; of severe trial, but still, happily, as the returns of students show, and as the audited balance-sheet proves, of success. With unanimity, and in the words of my co-trustee, Chancellor Mr. Law, ‘with God's blessing, the College may still do excellently well.’—I remain, my Lords and Gentlemen, your obliged servant, WILLIAM SANDS COX, Treasurer, *pro tem.* To the patrons and friends of the Queen's College.”—The total number of students in the Medical Department during the academical year, October, 1862, to August, 1863, has been fifty-five. Of these, fifteen have been in residence.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The following arrangements, rendered necessary by the lamented death of the late chairman, Joseph Henry Green, Esq., D.C.L., F.R.S., have been made in the direction of this Society. The Right Hon. J. R. Mowbray, M.P., has been appointed chairman; Wm. Bowman, Esq., F.R.S.A., and Sir Charles Locock, Bart., deputy-chairmen; and James Paget, Esq., F.R.S., Surgeon to St. Bartholomew's Hospital

and Surgeon Extraordinary to the Queen, has been elected to fill the vacant seat at the Board. The other Medical directors, who, with the three last-named, make up the number required by the deed of constitution, are Henry W. Acland, M.D., F.R.S., Patrick Black, M.D., James Dunlap, M.D., Arthur Farre, M.D., F.R.S., and Alex. J. Sutherland, M.D., F.R.S.

THE CHEMISTS' AND DRUGGISTS' OPPOSITION TO THE PROPOSED AMENDMENTS IN THE MEDICAL ACT.—The *Birmingham Daily Post* of January 14 contains the report of a meeting of the chemists and druggists of the Staffordshire Potteries, held on January 12, at the Town-hall, Hanley, for the purpose of considering the proposed amendments in the Medical Act of 1858. An idea of the tone of the meeting may be gathered from some passages in the opening speech of the chairman, Mr. Yates. He characterised the amended clauses as unjust, inquisitorial, and un-English:—"The injustice was the more monstrous because the body seeking these powers had a direct interest in shutting up as many chemists' shops as possible. The man who framed those clauses must think that the 30,000 chemists and druggists of this country a body of idiots, incapable not only of compounding medicines, but of valuing social, civil, and vested rights and interests—a body of men who might be stamped out of society without any loss to it. While, however, they denied their own degeneracy or inability to manage their own affairs, they must admit that some regulation which would place the sale of drugs in safe hands was imperatively required. He objected to examinations and diplomas, and thought the best plan to be adopted would be to grant licenses of from £3 3s. to £5 5s. to all chemists only who had served a proper apprenticeship, all other persons to be excluded from selling drugs or medicines." The following resolutions were passed:—"That this meeting unanimously condemns the 55th, 56th, and 57th sections proposed to be introduced by the Medical Council, as amendments to the Act of 1858, as unjust to the body of chemists and druggists, and resolves to memorialise Parliament to exempt all persons now in business from their action." "That the memorial be sent to Alderman Copeland, M.P., for presentation to Parliament." "That the Secretary write to the members for the county and borough of Newcastle, in the name of the meeting, requesting them to oppose the clauses referred to when the bill comes on for reading."

CONCEALMENT OF BIRTH.—The *Pembroke Dock and Milford Haven Gazette*, of January 13, contains an account of an inquest held on the body of the illegitimate child of a servant girl, named Margaret Davies. The evidence, as far as it is reported, appears to illustrate the difficulty there is in coming to a legal conclusion as to the crime of infanticide. To establish legally the fact of live birth, it is well-known that it is necessary to prove that the child whilst living has been entirely separated from the maternal passages. It is very seldom that such proof can be produced by the Medical witness. In the present case, the child was found wrapped up in a bundle in the mother's box, and there was ample evidence, in addition to her subsequent confession, that she had been recently delivered. The Surgeon, Mr. Gwynne Henry Harries, who examined the body of the child, deposed:—"It was a new-born child. I found that the child had breathed fully. I do not know that it was actually born alive. The cause of death was apoplexy. It is frequently the result of labour. It is the result of injury during labour, both in labour and after labour. I found the lungs fully developed as regards the air cells. I put them, with the heart, into water. They all floated. There were no external marks of violence on the child. I saw no symptoms, except of apoplexy, or marks of violence." The jury returned a verdict of "Death from natural causes."

THE AMENITIES OF IRISH DISPENSARY PRACTICE.—The *Nenagh Guardian*, of January 9, contains the report of a case, illustrating the pleasant relations between Doctor and patient which occasionally arise under the Irish Dispensary system. At the Newport Petty Sessions, Dr. J. Pitt Harris, Medical Officer of the Newport Dispensary, charged James Fitzgerald, of Newport, with an assault, and using threatening language to him; and Fitzgerald had a cross case against Dr. Harris. It appeared from the evidence, that one Sunday evening, about half-past six o'clock, when Dr. Harris was at dinner, Fitzgerald left a ticket at the Doctor's house, requiring him to call and see his son. As the ticket was not marked "urgent," the Doctor postponed his visit until the following day. The next morning, the defendant came to his

door, knocked violently, asked the servant why he (the Doctor) "didn't go visit his son?" The man returned, and was creating a noise, when Dr. Harris went out and asked him why he was disturbing the house. Defendant became so violent that he had to call a policeman to remove him. About a quarter past eleven, Dr. Harris called to see the patient, when the defendant refused him admission; and on the Doctor pushing open the door of the room where the son lay, Fitzgerald assaulted him, and threatened to injure him with the tongs. The question arose, whether the Doctor, having received the order from the authorities to visit the patient, had a right to force his way into the man's house. The magistrates seem to have thought not, and the case was dismissed.

SMALL-POX.—Small-pox is, *par excellence*, a Canadian disease. It is rarely absent from this city (Montreal), and never absent from the country. In every town and village throughout the province, numerous traces of its former presence are visible. If we visit the French Canadian districts, we find family after family "spotted" with it; and many a mother will tell us she has to deplore the loss of a loved one by a disease which added to the usual horrors of death the swollen, distorted features, that forbid the last embrace—nay, even the last sad look of recognition. In those districts where small-pox is most prevalent, vaccination is unknown; and I am assured by Professional gentlemen of the highest respectability in country districts, it is useless to attempt to convince many of the humbler classes that there is any conservative influence in the practice. Many regard small-pox as one of the necessary ills associated with our existence. The child must get its teeth, have measles, scarlatina, whooping-cough, and small-pox; and some go so far as to expose the child to the contagion of the latter, when its health is good, hoping thereby it might run the gauntlet with greater comparative safety. The untutored savages in this country fly from it in terror; and when one is stricken with the disease (and it is supposed to have had more victims than the "fire-water," introduced by the beneficent white man), he drowns himself—preferring a resting-place among the fishes to lying a bloated, putrid mass, with no one to venture near him to moisten his lips.—*Dr. Hingston in Canada Lancet.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. Kendall's letter was received too late for insertion this week.

Ignoramus.—The degree is granted by the Archbishop of Canterbury.

C. T. C.—We think not.

Dr. Richardson will reply to *Mr. Henry Thompson's* letter at the close of his article on Norwich and Lynn.

A CHEMICAL QUESTION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Would any of your correspondents inform me what should be the strength of a solution of chloride of zinc, which a French author recommends should be employed at 25° of Gay-Lussac's areometer? How many grains to the ounce would this be equivalent to? I am, &c.
January 18.

T. H. D.

PROFESSOR SYME AND THE EIGHT HUNDRED FEVERS!

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—*Mr. Syme's* remarks on Medical Education, delivered at the Royal College of Surgeons on the 17th ult., have now assumed the form of a pamphlet, one difference between which and the original delivery consists in the attachment of a foot-note to page 8, relative to the "printed list of no fewer than 800 fevers," by his colleague, the Professor of Practical Medicine.

In such note he says that his statement was made "on the authority of a student;" and, further, that he has "since been informed that there are only five or six hundred."

Would it not have been more to the credit of the Surgical Professor if, before trying to hold up his colleague (whomsoever he be) to ridicule, he had sought means to back up his remarks by some more reliable proof than a statement uttered by a mere student, perhaps in earnest, but more likely loosely and in a wide sense, and with no idea at the time that his words would be repeated without their accuracy having been first tested? But there is now no further need for wonder, when, as is shown by the foot-note, he tries again to make his colleague appear ridiculous, by reducing the number from eight to five or six hundred, which he (*Mr. Syme*) evidently appears to think a good joke, to judge from the prefixed italics, "only." He does not, however, this time so broadly state it as a fact, merely saying he has "since been informed,"—I suppose by another student, and one whose powers of calculation must be "below par," and whose information is as valueless and without foundation as that of the advancer of the eight hundred. Surely the Professor of Surgery might have seen that this, his second disparaging statement, was a correct and accurate one, even if it had necessitated a scrutiny by himself of the terrible "printed list" in question.

If the numerical method, as applied to the advance of Medical science, be no more accurate than these two stated facts, what reliable benefit would result?

I think the laugh, if there be any, must, under the circumstances, be turned against the Professor of Surgery; for any one taking the trouble (as Mr. Syme evidently has not done) to examine the little list, will soon see whether the statements are correct or the reverse; at all events, it is time that informants be dispensed with if they cannot furnish more accurate facts than the ones given forth, especially when such remarks tend to the disparagement of others, and are allowed to appear in print.
Edinburgh, January 14. I am, &c. STERNUTAMENTUM.

WAKE; ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Mr. T. M. KENDALL.

BOOKS RECEIVED.

How can the Town Sewage be Best Preserved and Utilised? London. 1863.

* * A small pamphlet signed by Mr. James Edmeston, architect, accompanied by a set of four elevations and plans. It describes the operations of the Compagnie Chauffournière de l'Ouest, as established in Paris and several other large French towns.

By this system, a portable reservoir is attached to each privy, with a contrivance for separating solid faecal matters from fluid. The latter are allowed to overflow into the usual drains. The former are removed periodically, and carried to the factory to be mixed with equal parts of ground lime. This "chaux animalisée" is inodorous, and can be sold profitably for 38s. per ton.

It is suggested to introduce the method in our metropolis, and it is hoped that prejudice may be found not to be an insuperable impediment in the way of necessary reform.

Functional Diseases of Women: Cases illustrative of a New Method of Treating Them, through the Agency of the Nervous System, by means of Cold and Heat. Also an Appendix, containing Cases illustrative of a New Method of Treating Epilepsy, Paralysis, and Diabetes. By John Chapman, M.D., etc. London: Trübner and Co. 8vo, pp. 74.

* * * In this pamphlet Dr. Chapman reprints two communications to this Journal, which may be in the recollection of our readers. He therein described a new method of treating epilepsy, convulsions, laryngismus, diabetes, and other diseases, by the systematic application of ice to the region of the spine. The bulk of this work, however, is devoted to an adaptation of the same system to a different class of disorders. The preface gives shortly the principles on which his practice is based. He shows that cold applied to the back has the effect of raising the pulse, and producing warmth of the extremities, while warmth has an opposite influence. He, moreover, expresses his belief that many maladies not usually held to depend on nervous agency—such as those in the title (diabetes and constipation)—really originate in that manner. He expresses thanks to the members of the staff of St. Thomas's and Guy's Hospitals for invitations to exemplify and test his methods of treatment at those institutions. The sections into which the pamphlet is divided begin with defective and painful menstruation, giving six cases; next, deal with leucorrhœa, and then incidentally consider coldness of the feet as a symptom of uterine disorder. Menorrhagia is somewhat unexpectedly treated by means of heat. Lastly, the influence of cold applied to the back on the development of the mammæ is briefly mentioned. Concluding remarks sum up the writer's novel views in the matter.

The subject deserves the serious attention of the Profession, not only from the high character of its originator, but also from the amount of evidence which he has already brought to bear upon it. He, however, seems to be as yet only at the outset of his investigations, and promises more detailed information hereafter. In so doing, he will confer a great boon on physiology and practical Medicine.

Notice on the Law of the Production of Sexes in Plants, Animals, and Men. By Marc Thury, Professor of the Academy of Geneva. 1863. Printed by Odell and Ives, 18, Princes-street, Cavendish-square, London.

* * * Whatever may be thought of the conclusions at which the author of this pamphlet has arrived, and careful and extended experiments are the only basis on which an opinion can be fairly founded, it will not be denied that its subject is an excessively curious one, well worthy the attention of physiologists; and moreover, one whose examination may lead to very important practical results. We by no means give our assent to the statement contained in the first line of the author's introduction—that the question of the production of the sexes in plants and animals has been solved by him. It will require the evidence of a vast number of experiments conducted on a much larger scale, and recorded in a far more explicit and scientific manner than any which he relates, before his solution can be accepted. Yet, we think his observations and reasoning of sufficient interest to claim notice. Professor Thury appears first to have been led to the subject of the production of sex by a passage in Professor Lindley's "Theory of Horticulture," which states that, according to Knight's experiments, "heat is favourable to the production of male flowers in dioecious plants." In reflecting on this statement of Knight's he came to the conclusion that "heat operates mediately on plants, by bringing on a more complete elaboration of the juices, and, therefore, a more thorough maturation of the organs. Thus, the production of the male element answers to a more thorough maturation, otherwise to a more complete development of the organs." The fundamental identity of stamens and pistils as modified leaves, and the discovery that most dioecious plants are hermaphrodite, or become dioecious through abortion, are believed by the author to favour his view. In animals the author has convinced himself that both male and female sexual apparatus are constructed on one single plan, and that the differences between them are "mere harmonic discrepancies in the mode and

quantity of the growth." The determining causes of these discrepancies he believes to be those very causes that lead to a more complete maturation of the organs. If the ovum has reached the more complete stage of maturation when it is fecundated it yields a male, but if fecundation takes place when the ovum is less mature a female is the result. Huber had long ago observed that in bees, fecundation, when taking place early, generates females, whilst, if later, it always produces males. Some observations made by Professor Thury on fowls led to the same result. He, however, rests his conclusions chiefly on what he terms a "decisive trial upon mammifers." He obtained opportunities for experimenting at a large farm at Montet, belonging to a M. Cornaz. The animals experimented on were cows. The author writes:—"It is a well-known fact, that mammalian ova get loose from the ovary at the beginning of the rut, and that they are in a condition to be fecundated as long as the period of heat lasts; that is, therefore, even when they have reached a comparatively mature point. Truly, that period is short, but during the first stages of genetic development, when all the essential elements of the coming being are as yet undeveloped, the creative power is actively at work, and capital alterations follow each other in a very short time. I therefore directed M. Cornaz to get his cows served in the beginning of the rut, in order to procure females, and at the end of the rut to procure males." The result was, that in twenty-nine experiments, without any exception, M. Cornaz obtained, at pleasure, heifer and bull calves. M. Cornaz, in an appendix, expresses his opinion, that this discovery "will regenerate the business of cattle-breeding." It will be seen that M. Thury believes that the turning-point in the maturation of the mammalian ovum, which decides whether it shall be female or male, takes place whilst it is in the Fallopian tube. Although M. Thury's title-page speaks of plants, animals and men, he merely observes that the law he seeks to establish is general, and, therefore, applicable to all organised beings,—plants, animals, and mankind;—a rather broad generalisation to draw from twenty-nine experiments or coincidences observed in one domesticated species of ruminants!

By the peculiarly equitable manner of dividing the profits, the Policies issued by this Association *become payable during the lifetime of the person Assured without extra Premium.* After having been in force a period of five years, all Policies are absolutely indefeasible and indisputable.

Attention is directed to the facility afforded by this Institution for the assurance of declined or diseased lives. The experience of the large staff of Medical officers connected with this Association has enabled the Directors to prepare a set of Tables which they believe place such lives on an equitable footing in relation to other assured Members of the Company.

Qualified Medical Attendants who are named by Proposers to this Association are consulted as the Medical Advisers of the Directors, by whom all Medical Fees are discharged.

Every description of Life Assurance transacted; terms for which, with detailed Prospectuses and every information, may be had on application to

JOHN MESSENT, F.S.S., *Manager and Secretary.*

Applications for Agencies are invited.

Third Edition of Boudault on "Pepsine," with further Remarks by Dr. Corvisart, Physician in Ordinary to the Emperor of the French. Price 6d. Edited by W. S. SQUIRE, Ph.D., published by J. Churchill and Sons. May be had also of the Author, 277, Oxford-street, London.

ORIGINAL LECTURES.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,

AND THE

VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College
Hospital.

LECTURE I.—JANUARY 27, 1864.

MR. PRESIDENT,—I believe I am correct in stating, that some thirty or more years since, an attempt was made by this College, in conjunction with the Colleges of Physicians of Edinburgh and Dublin, to effect a union of the Pharmacopœias of the three countries; but after about two years' correspondence between them, it was thought desirable to break off the negotiations, it being found impossible to reconcile the many and great differences of opinion which were held by the three Colleges in regard to the general construction and details of a National Pharmacopœia. The reconciliation which the Colleges of Physicians were unable to effect, has at length been accomplished, but only by the aid of an Act of Parliament, which delegated the task into the hands of the General Medical Council, formed under this Act; and I have now to congratulate, not only this College, but the Profession at large, on the appearance, within the last few days, of the "British Pharmacopœia,"—a work so long and anxiously looked for, and which I trust will not disappoint the expectations that may have been formed of it. That it will completely satisfy all, it would be madness to suppose; for the opinions entertained by the Profession of a perfect Pharmacopœia are as diverse as it is possible to conceive. During the time that I have been engaged in the work, I have, as might be anticipated, had the feeling of many eminent Physicians and Surgeons freely expressed to me.

Some would desire that the number of our remedies should be made as few as possible; and one Physician, of no small repute, begged of me to use my influence in attempting to reduce the list of drugs to not more than twenty-five, considering that all the good results capable of being accomplished by medicine could be effected by these few agents. Others, again, would gladly see the list of officinal medicines swollen out considerably, in order to give a more extended choice to the Physician. A third set consider that a Pharmacopœia should include only the simplest forms in which drugs are capable of being administered; but, on the other hand, a fourth class look upon the work as one which should include in its pages almost every medicine which has been proposed, and likewise the formulas for all compounds which have proved efficacious in practice.

It will be found, on perusing the British Pharmacopœia, that the committee engaged in its compilation almost of necessity, and, I believe, judiciously, chose a middle course—introducing into the list of the *Materia Medica* substances the reputation of which has been established, and which had earned a well-founded claim, and giving only such compound formulæ of which the value was undoubted, and which were so generally employed as to render them indispensable in practice. There are, doubtless, many both simple and compound medicines still present which might well be omitted; but we must all be aware that we often have prejudices in favour of certain remedies for which it might be difficult to give reasons satisfactory to our brethren.

It must also be remembered that in a committee, subdivided into three sections, and containing in all about twenty members, the opinions and wishes of many had to be consulted, and no such definite plan, with regard to the introduction and omissions, could be followed out, as might have been the case had the task been confined to a few. Still, it was necessary that such a committee should be constructed in order to reconcile the different divisions of the United Kingdom and the

various corporate Medical bodies in each. Irrespective of the value of the contents of the British Pharmacopœia, it must, I think, be acknowledged by all that a great and important work has been accomplished, in the fact, that in lieu of having three separate Pharmacopœias in this kingdom, containing preparations bearing the same names, but of different strengths, with weights of the same denomination, but of different values, we have now one national Pharmacopœia, not only for the United Kingdom, but for all our various and extensive colonies.

No one who has studied the progress of Medicine within the last quarter of a century can blind his eyes to the fact that a great change of opinion has been, and is slowly but steadily going on in regard to the treatment of disease—a change which will doubtless ultimately prove of the highest importance and value, although for a time causing shipwreck to many minds, leading some to the very depths of scepticism as to the effects of medicines, others to embrace hypotheses the most fanciful and absurd. Perhaps it may be some poor consolation to us to know that it is not among the votaries of Medicine alone that such revulsions are taking place, but that it is a necessary evil consequent on the arousing of the minds of men,—an awakening from a prolonged sleep of ignorance,—a struggle to gain some landmark upon which to rest in safety.

The knowledge of therapeutics, or the real action of medicines in controlling disease, is confessedly far behind many of the other branches of Medicine. Who amongst us, engaged in the active practice of his Profession, has not felt how powerless he often is at the bedside, even in cases where he feels assured that his knowledge of a disease is correct?—and how often do we feel confident as to the nature of disordered action, but impotent in our power of relieving it! The study of treatment, although one of the greatest difficulty, and one requiring the exercise of patience, of the absence of prejudice, and the possession of a logical mind, must necessarily, to the practical Physician, be of the highest interest, not only in an intellectual point of view, but, in addition to this, as leading us to effect the highest object of our Profession,—the prolongation of life, and the administration to the physical welfare and comfort of our fellow-creatures. Surely, then, more labourers in this field should be found; for, in addition to other inducements to its study, it is a field which, at the present day, offers the greatest probability of successful results.

In all therapeutic inquiries there is one point which it is most important not to overlook,—I allude to the natural and powerful tendency of disease to run a definite course, and the difficulty, in many cases, of influencing this progress, even by what we are induced to look upon as potent remedies. This is a most important consideration, and the neglect of it has often caused much difference of opinion as to the best mode of treating various diseases. Statistics are appealed to, and it is found that treatment, apparently the most opposite, leads to results the most similar. Such discrepancies may often be reconciled; but, in many cases, it is owing to the fact, that our treatment has been inoperative either for good or for harm, and the disease has followed its own course, without heed to the medicines which we have employed for its arrest. I need not here, before such an audience, quote examples to prove the correctness of this statement.

On the other hand, who can doubt the efficacy of drugs, if he has watched their effects in alleviating suffering and effecting cures? Who can doubt our power of alleviating pain—of arresting inflammation—of checking intermitting fever—of allaying irritability of various organs—of procuring sleep? One must be blind not to allow this power; and this proved, we have at once a groundwork upon which to proceed further.

But to return to our more immediate task. It may be well for the information of those of my hearers who have not studied the subject of Medical politics, that I should give a slight sketch of the origin of the British Pharmacopœia, and the various steps by which it has been accomplished.

In the Session of 1858 an Act called the Medical Act was obtained, and in it (sect. liv.) the following clause is found:—

"The General Council shall cause to be published under their direction a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matter and things relating thereto as the General Council shall think fit, to be called 'British Pharmacopœia,' and the General Council shall cause to be altered, amended, and republished such Pharmacopœia as often as they shall deem it necessary."

Again, in a supplementary Act, it is enacted:—

“The British Pharmacopœia, when published, shall, for all purposes, be deemed to be substituted throughout Great Britain and Ireland, for the several above-mentioned Pharmacopœias; and any Act of Parliament, Order in Council, or custom relating to any such last-mentioned Pharmacopœias, shall be deemed after the publication of the British Pharmacopœia, to refer to such Pharmacopœia.”

The power of publication of the national Pharmacopœia therefore was, by these Acts, removed from the three Colleges of Physicians, and vested in the hands of the Council, constituted according to the provisions of the Medical Act, and styled “The General Council of Medical Education and Registration of the United Kingdom.” This Council at once appointed a Pharmacopœia Committee from amongst its members, with power to add to their number; and it was resolved that the three Colleges of Physicians should be communicated with, and requested to give their co-operation in preparing the Pharmacopœia, and for that purpose to appoint Fellows of the several Colleges to be associated with the Committee of the General Medical Council. It was also resolved that the Pharmaceutical Society of Great Britain should be communicated with for the same purpose.

The delegates honoured in being selected by this College to co-operate with the Committee of the General Council in the construction of the Pharmacopœia, were Dr. Fred. Farre and myself. Of Dr. Farre, I may be allowed to say thus much: that his extensive knowledge of the method of constructing a Pharmacopœia, gained from his labours during many years as a member and as chairman of the Pharmacopœia Committee of this College—that his clearness of thought, his logical mind, and, moreover, his untiring perseverance, combined to render him an invaluable member of the British Pharmacopœia Committee; and I am sure that he has proved himself a delegate of whom the College of Physicians may well feel proud. Of your other delegate, I can only state, that, although inexperienced in such Pharmacopœia labours at the commencement of his task, and with no pretensions to the possession of the qualities so prominent in the Physician just alluded to, still, I trust that he has not been forgetful of the honour, nor neglectful of the important duties imposed upon him by your selection.

The first point to which the attention of those accustomed to the use of the London Pharmacopœia will be naturally directed is the language in which it is written; and doubtless there will be many learned and erudite Fellows of the College of Physicians who will regret in no small degree the change that has been made. If any such be present, I must call to their minds the fact, that although the Pharmacopœia of the *London* College has always been published in Latin, yet both the *Edinburgh* and *Dublin* Pharmacopœias have been in English; and, moreover, lest any of the Fellows of this College may feel inclined in the least degree to throw blame upon its delegates for not strongly advocating the use of the Latin tongue, I must add, that the question of the language of the British Pharmacopœia was never brought under the consideration of the Committee, as it had been previously moved in the Council by Mr. Lawrence, and seconded by Mr. Teale, and agreed to: “That it be an instruction to the Pharmacopœia Committee that the Pharmacopœia be published in the English language, with the list of the *Materia Medica* and *Compounds* in the Latin language.” You will, therefore, see at once that your delegates were altogether powerless in this matter.

In the section of the Medical Act which I first read, it is enacted that the British Pharmacopœia, besides containing a list of medicines and compounds, and the method of preparing them, shall likewise define the true weights and measures by which they are to be prepared and mixed; and as some very important changes have been made, I must direct your attention for a few minutes to the consideration of this subject.

The measures of the British Pharmacopœia remain unaltered. The imperial gallon, pint, and ounce, are introduced, and the latter measure subdivided into fluid drachms and minims.

With the weights, however, the case is different. In lieu of the employment of the troy or apothecaries' pound of 5760 grains, divided into 12 ounces of 480 grains each, the avoirdupois pound of 7000 grains is substituted, divided, of course, into 16 ounces of 437½ grains each, and no intermediate or smaller weights are required—in fact, no solid drachms or scruples; for weights of 60 and 20 grains would

form no submultiples of the ounce avoirdupois. You will probably be inclined to ask,—Why was this alteration made? Where was the necessity for so great a change in weights, the use of which in Pharmacy had been so long established in this country? I will try and explain. Those familiar with the Dublin Pharmacopœia of 1850 (I presume I may call it even now the present Dublin Pharmacopœia) are aware that avoirdupois weights were introduced in that edition in lieu of apothecaries' weights; and it will be also observed that in the Preface of the last edition of the Edinburgh Pharmacopœia, the Edinburgh College felt well disposed to the substitution of avoirdupois for apothecaries' weights. It must also be remembered, that the British Pharmacopœia committee contained members from each of the three divisions of the United Kingdom, and in about equal numbers. Under these circumstances, the advocates for the employment of the apothecaries' weights were outnumbered, and the victory on the side of avoirdupois was very decided. This point being settled, a great difficulty still remained: how should the avoirdupois ounce be subdivided for pharmaceutical purposes. There exists an avoirdupois drachm—a sixteenth part of the ounce—containing 27 grains (troy); such a weight, however, is but little known, and only used in some particular branches of trade. It was evident, therefore, that this could not be introduced into Pharmacy, differing, as it does, so greatly from the apothecaries' drachm, yet bearing the same name. Again, the Dublin College had, in 1850, divided their (the avoirdupois) ounce into 8 drachms, each, therefore, containing 54 grains; this was another argument against the introduction of the old avoirdupois drachm. At length, Dr. Charles Wilson, the Secretary of the Edinburgh section of the Pharmacopœia Committee, proposed the following expedient—namely, the alteration of the value of the grain weight; in fact, the introduction of a new grain, differing very slightly from the troy grain, and to be designated “the apothecaries', or pharmaceutical, grain.” The weights would have then stood thus:—An avoirdupois pound, containing 16 avoirdupois ounces, composed of 8 pharmaceutical drachms, 24 pharmaceutical scruples and 480 pharmaceutical grains; in short, the avoirdupois ounce subdivided exactly in the same manner as the apothecaries' ounce at present. This proposition of Dr. Wilson was carried at the first conference of the Pharmacopœia Committee, and on such basis the manuscript of the work was composed. Although never feeling quite satisfied with this adjustment of the weights, I have still no hesitation in stating, that for pharmaceutical purposes, it would have been a most convenient system, and the difference between the weights of the same denomination so slight, that the substitution of the one for the other would have been unappreciable in all therapeutic inquiries. The weights and measures, from the ounce downwards, would have exactly corresponded with each other; that is, in the case of distilled water, the fluid ounce would have been equal to the ounce by weight, and so on for the fluid drachm, scruple, and minim, which would have weighed respectively 60, 20, and 1 grains.

When it became noised abroad that the manuscript of the Pharmacopœia was approaching completion, and that this system of weights was to be employed, many and grave objections were raised against its introduction. The chief difficulty—that which weighed most powerfully in the minds of those best capable of forming a judgment—was the alteration of the grain weight; and it was asserted that the grain,—that is, the troy grain—was the standard of all the weights of this kingdom,—that, in fact, the avoirdupois pound was defined by Act of Parliament to consist of 7000 grains troy, and the apothecaries' or troy pound of 5760 such grains. The Medical Council were subjected to pressure from without, and a resolution passed at a Comitia of this College doubtless had great weight with them; and in the end, a meeting of the Medical Council was convened to determine the point, and, as a result of their deliberations, Dr. Wilson's system of subdividing the ounce was abandoned, and it was finally decided to retain the avoirdupois pound and ounce, to abolish the drachm and scruple, and to have no subdivisions of the ounce other than the grain. This system will possess both advantages and inconveniences.

The advantages will consist, first, in the abolition of weights which are comparatively seldom used, and for which there is proof that the avoirdupois was often substituted in the preparation of medicines on a large scale; and, secondly, in the weights of Pharmacy corresponding with those ordinarily employed in this country for other purposes. One of its

disadvantages will be the necessity for the employment of large numbers in prescriptions, which will, I fear, be found very inconvenient; and the only method I can see for surmounting the difficulty is, to adopt the habit of prescribing a single dose, and then ordering a certain number to be dispensed. This is the method by which I invariably prescribe in the Hospital, and it is one which has this to recommend it,—viz., that a single glance at the prescription is sufficient to enable the prescriber to ascertain the exact amount of each component exhibited at one time.

Before leaving this part of our subject, I would remark that the London section of the Committee would gladly have seen the apothecaries' weights retained for the present; but this was found impossible, from the desire of the other sections to have the *avoirdupois* substituted in its place.

Probably, there are those who would have wished to have had the metrical system of weights and measures introduced; but I question, had such gentlemen been placed in a position of responsibility, if they would have been anxious to adopt it. To have substituted it in place of other weights and measures would have been unpardonable, seeing that the British Pharmacopœia is published by Act of Parliament, and therefore a compulsory work, and that many of those whom it will affect are entirely ignorant of such a system, and that slight mistakes, as between grains and grammes, might have led to fatal errors. To have placed the metrical system side by side with other weights and measures would have complicated and disfigured the work, and caused much confusion. Should the metrical system ever become legalised in this country, then, and not till then, in my opinion, should it find a place in a National Pharmacopœia. In a merely scientific work, which is, in many other respects, only intelligible to, and employed by, educated men, the case is far otherwise.

I will next endeavour to explain the construction of the British Pharmacopœia, and to point out in what respect it resembles and in what it differs from the Pharmacopœia of this College.

You will observe that the volume is divided into two parts and an appendix. The first part contains a list of the *Materia Medica*; the second part includes processes for making not only the ordinary pharmaceutical preparations, but likewise the various chemical substances contained in the first part. The appendix, or rather collection of appendices, we shall have an opportunity of explaining in a future lecture.

The first part, or catalogue, which may be termed the *Materia Medica*, differs from that of the London Pharmacopœia in many important respects. In the first place, as to its extent. In the octavo edition of the latter work it occupies only 43 pages; in the former, or British Pharmacopœia, as much as 157 pages are devoted to it; but as less matter is contained in the pages, we may roughly estimate it at about three times the extent. This augmentation is by no means due to the number of articles contained in the list, but chiefly to the manner in which the subject is treated.

In the list of the London Pharmacopœia, those substances only are contained, for the preparation of which no process is given in the second part; but in the British Pharmacopœia this distinction is not found; but, as stated in the Preface—"The *Materia Medica* contains, in its simplest pharmaceutical form, every definite medicinal substance, whether obtainable in ordinary trade, or prepared by the chemical processes in the second part, which the Committee of the Council found, on careful inquiry, to be so far approved in practice as to be entitled to a place in the National Pharmacopœia." And this holds good, whether a process for its preparation be introduced or not into the work. The list, therefore, is a complete one, and by reference to it alone we can at once perceive what medicines are made officinal.

Perhaps I can more readily explain the subject by giving an example or two. If we turn to the list of the London College, we fail to discover either Calomel or Corrosive Sublimate. The reason is, that processes for preparing these two salts are contained in the second part. So likewise, for the same reason, Tartar Emetic is omitted, although the Black Sulphate of Antimony is introduced, being a production of nature.

In the British Pharmacopœia, Calomel, Corrosive Sublimate, and Tartar Emetic are all introduced in the *Materia Medica*, although the methods of making them are in Part II.

Although the list of the London Pharmacopœia is deficient in many medicines, yet it contains several articles not employed as remedies, but only used in the processes for their preparation—such as the Black Sulphuret of Antimony, Powdered

Flint, and numerous others: in the British Pharmacopœia these are altogether excluded from the *Materia Medica*, and placed in one of the Appendices; and thus the first part of the work is not only a complete list of the *Materia Medica*, but, at the same time, it contains no superfluous articles, or such as are merely made use of in pharmaceutical operations.

Next, the method in which the subject is treated in the British Pharmacopœia differs in many respects from what is found in the London Pharmacopœia. In the latter, it is true, many important characters and tests are frequently appended to the individual remedies,—still this is, perhaps, the exception rather than the rule; but in the former book, under every article in the list, much important information is afforded. In the words of the Preface, there is—"1. A Latin pharmaceutical name, by which it may be prescribed; and an English name, for use in describing the processes in the second part. 2. Its definition, together with its chemical symbol, if it be a substance of definite composition; its botanical name, if it be a plant; or its botanical source, if procured from a plant, and also in most cases a reference to a correct figure of the plant, and a statement of the quarter whence the article is obtained. 3. The characters by which it may be distinguished from all other articles of the *Materia Medica*. 4. The test by which it may be ascertained to be of due strength and free from known impurities or adulterations. 5. The preparations of which it is an active ingredient."

Let us take two or three short examples from the work itself; first, a chemical substance, say Oxide of Silver.

1. Its Latin pharmaceutical name, *Argenti Oxidum*, and its English name, Oxide of Silver, but not necessarily a literal translation of the Latin name.

2. Its definition and symbol *AgO*; the symbol constitutes in this case its definition, and, even more, it expresses accurately its composition.

3. The characters by which it may be distinguished from all other articles of the *Materia Medica*. *An olive-brown powder, which at a low red heat gives off oxygen, and is reduced to the metallic state. It dissolves completely in nitric acid without the evolution of any gas, forming a solution which has the characters of nitrate of silver.* You will observe, that if the chemical substance has two elements, the characters given are such as to indicate each of them—in the example now taken, both the oxygen and the silver; and this method is carried out through the entire range of the medicines with a definite chemical composition.

4. The tests by which it may be ascertained to be of due strength, and free from known impurities or adulterations. In the use of the Oxide of Silver, the article under consideration, the following is sufficient:—*29 grains heated to redness leave 27 grains of metallic silver.* The equivalent or combining proportion of silver being 108, and of oxygen being 8, it follows that 106 : 108 :: 29 : 27, or 29 parts by weight of silver combined with oxygen, yield, when deprived of this oxygen by heat, 27 grains of pure silver. The quantitative estimation of the elements, in this case very simple, is of itself sufficient to determine the purity of the compound.

5. The preparations of which it is an active ingredient.

In the case of the Oxide of Silver, no preparation exists in the Pharmacopœia.

As an example from the vegetable kingdom, let us take Bael, commonly termed Indian Bael.

Its Latin name is *Bela*, its English *Bael*, from the *Ægle Marmelos de Candolle*. Plate of the plant in *Pharmaceutic Journal*, vol. x., page 166. Its definition: *The half-ripe fruit, dried; obtained from Malabar and Coromandel.*

Its characters: *Fruit roundish, about the size of a large orange, with a hard, woody rind. Usually imported in dried skin, or in fragments consisting of portions of the rind and adherent dried pulp and seeds. Rind about a line and a-half thick, covered with a smooth pale-brown or greyish epidermis, and internally, as well as the dried pulp, brownish orange or cherry red. The moistened pulp is mucilaginous.*

Such are the characters, themselves quite sufficient, not only to recognise the drug, but likewise ascertain its goodness, and hence no special tests are required. Its only preparation in the Pharmacopœia is termed, *Extractum Bæle Liquidum*, or Liquid Extract of Bael.

As a last example, we will allude to a substance obtained from a vegetable source, Santonine, a remedy of whose action we shall speak in the course of our lectures.

Its Latin name is *Santoninum*; its English, *Santonine*.

Its definition: *A crystalline neutral substance, obtained*

from Santonica; and its composition, or at least percentage of elements, is represented by the formula $C_{30}H_{18}O_6$.

The characters: Colourless, flat rhombic prisms, feebly bitter, fusible, and sublimable by a moderate heat. Scarcely soluble in cold water, sparingly in boiling water, but abundantly in chloroform, and in boiling rectified spirit. Sunlight renders it yellow.

As tests, we find stated: Not dissolved by mineral acids. Entirely destructible by a red heat with free access of air.

No preparations exist in the Pharmacopœia; but it is itself referred to as a preparation or active principle of Santonica, a drug consisting of the unexpanded flower-heads of an undetermined species of *Artemisia*.

I have selected for illustration some of the shorter articles, that I might not weary you with details; but you will find, under the more important medicines of the Pharmacopœia, a considerable amount of information—so much, indeed, that I think I may say, although, perhaps, it may be looked upon as heresy in a Professor of Materia Medica to do so, that the Medical Practitioner will be able, almost from this work alone, to obtain all the information he requires, as far as strict Materia Medica is concerned, of the various remedies which he will have to employ in the practice of his Profession.

In the first part of the work, therefore, every simple drug is contained, and every preparation is named or referred to.

I propose in these lectures to occupy your time chiefly in the investigation of the therapeutic value of those medicinal substances and preparations which find a place in the British Pharmacopœia, but are not in the present London Pharmacopœia. Most, or I may say all, of these remedies have been already employed in Medicine, and some of them are contained in the Edinburgh and Dublin works. I shall not attempt to give any amount of detail concerning the natural history, the physical and chemical properties, and the composition of such remedies; for, had I even time so to do, I should not consider it desirable in such a place and before such an audience; but instead of this I will endeavour to give such information concerning them as shall enable you to pursue with advantage further investigation into their physiological action, and the therapeutic powers which they possess. I propose now to pass in review the first part of the Pharmacopœia, or the list of the Materia Medica; to select those newly-introduced remedies which I consider of importance, and speak not only of them, but of any of their preparations which possess interest to the Practitioner. I shall afterwards allude to the second part of the book, giving a short account of its construction and of each group of preparations contained in it; and finally, I hope to be able to make some short allusion to the different Appendices attached to the work.

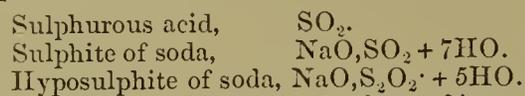

Any alterations in the nomenclature I shall allude to when discussing the different groups or individual substances in which they occur; and I shall now and then have occasion to refer to certain omissions which have been made, and allude to the causes which have led to them.

The first preparations to which I shall draw your attention are the Acids of the British Pharmacopœia, in which some changes have been made sufficiently important to call for a few remarks; and, first, with regard to Acetic Acid, or compounds containing it. British vinegar has been removed, and French vinegar substituted as usually the purer of the two, and Acetum Distillatum omitted. The so-called Acetic Acid has been altered in strength; it now contains 28 per cent. of anhydrous acid ($C_4H_3O_2$) in lieu of 30.8 per cent.; it is defined as being prepared from wood by destructive distillation. The dilute Acetic Acid is made by mixing the stronger acid with seven times its volume of water, and is slightly weaker than the preparation of the London Pharmacopœia. Another form of Acetic Acid has been introduced, termed Acidum Aceticum Glaciale, or Glacial Acetic Acid. It is so named for remaining in a crystallised state at moderately cool temperatures, as you will observe in the specimen; it is monohydrated Acetic Acid, or simply an Acetate of Water, and contains in its composition only one equivalent of water, which exists in the form of a base; the composition will, therefore, be represented, as is seen on the board, by the formula $HO, C_4H_3O_3$.

The value of Glacial Acetic Acid is partly chemical, partly therapeutic. In the former capacity it may be employed as a solvent; but in the Pharmacopœia it is, with the exception of being a component of the Creosote Mixture, only introduced as an external agent. It is a very powerful caustic; when applied to the skin it produces intense redness and pain, followed by speedy vesication. It is also used as an escharotic to warts and corns. It dissolves Cantharidine pretty freely,

and a solution, so prepared, has been employed for rapid blistering. The sore produced by this acid is very severe, as the action often extends to a considerable depth; it should, therefore, be used with much caution. I have occasionally employed it with advantage in cases where the absorption of Cantharidine would have been prejudicial, as in some affections of the kidneys.

A second acid, called *Acidum Sulphurosum*, has been placed in the British Pharmacopœia for the purpose of being employed as an external agent. It is a saturated, watery solution of sulphurous acid gas, and possesses its strong, suffocating odour. There is also, in the Appendix, a salt termed the Hyposulphite of Soda, which, as well as the sulphite of the base, may be used with the same intention as the sulphurous acid itself. The composition of these may be thus represented:—

When sulphurous acid itself, in the form of its watery solution, is applied, the full action of the acid at once ensues. When, on the contrary, the sulphite of soda, first dissolved in water, and acidified with acetic acid, is employed, the sulphurous acid is slowly evolved; and, when the hyposulphite is made use of, sulphur itself is liberated, in conjunction with the sulphurous acid.

Sulphurous acid is endowed with certain peculiar chemical properties, to which, doubtless, any therapeutic powers which it possesses are due. It is a strong deoxidising body, which has considerable bleaching powers; it is also a powerful disinfectant and an antiseptic agent; and, lastly, it is strongly destructive to vegetable life.

Sulphurous acid is only employed as an external agent, and it is chiefly made use of in the treatment of skin affections connected with the growth of vegetable parasites, or in cryptogamous skin diseases; and in such cases it is a valuable remedy; a good mode of application is in the form of a lotion, in which the acid is previously mixed with an equal volume of glycerine. There are inconveniences in the employment of the sulphurous acid arising from its liability to decomposition, and also from the readiness with which the gas escapes from the applied lotion; and in my practice I have usually chosen the sulphite or hyposulphite of soda, in lieu of the acid itself. Either of these salts may be dissolved in water, and the solution acidulated strongly with acetic acid; in the proportion, for example, of one ounce of salt, one fluid ounce of acetic acid, and about seven ounces of water. When the diseased surface is either sponged with this lotion or covered with a piece of lint moistened with the same, sulphurous acid is slowly evolved, and acts slowly but continuously upon the part. The simultaneous separation of sulphur in the case of the hyposulphite is of no disadvantage; on the contrary, in many cases, of benefit. I have heard it now and then suggested, that the acetic acid in such lotions is the remedial agent, rather than the sulphurous acid; and, to ascertain the correctness or incorrectness of such an opinion, I have repeatedly put the point to a test. For example, I have selected a patient with pityriasis versicolor, treated the eruption on one side of the body with the lotion before alluded to, and the other with a dilute acetic acid of exactly the same strength; so that, in fact, every circumstance remained the same, with the exception of the sulphite or hyposulphite of soda. In all my trials, the results of which were carefully noted in the Hospital books, the advantage has always been greatly in favour of the salts, although there is no doubt that the acetic acid is likewise a remedial agent in cases of this kind. As an internal remedy, the hyposulphite of soda or the sulphite has appeared to be of service in some cases of chronic vomiting, accompanied by the presence of the *sarcina ventriculi*, probably from the evolution of sulphurous acid. I feel assured that sulphurous acid, and more especially the salts yielding the gas slowly, deserve a more extended trial as remedial agents.

Among the Strong Acids, the only alteration I need allude to is the alteration in the strength of the Nitric. In the London Pharmacopœia its specific gravity is stated to be 1.42; in the British Pharmacopœia, 1.50. Looked upon in a Medical point of view, this is of little or no importance; its difference of causticity would not be very appreciable.

I have lastly, in this group, to call your attention to the Dilute Acids, and here some considerable alterations will be discovered. Dilute Hydrochloric Acid has been slightly increased

in strength; Dilute Phosphoric Acid more so; the amount of phosphorus contained in the pint being now 413 grains, in lieu of 360 grains. Dilute Sulphuric Acid is not materially altered; but Dilute Nitric Acid is raised in strength. I do not, however, consider that we need pay much heed to these alterations in prescribing, seeing that we usually allow a wide range from their minimum to their maximum doses; from 5 to 10 or 15 minims will still be the amounts in which these dilute acids can be conveniently administered. A compound dilute acid is now made officinal, namely, Dilute Nitro-hydrochloric Acid; the ratio of the acids is two parts by volume of hydrochloric acid to one of nitric acid, and the dilution ordered is such that the saturating powers for alkaline solutions is somewhat less than that of the dilute Nitric or Hydrochloric Acids; the dose, therefore, may be about the same.

With regard to Arsenious and Dilute Hydrocyanic Acids—remedies whose influence on the system has no relation to their acid properties—to these I shall have occasion to allude in a future lecture.

On referring to the list of the *Materia Medica*, a vegetable will be found contained in it, which will, perhaps, be looked for with some interest, as it is one in favour of which there is much prejudice with the public, and even with some of the Profession. I allude to *Arnica Montana*, or Leopard's-bane, belonging to the natural order *Asteraceæ*. The part of the plant which is now made officinal in Britain is the dried root, and from this a tincture is ordered to be prepared, with one ounce of the root to the pint of rectified spirit. As an internal remedy it is scarcely or never employed in this country, except by Practitioners holding peculiar opinions, and then in infinitesimal doses. It appears to act as a powerful irritant, exciting sneezing when applied to the nose, and producing emetic and purgative effects if given in large quantities: in milder doses it is stated to act as a stimulant to the nervous system, causing spasmodic twitchings, and it was once thought to contain a principle not unlike strychnine in its action; it has also been looked upon as an excitant to the circulation, and as producing either diaphoresis or an increased flow of urine. I must confess that my experience of this drug as an internal remedy is very slight. I have, it is true, given the tincture in some cases of chronic rheumatism, when I should otherwise have been inclined to administer serpentary; but the result of my observations was not very definite. It has been recommended in cases of paralysis, nervous headaches, and so on.

It is, however, in its influence as an external application that the chief interest of *Arnica* lies. Many look upon *Arnica* as a sovereign remedy in the treatment of contusions, sprains, lacerations, and, in fact, in almost every kind of external injury; and the amount of the tincture employed for such purposes in this country is very considerable. As the drug is now introduced into the British Pharmacopœia, it may be desirable that I should place before you any information I possess regarding it. As far as its composition is concerned, the whole plant, or, at least, the root and flowers, the parts which have been made use of, are known to contain a little volatile oil, a bitter matter, and also an acrid resin. *Cytisin* has been asserted to be its active principle by some, and an alkaloid, *Arnicine*, by Mr. Bastick.

When the Tincture of *Arnica* is employed as a liniment, or when it is diluted and applied as a lotion to injured parts, it is supposed to aid greatly the reparative powers. To determine this point, I have made many observations which, I think, will not be altogether without value.

If *Arnica* proves useful when applied to contusions or bruises, the results of accidents, it should be equally effectual when these injuries are artificially produced; and in making my trials I devised the following method:—Patients were selected, from time to time, in whom it was desirable to make use of dry-cupping, by which, as we all know, ecchymoses are caused more or less severe according to the amount of exhaustion of the glasses and the length of time they are applied. Under such circumstances we can produce at will bruises in situations well suited for the application of remedies, and can likewise have symmetrical parts of the body injured at the same time and to the same degree; and thus everything becomes well adapted for obtaining trustworthy results, as there can be no disturbing causes from the difference in the healing power of various parts of the surface, or difference in the condition of the patient. In the first series of trials six patients were chosen; on the chest of each two symmetrical bruises were made—one on each side of the sternum; on one side an *Arnica* lotion was applied, containing one part of

Tincture of *Arnica* to three parts of water; upon the other side, spirit and water of the same alcoholic strength. In one case the result appeared to be in favour of the *Arnica*; in a second in favour of the spirit; and in the remaining four no perceptible difference could be detected. When these results were compared with those obtained from other cases in which no treatment had been used, it was found that they were very similar to each other. I should mention, that after the application of the cupping glasses, from twelve to twenty-four hours were allowed to elapse before the use of the *Arnica* and spirit lotions, in order to permit of well-marked ecchymosis being formed. In all the cases the lotions were kept constantly upon the injured parts for two or three days.

In the second series of trials, six patients were again chosen: from three to four bruises were made on the chests of each; one was kept constantly wet with undiluted Tincture of *Arnica*, another with rectified spirit, and one or two left to themselves. In two of these cases the result was most decidedly in favour of the undiluted spirit; and in four the results were, as nearly as the eye could judge, equal. The bruises left to themselves ran through all the stages of coloration, and the ecchymoses extended far beyond the original circular mark produced by the cupping-glasses; whilst in those treated with the spirit or tincture all discoloration was checked, and the bruises faded rapidly.

In the third series of trials, four patients were selected; three or four bruises were made on their backs, and treated—some with spirit alone, some with Tincture of *Arnica*, but in all instances oil-silk was placed on the lint saturated with the lotions, in order to prevent evaporation. In three of these cases the results were decidedly in favour of the spirit, and in one in favour of the *Arnica*.

In comparing the trials made with the oil-silk coverings with those in which evaporation was allowed, no very perceptible difference was observed; by the first methods much trouble is spared, as the lotions need not be applied so frequently.

For carrying out these observations, attended, as they were, with considerable labour and expenditure of time, I am indebted to Mr. H. L. Kempthorne, the present House-Physician at King's College Hospital. I may remark, that some two years since I made a similar series of trials, and with the same general results.

What are we to deduce from these observations? Certainly thus much—namely, that the application of spirit to a bruise is of very decided advantage; and hence the use of the lily leaves and brandy,—so popular an application; but, at the same time, it would appear, from chemical experience, that the addition of *Arnica* to the spirit is unattended with appreciable good effects; at any rate, in bruises having the characters of those induced by cupping-glasses. Under these circumstances, surely the *onus probandi* rests with those who assert that, in sprains and more severe contusions, *Arnica* is an efficacious external remedy.

I should state, before concluding this subject, that the tincture made use of was prepared from the flowers of the *Arnica*, and the Pharmacopœia tincture is one of the roots; but we know for a certainty, that any active matter contained in the root is present in the flowers; and I believe it is this portion of the plant which has been most extensively made use of in the treatment of the cases to which I have alluded.

THE PERUVIAN COCOA (*Arythroxylon coca*).—The French authorities at Peru have had their attention directed to this substance with a view of naturalising it in the French colonies, as a plant likely to prove of great utility in the military and naval service. The leaves, when chewed in moderate quantity every three hours, are said to have the power of enabling a man to do without food during three days, while it develops his muscular powers and animal spirits, and protects him against the insalubrity of climate. Its stimulant principle is three times stronger than that of coffee, and four times than that of tea. Miners and travellers are said by its aid to be enabled to take journeys of four days' duration without any other support, and it is obvious that, supposing this property to really exist, the plant may prove invaluable in forced military marches. It is to be expected, however, that these remarkable results will not be exhibited to the same extent in the persons of Europeans. Still, Dr. Montegazzi, of Milan, affirms that, although of a feeble habit of body, he was enabled to go forty-eight hours without any other aliment, and suffered no inconvenience.

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

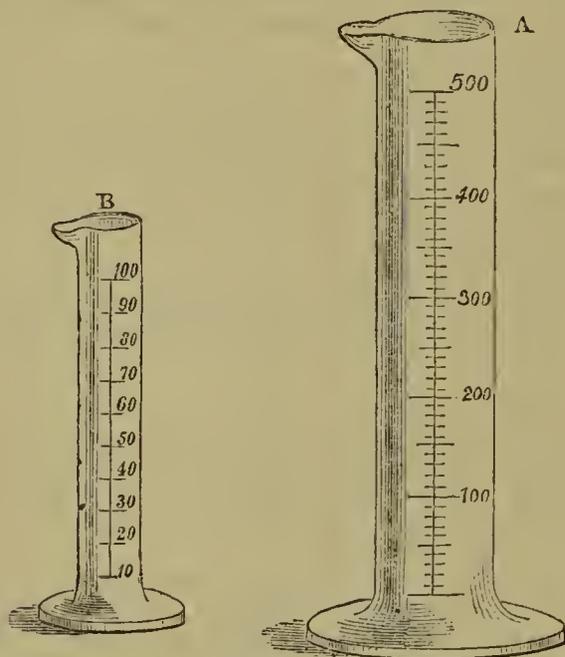

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University
College Hospital.

(Continued from page 86.)

In all cases where we desire to make a quantitative analysis of any of the urinary constituents, healthy or morbid, we must not only have a sample of the twenty-four hours urine, but at the same time be aware of the absolute quantity that has been passed. For this purpose the collected urine may be either carefully measured in an ordinary ounce measure, and the number of cubic centimetres calculated therefrom, (b) or still better, the urine may be measured in a glass jar, Fig. 4 (A), or Fig. 4 (B), graduated in cubic centimetres, and the quantity thus at once exactly ascertained.

FIG. 4.

As there are certain physiological as well as pathological conditions which influence the amount of water voided during the twenty-four hours, it is necessary that I should at once make you acquainted with the physiological conditions on which the quantity and quality of the urine depends. These are the drink, the kind of food, the state of the cutaneous and pulmonary exhalations, the length of time the urine is retained in the bladder, the condition of the stools, the sex, the age of the individual, and the influence of remedies.

1st. *As regards the Influence of the Drink on the Amount of Urine.*—The quantity of urine passed during twenty-four hours is generally, though not always, in excess of the fluid ingesta. Böcker found that when he drank 1260 c. c. (40½ oz.) his urine amounted to 2621 c. c. (84½ oz.), and when he drank 3360 (108½ oz.) it reached the large amount of 4994 c. c. (161 oz.) in the twenty-four hours. In each case you observe the quantity of water ejected is considerably above the amount of drink taken. Professor Vogel made some interesting observations on this point. He daily weighed the food and drink of a person during 189 days, and found, as a rule, that the kidneys gave off from $\frac{1}{20}$ to $\frac{1}{10}$ more water than the fluid drunk; (c) but it occasionally happened that only $\frac{1}{3}$ of the liquid taken was thrown off by the kidneys. The more active the skin, *ceteris paribus*, the less water is excreted by the kidneys. Whenever the quantity of drink is diminished, the amount of urine passed is correspondingly decreased. We next come to the important question of

2nd. *The Influence of Food upon the Amount of the Urine.*

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

(b) The French measures are, when once learned, so very much easier to calculate than the English, that they are now being generally adopted. 1 ounce = 31 cubic centimetres; 1 c. c. or 1 gramme = 15½ grains of distilled water.

(c) The largest quantity was passed after a cold bath, in consequence of the combined effects of absorption of water and suppressed transpiration.

—This is not so easily understood as the influence of drink; it is, however, quite as remarkable. Various experiments have been made on this point, but I think the most interesting are those of Lehmann. They were made during the summer months, when the amount of water is much less than in winter, and the effect of different kinds of food was as follows:—While taking 1233 grms. (39·79 oz.) of animal food (eggs), the daily amount of urine excreted was 1202·5 c. c. (38·79 oz.) of urine. When living on vegetable food, which was certainly taken in larger quantity than the animal food, he passed only 909 c. c. (29·3 oz.) of urine. Lastly, when a mixed diet was taken, the amount of the urine stood between the two cited examples. This influence of food over the daily quantity of urine seems to depend chiefly on one of its elements, namely, the nitrogen. (d)

For example, Bidder and Schmidt found that a cat fed on animal food passed 45½ e. e. (1·46 oz.) of urine for every pound of its weight. Valentin ascertained that a horse fed on corn and hay passed only 6 c. c. (0·19 oz.) of urine for every pound of its weight (e); and I ascertained that a man on a mixed diet passed, on an average, 14 c. c. (0·45 oz.) for every pound of his weight; so here we see that, even in different species of animals, the rule regarding the influence of the kind of food over the daily quantity of urine, still holds good. Another equally interesting fact is, that it is not only the quality of the food, but also the quantity, that exerts an influence over the amount of water excreted by the kidneys. This I can scarcely better exemplify than by quoting the following experiment of Bidder and Schmidt:—

A cat when fed upon

Grammes.	grains.	Per lb. of bodily weight.	
		c. c.	oz.
108	= 1674 flesh,	91	= 2·9 of urine.
75	= 1162 „ „	71	= 2·2 „
44	= 682 „ „	53	= 1·7 „

Here the animal had drink *ad libitum*; and when the water was removed, though still receiving 44 grammes (682 grains) of flesh, the urine diminished to 26 c. e. (0·83 oz.) in the twenty-four hours.

Many animals on a flesh diet do not drink any water at all, and yet continue to pass fluid in far greater quantity than they can possibly receive with the food. In the winter of 1859, I kept six dogs during three months solely on animal food (boiled tripe), during which time, notwithstanding that they received no water, the average quantity of urine daily passed by each was 186 c. e. (6 oz.) They never appeared to be thirsty, and when offered water refused to drink it. Here we have another illustration of the fact, that more liquid may be excreted by the kidneys than is taken into the stomach. From whence, then, does this liquid come? The dogs just spoken of were kept in a cool atmosphere, and there can be no doubt that the fluid was absorbed by the lungs. In a hot and dry atmosphere, the lungs would have exhaled instead of inhaled moisture, and the result would have been, that the animals would have required water.

3rd. *Influence of the Cutaneous and Pulmonary Exhalations.*—The more rapid the pulmonary and cutaneous exhalations, the less the amount of urine excreted. Hence, we invariably observe that, after much exercise, the urine is scanty, dark coloured, and of high specific gravity. It is sometimes, indeed, so concentrated, after profuse perspiration, that it irritates the urethra. This counterbalancing influence of skin, lungs, and kidneys is of the utmost value in the treatment of renal disease. In acute nephritis, for example, when the suppression of urine is the result of renal congestion, and the patient is too weak to stand active treatment, the simplest and safest way to relieve the kidneys is to induce free cutaneous perspiration. A hot air bath in such cases will often save the life of the patient. The perspiration, be it borne in mind, does not only carry off water, but many of the urinary solids, inorganic as well as organic. Normal sweat contains uric acid, urea, phosphates, and chlorides; and in disease, as I shall afterwards show you, even the insoluble oxalate of lime may be excreted by the perspiration in such quantity as to cover the skin with a white crystalline crust. It is, therefore, easy to understand how the cutaneous exhalation may replace for a time the renal function.

That the influence of the pulmonary exhalation is nearly of equal importance, is well illustrated by the effect of a

(d) 100 parts of animal food contain on an average 15 per cent. of nitrogen; whereas the same amount of vegetable food contains only from 2 to 5 per cent.

(e) *Vide* "Budge's Physiology," sixth edition, p. 214.

change of weather on the urinary excretion. All of you must have noticed that you pass much more urine in winter than in summer. In some cases, as much as double the amount of urine is voided in the cold as is passed in the hot season of the year, and this, to a certain extent, is independent of the cutaneous influence. The same remark is applicable to the kind of day: in a cold and damp day much more water is passed than in a warm and dry one, when the pulmonary exhalation is in full activity.

According to Wiederhold, (f) the lungs, like the kidneys and skin, excrete both organic and inorganic substances; for, on collecting a large quantity of expired air, and testing it with suitable reagents, he found that it contained chloride of sodium, uric acid, urate of soda, urea, and urate of ammonia.

4th. *The quantity of urine passed also depends, to a great extent, upon the time it is retained in the bladder*; for, during its sojourn there, its aqueous particles, and, according to Kaupp (g), even many of its solids, are continually being reabsorbed into the circulation. Any one can easily prove the first part of the proposition by making the following experiment upon himself. Let him resist a call to make water, and immediately proceed to take active exercise. In a very short time the inclination to micturate will pass away, and perhaps not return for an hour or two, when it will then be found that, instead of much, very little urine is voided, and that little is of a dark colour, and high specific gravity. In such a case, the water that was previously in the bladder must have been reabsorbed into the blood, and exhaled partly by the skin and partly by the lungs, and with it, no doubt, some of the volatile and more soluble of the urinary salts.

Since physiology has shown that the quantity of fluid present in the blood during health varies but slightly, and that this is in consequence of the renal secretion fluctuating in direct proportion to the increase or diminution of the pulmonary and cutaneous exhalations, the kidneys may, with perfect justice, be said to be the safety valves of the system, as they are assuredly the most important regulators of the amount of fluid present in the body.

5th. *Influence of the Stools*.—All that can be said on this point may be summed up in a few words. The greater the quantity of liquid passed from the bowels, the less is ejected from the bladder; so that, in cases of diarrhoea and dysentery, patients void much less urine than in a state of health.

6th. *Influence of Sex and Age*.—As a rule, males pass more urine than females, the proportion being about,—

Sex.	Urine in Twenty-four Hours.			
	c. c.	oz.	c. c.	oz.
Men . . .	1000 = 32	to 2000 = 64		
Women . . .	800 = 26	„ 1400 = 45		

The influence of age is equally remarkable. Children, for their size (as Scherer first observed), pass proportionally more water than adults. I estimated the quantity of urine passed during four days by a girl aged eighteen months, and her mother aged twenty-seven years, and the result was, that the child passed 13 c. c. (0.42 oz.) for every pound of her weight, and the mother only 8 c. c. (0.26 oz.) for every pound of hers.

As age advances, the absolute, as well as relative, proportion of urine again diminishes. The amount of water passed by the kidneys appears, therefore, to be proportional to the metamorphosis of the tissues.

7th. *The Influence of Disease and Remedies*.—Disease greatly affects the quantity of the urine: in some few it is increased, as, for example, in polydipsia and diabetes; in others, it is diminished, as in cholera, fevers, and inflammatory affections. Remedies have also a very powerful effect on the amount of water excreted by the kidneys. We all know how diuretic some medicines are—spiritus ætheris nitrici, for example—while others have just the contrary effect. Mineral substances—such as iron and copper for instance—lessen the quantity of the urine, while cantharides and arsenic almost totally arrest its secretion.

In a carefully-observed case, I saw the citrate of quinine and iron in the space of twelve days reduce the quantity of urine from 2325 c. c. (75 oz.) to 1860 c. c. (60 oz.) in twenty-four hours; the specific gravity (1017) remaining the same.

Again, I have noticed in the same individual the quantity of urine still further reduced by means of conia from 1860 c. c. (60 oz.) to 1240 c. c. (40 oz.) in the space of twenty-two days;

but in this case the specific gravity rose to 1027, as the quantity of water diminished.

In another case of confirmed polydipsia occurring in a man aged fifty-six, the one whose urine is now on the table, and which is still under observation, the urine has diminished 1240 c. c. (40 oz.) in the space of six days, during which time the patient has been taking the ammonio-citrate of iron in conjunction with quassia. The exact quantities of urine passed by this patient are,—

Date.	Quantity of Urine in Twenty-four Hours.		Specific gravity.

November 16 . . .	4960 =	160	1010
November 22 . . .	3720 =	120	1017

ORIGINAL COMMUNICATIONS.

ON RUPTURE.

By JOHN WOOD, F.R.C.S.,

Demonstrator of Anatomy, King's College, London, and Assistant-Surgeon to the Hospital.

No. II.

ALTHOUGH this is not the place for a description of the anatomy of hernia, yet, for the purpose of illustration, it is necessary to call attention to a few points in that of inguinal hernia, in order to point out its practical bearings.

The canal through which this rupture descends is formed between the muscular, tendinous, and fascial layers which retain the viscera at the groin. These are bound together and held firm by the important Poupart's ligament, a strong band of tendinous fibres reaching from the spine of the ilium to that of the pubis. In the male the distance it stretches over is from three to three and a-half inches, in the female, three and a-half to four and a-half inches. This structure is of equal importance to inguinal and crural ruptures, the former converging above, and the latter below it. Above, it is attached, in the male, to three muscles, to a strong aponeurosis covering them in front, and to a firm and close fascia clothing them behind. The muscles are the transversalis—the deepest, attached to the outer third of the ligament; the internal oblique—arising from the outer two-thirds or more; and the cremaster—arising from the inner half or third of the ligament. The aponeurosis is that of the external oblique, with which Poupart's ligament is so closely blended as to be identified with it. It is arranged in parallel fibres of great strength, which pass obliquely downwards, inwards, and forwards in a curve to the pubis and linea alba. These fibres are directed nearer to the perpendicular than those of Poupart's ligament. At the inner attachment of the latter, just above the pubic spine, they separate into an oblique, elongated, triangular opening, the superficial abdominal ring (Fig. 1, a) having a base of about half an inch at the pubis, the apex pointing upwards and outwards to the short ribs, and sides varying in length from an inch to an inch and a-half. These are the pillars of the ring. The inner or upper is broad and band-like, and attached below in an oblique line in front of the pubic symphysis, half an inch below its upper edge. The outer or lower is triangular, with its broadest part above, and its point below, where it is implanted upon the pubic spine and blended with Poupart's ligament. Passing from one pillar to the other, and converting the ring into an oval opening, is a band of curved fibres (arciform) connected by a fascia (intercolumnar). This band is much stronger in some individuals than in others, and may be traced from the iliac spine or outer end of Poupart's ligament to the linea alba, spreading out in curves with the convexity downwards. Upon the firmness, closeness, and resistance of this connexion of the two sides of the ring depends much of the resistance offered to the passage of a rupture through the ring.

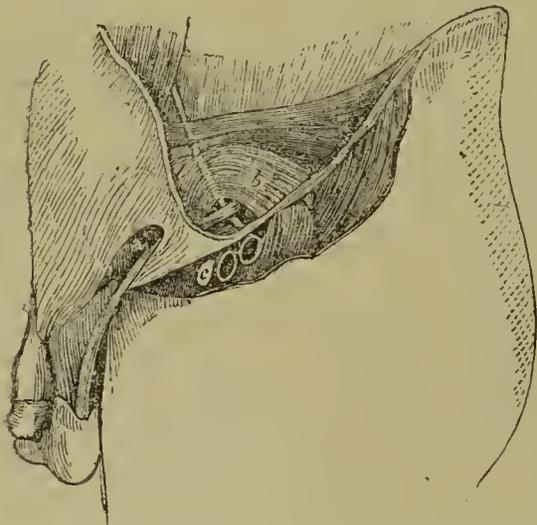

The spermatic cord and its cremaster muscle when emerging through the ring lie upon and groove the outer pillar, to the outside of the pubic spine, and are invested by a prolongation of the intercolumnar fascia, from the edges of the ring (external spermatic). With very few exceptions all herniæ of the inguinal variety pass through the superficial ring. These exceptions are in cases where the resistance of the intercolumnar fascia at the ring is such, that the fibres composing either pillar are more easily split by the protrusion. Such ruptures usually are deficient in a covering corresponding to the intercolumnar. They are most frequently seen in females..

(f) *Deutsche Klinik*, No. 18.

(g) Kaupp found that when the urine is retained in the bladder the water is taken up most readily, then the phosphates, the chlorides, the sulphates, and, lastly, the urea.—(Parks, p. 108.)

The firm fascia which covers the deep surface of the transversalis muscles (*fascia transversalis*) is connected firmly with Poupart's ligament, under which it sends a portion of the sheath of the femoral vessels. It intervenes between the muscles and the peritoneal structures. It is much the strongest in the groin. About half an inch above, and a little to the inside of the centre of Poupart's ligament, midway between the spines of the pubis and ilium, is an opening in this fascia for the passage of the spermatic cord in the male, and round ligament in the female (the deep or internal abdominal ring). Its distance from the superficial ring is about an inch and a-half in the male, and two inches or more in the female. It is larger in the former by about one half, varies much in size, but is usually an oval opening about three-quarters of an inch in its vertical, and half an inch in its transverse diameter. Its inner margin is falciform, being usually more distinct and pronounced than the outer, and when thickened by the friction of a hernia, it forms the most common seat of strangulation, and is apt to cause ulceration of the gut by its pressure. From the margins of the deep ring is given off a thin, funnel-shaped fascia over the cord (the infundibuliform, or *fascia spermatica interna*) of no practical importance. Lying between the *fascia transversalis*, from one-half to three-quarters of an inch from the inner margins of the deep ring, among the fatty fascia which immediately covers the peritoneum, are the deep epigastric vessels arising from the external iliac below and behind Poupart's ligament, and directed toward the umbilicus upwards and inwards. The artery thus lies to the inner side of the cord, or a rupture passing through the deep ring, and crosses its posterior face. On account of this relation, and of the size and importance of this artery in reference to an operation for a strangulated hernia, ruptures which pass through the deep ring have been called external. This variety, more generally known as oblique inguinal hernia, is by far the most common. It traverses both the abdominal rings and the inguinal canal in its whole length. The deep surface of the deep ring is covered by the peritoneum and its adipose layer. Both these are connected by a firm band of tissue to the margins of the ring, the remains of the serous tube forming the *tunica vaginalis*. The superficial surface is covered and protected by the lower fibres of the internal oblique muscle.—(See Fig. 1, *b*.)

FIG. 1.

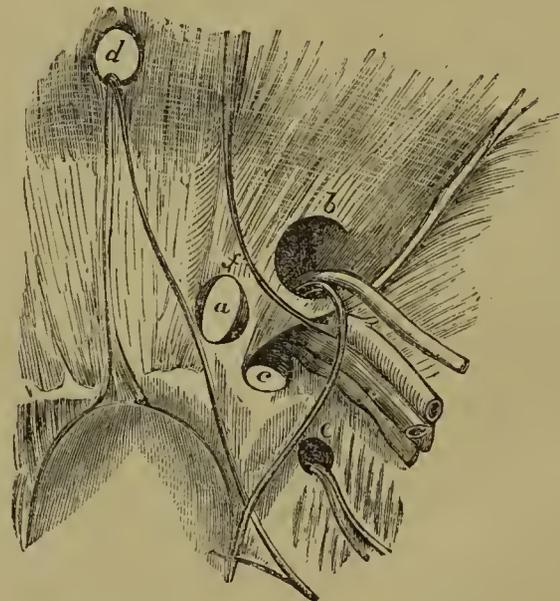

This muscle, passing obliquely over the inguinal canal by a distinct arched border, is inserted into the front surface of the transversalis tendon, at the inner side of the deep ring. This important conjoined tendon, placed behind the cord, and forming the most resisting part of the deep wall of the canal, is implanted upon the pubic crest and spine, and, passing behind the outer pillar of the superficial ring, becomes blended with the deeper fibres of Poupart's ligament, and inserted with them for an inch and a-half, upon the pectineal line of the pubis—forming the curved fibres which bound the inner side of the crural ring (Gimbernat's ligament). These are the most common seat of strangulation in femoral rupture. The conjoined tendon is blended externally with the *fascia transversalis* in front of the epigastric vessels, and internally with the aponeurosis of the external oblique, to form the front covering of the rectus and pyramidalis muscles. It varies much in power of resistance. In some persons it is composed of oblique scattered fibres attached to the crest and spine of the pubis only, and only distinguished from the *fascia transversalis* by a few separated tendinous fibres. In

others it is dense and strong, presenting, when traction is made, a distinct border close up to the epigastric artery, or even to the deep ring. In many, especially in females, it is strengthened by the addition of a triangular layer of fibres passing upwards and inwards to the *linea alba*, and continuous by decussation with the external oblique aponeurosis of the opposite side. By this means the weak part at the outer border of the rectus, directly opposite to the superficial ring, is further supported (see Fig. 1, *a*). The conjoined tendon can always be raised into salient relief by passing the finger along the canal behind the internal oblique muscle, and making forward traction. The cremaster muscle is a layer of scattered and looped fibres, held together by a thin fascia derived from the internal oblique and transversalis muscles. They arise from the inner third or more of Poupart's ligament, connected both with the internal oblique and transversalis, and are inserted in three sets. The upper form complete loops over the cord, and passing through the superficial ring and back again, to be implanted upon the surface of the conjoined tendon. Others are lost in their containing fascia about the angle of the pubis. The lowest and outermost are attached to and lost upon the *tunica vaginalis testis*. They are of little importance except as a guide to the operator in strangulated oblique hernia, their muscular fibres indicating that he is close to the sac of the rupture, from which they are separated only by the thin infundibuliform and subperitoneal fasciæ. Occasionally they are said to cover a direct hernia in those cases which emerge close to the epigastric artery, with the conjoined tendon and its attached cremasteric fibres placed entirely to the inner side of the neck of the sac. The inguinal canal thus constituted is a passage oblique in three senses—from without inwards, from above downwards, and from behind forwards. The spermatic cord transverses it also obliquely, being placed further from Poupart's ligament at the deep than at the superficial ring. In Fig. 1, *b* is placed upon the site of the deep ring covered by the lower fibres of the internal oblique, and *a* upon the superficial ring, with the cord lying upon its outer pillar external to the pubic spine. Behind the cord is seen the conjoined tendon and triangular aponeurosis, epigastric artery, and *fascia transversalis*; in front of it, the outer pillar of the superficial ring and lower fibres of the internal oblique; above, the arched border of this muscle and the transversalis; and below, Poupart's ligament crossing the external iliac vessels, the crural ring (*e*), and the *psaos* and *iliacus* muscles, seen in section.

Now, an oblique inguinal hernia, following closely the course of the cord and lying in front of and above it, is invested with all its coverings in order. Of these, the cremasteric fibres are the most conspicuous, and occupy an intermediate position. The epigastric vessels cross behind it, and are placed internal to its neck. Fig. 2 represents

FIG. 2.

the relative positions of the deeper openings of oblique (*b*) and direct (*a*) inguinal, crural (*e*), umbilical (*d*), and obturator (*e*) hernia. Direct inguinal rupture makes its way through the conjoined tendon (*f*), at a point directly opposite to the superficial ring (seen through the opening at *a*). It is consequently inside and below the epigastric artery, and just above the pubic spine. The neck of the sac is usually placed between the epigastric and obliterated hypogastric arteries at the

border of the rectus muscle (triangle of Hesselbach); but sometimes it is found inside the obliterated hypogastric, carrying the loose superior false ligament of the bladder before it as its sac. It generally pushes before its sac a pouch of the conjoined tendon, but often splits its fibres, and is then covered only by the fascia transversalis, the intercolumnar, and the tegumentary tissues. It may be distinguished by the finger from oblique rupture by the absence of the sharp edge of the conjoined tendon and epigastric vessels at its inner side, which is bounded only by the thick, smooth border of the rectus muscle (seen in the figure inside *f*). If the finger cannot be introduced into the opening, its more direct cropping out of the superficial ring, close above the pubis, without any appearance of following the oblique course of the spermatic canal, will usually distinguish it. But in very large cases of the oblique variety the two rings may be so much approximated, the epigastric vessels dragged inward, and the conjoined tendon obliterated in the coverings of the sac, that distinction becomes difficult, if not impossible, without dissection. In such cases, when relieving strangulation by operation, the epigastric artery may be avoided by cutting directly upwards. It will now be seen that the influence of Poupart's ligament on all these structures is very great. As relaxation of this ligament predisposes to both inguinal and crural rupture, so it facilitates much the reduction of either kind of hernia when strangulated. To relax it, the knees should be drawn together and bent upwards towards the abdomen. Also, no truss pressure will be effective unless it includes this structure in its influence. It will be seen, moreover, that the inguinal canal is a valvular passage, of which the most important part is the hinder wall of conjoined tendon and fascia, which normally pressed toward the front wall by the viscera, tends to keep the passage closed. Failure of this valve action at the deep opening brings about oblique rupture; weakness or injury of its hinder wall produces direct hernia. When a rupture is present, to close this valve permanently is to produce a radical cure; to close it temporarily is the end of effective truss pressure. In another paper we shall examine how this may be done, and how failure or an increase of the size of the rupture commonly results from inattention to the mechanism of these parts.

CASE OF

CEREBRAL DISEASE, APPARENTLY
TUBERCULAR MENINGITIS—RECOVERY.

By ARTHUR LEARED, M.D., M.R.I.A.,
Physician to the Great Northern Hospital.

IN April, 1862, I was called to see, in consultation with Mr. Wright, of N. Brixton, a young gentleman who was suffering from an affection of the brain. He was a delicate boy, 14 years of age, and had been long subject to glandular swellings in the neck. He lost a sister at the age of 8 years, from tubercular meningitis, according to the late Dr. Golding Bird and Mr. Wright, who attended her.

It was observed for some weeks that the boy's memory was deficient; he said himself that his thoughts came slowly, so that it cost an effort to reply to a question, and he imagined that "the ciphering at school had tired his head."

On April 9, six days before our visit, he returned from school complaining of a good deal of fatigue.

At one o'clock on the following morning, he was seized with a convulsive fit. During the day, Mr. Wright gave him aperient medicines, and he was so far recovered by the second day afterwards (12th), that he went to school for a short time, but sat with the books before him, unable to learn his lessons. That evening, about six o'clock, he had another bad fit.

Throughout the next day (13th) he continued poorly, and about mid-day was very faint, and had a shivering attack, but no fit.

On the 14th he was confined to bed, and vomited, and at six o'clock he had a bad convulsive fit for the third time. His mother described these attacks as differing from epilepsy in the movements, being less violent, and there being no frothing at the mouth.

I saw him for the first time on the evening of the 15th. There had been no convulsions during the day, and he was lying in bed apparently collected in mind, but said it was a trouble to him to reply to us. He complained of vertical headache, and the scalp over the vertex was increased in heat. Elsewhere the skin was dry, but the temperature was not high.

Eyes natural, and pulse undisturbed. The tongue had a white, creamy coating. I agreed with Mr. Wright in considering the case one of tubercular meningitis.

16th.—Had a convulsive fit at 6 p.m., and partial convulsive movements for hours.

17th.—Another convulsive attack at one o'clock this morning. We found him, at our visit (3 p.m.), in a comatose state, so that we could not rouse him; the thumb of the left hand was contracted across its palm. He recovered from this after a short time, and the thumb now relaxed. He replied correctly to questions, and said he was free from headache; pupils movable; tongue much coated; pulse 72 in the minute, but much increased by even slight movements of the body. I suggested to-day, that, in addition to the cold lotions to the forehead, his head should be shaved, and the tinct. iod. comp. should be freely applied to the scalp.

18th.—At times comatose, and squinting occasionally observed.

19th.—Several attacks, in which face was convulsed about a minute each time. Skin moist; pulse varying from 56 to 120 in the minute, within a few minutes, independently of exertion. Tongue very foul. The internal treatment has consisted up to this in attention to nutrition, to the bowels, and in giving saline diaphoretics. Iodide of potassium, gr. v., every six hours, was now prescribed,—the scalp to be painted as often as could be borne.

21st.—No convulsive movements observed yesterday or to-day; but on several occasions on both days the eyes have become fixed, pupils dilated, and he has been apparently unconscious. This state lasts only a few minutes. No sleep last night; says his head is free from pain or uneasiness. Bleeding from the nose occurred twice to-day. Iod. pot., gr. v., 4tis hōris.

23rd.—Two or three slight fits of unconsciousness since; in other respects doing well.

25th.—A slight fit of unconsciousness yesterday; none to-day. Begins to feel appetite. Adde mist. liq. chincon., ℥xv.; ol. morrhuae, ʒj., bis in die.

28th.—Going on well; no fits since; much reduced in flesh; discharge from nose, evidently the effect of iod. pot. Iod. pot. to be reduced to gr. ijss. pro dosi.

May 1.—No bad symptom remaining. Iod. pot. gr. ijss. 6tis hōris. The application of iodine to head to be continued as before.

The iodine treatment was continued some time. The patient gradually recovered strength, and is at the present time, December, 1863, in the enjoyment of excellent health. His intellectual faculties are perfect, and his proficiency at school is quite satisfactory.

Remarks.—Practical men will admit the diagnosis of tubercular meningitis to have been fully warranted by the symptoms and history of the case. Fortunately, the opportunity almost invariably afforded of confirming the diagnosis after the death of the patient was wanting. The patient's sister had been treated with mercury, and leeches to the shaven head, as has been said, with a fatal result. Having some time previously treated a case of hydrocephalous successfully with iodine, it seemed to me legitimate to give the same remedy a fair trial in the present case, and in this Mr. Wright concurred. We also took care to support the patient's strength by freshly prepared extract of beef and other concentrated nutriment, and wine was cautiously given when the vital powers were flagging. Recovery, from a condition that seemed hopeless, ensued, and it is a fair inference that the iodine was the efficient agent in effecting this. There are good reasons for believing that tubercular exudation is, in many cases, thrown out within a very short period of time, and that the absorbent action of iodine may, therefore, remove the deposit while yet in a semi-fluid or nascent condition. Tubercular disease of the meninges is very constantly, but not invariably, associated with tubercles in the lungs; and the present case appears an exception, as the boy is quite free from phthisical symptoms. The case is encouraging, as showing that we ought not to despair of recovery even when the evidence from vital symptoms of tubercular meningitis is very strong.

12, Old Burlington-street.

A SERVANT girl, aged 19, lately in service in Hyde-park-gardens, has died, after a four months' illness, occasioned by a fright; a nursery governess having thoughtlessly dressed herself up as a ghost, and sprung out upon her on the stairs.—*The Guardian*, January 27.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

BIRMINGHAM GENERAL DISPENSARY.

CASES OF DIPHThERICAL PARALYSIS.

(Under the care of, and reported by, Dr. WADE.)

Case 1.—Diphtheria—Imperfect Convalescence, interrupted by Kidney Disorder, followed by Paralysis—Cure.

C. P., aged 24, married, was sent to me, by a Surgeon, as a case of stricture of the œsophagus, on March 1, 1860. Has had four children; is still suckling the youngest, aged 9 months. Has had good health, and was as well as usual till twelve weeks ago. Was seized suddenly one Sunday night with shivering and a "feeling of weakness all over," and vomiting; the next morning found slight but distinct sore throat and pain in swallowing, with hot skin, much thirst, and headache. Had no advice till the following Friday, by which time the febrile symptoms had gone, but the throat was worse. On the third day of her illness the right side of the neck swelled much after friction with harts-horn and oil; the left side was also swelled, but not so much. In two weeks she got better, but still kept her bed; her voice was not nasal, nor did food return through her nose, and the urine was copious; the throat never got quite well. By the end of the third week from the time she first had advice, she was able to get about and do her washing, etc., but never felt strong. This went on for two weeks more, when she was again seized with fever, but less severe than at first, with great diminution in the quantity of urine, frequent and painful micturition, and pain across the loins; no dropsy; throat got no worse. The same Surgeon attended her again for a fortnight, and she was better in all respects for the following two weeks. She then began to be aware of a difficulty in swallowing, but without any soreness in the throat; her voice became nasal, and food used to return through her nose; a feeling of obstruction in the œsophagus at its top part, and indistinctness of vision. All these symptoms have been getting worse up to the time of her applying to me. She consulted another Surgeon, who sent her to me. She has all the symptoms above detailed, and cannot see to thread a darning-needle; has flashes of light, but no pain, in the eyeball; no photophobia; pupils very large; thinks she can see rather better towards night, but the quantity of light has no effect upon vision. She has also numbness in the hands, legs, and feet; arms and legs feeble, and gait tottering; all food returns through the nose, unless she "takes time" to swallow it; can manage solid food best; coughs a good deal, but there are no abnormal physical signs in the chest; never had any discharge from nose. Throat rather congested; tonsils not enlarged; velum palati and pharynx insensible. Urine: lithic acid cylinders, lithate of ammonia; bladder epithelium; quantity obtained not sufficient to take specific gravity; no albumen; quantity stated to be nearly average. Prolabia good colour; face dingy and pale. Her husband is a sweep, but she says that a brownish hue on the face has only been observable since she has "been so very ill." Bowels rather confined; had two blisters on the throat, three weeks ago, without benefit. No one else in the house has had sore throat; but one child had scarlatina a year ago, and his throat has been sore at times since. There seems to be a little tenderness on each side of the thyroid cartilage. \mathcal{R} . Liq. hydr. bichlorid., \mathfrak{z} iv.; decoct. cinchon., \mathfrak{z} vijss.; \mathfrak{z} j. ter. die. Pil. colo. c. hyos. (\bar{a} a p. æ.), gr. x., pro re nata.

5th.—Scarcely speaks at all through her nose; swallows solids much better, fluids no better; eyesight a little stronger; fauces less congested; urine reported clearer; hands and feet no better.

8th.—Throat has felt a little sore; no increased difficulty in swallowing.

12th.—Sight much better; voice ditto; swallowing ditto; the numbness continues; feels rather more power in the hands; complains of constant pricking pains darting through her fingers and toes; a little, also, but much less in arms and legs; these latter were much cramped three days ago.

19th.—Much better in nearly all respects; eyesight quite well; pupils not so large as at first note; voice very nearly

well; swallowing still imperfect; pricking no better, but has more use in hands, feet, etc.

26th.—Eyes keep well; swallowing much better.

April 2.—Pains in each wrist, especially right; fingers still weak; swallowing much better; occasional dimness of vision. \mathcal{R} . Potass. iod., \mathfrak{z} ij.; aquæ, \mathfrak{z} vij.; \mathfrak{z} j. ter. die.

9th.—Not so well with this medicine as with the former one, which repeat.

23rd.—Occasional numbness of hands and cramping of toes, but is better.

May 10.—"Is as well as ever she was in her life," except occasional cramps and numbness of toes. She ceased to attend the Dispensary. I saw her about a year ago, and found that the cure was permanent.

The history of this patient before she came under my notice and the symptoms which I myself observed, taken in conjunction with the ascertained phenomena of diphtherical paralysis, leave no reasonable ground for disputing that this is an example of that form of disease.

Case 2.—Diphtheria, untreated—Imperfect Convalescence—Recurrent Slight Exudation—Paralysis—Intercurrent Kidney Disorder, with Albuminous Urine—Cerebral Symptoms—Cure.

Elizabeth S., aged 11, admitted March 19, 1858. Six weeks ago began to complain of painful lumps on each side of the neck, and, after the first few days, some pain in swallowing. Her mother rubbed the lumps with goose oil, and they disappeared. The mother states that she had rigors two or three days after the neck began to swell, and there was fever from the first. On the second day after her neck began to swell, her breath stank horribly. No delirium was noticed. The illness commenced with vomiting, and she was then purged with senna tea. No eruption was ever noticed. In a week or nine days from commencement of illness, the fever disappeared after a perspiration, and her breath got sweet; the lumps also vanished, but she continued to look pale and ill, and did not gain strength. Her voice became nasal before the fever went away, but her mother does not exactly know the time. She continued to get feebler, and the voice to get worse. Dysphagia came on; no fever. I saw her on the 19th; she had not had any Medical advice previously. No eruption had ever been noticed. There was no exudation on the throat; it was not unnaturally red; the uvula seemed long and pendulous; the soft palate seemed to hang lower down than usual; countenance depressed, looks pale and feeble; voice very nasal; great difficulty, but not pain, in swallowing; appetite indifferent; functions generally pretty well performed. Urine boiled in a spoon did not appear to contain albumen; it was clear and pale. I ordered her to come to the Dispensary on the 22nd.

On the 20th her mother got frightened, and took her to Mr. Robins, who sent her to me. Throat a little redder than before; one spot of exudation on the right tonsil, apparently projecting from a follicle. \mathcal{R} . Syr. ferri iodid., \mathfrak{z} iv.; acid. citric., gr. x.; inf. quassia, \mathfrak{z} vijss.; m. ft. mist., \mathfrak{z} j., ter. die. sumend.

25th.—Not so well; is heavy, but not actually drowsy. Urine much less copious. I obtained only about two drachms for examination, and found it highly albuminous. Omit mist. ferri iodid. \mathcal{R} . Potass. iod., \mathfrak{z} j.; potass. acetat., \mathfrak{z} ij.; syrup., \mathfrak{z} ss.; aquæ, \mathfrak{z} vijss.; m. ft. mist., \mathfrak{z} j., 4tis hōris sumend., and to take freely of fluids.

27th.—Had an attack of delirium about dinner-time yesterday, which lasted for half-an-hour. Is better to-day. Urine not albuminous in a spoon. I could not ascertain if it was more copious: it is pale and pretty clear. I learn to-day, for the first time, that her eyesight is hazy, indistinct, confused, and has been so for a month. No diplopia, photophobia, dilatation of pupils, or squinting. Bowels confined. Has taken pil. colo. et hyosc. since the 25th without result. To have some senna tea. Has taken the medicine three times a-day only.

29th.—Reported better. Has drunk more freely and taken the medicine more regularly, and made a larger quantity of water,—pale, pretty clear, specific gravity 1010; no tube casts or epithelium; a small quantity of albumen detected by boiling in a test-tube. No return of delirium; bowels regular; appetite improved.

April 1.—Better. Urine more copious; specific gravity, 1015. Swallows better; voice less nasal. Has not lain in bed any of the time. Pergat.

3rd.—Was drowsy yesterday, but to-day is better. Urine reported about Ojss. daily. This morning on each tonsil are

several spots, apparently of lymph exuded from follicles; they do not spread over adjacent mucous membrane. Voice and swallowing a little better.

5th.—Reported about the same.

7th.—Throat less red, and scarce any exudation; no more drowsiness.

8th.—Urine more copious, 1010; no albumen; slightly alkaline.

12th.—Reported better. A small quantity of urine brought down to the Dispensary was turbid, but appeared free from albumen.

14th.—Continues to improve; looks bright, and good colour; eyes and voice better; and can swallow pretty well.

15th.—Urine free from albumen.

May 10.—Sight, voice, appetite, and swallowing perfectly normal; complains of weakness, and looks pale. Urine copious, but none brought for examination. R. Tr. ferri mur., ʒj.; inf. quassia, ʒiv.; m. ft. haust., ʒss., ter. die. sumend. Tonsils still a little enlarged, but no exudation.

20th.—Voice appeared to me a little nasal, but she and her mother say that it is normal; and she says she is well in all respects, but does not feel very strong. She looks very well.

I saw her about twelve months after, and she had continued well; her voice was a little nasal, but this, I fancy, is natural to her.

Some other bad cases of diphtheria occurred in this house afterwards.

HOSPITAL FOR EPILEPSY AND PARALYSIS.

CLINICAL REMARKS ON HEMIPLEGIA, WITH LOSS OF SPEECH—ITS ASSOCIATION WITH VALVULAR DISEASE OF THE HEART.

(Cases under the care of Dr. HUGHLINGS JACKSON.)

At a recent visit to the Hospital for Epilepsy and Paralysis, Dr. Hughlings Jackson remarked that in nearly all the cases of loss of speech that he had seen at that Hospital there had been hemiplegia. At first he was inclined to adopt the theory brought forward by Schröder van der Kolk, that such a defect depended on disease of the corpora olivaria. But then, as was frequently pointed out at this Hospital by Dr. Brown-Séquard, the defect is not one of talking, but rather of language. Besides, Mr. Lockhart Clarke differs altogether from Schröder van der Kolk. He thinks that the corpora olivaria form a sort of internuncial nervous system to the various ganglia of the medulla oblongata. (a) In some extreme cases Dr. Brown-Séquard used to point out that the patient had lost altogether the power of expression, not by oral language only, but even by making signs. One patient who was admitted into the Hospital, during the whole of his stay could only say "no" and "yes," and these words at the wrong time. He said "no" when he meant "yes," and "yes" when he meant "no." He could write, and used to copy paragraphs from the newspapers, but he never answered a question in writing. This is the worst case Dr. Hughlings Jackson had seen; but there was every gradation, down to the simplest mistake in words which have some idea in common, as calling an "orange" an "onion," or "cough medicine" a "worm powder."

In most cases of hemiplegia, there is some defect of talking; but this is generally from defective power in moving the tongue and lips, and is as different from loss of speech as want of power to sing from disease of the vocal cords, is from want of what is conventionally called "ear for music." Loss of speech cannot be too carefully distinguished from loss of power of articulation. To say that a person speaks ill because he cannot articulate well, is correct conventionally, but scientifically it is as inexact as the excuse a person once gave for errors in spelling—viz., that the pen he wrote with was a bad one. But it must be remarked, that when a patient has once lost the faculty of speech, on recovery he talks like a child. Then his articulation is imperfect as well as his words erroneous. And, of course, in all the cases the subjects of these remarks, so long as the hemiplegia lasts, there is some defect of articulation superadded on the defect of speech. But the defect of articulation in ordinary cases of hemiplegia soon passes off.

Recently it occurred to him, that in all the cases of this kind that he had seen (seven), there was valvular disease of the

(a) "I have never been able to trace any immediate connexion between the cells of the lamina and the roots of the nerves—not even of the hypoglossal nerves which pass through it."—Lockhart Clarke, *Phil. Trans.*, 1858.

heart; but he has since found three exceptions. Of course, there is no physiological connection betwixt disease of the aortic or mitral valves and paralysis on *one* side of the body. The clinical history of a disease is not its natural history. But the coincidence is, probably, to be explained in this way,—that, as is well known, vegetations may be detached from the diseased valves, and plug up the middle (and anterior?) cerebral arteries. The heart affection in two cases only has been the subject of previous treatment, as vegetations may cause a loud bruit, and but slight obstruction. It is, then, not so much a question as to the fitting of the valves as to the vegetations on them. Indeed, there may be vegetations and no bruit; and in this way, perhaps, some of the apparently exceptional cases may be explained. In short, the connexion is a mechanical one. The paralysis does not occur because the patient has heart disease, but because a vegetation is accidentally detached from one of its valves. This middle cerebral artery supplies the corpus striatum (the upper part of the motor tract, disease of which so often produces hemiplegia), and also part of the hemisphere. We have, then, paralysis of motion, as evidenced by the hemiplegia, and defect of mind, as shown by loss of speech. Many physiologists and Physicians have considered the anterior lobes to be the part of the brain in which resides the faculty of speech, and Dr. Kirkes long ago pointed out that in heart disease hemiplegia from plugging of the middle cerebral artery was not uncommon. The little novelty, then, in these remarks is merely the clinical illustration of the coincidence of the two defects from obstruction to the circulation to the hemisphere and the motor tract. Now, whether this explanation be correct or not, Dr. Hughlings Jackson insists on the coarse fact, that hemiplegia, with loss of the faculty of speech, often occurs in patients who have valvular disease of the heart. The fact that many of these patients are young, and, except for the diseased valves, in excellent health, or rather, having healthy tissues, is in favour of embolism; and the fact, too, that the hemiplegia is of the same kind as that so often found after apoplexy of the corpus striatum, seems to confirm the view that it depends on plugging of the middle cerebral artery, which, by branches near its origin, supplies this part of the brain, as well as part of the anterior and middle lobes by its continued trunk. But he draws attention to the fact that his cases are chronic, and that he has seen very little of recent cases, so that his experience may be one-sided.

It had been objected that the word "speech" did not accurately express the defect; but, perhaps, it might be allowed to pass, as the object Dr. Jackson had then in view was to discuss the clinical relationship of the symptoms, and not their psychological bearings. Indeed, neither the word "speech" nor the word "language" would do for all the cases. Talking may be divided into three things—articulation (larynx, voice, tongue, lips, etc.) for sounds, speech for words, language for the expression of ideas. The mind, then, forms the ideas, the memory furnishes the words, and the tongue, lips, etc., turn them out as certain recognised sounds. To illustrate, a man born deaf cannot talk, as he cannot learn to articulate sounds. A person who has lost memory talks badly, as he has forgotten the words with which he was wont to dress his ideas; and the person who lacks language talks badly, or does not talk at all, because he has not mind enough to form ideas to express. When the defect begins in language, it would imply, Dr. Jackson thinks, general loss of power of mind, so that a person cannot express himself either by talking, writing, or by signs. When in speech he forms ideas, but his memory cannot find the words for them, and he returns to the primeval language of signs; when his tongue, larynx, etc., are paralysed, he cannot talk well, as the apparatus is defective—in short, defect of ideas, defect of words, defect of sounds. In thus entering minutely into these differences, Dr. Jackson said he did not attempt to claim any great amount of precision. The subject was to him far too obscure to induce him to dogmatise.

HOSPITAL NOTES.

TREATMENT OF DYSENTERY BY LARGE DOSES OF IPECACUANHA.

This plan of treatment was introduced, or brought prominently forward, by Dr. Docker, of Mauritius. The use of ipecacuanha in dysentery is by no means novel; but the employment of such large doses, and in the method here described, is (Dr. Hillier said) of comparatively recent date.

The plan is to give a drachm of tincture of opium, to apply

a mustard plaster over the epigastrium, and, in twenty minutes, to give a drachm or a drachm and a-half of powdered ipecacuanha in a very small quantity of peppermint water, or simple water. Sometimes half an ounce or an ounce of castor oil is given, with half a drachm of laudanum, before beginning the special treatment; this is, however, usually found to be unnecessary. Vomiting is not often induced, and the cure is often immediate. A patient may be passing every half hour or oftener, blood and mucus, or bloody serum with pus. They cease at once for about twenty-four hours; he then has a natural stool, and is well. The diet is farinaceous.

In May, 1862, Mr. Baylis, of Ceylon, wrote to Dr. Hillier that he had treated fifty or sixty cases in this way, and only lost three, who were in articulo mortis when they came under his care. He writes that he has continued the plan of treatment up to the present time, and expresses himself equally satisfied with it. He gives the following as an illustration of the results of this treatment:—

“A highly phthisical young gentleman, in whose lungs softening had commenced, came out here for his health. I told him the climate would not suit him. However, he disregarded my advice, and I was soon called to see him. I found him in bed, unable to speak above a whisper; pulse very weak, about 100; face flushed; tongue thickly coated with yellow fur; tenderness and pain in abdomen, especially in the left iliac region. He had been suffering from diarrhoea for four days. During that day and previous night he had passed upwards of sixty motions; they were at first copiously feculent, latterly, almost pure blood, with a little slime. He had been feeding most imprudently. I gave him at once a drachm of laudanum, and put a mustard plaster on his epigastrium. In twenty minutes I gave a drachm of ipecacuanha powder in a wineglass of water. He did not vomit. Those who saw him at this time thought he could not live twenty-four hours. Next morning he was much the same; had fainted once or twice on going to stool, but had only passed seven motions, composed of blood and stuff like the washings of meat. He now had much pain in the stomach and bowels. I ordered an opiate injection three times a-day, and at 6 p.m. put on a blister and repeated the laudanum, followed by the ipecacuanha, as on the previous day. Next day he passed only two motions; there was just a trace of blood, but they were largely feculent. The morning after, the motions were solid and natural, and he rapidly recovered without more medicine. His diet was sago and arrowroot.”

Dr. Hillier has had the opportunity of trying this mode of treatment at the Children's Hospital. It was in the case of a child, aged 4 years, suffering from subacute dysentery contracted in Barbadoes. He gave five minims of laudanum, and, in half an hour, fifteen grains of powdered ipecacuanha. There was no nausea or any unpleasant symptom caused by the medicine; and although the patient had previously passed five or six motions, containing much blood and mucus, every twenty-four hours, there was no evacuation for thirty-six hours. He then passed an ordinary feculent motion, and from that time he continued quite well. It is stated that ipecacuanha has the effect of rapidly healing large dysenteric ulcers. Dr. Hillier suggested that it might be worth while to try it in the diarrhoea dependent on tubercular ulceration, or in typhoid fever. The opium is supposed to act mainly in preventing vomiting, but it may, with ipecacuanha, have a more specific action on the disease.

BROMIDE OF AMMONIUM IN WHOOPING-COUGH.

This new therapeutical agent, which was some little time ago found by Dr. Gibb to be an anæsthetic to the larynx, is now being turned to further practical account in the treatment of whooping-cough. Every one knows how very intractable this disease is in the great majority of cases, as well as how frequently it is fatal when it assumes a grave form. Any remedy, therefore, that offers even a moderate chance of success ought to be welcomed by the Profession, and receive a fair trial. Within the last nine or twelve months, Dr. Harley has been treating nearly all the cases of whooping-cough brought under his care at University College Hospital by means of the bromide of ammonium, and the results of the treatment seem to be highly satisfactory. As a rule, the dose of the remedy is a grain for every year of the age. This rule is, however, not always adhered to. In cases where the children are well-developed and strong, Dr. Harley occasionally gives as much as double that dose—namely, two grains for every year of the child's age. The bromide (Dr. Harley says) apparently acts by simply removing the whoop, which

is by far the most troublesome symptom, and after that has disappeared the case is treated as one of simple bronchitic cough. The remedy was at first administered by Dr. Harley with the view of inducing partial insensibility of the glottis, and thereby reducing, or even, if possible, altogether counteracting the spasm, as it appears to be the chief source of the child's misery. Bromide of potassium, which has a similar anæsthetic power over the pharynx and larynx, has also been used in whooping-cough by Dr. Radcliffe. The dose is about the same as that of the bromide of ammonium.

SATURDAY, JANUARY 30.

IS TOWNLEY MAD?

“Nulli vendemus, nulli negabimus, aut differemus rectum vel justiciam.”—*Magna Charta.*

“Though men believe that their reason governs words, it also happens that words retort and reflect their force upon the understanding.”—*Novum Organum*, Aph. 22.

“No word in the English language is so vague as the word ‘insanity.’”—*Baron Martin's Charge in Townley's Trial.*

“An acquittal on the plea of insanity is, on some occasions, a mere matter of accident.”—*Taylor's Medical Jurisprudence.*

EXPLAIN it how we will, the public conscience has received a severe shock. This is not the first time that a widespread feeling has arisen that justice has miscarried. Such shocks are dangerous. If punishment is to serve as an example—if the “*pœna ad paucos*” is to prove the “*metus ad multos*,” it should be, if not swift, as sure as human fallibility can make it. It may, indeed, be too swift—so swift that the public which it is intended to awe cannot acquiesce in its justice. An instance of this kind has just happened: a quiet, hard-working bricklayer, Samuel Wright, cohabited with a woman of very violent temper, who appears to have woke him in the middle of the night with the threat of running a knife into him. We do not know all the circumstances of the disturbance, but the end of it was that Wright killed her with a razor. He was not insane, although, if suddenly woke up from sound sleep, he might possibly not have been altogether fully cognisant of the crime which he was committing. He confessed the deed, and made no attempt to escape. This was on Sunday. On Monday, December 14, he was brought before a magistrate, and on Tuesday was arraigned for murder at the Central Criminal Court. Conscious that he had taken life, and ignorant of the distinction which the law makes between murder and manslaughter, the poor man honestly pleaded guilty, and declined the services of a counsel. Nothing was, therefore, left for the jury to do than to convict, and for the judge than to pronounce the sentence for murder. Subsequently, it appears that the prisoner stated that “he did not know the distinction between the crimes of manslaughter and wilful murder, and that, knowing the woman had died by his hands, he could not do otherwise than plead guilty, but that he meant thereby no more than to admit that he killed the woman in a fit of passion.” Had more time been given him, then, for con-

sideration, it is clear that he would have pleaded otherwise, and no one can positively tell what influence the arguments of his counsel might have had upon the tribunal that was to determine the nature of his crime. Wright's case called for public sympathy, and he had it. Never before, perhaps, was the Home Secretary more urgently pressed to extend the royal sceptre entrusted to his keeping by the gentle lady who, "*a lege sue dignitatio*" alone, can pardon the deepest crime committed within her realm. Sir George Grey has commuted the sentence of death after more heinous crimes than Wright's, and for worse reasons than the highly indecent haste with which conviction followed upon the murder. Yet Wright was hung.

Fortunately for George Victor Townley, no such error was committed in his case. The defence set up by his counsel, Mr. Macaulay, was *insanity*. It was admitted that up to the moment of the murder no one suspected mental unsoundness, although the disease had prevailed on the mother's side; no objection had been raised on this score to his contracting a matrimonial engagement, nor did there appear to be any facts which would have justified his confinement in an asylum, or the issue of a commission "*de lunatico inquirendo*" for the preservation and care of his property. The counsel simply urged that the murder was "a terrible development of this dreadful and hereditary insanity," and that "he had lost all sense of right and wrong by the influence which had acted upon and overturned his mind." The main evidence in support of this excuse was that of Dr. Forbes Winslow, Mr. Gisborne (the Surgeon of the gaol), and Mr. Sims (the governor). The two former were to prove his insanity during his residence in the prison, and Mr. Sims that he was in the same state when admitted as at any subsequent period. But, as an excuse for crime, it is not enough simply to prove insanity. All legal authorities unite in this—viz., that a person is responsible unless he is so insane as to be incapable of distinguishing right from wrong, or rather, that the act he is committing is wrong. Of this, every sane man has an innate sense, quite irrespective of his belief in God, or of a future state of reward and punishment—quite irrespective of any religious creed whatsoever. It is this innate sense which the law holds as sufficient to impart responsibility. Nothing but its absence will impart irresponsibility. Were it otherwise, all that would be necessary to excuse murder would be an obstinate or ignorant, but consistent, denial of the existence of God, and of the moral obligation of his commandments. Still, it was this disbelief and its alleged consequences that Townley's counsel endeavoured to confound with the innate sense of right and wrong. Dr. Forbes Winslow, when put into the witness-box, described two interviews which he had with Townley before the trial, and in which the prisoner had expressed to him that he felt no remorse for what he had done; that he considered he was perfectly justified in what he did; that he considered Miss Goodwin as his own property; and that he had a perfect right to kill or do what he liked with her, just as he had a right to dispose of any other description of property. He said "he was not responsible to God or man for his opinions or actions; he did not create himself, neither was he brought into existence by an effort of his own will; he was free to think and act as he pleased, recognising his perfect irresponsibility in the sight of God and man." He also said, "he would have killed the clergyman who had estranged her affections from him." He said he had no idea of God; that he did not view himself as an accountable agent; did not believe the Bible, and that he was a fatalist, together with a good deal more in the same strain, in all of which he had been forestalled by a host of infidel writers, of whose *sanity*, however, no one has ever hazarded a shadow of a doubt. Dr. Winslow's conclusions as to the responsibility of the prisoner at the time of his visits are as follows:—"Although, properly speaking, he cannot be viewed as in an acute state of insanity, I am nevertheless of opinion that his mind is in a disordered condition; such mental alienation exhibiting itself principally

in an inability to realise in a sane manner that he has committed a crime at all, in his attempt to justify his murderous act, and in the absence of all the natural and healthy feelings of regret, contrition, and remorse observed in the generality of persons similarly situated. His conduct exhibits a condition of mental derangement, associated with an inability to distinguish between right and wrong. In making this analysis of his mental condition, I cannot entirely ignore his openly avowed infidelity and scepticism." We should think not. Will not his adherence to these views fully explain his justification of his conduct, without dragging in any hypothesis which involves the idea of an absence of moral sense of right and wrong? Could he, indeed, have justified his own conduct as *right* if he had not also recognised Miss Goodwin's as *wrong*, and thus as deserving retribution—such retribution as he considered he had a right to dispense? Our readers can judge for themselves of the value of Mr. Gisborne's evidence after reading his extraordinary letter published in the *Times*. On that letter we commented last week, and shall not again refer to it except to observe, that, besides the pitiable state of oscillation it displays, it is evident that Mr. Gisborne entirely mistook his place. He was not about to go into the jury box, nor to sit upon the bench. But after all, as Baron Martin explained to the jury, the question was, whether Townley knew that he was doing wrong when he committed the murder. That he did was shown by his own words when he gave himself up, and expressed his conviction that he should be hanged for it. On this view he was convicted. The jury did not believe he was insane when he committed the murder, nor did the judge, nor do we.

But Townley's case was not yet hopeless. The law of England is, that if after judgment a man becomes *non compos mentis* "he shall not be ordered for execution; for *furius solo furore punitur*, and the law knows not but he might have offered some reason, if in his senses, to have stayed execution. It is, therefore, an invariable rule, when any time intervene between the attainder and the award of execution, to demand of the prisoner what he hath to allege why execution should not be awarded against him; and if he appears to be insane, the judge at his discretion may and ought to relieve him." (Stephen's "*Blackstone*," vol. iv., p. 554.) In this case the judge evidently did not consider that he did appear insane, or he would have relieved him there and then; but in view of the evidence of Dr. Winslow and Mr. Gisborne, he wrote to Sir George Grey suggesting the propriety of a further inquiry. "I cannot say," he writes, "that I have formed any decided opinion upon the point." Townley was convicted on December 12, and *the question was whether he was insane on the 13th and subsequently*. For it is to be observed that the prior insanity—that is, between August 21 and December 12—if it existed, had nothing to do with the question. The jury decided he was not insane when the murder was committed, and insanity was not adduced by his counsel as a bar to the trial, as it would have been most assuredly, could the plea have been sustained before a jury. For, "by common law, if a man in his sound memory commits a capital offence, and before arraignment for it he becomes mad, he ought not to be arraigned for it, because he is not able to plead to it with that advice and caution that he ought. And if, after he has pleaded, the prisoner becomes mad, he shall not be tried; for how can he make his defence? If, after he be tried and found guilty, he loses his senses before judgment, judgment shall not be pronounced." (Stephen's "*Blackstone*," vol. iv., p. 110.) On receiving the letter of Baron Martin, Sir George Grey accordingly dispatched three Commissioners in Lunacy to Derby, charging them to report to him for information "whether or not the prisoner is at the present time of unsound mind." The report of these experienced gentlemen, which we noticed last week, concluded thus:—"Being of opinion, therefore, that the prisoner continues to be now in the same mental state as when he committed the murder and underwent his trial, we think that, applying the law as laid down by Mr. Baron Martin to

this case, the prisoner, George Victor Townley, was justly convicted."

Although this was not an opinion on the point on which Sir George Grey asked for information, it sufficiently decides the question of Townley's present insanity, so far as execution of his sentence is concerned, the jury having settled that his peculiar religious notions did not involve irresponsibility for the murder, and his own counsel having regarded him sane enough to plead at his trial and to receive judgment after conviction. If we put this argument syllogistically, the conclusion is self-evident.

Sir George Grey seems, from his last letter to the Derby magistrates, to have felt completely the force of this kind of reasoning. After telling them that he was not called upon to act upon the report of the Commissioners alone, he says that, "Had he been so, although the Commissioners say that, for reasons set forth in their report, they could not consider Townley to be of sound mind, Sir George Grey yet would not have felt justified, from the general tenor of the report, in assuming that his unsoundness of mind was such as to exempt him from the penal consequence of an act for which, according to the law as laid down by the learned judge, he was legally responsible." But, as matters turned out, Sir George Grey was not permitted to use his judgment upon the merits of the case, as he would have been by the common law, for the whole thing was taken out of his hands by the friends of the murderer, who routed up an Act of Parliament, passed in 1840, by which it is provided that it shall be lawful for the Secretary of State to remove any person who appears to be insane (even if under sentence of death) to Bethlehem Hospital, on his insanity being simply certified to him by two justices of the peace and two Medical men. The Secretary of State, indeed, is not bound to act thus, but we can very well understand that there are few men in his unenviable position who would not act upon the permission, rather than incur the odium of refusal. He says himself,—“ Upon these certificates from four justices of the peace and two Medical Practitioners, the prisoner, in accordance with the construction which has been uniformly placed on the section of the Act before-mentioned, was ordered to be removed to Bethlehem Hospital, the capital sentence being respited, but not commuted.” It is a hard thing to say that justice has been thus defrauded by a quibble; but that it has been defrauded by the means of the statute-book which is intended to maintain it, we ourselves have no doubt whatsoever. Again we ask—“ Is Townley mad? ” If he is, then let him be taken care of like other insane felons; but the public are not yet assured of it, nor are we. If he is not mad, the statute under which he has been removed to Bethlehem, and which we quote below,^(a) indicates also the

(a) This Act is so short and so little known, that we may reprint it here in its entirety. “ 3 and 4 Vict., c. liv.—An Act for making further Provision for the Confinement and Maintenance of Insane Prisoners—That if any person, while imprisoned in any prison or other place of confinement, under sentence of death, transportation, or imprisonment, or under a charge of any offence, or for not finding bail for good behaviour, or to keep the peace, or to answer a criminal charge, or in consequence of any summary conviction or order by any Justice or Justices of the Peace, or under any other than civil process, shall appear to be insane, it shall be lawful for any two Justices of the Peace of the county, city, or borough, or place where such person is imprisoned, to inquire, with the aid of two Physicians or Surgeons, as to the insanity of such person; and if it shall be duly certified by such Justices and such Physicians and Surgeons that such person is insane, it shall be lawful for one of her Majesty's principal Secretaries of State, upon receipt of such certificate, to direct, by warrant under his hand, that such person shall be removed to such County Lunatic Asylum or other proper receptacle for insane persons as the said Secretary of State may judge proper and appoint; and every person so removed under this Act, or already removed, or in custody under any former Act relating to insane prisoners, shall remain under confinement in such County Asylum or other proper receptacle as aforesaid, or in any other County Lunatic Asylum or other proper receptacle to which such person may be removed, or may have been already removed, or in which he may have been in custody by virtue of any like order, until it shall be duly certified to one of her Majesty's principal Secretaries of State by two Physicians or Surgeons that such person has become of sound mind; whereupon the said Secretary of State is authorised, if such person shall still remain subject to be continued in custody, to issue his warrant to the keeper or other person having the care of any such asylum or receptacle as aforesaid, directing that such person shall be removed back from thence to the prison or other place of confinement from whence he or she shall have been taken, or, if the period of imprisonment or custody of such person shall have expired, that he or she shall be discharged.”

method of settling the question, as well as the duty of the Home Secretary. Capital punishment may not be the proper means of preventing the commission of murders, but no one can live in the anticipation of safety when the punishment which the law awards can so easily be avoided as it has been in the case of Townley.

HOW TO PRESCRIBE AND HOW TO WEIGH IN GRAINS.

ALTHOUGH the toils of practice have compelled us, as they have most of our readers, to look upon chemical manipulation as a thing only to be taken up on some rare occasions, yet, sitting with a good balance and set of accurate grain weights in our study, we cannot help wondering why so many who prescribe and dispense, and why the Medical Council which issues regulations for both processes, should prefer an intricate and obscure system of weights to one that is simple and obvious at first sight to every one.

In our present remarks we confine ourselves to dispensing and prescribing; as for manufacturing, that is no business of the Practitioner. The Medical Council have thought fit to give formulæ for the manufacture of drugs on the large scale, which manufacturers may laugh at or adopt as they please; and for processes such as these, the pound, with its even binary divisions of half, quarter, eighth, etc., and the ounce, with similar divisions, may be convenient and sufficient.

But we do not prescribe pounds or ounces for our patients. *The real unit for this purpose is the grain.* Every one who prescribes knows how many grains or fractions of grains he wishes the patient to take; and whether he direct one dose or many to be made up, the necessary calculation is trivial, and involves no difficulty whatever. And it is far easier to write down any given number of grains at once, than it is to first reduce them to drachms or fractions of drachms or scruples.

It will be more convenient under this new system to use Arabic numerals than Roman. Most of us now write in English the directions how medicines are to be taken. We have done so, since a chemist's lad once translated “cyath. vin. aquæ,” as “a glass of wine and water.” The substitution of the Arabic numeral will be but one step towards abolishing Latin altogether, a thing which, however regretted, is inevitable.

Prescriptions are already half English. When we see “grs. xx.,” we are fain to advise the prescriber not to jumble Latin and English together in one phrase, but to choose whichever of the two tongues he understands best, and write wholly in that.

Suppose, then, we wish to write a prescription for eight doses, each containing eight grains of carbonate of ammonia, ten of bicarbonate of potass, and fifteen of nitrate of potass—

R. Ammonia carb., gr. 64; potassæ bicarb., gr. 80; potassæ nitratis, gr. 120; aq. destillatæ, fl. oz. 8; m. ft. Mist.

Sig.—“One fluid ounce by measure to be taken every four hours, with half a fluid ounce of lemon-juice, and the same of water.”

Such a mode of prescribing quantities would answer every purpose. There could be nothing gained by writing “gr. lxiv.,” nor yet “ʒj. et gr. iv.,” instead of “gr. 64,” and so with the other quantities. To use scruples or drachms and Roman numerals would be to get into a calculation for no other purpose than to get out of it again.

Suppose a man has to perform a simple chemical determination—say the solid contents of a decigallon of water from some waterworks—first he weighs a capsule, which equals, say, 413.98 grains; (2) after evaporating the water therein, and drying at 250°, it weighs 416.4 grains; (3) after drying still further, 416.35 grains. This number is adopted, giving as the total solid impurity, viz., the difference between the first and third weighing, multiplied by ten, as per gallon, 23.7 grains.

These results are seen at a glance. But what chemist, except

his head were stuffed with straw, would write down, instead of the above figures, "Weight of capsule, ʒvj., ʒij., gr. xij., et xviij. partes grani e centum; after evaporation, ʒvj., ʒij., gr. xvj., et xxxv. partes grani e centum; weight of solid residue per gallon, ʒj., gr. iij., et septem partes grani e decem?"

If chemists do not vex their souls with these antique intricacies, why should we? But if the manner of expressing quantities in grains be easy, infinitely more so is the actual weighing, if, instead of the odious Apothecaries' weights, we have a set of plain grain weights.

With the Apothecaries' weights they give ʒij., ʒj., ʒij., ʒss., ʒj., ʒss., besides grain weights stamped to represent 6, 5, 4, 3, 2, and 1 grain.

It is practically difficult to distinguish between ʒij. and ʒss., and it takes up a good deal of calculation to make up odd numbers of grains.

A box of good chemical grain weights, on the contrary, has them in regular sets of four, out of which any combination can be made immediately by the simplest process of addition. The grain weights are made of wire, bent in such a way that each gives its value at a glance.

The highest set of weights, for hundreds of grains, is—600, 300, 200, 100. The next, for tens—60, 30, 20, 10. The third, for grains (of platinum wire)—6, 3, 2, 1. The fourth, for tenths (of platinum wire)—6, 3, 2, 1. Hundredths may be had in gold wire, but are not necessary, and tenths can seldom be wanted in dispensing.

It may be seen at a glance—First, that the series of "tens of grains" harmonises with ʒj., ʒss., ʒj., and ʒss., if any one loves the old system and chooses to use it. Secondly, that out of the above numbers any intermediate number can be formed. And it may be added, thirdly, that the custom of putting weights into the scale-pan in regular order is useful, like all other chemical processes, as a means of teaching exactness and order.

THE WEEK.

THE NEW PHARMACOPŒIA.

VERY great dissatisfaction is expressed at the fact, that the General Medical Council have issued a half-guinea edition of the Pharmacopœia, and, it is said, do not propose to issue a cheaper edition yet for a month. If such a device had been the work of a common publisher, it would have been called a shabby trick of the trade. The edition already published appears unnecessarily expensive.

SURGEON TURNBULL.

WE are glad to hear it reported that Surgeon Turnbull is not to be put upon half-pay, but will be allowed to exchange into some other regiment. The Medical Profession will know how to appreciate this act of justice on the part of H.R.H. the Commander-in-Chief.

THE COUNCIL AND THE COURT OF EXAMINERS OF THE ROYAL COLLEGE OF SURGEONS.

MOST of our readers are probably by this time aware that the Council of the College of Surgeons have elected Professor Partridge, of King's College, to the seat in the Court of Examiners, vacant by the death of Mr. Green, and have passed over the claims of Professor Gulliver, whose seniority in the Council to Mr. Partridge constituted him the candidate next eligible for election. By this course of proceeding, the Council have laid themselves open to the charge of combining to exclude all except metropolitan Hospital Surgeons from the examination of Surgical pupils. The injustice and short-sightedness of such a course are clear. It is contrary to the plainest dictates of right that a board of examiners should be composed alone of the teachers of the candidates examined. A board of examiners should comprise the best men, selected on the most eclectic principles, and should be, in the

eyes of the Profession and the public, above suspicion. The Charter of the College, and the right vested in the Fellows to elect the Council, have done but little for the Profession, if the body who in reality wields all the influence, exercises all the power, and, we may add, receives all the emolument, is to be confined to the *coterie* of London teachers of Anatomy and Surgery. The Surgeons of the London Hospitals are, undoubtedly, a most able body of men; they have great opportunities of becoming most accomplished in their art, but we assert that the Surgeons of *town* do not represent British Surgery. They are not military or naval Surgeons; they have few of them time or opportunity for cultivating those more abstruse branches of science on which the whole healing art is founded. In many of the provinces, on foreign stations, and in the colonies, fields of practice are open, where cases present themselves which are rarely or never seen in London Hospitals. We take up this matter, not on personal, but on general grounds; and we maintain that, in overlooking the claims of such a man as Professor Gulliver, the Council have set a precedent which will militate against the best interests of the Medical Profession.

But it may be said, that the course pursued by the Council on the present occasion has not been the one always followed, and the instance of the election of Mr. Kiernan may be cited. But the readers of this Journal will recollect that his election was carried by a narrow majority of one only, and in spite of strong opposition. Never was a man more fitted for an anatomical examiner than Mr. Kiernan, as his long service in that capacity at the University of London had proved; and yet, on the sole ground that he was neither a London teacher nor Hospital Surgeon, the services of that most accomplished anatomist were only secured to the College by the casting vote of the then president. On the same narrow principle Messrs. Swan and Copeland were passed over.

In the case of Mr. Gulliver, there were the strongest reasons why he should have been welcomed into the examining body of the College. His scientific researches have secured him the highest reputation, and have enlarged the bounds of physiological and anatomical knowledge. He has stood forward in the theatre of the College as the champion and defender of those claims of the British school of physiology which have met with but scant appreciation even from Englishmen. His long experience in the army, and his opportunities of practical study of the diseases and injuries met with in the public services at Fort Pitt, have given him a variety of pathological information which is scarcely to be obtained in a more restricted school. Since the death of Mr. Guthrie, the Army Medical Department has had no representative in the Court of Examiners. The election of Mr. Gulliver would only have been a fitting tribute to his distinguished scientific acquirements and to the military branch of our calling. The Profession will not be surprised to hear that, in disgust at the slight thrown on his labours and Professional and public services, this gentleman has resigned his seat in the Council.

But, as we before said, we notice this matter on general, and not on any narrow or personal considerations. If the Court of Examiners is to be a body composed of the very best men of all Surgical schools—if the patent mistake of confiding solely to the London teachers the examination of their own pupils, is to be amended—and if something more is to be expected from the English Surgeon than a superficial knowledge of descriptive anatomy, and a mere acquaintance with the class of cases to be met with in town Hospitals, the Fellows of the College must let their influence be felt within the walls of the Council. The members of the Council are their nominees. Indirectly, the members of the Court of Examiners must be the same.

ETHNOLOGICAL TRANSACTIONS.

IT is seldom one meets with a pleasanter and more satisfactory work than the second volume of "Transactions of the Ethnological Society," recently published. From the variety of

subjects, and the mass of interesting matter, it is hardly possible to do justice to it within the brief compass at our disposal. Thirty communications fill 468 pages; and though their contents are various, the unity of idea which pervades all would have surprised any scientific man some years back, before the form and features of ethnology as a distinct science had been carved out of the inert body of general history and research. Mr. John Crawford, the President, communicates no less than six memoirs, which, from the breadth of their treatment, and the importance of their topics, might well be separately published as essays. The first in the book is on the "Connection between Ethnology and Physical Geography." A second, on the "Numerals as Evidence of the Progress of Civilisation," takes these advanced abstractions as a measure of social condition. The "Antiquity of Man, from the Evidence of Language," argues in favour of a remote period for our species, on the ground of the adventitious character of speech, and its necessarily gradual formation. The "Memoir on the Commixture of the Races of Man as Affecting the Progress of Civilisation," starting with the supposition that man, on his first appearance on earth, consisted of many distinct and independent races, examines the breeding and cross-breeding which have occurred in several of the principal European nations. A paper on "Colour as a Test of the Races of Man," shows the great persistency of any particular pigmentary tint, and, like its predecessor, inclining towards original diversity of the human type, examines Albinos, individuals with excessive growth of hair, and other abnormalities. At the end of the volume is a collection of "Enquiries as to the Relation of the Domesticated Animals to Civilisation," which, although read by their author on different occasions at the meetings of the Ethnological Society and British Association, form, in fact, so many consecutive chapters on one general subject. At the head of "Domesticated Animals" is placed, somewhat quaintly, man himself; and after him follow, in a space of above eighty pages, many interesting facts respecting the various mammalia, birds, and insects which acknowledge his mastery, or contribute to his wants. Dr. James Hunt, Hon. Secretary of the Society, contributes, besides a "Report of Papers," a *resumé* of "Ethno-Climatology," or the acclimatisation of man. He leans to the opinion of Sir Ranald Martin, that acclimatisation is impossible, and endeavours ably "to suggest to ethnologists and geographers the necessity of a further investigation of the important question." Here we may notice one of the most valuable features of the work—namely, the synopsis of the consequent discussion at the meeting. The President's papers seem specially directed to encourage this laudable object of a society; and after the Hon. Secretary we find the names of Mr. Layard, Mr. Monckton Milnes, Sir Erskine Perry, Dr. Hodgkin, Sir Alexander Tulloch, Mr. H. Sandwith, and Dr. Ward.

The Bishop of Labuan gives a forcible and characteristic "Account of the Wild Tribes on the North-West Coast of Borneo. Professor Owen explains the "Osteology and Dentition of the Aborigines of the Andaman Islands, and the Relations thereby indicated to other Races." G. M. Tagore, Esq., very appositely furnishes a notice on "Buddhism," and another on the "Caste System." Professor Huxley sends a letter on the "Human Remains Found in Shell Mounds." Mr. Robert Clarke brings a singularly interesting series of "Sketches of the Colony of Sierra Leone and its Inhabitants." This is illustrated by numerous portraits of the various tribes, lithographed from his drawings. Some apology is made for these in the preface, perhaps not quite undeservedly, though an entire and faithful copy of all is promised at a future period. The "Ethnology of Egypt," "Vocabularies of Native Words," "Description of Human Remains and Disinterred Ornaments," "Information as to the Tribes of Northern Kurdistan," by Mr. W. Spottiswoode, and many other valuable materials, give the highest value to the publication, and indicate its scope. If such volumes can be obtained separately, they might form excellent additions to libraries and book societies, for they gather up the heads of great subjects *citò, tutò, et jucundè*.

FROM ABROAD.—THE SURGEON-GENERAL OF THE UNITED STATES ARMY—DREAMS AND REALITIES—SPONTANEOUS ORIGIN OF MALIGNANT PUSTULE.

SOME time since (*Medical Times and Gazette*, October 17) we noticed the remarkable circumstance, that Dr. Hammond, the Surgeon-General of the United States Army, in the very midst of a most successful career of enlightened administration, which was obtaining for him the highest public and professional approbation, had been removed from his scene of usefulness, and despatched to a distant region upon a comparatively unimportant mission. This seemed at the time quite unintelligible; and, although a motive has since been assigned, we are still unable to understand how, in a country professing a love for justice and fair play, it has been allowed to operate so mischievous a procedure. It appears that, in the course of the reforms he has had to institute, Dr. Hammond has found it necessary to rout out more than one nest of jobbers in public calamity, and has had the courage to execute his duties in face of great difficulties. Those whose interests he has thus interfered with seem to have possessed power enough to obtain his relegation from the proper field of his duties, and the appointment of a secret commission to investigate in his absence charges made against his management of his department. This inquisitorial procedure has naturally aroused the indignation of the Profession, especially as this is only one of many acts exhibiting a disposition to interfere with, and trammel, the legitimate action of the Medical Department, to which the army owes so much. A circular is now in the process of distribution, calling for united action in this matter, in order to press upon the authorities the necessity of a full and fair inquiry.

"If Dr. Hammond," says the circular, "has not forfeited his right to fill the position for which he was selected, he should be reinstated immediately. If, on the other hand, his honesty or competency is questioned, it is due to the President, the Senate, and the people, that this should be made known by the results of a formal procedure, and not from an investigation conducted by a secret, *ex parte*, and anonymous commission. Let the accused have the same hearing as his accusers. Let the examination be as severe and searching as you please, so that it be but fair and open."

The United States Sanitary Commission (a body which has done such immense service in seconding and supplementing the Medical Department during some of its most direful emergencies) has also addressed a strong remonstrance to the President upon the subject. After testifying, from ample opportunity of observation, to the great services and efficiency of the Surgeon-General, it protests against his removal from his post, by the agency of any secret cabal, as a step fraught with the grossest injustice, and one likely to lead to the most mischievous consequences.

Our contemporary, the *British Medical Journal*, fell into a somewhat droll error last week. It held up for the admiration and imitation of the Deans of our Medical Schools the wonderful doings in Paris for the accommodation of students. A magnificent edifice, designated "Grand Hôtel des Ecoles," was represented as existing in the Boulevard de Sebastopol, provided with a spacious garden, fountains, billiard and reading rooms, and a grand *salle à manger*. In an upper storey, nicely furnished and well warmed bed-rooms open into light and airy corridors, while for those who have the misfortune to fall sick a Hospital ward exists. This luxurious and charming abode is exclusively devoted to the reception of students, who are here lodged, fed at a well-appointed *table d'hôte*, and provided with fuel and amusements for the small sum of £4 a month per head. On perusing this statement, those who have recently visited Paris must have rubbed their eyes and lamented their stupidity in having neglected to notice this model of economy in the midst of the costly magnificence of that capital. They may spare their regrets, however, for search where they might they would still have come to the same result, *non est inventus*. Alas! this splendid erection, which our contemporary calls upon us to admire and imitate, exists

but in the fairy dream of that vivacious *feuilletoniste*, Amedée Latour, who presents it as the *beau-ideal* of what is to be desired. Awaiting its realisation, we shrewdly suspect that the Medical students of Paris would only be too well contented with the superior comfort and material advantages enjoyed by those of London.

The discussion on the vaccine virus at the Academy of Medicine being in abeyance, M. Gallard has taken the opportunity of reading a paper upon malignant pustule. Hitherto this has universally been considered a contagious disease, communicated from animals to man; and when such communication has not been demonstrable, it has been assumed as a matter of course. This view it is the object of M. Gallard's paper to dispute, believing, as he does, that the disease not unfrequently arises spontaneously in man. He refers to nine cases treated by M. Devers since 1857, in the small commune of Bénote, in the Department of Charente-Inférieure, in none of which the origin of the affection could possibly be traced. M. Gallard extended the investigation throughout the whole of the department, as well as the adjoining departments, interrogating more than one hundred Medical Practitioners; and nowhere else could he find traces of malignant pustule in man or beast. From this investigation, as well as from a consideration of various cases reported by authors, M. Gallard comes to the conclusion, that while in the bulk of instances this disease is a result of contagion, there are many cases which cannot be so accounted for.

REVIEWS.

Notes on Hospitals. By FLORENCE NIGHTINGALE. Third Edition, Enlarged, and for the most part Re-written. London: Longmans. 1863.

It is sad to see a work of so much value—full of such useful information—disfigured by a few serious and elementary mistakes. Much as all Medical men must appreciate the philanthropic labours of its authoress, it is a false kindness to pass erroneous views without a protest. This becomes the more incumbent on us, as the third edition sins more notably than its predecessors. While we do not withdraw one word of the commendation which was bestowed on former editions, we feel bound not to become tacit accomplices in the spread of opinions which are not accounted sound by competent authorities.

In the very first section it is laid down as an axiom, that the "sanitary condition" of Hospitals modifies the ultimate issue of cases which pass through the wards. The assertion, that there is no such striking difference in the mortality of different Hospitals, as one would be led to infer from their great apparent difference in sanitary condition, is then commented on; and it is judiciously granted that different diseases, ages, and states on admission may considerably affect the results of treatment. "But," continues the authoress, "the fact has sometimes been made use of in a way no one could have anticipated. A high and increasing death-rate has been actually put forward, not as the result of these causes, but as the result of increasing celebrity, which can have no other practical meaning than this: that a greater number of people go there to die next year, because so many have died there this year,—a principle equally applicable in private practice, and according to which the Physician or Surgeon who loses the largest percentage of cases is the man most worthy of confidence."

In all courtesy we must affirm that this extract is incorrect, illogical, and impulsive. It is incorrect because it misrepresents the statements of those who deny the accuracy of mere numerical comparisons as a test of Hospital efficiency; it is illogical, because the "practical meaning" is unfairly deduced; and it is impulsive, because, by a hasty *argumentum ad hominem*, covert sarcasm is made to do duty for argument.

Space forbids our recurring here to the question of Hospital death-rates. Dr. Peacock showed most conclusively some years ago, that their amount depended on causes almost wholly independent of "sanitary condition," and the same view has been established at large in the pages of this Journal. Although it is obviously unnecessary to deny that sanitary condition may influence disease and death, no more distinct

refutation of the quotation just made is needed than is supplied by page 5 of the same chapter. When speaking of the duration of cases it is remarked that "Hospital mortality statistics have hitherto given little information on the efficiency of the Hospital, *i.e.*, as to the extent to which it fulfils the purpose it was established for, because there are elements in existence of which such statistics have hitherto taken no cognisance. In one set of Hospitals in the table I find the mortality from $12\frac{1}{2}$ to $15\frac{1}{2}$ per cent. upon the cases treated, while in other Hospitals the deaths reach from 83 to $90\frac{1}{2}$ per cent. To judge by the mortality only in these cases would be most fallacious; because, in the first class of Hospitals, ailments not of a dangerous nature constitute a title to admission; while in the latter class of Hospitals, dangerous and special diseases, at all times accompanied by a high rate of mortality, are largely admitted."

As a specimen of the way in which it is proposed to employ the numerical data thus gained, we will next call attention to a table of mortality mentioned in our last extract, and which does not appear in the first edition of the work. It is one of a set of occasional tables from the Registrar-General's last annual report, and, therefore, perhaps Miss Nightingale can hardly be held responsible for it. In 1861, returns were obtained from 106 Hospitals, giving the number of inmates in each on April 8. The number of deaths registered in each Hospital during the year 1861 is also given. Our readers will hardly believe that on these two bases a percentage of mortality is struck. The inmates of a single day are balanced with the deaths of a whole year, and no wonder the results are "striking enough." It is to be hoped there are valid reasons for giving to the world what seems to us a simple piece of arithmetical legerdemain. Surely it is the very essence of percentages and of averages (both, we believe, fruitful sources of error), that the figures dealt with should stand on one and the same bottom, and that deaths for one year should be compared with admissions or discharges for that period, and no other. There is something audacious in the last column of this table, where twenty-four London Hospitals are accredited with a "mortality per cent. on inmates" of 90.84. No doubt it will be said this is the quotient of the figures employed; but we entirely deny their validity and the accuracy of the impression thus conveyed. The problem as here put is exactly that so often asked of forward schoolboys—What is the quotient of a hundred apples divided by fifteen red herrings. We can but compliment our mathematical friend, Lord Dundreary, on his appearance in a new and unexpected situation.

It is refreshing after this to find the authoress appealing to her own instinct and experience, instead of figures which we cannot endorse as "reliable." Careful observers, she says, "are now generally convinced, that the origin and spread of fever in a Hospital, or the appearance and spread of Hospital gangrene, erysipelas, and pyæmia, generally are much better tests of the defective sanitary state of a Hospital than its mortality returns. One insensibly allies together restlessness, languor, feverishness, and general *malaise* with closeness of wards, defective ventilation, defective structure, bad architectural and administrative arrangements, until it is impossible to resist the conviction that the sick are suffering from something quite other than the disease inscribed on their bed-ticket." Undoubtedly, a work directed to the remedy of such evils deserves praise, and has the good of the sick for its purpose, in spite of the slight uneasiness which springs up involuntarily in the mind on reading the last quotation, and the suspicion of a second diagnosis overruling that of the responsible Practitioner. This feeling is somewhat increased by the wholesale denunciation of "contagion and infection" which follows, and which, if not promulgated by a lady, would require rough treatment. It is proposed summarily "to lay these spectres, which have terrified almost all ages and nations." The subject is too large for discussion here; we can only express our surprise at the celebrated Black Hole of Calcutta figuring as an example of infection. It is represented in most accounts as an instance of simple suffocation and excessive heat, without a word as to any infectious disorder; but on this point we are open to correction.

A series of plans of existing Hospitals, with their defects, is illustrated by two excellent maps of London and Paris respectively, in which the various Hospitals stand in bold relief. Such a chart is interesting and valuable; we have long used one roughly made for our own convenience, and we heartily recommend this more elaborate specimen to all our readers.

In the third section, the principle of separate pavilions in Hospital construction is strongly urged; two floors, and no more, are recommended, with 80 to 100 square feet of superficial area to each bed in the wards. It concludes with many important details on minor points.

Chapter IV. gives improved Hospital plans, abundantly illustrated by drawings of English and foreign examples. In the fifth chapter, Convalescent Hospitals furnish very interesting matter, and a design for a convalescent Hospital arranged as cottages, which is a real gem, and is fortunately in progress as the Herbert memorial for the county of Wiltshire. A note on the Convalescent Hospital recently established by the Emperor of the French at Vincennes, contains full particulars as to this noble foundation.

The remarks upon Children's Hospitals are what a woman only could frame, and for this, among many reasons, are of the most sterling worth. The same commendation applies to Miss Nightingale's appreciation of Sisterhoods, both in and out of their place.

Indian Military Hospitals, Forms for statistical returns, and notes on systems of Hospital nursing, bring the volume to a close: some of these have already been noticed at length in our pages; others we hope to recur to hereafter. The remarks which have been made on limited points do not in any way preclude our heartily congratulating Miss Nightingale on the public appreciation which has given rise to a third, and all but rewritten, edition of her work. That it is calculated to be of great service to our Profession is past denial; and such a hope receives promise of speedy fulfilment from the temperate and judicious views expressed as to the removal of St. Thomas's Hospital. It is to be desired that the principles here enunciated may carry due weight with the governors of that important institution.

GENERAL CORRESPONDENCE.

MEDICAL SERVICE IN THE FEDERAL ARMY.

LETTER FROM MR. CHARLES MAYO.

[To the Editor of the Medical Times and Gazette.]

SIR,—Perhaps the enclosed extracts from a letter which has just reached me from a comrade in the Medical service of the Federal army may be interesting to some of your readers. I should explain that Dr. Hammond, who had fallen into disfavour with the Secretary of War (Mr. Stanton), had been kept for some months on a tour of inspection of the Military Hospitals in all parts of the States, while a substitute was installed in his place in Washington. The person referred to as "S—" was a subordinate in the Surgeon-General's office, who was, as may be inferred, no favourite in the service. His punishment is one to which penal servitude would be leniency. A journey of four or five thousand miles, including the passage of the Rocky Mountains in mid-winter, and ending in the wilds of a scarcely inhabited territory, is a task from which the boldest pioneer of civilisation might shrink. The concluding lines of the extract illustrate the hospitable character of my American friends.

I am, &c.

CHARLES MAYO.

New College, Oxford, January 26.

"Philadelphia, January 8, 1864.

" . . . Hammond (the Surgeon-General), after going through the region of the Gulf and Lower Mississippi, arrived, two weeks since, at Nashville, where, in coming down the steps of one of the Hospitals, he fell and so injured his head and back, that he has complete paralysis of the lower half of his trunk, and, of course, of both lower extremities. He will never stand upon his feet again.

"Acting Surgeon-General Barnes has been in his place in Washington nearly ever since Hammond left for New Orleans, and will probably be made Surgeon-General. That monkey, S—, has received at last a part of his dues. His history is a short and instructive one. After Hammond left Washington, S— assumed the purple, and held sway for just twenty-four hours, during which brief period he issued two impertinent orders, after his usual manner, to Assistant-Surgeon-General Wood, at St. Louis. On the following morning, Stanton ordered S— to report for immediate duty to Wood. On arriving at St. Louis, he was kept in Wood's ante-room for a few hours, and then ordered forthwith to

report for duty in the department of Santa Fé, New Mexico, where, I am very credibly informed, he was ordered to report in person for immediate duty at an outpost in Oregon. No doubt he is now wandering or plunging through the frozen snows of the Rocky Mountains. In his worse than Siberian exile he will enjoy ample leisure to reflect upon his many heartless acts.

"The 13th Army Corps is rejoicing in Texas, near the Rio Grande, I believe. I have left the army, and now again rejoice in a manly freedom. And now about yourself. I hope you have lost the complaint which your visit to Vicksburg inflicted on you. I ask with interest, because Dr. W— (the Sanitary Commission Agent, you remember, at Vicksburg) told me a few days since that he was troubled still. I thank you for calling at my house. Had I been at home you would have found the latch on the outside of the door. I hope, on some future occasion, to see you lifting it up and walking in; you will be heartily greeted, I assure you.

"Believe me, &c."

RAILWAY SURGEONS.

LETTER FROM MR. T. M. KENDALL.

[To the Editor of the Medical Times and Gazette.]

SIR,—I trust to your straightforward and truthful way of dealing with all cases, for insertion in your next of my letter relating to your article—"Railway Surgeons"—of the 16th instant.

No one who knows it can doubt it relates to the late sad accident on the Lynn and Humstanton line. I am Surgeon to the Company, and therefore feel aggrieved. In the first place, every sufferer was attended by their own Medical man where they wished, and the company paid every charge sent in. I only saw casual patients where they wished it, or by the request of the company, and then only in the presence, or by permission, of the Medical man attending, and in his presence. Referring to the case you particularly allude to, I beg to say, I never saw her as a Professional man until some weeks after the accident, and that after the action for increased damages had commenced, and then in the presence of her private Medical attendant and the two gentlemen who examined her as to her state; and I unhesitatingly gave a certificate that she was suffering from aneurism of the aorta. I never, directly or indirectly, attempted to settle any case on behalf of the company.

I feel these statements are due to myself, and request their early and full appearance in your Journal.

I am, &c.,

T. M. KENDALL, F.R.C.S., &c.

King's Lynn, January 20.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 19.

Mr. PRESCOTT HEWETT, President.

DR. WILKS showed the

SUPRA-RENAL CAPSULES FROM A PATIENT WHO DIED OF MORBUS ADDISONII.

These organs presented the usual appearances seen in morbus Addisonii, and came from a girl who was under Dr. Wilks' care in Guy's Hospital, and who presented a model case of the disease. She was 23 years of age, and for two years had suffered from discoloration of the skin, debility, some wasting, and occasional sickness, the sickness being at times worse. She sought the assistance of Medical men. She had seen several, and they all considered the case as one of liver disease. This mistake (Dr. Wilks says) should not have been made, seeing that her eye was not yellow, nor her urine jaundiced. When she came to the Hospital her skin was of a greenish-brown colour, like that of a native of the south of Europe; she did not appear very ill, judging from her expression, but was so weak that she was obliged to be carried to bed; she also had sickness. The latter abated, and she felt much better, so that indeed she was the merriest person in the ward. She was, however, at this time so weak, that she could not sit up in bed, and her pulse was like a thread. Wishing to leave the Hospital

at Christmas time, she went home, Dr. Wilks requesting that he should be informed when she became worse. Only a few days elapsed when he was sent for and found her in a dying state. She was quite sensible, and able to speak, but was utterly powerless, and her pulse could not be felt. She had been lying in this state for twenty-four hours, and in the course of the night she died. Dr. Wilks said the case was so marked that he invited several Medical men to see it, and took one of her Medical attendants with him, to perform the post-mortem examination. No disease was found in any part of the body, except in the supra-renal capsules, which were converted into a yellow, amorphous material, with some cretaceous deposit. Dr. Wilks remarked that several attempts had been made to investigate the subject of Addison's disease, by an examination of the supra-renal capsules in all bodies. He had done this for many years himself, and like Professor Mattei, of Siena, but his observations had been unattended with success. The reason seemed to be, that, if affected by any other disease than the special one, they were only partially or rapidly involved in some disease which infected the whole body, as cancer or tubercle; whereas, in morbus Addisonii, the change was a primary one, and altogether independent, pursuing its course for several years, and, probably, totally destroying the organ a long time before death. It was for this reason that the author of the discovery did not look upon the supra-renal capsules as vital organs, but which, when diseased, produced the remarkable asthenia by implication of the centres of the ganglionic system, which were closely contiguous.

THREE CASES OF MORBUS ADDISONII.

Dr. WILKS also exhibited some supra-renal capsules affected in a similar manner, and which had been sent to him by Dr. Hardwick, of Leeds since deceased. The patient was a man, 29 years of age. For some months he had pain in the back and leg, and, about nine months before his death, his companions noticed his skin becoming yellow, and they thought he was going to have jaundice. He got weaker, and the skin became darker, and the urine was always pale. He got a little better under treatment, when he had an epileptic fit, and subsequently he had vomiting and slight convulsive movements. He was then so feeble that he was obliged to be carried to the Infirmary. His body was of a dirty, olive-brown tint, giving him a close resemblance to a mulatto. He also had a psoas and lumbar abscess. His depression gradually increased until death. There was found disease of the lumbar vertebræ, and the supra-renal capsules were converted into a dense, tough, fibrous mass, with some cheesy, tuberculous matter. Dr. Hardwick stated in his communication, that since he had been connected with the Leeds Infirmary he had seen four other cases of morbus Addisonii besides the one just related. In two of them, although the symptoms were well-marked, the cases were not followed to their termination. In the other two—one was a man, 52 years of age, who had long suffered from great prostration and discoloration of the skin—death occurred by gradual sinking. No disease was found except in the capsules, which were converted into a grey, lardaceous material. The other was that of a woman, aged 69, who had great prostration, frequent vomiting, and her skin was of a dark brown colour throughout. No disease existed except in the capsules, which were filled with a mass of grey and yellow, soft, cheesy deposit. She was a patient of Dr. Hall.

Dr. HARLEY, in reply, stated, that although he had no wish to reopen the question which had given rise to so many animated discussions at their meetings a year or two ago, he could not allow some of the remarks which had fallen from the last speaker to pass unanswered. Dr. Wilks appeared to be both surprised and annoyed that pathologists of standing in Edinburgh and elsewhere still doubted the existence of the so-called Addison's disease, which he seemed to regard as a settled question. He (Dr. Harley), like Dr. Wilks, also thought that it was a settled question, but differed from him in thinking that it was settled in the affirmative; for, on the contrary, the highest authorities on pathology abroad, and nearly all at home (only one or two being exceptions to the rule), had either given a distinct negative or left the question as very doubtful; and no one who had carefully watched the progress of the discussion could be in the least surprised at such a result. Even the most staunch supporters of the theory of bronzed skin and supra-renal capsular disease had shifted their ground so often, and altered their views so frequently, that he for one must confess that at the present moment he had not the most distant idea of what Addison's disease consisted in. First, we were told it consisted in bronzing of the

skin, and destruction of the supra-renal capsules: next, we were told that the bronzing must be universal, not in patches; then informed that the bronzing of the skin only occurred in the most advanced stages of the disease; and, lastly, there came a time when we were informed that the bronzing of the skin was in no way essential to the affection, its presence or absence being a point of minor importance. And now the disease seemed to have entered upon an entirely new phase of existence; for we were just informed by the last speaker that there is only one form of diseased capsules which constitutes Addison's disease,—viz., a peculiar scrofulous affection. It seems, then, that the supra-renal capsules may be totally destroyed by tubercle, or any other disease except that just mentioned, and their functions utterly obliterated, without giving rise to Addison's disease. The supra-renal capsules may be one mass of cancer, and yet the disease which is said to spring from the absence of their functions not exist. It further appears, from what the gentleman has just stated, that even the highest authorities on the subject have no very clear notions as to what the affections consist in; for, be it observed, that in the present case, which has been brought before the Society as an unmistakable example of the affection, its contributor acknowledges, that not only the resident assistants mistook it, but that even two of his colleagues failed to detect it; and further, that it was not until he himself had subjected the patient to the closest scrutiny, that he was able to detect this well-marked example of the disease. How, then, it may be asked, can he be surprised that persons like himself (Dr. Harley) fail to recognise the so-called Addison's affection? In truth, he believed with the German authors, some of whom had named it the "ephemeral epidemic," that it would gradually die away; and if the supporters of the theory wished to preserve its name a little longer from utter oblivion, they must be much more careful in the selection of their data, and at once abandon the system of publishing cases as examples of the disease, which have not only not been seen by competent observers, but in which the capsules have not been examined at all; for several cases have actually been published while the patients were still alive. It is further necessary for them to state positively in what Addison's disease consists; for, looking at the thing as it now stood, it appeared to him that the supporters of the doctrine were themselves doubtful if either bronzing of the skin or disease of the supra-renal capsules were at all essential to the supposed malady. And if they abandoned the bronzing, and abandoned the disease of the capsules, there could be no longer an Addison's disease.

Dr. WILKS said, in reply, that although there might be a difficulty in explaining the symptoms, yet the fact of the disease being foretold in so many instances, left the truth of Addison's statements incontrovertible.

Dr. BRISTOWE was surprised to hear that Dr. Harley considered that the question as to the existence of Addison's disease had been decided in the negative. He (Dr. Bristowe) had no doubt whatever about it. He had seen patients die with the symptoms described by Dr. Addison, and had found, after death, no disease except of the supra-renal capsules.

Dr. HARLEY again asked if bronzing was an essential symptom or not?

Dr. WILKS replied that it was not absolutely essential.

Dr. HARLEY then asked if it was essential that there should be no disease of any other organ?

Dr. WILKS said, that in all the cases which he had seen, the only other disease found had been a little tubercle; but he knew of no reason why it should not be found associated with other morbid conditions.

Dr. RISON BENNETT then related a case of Hydatid Disease of one Capsule. The other was healthy. There had been no bronzing of the skin, and no other symptoms of Addison's disease. But in two other cases, Addison's disease was diagnosed during life, and, after death, the capsules were found to be diseased.

[The remainder of the report of this meeting is in type, and will appear next week.]

NEW PRIZE QUESTION.—The Paris Hospital Medical Society proposed the following subject for the Phillips prize of 1000 francs:—"Establish by means of positive facts the prophylaxis and curability of the form of meningitis termed 'tubercular.'" Essays, written in French, to be delivered to M. le Dr. Lailler, Secrétaire de la Société, 22, Rue Caumartin, before April 12, 1866.

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH, WESTMINSTER, JAN. 25.
(Sittings in Banco, before the LORD CHIEF JUSTICE, Mr. Justice CROMPTON, Mr. Justice BLACKBURN, and Mr. Justice MELLOR.)

EX PARTE SERGEANT V. THE GENERAL COUNCIL OF MEDICAL REGISTRATION.

THIS case raised an important question, under the Medical Act, 1858, affecting the Medical Profession. Under this Act a registry is to be kept of Medical Practitioners; and it is declared to be the duty of the registrars to keep it correct, and to erase the names of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses or qualifications of the persons registered, every person legally qualified according to the Act at the time of the passing being entitled to claim registration; and to enable the respective registrars duly to fulfil the duties imposed upon them, the registrar is to write a letter to any registered person, addressed to him according to his address on the register, to inquire whether he has ceased to practise or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter, his name may be erased; provided also that the same may be restored on the direction of the General Council, should they think fit to make an order to that effect. And by another section the Council have power to strike off the names of Practitioners whom they shall, after due inquiry, judge to have been guilty of infamous conduct in any Professional respect. And only those who are registered are to be deemed duly and legally qualified Practitioners. In this case the applicant was qualified and registered at the time of the passing of the Act; but the usual annual letter having been since sent to him addressed to his last place of residence, it had received no answer within the six months (owing to a change of address), and the Council proceeded to strike out his name. In Trinity Term last he applied for a *mandamus* to the Council to restore his name under their general power to do so, "if they should think fit;" but the Court doubted if this raised a legal duty to do so, so as to render them liable to a *mandamus*. They, however, granted a rule *nisi* under another section of the statute, to hear and determine on his application to be registered *de novo* on due proof of his possession of the requisite legal qualification.

Mr. M. Smith, Q.C. (with him Mr. Horace Lloyd), appeared on the part of the Council to show cause, urging that, if the application were acceded to, the result would be that Practitioners who had been struck off for misconduct would be able to insist on reinstatement.

The Court, however, pointed out that by the Act the registrar is only to insert the names of Practitioners if satisfied by proper evidence that he is entitled to registration, which he would scarcely be in the case supposed; and,

The Lord Chief Justice put the case of a Practitioner whose name was struck off through mere *laches* or neglect on his part in not answering the usual letter. Surely, he was not to be excluded for ever from the practice of his Profession?

Mr. M. Smith said the Legislature had entrusted these eminent persons who constituted the Council with such powers, and it was not to be presumed that they would improperly exercise them.

Mr. Henry James appeared in support of the rule; and after some discussion,

The Court said the question was one of far too much doubt and too great importance to be decided summarily either way, and the *mandamus*, therefore, had better issue, with a view to raise the question regularly upon the record, so as to admit of its due argument and deliberate determination. The Court, without calling on Mr. James to support the rule *nisi*, made it absolute for a *mandamus*.

VICE-CHANCELLORS' COURTS, JAN. 22.

(Before Vice-Chancellor Sir J. STUART.)

GOODWIN V. BRAINE.

This suit, which was instituted for carrying into effect the trusts of the will of the late Mr. Atkinson Morley, formerly the proprietor of the Burlington Hotel, in Cork-street, came before the Court upon further consideration. The testator by his will gave £50,000 to trustees, upon trust, to purchase

therewith a piece of land within seven miles of St. George's Hospital, for the purpose of erecting thereon a Convalescent Hospital in connexion with St. George's Hospital, and to which poor convalescent patients were to be sent for a period not exceeding six months. St. George's Hospital was empowered by Act of Parliament to take by will land, or money to be laid out in land, provided all the lands held by the Hospital did not exceed in annual value £20,000.

Mr. Greene, Q.C., and Mr. J. W. De L. Giffard were for the plaintiff; and Mr. Bacon, Q.C., Mr. Malins, Q.C., Mr. E. Hawkins, and Mr. C. T. Simpson, for the other parties interested.

The Vice-Chancellor directed proposals to be laid before him at chambers for a scheme for carrying into effect the trusts of the testator's will as to the sum of £50,000 bequeathed by him for founding a Convalescent Hospital in connexion with St. George's Hospital.

OBITUARY.

JONATHAN OSBORNE, M.D., M.R.I.A.,

PROFESSOR OF MATERIA MEDICA AND PHARMACY IN THE SCHOOL OF PHYSIC IN IRELAND.

IN our last impression it was our melancholy duty to chronicle the death of the esteemed Vice-President of the Royal College of Surgeons in Ireland; before the week closed, another member, likewise holding a public position of some importance, was removed from the ranks of the Profession, in the metropolis of the sister isle. Dr. Osborne, for many years King's Professor of Materia Medica and Pharmacy, and Physician to Mercer's Hospital, died on Saturday, the 23rd instant, at his residence at Blackrock, near Dublin. He was a member of the Royal Irish Academy, and of the Royal Society of Quebec. He graduated in the University of Dublin as M.B. in 1818, and as M.D. in 1837. His writings, which are not voluminous, consisting chiefly of contributions to the *Dublin Journal of Medical Science*, are characterised by originality of thought, and by classical learning. In proof of our statement we would refer more particularly to his paper on "Albuminous Urine," published in 1851, and to those on "Some Actions Performed by Voluntary Muscles, which by Habit become Involuntary," which appeared in 1859. According to Act of Parliament, the Professorship rendered vacant by Dr. Osborne's death cannot be filled up until after the expiration of three months.

Dr. Osborne's funeral took place on the 26th inst. The following members of the Medical Profession attended:—Professors Law, Smith, M'Dowel; Doctors Croker, Kennedy, Duncan, Wilme, Bevan, Stokes, Corrigan, Banks, Jacob.

DR. ROBERT GEORGE HARDWICK.

There will be but one feeling of deep regret in the town at the announcement of this event. Dr. Hardwick was a native of Leeds, had studied at the Leeds Medical School, had subsequently taken distinguished honours in the Medical examinations of the London University, had held the office of House-Surgeon to the Leeds General Infirmary during four years, and had settled for the last four years in Leeds as a Physician. His high attainments and testimonials secured him the appointment, against a formidable competition, to the post of Junior Physician at the Leeds Infirmary. Dr. Hardwick was also Physician to the Leeds Dispensary and to the House of Recovery, and Lecturer on Medicine at the Medical School. Though only just turned thirty years of age, and not long established, he was beginning to gain a good practice, and was generally looked upon as a rising man in his Profession. On Thursday last he was seized with inflammation of the bowels, which became so violent that, though attended by several of the ablest Medical men in the town, his case was regarded yesterday morning as almost hopeless. During the day he continued to grow weaker, and died at seven minutes past twelve o'clock this morning. His loss will be felt in the town by a considerable body of patients, and by the Medical School and Infirmary, with which he had been in different capacities for many years honourably connected, as well as deeply lamented by a large number of private friends. He was married about three years ago to Miss Cook, Richmond, Yorkshire, and leaves, besides his widow, two infant children.—*Leeds Mercury*, January 19.

THE LATE MR. SMYLY.

MEMORIAL ADDRESS BY DR. STOKES,

DELIVERED AT THE MEATH HOSPITAL AND COUNTY DUBLIN
INFIRMARY.

ON Tuesday, January 26, instead of the usual clinical lecture, Dr. Stokes, the Senior Physician to the Meath Hospital, delivered, in the Lecture Theatre, an address in memory of the late lamented Mr. Smyly, who had been for so many years connected with the Hospital, and latterly as the Senior Surgeon. Amongst those present were:—Mr. Porter, Mr. Maurice Collis, Mr. Wharton, Dr. Philip Crampton Smyly and Mr. Macnamara, Surgeons to the Hospital; Rev. William Greene, Dr. Collins, Dr. Quinan, Rev. Dr. Marks, Dr. Alexander Marks, Mr. F. Lowe, Mr. Sweetman, Dr. Churchill, Mr. Robert Wilson.

Dr. STOKES said—Gentlemen,—We meet here to-day to do honour to the memory of him whose remains we followed so lately to the grave, whose death we all feel to have been a misfortune to society, to the interests of Irish Surgery, and to ourselves individually, whether as friends, colleagues, or pupils. Yet let us not mourn as men without consolation. In this life it is wisely ordained that few things can happen to us which, when they are made the subjects of an earnest reflection, fail to show that in God's dealings with us he can make good to come out from apparent evil, and hope for the future happiness of man on earth from all his judgments, dark and inscrutable though they be. For now we have to interrupt our daily work, and pause to study the best and brightest object of all things earthly—the life of a good man, one of ourselves, whose labours we can sympathise with, whose difficulties we can understand, whose command of his Professional knowledge we have so long admired, whose charities to all, and whose delicate sense of the right, were so large and so manifest. When I look back on my Professional life, nothing seems so strange as the havoc which death has made among the Physicians and Surgeons of Dublin who flourished when I was a young man. If we take this Hospital merely from the year 1826, when I was elected to the post of Junior Physician, the death-roll is appalling. We have lost Roney, Hewson, Colles, Macnamara, Graves, Crampton, Porter, Ledwich, Rynd, Lees, and now Smyly; and, adding the deaths of Dr. Harkan and my father, we have thirteen deaths of officers of the Meath Hospital since 1826—that is to say, one death in somewhat less than every three years. But let us look at the mortality of the Profession in Dublin during the same time—Cheyne, Carmichael, Colles, Wilmot, Cusack, John Crampton, Peile, Marsh, Kirby, Greene, Harrison, Houston, O'Beirne, Curran, MacDermot, Power, Williams, Neligan, Robert Shekleton, Douglass, Orpen, Brooke, Litton, Jackson, Lebat, Leahy, Keran, Hunt, Barker, O'Brien, Sargeant, Nunn, Stoker, Romley, Lynch, Tagart, Stack, Peebles, Bellingham, Montgomery, and Osborne. Now, I have to say that this list of names does not embrace the half of those members of our Profession who have died since 1826, and by whose death-beds it was my misfortune, or my privilege, to have stood. Excluding those who have not been distinguished by their contributions to Medicine, we have this result, that during the last thirty-eight years we have lost one distinguished man for about every year. This is a startling result. We are now to turn to the loss of nearly the last of these true soldiers of Medicine. I say nearly the last, for, while I am now speaking, the remains of Professor Osborne are being carried to their last resting-place. Let me here observe, that many of those whom I have now mentioned attained to a good age, and died as full of honours as of years, and in the schools of Ireland their names are as household words. But, on the other hand, the wear and tear of Medical life is not to be overlooked. The chances of death from pestilential disease which our brethren have to meet as devoted, and, I grieve to say it, too often sacrificed, soldiers, are terrible, and are as yet unrecognised by their country. Let us look back to the epidemics of 1847 and 1848, when it was proved by the most careful statistical researches that, during the epidemic, 500 Medical men throughout the country suffered from fever, for the most part contracted in the discharge of their Medical duties among the poor; and again, that during one year death struck down nearly one-fifteenth of the entire Medical community of Ireland. You will pardon me for this digression. It has a close

relation to the business of this day. Many circumstances concurred to place Mr. Smyly in the highest rank in our Profession. He was the child of parents in the middle class of society—that class which, when it is rightly viewed, must be admitted to be the highest, the source of the greatest virtue, happiness, talent, and power. He obtained the degree of Bachelor of Arts in the University of Dublin; and this I beg you to take note of, for all experience shows that University education is one of the circumstances which help men to rise in Medicine—first, from the effect of proper mental training; and next, from the social position that is thereby attained. In this place I have already spoken of the status which the Profession in Ireland, and especially in Dublin, has long enjoyed; a result which is in a great measure to be attributed to the wise determination of the University of Dublin to confer no degree of Medicine without the full education in arts. And you will remember that at the opening address which Mr. Smyly delivered only three months ago in this theatre, he advocated the great importance of University education to the Medical student. After having studied Surgery in the schools of Dublin, under the auspices of Sir Philip Crampton, his maternal uncle, he spent a session in Edinburgh, and then proceeded to pursue his studies in the Hospitals of Paris. He was soon after elected as Surgeon to this Hospital, being then 27 years of age. Like most of those of our brethren who have built up the reputation of the Irish School of Medicine and Surgery, Mr. Smyly, notwithstanding the pressure of a large and increasing practice, added largely to the literature of his Profession, by a succession of papers which appeared in the *Dublin Quarterly Journal of Medicine and Surgery* and in the *Dublin Hospital Gazette*. In the 3rd and 4th volumes of the first of these serials we have his "Memoirs on Lithotrity;" in the 11th volume, a paper on "Erysipelatous Laryngitis;" in the 18th volume, a case of the rare accident of the dislocation of the metatarsal bones downwards and backwards; in the 26th volume, two papers, "On the Median Operation of Lithotomy;" in the 27th, a most important communication, "On the Compound Fracture of the Patella;" in the 28th, an important report "On the Operation of Thoracentesis;" and in the 34th, a memoir "On Stricture of the Urethra;" and in the following volume, so late as May, 1863, we have the record of his large experience of the operation for strangulated hernia. Turning now to the *Dublin Hospital Gazette* we find the following contributions:—1. "On Amputation in Popliteal Aneurism, when Compression Failed." 2. "On Benign Osteo-Sarcoma." 3. "On Diseased Stump." 4. "On Strumous." 5. "On Pelvic Tumour." 6. "On the Condition of the Arteries in Potts' Gangrene." 7. "On Dislocation of the Forearm outwards." The enumeration of these papers is sufficient to show the bent of his mind, and his desire to add to the stores of Surgical knowledge; they are not to be dismissed, however, with a bare enumeration. If we refer to his case of the dislocation of the metatarsal bones, we find that it occurred in his practice eleven years before the record of Mr. Tufnell of a similar accident, differing from it, however, in this, that the whole range of metatarsal bones was dislocated, causing a more extensive laceration of the ligaments, and again, permitting a more efficient use of the extending powers than could be applied in Mr. Tufnell's case, in which only three bones were displaced, the two which remained *in situ* impeding and resisting extension. In this paper, while he gives Mr. Tufnell the credit of priority in the description of this accident, he takes blame to himself for not at the time putting his own case on record. An important paper is on the operation for lithotomy, as advocated by Mr. Allerton. To this the name of the median, as distinguished from the lateral operation, has been given. He is strongly in favour of this method, and successfully shows that the immediate dilatation of the prostatic portion of the urethra, especially in children, is feasible and safe, the operation being thereby comparatively easy and harmless. By this method, he says, we escape,—1st. The danger of hæmorrhage. 2nd. The wound is not likely to bring on peritonitis. 3rd. Urinary infiltration cannot occur. 4th. The operation being not so severe, there is much less shock to the system. 5th. Therefore less likelihood of hectic fever. 6th. The wound does not become fistulous. 7th. There is no possibility of rectal fistula. Turning to his memoir on paracentesis of the thorax, I may observe that of this operation he had a large experience, and in it a singular success. I believe that he was the first Surgeon in this country who followed the method of Dupuytren, getting rid of the painful, tedious, and often dangerous process of the division of the intercostal muscles. The instru-

ment consisted of a semi-cylindrical canula, a lancet of the same form, together with the exhausting apparatus, so adjusted as to prevent the entrance of a bubble of air into the chest. His three most important papers are those on compound fracture of the patella, on stricture of the urethra, and on strangulated hernia. These are all of the highest value, and are, like those which precede them, models of that style in which the truths of Medicine and Surgery should be conveyed. They remind us of the papers in the Old Dublin Hospital Reports, from such masters as Cheyne and Colles, Wilmot and Cusack, Graves and Porter, M'Dowell and Adams. They are distinguished by clearness and moderation, without the approach to self-laudation, or a word of inflated language. This admirable style of writing was long characteristic of the Irish School of Medicine and Surgery. Let us never cease to uphold it, and in so doing follow in the footsteps of those great men who have won for their Profession and their country such lasting honour. I have shown you that Mr. Smyly did not neglect to add to the record of Medicine and Surgery. As an Hospital officer, we all know how conscientiously he performed his duties. Diligent in his visiting, gentle, charitable and painstaking; distinct in his diagnosis; calm, collected, and humane in the hour of operation; teaching as much, or even more, by example than by precept, he moved year after year in the circle of his duties among us, "clear in his great office." His presence repressed whatever was coarse or bad; he encouraged the good by example, while, without ostentation, he laboured for all who were entrusted to his care. Before we leave the contemplation of his Medical character, it is right to notice his advocacy of the principle of total abstinence from alcoholic drinks in the case of the healthy man. For many years he was a total abstainer; but this course he took solely as a means of discouraging the vice of drunkenness in others. I am anxious to say a few words on this matter, because some have believed that he carried his views on this question to the verge of fanaticism. Thus his character as a Physician has been, by a few, impugned as that of one who withheld stimulants even when they were called for in disease. That such was not the fact I can aver. No man knew better when, as in fever and other cases of debility, stimulants were called for. I never knew him object to them in consultation, or withhold them when required. To do so would have been quite opposite to the nature of his Medical mind, which was always practical and right judging. Now, while all must admire the motive which actuated him in the adoption of the total abstinence system in his own person—a matter, as I have shown, quite distinct from his use of stimulants in the treatment of disease—it is right to inquire whether the advocates of total abstinence do not occasionally fall into error. I have long come to the conclusion that the most common cause of the disease of old age, or at least the most common and important complication with them, is an enfeebled state of the heart. And I believe that when a man arrives at the age of sixty or upwards without local or organic disease, he should, if he wishes to live to the natural period of human existence, take his generous glass of wine. How many cases of slow decay of the nervous powers, whether of mind or of muscular motion, we do not see associated with this condition! A large number, too, of cases of the so-called determination of blood to the head, causing paralysis and apoplexy, are in reality the result of the very opposite condition—a deficient and enfeebled circulation in the brain. Venous congestion, hepatic enlargement, cardiac asthma, some forms of dropsy, mortification of the extremities, and other evils, may be traced to this cause, or are associated with it. And there is nothing wonderful in this. Look at the living heart, that from its period of microscopic formation in intra-uterine life, to its last throb when the old man dies, is the only organ that never sleeps—that never rests. Look at the gigantic amount of force thus produced. Take 70 beats in the minute, multiply that by 60, and you have one hour's work; multiply that by 24; that result by 365; that even again by 70—the threescore years and ten—and you have the total pulsations of the heart in a man's life amounting to 2,575,440,000. Yet, if we seek to estimate the amount of work done by the human heart during this same period of threescore years and ten, the results are more wonderful. Professor Haughton, in his recent "Researches on Muscular Force," has calculated that the force exercised by the heart during twenty-four hours equals that which would lift 124 tons one foot vertically. If we multiply this by 365, and again by 70, we get this result, that, in the life of a man of seventy years, the work done

by his heart is equivalent to that which would raise upwards three millions of tons a foot. What wonder that this little organ should be the first to show exhaustion! What wonder that this exhaustion may go to a great length, even though the rest of the body be in apparent health! In the life of Cornaro we see that, as he approached the age of 100 years, he greatly diminished the use of animal food, but he always took his wine. Now, to apply this to ourselves as members of the Medical Profession. We are to remember that of all walks of life there is, perhaps, none in which mind and body suffer such wear and tear. None but those who are in full practice as Consulting Surgeons and Physicians in a metropolis, or, again, as the overworked and harassed country Surgeon, harassed and driven under a cruel law, by rich as well as poor, can know how often nature fails under the pressure of the day's work. Therefore, I wish you not to let the candle be burned at both ends. Avoid intemperance, for that is debilitating more than abstinence; but remember, that for mental and physical effort there must be a right proportion between the expenditure and the supply. No one knew this better than Mr. Smyly; but he was a rare instance of constancy in whatever course he thought calculated to further God's work upon earth, and so he made his life a continued and a willing sacrifice. Gentlemen, as we have profited by the life of him so lately taken from us, let us try to make his death also fructify to good. We cannot better bring our minds into a fit state for looking rightly at this matter than by reading from that Holy Book which was the study and the guide of his life, and thus we may read:—

"Blessed is the man that feareth the Lord, he hath great delight in his commandments."

"Unto the godly there ariseth up light in the darkness; he is merciful, loving, and righteous."

"For he shall never be moved, and the righteous shall be had in everlasting remembrance."

"He will not be afraid of any evil tidings, for his heart standeth fast, and believeth in the Lord."

"He has dispersed abroad, and given to the poor, and his righteousness remaineth for ever. His horn shall be exalted with honour."

In the Profession of Medicine, we may observe various and distinct classes of men: some seem to pursue it solely as a means to obtain wealth and worldly position, self being their object and guiding star; others, of a nobler order, adopt it as a liberal and honourable Profession, and if they rise to eminence, it is with the concurrence and good wishes of their brethren, and of all good men. It is in this class that we find the greatest number of the good, the useful, and the deservedly eminent members of our Profession. Another class adopt it as a necessity—as a means of earning a narrow and painful subsistence—and in this class we may find some of the noblest, bravest, and best of men. Another class cultivate Medicine, as well as its accessories, as matters of purely scientific investigation, and look on the patient as a specimen of pathology, rather than as a suffering brother. Now, though such men do great good in advancing Medicine and its collateral sciences, yet they are not Physicians. But there is a class or order of men in which it would be a privilege to be enrolled. Here we find men who either devote a large portion of their income to charity, or, if they accumulate wealth, determine to bequeath it for some noble purpose. With them, money has value only as a means of doing either immediate or posthumous good. Dublin can boast of men of this class. Let me name Sir Patrick Dun; Dr. Mosse, the founder, and we may say the endower, of the Lying-in Hospital; and Dr. Steevens. Each of these Physicians have left behind them the monuments on which their names must always exist: Sir Patrick Dun, as the endower of chairs for the teaching of Medicine and its accessory sciences; Mosse, for the foundation of our noble Lying-in Hospital; and Steevens, for that great establishment which bears his name, and that of the pious sister who carried out his last wishes—

Ricardus Steevens, dotavit,
Griselda Steevens, soror ejus,
Ædificavit.

Yet, much as we may admire that wish to leave our earned wealth for philanthropic purposes, we may ask, is it not perhaps a nobler, because a more self-denying course, to contribute day by day to the immediate necessities of our kind, than the securing the privilege and *prestige* of a lasting monument to our personal character and name? I believe that it is so. At least, those who adopt such a course cannot be accused of the longing to have their names honoured in this world—an

instinctive feeling, no doubt, but one which, without offence to the memory of the illustrious men and Physicians I have named, has been for them satisfied. But there is a charity of another kind, preached by our Redeemer—that in which the right hand is not to know what the left hand doeth—taught by Him who has said that a cup of cold water given in His name shall in no wise lose its reward. What say you to a life, and that not a short one, thus earnestly and unflinchingly spent? What are we to think of one who made all his powers, all his knowledge, all his disciplined patience and labour, to serve the cause of his and our Father, of his and our Christ, and to enlarge by his life and his labour the boundaries of the kingdom of love? Gentlemen, in this country of Ireland, where true history reads like a romance—the nursing mother of religion and of letters in the dark ages—the centre from which the light of the Gospel irradiated over Western Europe, torn by kingcraft and religious wars for a thousand years—vanquished, but never conquered—still divided by political strife and religious animosities—it was his fate to be born, and to have come to his manhood just at the time when Ireland was awakening from the state of torpor and collapse which followed on the events of 1800. He believed that there was one thing needful for all—the knowledge of Christ crucified, in whose fold there can be nothing but peace. It was his longing—and I speak that which I know—to labour for the end, remote though it might be, to make of his country “the city that had no need of the sun, neither of the moon, to shine on it—but the glory of God did lighten it, and the Lamb is the light thereof.” It was natural that, with such deep convictions, with such unswerving constancy, with such a power and mastery over the inclinations of our nature, with such activity in the cause believed by him to be the right one, and occupying a high position in his Profession in a country so circumstanced as this is, he should be considered by many as one of those—unhappily so plenty in Ireland—who are influenced by sectarian feelings and old political animosities—feelings from which, God be thanked, our Profession at least is singularly free. Yet nothing can be more remote from the truth than this view of his character. I have often heard him speak on these matters, and I tell you that he was no bigot. He was a true Catholic, and sought to serve his kind, no matter to what denomination of religious belief any of them might adhere. I have heard him say that the cause for which he so laboured was often imperilled and influenced by indiscretions in controversy, by want of charity, by want of humbleness of mind, by ignorance of human nature, by want of respect for those feelings which old traditions engrave on the heart so deeply that they become, as it were, a part of our mental and almost physical nature, and pass from father to son. All this is true; and whatever the world may think of the wisdom of the course he elected to adopt—whatever it may hold as to whether we are yet in a position to argue, as from incontrovertible evidence, on many points of religious doctrine, it must award him the exalted merit of devotion to what he believed to be the truth, and admire the example of a life of pure love of his country and of his kind—a love only second to that for Him whose life he strove to imitate, so far as it was possible for erring and sinful man to do. Gentlemen, in the rolls of the departed Physicians and Surgeons of our Hospital, there are many names that our country and our Profession must remember with pride, as having been enabled, when called by their Master, to return the talents entrusted to them with interest. With sorrow and with pride, we may now inscribe another name in that long roll of honours.

REPORT ON SARRACENIA PURPUREA IN SMALL-POX.—A committee appointed by the New York Medical Society to report upon the recorded experience as to the merits of the sarracenia, arrives at the following conclusions:—1. That the analyses already made of the plant do not give any active principle or element which would indicate any Medical potency. 2. That the discoverers and advocates of its specific remedial power have apparently given too great credit to the *post hoc* circumstances as being *propter hoc* influences; one reason for this latter inference being suggested by the loose, unscientific, and eulogistic style of the communications. 3. That the reliable recorded experience appears to preponderate against the remedial efficacy of this plant in those forms of the disease which do not generally recover under the administration of ordinary remedies.—*American Medical Times.*

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 26th inst. :—

Charles Durrant Pearless, East Grinstead; William Henry Power, Queen-square, Bloomsbury; Jean Baptiste Blanchet, M.D., and Master in Surgery, Univ. Montreal, Quebec; Thomas Hewlett Worger, Chiswell-street, Finsbury; Charles Thomas Dalley, Markfield, Leicestershire; Thomas Graham Bennett, Brighton; and Alexander James Low, Jersey, students of St. Bartholomew's Hospital; George Eastes, Folkestone; Samuel Forest Leach, Mile-end; William Cubitt Lucey, Bermondsey; John Jones Phillips, Towyn, N. Wales, of Guy's Hospital; John George Waters, Cheshunt; and Edward Colden, Wandsworth-road, of St. George's Hospital; William Wigmore, Oswestry, of the London Hospital; Richard Hughes, Llanddeniolen, Carmarthen, of King's College; George Henry Watson, Jersey, of St. Thomas's Hospital; John Gordon Couiter, M.D. Queen's Univ. Ireland, Belfast; George Shannon, M.D. Queen's Univ. Ireland, Magherafelt, Co. Derry; John Edwin Eddison, Leeds; David Palmer Ross, M.D. Edin., Penang, East Indies; John Roaf Ireland, Kingswinford; and Charles Carr, Newcastle.

And on the 27th inst. :—

William Cheetham, Rochdale; James Skackleton, Whitworth, Lancashire; and Charles John Denny, Aston, Warwickshire, students of the Manchester School. James Joseph Rablah, Walsall, Staffordshire; Frederick Powell, St. John's Wood; and Eugene St. Paul Hadwen, Waterloo-road, of the Westminster Hospital. Albert Egerton Hale, Nantwich, Cheshire; John Lloyd, Birmingham; and William Daniel Dunn, Devonport, of the Birmingham School. Samuel Morris, Preston, and Thomas Griffiths, Merthyr Tydfil, of St. Thomas's Hospital. Samuel Roath, M.D. Queen's University Ireland, Chesterfield, and Richard Thomas Freeman, Hatcham, of Guy's Hospital. George Henry Cresswell Cooper, Woburn-place, of University College. John Swinburn Anthony Dickinson, Norfolk-street, Middlesex Hospital. Hermann Boerhaave Holman, Crediton, Devon, London Hospital. William Battye, Plymouth, of St. Bartholomew's Hospital. Robert George Gamage, Sunderland; William Frederick Watts, Dewsbury; William Wallace Somerville, Wakefield, and George William Harrison, Whitechurch.

At the same meeting of the Court, Mr. Henry Ashlin Close, of H.M.S. *Royal Albert*, Plymouth, passed his examination for Naval Surgeon; this Gentleman had previously been admitted a Member of the College, his Diploma bearing date April 11, 1859.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, January 21, 1864 :—

Warner Atkinson, 22, Harrington-square, N.W.; Frederick McNair, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALDRIDGE, CHARLES J., M.R.C.S. Eng., has been appointed Surgeon to the St. Pancras and Northern Dispensary.

BAYLIS, CHARLES O., M.D. Aberd., has been appointed Medical Officer of Health for Birkenhead.

CARTER, R., M.R.C.S. Eng., has been appointed Resident Medical Officer to the Eastern Dispensary, Bath.

CAVANAGH, JAMES W., M.R.C.S. Eng., has been elected Honorary Medical Officer to the North Dispensary, Liverpool.

CONNOR, WILLIAM, M.B., has been appointed Medical Officer to the Royal Victoria Patriotic Asylum and Boys' Temporary Home, Wandsworth-common.

LANGDON, THOMAS C., M.R.C.S. Eng., has been elected Surgeon to the Hants County Hospital, Winchester.

OXLEY, WILLIAM, M.R.C.S. Eng., has been elected a Medical Officer of the Rotherham Dispensary, Yorkshire.

ROBINSON, EDWARD, M.R.C.S. Eng., has been elected a Medical Officer of the Rotherham Dispensary, Yorkshire.

SIMS, F., has been elected an additional Dental Surgeon to the Birmingham Dental Dispensary.

WATTS, F. H., M.R.C.S. Eng., has been appointed Resident Apothecary to Middlesex Hospital.

WILSON, J. C., M.D., has been appointed House-Surgeon to Chalmers' Hospital, Edinburgh.

DEATHS.

FEARNLEY, GEORGE, M.D., at Grove-house, Dewsbury, Yorkshire, on January 8.

HOBART, S. HENRY, M.B. Dub., at Marlborough-street, Cork, on January 16.

HONEYWOOD, JAMES, M.R.C.S. Eng., at Blackfriars-road, London, S., on January 20, aged 45.

LÛE, J. BLACK, M.D. Aberd., at Castle-street, Hereford, on January 17, aged 76.

OSBORNE, JONATHAN, M.D. Dub., at Clermont, Blackrock, Dublin, on January 22.

PALK, WILLIAM, M.D., at Union, Missouri, United States, on January 1, aged 63.

REES, DAVID, M.D., at New-cross, Deptford, on January 20, aged 83.

RIND, M. McNEILL, Deputy Inspector-General of Hospitals, Saugor-circle, at Saugor, Central India, on December 17.

THE ELECTION TO THE COURT OF EXAMINERS AT THE COLLEGE OF SURGEONS.—The friends of Mr. Gulliver complain that, before the late election, every means was adopted which could prejudice his chance of success. They state that an active canvass was set on foot by certain supporters in the Council of Professor Partridge, and that unfounded statements were inserted in some of the Medical journals to the effect that Mr. Gulliver, not being a Surgeon to any Hospital, would probably not present himself for election, and that the contest would be between Messrs. Partridge and Hilton. We need scarcely state that this assertion did not emanate from Professor Gulliver, and had no foundation in truth. Mr. Gulliver abstained from everything like a solicitation of votes; he never opened any communication with any member of the Council on the subject, and was content that his claims should stand on their own merits. That our readers may judge what these claims were, we append a list of some of Mr. Gulliver's services and contributions to Surgical and pathological knowledge. We omit in the list his larger labours in the higher branches of animal and vegetable physiology, which are universally known, and to which our own pages have in the last two years borne ample evidence. Mr. Gulliver was a long time in charge of the General Military Hospital at Fort Pitt, performing all the Surgical operations there. For upwards of twenty years since he was never without charge, in the regular course of duty, of other Military Hospitals. He made great part of the museum at Fort Pitt and of the catalogue thereof. He had there the superintendence of numerous junior Medical officers, with whom he always maintained the most friendly relations. When he left the army, and ever since up to this date, he was engaged in a small, but active Professional practice amongst his old military connection, never seeking to extend it, because he possesses independently ample means, and is attached rather to the scientific pursuits of his Profession than to its more lucrative department. Amongst his published papers on Surgery and Surgical pathology are—"Experimental Inquiries concerning Necrosis," *Med.-Chir. Trans.*, 1836; "Discovery of the Softening of Coagulated Fibrin as a Pathological Element Distinct from Pus," *Med.-Chir. Trans.*, 1839; "Discovery of the Fatty Degeneration of Arteries, Testes, Lungs, etc., and that this Disease is the Proximate Cause of Aneurism, Sanguineous Apoplexy, and Decay of the Tissues," *Med.-Chir. Trans.*, 1843; "On the Reparation of Fractured Bones," *Edin. Med. and Surg. Journal*, 1835; "On Shortening of the Neck of the Femur in Young as well as Old People," papers in different numbers of the *Edin. Med. and Surg. Journ.*, 1836; "On Fracture of the Femur, with Inversion of the Limb," *Ibid.*, 1836; "Experimental Inquiries concerning Fracture of the Patella, showing under what Conditions Union by Bone will or will not occur," *Edin. Med. and Surg. Journal*, 1837; "On Diseased Joints in the Army Medical Museum," *Edin. Med. and Surg. Journal*, 1837; "Experimental Inquiry concerning Buffy Blood," *Ibid.*, 1845.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a General Meeting of the Fellows, held on Tuesday, January 26, James Alderson, M.D., F.R.S., Treasurer of the College, was duly elected Representative of the College in the General Council of Medical Education and Registration of the United Kingdom.

COLLEGIATE ELECTION.—At a special meeting of the Council of the Royal College of Surgeons on Friday last, Professor Partridge, F.R.S., was elected a member of the Court of Examiners in the vacancy occasioned by the decease of the lamented Joseph Henry Green.

THE UNIVERSITY OF DUBLIN V. THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.—The arguments in this case in the Rolls Court have concluded, but the Master has reserved judgment. It is not likely that the decision of the Court will be pronounced for a week or ten days.

THE LATE MR. SMYLY.—The funeral of the late distinguished Surgeon took place on January 23. The remains were conveyed at nine o'clock, from the residence of the deceased in Merrion-square, to Mount Jerome Cemetery. A very large number of carriages followed the hearse. The chief mourners were Mr. Philip Crampton Smyly, Mr. Smyly, Q.C., brother of the deceased, and Mr. Thomas Franks. A large number of the most eminent members of the Medical Profession and of Medical students were present. The latter walked in procession, followed by the children of the Ragged Schools, in which Surgeon Smyly took a lively interest. The

funeral service was read by the Rev. C. F. M'Carthy, and an address was delivered by the Rev. M. Day.

RETIREMENT OF SIR JOHN LIDDELL.—Sir John Liddell, the distinguished Director-General of the Medical Department of the Navy, has been compelled by advancing age and impaired health to resign the position which for many years he has worthily filled. He is succeeded by Dr. Bryson, Inspector-General at Somerset House, an officer who is well known for his contributions to the Medical statistics of the navy, and for his labours in the field of epidemiological science.

CHANGES IN THE STAFFS OF THE METROPOLITAN HOSPITALS.—Dr. Kirkes has succeeded to the vacant Physiciancy, and Mr. Holmes Coote to the vacant Surgeony, at St. Bartholomew's. The latter gentleman has resigned the Assistant-Surgeoncy at the Orthopædic Hospital. The offices of Assistant Physician and Assistant Surgeon to St. Bartholomew's are vacant. There is also a vacancy for an Assistant Physician at the Hospital for Sick Children, Great Ormond-street.

SCHOOL OF PHYSIC IN IRELAND.—At a meeting held on Tuesday, January 26, in the University of Dublin—present, the Rev. the Provost of Trinity College, the Regius Professor of Physic, and the three electors chosen by the King and Queen's College of Physicians in Ireland (the President, Drs. Croker and Mollan)—Dr. John T. Banks was again elected King's Professor of the Practice of Physic.

PROFESSOR HUXLEY, F.R.S.—This gentleman will resume his course of twenty-four lectures on "The Structure and Classification of the Mammalia," in the theatre of the Royal College of Surgeons, on Tuesday next, commencing with the Zoological Anatomy of Man, with especial reference to the bony skeleton and the muscles; the resemblance and difference of the pectoral and pelvic limbs; the characters and the nomenclature of the teeth; the brain and the organs of sense and voice; the organs of reproduction, and the process of development; variations of structure.—The Comparative Anatomy of the Apes and Lemurs—The Insectivora, Cheiroptera, and Rodentia—Remarks upon the Classification of the preceding groups—The Carnivora—The Ungulate Mammals—The Sirenia, Cetacea, and Edentata—The Proboscidea and the genus Hyrax—Remarks upon the Classification of the preceding groups—The Marsupialia—The Monotremata—Remarks upon the Classification of the Mammalia generally.

THE FARRINGTON GENERAL DISPENSARY AND LYING-IN CHARITY.—Dr. Frederick Cock has resigned the office of Physician to this Dispensary. At a meeting of the Committee of the Dispensary, held on Thursday, January 7, Mr. Harvey in the chair, it was moved by Mr. J. L. Shuter, seconded by Mr. S. Green, and resolved unanimously, "That, in recognition of the long, valuable, and efficient services rendered to this Institution by Frederick Cock, Esq., M.D., he be elected Consulting Physician thereof."

ODONTOLOGICAL SOCIETY.—At the annual general meeting held on the 4th inst., the following gentlemen were duly elected officers for the year 1864:—*President*—Edwin Saunders, Esq. *Vice-Presidents (Resident)*—T. A. Rogers, Esq., W. A. N. Cattlin, Esq., W. Imrie, Esq., W. Perkins, Esq., G. A. Ibbetson, Esq. (Non-Resident)—C. S. Bate, Esq., Plymouth; W. K. Bridgman, Esq., Norwich; S. Tibbs, Esq., Cheltenham; Dr. Roberts, Edinburgh. *Treasurer*—Arnold Rogers, Esq. *Librarian*—J. B. Fletcher, Esq. *Honorary Secretaries (Ordinary)*—Alfred Coleman, Esq., Charles Vasey, Esq. (For Foreign Correspondence)—Thomas Underwood, Esq. *Councillors (Resident)*—W. D. Saunder, Esq., J. Sheffield, Esq., W. A. Harrison, Esq., C. J. Fox, Esq., H. T. Kempton, Esq., R. T. Hulme, Esq., J. Tomes, Esq., W. M. Bigg, Esq., F. W. Rogers, Esq., G. Owen, Esq., A. Hill, Esq. (Non-Resident)—D. Hepburn, Esq., Edinburgh; C. D. Rogers, Esq., Newbury; S. L. Rymer, Esq., Croydon; G. Buchanan, Esq., Glasgow; E. P. Parkinson, Esq., Brighton; W. Hunt, Esq., Yeovil. The President, in his address, congratulated the members on the present satisfactory condition of the Society, evinced by its numerical strength of 319 members, and the balance of £546 8s. 8d. in the hands of the treasurer at the end of the last session.

CIDER IMPREGNATED WITH LEAD.—A case of death from drinking cider which had been allowed to stand in a cider-mill that had been lately repaired with lead, is reported from Powick, in Worcestershire. Four or five persons who drank the cider were taken ill with symptoms of lead poisoning.

At a late meeting of the Metropolitan Association of Medical Officers of Health, the following correspondence was laid before the members. There are not many persons aware that the Board of Trade has a control over the water companies:—

Offices, Maltby-street, Bermondsey, January 5th, 1864.

Sir,—By direction of the Vestry, I beg to forward you the copy of a letter which has been received from the Board of Trade, in reply to the memorial addressed to that Board in November last by yourself and other householders of the parish, respecting the quality and quantity of the water supplied by the Southwark and Vauxhall Water Company to this district.

I am, Sir, your obedient servant,

J. J. RICHES, Assistant Clerk.

COPY.] Office of Committee of Privy Council for Trade,
Whitehall, December 26th, 1863.

Sir,—I am directed by the Lords of the Committee of Privy Council for Trade to transmit to you, for the information of the Vestry, and of the householders who signed the memorial dated 11th November last, respecting the quality and quantity of the water supplied by the Southwark and Vauxhall Water Company, the accompanying copy of a letter which my Lords have addressed to that Company on this subject.

I am, Sir, your obedient servant,

LOUIS MALLET, Pro Sec.

The Assistant Clerk, Bermondsey Vestry
Offices, Maltby-street, E.C.

COPY.] Office of Committee of Privy Council for Trade,
Whitehall, December 26, 1863.

Sir,—I am directed by the Lords of the Committee of Privy Council for Trade, to inform you that on the 13th November last their Lordships received from certain inhabitant Householders of the Parish of St. Mary, Bermondsey, in the County of Surrey, a Memorial (copy of which is enclosed), complaining of the impure quality and insufficient quantity of the water supplied in that district, by the Southwark and Vauxhall Water Company.

In pursuance of the 9th Section of the Metropolis Water Act (15 and 16 Victoria, c. 84), My Lords appointed Captain Tyler, R.E., to inquire into the grounds of that complaint, and to report to their Lordships thereupon; and my Lords have now received from Captain Tyler his report upon the matter so referred to him, a copy of which is herewith enclosed.

Upon a consideration of that report it appears to their Lordships that the complaint of the Memorialists is well founded; and I am therefore directed, in pursuance of the 12th section of the Metropolis Water Act, 1852, hereby to give notice thereof to the Southwark and Vauxhall Water Company, and to point out to you that after the receipt of this notice the Company are, by the 13th section of the same Act, required, within a reasonable time, to remove the grounds of such complaint.

I am to request that the receipt of this notice may be acknowledged, and to state that my Lords will be glad to be informed of the steps which the Company propose to take in the matter.

I am, Sir, your obedient servant,

(Signed)

T. H. FARRER.

The Secretary, Southwark and Vauxhall Water Company,
Battersea.

THE WEAR AND TEAR OF MEDICAL LIFE.—For the most part, young Medical men commit a great mistake on first starting. They overhouse themselves. Their establishment eats them up. They have not the courage to live in a small way. Then they marry too early. It is a virtue on their part, and speaks volumes in their favour; but house expenses are certain, and Professional returns uncertain. Children must be fed: servants must be paid. The wife likes the habits of a lady, decorates her rooms, and receives her friends; while her husband lives in the streets, that he may sleep in a mansion. For a mansion it is to him, that vast pile of bricks and mortar, for which he pays an enormous rental, and which he has furnished beyond his need. For the sweets of life are unknown to him. He toils only for his daily bread. He has no time for visiting. He never can receive properly. His occupations unfit him for doing so. His real post, and the one in which he shines, are the sick chambers of the wealthy and the hovels of the poor. Add to these eccentricities and burdens an equipage—a shining, well-turned-out equipage. This is the climax of folly, that has brought many a general Practitioner to the ground.—*Hingston's Topics of the Day.*

JUVENILE SUICIDES.—During the past week, two lads, one aged 12, the other 15, have been charged before the police magistrates with attempts to commit suicide. The younger was found suspended by the neck; the elder tried to poison himself with white precipitate. In neither case was any cause or provocation assigned for the act. The lad of 12 had made a former attempt on his life, and for this reason was sentenced by the magistrate to a week's imprisonment. The most probable theory to account for such cases is, that they are the result of the too general publication of cases of similar crime by the cheap press. Fill the imagination and stimulate the imitative faculty in the young, weak-minded, and morally uneducated, with recitals of crimes, and they will be in as much danger of reproducing them as sheep are of following each other over a precipice. We believe this to be the true explanation of many so-called cases of suicidal and homicidal monomania.

WORSE THAN LONDON.—New Yorkers were tormented yesterday by one of those terrible dust-storms that make winter dreadful. Whether the election for Mayor has anything to do with it, we cannot say; but the fact that dirt has of late rapidly accumulated in the streets is manifest. Made thoroughly dry by the frost, and pulverised by hoof and wheel, it is ready for a rise at the first puff of windy provocation. Yesterday we had a crazy young tornado lying around loose, and about ten thousand tons of dirt were hoisted into the air, and tossed hither and thither all day and night, filling the town with a cloud of the consistency of a shoddy blanket, obscuring the sun, and making gaslight needful at mid-afternoon. Going abroad was like wading a slough; blinded and choked by dust, one stumbled along at risk of his neck, until the wild sweep of the hurricane around some exposed corner for a moment tore the veil, and let the sickly daylight upon his weeping eyes; and then he saw a close likeness to the sea in a great storm, as the billows of dirt swashed against the brick shores, and fell back in foul spray upon the imbedded walks. But why attempt to describe the indescribable? At night the storm was still worse; but the blessed darkness made us oblivious, in some degree, to the affliction. If the sweep of wind has been across the city, Boole is relieved of a heavy job, although the harbour commissioners may have to dredge the East river, to remove the enormous deposit. The only storm at all comparable with this was the storm of hard words over blinded eyes, sneezing noses, coughing throats, and spoiled clothes, got up by a million wrathful sufferers.—*N. Y. Tribune, Dec. 10.*

EARTHQUAKES.—“Amongst the many natural gifts referable to geographical position and geological structure with which Great Britain has been so lavishly endowed by Providence, none has been more important (though little recognised) in permitting our national development, than our immunity from frequent or severe earthquakes. We may in this respect, but in a different sense from him of old, ‘thank God that we are not as other men are.’ A single shock, no greater in violence than those which occur almost monthly within less than 2000 miles of us (in the Mediterranean Seismic Bands)—one, namely, the velocity of whose wave particle should be no more than twelve to fifteen feet per second (not so fast as we sometimes move in a carriage), would not only split and prostrate minster, spire, and column, but would leave Manchester, Liverpool, or London, mountainous heaps of brickdust and rubbish. Terrible as are the consequences of such utter overthrows in the cities of other lands, our artificial conditions would add new horrors to the overturning of our own; for, besides the conflagration that almost always succeeds the downfall, ignited by the buried fires or lights, we should have superadded, the falling in of great sewers, with the overflow of their polluted streams amidst the ruins; the damming, more or less, of great tidal rivers like the Thames, by falling bridges; burst and spouting water mains; gas escaping and exploding in all sorts of cavities amidst these overground ‘goafs;’ viaducts and iron bridges brought to the ground by their own inertia; tunnels collapsed; coal and saltpits and mines ruined; roof and floor in a moment brought together;—complications of horrors such as can be even but inadequately imagined. Happily there is little chance of such a catastrophe. Enough has already been ascertained as to the distribution in space over the earth's surface of Seismic or earthquake energy, to admit of our affirming the extreme improbability of the occurrence of any great earthquake in the British Islands; but there is no physical reason why such an event might not occur tomorrow.”—Mallet on “Earthquakes;” *Quarterly Journal of Science*, No. 1, January, 1864.

NOTES, QUERIES, AND REPLIES

He that questioneth much shall learn much.—Bacon.

The termination of Dr. Simpson's Lecture on Acupressure is unavoidably postponed until next week.

The Medical History of Lynn will appear in one complete notice next week.

We can only publish the letter of "Justitias" on the condition that he will append his name.

A Subscriber.—The small edition of the new British Pharmacopœia will not be published until next month. The contents will be the same in both; the price of the large edition is 10s. 6d.; of the small, 6s.

Mode of Heating Turkish Baths.—A correspondent of the *Northern Daily Express* writes:—

"I have often heard the fear of fire in Turkish baths expressed, and, from the faulty manner in which they are constructed, I do not wonder at it. Many such fires have occurred in different parts of the country, and it will be recollected that about three years ago a fire occurred in the bath of your Infirmary. Since then that bath has been reconstructed on a new, safe, and economical principle, which I shall presently refer to. The plan adopted in most of our Turkish baths is the 'Hypocaustum' of the Romans, that is, a series of flues ramifying about under the floors, by which a baker's oven sort of bath is obtained. These flues cause everything in their neighbourhood to get red hot; hence great danger is necessarily engendered from fire, and not only so, but danger to life and limb of the bather likewise. Many accidents of the latter description have occurred. One case occurs to my mind as having taken place in the Infirmary, in which a bather slipped and fell down, and so severely burnt himself as for a time to put his life in danger. But this is not all, for the ventilation in all these hypocaust baths is most wretched, and frightfully injurious to bathers, and the poisons generated on the hot floors are of the most noxious description. There ought to be in all these baths a constant stream of hot fresh air flowing in, and proper provision made to ensure the constant flow out of the foul air into the furnace below, and, as far as may be, cool floors, and a good but subdued light. All these are now available in the method of heating and ventilating, patented by Dr. Bolton, and which is fully set forth in a small pamphlet published by Ward and Lock, of London. Many baths have been altered or built on such a reasonable and logical method, among which I may mention your Infirmary bath, and the bath recently completed at Colonel Perkins', Birtley Hall. I append a quotation from the specification of Dr. Bolton's patent, in the Patent Office, so that your readers may see that it is possible to get in a hot-air bath something very different from fire and foul air:—"The fresh respirable air travels in an opposite direction to the fire heat and smoke in separate and distinct flues, in the manner of the arterial and venous circulation of the blood. The air is heated by being made to travel throughout its course in an opposite direction to the smoke current, the closest contiguity being maintained between the two currents. The effect of this is, the abstraction of caloric from the smoke throughout its course, and the prevention of smoke escaping into the fresh air duct; so that, in the event of leakage, air will always enter the chimney, instead of smoke escaping into the air duct."

ATROPINE GELATINE PAPER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Lancet* of the 16th instant there appeared a notice of a new mode of applying some external agents to the eye which I have lately brought before the Profession, in which my claim to its introduction was not in any way recognised. I then addressed a letter to that journal, which was not allowed to appear, and therefore I shall be much obliged if you will permit me to publish it in the *Medical Times and Gazette*.

The receipt of my letter was briefly acknowledged among the notices to correspondents in the *Lancet* of the 23rd instant. The editors remark that Mr. Hart and I have "followed a pretty parallel course," but they acknowledge my priority "of publication," which certainly is indisputable.

I am, &c. J. F. STREATFIELD, F.R.C.S.

15, Upper Brook-street, W., January 25.

TO THE EDITOR OF THE LANCET.

"Sir,—My attention has just been called to an article in the last number of your periodical (Jan. 16th). In it the reporter of Mr. Hart's cases at St. Mary's Hospital has made an error which may be easily explained, and which calls for some notice from me. He has evidently reported some remarks made by Mr. Hart in reference to an article recently published by me, as if they referred to Mr. Hart's own investigations. The communication to which I am alluding is in the *British and Foreign Medico-Chirurgical Review*, page 231, published on the 1st of January in the present year.

"I am glad to learn from Mr. Hart's remarks that he has found the gelatine so great an improvement upon the paper, that my 'new mode of applying some external agents to the eye' was quoted by him in almost the same words, and at any rate in the sense, in which I had recommended it in the *Review*. In the following paragraphs, for instance, I have said, 'It has occurred to me that an improvement might be made if we could secure, along with the convenience and efficacy pertaining to the paper, some vehicle which would not need to be removed from the eye after it had been applied and the desired result had been gained. I may allude to the alarm felt by some patients at any investigation of their eyes, even if only to remove the scrap of paper that has been introduced, and to the trouble sometimes found in removing it when it has got up beneath the upper lid. In order to obtain what I wanted, I first tried what is called

"wafer paper," but this is brittle when dry, and loses all consistence when wet, so that it becomes unmanageable as soon as it is moistened, and, moreover, the pulpy substance in the eye, if not washed out, might irritate. I am now employing gelatine, rolled out in sheets of the thickness of thin writing-paper, and imbued with a definite proportion of sulphate of atropine or any other salt required. This retains the advantages of, and only requires the same mode of application as atropine paper, but it need not be removed from the eye. It is soon dissolved in the tears, and acts in every way well,' etc.

"Other errors on the part of the reporter could be pointed out; for instance, Mr. Hart cannot have represented the matter as if I had expected to find the 'wafer paper' soluble.—I remain, etc.

"J. F. STREATFIELD.

"P.S.—I must claim for Mr. Squire the merit of having first prepared the gelatine imbued with atropine. It was suggested by me to him about two months ago—I cannot exactly fix the date; but an invoice which he has sent to me, dated December 7, shows that it was then delivered and supplied to me as I now use it, and have since supplied several of my friends who were willing to try it experimentally.

"January 16, 1864."

ICE TO THE SPINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In Swinhoc's "Narrative of the North China Campaign of 1860" occurs the following passage:—

"Among the Chinese themselves, it [ice] is much used to lie upon during the heat of the day. The ice for this purpose is crushed and scattered over the stove-couch, whereon it is then covered with a mat, on which the native casts his body as soon as he has divested himself of superfluous integuments; and thus released, refreshes himself with a cool siesta until the sun partially withdraws his mid-day heat, and enables man again to renew his energy."—Pp. 188, 189.

In a paper published in the *Boys' Own Magazine*, on "Alpine Ascents," it is stated that, "to refresh themselves, the guides thrust snow-balls down their backs—a means of refrigeration which does not appear to have any ill effect upon them." This practice is said to be resorted to when the climbers are at great heights.

A gentleman with whom I am acquainted, the son of a London Physician now deceased, informed me that, having suffered from acute rheumatism and pericarditis, he has been since peculiarly liable to palpitation of the heart and easy excitement of the vascular system; that when in Switzerland some time ago, he attempted the ascent of one of the mountains, and was seized with a violent palpitation, with great general excitement of the circulatory system and extreme distress, and that in this condition he was stripped of his coat by his guides, and made to sit with his back towards a large fire, which speedily and completely relieved him.

These facts are very curious instances of long-established customs which are in harmony with Dr. Chapman's theory and practice of applying ice and heat to the spine, which are proved thereby to have a sound empirical basis. I hope you will think them worth registering in the *Medical Times and Gazette*.

ALCOHOL AND ITS COMPOUNDS IN TYPHUS FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As this subject has been brought somewhat prominently before the Profession of late in the *Medical Times and Gazette*, and as the facts relative to it are of great importance to the Profession, we have to regret, even at the beginning of the inquiry, that some abler penman had not taken up the subject, in order that justice might have been done to it. Be this as it may, we think we have seen enough to convince the most sceptical that there can be no mid-way with so powerful an agent as alcohol; it must either be beneficial to our patients or hurtful, and, if hurtful, we must all acknowledge that it is still abused to an enormous extent by our Profession; for, as one of the writers in a late number of the *Medical Times and Gazette* somewhat sarcastically remarked, "some Practitioners give alcohol almost in every disease, from a fever to a broken leg." As we are not among those who believe that alcohol is useful in all diseases or under all states of those diseases, perhaps space will be granted us to give our opinion and experience; and, in doing so, we will not strive at fine writing, as we have a more important object in view; nor will we enter into the chemical labyrinth of the discussion as to whether alcohol is food to the system or caloric—whether it passes out of the system unchanged—or whether, in its ethereal permeation of the organism, it have a preservative effect on the tissues, retarding waste—preserving nerve force. These are knotty points, and we are not far from the truth when we say that, were we so baffled with the inquiry as to ask for authority, we could get many great names to support each and all of these opinions; and truly, when this is the case, there is little use in quoting authority. We, therefore, choose to take common observation for our guide, and would ask our Professional friends if they have not all observed that, when a very abstemious man, say up to twenty-five or thirty years of age, begins to indulge moderately in alcoholic liquors, he begins, not long thereafter, to become more bulky in appearance, and to weigh heavier; but though this be a part of common observation, we do not mean to say, or even to think, that this extra amount of fat or flesh is worth much, or, in fact, worth anything in keeping up the vital powers in a healthy person—in all probability it is of a vitiated kind, and is more likely to clog those powers than assist them. Still it is evident that, whether alcohol pass out of the system unchanged or changed, it has the power of making a change on it, for there is no gaining the fact, that people do get fatter under the influence of alcoholic compounds. With regard to typhus fever, we think the Profession are agreed that, when once fairly established, it will run a definite course despite of remedies.

In treating a case of typhus fever, then, our principal aim seems to be to put our patient in such favourable circumstances with regard to quietude, food, air, cleanliness, and medicaments, as will assist in averting the tendencies to death. These tendencies are a changed and alkaline state of the blood, with unhealthy secretions and excretions, congestions, inflammations, putrescences, exhaustion of the vital powers, and failure of the heart's action; hence the propriety of administering emetics, mild laxatives, diuretics, acids, and alcohol. But we do not give alcohol to support the patient's strength in the common acceptation of the term, because we have far better substances for doing that in beef-tea, chicken-soup, etc.

We give alcohol to support and assist the action of the weakened heart. We give it as a cardiac stimulant to support that quick ebbing of the vital stimuli so characteristic of typhus fever of an adynamic type; and this is the rock on which our Profession still split. Many among us still persist in giving large quantities of alcohol nearly all along in typhus fever by way of keeping up the patient's strength;—an old fallacy, which the sooner the Profession discard from their minds, the better it will be for their patients. We insist that alcoholic compounds should only be given to support the failure of the heart's action; thus given they may, like faithful sailors at the force-pump, keep the shattered bark afloat till it has reached its safety haven—till a crisis has taken place. But does alcohol really support the failure of the heart's action?—for I am afraid we have as yet been begging the question. All of us, then, must concede the fact, that the beat of the weakened heart becomes stronger, and the rhythm more regular or natural, under the influence of alcohol. And we also know that more warmth is diffused over the whole body, and that the capillary vessels of the skin assume a more healthy and natural appearance. We have seen the livid or pink-like capillaries of the skin in a case of scarlet fever assume a bright scarlet colour in a few hours under the use of alcohol. We to a certainty know, then, that under the influence of alcohol the heart becomes more powerful in propelling the arterial current to all parts of the system, which must of necessity tend to prevent congestion or stagnation of blood in those parts, and must, at the same time, tend to keep up their nutrition, and must, consequently, assist in warding off the beginnings of death. We may rest assured, then, that alcohol given in disease at the proper time is no myth; and it is, therefore, of great importance to watch carefully for that time, that we may not be too long in beginning to give stimulants, for if we allow our patient to sink very low before we begin to give them, ten to one if the vital powers of the system will react under their influence. Our practice has been to begin to give stimulants in typhus fever when the pulse has begun to get weak at the wrist, lifting quickly under the finger, and, along with this, when the first sound of the heart has begun to get weakened in force and shorter in sound. We are only reiterating the observation of others, then, when we say, that whenever the pulse becomes small at the wrist, lifting quickly under the finger, and, along with this, the first sound of the heart begins to fail, is shorter than natural, less audible to the ear, the two sounds, as it were, nearly combined, but the second louder and more distinct than the first, we will do well to give stimulants, whatever our preconceived opinion of them be.

I am, &c.

THOS. DOWNIE, M.D., L.R.C.P. Edin. by Exam., L.S.P.S. Glasg.
Blantyre, January 14.

ALCOHOLIC STIMULANTS IN FEVERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Mr. Harding's further insinuations upon the treatment of my case of typhus fever, and upon the principles involved in that mode of treatment, demand additional reply.

First, with regard to the case itself. I have submitted his own report of it to Mr. Higginbottom, F.R.S., of Nottingham, who, in a letter to me, says:—"Were I to express an opinion upon your case, I should state that your patient died from exhaustion from the administration of wine and brandy, and this from my experience of half a century." This opinion was unsolicited; I did not ask for it.

Secondly, with regard to the principles upon which I have acted. It is rather amusing to see the cool way in which Mr. Harding ignores the views of Mr. Higginbottom, supported as they are by his experience of half a century, and corroborated by many intelligent members of the Profession. If every new truth is to be set aside because "it is contrary to the received opinions," we shall soon do away with all improvements in our art, and there will be an end of all further progress. Is the condition of Medicine so perfect as to need no improvement? Is the treatment of typhus fever by port wine (with an average mortality of about 20 per cent.) so satisfactory that a plan which promises more success is not needed? There is as great a truth in the non-alcoholic treatment as there is in the discoveries of Harvey and Jenner; and let me remind Mr. Harding that they, in their day, were contrary to the "received opinions." They had the whole mass of the Profession against them. Medicine abounds with such instances. A very considerable portion of our progress has been made by the *un*teaching (so to speak) of established error. The history of Medicine for hundreds of years proves my assertion. The truth is no less true, although Mr. Harding may not see it.

The non-alcoholic treatment of typhus has now been an established fact for years. It has been practised by many members of the Profession with marked success, notwithstanding his assertion of only one; and it is a remarkable fact, that the only cases of exhaustion that have occurred under this system have been those in which wine has been administered surreptitiously. Mr. Harding is evidently not in a position to judge of this plan, since he has never tried it. The great mass of the Profession have been educated in the opposite school, and they are naturally slow in changing their opinions. Some of our best discoveries have been made by obscure individuals, with the whole mass of men against them. And that orthodox systems in Medicine are not always to be implicitly relied upon there is ample evidence to prove in the history of the last century. Any one advocating the advanced views of Dr. Bennett, of Edinburgh, a few years ago, would have been looked upon with equal "horror and astonishment" to the non-alcoholic Practitioner of the present day.

Mr. Harding very correctly traces the course of alcohol into the stomach, where it is absorbed without digestion, and into the blood-vessels, where, presently coming into contact with the heart, it excites it to increased action. But its operation does not stop here. Did it never occur to him that this increased action was followed by a corresponding depression very speedily,—a peculiar state of alcoholic exhaustion? What is the essence of delirium tremens but a state of nervous exhaustion from the use of alcohol? Besides, in fever, alcohol poisons the already-polluted stream of life. This is only increasing the mischief; to poison and depression it is adding poison and depression. I suppose this is acting upon the mistaken homœopathic law of "*similia similibus curantur*." Well may Mr. Higginbottom call port wine an "exhausting stimulant." It is highly probable that the port wine is the real exhausting influence in many cases, and not altogether the disease. Vitalised blood is the true stimulant of the heart; and, in typhus, our chief object should be to promote its renewal by the ingestion of true nutriment, which forms blood. All the brandy in existence will never, under any circumstances, make one drop of blood. The true vital stimulants are, fresh air abounding with oxygen, and nutritious food; and there is a remarkable difference between the action of these and alcohol, inasmuch as they do not produce exhaustion or narcotism. Quinine is an infinitely better medicine in fever than alcohol, for it acts as a true tonic, whose effect is lasting, while the effect of the latter is transitory and exhausting.

That alcohol is a narcotic in very small doses is shown by the fact, that a glass of ale will often make a person sleepy (especially if the sensibility of the nerves has not been deadened by its frequent use). It is often used for this purpose, as a common expression is—"I could not sleep without my glass of ale." In the case of opium, which is a type of the narcotic class to which it belongs, a stimulant operation precedes the sedative; so it is with alcohol, but the stimulant property is very transitory; exhaustion and narcotism soon follow. The term "stimulant," in its true sense, is not applicable to alcohol, seeing that its action is widely different to the true stimulants.

There is a fearful amount of moral and physical ruin resulting to mankind from this Medical use of alcohol. Too many cases of drink-produced woe, both within and without the pale of the Profession, are traceable to Medical advice in the use of alcoholics. This is perfectly unjustifiable, since ample experience has shown the use of them to be unnecessary. The diseases are exceptional, and very few in the whole nosology, in which "drink" is not the almost universal prescription both of the most eminent of the Faculty and of the public. One would almost think that it was only necessary to drink so much brandy to be free from every disease. Dr. Carpenter, in his "Human Physiology," says that "this indiscriminate use of alcoholics by the great mass of the Profession is one of the greatest pieces of quackery of the day."

Mr. Harding lays much stress upon the dose of alcohol, and insinuates that small doses must produce an altogether different effect to large ones. I beg to inform him that the effect varies only in degree, not in direction. A large piece of beef or bread is just as much a nutriment as a small piece. The difference is only in quantity. A small dose of alcohol is just as much a poison as a large one. The difference is in quantity, not in quality. Thus, Dr. Edward Smith, F.R.S., in 1859, said: "I venture to affirm that, for all medicinal and dietetic purposes, the dose (alcohol) only affects the degree, and not the direction of the force. Poisoning may differ widely in degree, according to the quantity of the poisonous agent. In the case of the pestilential poisons, it may pass from an almost imperceptible effect, up through the various degrees of intensity, until it culminates in the highest degree, the disorganisation of death." What unprejudiced man will say the smaller quantity is any less a poison?

Independently of the exhaustion of the nervous system which must speedily follow the administration of alcohol, it carbonises the blood, and thus renders the system liable to the action of this additional narcotic influence.

Mr. Harding has entirely misinterpreted M. Baudot's experiments. They amount to no proof at all. His inferences, as Dr. F. R. Lee says, are "mere assumptions from a negation." Lallemond, Perrin, and Duroy never professed to collect the whole quantity of alcohol ingested. No instrument in existence will collect the whole quantity, after being mixed up with the blood and tissues. Besides, M. Baudot is bound to collect the products of the decomposition of alcohol, aldehyde, acetic acid, and water; and this he has entirely failed to do. Any person may prove the elimination of alcohol from his person after drinking, by the sulphuric acid and bichromate of potash test. The truths of abstinence have not been in the least injured by these experiments. Can Mr. Harding not smell the alcoholic-tainted breath of one who has been drinking? Here is another plain proof of the elimination of alcohol. Nature is not so inconsistent as to eliminate one portion of a poison, and then to turn round upon itself and appropriate the remainder as food.

I admit the primary action of alcohol as an exciter of the nervous system, a so-called "stimulant," but this action is so speedily followed by exhaustion, as to render alcohol a most undesirable medicine in cases of nervous prostration from disease. This exhaustive action of alcohol has been too little thought of. In the treatment of fever, let the stimuli of a more permanent character be used, such as are not followed by exhaustion or narcotism. Herein we differ.

The facts—the experiments that I quoted in my last letter have an important bearing upon the subject, since it is by the action of substances in health that we have to a great extent ascertained their *modus operandi* in disease. No one can satisfactorily use medicines without knowing their action in health. As a general rule, a poison will poison more readily in a case of nervous prostration from disease than in robust health; and I think that ʒss. of Scheel's prussic acid would more readily extinguish life in a state of nervous prostration than in health, and the same with many other poisons. The inference that Mr. Harding has chosen to draw from my statement, belongs entirely to himself. I am not responsible for his inferences. I may here remark that there is not the least analogy between the cases of alcohol, strychnia, and opium. These two latter are useful medicines, whose value no one disputes. Many dispute the utility of alcohol. Besides, strychnine and opium are never used both as food and medicine for every conceivable complaint as alcohol is.

There are many Medical men, to my own knowledge, who are practising upon abstinent principles, and who have not appeared in this discussion. As much as ten years ago a London Surgeon of fifty years' standing in the Profession strongly advised me to make trial of these principles.

Mr. Harding seeks information about the treatment of parturients exhausted by hæmorrhage. He will find much information upon this subject (probably new to him) in the writings of Mr. Higginbottom, F.R.S., to which I refer him.

Mr. Harding seems to have modified his views since his last letter from a condition "of perfect horror and astonishment at any Practitioner treating disease, and especially fevers, without alcoholics." He now endeavours to set aside the experience of Mr. Higginbottom upon the gratuitous assumption, "that the cases were of an inflammatory type, not requiring stimulants." Surely the cases have not been all alike, happening, as they have done, over a period of fifty years? Mr. Harding again asserts that "the experience of one man ought not to be set against the whole Profession." It is not a case of one man; there are many. And, perhaps, they belong to the reflecting few upon this alcoholic subject. Here is another discrepancy in Mr. Harding's assertions. It is a very short time ago that he denied the opinion of the Profession was divided upon this matter.

I fear that there are few, very few cases in the records of Medicine in which alcohol has cured *per se*. It is highly probable that there are none if the truth could be known.

From the new volume of "Braithwaite's Retrospect," just out, I make the following extracts from a paper, by Dr. J. Henderson, as bearing upon this matter:—

"Typhoid Dysentery.—Typhoid symptoms commence within a few days, along with great prostration and brown tongue, Wine, brandy, ammonia, camphor, and opium seemed, in many cases, useless. Quinine, when retained, appeared to do good. As there is increased alkalinity of the

blood, with alkaline urine, Dr. Henderson gave hydrochloric acid, along with bitter tonics and laudanum, with great success. The use of same acid in all cases of fever, attended with low typhoid state, will be found an admirable adjuvant to other modes of treatment."

I will conclude this letter with one or two extracts from Mr. Higginbottom's writings, which I may equally commend to Mr. Harding's serious consideration:—

"Alcohol in every form may be dispensed with in Medical and Surgical practice, and is not required in a single disorder or disease."

"I should consider myself criminal if, in any case, I again recommended alcohol, either as food or as medicine."

The following extract is particularly applicable to Mr. Harding. Let me especially call his attention to it:—

"When a patient is in a sinking state from disease, and when a Medical man has thought an 'alcoholic stimulant' absolutely necessary to snatch the patient from death. In this case the great danger is that such a stimulant will extinguish the small spark of life remaining, and that the patient will be destroyed,—it was truly said of the Brownian system, that Dr. Brown had made no provision in his system for the recovery of exhaustion arising from the effects of taking alcoholic stimulants."

I am, &c.

Stourbridge, January 12.

R. L. BAYLEY.

NEW COLLEGE, OXFORD, CHORAL SCHOLARSHIPS.

An examination for the purpose of electing two Choral Scholars will be held on Tuesday, February 16 next.

The duty of the Choral Scholars is to take part daily in the Chapel Service, which is Choral, as in Cathedrals.

The Scholarships are of the annual value of £100, inclusive of rooms and tuition, and are tenable for five years, a power being reserved to extend the term.

The Choral Scholars are on the same footing, and enjoy the same privileges, as the other Scholars of the College.

It is particularly requested that no one will offer himself as a candidate who does not possess a good Alto or Tenor voice, and a facility of reading Church music at sight.

A candidate must also be qualified by a classical education to proceed with the regular studies of the University.

Candidates should be not less than eighteen, nor more than twenty-two years of age.

Certificates of birth and baptism, and testimonials of character, must be sent before the day of examination to the Warden, from whom also may be obtained a form to be filled up by the candidates.

New College, Oxford, January 22, 1864.

COMMUNICATIONS have been received from—

BOOKS RECEIVED.

The Teeth in Health and Disease: with Practical Remarks on their Management and Preservation. By Robert T. Hulme, M.R.C.S., F.L.S., etc., etc. London: H. Baillière. 1864. Pp. 236.

* * * The author of this little work is already favourably known to the Dental Profession by several original papers and lectures which have appeared in the *Dental Review*, and to the Medical as the translator of Moquin-Tandon's work on "Medical Zoology." The present treatise, although written in a popular manner, is, in reality, a very fair epitome of the chief facts relating to the anatomy and physiology of the teeth, and a sensible digest of present opinions as to the nature and treatment of their diseases and deformities. The section on the treatment of caries contains some good hints on the preparation of the cavity of the decayed tooth for stopping. In many unpromising cases, Mr. Hulme believes that, by adjusting a temporary stopping, *e.g.*, one made of cotton, with a solution of mastich in spirits of wine, and renewing it from time to time for a longer or shorter period, thus arresting the progress of the disease by preventing the access of the fluids of the mouth, sufficient time is given for nature to repair to a certain extent the injury by the formation under the decayed layer of new dentine, which will ultimately bear a permanent stopping. By this process the operation of opening the pulp cavity, and destroying the pulp before stopping, is avoided. "There can be no question," the author writes, "if it is possible to preserve the pulp and then stop the tooth, that such a tooth is in a far healthier condition than one in which the interior of the crown and the fang is filled with gold or any other foreign material. I am satisfied that many of the teeth which have been treated by destroying the pulp might, under another plan, have been preserved without sacrificing this essential portion of the organ. So long as there is a layer of dentine existing over the pulp, as a general rule it should never be removed." The author also has some good remarks on the treatment of caries of the milk teeth. He insists on the propriety of extraction in advanced cases, and on the error of allowing the tooth to remain a constant source of pain, gum-boil, and ill-health. On the whole, we think Mr. Hulme has performed well the difficult task of producing a book sufficiently popular in style to enlist the favour of the general reader, whilst its contents are quite worthy the attention of members of his own Profession.

The Medical and Surgical Reporter. Philadelphia. October and November, 1863.

* * * Besides the information contained in this publication, several inducements are offered to subscribers. The London *Lancet* is given at a reduced price, and vaccine virus gratis. Any one obtaining fifteen new subscribers, "with the money for a year in advance, will secure to the subscriber obtaining them a splendid pocket case of Surgical instruments, or add half a dozen volumes of standard Medical works to his library, with no expense for transportation." "In brief," says the Publisher, "send money; send United States money if you can, but send money."

Observations on Defects of Sight in Brain Disease, and Ophthalmoscopic Examination during Sleep. By J. Hughlings Jackson, M.D., etc., etc. Pp. 15.

* * * A reprint of some excellent cases from the Royal London Ophthalmic Hospital Reports. Some of them have already appeared in our columns. Dr. Jackson does not approach the subject in a specialist spirit, but "as a help to the study of diseases of the nervous system."

VITAL STATISTICS OF LONDON.

Week ending Saturday, January 23, 1864.

BIRTHS.

Births of Boys, 1063; Girls, 1013; Total, 2076.

Whole amount of rain in the week	0.47 in.

APPOINTMENTS FOR THE WEEK.

January 30. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m.

February 1. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital 1½ p.m.; Samaritan Hospital, 2½ p.m. EPIDEMIOLOGICAL SOCIETY, 8 p.m. Dr. Camps, "On the Hygiene and Epidemiology of the Indian Army, based on the Report of the Royal Commission." MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion. ODONTOLOGICAL SOCIETY, 8 p.m. Meeting. ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

2. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. "On the Construction of the Upper Jaw in the Skull of a Greenlander." By Professor C. G. Carus, with Notes by C. Carter Blake, Esq., F.G.S. James Reddie, Esq., F.A.S.L., "On Anthropological Desiderata, with Reference to the Origin of Man." PATHOLOGICAL SOCIETY, 8 p.m. Meeting. ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."

3. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Middlesex, 1 p.m.; London, 2 p.m.

4. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m. HARVEIAN SOCIETY OF LONDON, 8 p.m. Mr. W. Adams, "On the Pathology and Treatment of Fracture of the Patella." ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."

5. Friday.

Operations, Westminster Ophthalmic, 1½ p.m. MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of the Council. ROYAL INSTITUTION, 8 p.m. J. A. Froude, Esq., "On the Science of History." WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Mr. J. R. Lane, "Sequel of a Case of Vesico-Uterine Fistula, in which Pregnancy occurred after Closure of the Os Uteri by Operation."

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN,

By J. Y. SIMPSON, M.D., F.R.S.E.,

Professor of Medicine and Midwifery in the University of Edinburgh.

ON ACUPRESSURE.

(Concluded from page 85.)

THE HIGH MORTALITY FROM SURGICAL OPERATIONS—IS IT IN ANY WAY THE EFFECT OF THE LIGATURE OF ARTERIES?

The mortality attendant upon all the larger and severer varieties of Surgical operations is something quite striking and startling.

Out of 512 amputations of the limbs, that is to say, of the thigh, leg, arm, and forearm, performed in the Parisian Hospitals, from 1836 to 1841, and collected by M. Malgaigne, 281 proved fatal. In other words, 55 out of every 100 thus operated upon died; or more than 1 in 2. (*Archives Générales de Médecine*, tome 58, p. 389.)

Out of 2046 similar amputations of the limbs occurring in British Hospitals and private practice, collected by Dr. Fenwick, 524 proved fatal. In other words, about 26 in every 100 thus operated upon died; or 1 in 3.9. (*Monthly Journal of Medical Science*, for October, 1847, p. 238.)

Dr. Fenwick has collected together from civil and military practice in Great Britain, America, and France, a list of 4937 amputations of the limbs. Of these patients 1565 died; or 32 in 100; or 1 in 3.15. "The assertion," adds Dr. Fenwick, "that one person out of every three who suffers an amputation perishes, would have been repudiated a few years ago as a libel upon our Professional value; and yet such is the rate of mortality observed in nearly 5000 cases."

The latest and largest individual collection of the statistics of amputations of the limbs which I am acquainted with, does not display any great difference in the general result. Out of 291 amputations of the thigh, leg, arm, and forearm performed at Guy's Hospital, London, and published in 1859 by Mr. Bryant, 76 proved fatal, making a mortality of 26 in 100; or 1 in 3.8.

Far less severe and extensive operations than the dismemberment of a limb are followed by no small mortality when they include the ligature of a large artery. The Hunterian ligature of the femoral artery involves a clean incised wound about three inches only in length, and, perhaps, an inch in depth. Yet out of 204 cases, collected and published by Dr. Norris, in which the femoral artery had been ligatured by the Hunterian method, 50 died, or nearly 25 in 100, or 1 in 4. In 188 of these cases the operation was performed for the cure of aneurism, and 46 of these died, or 24 in 100, or nearly 1 in 4. (*American Journal of Medical Science*, October, 1849, p. 324.) Perhaps some of my Surgical brethren would be inclined to argue stoutly in reference to these statistics of the fatality attendant upon such a small operation as the ligature of the femoral artery, that the mode in which the operation was performed greatly influenced the result; that it would be much less fatal if greater care were taken not to disturb the ligatured vessel from its connexions to any degree above what was absolutely necessary to put a small round silk thread around it. But if this argumentation be true—as I believe it is—then it also follows, that if in this operation the vessel be much isolated or detached from its sheath—if a large or broadish ligature be used—or if a double ligature be adopted, as has been sometimes practised, the danger of the operation is greatly increased by such measures. These measures, however, amount to nothing more than an increase and exaggeration of the evil effects and dangers of the use of the ligature, by involving and producing a larger amount of ulceration, suppuration, and sloughing in the ligatured part of the vessel. The danger in the operation is, in other words, not so much the danger of the mere simple incision, as it is the danger of the deligation of the vessel, or rather of the mode and extent to which the vessel is disturbed and disordered by the mode of deligation adopted. At all events, in this instance it is the ligature of such a large supplying vessel as the femoral which is the source of peril and death in the operation.

VOL. I. 1864. No. 710.

The Special Source of Danger and Fatality in Surgical Operations.

In relation to these amputations and ligatures, and all other severe operations in Surgery, it is most undoubtedly true that the pathological state or disease which leads to a Surgical operation, is often much more the cause of the fatal result than the mere Surgical operation itself. The operation rather fails to save life than produces death. But still all large Surgical wounds and dismemberments of the body are sufficiently dire and disastrous in their consequences. We have already seen how greatly the presence and effects of the arterial sloughs produced by the ligature of vessels necessarily interfere with the local healing and primary union of wounds. But perhaps these ligatures and the strangulated pieces of tissue by which they are retained and affixed in the depths of the wounds, produce still more serious and grave results, by leading on in many cases to the excitement of formidable and too often of fatal constitutional fever, in consequence of the introduction into the general system of septic and ichorous matter placed by these ligatures in contact with the raw, absorbing surface of the wound.

Of patients dying after Surgical operations, some sink collapsed and exhausted before reaction supervenes, but the great mass of them do not perish under any purely Surgical complications, as gangrene, tetanus, hæmorrhage, etc. Out of 153 patients who died after Surgical operations or injuries at Guy's Hospital, and whose cases were ably analysed and published by Dr. Chevers, 18 or 19 only sank under purely Surgical complications such as the above; while in 134 of the 153, post-mortem examination found, as the more immediate cause of death, acute inflammatory and other morbid changes in different and distant internal organs or structures of the body, as the lungs, liver, pleura, peritoneum, joints, etc. These diffuse internal inflammations and lesions are the acknowledged results of that very frequent and fatal constitutional morbid state which Surgeons have latterly come to speak of under the various names of pyæmia, pyæmic fever, septicæmia, septic fever, traumatic fever, Surgical fever, etc. In one of the most deservedly-popular manuals of Surgery of the present day, Dr. Druitt defines this very common and very dangerous sequence of Surgical operations as "a diseased state of the blood, caused by the introduction of *decomposing animal matter*, often producing rapid effusions of fibrin or of puriform fluid into several internal organs." "The train of morbid phenomena constituting the disease are developed," says an eminent London pathologist, Dr. Kirkes, "by the introduction into the blood of the elements of pus, or other like disintegrating and *decomposing animal matter*." M. Berard briefly defines and names the malady by speaking of it as "*Fievre par resorption putride*." Dr. Tanner, again, tells us that this affection "is a morbid state of the blood, caused by the introduction into it of *ichorous or putrid matters*."

That in Surgical wounds treated by the process of deligation of arteries, there exists "*decomposing animal matter*," thus liable to be absorbed from the raw surface of the wound, and introduced into the blood and body of the patient, is a proposition not difficult to prove. Both (1) the ligatures themselves, and (2) the sloughing portions of the arteries which they strangulate and sphacelate, are foci from which such "*decomposing animal matter*" is most obviously derivable.

1st. *The Ligature Threads*.—In various experiments which I made some years ago upon the relative tolerance of the tissues of the living body for metallic and for organic suture threads, I found that threads of iron and silver, of silk and hemp, produced, as a general rule, nearly the same amount of irritation during the first two or three days of their insertion. After that time, however, had elapsed, there arose, as a general rule, around the tracks of the organic threads, more or less inflammation and suppuration, whilst the metallic threads did not excite such irritation by their continued presence. If either kind of thread, whether metallic or organic, happened to be so overdrawn as to compress the side of its track too tightly, that side always ulcerated, as I have already stated, as the result of the pressure. Making the experiments upon pigs, I further found, that when one of these organic or silk threads, which had been allowed to remain three, four, or more days in the lips of a wound, was taken out and inserted into the bottom of a new wound made upon the back of one of these animals, inflammation, sometimes of a furunculoid or carbuncular form, generally sprang up rapidly around the enclosed thread. Similar pieces of new silk thread inserted to similar depths in similar wounds on the opposite side of the body of the same animal, did not excite the same speedy and

unhealthy morbid reaction in the lips and sides of the wound. I believed at the time—and believe still—that the old suture threads were thus proved to be capable of being frequent sources of irritation and poisoning to the surrounding tissues, because, after being inserted in living structures for three or four days, they do what metallic threads do not,—namely, they swell from the imbibition of animal fluids in contact with them; and these dead, imbibed fluids speedily decompose and irritate the surrounding living tissues onwards to suppuration. The decomposing animal matters and pus thus retained in the thread rendered it, in the experiments I have spoken of, a nidus of irritation and poisoning to the surrounding tissues when it was buried in the centre of a recent wound.

But in the preceding respects, a silken thread applied to the deligation of an artery does not differ from a silken thread applied to the stitching together of the sides of a wound. A silken suture-thread is as good as an iron or silver suture-thread in cases where it can be safely removed within sixty or eighty hours of its insertion; but whilst the metallic thread for almost an indefinite time remains innocuous,—as far as regards the tolerance of the living tissues for it,—the retained silken thread or ligature, containing within its meshes imbibed decomposing animal matter, is always liable and ready to be a source of greater or less irritation to the textures with which it is in contact. Silken ligature threads, when tied around arteries, do not usually ulcerate through the texture which they strangulate till from four or five to twenty or even more days after they are applied. During that long period they necessarily contain dead animal fluids, and speedily imbibe the pus which is inevitably poured out along their tracks,—for they inevitably produce suppuration,—and they are thus amply provided, within their own meshes, with the materials of mischief, if these materials are, as we believe them (in the language of Drs. Druitt and Kirkes) to be, “decomposing animal matter.”

2nd. *The Arterial Sloughs.*—In wounds where arterial ligatures are used, another, and perhaps far more serious, source of such “decomposing animal matter”—of such “ichorous or putrid matters,” to use the words of Dr. Tanner—as are capable of exciting pyæmic fever, is to be found in the small sphacelating masses or sloughs made by the ligatures in the ends and stumps of the tied arteries. The ichorous putrid matter oozing from all soft tissues in a state of moist mortification or sloughing, is usually believed to be of an irritating and acrid nature. “Mortification,” observes Sir Robert Carswell, “of a portion of a limb succeeding to inflammation, to a mechanical injury, to an operation, is often followed by mortification of some internal organ. . . . The septic principle,” he adds, “is carried into the blood, and appears to give rise to a state of gangrene or sphacelus.”—(“Cyclopædia of Practical Medicine,” v. iii., p. 144.) “Putrid animal substances,” observes Dr. Robert Fergusson, “are amongst the most noxious poisons to the blood.”—(“Essays on the Most Important Diseases of Women,” part i., p. 75.) Dr. Fergusson makes this observation in regard to the cause and production of puerperal fever, a disease which I have elsewhere tried to show is analogous with Surgical fever. In reference to the same malady (puerperal fever), Dr. Rigby maintains that it essentially consists of “the introduction into the circulation of an animal poison generated by putrefaction.”—(“System of Midwifery,” p. 267.) “We have long,” he observes, “been convinced that one of the causes of puerperal fever is the absorption of putrid matters furnished by the coagula and discharges which are apt to be retained in the uterus and passages after parturition,” (p. 260). In reference to the small sloughs and ulcers which are liable to occur in the intestinal canal in continued or typhoid fever, the late Dr. Todd makes a remark perhaps still more pertinent to our case. In that disease, “the sloughing and ulcerative process,” as he observes, “furnishes a source of formation of a poisonous matter, which we know, by experience of analogous cases, when taken into the system, creates symptoms of the same character as those of the fatal instances of typhoid fever.”—(“Clinical Lectures on Acute Diseases,” p. 115.) There is certainly no reason to believe that the dead, septic, sloughing material of an artery differs in this respect from any other dead, septic, sloughing structure. And in Surgical wounds these arterial sloughs, more or fewer in number, are placed in the conditions and situations best adapted for the absorption of their gangrenous discharges; because they are lodged in the depths and centre of the raw wound, and almost closely in contact with the gaping orifices of the veins that run alongside of the tied and gangrenous artery. One Surgeon, Mr. Henry Lee, has ingeniously suggested the possibility of preventing the absorp-

tion of morbid matter, and consequent blood-poisoning, in cases of inflamed external veins, by applying acupressure higher up in the tube of the affected superficial vein. He has published two or three instances where this practice seemed to be followed by the happiest results. But, in passing, may we not venture to ask whether a similar application of acupressure to the deep veins of a wounded or amputated limb would not sometimes, under similar circumstances, be followed by similar success? At all events, Mr. Lee's and other cases show sufficiently the danger of sphacelating and decomposing tissues being placed in contact or contiguity with the open orifices of veins.

Possibly, in some exceptional cases, the sanious ichor from the arterial slough may be more deleterious and poisonous than in others. At all events, we see sometimes that the dead bodies of those that die—particularly of puerperal and Surgical fever—have all their tissues and fluids of such a poisonous nature that they dangerously and fatally affect the body of the dissector when introduced into his system in the smallest quantity by the smallest wound. What happens in the way of septic decomposition to the dead body as a whole, may possibly happen now and again to dead portions of a body, however small, in the form of local sloughs. Besides, there is one form of slough—viz., hospital gangrene—where contact of the ichor or, to use the expression of Professor Gross, “of the secretions of a gangrenous sore with a sore of a healthy character,” excites a dangerous gangrenous tendency in the latter.

Surfaces of Wounds capable of Absorbing Morbific Materials placed in Contact with them.

That mineral and organic poisons can be absorbed from the surfaces of wounds is testified to by ample experiment and observation. “In recent times,” observes Dr. Christison, “Professor Orfila has proved that various poisons, such as arsenic, tartar emetic, and acetate of lead, disappear in part or wholly from wounds into which they had been introduced.”—(“Treatise on Poisons,” fourth edition, p. 12.) “Any ulcer or wound,” remarks Dr. Taylor, “is a ready medium for the absorption of poison.”—(“On Poisons,” second edition, p. 23.) “The observation,” writes Liebig, “of Magendie, that putrid blood, brain, bile, or pus, when laid on fresh wounds, produces in animals vomiting, languor, and death, after a longer or shorter interval, has not yet been contradicted.”—(“Letters on Chemistry,” p. 229.) I have seen an animal poisoned by materials introduced into an old seton wound. Ulcers and wounds have absorbed poisonous doses of arsenic. We affect the body systematically by dusting strychnine and morphia upon the open surfaces or wounds left by blisters. Further, we have abundance of proofs of the absorption of animal poisonous material from wounds in the human body, in the inoculability of small-pox, cow-pox, syphilis, glanders, pustule maligne, etc., and in the fact, that bodies in dissecting-rooms sometimes pass into a certain state of decomposition which is communicable, by punctures and scratches, to the living subject.

Nature of the Poison in Surgical Fever.

Pathologists, up to the present time, are by no means agreed as to what actually constitutes the morbid matter which, when absorbed or imbibed into the blood from wounds, produces the disasters of pyæmic or Surgical fever. Some hold that the matter consists of entire pus-globules; others that it is the putrid, thin or serous portion of the pus; or septic matter not necessarily connected with suppuration; or, in its initial genesis, forms, as I believe more probable, of organic poisons arising from animal decomposition, more like alkaloids in their chemical type and poisonous effects than aught we can otherwise well compare them to. It is of no moment, in reference to our present inquiry, which of these doctrines be true; or whether there be not different species or varieties of septic or Surgical fever due to different species and varieties of the poisonous matter introduced. Allow me, however, to remark that the morbid materials existing on the raw surface of the wound would probably be absorbed or imbibed even more frequently than they are, and hence the devastations of pyæmic or Surgical fever would be greater than they are at present acknowledged to be, were it not, that in a certain proportion of cases the granulating walls of the wound with which the ligatures are in contact, and the ovoid mass of new fibrin or lymph, which surrounds the strangulated and sphacelated end of the artery, form, against the evil influences of absorption, guards which too often give way when the reparative process in the wound in any way fails. Besides, frequent though the disease is, its greater frequency is perhaps still more prevented by the happy absence from the blood of

an adequate and fit pabulum of organic materials, upon which the poison from the wound—when once absorbed and introduced into the circulating system—could produce the necessary organic changes or ferment which the commonly received theory of puerperal and Surgical fever involves.

What Acupressure Avoids.

The interior of a wound treated by acupressure is in principle so different from the interior of a wound treated by the ligature of its arteries, that there is every reason to believe that, when more generally adopted, the occurrence of pyæmic or Surgical fever will become lessened at least and diminished. A long series of careful observations, however, can alone definitely determine this most important matter. But, hypothetically, we would expect such a favourable result to follow, if the present ideas of the best Surgical pathologists regarding the origin of this fever in the introduction of decomposing animal matters into the blood, be founded in truth. For (1) the inevitable presence, in cases of deligation, of as many dead mortified sloughs as there are vessels tied, and the total absence in acupressure of any such irritating decomposing bodies, form, as we have already seen, one of the principal distinctions between the use of the thread and of the needle as a hæmostatic. (2.) It is scarcely to be doubted that pieces, however small, of dead, devitalised tissue, deeply lodged and embedded in raw wounds for days or even for weeks, could have any other than a dangerous and contaminating influence, both upon the wound and upon the invalid—both upon the rapidity of the patient's recovery and upon the chances of his recovery at all. (3.) The processes of elimination, ulceration, and suppuration which, in deligation, each individual arterial slough, however minute, necessarily and inevitably excites in the living tissues around it—a process that is totally wanting in acupressure—constitutes another great difference against the use of the ligature, and in favour of the use of the needle. Besides (4), the body or limbs of the ligature, with its imbedded, decomposing, putrid, and purulent materials, may, in cases of deligation, form, as we have seen, a source of irritation of both a local and a constitutional character. Surgeons have generally, as I am inclined to think, totally overlooked these various deleterious effects of the ligature, not only in relation to their local morbid action upon the wound, but also in relation to their morbid action upon the system at large.

In the largest and last work on Surgery published in Great Britain ("Holmes' System of Surgery"), Mr. Callender, the author of the article on pyæmic or Surgical fever, states that, "although no satisfactory explanation can be offered of the fact, it must be assumed that wounds may themselves engender septic matter;" and he observes, a few sentences onwards, that, should suppurating wounds "become infected, their treatment must be as simple as possible. All sources of irritation (he adds), as foreign bodies or accumulations of pus, should be removed," etc. But, no doubt, the ligatures and the sloughs to which the ligatures are affixed frequently themselves engender septic matter; and there would be little use in removing foreign bodies or accumulations of pus if we were obliged to leave, as deligation necessitates, such foreign bodies and formers of septic and purulent matter. To prevent pyæmic or Surgical fever, Mr. Callender correctly advises us, in regard to Surgical wounds, that "care be taken to promote their *early* closure, for when this is attained exhausting suppuration is avoided, and the disposition to pyæmia is lessened. They should also be kept clean, and free from irritation." Now, all these preventive measures are so far aimed at, and in part attained, by acupressure; and all of them are so far boldly set at defiance when the ligature is employed. Nor is it necessary to insist upon the high importance of such indications as these are in a prophylactic point of view; for here, as elsewhere in all practical science—and particularly in Medical science—prevention will ever be found safer, and surer, and simpler than cure.

LOCAL HYGIENE OF WOUNDS.

In the modern history of Medicine no subject has made greater or more solid and successful advances than the study of the prevention of disease—hygiene or sanitary measures. All unprejudiced minds in our own and in other professions, who have attended to the subject, are convinced that the introduction into the body by inhalation or otherwise of decomposing animal matters form—and particularly under some special conditions of decomposition—a frequent source of debility, disease and death, and constitute especially the origin and promoter of various forms of fever. Even in instances where they do not actually produce diseases they aggravate greatly and dangerously maladies that are excited by other

causes. The removal and avoidance of these morbid causes—resulting from organic decompositions—form the acknowledged media by which much human life has been already saved, and much human disease and misery already prevented. But in the Surgical patient there are, if I may so speak, *local* as well as general sanitary arrangements to be attended to; for besides the general hygiene of the body of the patient there is the local hygiene of the wounded or diseased part. Nay more, the sanitary laws that are of the utmost moment for the patient's body, are the same that apply to the patient's wound.

The most perfect hygienic state for insuring the health of the general body is simply the most perfect attainable state of general cleanliness as regards abundance of air, abundance of water, freedom from decomposing materials and effluvia, etc.; and the most perfect hygienic state for the local wound is there also the most perfect attainable state of local cleanliness in the best and fullest sense of that term.

In the case of a man who is the subject of a large and dangerous Surgical wound, to keep spontaneously locked up and deliberately imbedded within the depths of the wound a series of dirty, decomposing dead sloughs, is surely not more irrational than it would be,—with deliberate intent and forethought,—to submit the body of that man to the morbid influence of a set of uncleanly decomposing organic materials placed immediately around him. "A poison (wisely remarks Mr. Travers) admitted by a wound or raw surface, and a poison admitted by the lungs, are equally excitants of a specific constitutional irritation."—"Inquiry concerning Constitutional Irritation," page 527.) Nothing, in the whole round of professional practices and customs, seems to me to be a more curious anomaly and paradox than to watch Surgeons sew up with the greatest artistic accuracy and nicety the lips of an amputation or other wound with metallic sutures, while they have left buried in the interior of the wound a series of silken ligatures, each of which will inevitably produce ulceration and sloughing at the ligatured points. The finished wound is apparently all tidiness and neatness without; but within there are strangulated, sloughy portions of tissue, the sphacelation of which must inevitably be attended by ulceration and suppuration. It is like enforcing cleanliness, as it were, and the best hygienic measures outside a house, whilst within doors there were retained and locked up filth and decomposition and the explosive elements of destruction and disease. It is, in short, the old story of the "whited sepulchre," "beautiful outwardly," but within "full of all uncleanness."

APPLICATION OF ACUPRESSURE TO OTHER MATTERS THAN THE CLOSING OF ARTERIES IN SURGICAL WOUNDS.

Our limits are not sufficient to allow of the discussion of all the many and various points of interest connected with acupressure. Hence, I have neither time nor space to speak of, at length, its application to other conditions besides common wounds.

A needle, more or less of the form of the acupressure needle, Fig. 1, has now been extensively employed by Wutzer, Bonnet, Rothmund, Wells, and others, in the operation for the radical cure of hernia.

Perhaps acupressure will yet be found in some cases an easy and effectual means of compressing arterial trunks for hæmorrhage, and other practical purposes, as, for example, the artery leading to an aneurism, such as the femoral artery in popliteal aneurism, thus changing the operation for that disease into a simple process of acupuncture, instead of a process of delicate dissection and deligation when, in any instances of this disease, the milder methods of external compression, of manipulation, and of continuous flexion of the limb, fail.

It has been hitherto a difficult problem to obstruct the vessels of the ovarian ligament in ovariectomy without leaving a foreign body upon the stalk of the tumour, either to ulcerate or to slough through it. The stump of the ovarian pedicle—in cases where the pedicle is ligatured *en masse*—forms necessarily a dangerous element against the success of the operation; for it is allowed to pass backwards into the cavity of the peritoneum so strangulated as inevitably to produce ulceration or mortification in the ligatured part. Again, when the clamp is used, the straining and drag upon a shortened pedicle is sometimes so great as to endanger the life of the patient, on the same principle as a piece of stretched omentum in a strangulated hernia does so. Besides, the pedicle when clamped and dragged out externally prevents the lower part of the wound from healing until the clamp

is removed and the pedicle retracts. It sometimes is long in sloughing through the strangulated pedicle. In a case of ovariectomy which I performed last year, the clamp was twelve or thirteen days before it separated. The patient made a perfect recovery, but there was an umbilical-like wound in the abdominal walls from this effect of the clamp, which was long of healing. I left the clamp on in this case thus long in order to see the length of time it would take to ulcerate through the pedicle, particularly as there were no symptoms urging its removal. When removed early, that is, on the second or third day, the pedicle is apt to become retracted with a piece of dead and compressed tissue attached to it. In the *Medical Times* for March, 1860, page 285, I ventured to suggest a mode of applying acupressure to the ovarian stalk in cases where ovarian disease was removed by extirpation, but I am not aware that that method has yet been tried. In the following case of ovariectomy I lately applied acupressure successfully in another and a different way.

Case 21.—Ovariectomy — Acupressure applied to the Stalk, and removed in Forty-six Hours.—The patient was married, the mother of one child, and had been three times tapped. The multilocular ovarian tumour weighed upwards of 30 lbs. The largest cyst contained 23 lbs. of pure pus. The tumour was universally adherent, in front, to the abdominal walls. After detaching it, and having drawn it out externally, I applied a clamp to the ovarian stalk so near the tumour as to include a portion of it. After the tumour was removed, the uterus and attached parts showed a strong tendency to pull the clamp downwards to the pelvic brim. It was evident that it could not be left on without great and inevitable dragging upon the pedicle. I then passed a glass-headed needle, two and a-half inches long, twice through the ovarian stalk, immediately below the clamp. In passing it thus twice, I left out at either side a portion of tissue, to which no compression was to be applied, with the hope that it would supply with blood and vitality the strangulated stump of the ovarian stalk. The needle was thus placed under nearly the same conditions as in the method of acupressure which I have previously described and delineated as No. 3, and which, let me add, I believe Practitioners will find the simplest and most serviceable of all the forms described for common wounds. To compress the stalk sufficiently, I threw over the point-end of the needle a loop of strong tinned iron wire, of the size described by iron-workers as No. 22, twisted it half round the headed end of the acupressure needle, and then drew it with sufficient tightness to prevent any discharge of blood from the included vessels. A slender cylindrical iron hood, three-quarters of an inch in length, was placed over the sharp end of the needle to prevent injury and lesions from it; and this hood was fixed to the head-end of the acupressure needle by a duplicature of slender suture wire of the size No. 32. The clamp was then removed; the small remaining portion of the tumour which it embraced was excised; and the acupressure needle was carefully placed across the brim of the pelvis. A string attached to the beaded head of the needle and the wires used in compressing the stalk were left out at the lower edge of the abdominal wound. The wound itself was united by stitches of iron thread, passed so as to embrace the peritoneum, except in one instance, where the stitch was only superficial. The wire threads were carefully moulded to the exact shape of the parts in which they were each respectively placed, by pressing each in succession with two fingers, one applied inside and one out. The acupressure apparatus was removed in forty-six hours by merely pulling at the head of the acupressure pin. The two sets of wires, one of them carrying the hood, came out with it. Four days after the operation, all the deep iron stitches, without a drop of pus following any of them, were removed, and the wound was found healed from end to end by the first intention. The superficial iron stitch was left in a few days longer, and two or three drops of purulent matter followed its withdrawal. Thirteen days after the operation, the cicatrix at its uppermost end opened under a fit of coughing, and a quantity of pus which had been forming a small swelling there for a few days escaped. In this instance there existed before the operation the purulent diathesis in the most marked form; the patient's pulse was never for weeks under 100, and usually considerably higher, and there was a purulent collection of 23 lbs. of matter within her body. Since the small abscess in the abdominal walls has given way, the pulse has sunk towards the natural standard, and she is rapidly regaining health and strength.

Probably it will turn out, that allowing the tied ovarian pedicle to pass back into its normal situation under the com-

pression of an acupressure needle, and removing that needle in a day or two after its application, will diminish the risks and mortality attendant upon ovariectomy. I am the more inclined to take this view, from seeing it stated, in the last edition of Dr. Churchill's very able work on the Diseases of Women, that my friend, Dr. Tyler Smith, of London, has only lost three out of eighteen cases of ovariectomy; and the principal peculiarity, I believe, in Dr. Smith's mode of operating consists in allowing the stalk of the tumour, tied with an organic ligature of silk or cord cut off short, to slip back at once into the cavity of the abdomen. In this method we encounter the dangers occurring from a foreign body, such as a ligature being left permanently within the cavity of the abdomen, and from the tied end of the stalk being ulcerated and sphacelated by that ligature. In acupressure we avoid both of these dangers.

CONTRAST BETWEEN LIGATURE AND ACUPRESSURE.

Lastly, allow me to present to you, in a brief tabular form, a summary, as it were, of the leading differences and distinctions between the ligature and acupressure, and their respective consequences and effects. The comparison might, if it were desirable, be made much longer. It refers, as I have said, to the leading differences only.

COMPARISON BETWEEN THE LIGATURE AND ACUPRESSURE.

<i>The Ligature.</i>	<i>Acupressure.</i>
1. Requires isolation, and consequently some detachment, of the end of the vessel.	Requires none.
2. Produces laceration of the two internal coats of the artery.	Produces none.
3. Produces strangulation of the external coat.	Produces none.
4. Leads on to ulceration or molecular destruction of the external coat at the constricted part.	Produces none.
5. Causes mortification of the artery at the tied point, and usually also below it.	Produces none.
6. Produces consequently a dead, decomposing slough of each part ligatured.	Produces none.
7. If organic, it imbibes animal fluids, which speedily decompose and irritate.	Requires only metallic needles or threads, which are incapable of imbibing animal fluids.
8. Requires to produce the highest stages of inflammation at each ligatured end, viz., ulceration, suppuration, and mortification.	Requires to produce inflammation up to the stage of adhesion only.
9. Is not removable except by the slow ulceration and sloughing of the ligatured vessel, which requires a period of from four or five to twenty days and more.	Is removable in an hour, a day, etc., at the will of the operator.
10. Generally requires two persons for its application.	Requires only one person.
11. Is sometimes followed by secondary hæmorrhage, as an effect of ulceration and sloughing.	Is seldom followed by this form of secondary hæmorrhage, as there is no ulceration or sloughing.
12. Sometimes fails altogether in cases of recurring secondary hæmorrhage.	Has succeeded under such circumstances where the ligature has failed. (See Case 17.)
13. Sometimes cannot be applied till the Surgeon first exposes the bleeding vessel by the knife.	Does not necessarily require the exposure of the vessel, and, therefore, has sometimes prevented the necessity of using the knife. (See Cases 12—16.)
14. Prevents, as a foreign body, adhesion by first intention along its tract as long as it remains.	Is early withdrawn, and is hence far less opposed to primary union.
15. Stops only the artery tied.	Stops generally both artery and vein.
16. Stops only one artery.	May close two or more smaller arteries by means of a single needle. (See Cases 1 and 11.)

The Ligature.

17. Is not unfrequently followed by Surgical fever from leading to the formation and allowing absorption of septic matters.

18. For these various reasons, primary union rare, healing slow, and septic or Surgical fever not uncommon.

I will delay you no further by offering to make any observations on this contrast. Such a table requires no comments. It speaks sufficiently for itself.

Acupressure.

Is much less likely to be followed by Surgical fever, because it does not lead to the formation of septic matter, and closes the veins as well as arteries.

Primary union more frequent, healing quicker, and septic or Surgical fever less common.

LECTURES ON

THE BRITISH PHARMACOPŒIA:

ITS CONSTRUCTION, ITS COMPARISON WITH THE LONDON PHARMACOPŒIA,

AND THE

VALUE OF ITS NEW REMEDIES IN THE TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE II.—FRIDAY, JANUARY 29.

MR. PRESIDENT,—At the conclusion of my Lecture on Wednesday, I had commenced discussing the value of some of the new introductions in the *Materia Medica* of the British Pharmacopœia; I propose to continue this investigation to-day; but, prior to so doing, it may, perhaps, be desirable that I should occupy a short time in speaking of the changes of nomenclature which will be found in the work. On turning over its pages, one cannot help being struck with some of the alterations, from the apparent strangeness of the names newly introduced; and no small surprise will be expressed, and, probably, censure thrown on the Committee, for making such deviations from a nomenclature to which all Practitioners have become accustomed. However, these changes, although scarcely approved of by all the members of the Committee, have not been made without due consideration and after much discussion. Several of the alterations I allude to have been effected only in the scientific, or Latin, name of the medicine; others, in the very essence of the name itself.

Let us first turn to one or two of the elementary bodies—Chlorine, for example. The Latin name has been changed from Chlorinium, of the London Pharmacopœia, to Chlorum; and hence a solution of the gas in water is now termed Liquor chlori, instead of Liquor chlorinii; and its combinations with lime and soda are named Calx chlorata and Soda chlorata, in lieu of Calx chlorinata and Soda chlorinata. In the same way, the old Latin name for Iodine, Iodinium, has been changed into Iodum; and amongst the tinctures, liniments, and ointments will be found Tinctura Iodi, Linimentum Iodi, and Unguentum Iodi compositum. It will naturally be asked, why was this change made; what advantages do the new names possess over the old? Let us examine the construction of the word Iodinium. It will be seen that it is simply the adopted English name Iodine with a Latin termination. The same applies to Chlorinium. It was the opinion of some of the Committee, that such a construction of Latin words was incorrect, and that their roots, rather, should be appealed to. If this principle be adopted, the Greek word *ιωδης* would become Iodum, and *χλωρος*, in like manner, Chlorum. Had the element Bromine been introduced in its free state, it would have been termed Bromum, and not Brominium, as on a former occasion. This being granted, in the combination of chlorine with bases, the participle naturally becomes chloratus, in lieu of chlorinatus. The word Chloroformyl—the London Pharmacopœia Latin name for Chloroform—is now Chloroformum, and its preparation Spiritus Chloroformi. Several changes will also be observed in other preparations, which are either not very definite in constitution, or in which the arrangement of the elements is imperfectly understood. For example, the old preparation, Potassii Sulphuretum, is now Potassa Sul-

phurata, Ferri Potassio-tartras becomes Ferrum Tartaratum, and Antimonii Potassio-tartras, Antimonium Tartaratum—a restoration in the last two instances to the old names by which they were known, except that the word tartaratum is employed in lieu of tartarizatum. It may be objected, and with some reason, that we have not fully carried this principle out, as the citrate of iron is designated Ferri et Ammonie Citras, and not Ferrum Citratum.

There are certain metallic preparations, the names of which, in different pharmacopœias, and even in different editions of the same pharmacopœia, have undergone numerous changes, dependent on the altered opinions of chemists as to the true atomic weights of the elements of which they are composed; and such changes have not only proved of serious inconvenience to the Practitioner, but have even occasionally been attended with danger—I allude more especially to the mercurial salts. To obviate such inconvenience, the Committee have deemed it advisable in these instances to attach names to the drugs having often little or no relation to their composition, but rather to their characters, or the familiar names by which they have long been known both to the Profession and public; for example, the Chlorides of Mercury are now termed Calomelas and Hydrargyrum corrosivum sublimatum, or, in English, Calomel and Corrosive Sublimate. Hydrargyri ammonio chloridum is changed to Hydrargyrum ammoniatum, and the two Iodides are respectively called Hydrargyri iodidum rubrum, and Hydrargyri iodidum viride, or the Red and Green Iodides of Mercury. Lastly, Hydrargyri nitrico oxidum is designated Hydrargyri oxidum rubrum, or Red Oxide of Mercury. Such are the names by which these salts are to be prescribed; but, on referring to the definitions, it will be found that their true composition is expressed, and thus Calomel is defined to be a subchloride of mercury, consisting of two equivalents of the metal united with one of chlorine, and so on for the other preparations now alluded to.

An alteration has also been made in the name of the Bismuth salt, which has undergone so many vicissitudes, sometimes being designated a nitrate, then an oxide, then a subnitrate, at other times, a trisnitrate, until, at last, in the edition of the London Pharmacopœia of 1851, it again returned to its condition of nitrate. In the British Pharmacopœia it is called Bismuthum album, and defined to be a nitrate of bismuth, consisting of one equivalent of teroxide of the metal united with an equivalent of nitric acid. Changes have also been made in the names of two of the alkaloids; Quinia, for example, is now substituted for Quina, and Aconitia for Aconitina.

I have, I believe, mentioned the principal changes of nomenclature in the new work; others of less importance exist, but will be readily understood after what I have now stated. I will conclude this part of my subject with one remark. Substantives ending in *as* are made feminine in the British Pharmacopœia; hitherto they have been—*masculine* in the United States Pharmacopœia, *feminine* in the London, and *neuter* in the Pharmacopœias of Edinburgh and Dublin.

We shall next treat, somewhat in alphabetical order, of certain medicines derived from Aconitum napellus; and it will be observed that some alterations have been made in the preparations of this plant deserving a passing notice. Its alkaloid, Aconitia, for example, has been introduced; and probably most of you remember that this active principle was made officinal by the London College in 1836, but removed from the list of their *Materia Medica* in 1851. With the causes leading to this step I am unacquainted; but in the interval which elapsed between the publication of the two editions, Aconitine had gradually become a remedy of not unfrequent use as an external agent.

In lieu of the term Aconitina, its Latin name has been changed to Aconitia, and it is defined to be an alkaloid obtained from aconite root. As it is a substance of high price, although much less so than formerly, it is very liable to adulteration; hence the necessity of characters and tests being inserted, so that the Practitioner and Druggist may be able to ascertain its purity. Much disappointment has been experienced from the use of spurious Aconitine, and much of that which is imported from the Continent is comparatively or altogether inert. When pure it is an intense poison; and if its ointment, such as that introduced in the British Pharmacopœia, be rubbed upon a part where the skin is sensitive, considerable tingling is experienced, and this symptom is soon followed by numbness, lasting hours or days, according to the amount employed. When given internally it is a most dangerous agent—in fact, so intense is its action, that it should

not be used at all in this manner. Some eighteen years since I had occasion to make several trials of the action of Aconitine upon animals, and I invariably found that $\frac{1}{50}$ th of a grain was sufficient to destroy a large dog; its action, although so energetic, is by no means rapid—usually more than half an hour elapsed from the administration of the poison to the death of the animal; its influence appeared to be directed more especially to the nervous system, and through it the heart became implicated; the animal seemed to lose all sensation, and its staggering gait or inability to walk apparently depended upon want of sensation rather than of motor power; it was likewise quite unconscious of any external injury; the heart's action became gradually slower, from about 110 pulsations in the minute to 25, or even less, and the animal died from asthenia. In the human subject, when poisoning has occurred from Aconite, symptoms very similar to those I have just mentioned have been noticed. Aconitine is certainly a most valuable external remedy; and for the purpose of alleviating neuralgic pains, I know of nothing equal to it. In the form of the Unguentum Aconitiæ, in which 8 grains of the alkaloid are dissolved in a little spirit, and then thoroughly mixed with an ounce of prepared lard, it is a clean and elegant preparation.

The changes made in the preparations of Aconite are important to be remembered. The Tincture of Aconite of the British Pharmacopœia is very much reduced in strength, compared with the London tincture: each fluid ounce of the new tincture contains the powers of about $54\frac{1}{2}$ grains of the dried root; whereas the London tincture contains as much as 180 grains per fluid ounce; it is, therefore, more than three times the strength. The London tincture is, perhaps, too strong for convenient exhibition as an internal remedy, and certainly too weak as an external agent; the British Pharmacopœia tincture will, I think, be well adapted for the former purpose, and for the latter there is introduced a very strong spirit solution of the root, stronger than what is called Fleming's Tincture—not designated, however, by the name of Tincture, but called Linimentum Aconiti, or Aconite Liniment—in which each fluid ounce of the preparation is intended to represent the powers of an ounce of the dried root; it is, therefore, more than eight times the strength of the new tincture: a little camphor has been added to give it some of the characters of a liniment.

Under the head of *Aconitum*, the leaf and flowering tops of *Aconitum Napellus* have been introduced, as in the London Pharmacopœia, and from the fresh juice an extract is ordered to be prepared. It would appear that this preparation is very uncertain as to its strength, and it is somewhat difficult to understand why an extract of the leaf should be required, seeing that the activity of the root is so great. An alcoholic extract of this part is occasionally used, and is very much more potent than that obtained from the leaf.

You are all aware that three kinds of aloes are made officinal in the London Pharmacopœia, namely, the Socotrine, Barbadoes, and Hepatic aloes. In the British Pharmacopœia, this last variety, the Hepatic, has been discarded. There could not be found any good reason for retaining the Hepatic. It did not possess any qualities superior to either the Socotrine or Barbadoes; and, in fact, although it somewhat resembled Socotrine aloes, yet it was decidedly inferior to it. Whether there is any essential difference between Socotrine and Barbadoes aloes, I am not prepared, from any clinical experience, to decide. Both contain the same crystalline principle (aloine), but the amount of matter insoluble in water is much greater in the Barbadoes variety. Before leaving the consideration of aloes, there is one point to which I wish to call your attention, as having some practical value. There is a very widely-spread opinion that the water extracts of aloes differ much in their action from aloes themselves; in short, that the insoluble, or so-called resinous matter is much more irritating than the part soluble in water. Wishing to ascertain the correctness of this very popular opinion, I made the following trials at the time the subject was under the consideration of our Committee. Socotrine aloes were treated with water, by the process given in the Pharmacopœia for making the extracts, and thus the insoluble and soluble portions were isolated. Pills were then formed with each, of the same weight, and administered. Sometimes the two kind of pills were given alternately, sometimes consecutively; in fact, every precaution was taken to ensure a correct result, for the number of cases in which they were administered was considerable, and a note was taken by the clinical clerks of the frequency and character of the action of each dose. From these observations, I was led to conclude that the watery extract of Socotrine aloes is

much more powerful as a purgative than the resinous insoluble matters, but that the griping caused by it was also much in excess of that produced by the resin; in short, the latter body is, comparatively speaking, a feeble agent either for good or harm.

I am happy to be able to add Dr. F. Farre's testimony to the accuracy of the statement; for at the same time, and with the same ingredients, he made a similar series of observations, and with the same results. As yet I have not made a similar series of trials with Barbadoes aloes.

In the British Pharmacopœia you will find among the preparations a Barbadoes and a Socotrine aloes pill alike in composition, the variety of aloes and volatile oil excepted. This will enable us to test more easily the relative value of the two kinds of aloes. In the compound colocynth pill of the new Pharmacopœia, Barbadoes aloes enters; but in the compound extract, the Socotrine, and so on for many other preparations containing this drug.

Amongst the ammonia salts some important changes and additions have been made in the British Pharmacopœia. The old sesquicarbonate of ammonia is now termed the carbonate, although still defined to be a sesquicarbonate, and with a symbol denoting such a composition; its solution has been discarded. From the compound spirits of ammonia the cloves and cinnamon have been omitted, and hence it is not liable to change colour, as was the case with the London preparation, from the presence of the oil of cloves. It is also stronger in alcohol, and by connoisseurs is looked upon, I believe, as a very improved article. The fetid spirits of ammonia, and the compound tincture, have been omitted; the former as beyond human endurance, and the latter as little employed and unnecessary. A great change has been effected in the strength of *Liquor ammoniæ acetatis*. In the London Pharmacopœia it is ordered to be made by neutralising dilute acetic acid with carbonate of ammonia; when so prepared it is very liable to undergo change, becoming mouldy, and the dose required to produce any appreciable effect on the system is somewhat large. In the British Pharmacopœia, acetic acid of 28 per cent. is neutralised by the addition of strong ammonia, and a preparation is thus formed which is about five times the strength of the London solution. This fact it is important to bear in mind. Perhaps you may have wondered why acetate of ammonia itself is not introduced into the list of the *Materia Medica*, and the solution formed by dissolving the salt in water in definite proportions. The reason is simple. Acetate of ammonia can only be crystallised with the greatest difficulty, from its deliquescent property, and cannot be procured as a pharmaceutical article, and hence it was necessary that it should be represented in the *Materia Medica* by its watery solution. This is the case, likewise, with certain other salts; for example, the subacetate of lead.

The preparation termed *Liquor ammoniæ citratis* has not found a place in the British Pharmacopœia.

The new salts of ammonia are the benzoate and phosphate.

Benzoate of ammonia, represented by the formula on the board, $\text{NH}_4\text{O}, \text{C}_{14}\text{H}_5\text{O}_3 + \text{HO}$, is formed simply by neutralising benzoic acid with solution of ammonia, and occurs, as you will observe, in beautiful white laminar crystals, which are readily soluble in water, in this respect differing from benzoic acid; soluble also in spirits.

What is the value of benzoate of ammonia as a remedy? It has the advantage over benzoic acid, in its greater solubility, which renders it available for administration in the liquid form, in many cases very desirable. It is rapidly absorbed, and its benzoic acid is converted into hippuric acid by the assumption of the elements of glycocholl, probably of glycocholl itself, which, doubtless, exists in the blood. The urine becomes altered in character, from the presence of the hippuric acid, which appears to be eliminated entirely by the kidneys; hence it becomes more acid, and even slightly irritating. This change in the quality of the urine renders benzoate of ammonia of much value in medicine—sometimes as a diuretic, in cases where the kidneys require stimulating, but more frequently on account of the influence produced upon the mucous membrane of the urinary passages. It is often of considerable service when there exists a tendency to phosphatic deposits; and in many cases of chronic inflammation of the bladder I have found much benefit from its employment. It has no influence upon the formation or secretion of the uric acid, the elimination of this acid remaining unaffected by its administration.

The formula representing the changes which benzoic acid undergoes when in the blood may be thus represented:—

Benzoic acid, therefore, differs from almost all the other vegetable acids used in Medicine, in not undergoing decomposition, or being broken up into simpler compounds; instead of that, it assumes the elements of another principle—glycocoll—and is built up into a more complex organic body.

It may be asked why the urine is rendered more acid by the exhibition of benzoate of ammonia, seeing that the benzoic acid is combined with an alkaline base—the oxide of ammonium. The reason is as follows:—Ammonia is a base which differs altogether from the fixed alkalies—potash and soda—in not passing through the renal organs, but in being separated from the acid with which it may be combined, and becoming, perhaps, partially oxidised and converted into nitric acid, but chiefly, I suspect, eliminated by the skin and mucous membranes; hence a salt of ammonia with a vegetable acid, such as the acetate, citrate, or tartrate, exerts no influence in alkalising the urine, and in this respect is opposed in action to the corresponding salts of the fixed bases, which are found in that fluid in the condition of carbonates. Should the ammonia be thrown out of the system by the skin and mucous membranes, it would at once explain the action of the salts of this base, as diaphoretics, expectorants, and so on.

Benzoate of ammonia is a salt which causes no injurious effects even when administered in considerable quantities. The usual dose for producing diuresis, or for influencing the urinary mucous membrane, is from 10 to 20 grains.

The second salt of ammonia, of novel introduction, is the Phosphate, consisting of three equivalents of oxide of ammonia to each equivalent of tribasic phosphoric acid, and in the crystalline salt with five equivalents of water, and is represented by the formula— $3\text{NH}_3\text{O}, \text{PO}_5 + 5\text{HO}$. It occurs in large, transparent, colourless prisms, having a slightly ammoniacal odour, on account of the feeble affinity by which part of the base is held. The salt is freely soluble in water, and the solution, if well diluted, not unpalatable to the taste.

You are probably aware that the salts of phosphoric acid possess many peculiarities, which render them of great importance in the animal economy, and that phosphoric acid in its tribasic condition differs considerably from other acids, either mineral or vegetable. With one atom of fixed base, as soda, its salt is strongly acid in reaction, and probably gives to the urine the acid reaction which it exhibits in health; on the other hand, with two atoms of soda, it forms an alkaline salt, and to its presence the alkalinity of the blood is probably due. Another peculiarity of the alkaline phosphates is, the capability of their solutions being rendered acid by the addition of uric acid without the precipitation of this latter body, a property of considerable value in preventing the deposition of this salt in the tissues of the animal economy. A weak solution of phosphate of ammonia has the property of dissolving and holding in solution a considerable amount of urate of soda. Apart, however, from these considerations, there appears to be a considerable amount of clinical experience in favour of the employment of this phosphate, and not only in certain urinary diseases, but likewise in the treatment of chronic conditions of the gouty habit.

Although freely acknowledging the difficulty of arriving in such cases at the true value of a remedy, I may state, from an extensive experience, I have reason to believe that much good may be derived from its long continued employment; it has also the great advantage of being a salt not foreign to the system, and from the use of which no injurious effects are likely to result.

(To be continued.)

THE ACCIDENT AT THE AGRICULTURAL HALL, ISLINGTON.
—The account in the daily papers of the injuries received by the unfortunate keeper who was attacked by the lions at the Agricultural Hall, was in some respects incorrect. It was stated, "that the flesh was torn off the arm in most parts to the bare bone, very nearly from the shoulder to the wrist." The truth, however, is, that the man's hand, and hand only, was crushed by the lions. The middle finger and corresponding metacarpal bone were separated down to the base from the rest of the hand, and the soft parts round the wrist were deeply and irregularly torn, except at one small spot. The forearm and a part of the upper arm were slightly grazed, probably from being drawn through the bars of the cage. There was nothing amounting to laceration of the arm. The hand was amputated by Mr. Lawrence at the wrist-joint, and the patient is, we hear, doing well.

ORIGINAL COMMUNICATIONS.

ON SOME POINTS IN THE MEDICINAL TREATMENT OF CHRONIC PULMONARY CONSUMPTION.

By JOHN K. SPENDER,
Surgeon to the Eastern Dispensary, Bath.

THE multiplicity of remedies recommended for the treatment of pulmonary consumption is apt to embarrass the Practitioner whose experience of the disease is small, and who has not gathered very accurate and definite views of its pathology. Careful clinical records, drawn with precision, but not too long, are a better help to the study of constitutional and local phthisis than most "systematic" treatises; the bedside itself being, of course, the best place of all.

In a recent work on "Diseases of the Chest"—a work of considerable merit and importance—we may find illustrations of a common defect in what are called systematic books. "Undue acidity of the stomach" is mentioned as a frequent concomitant of pulmonary consumption; but we are advised to give the patient "mineral acids, with vegetable bitters and taraxacum," and if these do not answer, "liquor potassæ, carbonates of the alkalies, or nitrate of bismuth." It is not easy to understand how "undue acidity" can be removed by administering more acids, and it would seem more intelligible at least to try the alkalies first. A number of substances are specified as possessing useful "alterative" properties, and the cough is to be allayed by one or more of a long catalogue of drugs. The most serviceable medicine for relieving night-sweats is not named at all. The treatment of acute phthisis is dismissed in remarkably few words. There is, in short, an entire absence of any emphatic recapitulation of what we have to do, why it is to be done, and how we can most satisfactorily do it.

It has passed almost into an aphorism, that the fact of a large number of substances being alleged to cure a disease is a demonstration of its incurability. But the surest method of lessening our therapeutic ignorance is, first, to ascertain the exact limits of our knowledge, and then to make the most of all the certain knowledge we possess. And the history of the treatment of consumption shows that the number of authentic remedies for it has diminished in a tolerably close ratio with the increase in our trustworthy information concerning its pathology.

(a) Dr. Hughes Bennett lays down as a fundamental fact, that "phthisis pulmonalis is a disease of the primary digestion;" this disease producing scrofulosis, or that constitutional state which precedes the development of tubercle. The "excess of acidity in the alimentary canal" is the peculiarity of phthisis, so that the "alkaline secretions of the saliva and of the pancreatic juice are more than neutralised, and rendered incapable of either transforming the carbonaceous constituents of vegetable food into oil, or of so preparing fatty matters introduced into the system as will render them easily assimilable." Upon this pathological axiom we build the first therapeutic necessity, that alkalies are, as a rule, beneficial in phthisis.

(b) The blood of a consumptive person is almost always deficient in red corpuscles; for red corpuscles can be fashioned only from healthy chyle corpuscles, and healthy chyle corpuscles cannot come from "diseased primary digestion." Hence, we deduce the second therapeutic necessity, and we administer iron in addition to abundant meat food, for the power of iron in helping the formation of red blood corpuscles is a therapeutic proverb. With reference to the general question of the administration of iron in phthisis, the great authority of Trousseau must, in my opinion, be set aside.

(c) The emaciation which accompanies—and is one of the special peculiarities of—pulmonary consumption suggests the third therapeutic necessity,—that of prescribing the hydro- and the hydra-carbonaceous foods and medicines. Owing to some unique chemie and dynamic qualities, cod-liver oil fulfils this necessity in an unrivalled way.

Other remedies may be required in pulmonary consumption, but they are demanded as mere auxiliaries, and should be supplied as such. They are simply to be grouped around those that satisfy the three main therapeutic postulates just enumerated,—that is to say, (a) we ought to give an alkali; (b) we ought to give iron; and (c) we ought to give cod-liver oil. Let us now examine the manner in which these postulates can be carried out.

(a) Potash water, bicarbonate of potash, lime-water, and the aromatic spirits of ammonia, are the alkalies which would be naturally employed. Dr. T. K. Chambers is the unwearied advocate of the benefits of lime-water; it may be taken as a common beverage, or in union with fresh cold milk. Tradition pronounces the aromatic spirits of ammonia to have "diffusible stimulant" virtues, whatever those may be; it is a most useful medicine when diarrhoea is absent, but otherwise the bicarbonate of potash and lime-water are to be preferred. I do not pretend to affirm that acids are never called for, and never serviceable; for sometimes they do good simply as a short change from an over-alkaline treatment.

(b) What salt of iron can be combined in solution with an alkali? This is the practical question to solve. The tincture of sesquichloride of iron is clearly out of the question; while the ammonio-citrate and the sulphate of iron are decomposed and precipitated when an alkali is added to them. An inquiry into the resources of the Pharmacopœia discloses a potassio-tartrate of iron, resembling in physical properties the ammonio-citrate, but endowed with the chemical property of allowing an alkali to be added to it without decomposition. A draught such as the following is a pleasant piece of pharmacy, and may be taken by a patient twice or three times a day:—

R. Ferri potassio-tart., gr. v.; spts. ammoniæ arom., ℥ xv.; spts. ætheris chlor. ℥ x.; aquæ puræ, ad ℥ j. M. ft. haustus.

This is the elementary iron and alkaline draught which, when opportunely given, has produced results that have seldom disappointed me. To this draught iodide of potassium and chlorate of potash may be joined, if either of these salts seem to be required by any intercurrent malady. The administration of iron is usually contra-indicated by diarrhoea; but if this exist as a mere passive flux, the saccharated carbonate of iron may be united with the compound chalk and opium powder, and continued for a long time. Here the remedies themselves are unaltered, but their form is accommodated to a casual incident of phthisis, which imperatively requires to be relieved before the "primary digestion" can do its proper functions.

(c) It is desirable to prevent an undue multiplication of the "times and seasons" for taking physic; and so the appropriate doses of cod-liver oil may, if the patient choose, be added to the iron and alkaline draught, with which it is easily miscible.

Subordinate to these three great principles of medicinal treatment, which can almost always be simultaneously carried out, particular remedies may be requisite to meet particular exigencies.

Dr. Hughes Bennett justly condemns that over-drugging plan which treats symptoms rather than causes; and which, among other things, suffocates a cough by narcotic medicines. But before the constitutional remedies have had time to amend that irritative state of bronchial passages and tubes on which cough mostly depends, morphia may be very useful—taken in a daily dose at bed-time. With this may be combined some port-wine, and a few grains of oxide of zinc, the agency of which salt in alleviating night perspirations Dr. Theophilus Thompson has not in the least overrated.

During the last twelve months, I have watched almost from day to day nearly thirty cases of pulmonary consumption, in which the medicinal treatment now sketched has been faithfully carried out, and with very notable success. Concerning the permanence of this success, time will bear its testimony. The orthodox diet and hygiene have, of course, had ample share in realising this good result. Experience teaches patience, however; and it is the merest empiricism to be in any hurry about the management of what is often the type of a chronic disease. The "pre-tubercular" stage of phthisis is not a formula only, but an important vital fact; and whenever, as Professional men, we get hold of this "pre-tubercular" stage, we should try and lay our therapeutic and hygienic foundations firm and deep, in the hope of literally obeying that true, though hackneyed, precept, that "prevention is better than cure." But, when opportunity does not allow us to "prevent," let us not always despair of curing; and, at the worst, let no adherence to a stupid and ignorant routine forbid us to grant, when possible, that euthanasia which is to no one a more blessed boon than to the consumptive sufferer. (a)

Gay-street, Bath.

(a) In a paper, read many years ago before the Medico-Chirurgical Society, by Mr. Spencer Wells, chloroform inhalations are recommended in the palliative treatment of phthisis. I have seen once or twice some of the dying horrors of "laryngeal phthisis" immensely relieved by this simple means.

CASE OF

UNILATERAL PALATINE PARALYSIS AND ANÆSTHESIA AFTER DIPHTHERIA.

By S. J. GEE, M.B. Lond.

A LADY, on June 4, 1863, complained of sore throat and of feeling chilly.

On June 8 (4th day), the skin was hot and dry, the pulse frequent and soft. Under the left angle of the jaw an enlarged lymphatic gland was perceptible; the whole fauces were too red; the uvula enlarged and semi-transparent; the left tonsil was covered with a thick, white, false membrane; the right tonsil did not present any unusual appearance, except slight swelling and redness. The false membrane seemed to be exactly limited to the left tonsil; around it, the strong hydrochloric acid diluted with an equal bulk of syrup was applied. Alimentation was insisted upon.

11th.—In fifty or sixty hours after the cauterisation, all the false membrane had cleared off, and none appeared afterwards on the same spot or elsewhere, and the subsequent course of the disease was that of a simple sore throat.

28th.—Throat normal in every respect. Patient rather weak, but walks out daily.

July 1 (27th day from onset of disease).—Voice began to be somewhat nasal.

3rd (29th day).—Voice excessively nasal, and fluids began to return through the nose.

7th (33rd day).—Seen, for first time since the occurrence of the above symptoms. On examining throat, I was at first struck by the perfectly normal appearance of all the parts. A closer examination showed that the left half of the soft palate was almost straight, and hung against the pharyngeal walls; whilst the right half was normally concave and prominent. The left half could be scratched or tickled without the patient feeling it, or producing any attempts to vomit. The right half was perfectly sensitive, and irritation produced reflex movements. No trustworthy comparison could be made between the two sides of the uvula. There was no other "diphtheric neurosis." The amount of nasal quality in the voice was always less in the morning, and after a prolonged rest, than when the voice had been exercised. There was a feeling as if the food stuck in the fauces, and it was swallowed with difficulty.

28th (54th day).—The paralysis and anæsthesia of the left half of the soft palate was still complete.

August 3 (about the 33rd day of the nervous symptoms).—The nasal quality of the voice and the other symptoms abated rather suddenly, and in a day or two had completely disappeared. Subsequent health perfect. The urine was not examined.

Maingault, in his Memoir (p. 65), gives a case of ptosis of the left eye after diphtheria, the right being presumably intact. This is the nearest approach to the above case that I have been able to find. On the correctness of the diagnosis, compare the history with which Trousseau opens his chapter on Pharyngeal Diphtheria.—(Clin. Med., i., 313.)

MEMORIAL TO THE LATE SURGEON SMYLY.—We are happy to learn that a movement is in progress to connect the name of this distinguished Surgeon in a permanent and practical manner with the Meath Hospital and County Dublin Infirmary, where he so long laboured, and where his Professional skill was so signally blessed to the relief of the suffering poor. It is in contemplation to erect and endow a ward for children in the Hospital, to be called "the Smyly Ward." The advantages, moral and hygienic, of separating the junior from the adult inmates, and the benefit to Medical teaching, and, by consequence, to the public, in a better treatment of diseases in children, are too apparent. The erection of such a ward was an object near to Mr. Smyly's heart, connected as he was so deeply with institutions for the education and support of the children of the destitute. There can be little doubt that this proposal will be cordially supported by an extensive circle of Mr. Smyly's friends and former patients. A sum of £200 would be sufficient to build the ward, and about £2000 would endow it for ever, the cost of maintenance of six beds amounting to £100 per annum.—*Saunders' News Letter*, January 29.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

CASE OF EXTRAVASATION OF URINE—PERINEAL SECTION—DEATH—CLINICAL REMARKS.

(Under the care of Mr. HULKE.)

A DISSIPATED, bronchitic old man, long troubled with stillidium urinæ, found his scrotum swell. A Surgeon, suspecting extravasation, passed a No. 4 catheter, and drew off Oj. of urine. This was repeated next day, and, as the swelling had not extended from the scrotum to the perineum, it was thought that it might be merely dropsical. On the third day the scrotum was more swollen; the penis also was swollen and discoloured. This confirmed the first suspicion. A catheter was tied in the bladder, and incisions were made in the swelling. He pulled out the catheter the same evening, and, as it could not be replaced, he was sent to the Hospital.

On his admission, 9 o'clock p.m., February 22, the penis was very swollen, and dusky red. It crackled under pressure, from gaseous distension of the cellular tissue; and there was a black slough, the size of a florin, on its left side. The scrotum was greatly swollen, livid, and excoriated, and had a black slough, at its most dependent point, on the left side. From the scrotum, the œdema and redness extended upwards, above the left groin, as high as the level of the crest of the ilium. A catheter met with an obstruction at the middle of the scrotal part of the urethra, from which point it took a superficial course under the skin towards the perineum. The supra-pubic region was resonant, so the bladder was not distended. He was exceedingly feeble. A glass of hot brandy-and-water having somewhat restored his circulation, and warmth slightly, he was placed under chloroform, and a small catheter-staff was passed through the first and through a second stricture in the situation of the bulb, its entrance into the bladder being evidenced by the escape of urine. The staff was cut upon through the perineum, and for nearly an inch and a-half was found lying in a greatly dilated part of the urethra, beyond which, at the spot where the bulb joins the membranous portion, the posterior stricture was found surrounded by a hard, fibrous mass. This was divided, and the handle of the staff having been replaced by the long steel rod, a large elastic catheter was slipped over this along the staff into the bladder, and the staff withdrawn. The catheter was secured. Incisions were made in the infiltrated parts, and poultices were applied when the bleeding had stopped.

Brandy, ʒss., was ordered every hour, and as much strong beef-tea as he could be induced to take.

Next day, less swelling; the urine flowed freely through the catheter; pulse 98. At night he grew restless, and pulled out the catheter. The House-Surgeon replaced it shortly after without trouble. On the second day he was weaker; the wounds were glazed; suppuration, which had begun, ceased, and sloughs had formed in the left groin. On the third morning he died.

The bladder was small, its walls thickened, its mucous membrane congested and ecchymosed. The urethra was contracted just in front of the bulb, and at the middle of the scrotum; the intermediate part was greatly dilated, and here the extravasation had taken place through a rent. The scrotum, penis, and tissues, as high as the ribs on the left side, were gangrenous.

In reference to this case Mr. Hulke remarked, that had the first suspicion been acted on, and free incisions made in the swollen scrotum, a limit would probably have been put to the extravasation, and the sloughing would have been circumscribed or prevented. Early and free incisions cannot be too strongly enforced. Where it is necessary to cut into the urethra and divide a stricture through the perineum, in order to place a gum-elastic catheter in the bladder, Mr. Hulke finds the catheter-staff more serviceable. By allowing the gum-elastic catheter to be slipped over it into the bladder, it obviates what is sometimes the most difficult step in the proceeding—the introduction of the catheter after the staff has been withdrawn.

A CASE OF VERY OBSTINATE STRICTURE OF THE URETHRA TREATED BY HOLT'S DILATOR—CLINICAL REMARKS.

(Under the care of Mr. HULKE.)

A tailor, aged 52, was sent to Mr. Hulke, October 18, with an obstinate stricture, after several unsuccessful attempts had been made during eight weeks to pass a catheter. He had catarrh of the bladder, voided his urine very frequently, with much straining, and by drops rather than in an unbroken stream. His appetite was bad, his sleep broken, and his appearance worn and jaded. Nineteen years before his stricture had been dilated by Mr. de Morgan; afterwards contracting it had been again dilated by Mr. Fergusson; then, in 1852, dilated by Mr. H. Lee; and, lastly, in 1857, Mr. J. Wood had divided it with his urethrotome. On each occasion, after full dilatation, contraction had quickly returned when the use of dilating instruments had been discontinued. After some trouble, Mr. Hulke introduced a No. 1 silver catheter through the stricture, a few days after this a No. 2, and in about a fortnight a No. 3 catheter, beyond which he could not get.

December 16.—The stricture was split with Holt's dilator, and a No. 10 catheter was immediately passed. He took a glass of hot grog and went to bed, but had a rigor in the evening and another next morning. A large catheter was passed every second day during the first fortnight, and after this twice a-week. He now passes the catheter himself, and is ordered never to omit its periodical use; the vesical catarrh has ceased. His appetite has returned; his appearance is improved, and he says that he is now in better health than he has known for years.

Mr. Hulke used the largest dilating tube at once, pushing it home rapidly. He does not retain a catheter in the bladder, but passes one every second or third day at first, and afterwards at increasing intervals. He has never seen extravasation follow Holt's rapid and forcible dilatation. He does not think the stricture is less prone to recur after this than after other methods of treatment, and advises that all intelligent patients should be taught to introduce the catheter themselves. This is especially desirable in Hospital practice, because the loss of half a day's work, which attendance at the Hospital often involves, too often leads working men to neglect themselves.

ST. BARTHOLOMEW'S HOSPITAL.

CASE OF OVARIOTOMY—DEATH—AUTOPSY.

(Under the care of Mr. PAGET.)

MR. PAGET operated on a young woman, aged 23, who had been admitted a few weeks previously with ovarian disease into Coborn ward. She had been married two years, and the tumour had been noticed for about the same time. It had not been tapped.

Beyond the presence of some rather firm adhesions between the anterior surface of the tumour and the abdominal walls, there was nothing to cause any special difficulty in the operation, which was performed in the usual manner—by tapping the cyst, which formed the greater portion of the mass, and then drawing it out gradually, together with the more solid multilocular tissue, which formed the lower part of the tumour. A clamp was applied to the pedicle, and the abdominal wound closed by pins, &c.

After the operation, all seemed to go on well for some hours, but unfavourable symptoms appeared on the following day, and she died fifty-three hours after its performance.

At a post-mortem examination, purulent lymph was found effused in the abdominal cavity, and the other signs of acute peritonitis were well marked, especially in the pelvic region. No other morbid condition of the intestines or other abdominal or pelvic organs could be found.

THERAPEUTICAL NOTES.

The following brief remarks were made by Dr. Wilks, at a recent visit, in reference to cases then under his care in Guy's Hospital:—

Various Forms of Bright's Disease.—Discovery of Casts in Urine, not of high practical importance.—Treatment of Renal Dropsy.—Salines, Iron, Elaterium, &c.

The cases of Bright's disease were very numerous. Dr. Wilks said that our prognosis depended altogether upon the

power of diagnosing the age of the disease. In cases of chronic degeneration of the kidney, of course, nothing but alleviation could be expected; but in more recent cases, and those associated with dropsy, the disease was curable up to a certain period, and, therefore, it became very important to discover the exact duration of the malady. It was for this reason that the microscope had been so diligently used in the expectation of determining this point; but, although in many cases very interesting facts might be observed, he thought, as a rule, that the investigation of the character of the casts of the tubes had not been fraught with the good result which had been anticipated. He said so not only from his own observation, but from having known very erroneous diagnoses given as to the character of the malady by those who had relied too much upon the diagnostic value of these casts. The plan of treatment for renal dropsy at Guy's was very much that which was many years ago adopted by Bright, with the exception of the cupping on the loins, which was now very rarely adopted. The patient was wrapped in flannel, and action on the skin promoted by occasional warm or air bath, Dover's powder and a simple saline of liquor ammoniæ acetatis with antimony, at the same time purging by jalap powder or elaterium, and during the convalescence, the administration of iron, as Bright recommended. This Physician, as is known, denounced the use of saline diuretics, as injurious to a kidney which was inflamed, but this opinion has been impugned. Dr. Wilks stated that there certainly was a time, in many of the cases, where the saline matters so administered were thrown off by the kidneys, with a proportionate amount of water, and thus a diuretic effect obtained; but, on the other hand, he could confirm Bright's observation as to their very frequent harmfulness; that after giving medicine of this kind, the renal secretion would become more scanty, and all the other symptoms of the disease more aggravated. The elaterium is now very constantly given in the form of a pill, which is less apt to cause sickness. A patient, an Irishman, had taken as much as one grain of the extract every other day, and at each purging his dropsy lessened, until, having been of immense size, he was reduced to his ordinary proportions. The great value of purging in the dropsy of renal disease is probably due, not only to the water which is evacuated, but to the urinary salts which are also carried off by the intestines.

Value of Turpentine as a Styptic.

Dr. Wilks said that he believed this old-fashioned remedy, turpentine, did not hold the place amongst styptics which its merits deserved. He had long been in the habit of giving it, and often found it arrest hæmoptysis when other ordinary remedies had failed; also in one or two cases of purpura hæmorrhagica it had been very beneficial.

The Treatment of Chorea—Violence of the Jactitations no Test of the Severity of the Disease.

A girl with chorea had been in the Hospital a week, and was considerably better on the treatment of a little syrup and water. Dr. Wilks did not deny the value of zinc, iron, and such remedies, for tonics were generally useful; but he often refrained from giving a medicine when he found his clinical clerks looking upon it in the light of a remedy for the disease, and when he wished to show them the course towards recovery which such a malady as chorea generally pursues when the patient is removed from home to a Hospital. He also made the remark, that if those exceptional cases be not considered which are fatal, the worse the chorea the better the prognosis; that if the jactitations be very violent the patient is generally well in a week or two; whereas when they are less severe a longer time is required for their abatement; and if the disease should exhibit itself in the form merely of a fidgety movement, all treatment is very often unavailing. This should be remembered by those who may boast of some new drug having cured a most violent attack of chorea.

So-called Gastric Fever.

A child with gastric fever was convalescent. This disease Dr. Wilks had never regarded as a specific form of fever, but a pyrexia, dependent upon gastro-intestinal disturbance, and of various durations. Seeing a large number of cases at the Infirmary for Children, he adopted a simple method, which was efficacious in the majority—the administration of saline rhubarb powder, composed of sulphate of potash and rhubarb, for a few days, until the febrile symptoms subsided, and then quinine. He never gives mercury.

SATURDAY, FEBRUARY 6.

SUDDEN DEATH.

JEREMY TAYLOR, in a passage of great force and beauty, enumerates the many ways and manners in which death may overtake us. But although he has collected, in a string of bold antitheses, the most diverse and unexpected calamities, experience could hardly furnish, nor imagination fabricate, so wholesale and horrible an instance as has recently occurred.

It is not in our province to swell the chorus of terror which the event has called forth. Already comments the most contradictory have appeared before the public, and doubtless many more versions will arise before the proverbial nine days have come to a termination. Neither is it honest to raise the cry of superstition, always so ready in the mouths of our Protestant countrymen. At the deeds of an Inquisition, we may truly say with the poet,—

“Tantum religio potuit suadere malorum;”

but, in this example, the faithful were themselves the victims, and the “auto-da-fe” was only accidentally consummated by martyrdom. It is the case of the Galileans on whom the tower fell; and although we may point out certain proximate efficient causes to the catastrophe, it would be as unjust as unscriptural to suppose that these were more sinful than others.

There seems no doubt, however, that the observances and festivals which terminated so tragically were of the character of a revival. The dangerous effects of these well-meaning, but overstrained, manifestations of religious zeal, in a Medical point of view, have been ably described in our own country. It is another evidence of the strange uniformity, or, as it may be termed, polarity, in truth, that from one and the same excess, even in a meritorious direction, results the most melancholy should ensue, in countries far divided, under ecclesiastical systems not only different, but antagonistic. It is obvious that the machinery of the fatal issue differs entirely in the two cases: the revivalists of our country endangered health and reason by religious excitement uncontrolled; while those of the Spanish colony, true to the materialism of their church discipline, actually burned the bodies of those whose senses only were to be kindled, and whose minds were to be inflamed by the blazing of the decorative fire.

The introduction of a sensational and theatrical element into religion lies at the root of the danger in each case; and in this latter accident it is singular how exactly the scene of the theatre is reproduced. We have the flimsy, combustible fabrics, the pasteboard properties, and the wooden structure, dried, heated, and prepared by long continuance of artificial illumination. All this, *mutato nomine*, is what we read one morning, some years since, when the news came that, after a fortnight or so of night and day performances, an extra blaze of gas was turned on for a masked ball, until the heat, never allowed to lessen, rose to ignition, and in a few hours the great theatre in Covent-garden was a heap of ruins. In that.

case, fortunately, the chance of time prevented horrors which have been inseparable from such scenes elsewhere. We now see the insufficient means of egress reduced to total blocking up by the agonised and frantic struggles of the victims themselves; and we have the maddening powerlessness of brave and strong men outside to help the sufferers.

Beyond this, there is singularly little to be said. Fire has shown once more that it is a good servant, but a bad master; and, familiar as it is, has once more, like the tamed lion, turned upon its keepers. Architects and clergy can hardly be blamed for the insufficiency of egress, which is common to all ecclesiastical structures, in such exceptional circumstances. Perhaps some good may come out of the great evil, in leading not only theatrical managers and proprietors of large halls, but builders and churchwardens, to reflect on the frightful possibility of a like accident in the very heart of London. Most men will shudder when they remember the double galleries, the well-staircases, and the massive closed doors of their parish church. Our ritual does not, indeed, load the interior with gauze and pastebord, but the old pews, pulpits, and other woodwork, cased thickly with paint and varnish, would burn like tinder, in spite of the venerable parish engine.

It is to be hoped that the disaster will not furnish material for sectarian reviling. Even if it should, let it be far from us. The Medical man, of all others, ought to be tolerant; whatever differences of doctrine may exist, it is his part to join heartily in the suffrage of a litany uttered alike in our churches and in the one which is now a sepulchre. While we pray to be delivered from plague, pestilence, and famine, let us add, in true charity and catholicity of spirit, from the sudden death which has fallen on two thousand of our fellow-creatures.

THE WEEK.

THE TOWNLEY CASE.

BELOW we publish what we may regard, we hope, as the last act of the Townley tragedy, and we publish it with great pleasure for more reasons than one. It is of great importance that justice should be at last vindicated, if not fully satisfied. No convicted murderer, once respited, has ever, we believe, been delivered over to the executioner; we are, therefore, content that Townley should be now condemned to penal servitude for life. But of perhaps still greater importance in our eyes is the complete vindication of rational Medicine contained in this last Medical report—of true Medical science as distinguished from the hazy theories of amiable enthusiasts in insanity. Admit the grounds on which it was attempted to found Townley's lunacy, and you may do away with punishment for crime altogether, for you do away with crime. Let a man only be shrewd enough, or brazen enough, to assert, that as he was brought into the world without his leave being asked, therefore he is not justly responsible for what he does in it, and no man has a right to judge him for any of his acts—though he is ready to judge and punish others, as Townley did that poor girl—let him only show or affect such cynical indifference and depravity as will shock any amiable expert who may examine him, and he will be deemed so wicked that he ought not to be punished. The greater his crime and hardness of heart, the greater his safety. Admit such doctrine as this—and we may as well—we *must* logically accept the famous or rather infamous theory propounded some years ago by a celebrated authoress—that no man is responsible for his acts; he is the creature of his organisation, the victim of his cerebral and corporeal endowments. Townley adopted this theory, and, to his surprise, found that it was accepted as proof of his irresponsibility;—to his surprise, we say, for he himself acknowledges, “I expected to be hanged, because I killed her; and am not such a fool as not to know that the law hangs for murder.” Unfortunately for him, he has now fallen into the hands of able and scientific Physicians, who, while they

have deservedly high reputations for their knowledge of insanity, have no crotchets as to crime and insanity being convertible terms, and have no special tender desire to protect criminals against society, while forgetting that society needs protection from criminals; they bring to bear on his case what are called common-sense views, as well as scientific and special knowledge, and the result is a most admirable report, in which the so-called “proofs” of his insanity are blown to the winds.

We will only add that society at large is much indebted to the magistrates of Derbyshire for the pressure they put on the Home Secretary. Had it not been for their pertinacity and courage, the baseless hypothesis of Townley's insanity would probably never have been exploded, and a most dangerous precedent would have been established.

The Visiting Justices of Derby have received the following important communication from Sir G. Grey:—

“Whitehall, Feb. 1, 1864.

“Gentlemen,—I am directed by Secretary Sir George Grey, with reference to previous correspondence with you as to the case of George Victor Townley, to inform you that, with the concurrence of the Lord Chancellor, he requested Dr. W. C. Hood, and Dr. J. C. Bucknill, Visitors of Chancery Lunatics, together with Dr. Meyer, the Medical Superintendent of the Criminal Lunatic Asylum at Broadmoor, and Dr. Helps, the Medical Superintendent of Bethlehem Hospital, to examine into Townley's state of mind, and to report thereupon.

“Sir George Grey has received from these gentlemen a report, a copy of which is herewith transmitted to you. While the letters—copies of which were sent to you on the 23rd and 25th ult.—from the magistrates who signed the certificates of Townley's insanity, leave no reason for doubting that they were convinced of his insanity at the time when the certificates were signed by them, the present report from four Medical gentlemen of great experience in mental diseases appears to Sir George Grey conclusive as to Townley being of sound mind. A certificate to that effect, as required by the Act, 3rd and 4th Victoria, cap. 54, has since been received by the Secretary of State.

“I am further to inform you that, taking all the circumstances of this case into consideration, her Majesty's Government are of opinion that it would not be right that the capital sentence should now be carried into effect, but that it ought to be commuted to penal servitude for life. This course has, therefore, been taken, and the prisoner will be dealt with accordingly.

“I am to add that it is the intention of her Majesty's Government to propose an amendment of the Act under which the certificates of insanity in this case were given.

“I am, Gentlemen, your obedient servant,

“H. WADDINGTON.

“To T. W. Evans, Esq., M.P., and W. Mundy, Esq., M.P.

“Bethlehem Hospital, January 28.

“We, the undersigned, having been requested by Secretary Sir George Grey to examine into the state of mind of George Victor Townley, a prisoner under sentence of death in Bethlehem Hospital, and to report our opinion as to whether he is of unsound mind, report as follows:—

“We have carefully considered the copies of papers supplied to us, and on the 26th and 27th days of this month we have had two lengthened interviews with the prisoner, and the conclusion at which we have unanimously arrived is, that George Victor Townley is of sound mind.

“The demeanour of the prisoner during each interview was calm and self-possessed, with the exception that at the commencement of the second interview he displayed and expressed annoyance at the repeated examinations to which he was being subjected. Neither in mode of speech nor in look and conduct was there any sign of insanity observable in him.

“His prompt apprehension of the purport of our questions, and the manner in which he replied to them, indicated the possession of good intellectual capacity.

“The opinions which he avows, that men, as the creatures of circumstance, are not justly responsible for their actions; are opinions at which he appears to have arrived by ordinary processes of reasoning.

“That he knows that he is responsible for the commission of crime is made clear by his own words used to us,—‘I expected to be hanged because I killed her, and am not such

a fool as not to know that the law hangs for murder. I did not think of it at the time, or I should not have done it.'

"We think that his statement, that he killed Miss Goodwin to repossess himself of her as his property, was an after-thought adopted to justify his crime. He acknowledged to us that he had come to this opinion after the deed was done.

"The supposition, that he killed Miss Goodwin under the influence of the opinion that in so doing he was repossessing himself of her as his property, is inconsistent with his own repeated statement to us, that without forethought of any kind he killed her under the influence of sudden impulse.

"He explained to us, that by killing Miss Goodwin to repossess himself of her as his property, he simply meant that he took her out of the hands of his enemies, and placed her in a position where she would wait, and where he would rejoin her when he died.

"The prisoner endeavoured to represent the catastrophe to us as due to the influence of sudden impulse; but the details which we elicited from him show that he used threats of murder for some time before he struck the first blow. We think that his clear memory of the events attending the crime, and also the attempts which he has made to misrepresent the state of his mind and memory at the time of these events, are evidence of his sanity.

"We are of opinion that he does not entertain any delusion on the subject of a conspiracy against him, but that he uses the term 'conspiracy' to express the real opposition which he has met with from the members of Miss Goodwin's family to his engagement with her, and also to express the feeling that they are hostile to him.

"We have considered the evidence of hereditary predisposition to insanity given in the papers supplied to us, and our opinion of the prisoner's state of mind has not been altered thereby.

"We examined the apothecary and also the chief attendant of Bethlehem as to the conduct of Townley since he has been in detention at the Hospital—both of them have had him under daily and special observation—and they assure us that neither in conduct, manner, nor conversation had they been able to observe in him any of the peculiarities which they are in the habit of remarking among the insane.

"W. CHARLES HOOD, M.D., Visitor of Chancery Lunatics.

"JOHN CHARLES BUEKNILL, M.D., Visitor of Chancery Lunatics.

"JOHN MEYER, M.D., Medical Superintendent of the Criminal Lunatic Asylum.

"W. HELPS, M.D., Medical Superintendent of the Royal Bethlehem Hospital."

ENLARGEMENT OF THE LONDON HOSPITAL.

THE necessity for extending the only great Hospital that ministers to the wants of the largest mass of the labouring classes of London, namely, that concentrated around the docks, warehouses, and factories of the east, has long been urgently felt. The committee of the London Hospital have, therefore, determined to build another wing, which will afford greater accommodation for the out-patients, as well as increase the number of beds. The Hospital at present contains 450 beds, which are always full.

THE MEDICAL EXAMINATIONS IN THE UNIVERSITY OF EDINBURGH.

THE following paragraph, which has appeared in the *Scotsman*, announces the success of the arguments which Mr. Syme has recently addressed to his colleagues in reference to the mode of conducting the examinations in the University. As by far the greater number of students who graduate at Edinburgh attend the classes of the University, and the Professors are already the Examiners, the practical effect of Messrs. Syme and Christison's innovation will be simply a subdivision of the examinations for Medical and Surgical degrees in the University of Edinburgh. Still, there are strong objections to the measure, on the ground that it is a public affirmation of the principle, that the student is to be examined for his degree or license by his own teacher. We should excessively regret to see a like acknowledgment publicly made by any examining body in England. Its propriety will, doubtless, be a subject for discussion in the General Medical Council. It

is bad enough that a board of examiners should be composed solely of teachers; but that the opinion of the individual instructor should be made the ultimate test of the proficiency of his own pupil, is a proposition which is opposed to the plainest and most obvious dictates of propriety and right feeling. By associating Medical assessors with the Professors in the examinations, the Edinburgh Senatus have sought to remove the objectionable aspect of their recommendation. But we repeat that we are sorry to see the principle we have animadverted on thus publicly sanctioned by the first Scottish Medical University:—

"The Senatus Academicus of the University of Edinburgh, at their meeting on Saturday last, agreed to sanction the following recommendations of the Medical Faculty:—1. The Medical Faculty recommend that there should be from three to five class examinations each session, conducted by means of questions and written answers, without aid from books or notes. 2. That with each Medical Professor who conducts written class examinations there shall be associated one or more assessors, to be selected by the Medical Faculty from the Examiners in Medicine or from the members of the Faculty, to whom the questions to be proposed shall be submitted for approval, and who, along with the Professor, shall examine the answers and determine their value. 3. That in the event of any student gaining 75 per cent. of the marks in any department, he shall be exempt from further examination on that subject when he appears for his degree examination. 4. That in the event of a student gaining 50 per cent. of the marks in any department, he shall only be required to undergo an oral examination on that subject when he appears for his degree examination."

SIR WILLIAM ROBERT WILDE, M.D.

WE are delighted at having to announce that the order of knighthood has been conferred on our distinguished contributor, Dr. W. R. Wilde, of Dublin, with unusual marks of honour. After conferring the Order of St. Patrick on Lord Dufferin—

"His Excellency, the Lord Lieutenant, who retained his seat in the chair of state after the Chapter of the Order of St. Patrick had broken up, when the Knights Companion had retired from the Throne Room, said:—

"Is Mr. Wilde here?"

"Dr. W. R. Wilde came forward, when

"His Excellency said: Mr. Wilde, I purpose to confer on you the honour of knighthood, not so much in recognition of your high Professional reputation—which is European, and has been recognised by many countries in Europe—but to mark my sense of the services you have rendered to statistical science, especially in connexion with the Irish census.

"Dr. Wilde here knelt before his Excellency, who, having been handed a sword, touched him in the customary manner, and said, 'Arise, Sir William Wilde.'

"A more popular exercise of the viceregal prerogative," says the *Freeman's Journal*, "nor one more acceptable to all classes in Ireland, could not possibly have been made, for no member of the Medical Profession has been more prominently before the public for the last twenty-five years, in all useful and patriotic labours, than Dr. (now Sir William) Wilde. He has cultivated, with effect, a special branch of the Profession, which has earned for himself a wide and just reputation in Europe and America; and the fact that he established, and has recently endowed, one of the most useful Hospitals of the metropolis, will, we are sure, never be forgotten by the citizens of Dublin and the poor of Ireland. He has been so long and so prominently before the public as a popular writer, Medical teacher, statistician, and antiquary, that an enumeration of his labours would occupy more space than this passing notice of his recent elevation would justify. Yet we cannot refrain from reminding our readers of the interest with which his fresh 'Narrative' of Eastern Travel was received in 1839, a work for which Alexander von Humboldt forwarded to him an autograph letter of thanks from the then King of Prussia, and which, like most of his works, speedily ran into a second edition. His book on the 'Vital Statistics and Medical Institutions of Austria,' published soon after, attracted the attention of the Government, and caused him to be associated with Lieutenant (now Sir Thomas) A. Larcom, and others, in compiling the Irish census of 1841, when he laboured effectively to advance the science of vital statistics in

Ireland. He was appointed Assistant Census Commissioner in 1851, and again in 1861, the labours of which latter have but just terminated. Sir William Wilde is, perhaps, the only person now living amongst us who has taken part in the compilation of three successive censuses for Ireland; and his public services in this department, including the valuable and comprehensive volume on the analyses of the great pestilential period from 1846 to 1852, have, no doubt, induced the viceroy, as stated in his address, to compliment him in the distinguished manner we have the pleasure to announce. Sir William Wilde's Professional works have been numerous, and many of them have been translated into the leading European languages, and included in the student's curriculum both in Germany and America. Amongst his miscellaneous writings we may notice the interesting volume on Dean Swift, his charming 'Beauties of the Boyne,' and his 'Irish Popular Superstitions,' all of which were warmly appreciated by the public. Recently he published a most erudite catalogue of the Irish antiquities in the Royal Irish Academy. A work of immense labour and research, for which he received the thanks of all the great archeologists of northern Europe. Sir William is a member of most of the learned institutes of the continent, and has received many honours from abroad. The Academy of Science of Upsala made him an honorary member, and not long since the King of Sweden presented him with the decoration of the Polar Star. The distinction, therefore, which his excellency has now so graciously bestowed will be as fully appreciated on the continent as at home; and we have only to say, long may Sir William and Lady Wilde live to enjoy his well-deserved honours!"

CAN A PHYSICIAN SUE FOR HIS FEES?

IN our article, entitled "Annus Medicus, 1863," we stated:—"In *Gibbon v. Budd* it was decided that a Member of the Royal College of Physicians has a legal right of action for his fees without a special contract. This right arises from a bye-law of the College. We much regret it, as likely to lower the *status* of a Physician in the estimation of the public." Two of our Medical contemporaries declare, apparently in all seriousness, that this statement is "a complete error," and that we have done the College an injustice. The facts as to a Physician's legal right to his fees are simply these:—Before the passing of the Medical Act he could only claim under special contract. The judgment in *Veitch v. Russell* (3 Q. B., 28) was to this effect:—"A Physician has in general no legal right of action for his fees, but he may have it by actual contract." And Lord Kenyon, in another action, said,—“It has been understood in this country that the fees of a Physician are honorary, and not demandable of right.” The Medical Act gave to every registered Practitioner the right to recover in a court of law "reasonable charges for Professional aid, advice, visits," etc., but added, "provided always it shall be lawful for any College of Physicians to pass a bye-law to the effect that no one of their Fellows or Members shall be entitled to sue in manner aforesaid in any court of law," etc. The College of Physicians did pass a bye-law preventing its *Fellows* from suing under the Act, but it did not apply the bye-law to its *Members*. We had stated all this at length in a previous article (May 2, 1863), and did not think it necessary to go into details in our *résumé* of the events of the year, and we do not see how it can be maintained that the phrase, "this right (of Members to sue for their fees) arises from a bye-law of the College," is "a complete error," and an injustice to the College. It may be said that the expression was an elliptical one, and assumed that our readers had some previous knowledge of the subject; not a very unnatural assumption, we think. Taken purely by itself, perhaps it does seem to impute to the College a sin of commission, while the sin was really one of omission. By a *lache* on its part, its Members can use the right conferred by the Medical Act, though its Fellows are forbidden to do so. Our contemporaries go on to say—"It is, therefore, a simple error to say, that this right arises from a bye-law of the College, and that it is likely to lower the *status* of the Physician in the eyes of the public." How this statement can be a simple error, we must leave to grammarians and our contem-

poraries to decide; to us it appears that, if erroneous, it must contain two errors—one of fact, the other of judgment; and as to the latter, we are content to again quote Lord Kenyon. After stating that the fees of a Physician are honorary, and not demandable of right, he goes on to say—"And it is much more for the credit and rank of that honourable body, and perhaps for their benefit also, that they should be so considered. . . . I much doubt whether they themselves would not altogether disclaim such a right as would place them upon a less respectable footing in society than that which they at present hold." We do not comprehend how our contemporaries can support their views, unless on the ground that the Members of the College are not, like the Fellows, Physicians—absurdly and unjustifiably confounding them with the new order of Licentiate. It cannot be supposed that the College deny the members to be true Physicians in all senses of the word; or that they can be indifferent to their repute and *status*. We hold that the omission of the words "or members" in their bye-law was simply an error in judgment, which may have the effect of raising an unnecessary distinction between the junior and senior ranks of Physicians. It is not likely, however, that the public will confound one who lives and practises as a Physician with a general Practitioner and L.R.C.P., spite of the *lache* of the College, which we never expected to see justified in the pages of a Medical Journal.

REPORTS OF PROFESSOR HUXLEY'S LECTURES ON "THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA," DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE I.—FEBRUARY 2.

AFTER a few introductory remarks, Professor Huxley stated that further observation and reflection had served to convince him more fully of the truth of the tripartite division of the vertebrate sub-kingdom, which he had announced in the lectures delivered at the College last year. The first section or province (*Ichthyopsida*), containing the Fish and the Amphibia, all possess, he said, branchial respiratory organs, at least at some period of their existence: in the embryonic condition they are without amnion, and the allantois is absent or rudimentary, their blood corpuscles are nucleated, and their lower jaw does not articulate directly with the skull. The members of the second province, comprising the classes Reptilia and Aves (*Sauropsida*), never possess branchiæ; have the amnion and allantois well developed, the latter generally taking on a respiratory function; their blood-corpuscles are nucleated; each ramus of the lower jaw is composed of several pieces, and articulates by means of the quadrate bone with the skull; they have a single occipital condyle, and the appendages of their epidermis take the form of scales or feathers. The third division contains the Mammalia alone; these never have branchiæ; the amnion and allantois are always developed; the large majority of their blood-corpuscles are non-nucleated; each ramus of the lower jaw is simple, and articulates with the squamosal element of the skull; there are two occipital condyles; the epidermal appendages are in the form of hair, and the females have mammary glands. As far as our present knowledge extends, both of living and extinct vertebrate animals, these three great groups are absolutely defined in nature; while, on the other hand, between fish and amphibia, birds and reptiles, respectively, numerous points of affinity may be found.

The class Mammalia being the subject of the present course, Man, as the form with whose anatomy most of the audience were best acquainted, was selected as a type, and a sketch of the salient point of his structure was given first, to assist in following out in subsequent lectures the various modifications of organisation found in other mammals. The lecturer commenced a description of what he termed the "zoological anatomy of man" (having especial reference to those parts which offer the best terms of comparison in descending through the mammalian series) by stating that that which first strikes

the most superficial observer of the human body, is the erect attitude. This alone, however, is not distinctive; it is shared by the penguin and kangaroo, but in these animals the body is suspended on the flexed femur; the vertical trunk placed on an extended hind-limb is peculiar to man. The principal remaining external zoological characters of man are—the plantigrade sole, the backward arching of the spine in the dorsal region, the hollow in the lumbar region, the wide chest, the muscular prominences formed by the powerful abductors of both pairs of limbs, and the peculiar proportions of the body, the length from tip to tip of extended anterior extremities equalling the height, the vertical central point being a little below the symphysis pubis, the whole height being seven or eight times the vertical height of the head, the legs being longer than the arms, and the proximal segments of both limbs longer than the distal. The pollex is perfectly free and opposable, and does not lie in the same plane as the other fingers; the palm is very nearly square; the carpus is shorter than the metacarpus, this shorter than the digits; the forearm capable of free rotation. In the lower limbs, the hallux is only imperfectly mobile, and scarcely at all opposable, and lies nearly in the same plane as the other toes; the second toe is generally the longest; the sole is longer than broad; the tarsus longer than the metatarsus, this longer than the digits; there is more or less union by integument or “syndactyly” of the three middle toes. One of the greatest peculiarities of the human body is the distribution of hair upon its surface; on the head this is more abundant on the dorsal than the anterior aspect, on the body more developed in front than behind, on the limbs more on the extensor than the flexor surfaces, without relation to front or back. The nails are comparatively flat, and do not cover the whole surface of the phalanx on which they rest. The septum of the nose is narrow and elongated, causing the external projection of the organ; the nostrils are directed downwards. The penis is pendulous, the testes contained in a well-developed scrotum placed behind the root of the penis, the perinæum is distinct, and the mammae are pectoral.

The special zoological characters of the human skeleton are as follows:—The spinal column consists of thirty-three vertebrae, of which seven are cervical, twelve dorsal, five lumbar, five sacral, and four coccygeal. In the adult state it forms a double sigmoid curve, caused, in the dorsal and sacral regions, by the conformation of the vertebrae—in the cervical and lumbar regions, by the elasticity of the *ligamenta subflava* connecting the posterior arches. In the skull, the occipital condyles are placed, if not exactly in the centre, within the middle fifth of the base, being slightly behind the centre in the lower races. The mastoid processes are largely developed. The cranio-facial angle in well-formed skulls is about 90°, and probably never exceeds 120°. In consequence of the enormous size of the cerebral cavity, the length of the head is always more than twice the length of the basi-cranial axis. (a) In the interior of the skull the ethmoid and presphenoid meet in the floor of the cavity, and are not concealed by the frontal; the inner surface of the petrosal has no fossa for the lodgment of a process of the cerebellum; and the planes of the occipital foramen, cribriform plate, and tentorium are parallel to one another. The hyoid bone is comparatively narrow from above downwards, and, though concave posteriorly, not deeply excavated. In the limbs the pectoral arch has a well-developed clavicle, and a large and broad scapula; the humerus has a large globular head, and at the lower end a rounded facet upon which the radius plays, allowing free pronation and supination. The form of the pelvis is eminently distinctive—the breadth and curvature of the sacrum, the great extent and concavity of the inner surface of the iliac bones, the sigmoid flexure of their upper margin, the mode in which the pelvis is set on the spinal column, the breadth of the upper aperture, and the width and shortness of the whole cavity, may specially

(a) These terms are explained in the last Course of Lectures. See *Medical Times and Gazette*, 1863, vol. i, p. 607.

be noted. In the lower extremity may be observed the great angle at which the head of the femur is set on its shaft, the greater length of the internal than the external condyle, the flatness of the upper surface of the tibia, the form of the ankle-joint, and the downward projection of the malleoli.

To sum up the peculiarities of the human skeleton, we find that its special characteristics, as distinguished from those of the general Mammalian type, have all (leaving aside the upper extremity) reference to the erect posture. To this end contribute the form of the ankle-joint, of the upper surface of the tibia, of the condyles and head of the femur, and of the pelvis; the curvatures of different parts of the spinal column, the position of the ribs, the breadth and flatness of the sternum, and the situation of the occipital condyles. Moreover, related to the same posture are the absence of great bony crests on the skull for the attachment of the muscles which support the head in the lower animals, the smallness of the jaws and teeth, and even the great mass of the brain, which would be of little avail unless the anterior pair of limbs had been set free to carry out its requirements.

FROM ABROAD.—MATTEUCCI ON GALVANISM IN TETANUS—INNOCUOUSNESS OF SMALL QUANTITIES OF VERDIGRIS—THE LESION PRODUCED BY RAISING CHILDREN BY THE ARM—ACTION FOR MALPRAXIS IN AMERICA.

The celebrated Italian physiologist, Matteucci, has addressed a communication to the French Academy of Sciences upon the employment of the continuous electrical current in the treatment of tetanus; and in a note to M. Flourens he earnestly begs that the attention of physiologists and Physicians may be turned to the subject, as he firmly believes that a therapeutical procedure will result, which, if it do not effect a cure in this terrible disease, will, at all events, produce great diminution of suffering. Seeing recently, in an American journal, the fact stated, that the continuous current had been advantageously employed in a case of hydrophobia, he called to mind a case of tetanus published many years since by Nobili and himself. It is well known that a condition of tetanic contraction may be excited under two circumstances, viz., the interrupted passage of the electric current into the nerves and muscles of an animal at very short intervals, and the continuous passage of the current into the nerve in the opposite direction to its ramifications. It has been the object of some of Professor Matteucci's communications in the *Philosophical Transactions*, to explain how this is brought about by the production of secondary polarities. What, however, we have to do with at present is the fact, that a nerve which has in this way acquired the property of exciting tetanic contractions, instantly loses such property as soon as it is submitted anew to a continuous current. Reasoning from analogy it was thought that tetanus might be assimilated, as regards the state of the nerves, with the condition of an animal in which interrupted currents or a continuous inverse current have been employed, and the hope was entertained that a direct continuous current would produce the cessation or diminution of the contractions in the one case as in the other. And so in effect it was found that the patient, while he was subjected to a continuous electric current from 30 to 40 pairs of plates, no longer suffered the same violent convulsions, and was able to open and shut his mouth. This amelioration continued during several minutes, after when the contractions returned, notwithstanding the passage of the current. The current was suspended awhile, and then reproduced with from 50 to 60 pairs. Amelioration again followed; and these alternations continued during several hours, the salutary effects of the current gradually diminishing, and at last ceasing entirely.

MM. Pécholier and Saintpierre have forwarded an interesting note to the same Academy, giving an account of an investigation which they have been conducting respecting verdigris (basic-acetate of copper), in the department of L'Herault, in which this substance is abundantly manufactured.

Energetic poison as it is known to be when taken in a considerable dose, verdigris is well tolerated in fractional quantities, continued even for a long period. Poultry fed almost exclusively on the refuse of the raisins employed in its manufacture, and which always contains ponderable quantities of this salt, thrive excellently and fatten rapidly. The work-people also, although in constant contact with this substance, and the absorption of which is proved by its detection in their urine, also enjoy excellent health. Copper colic is unknown among them. The absence of chlorosis in girls at the age at which it is usually observed is also remarkable. In its pulverulent state, the verdigris, like all other dusts, irritates the ocular and respiratory mucous membranes.

M. Verneuil brought under the notice of the Paris Surgical Society the accident which is not infrequently met with in children when raised by the hand. A severe pain is felt, and the head falls pendent and motionless, and supination is no longer possible. M. Goyraud attributed this occurrence to a displacement of the triangular cartilage of the cubito-carpal articulation, and stated that forced supination imparted to the arm causes the immediate disappearance of all the symptoms. The case now related by M. Verneuil, in his opinion, entirely confirmed this view. MM. Giraldès and Marjolin, however, believe that the seat of the lesion is not in the wrist at all, but in the elbow, and that it is nothing else than an incomplete dislocation of the head of the radius, relief being at once obtained by either forced supination or pronation. M. Chassaignac has seen a good many of these cases, but has never found the pain or paralysis cease after the manœuvre described by M. Goyraud.

Formerly we were accustomed to consider unjust actions for malpractice almost as an American peculiarity; but certainly the frequency with which these have of late years occurred among ourselves, leaves us but little ground for congratulation. Indeed, probably from the more determined defensive position assumed by the Profession, actions of this kind have now become much rarer in the United States. One has, however, recently been brought at Newport, New Hampshire, which has excited much interest; the trial, in fact, lasted a week, and arose from a charge of negligence in treating a fracture of the arm, whereby a false joint, requiring an operation for its remedy, was induced. The array of Medical witnesses on opposite sides—so common with ourselves—was present, but the jury found a verdict for the Surgeon in ten minutes, the ill result of the case being evidently due to the carelessness of the patient. We notice the case in consequence of a somewhat novel feature in the evidence of Dr. Bigelow, Professor of Surgery in the Harvard University, under whose care the patient came after the failure of a seton to induce osseous union. His evidence was in favour of the defendant; and the question as to malpraxis having been replied to, one would have thought the vocation of the witness ended. Not so the Professor, for he detailed to the court all the steps of the operation which he had deemed advisable for the remedy of the deformity, and which restored to the patient the use of his arm. "The gristly ends of the bone were cleaned and turned out so as to get at them, and the periosteum was turned back from each end. The periosteum is a membrane which forms the bone, so that by turning this back like the cuff of a shirt-sleeve for about an inch from the nearest healthy bone, and then sawing off this uncovered bone, and by then bringing the cuff down again where it belonged, it would go at once to work to make new bone, and this bone would cause the broken place to unite, that is, it would solder it together. This was the operation which was done. The periosteum was stripped back from the adjoining sound bone, which was sawed off with the gristle. The cuff was then turned down again, and the two ends of the bone brought together, and wired close with a silver wire passed through holes drilled for that purpose. The periosteum then caused the fragments to unite by new bone, shaped somewhat like the solder round the joint of a lead-pipe." The court even became interested in the history of the operation, and asked the witness, "To

what extent had this operation been known or practised in Surgery?" The witness replied, "Only a few times. I have done it several times myself with success. The first time I did it I supposed I had invented it; but a short time, however, after my first operation, there came to this country an account of a similar operation just done in Europe, of which I had not heard. I have seen only one American case published here since my first was published."

FIRST IMPRESSIONS OF THE BRITISH PHARMACOPŒIA.

By A CHEMIST.

1. It is stated that £6000 have been expended upon it; = £13 10s. 3d. per page, for a mere compilation. The first 160 pages do not contain an original observation, fact, or expression. Would not £600 have been excessive?

2. The abolishing drachms and scruples seems to be frivolous.

3. The Act of Parliament for giving the Council the copy-right—fixing the price of the volume at 10s. 6d.—postponing the issue of the 6s. edition—urging the possession of the book by all Medical men and druggists—are mercenary tricks, worthy of the astutest quacks.

4. The extremely limited range of the *Materia Medica* speaks the limited resources of our art, as apprehended by its compilers. In fact, if this book represents the current amount of therapeutical knowledge, practical Medicine has retrograded vastly, and the question should be entertained how it is to be advanced.

5. In all respects the British Pharmacopœia contrasts most unfavourably with the new edition of the American Pharmacopœia.

6. What is the meaning of the adoption of substances into the list of *Materia Medica*, and forms for preparing the same among preparations?

7. Has *glacial acetic acid* any use in medicine?

8. Acid. Hydrochloric. The process will not produce it.

9. Preparation of Lard—Frivolous.

10. White Bismuth, page 190. Is the chemical nature of the product not known?

11. Linseed Poultice. The addition of olive oil?

12. Conf. Scam.—*Crude commercial scammony*, or resin of scammony—to be used indifferently. Surely this allows two very different results.

13. Conf. Sulphuris. Frivolous, empirical.

14. Why reject Decoct. Hordei Co.?

15. Enema Magnesia Sulph. Frivolous.

16. Ext. Col. Co. Commercial scammony or resin of scammony may be used indiscriminately. Surely a great mistake!

17. Ext. Tarax. Not an extract, but an inspissated juice.

18. Resin of Podophyllin. The process given will produce a resin nearly, if not quite inert. The eclectics who introduced podophyllin, assert that its efficacy depends upon the retention of the several cognate resinous substances yielded by the root to sp. rect. If only one of these resins—that soluble in ether—is used, it is not podophyllin. The employment of acid. hydrochlor., therefore, is fatal to the therapeutic value of the result.

19. Pulv. Antimonialis. Bad—not James' powder.

20. Page 317, Scammony Res., called resin of jalap. A printer's error, doubtless, but this shows how loosely the book has been edited.

21. Suppositories. Frivolous and bad—cow butter much better as a vehicle.

22. Troches. Frivolous—so, also, many other preparations, *ex. gr.*, Ung. calomel., Ung. creosoti, Ung. gallæ, etc., etc. Surely the proportions in which substances may be combined with lard is a proper subject for each several prescription?

23. Liq. Arsenicalis, and other preparations, which ought to be strictly chemical, and not merely empirical forms.

Upon the whole, my impression is, that the British Pharmacopœia is a sad failure.

A. It does not represent the present state of therapeutics.

B. It is half made up of frivolous prescriptions.

C. It contains scarcely a single new substance or form, except a few pilfered from private persons—chemists.

D. It retains many mere empirical formulæ, borrowed from *quack medicines*.

E. If taken to represent the state of practical Medicine in this country, it would show that it is behind every other country in the world.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF LYNN.

THE town of Lynn, or King's Lynn, Lynn Regis, stands on the eastern side or bank of the Ouse, on the marshland, or Great Fen level. Richards, the author of the best history of the place, assumes that originally the town was built on the western side of the river; and, indeed, there still remains on that side a few houses and a church, constituting a small parish known as "Old Lynn." The river, at the point where the modern town stands, is wide—almost as wide as the Thames at Hammersmith-bridge; but the long, irregular, muddy banks destroy all picturesque effect. The water, also, looks unusually dirty, and overhanging it is no trace of forest or tree. There is no Kelvin Grove in Lynn; and the writer of the lovely song-book which charmed the wits and rang from the stage in the reign of good Queen Anne, in selecting Lynn for the name of one of his fair maidens, might at least have discovered a more romantic situation. But we must take the old town as it is, and there on the eastern bank of the muddy Ouse it stands, a large town now, with 17,000 inhabitants and an active commercial life.

There is a history connected with Lynn which opens up many interesting subjects for the consideration of the sanitary not less than the antiquarian scholar. It is probable that at one time the river Ouse took a natural course to the sea by Wisbeach, so that as late as the reign of our King John the Ouse at Lynn was a small and insignificant stream. The traditional account of the cause of the present large river is, that originally, when the great river made its way freely to the ocean by Wisbeach, all went well with the people of the fens or English low countries. But, behold, one day there was a great inland flood,—in fact, a local deluge,—and the waters, meeting with obstruction, carried all solid parts, loose bank, and mud, with them; at last the natural channel of the river was retarded, and the currents, still demanding way, were spread out over the lands, deluging the fens, and making them sad wrecks of lands once rich and cultivated. And then the tradition goes on further to state that the fen people, when the actual deluge was over, were tormented by water to such a degree, that they held consultation, and agreed that a channel must be cut, so that the great river should once more roll into the sea. But where should they cut the channel? It would have been wise to have cut it near the outfall at Wisbeach, which was the natural course, and was only temporarily and partially closed; but they did not see that, and, therefore, determined to divert the current by forcing it on to Lynn by the channel of the Lesser Ouse,—a feat which, when completed, rendered the harbours of Lynn and Wisbeach inconvenient and small, and, by arresting the flow of water, placed determinate obstacles both against the inland navigation and the effective drainage of all the fen districts. This mistake is presumed to have been made in the reign of Henry the Third.

The old foundations of Lynn are supposed to have been laid by the Romans, probably during the reign of Nero, and while Roman engineers were endeavouring to drain the fens and prevent the influx of the ocean. To effect these purposes it is believed that a body of colonists of Belgic and Batavian origin were brought to work under the protection of the Roman eagle. Hence, according to my authority (Richards), the name *Len*, *Lyn*, the Belgio-Celtic for a fen or marsh.

During the continuance of the Roman rule, Lynn became the mother town of the fens; afterwards it declined, and during the Heptarchy it sank almost to the last; then it rose again, and extended across from the western to the eastern side of the river. Becoming of more importance still, the town was seized, wholesale one may say, by the ruling power, the Church, and in the reign of Edward the Confessor belonged to two Bishops—Ailmar, Bishop of Elmham; and Stigand, Archbishop of Canterbury—hence it was then called Bishop's Lynn. Under the dominion of the Church, Lynn remained until the reign of Henry VIII.; for John, though he liked Lynn, did not rescue it. At last it was emancipated from the Church by bluff Harry, and made a royal town, when its name changed to King's Lynn, or Lynn Regis. In these days it has regained its original appellation, Lynn, the mother town of the Fens.

So soon as Lynn was liberated from its thralldom, it became a busy and thriving centre. It was especially celebrated for its

yearly "mart," or fair, which was, and is still, proclaimed on the 14th of February, and continues for six days or more. For many years—I might almost have said centuries—this mart was the great occasion during which the townsfolk bought all their leading wares; but now it is a fair of inconsiderable importance. It had the effect of inducing commerce, and that has steadily increased. At the present time various branches of trade and exchange flourish vigorously. There is a large foreign import trade in corn, linseed, coal, and timber. The fishing trade is extensive, and there are several large manufactories for agricultural implements, and two large oil-cake manufactories.

The town itself stands in a small curve, or little haven, in the Ouse, and the river encircles perhaps two-thirds of the town on its eastern side; extending from the river into the town are several inlets, called "fleets," on the sides of which houses are built, and which act as open sewers. I shall have occasion to dwell on these when speaking of the sanitary condition of the district.

The streets are generally narrow and long, but there are some fine open spaces, and the principal market-place is one of the largest and most commanding I have ever seen. The churches, all very ancient, one excepted, are beautiful, and the antiquities are numerous. Remains of the old wall are extant. Recently some new public walks have been laid out, and afford agreeable walking-grounds and places of summer resort; but, as with Norwich, so with Lynn, the modern town reformer has to deal in his work with a place which was constructed to be fortified—where, that is to say, as many houses were laid out, or rather laid in, as could possibly be compressed into a limited space, and surrounded by ramparts accessible only by a few castellated gateways. Leaving the town as a whole, let me pass to those points relating to it which are most interesting to Medical men; and, first, to the Hospital.

THE WEST NORFOLK AND LYNN HOSPITAL.

The West Norfolk and Lynn Hospital was opened in the year 1835. It is situated a little distance from the town, and contains fifty-two beds. The building is plain and good; it is in two stories, and is admirably lighted. The wards are ten in number, and the freest ventilation is permitted by means of the windows from side to side. The gas burners are also applied to ventilating purposes during the night. Over each burner there is suspended a large funnel with an escape tube, which passes into the shaft of the chimney. This, which is a new Hospital appliance introduced by Dr. Lowe, one of the Surgeons to the Hospital, answers extremely well, and is a good, cheap, and practical means of inducing a free current of air. The floors are of deal, and are washed with soap and water; dry scrubbing has never been practised. The bedsteads, made of iron, are free from curtains, and 1102 cubic feet are allowed to each bed. The warming is by the open fire-grate. The Medical and Surgical cases are mixed, both on the male and female side, except in the accident ward, which latter is set apart for Surgical cases alone.

IMPROVED HOSPITAL ARRANGEMENTS.

From the above general description it will be useful to pass to certain improvements which seem to me worthy of special imitation in all infirmaries. The method of ventilation during the night, by means of the gas-burner, is an excellent provision. I have already described the plan. In the accident ward there is an improvement; that ward is so situated that its door opens on the pathway, so that patients can be carried in without being lifted even a single step. Any one who has seen in town Hospitals the method of carrying an injured man up long and steep flights of stairs, will appreciate the value of this common-sense and ready arrangement. For the convenience of patients in bed, who are too feeble to rise and sit, for meals or for change of position, a simple and effective plan is carried out for their assistance by means of a strong white cotton-netted sheet, which looks something like a small hammock flattened out. This, when the patient is reclining, lies under the shoulders or pillow across the bed, and is a cause of no inconvenience; when required for service, it is gently spread out beneath the patient, and the ends of it on each side, to which light fastenings are attached, are brought to the posts at the foot of the bed, and secured there after the patient has been raised to the required height, and the fastenings have been proportionately tightened. The patient, on being let back, finds himself or herself reclining on the cotton netting, which is so light and so strong, and so readily adaptable to the back, that the utmost support is secured without

any fatigue or pain. In this way many of the patients take their meals, the food being placed before them on a light deal table, which rests by its feet on the edge of the bed on each side; in this way, too, they sit to carry out amusing occupations, such as sewing, knitting, or reading.

But that which pleased me most in this Hospital was the adornment of the walls. How wretched in most Hospitals is the prospect that meets the eye of the invalid! A blank, white surface, a deal table, and, side by side, other sufferers. Nothing on which the eye can rest but blankness and sorrow. The authorities at the Lynn Hospital have, for some time past, reformed a system, so prejudicial to recovery, by introducing something which can interest and create variety of scene and thought. On the walls of the wards they have suspended in neat frames, and within sight of the patients, the best pictures which their means and the generosity of the lady patrons can afford. The better class coloured plates, published in the *Illustrated London News*, have here come in most serviceably; and if the lamented and esteemed founder of the great pictorial newspaper had lived only to cheer up humanity, in its lowest depths of sorrow, by this one simple artistic effort, his life had been well spent. Flowers, also, are, I believe, not forbidden in summer-time. On entering some of the wards of this Hospital, the effect of these few and simple representations of art is most striking. The gloom of the sick-ward is expelled, and throughout a cheeriness prevails, which is as obvious on the countenances of the patients as sunshine on a landscape. I do not mean to say that all is done that art could do, nor a tithe of it; but here is an attempt, at all events, to lift up the poor sick body through the mind, that might be used in every sick ward as an important adjunct to the Pharmacopœia; for there is something in chaste art, however rude its type, which goes so deeply into the soul of the most illiterate man, that the body feels the impulse, and all for its good. The poor—I was going to say the Profession, and that would not be wrong—are deeply indebted to Mr. Charles Hawkins for his strenuous advocacy of the introduction of artistic embellishments into the sick Hospital; and in time, I doubt not, the object for which he has striven will be appreciated and carried out, as it is in Lynn. Lastly, in the Lynn Hospital, for the amusement of children, toys are granted, and for the adults there is a library, in which more than one style of books is allowed.

There are histories, travels, and other works of an instructive and entertaining character.

The rules for the admission of patients is exclusive. No child is admitted under six years of age as an in-patient, except in extraordinary cases of Surgery, fractures, or where cutting for the stone or other capital operation is required; neither is any consumptive person admitted; nor any one of disordered mind, or subject to epileptic fits, or suspected of having small-pox, venereal disease, itch, or other infectious disorder. Pregnant women are also excluded; dropsical persons, cancerous cases (except when operation is required), and all who are suffering from chronic ulceration of the legs.

If it be considered that these rules of admission are too strict, admitting, as they do, the entrance of none but acute or sub-acute cases of disease, there is a strong recommendation of the governors, to the subscribers, which the Profession will consider as peculiarly sensible. The governors "earnestly request that each subscriber, previously to giving a recommendation, will ascertain the circumstances of the applicant; as persons have been admitted into other Hospitals who were well able to pay for the assistance they required. The charity must sustain serious injury if attempts at imposition of this sort be not promptly frustrated, and Medical gentlemen will have reason to complain of the injustice of breaking in upon their private practice and emoluments."

DIET OF THE HOSPITAL.

The diet scale of the Hospital, given below, is liberal, but the proportion of boiled mutton is out of all reason. The system of weighing out the food, the folly of which I have noticed in a previous paper, holds place; puddings and slops are, moreover, in excess; and the daily quantity of bread, fourteen ounces in the "full diet," seems, by comparison with the other articles, excessive, especially when it is combined on the same day with twelve ounces of pudding. The liberality of the scale certainly admits of revision, not in reference to expense, but in regard to the mode of expenditure and the character of the food allowed. Animal food, in some quantity, should surely be on the table every day, in Hospital, for those patients who are able to take it. It is in the end also the cheapest food; it supplements other food so well, and in convalescence so greatly expedites perfect recovery. It is fair to add that Dr. Lowe thinks the scale very suitable to the patients of the Institution.

West Norfolk and Lynn Hospital Diet Scale.

	Extra Full Diet.			Full Diet.			Extra Middle Diet.	Middle Diet.	Milk Diet.	Broth Diet.
	Men.	Women.	Children.	Men.	Women.	Children.				
Breakfast	One pint of milk. Bread and butter.			One pint of milk. Bread and butter.			One pint of milk. Bread and butter.	One pint of milk. Bread and butter.	Milk 2pts.	Milk 1 pt.
Dinner	Meat (cooked) 6oz. Boiled mutton. Potatoes (cooked) 6 oz. Bread. Same quantity of roast beef on Sundays.		Meat (cooked) 3 oz. Mutton.	On alternate days: Meat (cooked) 6 oz. Potatoes (cooked) 6 oz. Mutton. On alternate days: Pudding 12 oz.		On alternate days: Meat (cooked) 3 oz. Potatoes (cooked) 6 oz. Mutton. On alternate days: Pudding 8 oz.	Meat (cooked) 3 oz. Mutton. Potatoes (cooked) 6 oz. Bread. Roast beef on Sundays.	On alternate days: Meat (cooked) 3 oz. Potatoes (cooked) 6 oz. Mutton. On alternate days: Pudding 8 oz. Bread. Roast beef on Sundays.	Rice milk 1 pt., or light pudding 8 oz.	Broth 2 pt.
Supper	One pint of broth, gruel, or milk. Cheese 1 oz. Bread.		½ pint of broth, gruel, or milk.	One pint of broth, gruel, or milk. Bread. Cheese 1 oz.		½ pint of broth, gruel, or milk. Bread.	One pint of broth or gruel. Bread.	One pint of broth or gruel. Bread.	Bread 14 oz.	Bread 9½ oz.
Daily allowances.	Milk 1 pint. Gruel, broth, or milk 1 pint. Meat (cooked) 6 oz. Potatoes (cooked) 6 oz. Bread 14 oz. Cheese 1 oz. Butter ½ oz.		Milk 1 pint. Gruel, broth, or milk ½ pint. Meat (cooked) 3 oz. Potatoes (cooked) 6 oz. Bread 9½ oz. Butter ½ oz.	Milk 1 pint. Gruel, broth, or milk 1 pint. On alternate days: Meat (cooked) 6 oz. Potatoes (cooked) 6 oz. On alternate days: Pudding 12 oz. Bread 14 oz. Cheese 1 oz. Butter ½ oz.		Milk 1 pint. Gruel, broth, or milk ½ pint. On alternate days: Meat (cooked) 3 oz. Potatoes (cooked) 6 oz. On alternate days: Pudding 8 oz. Bread 9½ oz. Butter ½ oz.	Milk 1 pint. Broth or gruel 1 pint. Meat (cooked) 3 oz. Potatoes (cooked) 6 oz. Bread 9½ oz. Butter ½ oz.	Milk 1 pint. Broth or gruel 1 pint. On alternate days: Meat (cooked) 3 oz. Potatoes (cooked) 6 oz. On alternate days: Pudding 8 oz. Bread 9½ oz. Butter ½ oz.		

Extras to be specially ordered.

Beer, porter, wine, brandy, other spirits, beef for beef-tea, mutton chops, fish, eggs, jelly, fruits.

USE OF ALCOHOLICS.

The quantity of alcohol used in the Hospital is exceedingly small. Beer and porter, which rank as extras, are allowed in the proportion of rather less than a pint per patient per day. The use of wines and spirits does not exceed a third of an ounce per patient daily.

(To be concluded.)

REVIEWS.

The Second Step in Chemistry; or, the Student's Guide to the Higher Branches of the Science. By ROBERT GALLOWAY, F.C.S., Professor of Practical Chemistry, Museum of Irish Industry, etc. London: John Churchill and Sons. 1864.

Manual of the Metalloids. By JAMES APJOHN, M.D., F.R.S., M.R.I.A., Professor of Chemistry in the University of Dublin. London: Longmans. 1864.

THE former of these two useful manuals forms one of Mr. Churchill's series; the latter has been written at the desire of two distinguished Fellows of the University of Dublin, the Messrs. Galbraith and Haughton, to form one of their series on different branches of science.

The author of the first work states in a preface that his concern has been especially with those newer views which are now being very generally adopted. As these are founded mainly on volume relations, all the branches of this subject are at the commencement explained and illustrated by exercises to be performed by the student. The history of the rise and progress of the new views is given, commencing with Dr. Clarke's and Mr. Griffin's, passing on to the unitary system of Gerhardt, Williamson's views on the constitution of bodies, Laurent's on the ammonias, and finally Gerhardt's method of classification. The chapters which follow are intended as a practical and systematic manual of organic chemistry, based on the work of the last-named writer. About three-fourths of the volume having been thus occupied, long and practical chapters are devoted to subjects daily rising in importance, such as fractional distillation; the law and method of determining the boiling point of liquids; specific and atomic heats, with kindred details which occur in the first; followed by a second containing Graham's experiments on diffusion, dialysis, and osmose; and a third on chemical analysis by spectrum observations. Two appendices, one on weights and measures; another, containing a selection of examination papers, bring the goodly volume of nearly 800 pages to a close.

Dr. Apjohn's book is of a somewhat smaller size, corresponding with the comparatively limited field open to it. Students of medicine, moreover, and of engineering, do not require the minute information as to triamines and tetrammoniums, which is properly characterised as a second step in chemistry; and it is principally for these that the task has been undertaken. An introduction of 105 pages deals with the general laws of matter and combination, giving "in as compressed a form as possible all information required by the student. In carrying out this desirable reform," says the author, "and to secure not only brevity, but precision, I have not hesitated in some few instances to call in the aid of some of the simpler forms of algebraic calculation."

A good instance of this condensed method occurs in the account of Gerhardt's unitary system spoken of above. After briefly acknowledging that chemist's merit and originality, Dr. Apjohn says, "The system of Gerhardt, as at present taught, may be supposed to rest on the three following propositions:—

"1. That the atomic volumes of all the simple substances are equal.

"2. That the same is true of the atomic volumes of the compound bodies.

"3. That though the atomic volume of a compound appears in some instances to be double that of an element, the ratio between the volumes of the smallest quantities of each which can exist in a separate state is really one of equality."

After mentioning objections to doubling the equivalents of certain simple substances, the writer concludes: "But even though this and other difficulties could be surmounted, grave doubts may be entertained of the expediency of making Gerhardt's theory the exclusive basis of instruction in chemistry. The existing method seems entitled to preference, from its comparative simplicity, and because of its resting exclusively on experimental evidence; and, for these reasons, will probably continue to be long employed by those who are occupied in chemical teaching."

Six consecutive chapters, devoted to the metalloids in succession, form about three-fifths of the work; and six short appendices, mainly on metrical points, bring it to a close.

It will be seen that these two works, though differing materially in their scope and size, are both well adapted to the purpose for which they are intended, and will in all probability be fully appreciated by students.

On Life and Death. Four Lectures Delivered at the Royal Institution of Great Britain. By WILLIAM S. SAVORY, F.R.S., etc., etc. London: Smith, Elder, and Co. 1863.

IT needs a bold man to undertake a subject so extensive and difficult as that which forms the title here given; and the recollection which it calls up of Bichât's great work does not tend to lessen the gravity of the undertaking. But Mr. Savory disarms comparison in a brief, frank preface. These lectures, not originally intended for publication, now appear at the request of some that heard them. They present an excellent digest of modern physiology, in a form well adapted for a general audience, and doubtless derived an additional charm from the delivery of a lecturer so accomplished as their author. They do not pretend to any striking originality, nor are they intended to inculcate views at variance with the received opinions of anatomists. Acknowledgment is made of the labours of other observers as incorporated in the body of the work, especially those of Von Baer and Dr. Carpenter; perhaps, moreover, we may add that there is throughout a perceptible adstipulation to the views and doctrines of the able author of "Lectures on Surgical Pathology." All this and more is very gracefully admitted by the writer, who says,— "After all, much—most of what is here set forth—cannot, part by part, be fairly placed to the account of individual minds, for it has, in the course of many years, gradually grown out of the labours of many men."

In the first lecture, types of organisation in living beings are distinguished from grades of development, and the concurrence of the two to determine special forms is established. The law of progress is shown to be from the general to the special, and to be pervaded by definite unity of plan. It concludes by explaining a familiar phrase—"Law of nature;" stating that "natural laws are not analogous to human laws. No one can for a moment imagine that the Creator is bound by any law; but in recognising the Divine plan to have been throughout perfect and complete, we understand why it is immutable. The term 'law of nature,' then, is only an expression of the uniformity observed by the philosopher in the phenomena of the universe. The law of nature is the will of God."

The second lecture deals with the essential features of life when reduced to its simplest terms; with structure and function, nutrition, the mutual relation of organs, their sympathy, well illustrated by the phenomena of the brain, and terminates by some remarks on the character of vital actions at various periods of life.

The third lecture considers the external conditions of vital action, the supply of waste, production of heat, the destination of food, and incidentally mentions a fallacy as to the effect of pure oxygen on respiration committed by sciolistic theorists both at home and abroad. The material agents give place to dynamical agents—heat, light, and electricity; regarding these—"Although the data are not as yet rigorously exact, we cannot resist the conclusion, that in plants and animals there is, within certain limits, a definite relation between the vital activity of each individual, and the amount of force which it receives from external sources." The prejudice against explaining the phenomena of life by the operation of physical forces is ably combated; and, with a confession of our comparative ignorance in this direction, this part comes to a close.

The fourth and last section opens with the consideration of death, both in its somatic and molecular forms. Bichât's views, as extended by Alison, Watson, and others, are reviewed; the comparative painlessness of the process is insisted on; the signs of death, including rigor-mortis, are explained; and with some general speculations the work ends.

Although obviously intended for a wider circle of readers than is included by our Profession, these lectures may be profitably read by all. At a time when much stress is with reason laid on the extension of sound physiological information among the laity, it is a subject of satisfaction that its diffusion should be entrusted to so thoughtful, competent, and impartial an inquirer as Mr. Savory here shows himself to be.

PROVINCIAL CORRESPONDENCE.

EDINBURGH.

THE year, guiltless as yet of snow, has come "in russet mantle clad," and the second half of the winter session (thanks to the recent thawing of the ice) has begun.

Ice has a curious effect on this city. No one has a chance against it. If you ask a man, is he going to business of any kind, he looks at you with wonder, and says—"The ice is bearing." Not only do young ladies and men skim over Duddingston Loch by day, but the passer-by all through the moonless winter night may hear the hum of skates. But more fascinating still is the canal, that eccentric aqueduct which is perched so high that you can see on each hand the surrounding country; you are above country-houses' chimneys with their curling smoke—above that train from Glasgow whizzing along—above everything, even the lingering fragment of conscience which told you on starting that, as the Frenchman said, you "had to fry some feesh." You skate, say to Linlithgow, get on to the loch there, past the old palae, through the beautiful park, where—

"In jovial June how blithe the merry linnet's tune,
How sweet the blackbird's lay!"

As you rest on some of the canal bridges there are few prettier sights than a string of students, with their sticks and knapsacks, coming along in Indian file, with some strong skater at their head, say John Duncan. Oh dear, how I envy their wide sweeps as they shoot by me!—how vain my attempt to follow! On my return I meet them again, and we run along easily into Edinburgh under the dim light of stars.

I have seen several allusions in your columns to Professor Syme's lecture, which seem to be very just, and to have met the approval of all here. There is no doubt that the student's mind is overloaded, or rather would be, were he to work thoroughly at all his subjects, but few students do so; they very sensibly get up a minimum of those for which they feel no elective affinities, and a maximum for those they find suited to their mental capacities. And what a privilege it is for them that this varied curriculum does exist!—for many, by the time they gain a diploma, have had to change their plans,—loss of parents, of money, of health, and even a moderate amount of knowledge, may enable one to take another tack and make his daily bread. That there is a gradually increasing deficiency in anatomical knowledge, is manifest to all teachers. The lecturers on Surgery especially notice it. But that is principally from there being huge, unwieldy classes of anatomy, and a laxity of strictness—a carelessness as to neatness and to care in dissecting and cleaning arteries and muscles, which used to be the pride of demonstrators and the emulation of students. There is plenty of time, and there are plenty of subjects. The real reason, I believe, is, that students see men thriving on a modicum of anatomy as well as those who have gathered a large store. They hear men who scarcely know one end of a bone from the other, who, if you asked them to tell a carpal bone right from left, would doubt your sanity, talk of anatomy, as if it were their constant joy. Believe me, Sir, that is one reason why students do not care now for dissecting. Mr. Syme stated that Professor Laycock gave his students a list of 800 fevers. This has been already contradicted sufficiently, and our distinguished Professor of Medicine is well able to defend himself. The list alluded to is, or may be, in everyone's hands, and a gentleman who prides himself on his accuracy might have got his statistics from a surer source than that of a student who had been given his cue. It is a pity to begin the year thus, and to make these pleasant meetings at the College of Surgeons organs of unrest. How much pleasanter was Dr. Gairdner's lecture on the "History of Surgery in Edinburgh"—of the times when these old shavers were given yearly "ane condemnit man" to dissect, "but not till efter he be deid," so that they "might knaw all the vagries of the samyn, that they may mak flebothomea in dew tyme;" and when each entrant had to pay "fyve pundis of usuall money of this realme of Scotland for the altar of St. Mungow;" after which he had to stand "ane denmar" to his examiners.

The death of Dr. Newbigging has caused universal sorrow: without pomposity he was dignified, without slandering his neighbours he solved the problem of success; no one of his brethren will forget his handsome, truthful face and kindly smile, and I trust they may try to be the unassuming Christian gentleman he was.

The plan of Professor Syme, to supersede the examinations for a degree by class examinations, seems to be gaining ground among a certain class. I hear that the Medical Faculty of the University have unanimously agreed on the expediency of such a change. Before, however, this expression of opinion can have any effect, it must have the approval of the Senatus, the University Court, and even of the Privy Council. How curious it is that this discovery of the signal uselessness of examinations was never made until the Medical Professors were paid for examining. From all I have written, you may conclude that the millennium is not here yet. Persius says, "With pepper and other productions of the south, science came to the Romans," and certainly pepper and science seem here to go together. But if we choose to have our science peppered, why shouldn't we?

GENERAL CORRESPONDENCE.

MORBUS ADDISONII.

LETTER FROM DR. SAMUEL WILKS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Although I do not wish to prolong a discussion which commenced at a Medical Society, yet, as the opinion of Dr. Harley, as given in your report of the Pathological Society in to-day's Journal, in reference to Addison's disease, may improperly influence some of your readers who have not seen this remarkable malady, I trust you will allow me space for a few observations in explanation—the time of the Society not allowing me to do so in full. Dr. Harley implied that all was uncertainty respecting it, and that the advocates of Addison's views were constantly shifting their ground. This is not the fact; Dr. Harley has made a giant of clay in order to demolish it. Addison's original statement stands on as sure a basis as any received fact in pathology; the only changes which have been made in his views are of the most trivial kind, and which Addison himself admitted. These refer to the form of the discoloration, and to the character of the disease in the capsules. If the author had been content to publish his cases without any further surmises, not one of these charges could have been made; so true to life were they, and so exactly resembling in every respect those which have been described by every subsequent observer. The accurate pictures which Addison drew, would answer as well for representations of every case which has occurred since. So far from the disease or its symptoms varying, the uniformity amongst the cases is most remarkable, and greater than can be shown to exist in most diseases about which we are able to form a correct diagnosis during life. It is to be regretted that Addison did not limit his memoir to the detail of his four or five cases, for then his opponents would not have had a single weapon to throw against him.

To those who have not seen the monograph it may be stated that the author described four or five cases of persons who had died under exactly the same circumstances, that is, with a gradual prostration of strength and discoloration of skin, and in whose bodies no other disease was found but in the supra-renal bodies. As an observant and intelligent man should do, although he did not profess to see the connection, he necessarily associated the symptoms with the disease, and then endeavoured to put his conclusion to the proof, by remarking if other patients with similar symptoms presented the same morbid condition after death; he did so, and his expectation was fulfilled. Not unnaturally, with the ardour of discovery upon him, he had every body examined, in order to elucidate further the disease; and it happened that in one or two, where cancer existed, he thought that some discoloration of the skin was present. No further experience, however, has produced any similar cases, and therefore, in all probability, the surmise was wrong, and the true disease is that only which he described in his first cases. Let, therefore, this be granted and accepted as a shifting of the ground, and estimated at its real value. To my mind, it more firmly establishes the truth of Addison's discovery. Besides, it requires only a little reflection with regard to pathological conditions generally, to know that such must be the case; for if we wish to study the symptoms resulting from disease in any organ, we should select those instances where the alterations are of a primary kind. For example, if we would study hepatic or renal disease, we should select cirrhosis or morbus Brightii, and surely should

not look for the symptoms of kidney or liver disease in those cases where the organs are sprinkled with a little tubercle or cancer. Moreover, I have yet to learn that such diseases exist, except in the imagination. I do not know of a total primary destruction of any organ by cancer, and uncomplicated by disease elsewhere. I have never heard of such a disease of the supra-renal capsules, and my pathology is much at fault if I ever do. The true Addison's disease has its analogies in other primary and slowly-progressing affections, as phthisis, cirrhosis, granular kidney, etc.

As regards the discoloration of the skin, in all of Addison's cases the pigmentation was tolerably uniform; but in the case of a gentleman in whom the author thought the disease existed, the body was covered with black patches. No post-mortem was made to establish the diagnosis, and in all subsequent cases no discoloration of the kind has occurred. Dr. Addison, therefore, believed that this was more often of a uniform character, resembling, indeed, what is seen in the skin of a native of a southern climate. Out of more than thirty cases which are authenticated, and of which I have seen the diseased organs, in four only was the discoloration unobserved during life, and in one of these only was it found quite absent when the body was examined after death. Dr. Addison had himself seen two cases where all the symptoms of the disease existed, and the capsules were found affected in the usual manner, but no discoloration existed. In these, the capsules were of a very great size, and only recently diseased; and it was owing, it was thought, to the incessant vomiting and the implication of the semi-lunar ganglion, that death took place so rapidly and before time had been allowed for the pigment deposition.

Dr. Harley wants to know how the matter now stands. It stands thus. Persons are liable to a very gradual and slowly-progressing disease of the capsules, hitherto found to be of that kind called scrofulous, consisting generally of yellow amorphous cheesy matter, with cretaceous degeneration, and with this they suffer from symptoms which are strikingly alike in all, viz., an increasing want of power, or asthenia, sickness, and discoloration of the skin, or, to be more accurate, discoloration of the skin in about 95 per cent.; this being absent if the disease be acute. To prove the correctness of the statement, I apprehend there is no other method than to observe closely patients with these symptoms, and see if after death they present the disease of the capsules described. This has been done, in not one, but in fifty cases. In spite of these facts, there are those who would add to the remarkable features of this disease the greater marvel still, that these so-called diagnoses were nothing more than guesses. Very happy guessing! Would that it could be used so successfully in other obscure diseases! In the cases I took to the Society, the one was diagnosed by myself, and the other by Dr. Hardwick. In a case preceding this, whilst more than twenty miles away from my home, on a visit to a patient, I mentioned to two Medical men—Drs. Butcher and Bowden, of Ware—that a case of supra-renal disease was then being examined at Guy's Hospital, all that I knew being that the lad had died that morning with well-marked symptoms of the disease, and a post-mortem examination was to take place. Not being a clairvoyant, I should like to know how I became aware of the fact, unless by a true scientific induction. On opening the Catalogue of Guy's Hospital Museum, besides the cases coming from within its own walls, I find specimens taken from patients in whom the correct diagnosis was made by gentlemen in all parts of the kingdom—as Drs. Ranking and Vincent, of Norwich; Mr. Valentine, of Somerset; Dr. Glover, of Newcastle; Dr. Bacon, of Norwich; Dr. Aldis; Dr. Houseley, of Warsop; Mr. Toulmin, of Hackney; Mr. Stedman, of Godalming; Mr. Harris, of Hackney; Mr. Truman, of Nottingham; and many others. I might mention that Dr. Watson and Dr. Aitken, in their works on the "Practice of Medicine," adopt Addison's conclusions. Also, within the last few weeks, cases have been reported from Dublin, Brussels, Berlin, and St. Petersburg. If Dr. Harley does not choose to examine the facts for himself, I would make him this request—to submit the histories of all the cases in which the specimens have been sent to Guy's Museum (I mention these because I know them) to a non-Medical friend—say a lawyer—and see if any other conclusion can be arrived at than the one adopted by Addison. If he can, I will give up the whole matter, and regard my intellect as clouded.

The only arguments used against Addison's views are of this kind—that the association of the symptoms and the disease of the capsules is a coincidence; that these are con-

stantly found disconnected, and, therefore, have no relation to one another. The answer to this is, that, where the discoloration and symptoms have existed together, the disease has always been rightly diagnosed; but that discoloration of the skin alone, especially in those cases where large black patches of melasma exist, is certainly not a symptom. Addison never said it was, nor his followers. He knew melasma occurred under many various circumstances. Then, as regards the accidental discovery of the disease after death. This, it must be admitted, has happened. But in some cases it was clearly the cause of death; in others, death occurred from an acute inflammation, just as might happen in Bright's disease, where a kidney affection was not known to exist. But not half-a-dozen such cases have been recorded.

If you will allow me to add another line to this long letter, I would say a word with respect to the unbelief which Dr. Harley says exists among the most eminent men on the Continent. That this does exist amongst those who have only had a superficial knowledge of the subject, I do not doubt; but I cannot believe that any man who has weighed the evidence can do otherwise than accept its truth. My observation, gathered from the history of discovery, is this,—that at any given period of human progress, a certain amount of knowledge exists, and that then, if any new scientific statement be advanced, it will be accepted favourably, just in proportion as it agrees with preconceived ideas, or places the old notions on a clearer foundation. There are certain theoretical books and essays which are invariably received with favour by readers and reviewers, although they cannot verify the statements therein contained,—“they are beautiful, and therefore they must be true;” whilst, on the other hand, if a new fact should be discovered which seems opposed to, or is different from, our ordinary modes of thought, a scepticism is produced. This has always been the case; and although, in the present instance, I do not use the opposition as an argument in its favour, I should consider a universal and ready acceptance of Addison's doctrine as an argument against it. Allow me, in conclusion, to say, that I have written these few remarks, not to convince my friend, Dr. Harley, for his opposition is of that kind which will require, I think, two or three years for recantation, but for the purpose of placing before your readers what the real facts are, and how futile are the statements of the opponents to Addison's discovery,—a discovery, to my mind, one of the most remarkable of the present century.

I am, &c., SAMUEL WILKS.

St. Thomas-street, Southwark, January 30.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 26.

MR. FERGUSSON, Vice-President, in the Chair.

A PAPER, by Dr. S. O. HABERSHON, was read, entitled
CLINICAL OBSERVATIONS ILLUSTRATING THE EFFECTS OF IMPLICATION OF THE PNEUMOGASTRIC NERVE IN ANEURISMAL TUMOURS AND MORBID GROWTHS.

After referring to the complex distribution of the pneumogastric nerve, and to the important symptoms of disease produced by the implication of its branches, the author proceeded to describe several cases of thoracic aneurism in which the branches of the recurrent laryngeal nerve, or the trunk of the pneumogastric, were involved. The first case was that of a man, aged 39, who had been engaged in laborious work at Chatham and Woolwich dockyards. Two months before death he began to suffer from hoarseness, and the laryngeal symptoms were more marked than any other. There were paroxysms of urgent dyspnoea and slight dysphagia. Five days before death hæmorrhage from rupture into the trachea commenced; and on the morning of his death the bleeding suddenly became profuse, and was quickly fatal. Dilatation of the aorta, double aneurism of the arteria innominata, and perforation into the trachea, were found. There was pressure upon the commencement of the recurrent nerve, and commencing degeneration of the muscular fibre of the laryngeal muscles on the same side. As to the physical signs, dulness

and double bruit were produced immediately over the first bone of the sternum, but there was no bruit over the aortic valves. No pain had been complained of. The value of the laryngoscope had been shown in demonstrating that no disease of the larynx existed, slight œdema of the mucous membrane only being present. The second case was that of a sailor, aged 35, who had apoplexy, with aphonia and symptoms resembling phthisis; aneurism was, however, suspected. The recurrent and the pneumogastric nerves were both compressed; the muscles of the larynx were on one side pale and wasted, and the lung on the same side was in a state of asthenic pneumonia. The thoracic duct had also apparently been compressed. In the third instance recorded, the symptoms of cardiac disease obscured those of aneurism. There had been pericarditis and endocarditis, and fibroid degeneration of the muscular fibre of the left ventricle existed. The patient was a groom, aged 45, and two months before death symptoms of catarrh and bronchitis came on; the heart's action was irregular and tumultuous; the pulse very feeble, but without bruit. Afterwards a triple sound was produced below the nipple, and with renewed bronchitis there were signs of pleuro-pneumonia of the lower lobe of the right lung. No pain and no dysphagia were complained of, but paroxysms of urgent dyspnoea, with extreme faintness; in one of these attacks he died. In addition to the degeneration of the heart, an aneurism was found at the commencement of the transverse arch; and the pneumogastric, after giving off its recurrent branch, passed directly over the sac, and the compression of this nerve had determined the pneumonic consolidation of the lower lobe of the right lung. In the fourth case, the recurrent laryngeal nerve was compressed, and had produced paroxysms of urgent dyspnoea, but the dyspnoea was in great measure due to direct pressure upon the trachea. There had been feebleness of the voice, with dysphagia. Pain was of an agonising character, but also paroxysmal, and it was apparently due to direct pressure on the nerves. The aneurism of the aorta was situated immediately beneath the subclavian, and had ultimately perforated the trachea; but rapid effusion of blood had been prevented by layers of fibrin, and it was probable that the first oozing of blood took place nine months before death. No bruit had been produced, but a ringing second sound; the heart was healthy. The author stated that pressure on the pneumogastric nerve and its branches by aneurismal tumours in the chest led, first, to paroxysmal and spasmodic contraction of the muscles of the larynx; secondly, to diminished muscular power, and to paralysis and wasting of the laryngeal muscles; and thirdly, to pulmonary congestion and consolidation;—but that gastric symptoms, such as were found in peripheral pulmonary irritation of incipient phthisis, were not observed in thoracic aneurism. The effect of changed nervous supply of the œsophagus was briefly referred to; spasmodic contraction, and possibly also ulceration, taking place without direct pressure; the author stating that spasmodic contraction from this cause aggravated the effects of the direct pressure of tumours generally. It was likewise mentioned that occasionally no dysphagia existed, because the whole of the œsophagus opposed to the tumour was pushed aside *en masse*. In conclusion, the author detailed an instance of disease affecting the supra-renal capsule, with bronzed skin; and exhibited a drawing from his dissection of a branch of the pneumogastric to the capsule. The irritability of the stomach often present in these cases was referred to this connexion. A dissection showing the larger branches of the semi-lunar ganglia, and the manner in which some of these branches were involved in the diseased capsules, was also exhibited.

Dr. JOHN HARLEY read a paper on

HÆMATURIA OF THE CAPE OF GOOD HOPE.

In the beginning of October last, a gentleman, resident in the Cape, consulted the author about a slight hæmaturia which he had had for some years. After micturition a little blood, never exceeding a teaspoonful, or some dark "veins," appeared with the last half ounce of urine. The urine itself was never bloody. Sometimes the "veins" would block up the urethra, and cause obstruction for a few minutes. He had an occasional twinge of smart pain in the loins. These were all the symptoms that ever appeared in connexion with the urinary apparatus. He said great numbers of people of both sexes were affected in precisely the same way in certain parts of the Cape. While awaiting a sample of his urine, Dr. Harley made inquiries amongst his Cape friends and acquaintances; and, as the result corroborated his patient's statements, he was

now satisfied of the existence of endemic hæmaturia in Nitenhage and Port Elizabeth, and it remained for him to ascertain the cause. In the various samples of urine sent to him by his patient, he invariably detected the eggs of an entozoon; and in one specimen he had the good fortune to discover the perfect embryo after its escape from the eggshell, under the form of a minute, ciliated animalcula. From its anatomical characters and developmental changes he was led to refer the parasite to the *Trematode* class of worms, and to the family *Distomum*. Of the five species of this genus which inhabit man, it had no relation with three. *Distomum heterophyes* presented some points of resemblance, viz., in the size and conformation of the alimentary canal, if he (Dr. Harley) might be allowed to compare it with an organ he met with in one sample of his own, and which he supposed to be the intestinal canal of the adult parasite. But the animal which it seemed to most nearly resemble, in the outward form of the eggs as well as in the symptoms of the disease it produces, was the *Distomum hæmatobium*. This parasite, according to Bilharz and Griesinger, was very common in Egypt, and inhabited all parts of the urinary apparatus. But since the parts he had described differed in several respects from the corresponding parts of the hæmatobium, and since, from want of recorded information respecting the corresponding parts of *D. heterophyes*, he could not compare them with these, he was obliged to comprehend them under a new species, which he would call *D. capense*. Having finished his observations of this case, he was strongly persuaded that the hæmaturia of the Cape was due to the parasite, the early stage of whose development he had been able to observe; but still, as its presence in a single case might be nothing more than a coincidence, he felt that more extended observations were needed to prove that this was the constant cause of the local disease in question. With singular good fortune he had the pleasure of an introduction to Mr. Dunstrovill, Surgeon to the Port Elizabeth Infirmary, and who, having practised for twenty-seven years in the Cape of Good Hope—which was one of the two places in which he (Dr. Harley) found the hæmaturia to be endemic,—was quite familiar with the disease, the cause of which, however, from want of leisure and means of observation, had never been ascertained. Mr. Dunstrovill's two sons, in common with most other young men, suffered from the disease, but considered themselves to be now free from it. At the author's request, Mr. Dunstrovill kindly supplied him with samples of their urine, and he (Dr. Harley) was at once enabled to demonstrate to Mr. Dunstrovill the existence of the characteristic eggs of the parasite in question in the secretion from both. Having thus demonstrated the existence of the same parasite in three individuals suffering or having suffered from the hæmaturia endemic in some parts of the Cape, Dr. Harley concluded that the animal was the constant cause of the disease.

Dr. SYMES THOMPSON observed, that the disease described by Dr. Harley as endemic at the Cape must be either rare in its occurrence or very limited in its distribution. He had received communications from three Medical men who had practised for several years in South Africa and had not met with idiopathic hæmaturia either at Port Elizabeth or in the neighbourhood of Uitenage. Dr. Johnston (Surgeon to the 85th L. I.) had seen many cases of hæmaturia in Natal, occurring in children between the ages of 6 and 15, more commonly in boys than girls, which he had regarded as dependent on congestion of the genito-urinary mucous membrane, arising from ascarides, tape-worm, or depraved secretions. He had found these cases very amenable to treatment directed to the removal of the conditions referred to, with the subsequent administration of turpentine, matico, or the sesquichloride of iron. Dr. Thompson added to this testimony that of a non-Medical observer, the Bishop of Natal, whose sympathies are, perhaps, as much scientific as clerical, who had not, in his intercourse with Medical men in the colony, heard the disease mentioned as endemic in any part of his diocese. With regard to the question, whether the fluke described was the same as that occurring in Egypt, though zoologically almost identical, the *Distoma capense* (so called by Dr. Harley) seemed far less hurtful in its effects on the human constitution than the *Distoma hæmatobium*. The first-named entozoon was, perhaps, a variety of the same species. The speaker suggested that the principal Medical officer of the Cape be requested to investigate the whole subject, and draw up a report, to be presented to the Royal Medical and Chirurgical Society at a future meeting.

Dr. COBBOLD remarked that no person who had previously

familiarised himself with the appearances presented by the eggs of the various distomes could doubt for a moment that Dr. John Harley's illustrations represented the ova of the so-called *Distoma hematobium*. In short, the symptoms, pathological products, eggs, and embryos described by Dr. Harley, all tended to show that this hæmaturia of the Cape was identical with the well-known Egyptian malady. Dr. Harley's discovery was, however, a most important one in relation to the geographical distribution and prevalence of entozootic diseases; for the author had now demonstrated, in a most satisfactory and able manner, that the helminthiasis in question was not confined to Egypt, as had hitherto been supposed, but was more or less prevalent in Southern Africa and in the Mauritius. Speaking zoologically, this parasite was not a true distome, as it represented the type of a distinct genus, to which Diesing, of Vienna, gave the name of *Gynacophorus*; Weinland, of Frankfort, had called *Schistosoma*; Moquin-Tandon had denominated *Thecosoma*; and himself had previously entitled *Bilharzia*, after the name of the original discoverer, Dr. Bilharz, of Cairo. He (Dr. Cobbold) had discovered this so-called *Distoma hematobium* in the portal blood of an African monkey (*Cercopithecus fuliginosus*) six months before Diesing had communicated his paper to the Vienna Academy, and, therefore, he hoped Dr. Harley (in concert with Weinland and others) would retain the generic name *Bilharzia*, which had the priority. At all events, this was not a new species of fluke, and, therefore, the name *Distoma capense* could not stand. But Dr. Harley's discovery was none the less important on this account. It was quite clear to him (Dr. Cobbold) that our fellow men at the Cape, in the Mauritius, on the banks of the Nile—and also, if you please, our friends, the monkeys—obtained this parasite by swallowing the "intermediate bearers" of the *Bilharzia*. These "bearers" or "hosts" were small mollusks or aquatic animals, inhabiting the African rivers. They contained the higher larval states of this parasite, the larvæ being introduced into the human body by drinking the African waters unfiltered.

Dr. DUNSTROVILLE said that he had given Dr. Harley all the information he possessed on the subject. In reference to what Dr. Symes Thompson had said, he stated that the disease never attacked adults. There was no doubt that the water had to do with the disease, but how, it was difficult to explain. He (Dr. Dunstroville) intended, by the help of his friends, fully to investigate the disease. He remarked that stone was uncommon, and had only seen two cases.

Dr. LEARED said, in reference to the observations of Dr. Cobbold on the possibility of preventing the occurrence of parasites in the human body, that his proposal for the prevention of the fatal cystic disease of Iceland, by treating all the dogs in the island simultaneously for worms, had been very favourably received. The paper had been translated into Icelandic, and published in an Icelandic newspaper. Dr. Leared had also communicated with the late Baron Eschricht, of Copenhagen; the result was, that Dr. Krabbe had been sent to Iceland last summer for the purpose of ascertaining whether the sheep-dogs of the country are really infested with the tænia echinococcus, the mature form of the cystic worm which infests the bodies of men. With this view one hundred dogs had been killed, and their intestines examined. The worm was found in about one-fourth of the number. What further steps the Danish Government intended taking Dr. Leared was unable to say, but he felt confidence in the efficacy of the plan he had proposed.*

Dr. HARLEY said, in reply to several points alluded to by those who had taken part in the discussion, that since there could be no doubt the parasite in question belonged to the genus *Distomum* or *Gynacophorus*, the determination of the exact species was a matter of secondary importance. He had referred it to a new species, because, after careful comparison with Griesinger's figures and description, and Leuchart's review of them in his recently published work, he could hardly refer the ciliated embryo he had described to *Gynacophorus hematobium*. On the other hand, the resemblances were so close and so many that it was probable they were identical; but from a bare comparison with the figures, he could not justly infer that they were actually so. He called attention to the fact that, although the symptoms of the hæmaturia disappeared after a time, the parasite still remained in the system as actively generating its kind as ever. Stone, it had been observed, was not at all of common occurrence in the locality

in which the hæmaturia prevailed, but he would particularly draw attention to the fact, that gravel was very prevalent. He had found that a highly saline condition of the urine accompanied the discharge of ova, and that the fine crystalline deposits very soon incrustated the ova; and he had been particularly careful to satisfy himself that ova formed the nuclei of several renal calculi that had been submitted to him for examination by one of the patients suffering from the disease.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 28th inst. :—

Frederic Charles Griffith Griffin, Weymouth; Edward William Bennett Garlike, Tulse-hill; James Edmund Anthonisz, L.S.A. Ceylon; Charles John Bennett, Buxton, Derbyshire, and Frederick King Green, Stoke Newington, students of St. Bartholomew's Hospital; Edwin Bold Pearson, Ycavely, near Ashbourne, Derbyshire; Alfred John Cockerton, Islington; George White, Dalston, and Caleb Law, Australia, of the London Hospital; John Petch Hewley, Ripon, Yorkshire; William Cecil Penn, Edwardes-square, Kensington, and Joseph Langhorn, Savile-row, of St. George's Hospital; William Grafton Curgenven, M.D. St. Andrews, Plymouth, and Frederick Samuel Hope, Kirby Fleetham, Yorkshire, of the Middlesex Hospital; Frederick Philpot, Lic. Fac. Phys. and Surg. Glasgow, Chelsea, of University College; Henry Plater Long Barham, Canterbury, of the Westminster Hospital; George Brigg Peirson, Leeds; William McConnell, Lisburn, Ireland; William Skinner, Sheffield, and Hermann Johnston Jones, M.D. Heidelberg, Upper Clapton.

At the same meeting of the Court, Mr. Josiah Frederick Kydney, L.R.C.P. Dub., passed his examination for Naval Surgeon; this gentleman had previously been admitted a Member of the College, his Diploma bearing date July 19, 1859.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, January 28, 1864 :—

James More, Rothwell, Northamptonshire; Richard Orlando Arnold, Charing-cross Hospital; Richard William Davies, Colnbrook, Bucks; Thomas Langston, Hulme, Manchester; John Quick Costin, Kimbolton, Hunts; Peter Charles Duncan, 46, Great Marlborough-street.

The following gentleman, also on the same day, passed his First Examination :—

David Martin Williams, Charing-cross.

The following gentlemen passed their Preliminary Examination in Arts, and received Certificates of Proficiency in General Education on January 29 and 30, 1864 :—

E. G. Archer, Feltwell, near Brandon; R. Atkinson, Coniston, Waterhead; C. Bennett, Bury, Lancashire; W. J. Bennett, Dorchester; F. M. C. Beechey, Norfolk-square; G. Bland, Stourbridge; J. H. Castle, Euston-square; Clifford Crew, Ross-place, Guernsey; D. S. Costerton, Lucas-place, Commercial-road; R. H. Coombs, Rydon-crescent, Islington; F. P. Davies, Birmingham; F. J. Glencross, Devonport; S. Griesbach, Leeds; C. V. Helsdon, Frances-street, Torrington-square; J. A. Lea, Congleton; G. J. Moxon, Brigg, Lincolnshire; S. Morrison, Westbourne-park-terrace; J. Massingham, Green-street, Bethnal-green; H. Norton, Westbourne-grove West; E. M. Owens, Sutton, Surrey; G. Payne, Wallingford, Berks; W. Powell, Cheltenham; O. R. Pranker, Langport, Somerset; J. J. Swindell, Whetstone; A. M. Sculthorpe, Bedry, Worcestershire; W. R. Trezise, Penzance.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BOWEN, ESSEX, M.D. St. And., has been elected Honorary Surgeon to the Birkenhead Borough Hospital.

BUCKLE, FLEETWOOD, M.D., L.R.C.P. Lond., has been appointed Assistant House-Surgeon to the Kent and Canterbury Hospital.

COCK, FREDERICK, M.D. Edin., has been elected Consulting Physician to the Farringdon General Dispensary.

EVANS, THOMAS M., M.R.C.S. Eng., has been elected Resident Hon. Surgeon to the General Infirmary, Hull.

GALTON, JOHN H., M.D., has been elected Resident Medical Officer to the Public Dispensary, Carey-street, Lincoln's-inn.

HARDESTY, J. JEFFREY, L.R.C.P. and S. Edin., has been appointed Medical Officer and Public Vaccinator for the Parish of Yester, Haddingtonshire.

HEAD, EDWARD, M.B. Lond., has been elected Hon. Physician-Accoucheur to the St. Pancras and Northern Dispensary.

JACOB, DAVID B., M.D. Q.U.I., has been appointed Visiting Physician to the Maryborough District Lunatic Asylum.

JACOB, EDWARD L., M.R.C.S. Eng., has been re-elected Hon. Surgeon to the Birkenhead Borough Hospital.

JACOB, HENRY L., M.R.C.S. Eng., has been elected Dental Surgeon to the Birkenhead Borough Hospital.

* This will be found in full detail in the *Medical Times and Gazette*, September 12, 1863.

LAMBERT, JAMES, M.D. Glasg., has been elected Hon. Surgeon to the Birkenhead Borough Hospital.
 SCULLY, THOMAS, Jun., M.D., has been appointed Assistant-Physician to the Clonmel Union Infirmary and Fever Hospital.
 STEVENSON, JOHN F., M.D. Edin., has been elected Hon. Physician to the Birkenhead Borough Hospital.
 WOOD, E., has been appointed Senior Dispenser to the Westminster Hospital.

DEATHS.

ANNAN, ROBERT, L.R.C.S. Edin., at Kinross, Scotland, on January 22.
 CLIFFORD, HERBERT W., M.R.C.S. Eng., at Tivoli-villa, Cheltenham, on January 28, aged 28.
 COWCHER, EDWARD, M.R.C.S. Eng., at Abingdon, Berks, on January 31, aged 77.
 CRAIG, WILLIAM, Surgeon R.N., at Seymour-street, Holt-hill, Birkenhead, on January 18, aged 72.
 ESTE, MICHAEL L., M.D., late of 1st Life Guards, at 207, Marylebone-road, on January 26, aged 85.
 FAUSSETT, RICHARD, M.D. Edin., at Ballina, Co. Mayo, on January 17, aged 86.
 HARVEY, EDWARD R., M.D. Oxon., of 34, Clarges-street, Piccadilly, W., at San Remo, North Italy, on January 24, aged 32.
 NICOLL, WILLIAM, Surgeon, at Caistor, Lincolnshire, on January 31, aged 60, formerly of Hendon.
 OSBORNE, GEORGE M., M.D. Glasg., at Nethergate, Dundee, on January 6.
 WICKHAM, WILLIAM JOHN, F.R.C.S. Eng., at Winchester, on January 19.

SCHOLARSHIPS IN NATURAL SCIENCE AT CAMBRIDGE.—

Two scholarships, each £40 per annum, tenable for three years, are announced to be given for Natural Science at Sidney Sussex College in October next. The subjects of examination: Electricity, Chemistry, Geology, Anatomy. They are open to all the world. The successful candidates will be expected to enter at the College. Further information may be obtained from the Rev. J. C. Ellis, tutor of the College.

ROYAL INSTITUTION OF GREAT BRITAIN.—General Monthly Meeting, February 1, 1864; William Polc, Esq., M.A., F.R.S., Treasurer and Vice-President, in the Chair.—The Hon. Slingsby Bethell, Robert George Clarke, Esq., the Lord Otho Fitz-Gerald, Jackson Hunt, Esq., William Senhouse Kirkes, M.D., F.R.C.P., George Cargill Leighton, Esq., John Peter, Esq., David S. Price, Esq., Ph.D., F.C.S., William F. Scholfield, Esq., and William Barrington Tristram, Esq., were elected Members of the Royal Institution.

DEATH OF PROFESSOR SCHÖNLEIN.—This celebrated clinical teacher, whose great skill in diagnosis was far-famed, died on January 23. He was successively Professor at Würzburg, Zurich, and Berlin, but lived for the last few years at Bamberg, in Bavaria, his native place. He died in the 70th year of his age, in consequence of stenosis of the trachea.

THE following notice appears in the *London Gazette* of January 26, 1864:—"Notice is hereby given, that the British Pharmacopœia has been published, under the direction of the General Council of Medical Education and Registration of the United Kingdom, and that the same has been printed by Messrs. Spottiswoode and Company, of New-street-square, in the City of London, Printers, under the authority of the said Council.—Dated the 25th day of January, 1864.—FRANCIS HAWKINS, Registrar of the General Council."

MATERNITY CHARITY AT CONSTANTINOPLE.—By the last number of the *Levant Review* we find that there has been established a British Maternity Society at Constantinople for the relief of poor women of all nations and creeds, and for the treatment of the diseases of women and children. Dr. Foote is the Physician-Accoucheur, and the other officials are composed of English and Greeks. The society professes to supply qualified midwives and nurses.

WE are glad to learn, from the annual report of the New England Hospital for Women and Children, for the year ending November 10, 1863, that Doctress Lucy E. Sewall, who visited London and Paris last winter, and whose great intelligence and quiet, ladylike demeanour gained her golden opinions in the Medical circles of both capitals, is giving the Institution the benefit of her services as Resident Physician, and Dr. John Ware, Dr. Horatio R. Storer, and Dr. Samuel Cabot are Consulting Physicians and Acting Surgeons; so that the patients have the benefit of masculine aid in Surgical cases. We are surprised to read—"The Committee need not remind any one familiar with the damp cellars, the wretched attics, the untidy and ill-ventilated apartments, in which the poor dwell, in sickness as in health, of the importance of establishing a Hospital, where women and children can have quiet and tender care." We hoped that evils such

as these did not infest a land unblighted by an hereditary aristocracy, and laws of primogeniture; at any rate we hope that the good Bostonians will not forget that a healthy home is the best gift to the poor.

PROFESSIONAL CHANGES IN DUBLIN.—The unexpected deaths of Mr. Smyly and Dr. Jonathan Osborne have led to many changes and some speculation in Dublin. The most important, however, of the appointments which have become vacant will be filled up, we believe, without any very serious contest. The election for a Vice-President of the College of Surgeons, *vice* Mr. Smyly, has been advertised to take place on next Thursday, and Dr. Jacob, the Professor of Anatomy and Physiology in the College, is, we believe, likely to succeed to the office. Then the Surgeoncy to the Meath Hospital is, we understand, on the best authority, to be filled up by the election of the son of the senior Physician, the young gentleman being at present studying on the Continent. By the death of Mr. Smyly, Dr. George H. Porter, one of the Examiners in the College of Surgeons, becomes Senior Surgeon at the Hospital, and thereupon has resigned his office to the South City Dispensary, and a spirited contest is likely to ensue. The principal candidates, out of thirty-five as yet in the field, as far as we know, are, Dr. Coulton, for some years Apothecary to the Dispensary; Dr. C. F. Moore, late Senior Surgeon to the Middleton Hospital, near Tynan; Dr. Grimshaw, the son of the well-known dental Surgeon; and Dr. Shortt, a young gentleman of about five years' standing in the Profession. By Dr. Osborne's demise the Professorship of Materia Medica in Trinity College becomes vacant, and we understand that Dr. Aquilla Smith, the Vice-President of the College of Physicians, and its representative on the Medical Council, will in all probability be appointed. We shall probably in our next be able to give more certain information.—*Dublin Medical Press.*

DEATH FROM HYDROPHOBIA.—On January 29 a man named Jones died in Alma-street, New North-road, from the effects of a bite of a mad dog, inflicted in November last. The unfortunate man's hand was much lacerated, but, being immediately dressed by a Surgeon, healed rapidly, although many weeks elapsed before the cure appeared complete. On the 21st of January the wound was so much better that Jones went to work; but on the 26th he felt very unwell and went home. On Thursday he was worse, and the symptoms of hydrophobia became fully developed. In the evening he appeared to be sinking under the disease, and he died a little after two o'clock the following morning.

THE CASE OF SURGEON-GENERAL HAMMOND.—The following order has been issued from the War Department of Washington: "War Department, Adjutant-General's Office, Washington, D.C., January 16, 1864.—Special Order, No. 24.—Extract 19. By direction of the President, a General Court-martial is hereby appointed to meet in this city at 12 o'clock m. on the 19th day of January, 1864, or as soon thereafter as practicable, for the trial of Brig.-Gen. W. A. Hammond, Surgeon-General U.S. Army, and such other prisoners as may be brought before it. Detail for the Court—Major-Gen. R. J. Oglesby, U.S. Vols.; Brig.-Gen. W. S. Harney, U.S. Army; Brig.-Gen. W. S. Ketchum, U.S. Vols.; Brig.-Gen. G. S. Green, U.S. Vols.; Brevet Brig.-Gen. W. W. Morris, Colonel 2d U.S. Artillery; Brig.-Gen. A. P. Howe, U.S. Vols.; Brig.-Gen. J. P. Slough, U.S. Vols.; Brig.-Gen. H. E. Paine, U.S. Vols.; Brig.-Gen. J. C. Starkweather, U.S. Vols.; Major John A. Bingham, Judge-Advocate of the Court. No other officers than those named can be assembled without manifest injury to the service. By order of the Secretary of War, E. D. Townsend, Asst. Adjt.-Gen." The charges and specifications against Surg.-Gen. Hammond are substantially as follows:—"Charge 1st.—Disorder and neglect to the prejudice of good order and military discipline. Specification.—Wrongfully contracting for and ordering the Acting Purveyor in Baltimore to receive blankets of Wm. A. Stevens, of New York; prohibiting the said Purveyor from purchasing in Baltimore, with intent to favour private individuals; ordering Medical Purveyor at Philadelphia to buy of Wm. A. Stevens, of New York, blankets, knowing that the blankets were of inferior quality, and that said Purveyor had refused to buy the same of Stevens; and also intending to aid said Stevens in defrauding the Government. Aiding John Wyth and Brother to defraud the Government, by ordering the Medical Purveyor of Philadelphia to purchase goods of said firm to the amount of 173,000 dollars, knowing that the goods which they had previously supplied were inferior in quality, deficient in

quantity, and exorbitant in price. Ordering of Wyth and Brother 40,000 cans of extract of beef, to be sent to Cincinnati, St. Louis, Cairo, New York, and Baltimore, which beef was unfit for Hospital use. Ordering the Medical Inspector to report direct to the Surgeon-General, in disregard of his duty, of the interests of the public service, and of the requirements of the Act to reorganise and increase the efficiency of the Medical department of the Army. Charge 2nd—Conduct unbecoming an officer and gentleman. Specification.—Writing a letter to Dr. Cooper, and stating, among other reasons, that he, Dr. Cooper, had been removed as Medical Purveyor because Halleck requested as a particular favour that Murry might be ordered to Philadelphia, which declaration was false." Surg.-Gen. Hammond is confident of his ability to disprove the above charges.

ROYAL VISIT TO THE NETLEY HOSPITAL.—It will be remembered that one of the first visits paid by her Majesty after her bereavement was to the large military Hospital at Netley, which was opened for invalids last spring. She has again shown her care for the army and for this Hospital, in which the late Prince Consort took a warm interest, by paying it a second visit. She steamed up from Osborne on Thursday, and landed at the hospital about 12 o'clock. Prince Leopold accompanied her, and she was attended by the Marchioness of Ely, Countess Blucher, the Hon. Mrs. Bruce, Sir Charles Phipps, Sir T. M. Biddulph, Colonel Ponsonby, and Dr. Holzmänn, the tutor to Prince Leopold. It was happily a splendidly bright day, with a fresh breeze from the north-west. Every one was delighted to observe that the Queen looked decidedly in better health than last May, although her face still gives evidence of her severe trial. She proved at once that she had not forgotten any of the incidents of her former visit, by desiring to see, first, the women's quarters, with which she was not pleased on that occasion. She found the rooms looking much more comfortable; and she subsequently inspected some rows of cottages which are now being built in the rear of the Hospital for the special accommodation of the wives and children of the sick men under treatment in the Hospital. She was satisfied with these arrangements. She then visited the wards—a less laborious task than last year, as there are very few patients in the Hospital, the invalids from the home stations having now ceased to come, and the ships with the tropical invalids not arriving till a month or two later. She said a few kind words to the men in bed, and then made particular inquiries of Dr. Anderson, the Inspector-General, as to the health of the men to whom she had spoken last year. That officer was no little surprised to find that the Queen had a distinct recollection of several cases, although her notice of them must have been almost momentary. She also entered the dining-hall, where the men who are able to leave their beds were at dinner, and carefully inspected the arrangements there. She then left the Hospital, and went to the Medical officers' mess-room—a fine large room, which has just been completed, and in which are placed her own portrait and that of the Prince Consort, presented by herself. She expressed her approval of everything, and desired that she might be informed when the invalids from the foreign stations would arrive; so that it is hoped Netley will be honoured by another visit. She inquired particularly whether there had been any effluvia from the mud during the summer, and when told there had been no annoyance of the kind, said she had never anticipated that there would be. She also made particular inquiries about the ventilation of the Hospital. During her visit she was attended by the entire military and Medical staff, including Colonel Wilbraham, C.B., the Commandant; Dr. Anderson, Inspector-General; Deputy-Inspectors Longmore and Maclean, Major Rawlings, the Professors of the Army Medical School, Mr. Tucker, the Rev. Mr. Crozier, and Staff-Surgeons Moorhead, Fyffe, Smith, Davidson, Dr. Minter, of the Royal Yacht, etc.

CASE OF TRICHINA-MIGRATION.—Professor Langenbeck related to the Berlin Medical Society the case of a man in whom, a short time since, he had extirpated an epithelial cancer, situated in the *trigonum cervicale*. During the operation, the *platysma myoides* exhibited a singular appearance, which, on closer inspection, was found to arise from the presence in the muscle of innumerable dead trichinæ, contained in calcified capsules. On inquiry, the following facts were elicited:—In the year 1845 there was a church visitation, in which eight persons took part, and, of these, seven afterwards took part in a breakfast, consisting of ham, sausages, cheese, roast veal, and white wine. In the course

of three or four days the whole of the seven persons were seized with diarrhoea, pains in the neck, and œdema of the face and extremities. Of the seven, four died, and the three who survived, among whom was the man operated upon eighteen years afterwards, remained ill for long afterwards. The suspicion arose that poisoning, through the agency of the white wine, had taken place, and an investigation was made, but without any result. The innkeeper, however, at whose house the breakfast was given, being still under suspicion, was obliged to give up his business and emigrate. Dr. Langenbeck pointed out the importance of this case in its forensic aspect.—*Deutsche Klinik*, 1863, No. 24. [It becomes an important subject of inquiry, whether some of our own cases of death from suspected, but unproved, poisoning may not be due to trichina disease, now proved to be so prevalent in Germany.]

LADIES' DRESS.—A writer in the *New York Tribune*, speaking of some of the hidden accessory outline-generating machinery of ladies' dresses, says they were not so necessary in the days of our grandmothers. In those days, when most of the wearers were no strangers to a horse's back, and the broom or bread-tray, those cunningly-devised little springy circlets, that now give such an exquisite and Venus-like curve to the *tournure*, as it sweeps downward, and falls into the grand and loop-like folds of the skirt, were entirely unknown. Truth to speak, dear ladies, the smaller circles were quite unnecessary; for women in those primitive days had a fairer chance for life and beauty. Muscle and a superb outline were not considered vulgar; nor did she of the acuminated elbows, and anatomised bust and hips, have a coadjutor in the crotchet-needle and the vinegar-bottle, in her malicious ridicule of a young woman whom nature had formed as woman ought to be formed, with the vital organs, breasts and pelvis, adapted to the grand end and object of her creation—the crowning glory of her sex—a family of healthy children. We consider the modern hooped skirt one of the most admirably-artistic and health-giving devices of our time. It is conceded by all correct observers, that the muscles of the thorax, and its appendages, the arms and abdomen, are not used more than one-fourth as much by our modern women as they are compelled to use those of the legs. Nearly all the movements which our unfortunate young people are permitted to perform, by the inexorable fiat of Japonicadom, are what may be called passive; her hands must be reverently and lovingly folded across her chest, in order that their whiteness may not suffer by permitting the least motion; the lungs, of course, must be kept quiet, not only because she is not allowed to walk fast enough to require much air, but because the position of the arms and the weight of the fore-arm and hand, resting upon the lower ribs, will not allow their elevation so that the air can enter the lower part of the lungs at all; at best, but a sixth part of those life-giving organs are used, and only their upper part fully inflated. Now, if the hooped skirt be hooked to the jacket, in four places at least, and not left to rest upon the hips, the reader will perceive that the backbone, and all the muscles which enclose and steady both the great cavities of the body, and keep them elegantly erect upon the hips, must carry both the hoops and the skirt; then, these may be made both light and elegant, or heavy and grand, as the seasons may require; while drawers of material adapted to our severe winters may be so artistically adjusted, and supported by suspenders, as completely to protect and clothe the limbs without the necessity of the skirts so girding the body by drawn cords, to keep them and the drawers in place, as not only seriously to cripple all the viscera, but to interrupt the healthful action of the muscles of the abdomen, and, worse than this, to compress all the veins that carry back the blood from the lower limbs to the heart for purification.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Railway Surgeons.—We fully believe every word in Mr. Kendall's letter, published last week; but his letter leaves our statement untouched. He was not called in till after the railway company had been asked for additional compensation, and had nothing to do with the original compromise. But he does not deny that a Surgeon who acted for the company, and was paid by them, did attend the girl, and did take, on the part of the directors, a receipt in full for all damage both to clothes and person. We attack wrong practice only, and do not wish to annoy persons; but because we give no names, we do not wish the wrong horse to be saddled.

Vindex must send his name.

Mr. Salt's New Truss.—Mr. Salt, of Birmingham, has devised a truss for inguinal hernia, which was exhibited at a recent meeting of the Medico-Chirurgical Society. It is light, easily concealed, and thoroughly efficient. The parts press inwards as well as backwards, and, by a very ingenious arrangement, permit of movements the most extensive and various without displacement, and without impairing the greatest nicety of support. There are several principles in the truss which are quite new, but which, we believe, are based on strictly anatomical and physiological data.

Mr. C. F. Buckle, of No. 77, Gray's Inn-road, is a scientific chemist who devotes his time to the preparation of culinary and dietetic substances, as luxuries for the healthy, and as comforts or restoratives for the sick. One of his latest preparations is a solid *paste* of apple and isinglass, which we pronounce excellent. It is evidently made of genuine fruit, and not of factitious essences; and, if we may borrow the Johnsonian antithesis, we pronounce it to be acid without acrimony, and sweet without sickness. It will allay the cough which awakens the hectic, and the thirst which torments the feverish; and does that, by means of a grateful aliment, which is often attempted in vain by the most nauseous medicaments.

We have received from MM. Armand et Fils, 75, Milton-street, E.C., a specimen of a substance called "Dentine," which is not tooth structure, as its name would lead the anatomist to believe, but a kind of perfumed soap to be used in cleaning the teeth. It has a less disagreeable taste than most soaps have.

Prescott, the historian, who died at the age of 63, lived a life of extreme regularity. He met with an accident to the eye early in life, which compelled him to a minute observation of every single circumstance that should affect the health. The great object of his life was to save health and eyesight. It may be worth knowing what his habit was regarding wine:

"The most embarrassing question, as to diet, regarded the use of wine, which, if at first it sometimes seemed to be followed by bad consequences, was yet, on the whole, found useful, and was prescribed to him. To make everything certain, and settle the precise point to which he should go, he instituted a series of experiments; and between March, 1818, and November, 1820—a period of two years and nine months—he recorded the exact quantity of wine that he took every day, except the few days when he entirely abstained. It was sherry or Madeira. In the great majority of cases—four-fifths I should think—it ranged from one to two glasses, but went up sometimes to four or five, and even to six. He settled at last upon two or two and a-half as the quantity best suited to his case, and persevered in this as his daily habit until the last year of his life, during which a peculiar regimen was imposed upon him from the peculiar circumstances of his health. In all this I wish it to be understood that he was rigorous with himself—much more so than persons thought who saw him only when he was dining with friends, and when, but equally upon system and principle, he was much more free. He generally smoked a weak cigar after dinner."

Maddox's Registered Invalid Bath is especially constructed for washing invalids in bed, is adapted for the use of ladies after accouchement, and is valuable after Surgical operations for fomentations, etc., and can be applied to any portion of the body where Surgical dressing is required, such as hæmorrhoids or prolapsus, etc. The wedged-shaped end is inserted under the body, from the front, without exertion or fatigue to the patient, and allows the back to rest on a soft cushion attached to the bath; it is so constructed that the water cannot possibly spill, thereby rendering it a great comfort to persons where bathing is essential, and removal from the bed would be attended with danger; also to those afflicted with paralysis, spinal affections, or delirium. It is light and portable, being only 20 inches in length, 12 in width, 4½ deep, graduated to 1½ inches, and is evidently well adapted for the purpose for which it is constructed.

Small-pox at Washington.—The New York correspondent of the *Times* (January 29), describing the condition of the fugitive and freed negroes who have thronged into Washington, writes:—

"There is no employment for a tithe of them in Washington, and they are huddled together like vermin in camps and Hospitals beyond the boundaries of the city,—men, women, and children indiscriminately, where they are fed at the expense of the Government. Small-pox has broken out among them, and in so virulent a form that they die off at the rate of hundreds in a day. It is no uncommon thing to see the poor creatures lying in the snow in the public streets in the last agonies of death, and still more common to see them wandering about with the unhealed and still purulent marks of the disease visible all over their hands and faces. So prevalent is the disease, that the life of the President himself was nearly sacrificed a month ago; and within the last week one member of the Senate and one member of the House of Representatives have fallen victims to it. In consequence of the dread of contagion, the New Year's reception at the White House was more than usually scanty, such persons as were compelled to pay their respects to the President hurrying through the rooms, and out into the open air, as fast as possible, and without even exchanging the compliments customary on the occasion. Some timid persons sacrificed their courtesy to their fear, and shook hands with Mr. Lincoln without taking off their gloves; while others, instead of the usually boisterous salutation of American good-will, were content with holding out the tip of the forefinger for a hurried touch, and an equally hurried "Happy new year to you, Mr. President!" Nobody will go to Washington who can stop away, and those whom business or duty calls within its infected precincts take care to be vaccinated before they go. It is calculated that there are to-day at least 10,000 cases of small-pox in the city and neighbourhood, all among or derived from the negroes, and great fears are entertained that the disease will spread to Baltimore, Philadelphia, and New York. The Government knows not what to do. The emancipation proclamation has brought the black swarm to Washing-

ton, and Mr. Lincoln cannot be guilty of the inhumanity of refusing them admittance, and food, if they cannot find work, and has not yet been able to devise the means for maintaining them in idleness, comfort, cleanliness, and health in their city of refuge."

The Army Medical Service.—The following letter appears in the *Calcutta Englishman* of December 10. The editor of that journal, in reference to the death of the Assistant-Surgeon of the 101st regiment at the Umbeyla Pass, asserts that—

"In several of our campaigns the loss of Medical officers has been greater in proportion to their number than that of their combatant brethren. In the army of Delhi it was so, if we count the five Medical officers who died soon after the city was taken; the strain upon their exertions was removed, and their work was done. This fact of Medical officers, whose energies have been strained in severe campaigns, sinking soon after the termination of hostilities, is well known to those experienced in war and its results; but should Great Britain be engaged in a serious war just now, the probability of these extensive casualties amongst the Medical officers is much diminished, seeing that, as the Profession is at present treated in the army, Medical men refuse to 'come and be killed.'

"TO THE EDITOR OF THE ENGLISHMAN.

"Sir,—I regret to observe the name of an Assistant-Surgeon of the 101st regiment included in the list of gallant men who have fallen on the snows of the Umbeyla Pass. Another Medical officer is added to the number who have shed their hearts' blood, not actually fighting the battles of their country, but engaged in the more difficult task of performing duties requiring the highest amount of nerve and self-possession, under an enemy's fire, unsupported by the excitement which stirs the blood and animates the heart of every man engaged in actual conflict. The position of the Medical officer is described as non-combatant, and rightly so in accordance with the ordinary meaning of the word. He joins not in the heady fight, feels not the wild excitement of the charge, adds not his voice to the cheer of victory. Calmly he must wait with his hospital 'in the rear,' while the shot-torn and dying, whose lives depend upon his firmness, are brought in. He knows not how the tide of battle ebbs and flows; at any moment a storm of shot may sweep his patients and himself into eternity; the position of his hospital may be carried by the enemy, or ridden over by a routed party of his own side, or should he be safe from these dangers, he may be called upon the field itself to perform, under fire, the most delicate of operations, or to accompany the storming party to the breach. Yet it is commonly supposed that the Medical officer is never in danger, and that his non-combatant position is a protection from the bullet and round-shot of the enemy. Not many years ago it was even held by some military officers that he should receive no pension for wounds, as he had no business to be in danger, his proper position being 'in the rear.' 'In the rear' indeed has always been his position, as far as advantages are concerned. 'In the rear' he remains at present, his proper rank denied him, his promised advancement withheld. So far, indeed, is he 'in the rear,' that he is now becoming difficult to find, and is likely soon to be left behind altogether.

"The death of an Assistant-Surgeon may seem a matter of small moment to the military authorities now, but, ere long, they will be ready to cry out—'We could have better spared a better man.' A day of heavy retribution is at hand for the Government which has, by its ill-treatment, permitted the Medical services to advance so far on the road to disorganisation; but it continues obstinate in its short-sighted policy, and still refuses to confirm those advantages, so often promised and withheld, which will alone induce Medical men to attach themselves to the army. We learn from England that the position of the military Medical services, and the treatment they have received, are thoroughly appreciated in the Medical schools. In former days, when reliance was placed on the good faith of the Government, no questions were heard in the schools about 'relative rank,' and the passed student thought himself lucky in obtaining a commission in the army Medical service. Now all stand aloof, and Professors warn their classes to avoid it. Why is this? There is no want of young Medical men of the highest promise at home. On board the merchant vessels lying in the Hooghly are to be found many gentlemen of excellent Professional attainments, who have given their services for a paltry fifty rupees per month. The shipowner for this pittance can obtain that which the Government fails to secure,—and why? Because he at least keeps faith with his servants, and holds out no promises which he does not fulfil.

I am, sir, yours faithfully,

"Calcutta, December 8, 1863."

"MEMOR.

ATROPISED AND CALABARISED GELATINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to Mr. Streetfield's letter of last week, permit me to state that, in the Ophthalmic Department of St. Mary's Hospital, atropised and calabarised gelatine, in various forms, has been used experimentally by Mr. Ernest Hart for upwards of three months, and other preparations, such as the atropine glycerine plasma, for more than six months. I think Mr. Streetfield's attention should also be directed to the subjoined extract from M. Warlomont's paper on the Calabar Bean, in the *Annales d'Oculistique* of September 30 to October 31, 1863, to which the words quoted by Mr. Streetfield in his January article bear the closest correspondence:—

(Extract translated.)

"The remainder of a square of paper, however small it may be, is not less irritating than is every foreign body to the eye; there results some lachrymation, which carries away a certain quantity of the active principle. On the other hand, it is, on the whole, a foreign body, which the Practitioner must himself undertake to remove, after having allowed it to remain the necessary time between the eyelids; and this is always a trouble which it would be good to have the power of escaping. We have made some researches in order to replace the paper by a mucilaginous substance, not irritating, and which, in contact with the tears, could dissolve itself; and although the result has not been absolutely satisfactory, we do not despair of attaining it; this would be, we believe, a grand perfection."

I may state that the sheets of gelatine which Messrs. Savory and Moore have supplied are of extreme thinness, and thus rendered unexceptionable in use.

I am, &c.

ARTHUR T. NORTON,
Demonstrator of Anatomy, St. Mary's Hospital.

4, Westbourne-grove West, February 2.

THE NEW PHARMACOPEIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The compilers of the new British Pharmacopœia have, in my opinion, been guilty of a very serious oversight in omitting to place after each preparation its properties, uses, and dose; more particularly the latter, as the important changes made will cause a great deal of confusion with regard to some of the more powerful drugs.

The following extract seems peculiarly appropriate to the present time; it is taken from a curious old work, entitled, "N. Culpepper's Dispensatory," January 1, 1663, page 80:—

"Kind Readers,—The Right Worshipful the Colledg of Physicians of London in their New Dispensatory give you free leave to distill these common waters that follow, but they never intended you should know what they are good for." I am, &c.

Sheffield, February 1.

M.

TREATMENT OF TYPHUS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I perceive with pleasure that Mr. Harding continues, in your columns, to discuss the propriety of administering alcoholic liquors in cases of what he is pleased to call "exhaustive diseases." As I have already taken a share, though a small one, in the discussion, you will allow me, perhaps, again briefly to canvass the merits of Mr. Harding's views.

As I understand him, Mr. Harding believes that alcohol is, in these diseases, both a food and a medicine. I really think, after the experiments of Dr. Ed. Smith, and the more recent reply of M. Perrin to M. Baudot, that no unprejudiced mind can still hold alcohol to be a food. I cannot think that M. Baudot's experiments are more trustworthy than those of the laborious and candid trio, MM. Lallemand, Perrin, and Duroy. No; if I mistake not, English Physicians now recommend alcohol for properties entirely distinct from any nutritious element to be expected from it. The praise of the drug is restricted to what is held to be its stimulant, and, consequent on that, its narcotic action. Suppose, then, that the action of the heart can be sustained, and sleep procured, as well or better without alcohol than with it, surely we are justified in preferring those other means; and the rather when we know that, apart from alcohol, convalescence is shorter and recovery surer than after the routine practice of alcoholic stimulation. Assiduous attention to the natural tonics, combined with the medicinal treatment by the dilute mineral acids, and the rendering of assistance to the digestive organs through the exhibition of camphor, cinchona, pepsine, etc., has reduced the mortality of typhus from 20 per cent. (the Hospital rate) to less than 10 in our rural districts.

Incidentally, Mr. Harding refers to the use of brandy in uterine hæmorrhage. To fly to brandy and to lean on it in such cases is to lean on a broken reed. I have sketched a more successful plan in my "Guide," etc., too long to be inserted here.

In reply to the remark, that the experience of one man ought not to counterbalance that of the most eminent Physicians throughout the empire, it may be said, that all improvements begin with one man, or a very few. How else are they to be brought about?

Physicians throughout the empire have been, and the majority of them still are, thoroughly wrong as to the dietetic use of alcoholics by the healthy. In this there is good ground for suspicion that they may be wrong likewise in their estimate of the value of these liquors in disease. The public, recognising our professional delinquency in the one case, are beginning to suspect us in the other. I have not yet had the opportunity of trying it, but I confidently expect that the wine which is truly the "fruit of the vine," and which has never had its natural constituents deranged by fermentation, will be found a valuable auxiliary in our treatment of long-continued exhaustive diseases. It will be well for us to bear in mind that such wine has become an article of ordinary commerce. I faintly hope that some of us—may be a few as yet—are acting out in this matter, very possibly at some self-sacrifice, the old advice of the poet,—

—"si quid novisti rectius ipsis

Candidus imperti"—

BOOKS RECEIVED.

The Dental Review: a Quarterly Journal of Dental Science. New Series. No. 1. January, 1864. Robert Hardwicke.

* * * This journal, which up to the end of last year appeared monthly, has now taken a more permanent and extended form, and is to be added to our list of quarterlies. This appears to be a wise measure on the part of the proprietors, as the Dental Profession has hitherto, we believe, possessed no quarterly organ for the publication of memoirs of greater pretension and scope than those which have appeared in its more ephemeral periodicals. The first number promises well. It contains papers "On the Use of Nitrous Oxide in Dental Operations," by Mr. Samuel L. Rymer; "On Hüllihen's Operation of Drilling into the Pulp Cavity," by Mr. H. T. Kempton; "On a Case of Inflammation and Partial Absorption of the Fang of a Second Molar Tooth, produced by the Eruption of the Wisdom Tooth," by Mr. R. T. Hulme; "On Mechanical Restorations of the Mouth and Face," by Mr. Hockley; "On the Use and Abuse of the Vulcanite Base," by Mr. Weiss; and "On Disinfectants and their Application to Dentistry," by Mr. Tribe. There are also a good selection of articles from other journals, reviews of books, editorial articles, etc. The reconciliation which has recently taken place between the two principal parties into which the Dental Profession has been split, seems to have paved the way for the success of such a journal as this. We doubt not that it will receive full support from dentists, and will fulfil the promise of its first number. We will only add that in the matters of appearance, type, and paper, it is very creditable to the publisher.

Obstetric Aphorisms for the Use of Students. By J. G. Swayne, M.D. Third Edition. London: John Churchill and Sons. 1864.

* * * "The object of this work is to give the student a few brief and practical directions respecting the management of ordinary cases of labour; and also to point out to him, in extraordinary cases, when and how he may act upon his own responsibility, and when he ought to send for assistance." We may be allowed to add, that many Practitioners, as well as students, may derive information from this most satisfactory manual. Within the compass of 134 duodecimo pages are compressed the results of much thought and extended experience. About a fourth of the space is devoted to the management of ordinary labour; the remainder is divided unequally between cases not requiring a consultation, and those where a second opinion is advisable. It is not possible, in the notice of a third edition,—itself a token of success and appreciation—to furnish detailed analyses; but as we have read the little work from beginning to end with the greatest pleasure, so we recommend it most heartily to all classes of our readers.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	30.099 in.
Mean temperature	39.6
Highest point of thermometer	54.0
Lowest point of thermometer	24.0
Mean dew-point temperature	34.5
General direction of wind	S.W.
Whole amount of rain in the week	0.23 in.

APPOINTMENTS FOR THE WEEK.

February 6. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. John Lubbock, Esq., F.R.S., "On the Antiquity of Man."

8. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital 1½ p.m.; Samaritan Hospital, 2½ p.m.
MEDICAL SOCIETY OF LONDON, 8½ p.m. Dr. Gibb, "On Subglottic Œdema of the Larynx."

9. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. Augustus Oldfield, Esq., "On the Ethnology of Australia."
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Callender's "Account of Amputations at St. Bartholomew's Hospital, 1853-63." Mr. Savory, "On the Absorption of Dead Bone."

10. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Middlesex, 1 p.m.; London, 2 p.m.

11. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopedic Hospital, 2 p.m.
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."

12. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 8 p.m. Professor Wanklyn, "On the Synthesis of Organic Bodies."

ORIGINAL LECTURES.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT
The Royal College of Physicians,
By A. B. GARROD, M.D., F.R.S.,
Fellow of the Royal College of Physicians; Physician to King's College
Hospital.

LECTURE II.—FRIDAY, JANUARY 29.
(Continued from page 147.)

Among the antimonial preparations some important changes have been effected—changes which I believe will be generally looked upon as valuable, and which will enable us to prescribe some of the salts of this metal with an increased feeling of confidence.

In the London Pharmacopœia, the antimonial compounds are the Tersulphuret or Black Sulphuret, found native, not itself used in medicine, but only employed in the preparation of the other antimonial salts; the Oxysulphuret, the Potassio-tartrate, and lastly the Compound Antimonial Powder. Of the value of the last-named preparation there has, as you are aware, been much difference of opinion, some considering it an active and effectual method of influencing the system by the metal; some, on the other hand, looking upon it as almost inert, or at least most uncertain in its effects, and far inferior as a remedy to the secret preparation which is sold under the name of "Pulvis Jacobi verus," or "true James' Powder." Perhaps it may be well that I should say a few words on this point,—explain why the London Pharmacopœia preparation is considered inferior to the secret remedy, and tell you of the experience gained during the investigation of this subject by our Committee.

I must remind you that the metal antimony forms with oxygen two well-defined oxides; the first, containing three equivalents of oxygen to one of the metal, is called the oxide or teroxide of antimony; the second, with five equivalents of oxygen, is termed antimonious acid; but besides these two there is a third oxide, containing oxygen in the proportion of one equivalent of the metal to four equivalents of oxygen, but this is probably not a simple oxide, but a compound of the two others; in fact, an antimoniate of antimony. The composition of these oxides can be thus represented, as seen on the board:—

Oxide or teroxide of antimony	SbO ₃
Antimonious acid	SbO ₅
Antimonious acid or antimoniate of antimony	SbO ₄ or SbO ₃ + SbO ₅

The teroxide of antimony is dissolved pretty readily by weak acids, and when in the stomach it is probably soon converted into a salt, and absorbed into the system. On the other hand, the so-called antimonious acid is extremely insoluble, and probably almost inert. It has usually been argued by the supporters of the secret preparation, that in it the antimony chiefly exists in its soluble form; whereas, in the London Pharmacopœia preparation, it is stated to be more commonly found as antimonious acid or in the insoluble condition. The Pharmacopœia Committee, (a) in order to settle

(a) In the following table will be seen the detail of the analyses made of the Compound Antimonial Powder, and the different specimens of James' Powder, as reported to the Pharmacopœia Committee, and referred to in the Lecture:—

	London Pulv. Ant.	James' Powder. (Newberry).	James' Powder. (Butler).
Percentage soluble in water	1.137	0.461	0.917
Consisting of			
Antimonite of lime	0.42	0.095	0.134
Sulphate of lime	0.15	0.267	0.381
Alkaline salts	0.43	0.220	0.500
Percentage analysis of residue insoluble in water:—			
Antimonious acid	39.98	32.216	42.35
Teroxide of Antimony	1.76	0.601	1.61
Phosphate of lime	54.52	62.124	53.55
Lime	1.55	1.954	0.99
Residue	1.74	1.603	Lost by accident.
Loss	0.45	0.502	1.50
	100.00	100.00	100.00

The amount operated upon to determine the portion soluble in water was
Vol. I. 1864. No. 711.

this point, had numerous analyses made, the results of which will, I hope, not be devoid of interest. One of the preparations so examined was the London Pharmacopœia Powder, originally procured from Messrs. Howard; a second was James' Powder (Newberry's); a third, James' Powder (Butler's),—both these latter firms, I understand, claiming to possess the original, or Dr. James' own formula; and a fourth was James' Powder, obtained by Mr. Squire, and stated to have been in store sixty years. From the analyses it appears that the antimonious acid or insoluble oxide varied in these different preparations, in round numbers, from 45 to 33 per cent., the amount being greatest in the old specimen of James' Powder; the teroxide or soluble oxide of antimony varied from 9 to less than 1 per cent., the greatest quantity being again found in the old preparation; next, in that made according to the direction of the London College, the bulk of all consisting chiefly of phosphate of lime. These analyses will certainly not explain the superior value that James' Powder is supposed to possess over the London Compound Antimonial Powder, and perhaps, after all, one preparation is as good as the other; certainly, I know of no trustworthy clinical experience which demonstrates the superiority of either.

We have, I hope, surmounted this difficulty of the oxides, and have arranged the antimonial salts in the following manner:—

The Black Sulphuret used for preparing the salts is placed in the Appendix; from it a solution of the terchloride is first formed, named *Antimonii Terchloridi Liquor*, a preparation to which we shall again have occasion to allude, and from this last preparation, by the action of water and carbonate of soda, the oxide is precipitated, which, washed and dried at a moderate temperature, forms *Antimonii Oxidum* of the British Pharmacopœia. It is, as you may observe, a white, moderately heavy powder, and, although insoluble in water, is readily taken up by hydrochloric acid; it is likewise rendered very soluble by the acid tartrate of potash or cream of tartar, and then forms tartar emetic.

As a preparation, there is introduced *Pulvis Antimonialis*, made by rubbing together one part of this oxide with two of precipitated phosphate of lime, which latter salt is placed in the *Materia Medica* chiefly for this purpose:—this powder, a substitute for *Pulvis Antimonialis Compositus* of the London Pharmacopœia, must be not only equal, but infinitely superior to James' Powder, provided the teroxide of antimony be the important ingredient; the mode of its preparation precludes the possibility of any variation in the amount of soluble oxide; in short, all the contained antimony is in the state most suited to allow of solution and absorption.

It is the opinion of many Physicians that all the good obtainable from the employment of the antimonial salts can be effected by regulated doses of tartar emetic; this may be true, but we can readily imagine that an oxide, which is insoluble in water, but slowly acted upon by the fluids of the stomach, would be less irritating, less sudden, but more lasting in its effects, than a soluble salt, like the tartrate of antimony, known to be capable of causing, under certain circumstances, intense local irritation. Oxide of Antimony is, undoubtedly, a preparation peculiarly adapted for administration in the form of powder or pill. The dose for an adult may vary from 1 to 5 grains, and that of the antimonial powder may be three times this amount. The question, whether the addition of the insoluble, and, probably, inert phosphate of lime is of any

about 100 grains in each case. The amount subjected to analysis was 30 grains. The alkaline residue determined consisted mainly of potash; no trace of tartaric acid was discoverable in either of the samples of James' Powder. Sulphuric acid enough to account for the lime extracted by water was detected in each.

Analysis of James' Powder received from Mr. Squire, and guaranteed to have been more than sixty years in store. 20 grains only were subjected to analysis.

value, or does more than add to the bulk, I must leave to your own judgments to decide. In giving remedies possessed of little solubility, we must always bear in mind that the state of the stomach, and the time of administration in relation to food, powerfully influence their action.

The *Liquor Antimonii Terchloridi*, which is a strong solution of the chloride of antimony, specific gravity 1.47, is a powerful caustic, and has been employed as such to poisoned wounds, and so forth; the chloride, in its solid state, has also been used as an escharotic.

The *Oxysulphuret* is retained in the *Pharmacopœia*, but under the name of *Antimonium Sulphuratum*.

In the list of the *Materia Medica* will be found a root called *Nectandra*, or *Bebeeru* bark; derived from the *Nectandra Rodiæi*, or the *Greenheart-tree*, and imported from *British Guiana*. It occurs, as you will observe, in large, flat pieces, greyish brown externally, and cinnamon-brown within, and having a strongly bitter and astringent taste. This bark can, of course, be given in the form of powder, infusion, or decoction, but no such preparations are introduced into the *Pharmacopœia*; but, in lieu of them, the sulphate of its contained alkaloid is inserted under the name of *Beberia Sulphas*, or *Sulphate of Beberia*, and to this substance I will call your attention.

The salt has not yet been crystallised, but is found in commerce in thin, dark-brown, translucent scales, soluble in water and spirit, very bitter to the taste, and possessing other characters which are fully described in the *Pharmacopœia*, but which it is unnecessary to detail here. The free alkaloid, which is readily separated from the salt, occurs as a yellow amorphous powder, and the composition of the sulphate is supposed to be represented by the formula on the board, $C_{38}H_{21}NO_6, HO, SO_3$. We must now inquire into the action of *Beberia*, or rather its sulphate, and I must inform you, should you not already be fully conversant with its powers, that it is one of the many substances which has been proposed as a substitute for quinine; it has been largely employed in *Edinburgh*, and said to be a tonic of much value, and an antiperiodic, little or not at all inferior to sulphate of quinine. It was chiefly through the inquiries of *Dr. Douglas Maclagan* that it was introduced into *Great Britain*. There is one advantage it is asserted to possess over quinine, namely, that it is not so liable to excite the circulation or affect the nervous system. My own experience of sulphate of *beberia* is limited, but still sufficient to cause me to entertain great misgivings as to its antiperiodic powers. I have administered it in about three cases to patients in the *Hospital* labouring under intermittent fever, either quotidian or tertian, and certainly in all instances it most signally failed in arresting the progress of the disease, although pushed to the amount of causing some disturbance of the stomach; the same patients were afterwards at once cured by the exhibition of the ordinary doses of quinine. On mentioning the result of these trials to an *Edinburgh Physician*, he told me that it was now admitted that sulphate of *beberia* possessed little power in arresting ague, but that its value was chiefly seen in the treatment of pains of a periodic character, in neuralgic headache, for example. I cannot, as yet, either affirm or confute this statement; but, as the salt is now rendered officinal, there will be no lack of opportunities of testing its value in the various forms of diseases of the nervous system. In ascertaining the powers of a proposed antiperiodic, I usually first observe the influence which the change of locality and diet has upon the disease; for it must not be lost sight of, that occasionally these circumstances are sufficient to arrest periodic affections, and results may in this way be ascribed to medicines, which in reality are due to an altered hygiene. I should mention that the dose of sulphate of *beberia* is usually considered to range from one to five grains; as an antiperiodic I have occasionally administered as much as ten grains.

There is a plant employed in medicine, the preparations of which are often complained of for their want of uniformity of action, to which I must now draw your attention for a few minutes—I allude to the *Conium Maculatum*, or *Hemlock*; and I refer to it more especially, as a fresh portion of this plant is now made officinal, and certain alterations have been effected in its preparations.

In the *London Pharmacopœia*, *Conium* is defined to be the leaf of the wild plant, and there will be found the tincture, ointment, and extract; and from the extract the cataplasm is made.

Hemlock appears to owe its activity to the possession of an alkaloid termed *Conias*; and this principle is somewhat peculiar, inasmuch as, when separated from the acid with which it is

combined, it occurs in the liquid form; it is an alkaloid which is represented by the formula on the board, $C_{16}H_{15}N$; it is a body which very readily undergoes decomposition from exposure to the air, so as to render it necessary, when in a free state, to be preserved in sealed tubes; and even when combined with an acid, as in the plant, it is still very liable to change.

These facts will at once enable you to understand how it is that the dried leaves and the extract are apt to vary in activity; and they explain equally the uncertainty in the strength of the old tincture, which is prepared from the dried leaf. These circumstances have induced the committee to introduce the fruit of the *hemlock* into the *Materia Medica*, and to substitute this part of the plant for the leaf in the formation of the tincture; and they have done so under the impression, doubtless correct, that the alkaloid is less liable to become injured in this form.

The tincture of the *British Pharmacopœia*, now termed *Tinctura Fructus Conii*, contains the activity of two ounces of the fruit to each pint of spirit. Another introduction has been that of the recent juice, *Succus conii*, made from the fresh leaf, with the addition of spirit sufficient to prevent decomposition. Within the last few years I have made many observations upon the action of *Conium*, the results of which may probably appear astonishing to those who have not given the remedy in a similar manner. I have also compared the tincture of the *London College* with that of the *British Pharmacopœia*, and will now shortly relate my experience.

Hemlock is looked upon as a powerful and direct sedative to the nervous system, more especially to the spinal cord: in cases of poisoning with the plant, paralysis of the extremities ensues, the functions of the brain usually remaining intact. I need scarcely state, that it is most frequently employed to allay spasm, more particularly of the respiratory organs; and that it has been recommended very highly for the purpose of alleviating the pain and altering the diseased action in carcinomatous affections; in these last cases its influence can hardly be said to have proved beneficial, certainly not curative.

When I commenced making clinical observations on the action of this drug, I was under the impression that the dose of the tincture sufficient to effect any good results was from twenty to thirty minims; and with such doses I commenced; but I soon found that, in order to produce any appreciable physiological symptoms, the amount must be greatly increased; and I was gradually led to augment the dose from half a fluid drachm even to the apparently enormous amount of a fluid ounce. In at least twenty cases, the details of which I hope to make public, from one drachm to half-an-ounce has been administered three times a-day; and within the last fortnight I had a patient taking a fluid ounce at each dose, without experiencing the slightest discomfort—in fact, without the exhibition of any symptoms from its employment. In many of these cases, the tincture made use of was prepared expressly from the leaves most carefully dried, and at establishments of which the reputation is undoubted.

In the above observations, the tincture of the *London Pharmacopœia* was used; but I have recently had opportunities of comparing its strength with that of the tincture of the fruit prepared according to the directions of the *British Pharmacopœia*. In the case of the man above alluded to as taking a fluid ounce of the *London tincture* for a dose, it was found, when the tincture of the fruit was substituted, even five fluid drachms was sufficient to cause the development of some symptoms; but these were only slight, and consisted in some sensation of tightness of the forehead and a little alteration of vision, and, perhaps—but it was difficult in this case to be certain—of some increased feeling of numbness of the lower extremities.

I consider the new tincture to possess at least twice the strength of the old tincture; but even this *British Pharmacopœia tincture* is, as you will gather from my observations, by no means very potent. From many trials, I am inclined to look upon the relation of strength of good fresh extract to the old tincture as in the ratio of about twelve grains of the former to half-an-ounce of the latter; and, if such be the case, the results obtained do not differ much from those derived from the use of the extract, of which almost fabulous quantities have been asserted to have been given in cases of cancer.

As to the use of *Conium* in large doses, I must now add a few remarks. I have been led to the employment of *hemlock* in cases of severe spinal disease, both functional or structural; and I may add that in many instances much advantage has followed its administration. In *paraplegia*, when there

exists a sub-inflammatory state of the spinal cord, as indicated by the pain in the back and startings of the limbs, hemlock proves of great service; and I have often seen the incontinence of the urine checked by the drug. It is in cases where strychnia aggravates the patient's symptoms that Conium relieves. In one well-marked case of paraplegia, of long standing, arising from a very prolonged exposure to wet and cold—in fact, from the man, during a shipwreck, having been immersed up to his shoulders in the sea, supported by a spar, for more than thirty hours—this remedy appeared to be of eminent service. When admitted into the Hospital, this patient could scarcely crawl from bed to bed, was unable to retain his urine, had pain in the back, severe startings of the legs at night, and was altogether in a very deplorable condition. From the employment of the hemlock in gradually increasing doses, the symptoms became much alleviated, and after its prolonged use he was enabled to walk about the wards, and go up and down stairs; and after a still further time he was sufficiently recovered to engage himself as a sailor on board a vessel bound for Norway, his native country. As a point of some interest, I may remark that, during his sojourn in the Hospital, and after partial recovery, he had very minute doses of strychnine administered to him; but it was found that this drug invariably brought back the more distressing symptoms, and more especially the incontinence of urine.

I cannot help suspecting that in very many cases of paraplegia, even when the ordinary symptoms of irritation of the spinal cord are not detectable, some lurking action may exist which is aggravated by the exhibition of strychnine, but generally soothed by fair doses of hemlock.

Of the British Pharmacopœia tincture, the dose may range from half-a-drachm upwards, according to the nature of the case and the urgency of the symptoms.

ORIGINAL COMMUNICATIONS.

ON RUPTURE.

By JOHN WOOD, F.R.C.S.,

Demonstrator of Anatomy, King's College, London, and Assistant-Surgeon to the Hospital.

No. III.

ON CONGENITAL RUPTURE.

A GREAT proportion of the cases of oblique hernia occurring in adults have their primary origin in causes operating at the period of development. In many cases, these result in the production of a congenital rupture appearing at the time of or soon after birth. These are often treated as of little importance, under the name of "windy rupture."

About the eighth lunar month of foetal development, the testes traverse the inguinal canal, and at the close of that period should have escaped from the superficial ring into the scrotum. Many causes may operate in retarding this process, so that these glands cannot be felt in the scrotum until some time after birth—the delay extending to months, and even years; and yet this object is finally effected. Nor does a rupture always immediately appear in consequence of this retardation. The arrest of the gland may take place in the inguinal canal, and the deep ring may be effectively closed before the testis escapes from the superficial ring. But in all cases in which the gland has attained a greater proportionate size before its descent, its passage through the ring leaves these more open than normal, less effectively sealed, and more disposed to allow of a rupture in after years.

At the end of the second month of intra-uterine life, the testes, or ovaria, are developed at the inner side of the corpora Wolffiana. These bodies are found in the lumbar region, below and in front of the kidneys. From the lower part of the convoluted structures which finally form the epididymis, descends, along the psoas muscle, through the internal ring, and finally connected with the dartos at the bottom of the scrotum, a cylindrical cord composed of unstriped muscular fibres arranged as a tube around a central areolar cylinder. This is best seen about the fifth month. It is "the gubernaculum testis." This structure may be ascertained, by careful dissection with a lens, to be connected with the peritoneum considerably lower down than the lower end of the gland itself. It is thicker at the upper part of the inguinal canal and in the abdominal cavity than it seems to be in the scrotum. It is connected also with the lower end of Poupart's

ligament externally, and with the conjoined tendon of the internal, oblique, and transversalis internally. During the fifth month, when the testicle has assumed its characteristic shape by becoming connected, through the transverse cœca, or "coni vasculosi," with the excretory tube, or vas deferens, it begins to shift its position, and to descend towards the inguinal ring. Preceding it through the canal during the seventh month is a tube, or pouch, of peritoneum, drawn down by the contraction or progressive development of the gubernaculum, and which finally becomes the tunica vaginalis testis. This pouch, thus preceding the descent of the gland, may, when the descent of the latter is arrested, become, if the child cries or struggles much, the seat of an intestinal protrusion, and thus give rise to a windy rupture, even before the gland itself can be felt. This condition I have many times observed. At the close of the period of gestation, the communication of the tunica vaginalis with the peritoneum at the internal ring usually becomes closed, by adhesion of the sides of the "canal of Nuck," and its replacement by a very tough fascia connecting the elements of the cord or round ligament closely to the peritoneum.

In certain cases, the canal which connects the tunica vaginalis with the peritoneum, instead of being completely obliterated along the inguinal canal from one ring to the other, becomes closed only at a small point below the deep ring, leaving a pouch still protruding through that aperture. This, becoming the seat of a hernial protrusion, protrudes into the tunica vaginalis below it, invaginating the latter before it as a double layer of serous membrane covering the true sac of a hernia. Such a rupture is called an "infantile hernia," and is characterised by the presence of three layers of serous membrane intervening between the skin and the bowel. This peculiarity becomes important only in case of an operation for strangulation being required. When the bowel is reduced and the true sac invaginated in these cases, the tunica vaginalis is unfolded and stretched out.

In the female also, a structure homologous to the gubernaculum exists, and may be demonstrated by a careful dissection. It is feebler than in the male, and connected with that portion of the excretory tube of the Wolffian body which is homologous to or becomes the vas deferens in the male; but, failing to become attached to the ovary and to form the excretory duct, as in the male, it degenerates into a round cord, the "ligamentum teres uteri." This cord follows the same course as the vas deferens, epididymis, and testicle in the male—*i. e.*, it is drawn down the inguinal canal by the gubernaculum, and fixed to the labia majora, the homologue of the scrotum. Along with and preceding it is drawn a small pouch of serous membrane,—"the canal of Nuck." This, on account of its small size, is soon obliterated. If, however, a portion of bowel be forced into it, it forms a windy rupture in the female infant. Such cases of congenital inguinal rupture in female infants are not very uncommon. I have in the last few years had many sent to me. Sometimes they become towards adult life larger and more troublesome. In two instances I have operated for the radical cure in such cases with complete success. In certain cases, the round ligament seems to form a more complete attachment to the ovary, approximating to the male formation as before alluded to; then the ovaries themselves may be drawn down by the gubernaculum, and either lodged in the inguinal canal or in the labia majora. In these cases an oblique inguinal hernia is usually, but not always, co-existent, and in the sac the ovary may be distinctly felt and recognised, or may be more plainly exposed by operation. At the Pathological Society's meeting in January, 1864, such a specimen was exhibited, and more are placed on record; in some, the ovary is drawn as far as the inguinal canal only, and escapes observation, until a protrusion of the bowel forces it further down into the sac. Here, also, as in the male, the protruded intestine is placed in front of the gland.

The causes of non-descent of the testicle are closely related to those of congenital rupture. In the latter the glands are retarded in their descent by an imperfect development or want of vigorous action of the gubernaculum, until they are so large as to leave the inguinal canal and rings dilated; the former is produced either by the complete atrophy of the muscle, or by adhesions of the gland taking place to some of the viscera (most frequently the colon) from inflammatory action "in utero." Such imperfect development of the gubernacular apparatus again has a relation to a similar imperfection and want of development of the lower fibres of the internal oblique, with which the gubernaculum is closely connected at Poupart's ligament, as well as at the conjoined tendon.

Mr. Curling's view of the relation between the gubernaculum and the subsequently developed cremaster, viz., that the latter is formed by the inversion of the lateral fibres of the former, seems to me at once plausible and ingenious. I have already pointed out that a frequent cause of oblique rupture in adults is an imperfect support to the deep ring and inguinal valve by a deficiency of the lower fibres of the internal oblique. In these cases there has been a retarded descent of the testis in early life, leaving a patulous condition of the deep and superficial rings. They are usually associated with a feeble development of the cremaster muscle; the imperfection in the apparatus has not revealed itself until a vigorous effort of the abdominal muscles has found the weak point of resistance; a relation is thus established between congenital rupture and a numerous class of oblique ruptures occurring in adult life. These ruptures, in many recorded cases, and probably in more which are unsuspected, have their sacs formed only by the tunica vaginalis. Such cases I believe to be characterised by their sudden formation, without a preparatory stage of bubonocoele, suddenly appearing as fully-formed scrotal herniæ, resting directly upon, and in front of, the testis, and usually obscuring this gland more than in ordinary cases. Upon some occasion of more than ordinary exertion, the membrane closing slightly, the opening of the inguinal canal gives way, and permits the bowel to pass into a ready-made sac of tunica vaginalis. The crowning act of the development of the individual, both in animals and plants, seems to be that of the reproductive organs; a failure of the vital force to complete their formation fully might be expected to show itself more frequently than other malformations from arrest of development, and is seen in the greater frequency of this form of rupture.

ON A CASE OF SPONTANEOUS THROMBOSIS IN THE LEFT FEMORAL AND SAPHENA VEIN.

By H. M. TUCKWELL, M.D. Oxon.,
Late Radcliffe Travelling Fellow.

A. B., aged 33, has previously enjoyed good health; during the past year has allowed himself but little rest in his profession, and has become thoroughly overworked. His present illness commenced about a month ago with severe pain in the head, which lasted five or six days without intermission, and left him much weakened. The pain then shifted to the loins, and continued there for two weeks, during which time he was extremely depressed and unable to get about. At the end of this time, rather more than a week ago, he was attacked suddenly in the night by a violent pain in the right side, which seems to have been purely neuralgic, for no signs of pleurisy could be detected at the time; this pain continued for three days and nights, during which time *he lay continually on the left side*, without sleep, and taking no food, till, on the fourth day, it left him almost as suddenly as it had come on. On attempting now to change his posture he found that the left leg was quite numb, that sensation began to return after rubbing the leg for a time, but that, with returning sensation, there came on an intense pain in the lower part of the leg, more especially in the calf; that he soon observed the leg and foot beginning to swell; that the swelling gradually involved the whole leg and extended up the thigh to the groin, the pain becoming generally diffused and intensified as the swelling extended and increased. I saw him on the fourth day after the swelling had commenced, when the following appearance presented itself:—

He is extremely prostrate, unable to raise himself in bed; the eyes hollow; the voice low and changed; skin generally cool, except that of the left leg, which is abnormally hot; pulse 60, very small, thready and irregular, intermitting at every third beat; thorax generally resonant on percussion; respiration feeble, but free from any morbid sound; urine natural. The left leg, from the groin to the toes, is enormously swollen, pitting everywhere deeply on pressure, its surface is hot and very sensitive; an indistinct hardness can be felt through the œdema along the course of the femoral and saphena vein as far as Poupert's ligament, above which point it cannot be traced; beneath the œdematous integuments large superficial veins are seen ramifying along the anterior and outer aspect of the thigh.

Diagnosis.—Thrombosis of saphena and femoral, perhaps of external iliac vein.

Treatment.—To relieve the pain, cold was applied to the whole limb in the form of evaporating lotions, and the limb was supported on pillows. Small quantities of brandy and wine were administered, with milk and beef-tea.

On the day following, Mr. Savory saw the case with me, and gave me the benefit of his valuable opinion. He fully concurred in the diagnosis, but advised that the leg should be wrapped in cotton-wool, and pressed upon me most forcibly the necessity of increasing the quantity of stimulants, bidding me, to use his own words, "measure the quantity not by the glass or bottle, but by the effect produced." From this time, brandy, rum, port, sherry, and champagne were given every two or three hours day and night, till, on the sixth day from the time that I first saw him, he was taking, in the twenty-four hours, brandy, ʒxiij.; rum, ʒxiij.; wine, ʒxx. The effect of this on the pulse was as follows:—It rose from 60 to 94, the intermissions at the same time becoming less frequent, and the volume better and better, till, on the tenth day from the time that the stimulants were first given, and while he was still taking the above quantity, *it fell to 84*, and ceased to intermit. His general condition improved, *pari passu*, with the pulse. At the request of the patient, I returned to the cold applications, after having made fair trial of the cotton-wool, and found that it made the leg uncomfortable, while the cold relieved the pain in a marked degree. On the twelfth day, the pain having quite subsided, while the swelling remained unchanged, the leg was carefully rolled in flannel bandages, moderate pressure being at first employed and gradually increased, and it was swung from a fracture cradle, with the foot slightly raised. This was continued during a period of seven weeks, at the end of which time the swelling had entirely disappeared. It may be remarked, that the œdema subsided rapidly for the first week after the application of the bandage, but then seemed, for a time, to remain stationary, and was at last slowly removed. The quantity of stimulants was gradually reduced after the fourth week.

He has now recovered his health, can walk two or three miles in the day, but still finds, after a walk, that the leg and foot feel heavy, and that the veins in the foot become, in spite of a lace-socking, considerably distended. There is now nothing abnormal to be felt or seen in the thigh in the region of the large veins, nor is there any visible enlargement of the superficial veins there.

Remarks.—The occurrence of spontaneous coagulation in the living veins, simply as a result of nervous debility, independently of the puerperal state, of fever, or of any wasting organic disease, as phthisis, cancer, etc., is, seemingly, a rare phenomenon. On reading through Virchow's (a) masterly paper on the subject, I cannot find, among the many cases of thrombosis there enumerated, one exactly similar; nor is there in Cohn's (b) monograph one case in which there was not either some organic disease or fever to account for the coagulation. Not that I wish to instance this case as one whose pathology is distinct or special, for the so-called "Marantischer Thrombus" of the Germans, or clot that forms in wasting diseases, is, as Virchow (c) has shown, dependent primarily on the same cause,—an enfeebled state of the heart's action; but the disease here presents peculiar interest, in that there was an absence of any dyscrasia or fever which might be supposed to give rise to the formation of a thrombus by altering the composition of the blood; it shows that to a feeble heart alone may be attributed all the symptoms and signs of the worst form of "phlegmasia dolens." It may be urged by some, in contradiction of this assertion, that phlebitis was here the real cause of the coagulation; but a careful observation of the way in which the disease showed itself seems to me to afford convincing evidence that no phlebitis whatever was present, and thus to confirm still further the doctrines of Virchow. The rapid development and extent of the swelling certainly point to a primary obstruction of the main venous trunk in the thigh. Now, if this obstruction had been due to phlebitis, surely the first symptoms of pain and swelling would have been noticed in the immediate neighbourhood of that venous trunk, whereas nothing of the kind was observed. The swelling and pain commenced in the leg and foot, and extended, last of all, to the thigh; nor was there at any time marked pain, along the

(b) "Klinik der Embolischen Gefässkrankheiten," 1860, p. 115.

(c) "In every case, where the heart's action is much enfeebled, there exists a tendency to partial stagnation of blood in the veins; and the veins most likely to be the seat of this stagnation are those of the lower extremities, those of the pelvis, and the cerebral sinuses."

course of the obstructed vein, distinct from that felt all over the leg. Besides, the general symptoms were not those of an acute inflammatory process; the skin of the body, generally, was cool, and the pulse quite unlike that of inflammation. The conversion of the saphena and femoral vein into a solid tube by coagulation of their contents, is quite sufficient to account for the hardness felt along their course.

John Davy (d) and Gulliver (e) were the first to notice the frequent occurrence of clots of this kind in the veins of those who had suffered from chronic diseases, with failing circulation and great prostration of the vital powers. After them, Hasse (f) and Bouchut (g) turned the attention of pathologists still further in this direction. But to Virchow must be awarded the largest share of praise, for he it was who first cleared away the mists which enveloped the whole subject; he showed, by repeated experiments and post-mortem examinations, that the doctrine of phlebitis, first promulgated by John Hunter, is erroneous; that the coagulation is not preceded by inflammation of the vein, and that there is no exudation on the free surface of its inner coat which determines coagulation; but that, through failure of the heart's power, the blood current is retarded and finally stagnates, and that the starting-point for coagulation is at the point of junction of the valve with the wall of the vein, the valve here (like the chordæ tendineæ in the heart) acting as a foreign body, and furnishing a centre round which the stagnant blood coagulates.

It is worthy of notice that, in circumstances predisposing to thrombus formation, a long continuance in one posture seems to favour the occurrence of the phenomenon, and that the side to which the patient inclines is often the side on which the clot forms. Virchow dwells upon this, and relates cases which corroborate the statement. Cohn has observed the same; he mentions one case in particular—a case of Bright's disease with effusion into the right pleura—where the patient lay continually on the right side and right arm, and where the whole right arm became œdematous from the formation of a thrombus found after death in the subclavian vein.

The contingencies to be feared in these cases are, first, that the heart may not be able to recover itself, and that death by asthenia may follow rapidly; secondly, that erysipelas may set in, followed by diffuse abscess, or even gangrene; thirdly, that a portion of the clot may be detached and washed into the pulmonary artery, causing sudden death; fourthly, that the clot may undergo the so-called retrograde metamorphosis, may soften and break down in its interior, and that this softened, ill-conditioned fibrine may be carried into the general circulation, and cause death from pyæmia. The heart must regain its lost power, and the clot must undergo a healthy process of organisation, before anything like a favourable prognosis can be given.

The question then arises as to how the circulation is re-established; the answer to which is, by the formation of collateral channels, if the vein be completely obliterated by the organised clot. But it may also happen that the canal of the obstructed vein may in part reopen; that the clot, during the process of organisation, may shrink away from one wall of the vein as it becomes adherent to the other; and that the blood may flow on again in its original channel, now of necessity much narrowed by the changes that have taken place. It is probable that the latter has occurred in the case related, from the fact that there are no large superficial veins visible.

The circumstances of principal interest in the treatment employed are, the beneficial effect of cold, the value of pressure, and the necessity of stimulants.

The application of cold—a remedial agent so largely employed in Germany—is strongly recommended by Virchow as the best and often the only means of alleviating the terrible pain that follows the sudden obstruction by an embolus of one of the large arteries of the extremities. The relief it afforded in this case was most marked. Pressure carefully applied and gradually increased by means of a flannel bandage—a plan of treatment employed by many obstetric Physicians in the later stages of the puerperal phlegmasia dolens—was here, too, attended with good results. The rapid and manifest improvement in the general condition of the patient, and the restoration of the heart's power in proportion as the quantity of stimulants was increased, sufficiently indicate their importance

in the treatment of such cases. And, surely, if alcohol acts thus beneficially after the mischief has been done, we cannot avoid the reflection, that the free use of alcohol in wasting diseases may often avert the mischief altogether, and that the stimulant plan of treatment has, at any rate, this much to be said in its favour, that it tends to prevent the formation of thrombi. In the history of this disease we have, certainly, one satisfactory example of the way in which a real advance in pathology leads to a corresponding advance in therapeutics.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

PHTHISIS, MITRAL DISEASE, AND BRONCHITIS.

(Under the care of Dr. THOMPSON and Dr. GREENHOW.)

THE following case presents two especially interesting features. First, the coexistence of tubercular phthisis with cardiac disease, emphysema of the lungs, and dilatation of the bronchial tubes, causing a highly venous condition of the blood; and, secondly, the subsequent arrestment of the tubercular dyscrasia. The patient had suffered for several years before presenting himself at the Hospital from gradually increasing palpitation of the heart, and annually, in the spring and autumn, from chronic cough. His work had consisted chiefly in wielding, for many hours daily, a heavy smith's hammer, and he had continued this labour until just before coming under observation. When he first presented himself at the Hospital in March, he was unmistakably suffering from phthisical disease in the apices of both lungs, and from disease in the mitral valves of the heart, attended by regurgitation. The latter disease was subsequently masked during the attack of acute bronchitis, for which he was admitted into the Hospital in November, but became again distinct before death. For some time after the case first came under observation, the hot skin, quick pulse, and raucous voice indicated that the phthisical disease was progressing; these symptoms, however, abated gradually under treatment; the patient decidedly improved in general health and strength, and his weight increased from 124 lbs. at the beginning of May to 130½ lbs. in September.

He returned to employment in May, and continued throughout the summer his blacksmith's work—a kind of labour very likely to aggravate cardiac disease.

When he presented himself at the Hospital in October, he was suffering from a severe attack of acute bronchitis, attended soon afterwards by anasarca. At this period, although the physical signs of phthisis remained, the disease itself had obviously for some time ceased to extend, and, as was shown by the post-mortem examination, had been actually arrested. It is unquestionable that this arrestment took place between March and October; and, in all probability, it was mainly owing to the progress of the cardiac disease causing a more highly venous condition of the blood.

Joseph H., aged twenty-six, blacksmith, unmarried, was admitted an out-patient, under the care of Dr. Greenhow, on March 20, 1863. Father died of heart disease with dropsy, but there had been no case of phthisis in the family, and patient had never suffered from rheumatism. Had suffered for some years from palpitation of the heart, which had come on so gradually that he could not date its commencement from any particular time. Had been subject to cough occasionally for several years, and had had an attack of hæmoptysis about a year before his admission, since which time he had gradually declined in health. Complexion very pallid; face full and puffy; lips very livid, almost cyanosed. No œdema of ankles, and urine free from albumen. Complained of dyspnœa and cough, with expectoration. Voice raucous; skin hot; pulse 90. Loud systolic murmur at nipple, heard also in axillary region. Dulness on percussion both in right and left, but especially in left infra-clavicular region; cavernous respiration, with gurgling in apex of left lung; coarse crepitation in apex of right lung.

R. Hst. Acid. nit. mur., ʒj.; vin. ipecac., ℥x.; tinct. hyosey., ℥xx. M. Ter. die. sum. Ol. balenæ, ʒj., ter. die. sum.

April 4.—Cough relieved, and patient feels much better;

but pallid complexion, livid lips, and physical signs remain as before.

R. Tinct. ferri sesquichlor., tinct. digitalis, āā., ℥xx. ; acid. hydrochlor. dil., ℥x. ; aquæ, ʒj. M. Ter. die. sum. Ol. balenæ, ʒij., ter. die.

May 3.—Patient still reports himself better, having gained strength and returned to his work. Weight 124 lbs.

R. Syr. iod. ferri, ʒj. ; aq. menth., ʒvij. M. Ter. die. sum. Ol. balenæ, ʒij., ter. die. sum.

Under this treatment patient decidedly improved, his weight gradually increased up to 130½ lbs., the cough and expectoration greatly diminished, and he was able to continue at work till the beginning of October.

October 30.—He presented himself after a rather longer absence than usual, suffering from acute bronchitis. The bronchial râles were so loud as to mask both the phthical signs and the mitral murmur. The lips were quite purple, and the whole face had a livid hue. Anasarca supervened in the course of a few days, and the patient's weight increased suddenly after its appearance to 136 lbs. Being now quite unable to attend as an out-patient, he was admitted into the Hospital, under the care of Dr. Thompson, on November 10.

State on Admission.—Face and lips much swollen and livid. Tongue livid and moist. Pulse 120, small and weak. Respirations 40, irregular. Integument of the chest œdematous. Right front of chest yields, on percussion, a full and clear sound. On the left front percussion yields a dull, though tympanitic sound. Præcordial dulness much increased in every direction. No valvular murmur heard. Under left clavicle bronchial breathing, accompanied by moist sounds of a sharp and almost metallic character. On the right front, and also on both sides behind, rhonchus and sibilus heard.

November 12.—Face dusky; frequent loose cough; expectoration muco-purulent and frothy; pulse 112, weak; respirations 52, chiefly diaphragmatic; slight œdema of lower extremities.

14th.—Moist sounds of rather metallic character at end of inspiration, and tubular breathing with expiration on left front; similar sounds above right scapula; slight roughness of second heart sound heard at base and along the course of the greater vessels; moist sounds over middle and lower region of back less abundant and less intense.

18th.—Cough much easier; complains of pain in lower part of abdomen; percussion sound in left flank, though tympanitic, is dull, and there is marked resistance to finger; no dulness on right side; much distension of abdomen; no fluid in peritoneum.

19th.—Edema has increased; a loud systolic murmur is heard about two inches below the mammæ and one inch to the left of the sternum; second sound is roughened at the second intercostal space; external jugulars turgescient and beaded.

20th.—Complains of pain in epigastric region, where there is also much tenderness on pressure.

21st.—Breathing greatly relieved, and face and lips much less livid; pain in epigastrium and left flank still continue.

24th.—Complains of tightness in upper part of abdomen; slight fluctuation on percussion.

26th.—Sounds under left clavicle much less of the ringing cavernous character, approaching more nearly to sub-crepitation; œdema and pain in abdomen diminished; pulse 120, excessively weak. He became worse on the 27th, and died on the morning of the 28th.

Autopsy Fifty-two Hours after Death.—Body generally well-nourished, but very œdematous, especially the lower extremities. Face livid and bloated. Thorax: right pleural cavity completely obliterated by old adhesions; very firm at apex of lung, loose at lower part. Upper part of left lung firmly adherent to thoracic walls. In lower part of left pleural cavity some ounces of clear serous fluid. Both lungs very voluminous, and emphysematous in front. Posterior parts congested. In the posterior part of apex of right lung was a cavity of irregular oval shape, about two inches in long diameter. Its inner surface was nearly smooth, and appeared to be lined by a delicate membrane. Some bronchial tubes could be seen ramifying on the walls of the cavity, but none apparently opened into it. Its posterior wall was formed by thickened pleura, and a very thin layer of condensed pulmonary tissue. There was also a layer of condensed and apparently collapsed pulmonary tissue, about half an inch in thickness, between the cavity and the apex of lung, which was puckered on the surface. In front, the pulmonary tissue, even immediately external to the lining membrane, was appa-

rently unaltered. Near this cavity was a smaller one, about the size of a hazel nut, the walls of which were thicker and had a cartilaginous appearance, and which, like the other, did not communicate with any bronchus. The bronchi were uniformly dilated and thickened. In the centre of the upper lobe was a small globular cretaceous mass of the size of a pea, and on further examination another cavity was found of the size of a walnut, near the apex of the right lung, filled with a yellow, semi-solid, cheesy substance, having the character of old tuberculous matter. This cavity, likewise, had not communicated with any bronchial tube. In the apex of left lung was a cavity of similar appearance to that on the right side, but of rather larger size. It was situated towards the anterior surface, and, on close examination, there appeared to be an extremely thin layer of condensed lung immediately around the lining membrane, which was delicate and smooth, except at one point, where it appeared to be cartilaginous. No communication existed between this cavity and the bronchi. The bronchi throughout the left lung were uniformly dilated and the lung congested. The cavities in both lungs, with the exception of the one filled with old tuberculous deposit, contained a little reddish semi-fluid matter, having the appearance of mucus. Microscopic examination showed that the cavities in the lungs were not lined with epithelium, but that the walls were composed of fibrous and elastic tissue, and could not be distinguished from the surrounding condensed pulmonary tissue. Here and there in the walls was a small piece of cartilage. Heart: pericardium contained about four ounces of dark-coloured serum. The heart was of very large size. The right cavities were enormously dilated and filled with dark clots. The tricuspid opening would admit four fingers with ease. Wall of right ventricle was three lines in thickness at base. Pulmonary artery was of very large size, the circumference an inch above the valves being nearly four inches. Tricuspid and pulmonary valves normal. Left cavities were also much dilated; mitral valve somewhat thickened at margins with a row of minute vegetations on auricular surface; opening of normal size. Aortic valves healthy, not admitting regurgitation of water. Aorta, an inch above valves, two and three-quarter inches in circumference. Wall of left ventricle six lines in thickness at base and four at apex. Weight of heart eighteen ounces. Abdomen: peritoneum contained about two pints of dark-coloured serum. Firm fibrous adhesions united the upper surface of liver to the diaphragm and abdominal walls. The spleen, stomach, and colon were matted together by similar adhesions. The descending colon was also adherent to abdominal walls. The liver was of small size, left lobe small in proportion to right. Capsule much thickened. In the adhesions between the liver and diaphragm was a quantity of yellow, gelatinous-looking fluid. On section the liver had a somewhat nutmeg appearance; lobules distinctly marked out. Kidneys: both very large; surface smooth; capsule non-adherent. On section the pyramids were congested. The cortex, which was upwards of an inch in thickness, was somewhat pale, otherwise of normal appearance. Near the surface of the left kidney was a deposit of triangular shape, the base towards the surface, and of a yellowish colour, surrounded by a red halo. Under the microscope the kidney tubes contained much oil, chiefly in the epithelial cells.

HOSPITAL NOTES.

KELOID.

In our Hospital Reports for November 26, 1859, we recorded a case of keloid, which occurred in the cicatrix of a burn on the side of the neck. The boy is now 17 years of age, and the growth has increased in actual size, but not relatively to the general increase of size of the body. We first saw the patient six years ago at the London Hospital, under the care of Mr. Gowland and Mr. Curling, and four years ago at St. Bartholomew's, under the care of Mr. Skey. Both these gentlemen removed parts of the tumour, but no radical operation was ever performed. The tumour is fully described in the report, and it now differs from what it then was only in size. The case was alluded to by Mr. Curling in the discussion that followed Mr. Longmore's paper on Keloid at the Medico-Chirurgical Society; and as several Surgeons have expressed a wish to hear more of the case, we again refer to it. Mr. Harle, of Islington, whose patient the boy is, has supplied us with much of the following information, and will be glad to

furnish the boy's address to any one specially interested in keloid.

After the last operation, the remaining portion of the tumour appeared to continue of the same relative size, but, from its eventual increase, it appeared to increase by insensible degrees. After a time, in consequence of its increase, further advice was sought, and it was brought under Mr. Coote's notice. Mr. Coote was inclined to treat it as the cicatrix of a burn, it being, no doubt, the consequence of a burn, as is stated in the published report. Mr. Coote recommended pressure, and Mr. Coleman moulded a substance to enclose the protruding and jagged cicatricial tumour, directing the friends that the wound should be enclosed in leather, and the whole strapped down. This the friends, either from some neglect or inability, did not procure for a month or so, when, having obtained the leather and straps, they found that the tumour was too large for the mould; in fact, it had grown so that the mould was useless, and Mr. Coote's plan could not thus be tried, and, therefore, pressure cannot be said to have been unsuccessful. We mention it as showing the plan recommended by Mr. Coote in such a case. The tumour still very slowly increases in size. The patient has latterly made a mould of gutta-percha, which he thinks prevents its growth; but even this treatment is not receiving justice, since he removes the moulding while in the house. Mr. Harle, under whose care he now is in private, directed him to continue the moulding of gutta-percha, so as thoroughly to enclose the tumour, and to wear it constantly.

The disease in this case is the keloid described by Alibert, and differs from that described by Addison, in the fact that it grows in a cicatrix. But, as such tumours are very rare and cicatrices common, Mr. Longmore, in his paper referred to, asks if there is not a keloid constitution; and that the disease is produced in one by an irritation that does not affect another; and that in the keloid of Addison the disease is excited by an irritation so slight as not to attract notice. So that the diseased tendency is the same, differing only in the amount of irritation required to develop it. Slighter degrees of cicatricial induration are not uncommon in cases of burns, as in one we saw lately at one of the Hospitals. The cicatrix remained glossy, red, raised, and exceedingly irritable for months.

In a case recorded by Mr. Sedgwick in this Journal, Oct. 27, 1860, in a child four years old, there were seventeen patches, but none of them occurred in cicatrices, although there were scars of several operations. In this case, too, there was a keloid tumour on the tongue.

The question is important as regards operations. If there be a keloid constitution, and tumours will return in the cicatrix, it is of little use to remove them.

In one of Mr. Longmore's cases the disease followed flogging. A photograph of the back of a slave, which presented a very similar condition, was shown to us by Mr. Birkett, at Guy's, a short time ago. It was sold in a shop in the Strand, not as an illustration of pathology, but as a stimulus to philanthropy.

HEMIPLEGIA, WITH LOSS OF SPEECH— ITS ASSOCIATION WITH VALVULAR DISEASE OF THE HEART.

In our Hospital Reports for January 30, we reported some remarks by Dr. Hughlings Jackson on a series of cases of loss of speech, with valvular disease of the heart. There were several, however, in which this relation could not be made out; and since we have seen at Guy's Hospital, under the care of Dr. Wilks, a patient who has hemiplegia with loss of speech, and yet there is no trace of a bruit, and no other evident signs of valvular disease. Again, Dr. Hughlings Jackson has had under his care another case of valvular disease with hemiplegia, with no loss of speech; the patient is, on the contrary, very voluble. There is thickness of articulation; but this, as was mentioned in the report alluded to, is not what Dr. Jackson, for purposes of clinical illustration, has taken to be loss of speech.

It may be said by some, of the first case, that the cause was not embolism; by others, of the second case, that it was probably an instance of embolism of the middle cerebral artery, and yet with no loss of speech. But these cases present features as different clinically as they do physiologically; and if the physiological symptoms, from damage to a part of the nervous system, do not point to embolism in the first, and to apoplexy or softening in the second, the clinical associations do. Dr. Wilks' patient is a young woman, 27 years of age, who, in perfect health, was found by her husband when he got up hemiplegic and speechless; and again the hemiplegia,

as in all Dr. Jackson's cases, was on the right side. So far, the case looks certainly like embolism; but the absence of cardiac disease, or rather of bruit to signify it, prevents the idea of that being its origin so plausible as in some of the other cases. In the second case, the hemiplegia is on the left side. The patient's age is 63. He has a large arcus senilis, movable arteries, but no albuminuria. There is a harsh, systolic murmur at the apex. A patient with such evidences of degeneration of the arteries is, of course, liable to softening and apoplexy, and thus to hemiplegia in the ordinary way. Then, too, although the attack was sudden, there was no loss of consciousness at the time.

The greater liability of the middle cerebral artery to be plugged on the left side—*i.e.*, of the vegetation to pass up the left carotid—is well known. This obstruction, of course, produces softening on the left side of the brain, so that the paralysis is of the right arm and leg.

We may state, too, that in looking over the first two volumes of records of Dr. Brown-Séquard's cases at the Hospital for Epilepsy and Paralysis, we found that hemiplegia occurred oftener on the left than on the right side. This, of course, makes the fact more striking, that hemiplegia occurs on the right side when it is attended with loss of speech.

In none of the cases can there be certainty as to the exact cause of the symptoms. We write these remarks chiefly to draw attention to the necessity of noting differences in speech in association with paralysis, and in the hope that at autopsies on patients who have died of cerebral disease, the local condition of the arteries, as well as their general disease, will be noted in connection with the life symptoms of the case.

BROMIDE OF POTASSIUM IN EPILEPSY.

Bromide of potassium is still a favourite remedy in epilepsy, and is much used at the Hospital for Paralysis and Epilepsy by Dr. Ramskill, Dr. Radcliffe, and Dr. Hughlings Jackson. The dose generally prescribed is about ten grains. This Dr. Radcliffe frequently gives at bed-time every night, but Dr. Ramskill and Dr. Hughlings Jackson generally give it three times a-day. The dose may be increased to twenty, or even to thirty grains. There can be no question as to its very great value in diminishing the number of fits, and it is certainly by far the best remedy in this respect. We have already reported cases in which it seemed to be of great benefit; but it is very doubtful whether it effects a cure. That it will keep the fits off for long periods, for months, or for a year, is quite certain; in many cases, however, the fits return when the drug is given up. We need scarcely say, that besides this specific treatment of the disease, the condition of the patient generally is carefully attended to. But any one may observe that, not unfrequently, epilepsy occurs in patients who are, except during, and for a short time, after the paroxysm, in good health. Here little else than specific treatment can be adopted. Probably, in such cases, there is some organic disease of the minute tissues of the medulla oblongata, or, as it is generally, but vaguely, expressed, the excitability of the medulla oblongata is increased. It is not likely that any drug will restore the damaged structures to their natural condition any more than it would thicken and contracted aortic valves; but it is quite certain that by treatment the fits may be kept off for very long periods. Again, and this is the next best thing to a cure, the patient's condition between the paroxysms is much improved. The bromide, it is well known, diminishes sexual appetite, and hence has been used in cases of epilepsy associated with masturbation. Its chemical congener, the iodide, has this property as well, but seems to have little or no influence on epilepsy. Again, the bromide, which is so useful on epilepsy, has, Dr. Brown-Séquard says, no influence over syphilis. This shows the truth of our remarks in reference to formiate of ammonia, that from chemical relationship we cannot indicate a therapeutical one.

THE HUNTERIAN ORATION.—It does not appear to be generally known, that this oration is now only a biennial affair. The last was delivered by Professor Gulliver; the next will take place in February, 1865.

ROYAL COLLEGE OF SURGEONS.—At the ensuing annual election of Fellows into the Council of this Institution, there will be at least three vacancies declared, caused by the death of Mr. Green, the resignation of Professor Gulliver, and the retirement in the prescribed order of Mr. Hancock, who will, however, offer himself for re-election.

SATURDAY, FEBRUARY 13.

THE SURGEON-GENERAL OF THE U.S. ARMY.

THE spectacle of a man, high in our own Profession, who has for two years been entrusted with the care of the bodies of more than half-a-million of men, standing arraigned before a court-martial on a charge of betraying his trust for filthy lucre, is a most melancholy one. The possibility of the charges being true is one that we scarcely like to contemplate. We can only say that, if it should be so, the rope or the bullet afford the only fit means of terminating such a career. But, from the knowledge which we happen to possess of the personal character of Dr. Hammond, against whom these grievous accusations are made, we venture to predict that he will pass the ordeal unharmed. As Surgeon-General of the United States' Army, he has had to support a vast weight of responsibility—more, perhaps, than his mental power was equal to; and in a machine of such enormous size and so great complication of parts, it was inevitable that, without, or, perhaps, even with, a man of first-rate administrative power to direct it, some things must go wrong. And many things undoubtedly have gone wrong: in plain words, there have been rogues in the Medical service of the United States, as in every other department of their public service; but we do not believe Dr. Hammond to have been one of them. His chief fault has been a want of decision, which sometimes prevented him from doing what he knew to be right from fear of the consequences; but, even in the atmosphere of corruption that has prevailed during the war at Washington, his reputation, so far as we know, remained free from taint. On the other hand, the frequent dissensions, and, at last, the absolute antagonism which were known to exist between himself and the Secretary of War, were notoriously of great detriment to the Medical service; but the opinion of the Medical officers in general was decidedly in favour of their own chief, and adverse to the overbearing, discourteous—and some said jobbing—Secretary Stanton. From this official, Dr. Hammond certainly did endure some affronts which would have caused many men to resign in disgust: most unfortunately for him his retention of office has resulted in a banishment from Washington of many months' duration, intended to be penal, and an enforced series of wanderings through the different seats of war. What effect the lamentable accident, which we recorded a fortnight ago as having befallen Dr. Hammond during one of these wanderings, will have on the result of the court-martial, we cannot tell; but it is evident that the inquiry must go on in some form or other; for a man, though a cripple for life, has still a right to his character. We can only hope that there will be some means of punishing the framer of the accusations if they should be proved untrue, as we doubt not they will be. The malignity which could suggest them ought to recoil on the head of the slanderer.

We hope to hear a public expression of the opinion of the

Profession in America on this question. Dr. Hammond is not an unknown man: he owed his position in a great measure to the influence of the heads of the Sanitary Commission, among whom are some of the first names in our Profession in the country. They must surely have established a claim to be heard in a question of so great importance: the voice of the country, raised at their bidding, must prevent Dr. Hammond, if innocent, from being sacrificed, as others have been, to personal spite.

THE PROPOSED LEGISLATION FOR CHEMISTS AND DRUGGISTS.

THE chemists and druggists have taken alarm at the proposed amendments in the Medical Act. The "trade" is in a high state of ferment; meetings are being held, resolutions passed, and petitions signed against what is called an infraction of their liberties, and an interference with the lawful exercise of their calling. As there are two sides to every question, and we believe that the interests of the Medical Profession are directly involved in a definition of the position and responsibilities of the dispensing chemist, we are compelled to notice some of the arguments advanced by the contending parties.

The first inquiry which presents itself is—What has hitherto been the position of a chemist and druggist? Is he a tradesman or a professional man? This is answered by the chemists and druggists themselves, who, at public meetings and in public documents, are constantly referring to their body as "the trade." If this be so, it may be well asked if the endeavour to impose restrictions on a trade be not contrary to the spirit of all recent legislation? As long as the chemist's business is simply a matter of buying drugs, compounding and selling them, it is an infraction of all free-trade principles to forbid any person who may choose to engage in it. It cannot be said that chemists and druggists are in an exceptional condition on account of the variety and amount of information they must possess. It would be very difficult to show that the standard of particular education required is higher than that necessary in many other trades; for instance, philosophical instrument making, watch and chronometer making, or bookselling and publishing. And this is more than ever the case now that the Pharmacopœia is in English, and the practice of writing the directions of prescriptions in English is becoming each day more general. In the preface to the Pharmacopœia the fact is asserted that the manufacture of most chemicals has been of late years transferred from the pharmaceutical chemist to the chemical manufacturer, so that the province of the former has become much contracted,—indeed, in by far the greater number of instances it is limited to mere dispensing. Now, it is a matter of daily observation that any intelligent, neat-handed lad or woman of ordinary education can be taught to dispense accurately and well in three months. Besides, if the amount of knowledge required by the pharmaceutical chemist is such as to make it incumbent on the State to examine him, his business is at once elevated from a trade into a profession, and the line of demarcation between him and the Practitioner of Medicine who keeps an open surgery is rendered proportionately more inappreciable in the eyes of the public. But this is not the argument generally advanced. It is said that Government are bound to impose restrictions on dispensers of medicines, because it is a *dangerous* trade; and instances of other trades in which articles dangerous to the public health are vended, are quoted as precedents. This argument, however, is entirely fallacious. Government has placed restrictions on certain articles of commerce, but it has not limited the class of persons who sell them. There has been no test imposed of personal fitness to engage in the traffic. The license required to be taken out by persons selling wine, spirits, tobacco, etc., although, on first appearance, a personal qualification, is, in reality, no such thing. It is merely another way of imposing a tax on certain articles of revenue.

Licenses to public-houses, again, are procured, not for the protection of those who frequent them, but, as a matter of ordinary police, for the protection of those who do not. These instances belong, therefore, to another category. On free-trade principles, the selling of drugs must be as open to every Englishman as the trade in paraffin or gunpowder. The risk is for the purchaser, who, fully aware of it, chooses the shop at which he buys. The public has no more right for special protection against the ignorance and blunders of chemists and druggists than it has against the blunders of railway officials. If death or injury occur through wilful carelessness or culpable ignorance, the druggist is liable to be prosecuted for manslaughter, or to an action for damages; but so is every other person who, in his avocation, causes his neighbour loss of life or health. We are not now arguing for the abstract right or the universal application of the free-trade principle. We only assert that free trade is now the basis of all commercial legislation; and more, it is a principle which the Medical Act accepts, even with regard to the Profession of Medicine, for it expressly recognises "qualified" and "unqualified Practitioners."

Having said thus much on the general question, we must freely acknowledge that the above views are not held by many amongst the chemists and druggists themselves, and are certainly not shared by the committee appointed by the General Medical Council to draw up amendments to the Medical Act. There are three parties who are directly or indirectly competing for the power of examining chemists.

(1.) The Committee of the Medical Council propose that a section be added to the Medical Act, to the following effect:—

"It shall not be lawful for any person to keep open shop for the compounding of Physicians' and Surgeons' prescriptions, unless he be a Licentiate of the Apothecaries' Hall of England or Ireland, or shall have received a certificate of competency to compound medicine from either of the above bodies, or from the Pharmaceutical Society, or from some other body duly authorised in England, Ireland, or Scotland, by the General Medical Council, to institute the necessary examination, and to grant such certificate, and at such rate of fee as the General Medical Council, with the approval of the Privy Council, may sanction; and any person keeping open shop for the compounding of medicine, unless qualified as aforesaid, shall, upon a summary conviction for any such offence, before any justice of the peace, pay a sum not exceeding £20; and for the better protection of the public, and to ensure the carrying out of the provisions as aforesaid, it is hereby enacted that the Medical Council may appoint from time to time one inspector for England, one for Ireland, and one for Scotland, whose duties it shall be to inspect, as often as may be required, all shops where medicines are compounded, and to carry into effect the provisions of this Act in regard to such shops; and that such inspectors be paid such salaries out of the Consolidated Fund as the General Council, with the approval of the Lords Commissioners of her Majesty's Treasury, may from time to time determine."

(2.) The Council of the Pharmaceutical Society have hitherto acted on the principle, that the institution of a voluntary examination, for persons engaged in dispensing, is all that the exigencies of the public safety require. They do not appear to consider a compulsory enactment necessary, believing that the choice between a certificated and uncertificated chemist may be left to the public. It is said, however, that they will probably support the proposition of the Medical Council.

(3.) The Executive Committee of the United Society of Chemists and Druggists have issued suggestions for an Act of Incorporation of the trade. They propose—

"That the Act shall be based upon a recognition of all claimants to an interest in the trade of a chemist and druggist until six months after the passing of the said Act. That, after such date, it shall be incumbent upon all who enter the trade of a chemist and druggist to undergo an examination by a board of examiners duly appointed. That the examination shall be of the following order and kind:—
1. Proof of having served an apprenticeship of not less than five years (exemption from this only to be allowed under

special and well-defined conditions for otherwise securing the practical knowledge required). 2. Ability to read prescriptions with ease and accuracy. 3. A competent knowledge of all drugs in general use, with their doses."

Of the three sets of claimants to power, we must assert that the course hitherto carried out by the Pharmaceutical Society—a course which is legalised by their charter—seems to us to be the least objectionable. It is not imperative on any chemist to possess its certificate, but it is open to any one to obtain it; and once obtained, it is a public guarantee that the possessor has a fair knowledge of his business. If the public choose not to employ him, but to go to the grocer who sells aperient pills over the way, they do it at their own risk. The proposition of the Committee of the Medical Council, as it at present stands, seems open to several objections. We will mention three. In the first place, the Medical Act gives them no legal right to interfere with chemists. It is a gratuitous assumption of power on their parts. Secondly, it would, were their proposition carried into effect, introduce a large class of men, who are not Medical men, as legal practitioners of pharmacy, into the Medical Profession. This result may be disclaimed, but practically, in the eyes of the public, no one can doubt that such would be its ultimate effect. Who would distinguish between the licensed practitioner of pharmacy of the Apothecaries' Hall of England or Ireland and the licensed Practitioner in Medicine of the Apothecaries' Hall of England or Ireland? Thirdly, would it be in reality a protection to the public? We answer decidedly, no. Nineteenths of the blunders in chemists' shops by which people lose their lives are made by assistants and shopboys, and no legislation can prevent chemists employing any servants they please. The proposition of the United Society of Chemists and Druggists is not open to the first and second objections, but it is entirely open to the third. Moreover, it is in too close accordance with the mediæval principle of legislation which gave special privileges to guilds and civic corporations, and is directly opposed to modern ideas of a commercial code. We repeat, the compounding of medicines is not a profession, but a trade, requiring no higher education than many other trades. The fact that some men of high intelligence and acquirements are engaged in it does not alter its intrinsic character. In professions, knowledge alone is sold; in trades, material. Society has a right to require that persons who offer for sale knowledge should previously afford some proof that they possess that commodity. The validity of their pretensions can only thus be estimated. But the case is different with those who sell material. The quality of the goods they offer is itself the criterion by which the trustworthiness and capacity of the vendors will be judged.

THE WEEK.

PARLIAMENTARY.

IN noticing the proceedings of Parliament during the present Session, we shall follow the course we have heretofore pursued—that of confining our summary to such subjects of legislation or debate as have a direct or collateral interest for, or bearing on, the Profession of Medicine.

In the House of Commons on Friday, February 5, Mr. Fortescue, in reference to the case of Colonel Crawley, asked the Under Secretary for War whether he would lay upon the table of the House the proceedings of the late court-martial, together with the plans referred to in the evidence; and whether an opportunity would be afforded to members of the House of inspecting the models produced before the court-martial?

The Marquis of Hartington said that, in this particular instance, although it was not usual that the proceedings of a court-martial should be laid before the House of Commons for revision, if the hon. member moved for the production of the papers, they would be laid on the table. They would be accompanied by a plan, drawings, and correct measurements,

which would enable hon. members to understand the proceedings. With reference to the models, he had to state that they constituted portions of the evidence on the record of the court-martial itself, and it would not, therefore, be convenient or desirable that they should be removed from the custody of the officer in whose charge they were at present placed.

On Monday, February 8, Mr. Fortescue moved an address to her Majesty for a copy of the proceedings of the late court-martial for the trial of Colonel Crawley.

General Peel asked the hon. member for Andover whether he intended to found a motion upon these papers; and if so, whether he would give early notice of its terms?

Mr. Fortescue said, that when the proceedings were produced he should make a statement upon them, and conclude it with a motion for papers. He would give early intimation what were the papers he intended to ask for.

The motion was then agreed to.

The Chancellor of the Exchequer moved for leave to bring in a bill to allow the making of malt, to be used in feeding cattle, duty free. He proposed, as the only restriction, for the purpose of protecting the revenue, that the malt used for cattle should be mixed with one-tenth of its weight of linseed meal or oil-cake. The debate turned on the comparative value of malt and barley as cattle food.

Mr. Bass said that he had received a letter from Baron Liebig, stating that the drying of malt, that is, of barley already germinated, instead of adding to its value as an article of food, would rather diminish it.

Mr. Caird thought that the member for Derby had unintentionally misled the House with regard to Baron Liebig's views, and read the following letter from the Baron:—

“Munich, July 6, 1863.

“In forming a judgment on the feeding properties of malt, when given to horses, cattle, and sheep, it is obvious that in comparing it with barley we must not lose sight of the fact that there is a larger amount of nourishment in barley than in the malt manufactured from it; for in the process of malting barley suffers a loss in weight amounting to from 7 to 11 per cent. of dry substance. The ‘rootlets’ constitute 3 to 3½ per cent. of this loss; and as they contain a pretty large quantity of blood-forming (nitrogenous) matter (25 to 30 per cent.), the grain, by their separation from it, undergoes a loss of one of its nutritive elements. Hence it is clear that if in practice the feeding qualities of malt are found to be greater than those of barley, this can only arise from the circumstance that the nutritive matter contained in malt is present there in a more soluble, more digestible state than in barley; and that, therefore, in feeding with barley, more nutritive matter leaves the body in an undigested state than in the case when an equal weight of malt is used as food. There can be no doubt whatever that in malt blood-forming matter is contained in a more soluble form than in barley; for the process of malting occasions a loosening of the component parts of the grain in so great a degree, that 100 volumes of dry barley yield (notwithstanding the loss of weight) 112 to 114 volumes of dry malt. Such a loosening of the inner parts of the grain, thus enabling the gastric juice in the animal body to penetrate it more easily and thoroughly, is not to be attained in a like degree by a mechanical process. The comparative analysis shows finally that the amount of readily soluble blood-forming elements in barley is 1¼ per cent., and in malt 2·2½ per cent. By the process of drying in the kiln, a part of the soluble blood-forming elements is rendered insoluble, and from this it cannot add to the feeding capabilities.”

The experiments hitherto made on malt as a cattle-food do not appear to have been on a sufficiently large scale to be conclusive. With regard to the restrictions proposed by Mr. Gladstone, most of our readers will agree with Mr. Bass, who said:—

“As to the mixing, brewers must be very much maligned, indeed, if they never put worse things in their beer than linseed. (Laughter.) Notwithstanding the progress of the teetotal principles advocated by his hon. friends behind him, and the general dislike to adulterations, he suspected there would be found plenty of labourers in charge of cattle who would be glad of beer from malt, even though one in ten of linseed were mixed with it. (A laugh, and ‘Hear.’)”

The motion was ultimately agreed to.

The same evening Sir G. Grey moved for leave to bring in a bill to amend the Act 3 and 4 of her present Majesty, cap. 54, relating to the care and treatment of criminal lunatics. Our readers will remember that this is the statute under which the reprieve of Townley was granted. After giving a full account of the existing condition of the law, with a minute review of the circumstances of Townley's case, and explaining and justifying the grounds on which he had acted, Sir G. Grey pointed out what he considered the great defect in the statute, viz., that it permitted its machinery to be set in motion, not by impartial persons, but by agents of the prisoner. The existing law provides that any two justices of the peace, with the aid of two Physicians or Surgeons, may certify as to the insanity of a prisoner; and on such certificate it is lawful for the Secretary of State to order his removal to a lunatic asylum. In the case of Townley, the two magistrates and the two Medical men were introduced into the gaol by the prisoner's solicitor, and signed the certificate at his request. Sir G. Grey proposes that, instead of any two justices of the peace, the responsibility of signing such a certificate shall be imposed on all the visiting justices of the prison collectively; and, instead of any two Medical men who may volunteer their services, the visiting justices shall be also responsible for the selection of the Medical men whom they employ to aid them in the investigation. Such Medical men—Physicians or Surgeons—selected by the visiting justices, must be registered under the Medical Registration Act. A special clause to this effect is introduced in the new bill, in consequence of Mr. Harwood, the Surgeon who signed Townley's certificate, not having been a registered Practitioner. Mr. Harwood, who is a Licentiate of the Society of Apothecaries of forty-three years' standing, is Medical officer to the Derby Union, but he has neglected to place his name on the register. On the question of the validity of the certificate signed by Mr. Harwood, however, Sir G. Grey referred to the Lord Chancellor, who gave a clear and unqualified opinion that Mr. Harwood was a Surgeon within the meaning of the Act. But the new bill has a still more important provision,—that the certificate of insanity signed by the visiting justices and Medical men shall not be necessarily final or conclusive. In reference to this point, Sir G. Grey said:—

“In the great majority of cases, no doubt, it will still be final. The certificate will be, not a mere surmise or suggestion to the Secretary of State, but the deliberate and recorded opinion, under the hands of the visiting justices, of the insanity of the prisoner to whom it refers. But by the insertion of words showing that it is not mandatory, but permissive, the Secretary of State, ‘if he thinks fit,’ will be able to institute further inquiries in any case before he directs the removal of the prisoner, so as to satisfy his mind, if he entertains any doubt, that the certificate is correct. If these alterations are made, I think effectual precautions will be taken against any such miscarriage of justice as may be thought to have happened in this case; and that the increased responsibility of the Secretary of State, and the new responsibility imposed on the visiting justices, will prevent any risk of the course of justice being improperly interfered with.”

Sir G. Grey, in concluding his speech, defended the course he had pursued in commuting Townley's punishment to penal servitude for life, instead of carrying out the original sentence. He stated that, in thus acting, he had obtained the concurrence of the Lord Chancellor.

In the debate which followed, Sir G. Grey's conduct in the case was criticised by Mr. Macdonogh, Mr. Locke, and Sir G. Bowyer.

Mr. Macdonogh argued that, assuming Sir G. Grey was acting legally in respiting Townley on the ground of his supposed insanity, he had acted illegally in commuting his sentence when his sanity was established. He argued from the precedent of women condemned during pregnancy, who are respited until after their delivery, that the temporary postponement of capital punishment is no bar to its being afterwards carried into effect.

Mr. Neate suggested the appointment of a commission on

(Second day.)

1. Examination of adulterated beer.
2. Examination of adulterated milk.
3. Microscopic examination of adulterated coffee.

II.—PATHOLOGY. (Dr. W. AITKEN.)

1. Examination of fluid containing parasitic remains.
2. Examination of morbid tissues.
3. Description of morbid specimens from the Pathological Museum.
4. Give the names of the parasites on the table.
5. Determination of the powers of lenses.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,

Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF LYNN.

(Continued from page 158.)

PRACTICE OF THE HOSPITAL.

PREVAILING DISEASES IN THE HOSPITAL.

No accurate records have been kept that would enable me to speak on this head with certainty. The Medical cases are generally of the subacute kind, and the Surgical are accidents, cases admitted for operation, and ophthalmic cases. In the year 1862, patients to the number of 344 were admitted, and this is a fair average; about 60 of the patients admitted were sufferers from accidents.

OPERATIONS.

No tables have as yet been kept in reference to the number and character of operations performed. I may mention that lithotomy is a much less common operation here than at Norwich. The cases during the past twenty-five years have averaged 2.36 per annum.

SURGICAL MORTALITY.

Reliable statistics on the Surgical mortality are also wanting, but I gathered that it was extremely low: only one death from pyæmia had occurred in the course of five years; that death had followed on excision of the knee-joint. For the past three years the operations have averaged twenty per annum, the deaths three.

CHLOROFORM.

Chloroform is administered, as in the Norwich Hospital, in the most simple method, usually on a piece of linen funnel-shaped, or with a handkerchief. Great care is taken to allow the free admixture of air. To secure this object, the hands are placed underneath the handkerchief, so as to lift it a little distance from the face. There has not as yet been a fatal case. The number of administrations since the introduction of anæsthesia into Surgery has not been less than 900.

NEW POINTS OF PRACTICE.

Chromic Acid as a Caustic.—Dr. Lowe, one of the Surgeons to the Hospital, has of late been employing, and with success, chromic acid as a caustic, in cases of indolent ulcer and in epithelioma and caneroid growths. I am indebted to Dr. Lowe for the following report on this interesting subject:—

“The action of chromic acid on diseased tissues is peculiar, and differs widely from that of every other caustic, though quite consistent with its known action on animal structures. There is for some time no discharge or offensive smell from the sore. The tissues seem merely killed and dried up to a depth varying with the length of time during which the acid has remained in contact with them. After five or six days, a line of demarcation begins to appear between the living and dead parts, followed by a small amount of suppuration around the outer margin of the sore. At the expiration of eight days, or longer, the slough may be enucleated by gentle traction with a forceps, leaving a clean, dry surface, from which fine healthy granulations soon make their appearance after the application of water-dressing. If the whole of the diseased structures are not destroyed by the first application, the process may be repeated as often as is deemed requisite. In epithelioma, it is not necessary to produce a deep eschar, and the acid should, therefore, be merely applied for a few seconds before it is washed off with water. One case of this nature, occurring in the tongue, and causing a loss of a fourth of its length, well illustrates the action of the acid. The patient was a female, aged 65, very feeble and emaciated. The ulcer was deep and malignant-looking, and there was enlargement of the submaxillary glands, with acute lancinating pains. Any operative

procedure was evidently out of the question. The solid acid was applied altogether six times. The first two applications were entirely free from pain, after which the sore began to granulate and assume a healthy aspect for a few days; but the granulations broke down, and the ulceration again extended. The acid was repeated, but with smarting pain for a minute or two, which subsided on washing the mouth with cold water. As the surface became more healthy, the pain from the acid increased. After the sixth application, cicatrisation was complete, and the glandular swelling disappeared. The only medicine she took was liq. arsenicalis, *mv.*, *bis die*. At this date, a year and a-half afterwards, the cure remains complete.

“In several cases of obstinate caneroid sores the acid has produced speedy cicatrisation. One case in particular, which had resisted treatment for a year and a-half when it came under my care, was perfectly closed on four applications. The sore was situated about the middle of the thigh, directly in the line of the femoral artery. The cure, however, could not be said to be complete, as a firm, deep, indurated mass remained, which showed no tendency to disappear under treatment, and which I, therefore, excised, with a wide margin of sound tissue, and speedily obtained union, which has remained in a satisfactory state up to this time.

“I have never used the acid in large cancers, as I do not as yet recognise the propriety of interfering with them by such means; but I believe it would be the best caustic to make use of where such interference is deemed proper. It would be found to destroy the diseased structures probably to a greater depth than any other, with less pain and without much offensive discharge.

“Hitherto, with the single exception above-mentioned, I have had reason to be satisfied with its action. It seems more disposed to affect diseased than living tissues, and shows no disposition to cause ulceration; but, on the contrary, its use is always followed by healthy granulation.

“The acid may be applied either in the crystalline form or as a fluid derived from the deliquescence of the crystals. I have generally made use of it in the solid state whenever it has seemed desirable to produce a deep eschar. The mode of application is simple: the crystals are taken up on the end of a feather, and placed on the affected part, where they soon dissolve. It is seldom necessary to take measures for confining the acid, but if any of it runs down over the sound skin it should be wiped off with a bit of lint. If, however, it is desired to produce a very deep eschar, this may be readily effected by surrounding the part to be operated on with a ring of gutta-percha, which may be stuck to the skin by heating the lower rim in a candle. The crystals of chromic acid may be placed in this to the required depth, and allowed to remain for ten or fifteen minutes, when the whole should be removed, and a piece of wet lint applied. Ordinarily, I find that the application, if only made for half a minute, suffices to produce a slough one-eighth of an inch thick. In slight cases the deliquesced acid may be used.”

The effects of chromic acid and of the bichromate of potassa have recently been interestingly illustrated in the researches of MM. A. Chevallier and Bécourt. These investigators have shown that such is the destructive power of the bichromate over the tissues, that the workmen in the bichromate manufactories, on inhaling the dust, lose, as a general rule, the whole of the septum of the nose. They are also attacked at times with violent itchings, followed, if they are badly protected by clothes, with suppuration and ulceration of the moist surface of the penis, around the glans. The researches show that for a chromate to exert its action there must be a moist surface, and they indicate that the caustic or destructive power of the salt is due to the chromic acid. There can be no doubt, therefore, that in chromic acid we have a body which more rapidly than any other would destroy morbid growths in cases in which it could be applied to a moist surface. I would, however, remark, as an intimation of a possible danger, that the observers to whom I have referred above have received reliable information, that on inferior animals the destructive process set up by the chromate salt goes on rapidly spreading, causing denudation of the hair and extensive ulceration; so that in the case of a horse that had been exposed in one of its hinder feet, suppuration progressed, extending through the limb, and invading almost the entire half of the body of the animal, as though a veritable metamorphosis of the cutaneous tissues of the flesh altogether had been set up, as by fermentative action. This animal died one month after the commencement of the malady.

In Dr. Lowe's hands, chromic acid applied to the human

subject has produced none of these dire effects. The destruction of tissue has not spread beyond due bounds: but in rapidity and effectuality of action to the extent required of it, it has answered admirably, and deserves to be extensively tried.

THE HOSPITAL MUSEUM AND LIBRARY.

A pathological museum has recently been opened in the Hospital, and, although it is still very small, it contains some interesting specimens. There is a good preparation of an excised elbow-joint, showing firm fibrous union, the case being the first in which the operation of excision was performed in the provinces. The late Dr. Cotton, of Lynn, was the operator. There is a most perfect specimen of calculus of the kidney, weighing 366 grains, the shape being fully retained. There is a complete fibrinous cast of the uterus and vagina; and a preparation showing a strangulated hernia, and so fitted up that the position and course of the strangulated bowel is seen from the inner surface of the abdominal wall. It struck me that for teaching purposes a preparation like this would be of immense service. I think the dullest student could be made to understand from it the mechanism of hernia, and the methods of cure both by the taxis and by the knife.

The Library is small, but is improving; the works are mainly of modern character, and are all essentially of a practical stamp.

THE MEDICAL STAFF.

There is one Physician, two Surgeons, and one House-Surgeon attached to the Hospital. Dr. Hawkins is the Physician, and T. M. Kendall, Esq., and Dr. Lowe are the Surgeons. C. S. A. Atkinson, Esq., is the House-Surgeon. His Royal Highness the Prince of Wales is Patron of the Hospital.

CHARITABLE AND PAROCHIAL INSTITUTIONS.

The poor of Lynn are well provided for by three charitable institutions—the Institution for Lending Child-bed Linen to Parturient Women, the Society for Visiting and Relieving the Sick Poor, and the Clothing Institution. These largely relieve the Union Workhouse, and, without ostentation, do much good. The Visiting Institution has been of late years very instrumental in introducing various important sanitary reforms into the houses of the lower classes.

The Workhouse contains 206 inmates, but it is built to receive 468. The sexes are nearly equally divided. Gas is introduced into every room, and good ventilation is secured by openings in the ceilings which lead to the turrets of the building. There is a school containing forty-six boys and forty-six girls, and an excellent infirmary. There are two other features in this house to which I must refer:—1. The chapel is one of the most beautiful I have ever entered in any building, much less in a workhouse. 2. A Turkish bath has been erected in the house, and proves of great service both to the sick and the healthy. The introduction of the hot air bath supplies a practical hint for workhouse management everywhere, and one which the Medical officers of these institutions should bear in mind. Mr. Kendall, the Medical Officer to the Lynn Workhouse, has the merit of first introducing the hot air bath for the benefit of the poor, in the manner described.

PAROCHIAL AND CLUB PRACTICE.

The sum of £213 was expended in the year 1861-62 for Medical attendance on the whole of the poor of Lynn. This does not include £57 12s. for vaccination fees. It is impossible to estimate the sum yielded per case, but it must be ridiculously small. The area in acres is 4840. There are three Medical officers to the district—H. Smythe, Esq., Dr. Hunter, and T. M. Kendall, Esq.

Club practice is rather extensively carried out. The members pay for Medical attendance 4s. a head per annum as a general rule.

LITERARY AND SCIENTIFIC INSTITUTIONS.

The Athenæum is the principal literary institution in Lynn. It is a handsome, well-arranged building, with an extensive museum, which, like that of Norwich, is specially rich in specimens of English birds. The classification of the specimens has been conducted with excellent scientific judgment and taste by Dr. Lowe.

THE SANITARY CONDITION OF LYNN.

The town, since the year 1853, when Mr. Lee made an official sanitary inspection, has undergone very great improvement. There are, nevertheless, certain great works yet to be accomplished before the town is either fair to the eye, or safe from telling and avoidable causes of death.

Population.—The Census returns of 1851 and 1861 indicate a remarkable fact in regard to Lynn—viz., that in the decennial period the population has declined in numbers from 20,530 to 16,701. This estimate is a little different from that rendered by local calculations made in, and confined to the borough; but the difference does not affect the general question. The population of the two great parishes of which the borough is composed—viz., St. Margaret's and South Lynn—was less in 1861 than in 1841, in the proportions given in the following table:—

Population of the Borough and its Parishes in every Census yet taken (the first four from White's "Norfolk").

	1801.	1811.	1821.	1831.	1841.	1851.	1861.
St. Margt.	9,395	9,319	10,647	11,424	12,517	14,417	11,470
S. Lynn .	707	940	1,606	1,946	3,522	4,731	4,511
Total .	10,096	10,259	12,253	13,370	16,039	19,148	15,981

It is natural and very proper that the inhabitants of Lynn should ask for the reason of this curious fluctuation; and, indeed, the question involved is of importance to vital statisticians generally. An English town that does not grow in twenty years must surely be in an abnormal state beyond compare. I am fortunate in having, in explanation of this phenomenon, a report made on the 4th of May, 1861, by Mr. John J. Coulton, the Superintendent Registrar of Lynn. Mr. Coulton says:—

"It will be seen that the population in 1861 is less by 3167 than it was in 1851, and by 58 than in 1841. The number of inhabitants temporarily absent (at sea and otherwise) in 1861 is computed at 436, and the number of visitors and others temporarily present at 228, showing a balance of 208 in favour of the population. These proportions probably do not materially differ from those in 1841.

"The excess of births over deaths from 1st April, 1841, to 30th March, 1851 (both inclusive), was 1422. As the increase of population during nearly the same period was 3109, it follows that 1687 strangers must have come into Lynn during that period.

The excess of births over deaths, from 1st April, 1851, to 30th March, 1861 (both inclusive), was 1362. As the decrease of population during nearly the same period was 3167, it follows that 4529 persons must have left Lynn during that period.

"Assuming the excess of births over deaths to have been in the same proportion during the ten years from 1831 to 1841 as in the ten years from 1841 to 1851, the natural increase of population in the first-mentioned ten years would be 1185. As the actual increase of population was 2669, it follows that 1484 strangers must have come into Lynn during the period.

"I do not remember any special cause for this immigration, and I therefore conclude that the increase of population from 1831 to 1841 was the result of a gradual and healthy extension of the trade of the town.

"But there is no doubt that in 1851 the population was unduly swelled by temporary inhabitants, attracted by the construction of the East Anglian Railways, by the Estuary works, and by the house-building which was going on. Allowing 1000 on these accounts, it follows that 3529 regular inhabitants (nearly one-third more than the natural increase of the population for the last 20 years) have left Lynn during the last ten years, leaving the population about the same as in 1841.

"The decline of population in the last ten years has fallen principally on the parish of St. Margaret, the numbers in each parish being as follows:—

St. Margaret	3047
South Lynn	120
Total	3167

"The proportion of females to males in 1851 was less than in 1841, but in 1861 it is more than in 1841. Taking the proportion in 1841 as the standard, the number of females in 1851 would be 10,645 instead of 10,267, and in 1861, 8364 instead of 9003.

"The total number of houses in 1861 is greater by 128 than in 1851, and by 630 than in 1841—502 having been built in the first 10 years, and 128 in the last 10 years. The number of uninhabited houses in 1851 is nearly one-fourth less than in 1841, showing that during the intervening 10 years building did not out-run, or, indeed, keep pace with, population. The

number in 1861 is about $2\frac{1}{2}$ times as great as in 1841, and about $3\frac{1}{2}$ times as great as in 1851, although the inhabited houses are much less fully occupied than formerly, the number in 1861 being greater by 335 (about one-eleventh) than in 1841, while the population is less. The total number of houses built in the 20 years (630) bears nearly the same proportion to the number of inhabitants who have left (4529) that the number of houses in 1841 does to the population at that time, showing that there has been little or no building beyond the wants of the population for the time being.

"Could the 4529 persons who left Lynn during the last ten years have taken their houses with them, the town would, so far as I can see, be much in the same state now as in 1841. But though the inhabitants are gone the houses remain, a burden to their owners and the cause of unexampled depression in the value of house property generally.

"The number of houses building in 1861 is only three, viz., two shells opposite the Terrace-walk, which have been in their present state for years, and a dwelling intended to form part of the new County Court as a residence for the bailiff."

To these observations, Dr. Lowe adds for me the following:—"The average population of the periods 1841-1851-1861 is 17,056. The excess of births from 1841 to 1851 equals 1,422, which, added to the population of 1841, would give 17,461; but, as Mr. Coulton has shown, there must have been an influx of 1687 persons during the ten years. In the next decennial period these immigrants disappeared, and a portion of the population in addition. The average population of Lynn for the three last decennial periods should be taken at 17,056, and on that average calculations should be based." Agreeing with these writers as to the causes of fluctuation and the averages given, I still think it an important and open question why the population *per se* should be decreasing. As the births exceed the deaths, the diminution must occur from emigration of the native-born or old settlers in the town.

VALUE OF LIFE IN LYNN.

Dr. Farr has been kind enough to allow me access to some unpublished records, showing the value of life in England and English towns during ten years, and including the causes of death during the same period. The ten years named are from 1851 to 1860. I append the results:

Average Annual Rate of Mortality in Lynn, from all Causes, at different Ages, to 100 Living, during the Ten Years 1851-60.

Lynn.	Un-der 5	5	10	15	20	25	35	45	55	65	75	85 or more.
Males	7.235	858	600	774	808	1029	1229	1825	3536	7100	14054	32857
Females	6.604	738	442	510	766	774	1190	1254	2222	6128	12308	29200

In regard to the value of life in Lynn as compared with England at large, the advantages are against the town; the value of life in England altogether, at all ages, being—for males, 2.305; for females, 2.132; while in Lynn it is—for males, 2.390; and for females, 1.989.

Ventilation.

But little attention is paid to the ventilation of houses in Lynn; I saw, in fact, no method adopted anywhere, except in the Hospital and the Workhouse; and I learned from all with whom I spoke that the necessity for a special provision for the free admission of air into dwelling-houses was not appreciated. Even in modern houses there is disregard on this important point.

Water Supply.

From the time when Lynn was first built up to the year 1423, the distress for water was frequent and serious. Not but that there was plenty of water around, but that such as was there was not fitted for domestic purposes. The inhabitants were in the condition of the "Ancient Mariner." There was—

"Water, water everywhere,
But not a drop to drink."

In the year 1423, in the reign of Henry the Sixth, the mayor and commonalty received powers to bring in a supply. They therefore cut a canal from a place near to the town, called "Kettle Mills," to a river known as the "Gaywood." The Gaywood rises from three springs seven miles from the town; and one can scarcely imagine a better source of water than that selected in the fifteenth century. In the time of the Protectorate of his Highness Oliver Cromwell,—viz., from 1655 to 1657—the water-supply was improved, the canal was cleansed, and the amount of water brought down was rendered more abundant. The ale-keepers were made to bear the expense. The supply through the streets of the town had

probably been, up to this time, by small canals; and perhaps it remained in this form until 1699. Then wood was fetched from Norway, out of which water-pipes were constructed. A water wheel was also used with three pumps, by which the water was raised into a great reservoir. In this condition the water-supply continued until the year 1829, when a tower and tank were built, and steam was allowed to replace water power. The wooden pipes were also replaced by iron ones. The reform in water supply was great, but it was not perfect; for the water, although it had abundant fall to supply every part of the town, was allowed to run into cisterns, from which it was again raised by hand power,—an absurd waste of force which can hardly be credited, and which is now happily altogether remedied. The houses are still supplied with well water in a few instances; and but recently, water was actually obtained from the ditches. Mr. Kendall, in giving evidence before the Sanitary Commission in 1853, reported that, at that time, he had cases of fever which he could fully account for:—"The people had no water but what they got from the ditches." No analyses have yet been made of the water at Lynn. The water from the Gaywood, the chief source of supply, is very good, is free from hardness, and is brisk and fresh. The supply is from 7 a.m. to 5 p.m., and extends over all the town. The following is the analysis of Gaywood water, made specially for this report by Dr. Wood:—

"Analysis of the Gaywood River Water, King's Lynn, after Filtration."

"The water contains less solid matter than many of the waters supplied to towns. The waters with which London is supplied average about 20 grains per gallon, while the Gaywood river water contains only 12.32 grains per gallon. Of these 12.32 grains, the greater part consists of carbonate of lime, with a trace of iron, the remainder being composed chiefly of sulphate of lime; there is also a small quantity of chloride present.

	In a Gallon. Grains.
Carbonates	7.824
Sulphate of lime	4.168
	11.992

The amount of lime-salts contained in this water renders it palatable, and enables it to retain a fair amount of gas in solution. It is admirably adapted for washing and cooking. It is free from organic matter in solution."

Drainage.

Good drainage in Lynn was at one time impossible. Up to the year 1821 the waters of the river had frequent mastery over the town, and flooded it. At all times then, the level did not admit of sufficient flow. But in the year 1821 the river was deepened for many miles, the outfall was widened, and the excavation of what was called the "Eau Brink" was completed. Great benefits followed; the sewers were lowered, and the floors of the houses, which in many instances were below the level of the ground, as is common in old towns, were rendered dry and comfortable. Within the last ten years a vast plan has been completed, by which an immense tract of land has been redeemed from the sea near to the town. The plan is not yet completed; 1200 acres on one side, and 700 on the other, each six miles from Lynn, have to be redeemed. The progress of the works has been stopped, to allow the sands to warp up. The drainage is as yet far from perfect. Surface drainage is not entirely done away with, and portions of the town which are provided with trapped drains lie on the margins of three "fleets," or open sewers, into which the whole of the sewage pours itself from the houses. When the tide is out, I know of no sight more disgusting than the worst of these fleets. The fleets proceeding across the town from the river form, I had almost said, a network of open sewers. The fleets are so wide and so deep that bridges have been built over them. Boats can sail up them when there is sufficient flow of water, and when there is not a sufficient flow boats can be, and are, moored in them. Looking down into the "Purfleet," I saw at low water the discharge of six water-closets down the steep of the sewer, while every kind of abomination lay at the bottom, with small boats stranded in the midst. The sewage is removed as far as is possible by the current of the river, the ebb and flow. I believe that it is in contemplation to cover in these loathsome channels, and let them remain what they ought to be, sewers simply, not sewers and rivulets for boats, at one and the same time.

The sewage from all parts of the town is lost in the river; no attempt has yet been made to utilise it.

Climate—Meteorology—Site.

The climate is rather cold and damp. The precise meteorological conditions I am unable to describe, for there is no meteorological station here, nor have any accurate readings been recorded. The site of the town is even and flat, and the soil is of sand and warp.

Streets and Dwellings of the Poor.

The streets are narrow, and paved mainly with large stones; but they are cleaner and more open than in Norwich. The dwellings of the poor vary considerably; in the old parts of the town the houses are miserably small, dirty, and overcrowded; but in the south, in what is called South Lynn, there are better classes of houses. The town is well lighted with gas in every part.

Diet of the People.

The diet of the poorer classes is insufficient. The Norfolk dumpling—flour and water—is the prevailing dish. Animal food is sparingly consumed; bread is taken freely, and tea and vegetables (potatoes). Probably fish is eaten in greater quantities than in Norwich, for the reason that large supplies of fish are brought into the port; but the fish trade is for export mainly.

Moral and Social Condition.

The town of Lynn, at the time when Mr. Lee inspected it in 1853, received an atrociously bad character from its Medical residents. Dr. Whiting, one of the gentlemen who gave evidence, said:—"I must beg leave to say that I think a great deal of the disease in this town originates in debauchery and drunkenness; debauchery principally, but drunkenness to a great extent. Prostitution is carried to a greater extent than in any town I have lived in." Further on, the witness stated that the use of poisonous drugs, especially opium, was largely used, and the production of abortion was a common offence. In all these respects, Lynn, during the past eleven years, has greatly improved.

Epidemics.

For many centuries the "remitting fever" was the great epidemical or rather endemical disease of Lynn. It was sometimes called the "bilious remittent;" and, according to Dr. Hamilton, who practised during the greater part of the 18th century, it was almost identical in type with the remitting fever of the Netherlands and Bengal, and the yellow fever of

the West Indies. In 1823 Dr. Whiting found this endemic disorder still extremely prevalent; and in 1826 there was a severe and very fatal outbreak. The improvements that have been effected seem to have robbed this disease of all its terrors. We may say almost that prevention has asserted its triumph to be perfect.

Cholera has been little known. In 1832 it passed over the town almost altogether; two or three imported cases, which spread for short distances, and forty-nine deaths from cholera and diarrhoea, occurred in the year. This is little above the annual average of deaths from diarrhoea or cholera; and in a population of 13,370 living in the year 1832, it was rather low than otherwise. In 1849, four deaths are on the local register as from cholera, but only two of these are accepted by the Registrar-General as satisfactory. In a population that had now increased to 20,530, this was a very low mortality. In 1854 there were nine fatal cases, principally imported, and all in the worst quarters of the town, near the fleets and amongst the boating population. In fact, cholera has never spread in Lynn. I shall refer to this great fact, and to the lesson it teaches in speaking of the etiology.

Of the other epidemic diseases, "fever" stands first, whether in the form of typhus or typhoid, as the most prevailing type has not been determined. Scarlet fever follows, then whooping-cough, small-pox, measles, diarrhoea and dysentery, and croup.

Vaccination.

Vaccination was for many years seriously neglected at Lynn, and the result was that, in 1845, an epidemic of small-pox occurred, which carried off 104 persons. For some years previously there had not been a fatal case; and it was probably from a feeling of false security that the great preventive measure of Jenner had been neglected. Up to the present time the process of vaccination is imperfectly carried out, though far more efficiently than formerly. In the return of 1861 there is no fatal case from small-pox.

Mortality from different Diseases.

The average annual rate of mortality in Lynn, from all causes, is, as we have previously seen, largely above what it should be, and indicates a serious prevalence of preventable diseases. Fortunately, I am enabled, through the kindness of my friend, Dr. Lowe, to give, in one precise and comprehensive table, the mortality of a full period of ten years, viz., from 1841 to 1850:—

Mortality of Lynn for Ten Years, from 1841 to 1850, including Special Diseases and Total. Average Population, 17,156.

Year.	Fever.	Scarlatina.	Measles.	Small-pox.	Bronchitis.	Croup.	Aphthae.	Whooping-cough.	Cholera.	Diarrhoea and Dysentery.	Inflammation of Lungs & Pleura.	Inflammation of Stomach and Intestines.	Phthisis.	Hepatitis.	Cardiac Disease.	Dropsy.	Paralysis and Apoplexy.	Meningitis.	Epilepsy and Delirium Tremens.	Convulsions.	Hydrocephalus.	Old Age.	Cancer.	Accidents and Sudden Deaths.	Atrophy.	Not requiring special notice.	Total.
1841	16	3	—	—	4	2	12	15	—	3	18	2	53	2	3	12	13	5	1	49	—	56	3	23	24	19	338

I am also enabled, through the kindness of Dr. Farr, to give a table showing the causes of death from 1851 to 1860:—

Average Annual Mortality from Different Causes to 100 Living, from 1851 to 1860.

Lynn.	Typhus.	Cholera, Diarrhoea, and Dysentery.	Other Zymotic Diseases.	Cancer.	Phthisis.	Scrofula, Tabes Mesenterica, and Hydrocephalus.	Disease of Brain.	Disease of Heart and Dropsy.	Disease of Lungs.	Diseases of Stomach and Liver.	Diseases of Kidneys.	Violent Deaths.	Other causes.
Males.....	·109	·116	·307	·028	·207	·105	·325	·181	·284	·116	·064	·117	·439
Females ..	·115	·085	·255	·071	·215	·072	·282	·131	·215	·088	·016	·028	·416

Deaths at Different Ages—Year 1861.

Males, total deaths of, 157. Under 1 year, 34; under 5 years, 56; from 10 to 15 years, 11; from 20 to 25 years, 7;

from 25 to 35 years, 10; from 35 to 45 years, 5; from 45 to 55 years, 19; from 55 to 65 years, 19; from 65 to 75 years, 17; and from 75 to 85 years, 8.

Females, total deaths of, 179. Under 1 year, 24; under 5 years, 47; from 10 to 15 years, 8; from 20 to 25 years, 11; from 25 to 35 years, 12; from 35 to 45 years, 9; from 45 to 55 years, 18; from 55 to 65 years, 19; from 65 to 75 years, 32; from 75 to 85 years, 8; and over 81 years, 1.

Males and Females—1861.

Males, births of, 234; deaths, 157; births over deaths, 77. *Females*—births, 247; deaths, 179; births over deaths, 68.

Etiology.

The etiology of Lynn is specially instructive. I need not trouble the Medical reader with a recapitulation of the facts, that the current prevailing diseases are traceable to remaining faults in the hygienic conditions; but there are three points to which I must allude:—

1. *The Cessation of Fatal Remitting Fever or Bilious Remittent* on the introduction of an improved drainage is one of the great facts of modern sanitary science. Just as gaol fever has been swept from gaols, remittent bilious fever has been swept from Lynn. Dr. Hamilton, writing not a century since, said:—"In riding through the country where it raged, the number of convalescents, with wan, dejected countenances, to be met with everywhere, was prodigious." Where would he meet them now in or near to Lynn?

2. *Why Cholera has never spread in Lynn.*—In this question a great truth is embodied. If mere bad smells could cause cholera, if bad drainage and open sewers could cause cholera, surely that disease ought to have been king over King's Lynn on the three great occasions when it was imported there. Why, then, did it not spread? For this reason, that the main supply of water for the town is from the Gaywood river, an independent source, into which the excrement of the town is not emptied. If the town, situated as it is, had been fed with water from its main sewer, the Ouse, what a tale would have been told of the ravages of King Cholera in King's Lynn, we all know, who have mastered Snow's immortal discovery of the distribution of cholera by water. Poor Snow! so earnest and so vigilant, so far-seeing and so little comprehended, how he would have used an illustration on so grand a scale as that we have here seen;—an *experimentum crucis*, forsooth, of the truth of his great law! Let us remember him the more gratefully as every such an experiment is recorded, and preserve the name of a countryman dead, as some atonement for our neglect of a countryman living..

3. *Calculous diseases* are of less common occurrence in Lynn than in Norwich; yet the diet of the poor is much the same, and the homes are not much better. The reason for this is, I think, explained on Mr. Williams' view as to the predisposing causes of calculus, narrated in my last report. That is to say, the tendency to diathetic rheumatic disease is less dominant.

MEDICAL BIOGRAPHY OF LYNN.

The Medical biography of Lynn is not lengthy. The only men of the past of whom I can gain information, and who were in any way celebrated, are the following:—

Dr. George Hepburn, M.D.—Dr. Hepburn settled in Lynn as a Physician about the year 1700. He soon obtained a large and fashionable practice, and in time made the acquaintance of Sir Robert Walpole, probably at the period when that statesman contested Lynn, viz., in 1713. Sir Robert selected Hepburn as his Physician, and confided greatly in his skill and experience. Hepburn lived to be 90 years of age, and died in 1759. He added nothing to the literature of Medicine.

Sir William Browne, M.D.—Dr., and afterwards Sir William Browne, practised in Lynn from the year 1721 to 1760. He was the grandson of Sir Thomas Browne, and son of Dr. Edward Browne, whose life was sketched in our Medical History of Norwich. Like his ancestors, Sir William Browne was strangely eccentric: he tried to take precedence of the Mayor of Lynn at a dinner on a great festival, and received from the Corporation a reprimand, which rather amused than annoyed him. On another occasion, when a pamphlet had been written against him, he nailed the offending sheets on the door of his house, and laughed like a satyr. In spite of his odd humours, he was respected, and was made Deputy-Lieutenant of the county. For some years before his death he went to London, and wrote a series of essays, known, in brief terms, as the "Opuscula," a strange, half-mad volume, on all kinds of subjects. Elected President of the College of Physicians, he opposed the claims of the Licentiates, and got laughed at for his pains. Foote put him into his play of "The Devil on Two Sticks," and made great market of him; but the old Doctor, so far from being offended, sent

the player who impersonated him a complimentary note and his own "muff," that being an article of dress which the actor had omitted. Sir William Browne graduated at Cambridge in 1721. He was a student of "Peterhouse," and endowed the College with a scholarship. He also left three gold medals, worth five guineas each, to the University of Cambridge, to be competed for every year. He did little for pure Medical or scientific literature, except to translate Gregory's *Catoptrics* and *Dioptrics*. He lived to be 82, and died in 1774, accounting for his prolonged good health on the ground that he "had neither wife nor debts."

Dr. Robert Hamilton, M.D., F.R.S., practised in Lynn from 1749 to 1793. He was a Physician of good repute, and contributed several papers, of importance to Medicine, to the *Philosophical Transactions*. I have already referred to his contributions on the prevailing diseases of Lynn and the district around. He wrote on the "Mumps," on "Puncture of the Bladder," on "Mercury and Opium," and on "Scrofula." His papers show him to have been a man of clear intellect and of learning. Born at Edinburgh in 1721, he lived to the age of 72 years, and died very much beloved by his fellow-townpeople. His name is often spoken in Lynn as one of the celebrities of the past.

Dr. R. Redfearn, M.D.—Dr. Redfearn, who followed soon after Dr. Hamilton, was a man of great talent and of good reputation. Not much is remembered of his life; but I name him specially as having contributed an important paper to the first volume of the *Medical and Physical Journal*, in 1799, on a method of treating diabetes by placing the patient purely on animal food, and administering, at the same time, alkaline remedies. This method, which is identical with modern practice, was not invented by Redfearn, but by Dr. Rollo, who suggested it on the chemical hypothesis, that in diabetes there was an excessive oxidation, and that this was only to be checked by the avoidance of foods that were given to ferment, and by the use of alkalis. Dr. Redfearn's object in publishing a case of diabetes treated on this plan was to show that the system was effective beyond expectation. The case, in his opinion, was cured. The alkali used by Dr. Redfearn was ammonia, in the form then known as hepatised ammonia.

Dr. Charles Cotton, M.D., is the last Medical man of whom I can speak. He practised in Lynn as a General Practitioner for many years, and with much success. He was, says one who knew him well, a thoroughly good Practitioner, and a very skilful operator. He was one of the first Surgeons in the provinces who performed excision of the knee joint, in which operation he was very successful. In character he was quick and impetuous; but truthful and honest in the highest degree. Dr. Cotton died on December 25, 1858, having but reached the meridian of his life and of his useful career.

In this history of Lynn, the reader will, I hope, find many useful facts: the greatest lesson taught in it is that having reference to sanitary facts;—to the manner in which the great scourge of modern times, cholera, was interrupted on three occasions by the water supply, and to the subsidence of remittent or bilious remittent fever on the institution of an improved system of drainage and embankment.

ANOTHER CASE OF OVARIOTOMY IN FRANCE.—M. Auphan communicates to the Academy of Sciences an account of an ovariectomy, recently performed at Alais by M. Serres, of that town. The subject was a girl, twenty years of age, the tumour dating back scarcely more than fourteen months. One of the cysts was found to contain about fifteen litres of fluid, and another three litres, a portion of the contents of the latter being effused into the cavity of the abdomen, owing to the bursting of the wall of the cyst. Considerable adhesions, extending as far as the diaphragmatic region of the peritoneum, existed; and, although the time it occupied is not stated, the operation seems to have been tedious. Menstruation came on in about fifty hours after the operation, and twenty days before its regular period. The clamp and sutures were removed on the eighth and ninth days; and at the time of the report being made (fifteenth day) the patient might be considered cured, were it not for a slight oozing of blackish, sanious fluid from around the pedicle.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.—At a meeting of the Medical Board, held on Tuesday, the 2nd inst., Mr. William Stokes, jun., M.D. T.C.D., L.R.C.S.I., was elected Surgeon to the Hospital, in the room of the late Mr. Smyly.

GENERAL CORRESPONDENCE.

MISS NIGHTINGALE'S "NOTES ON HOSPITALS."
LETTER FROM DR. FARR.

[To the Editor of the Medical Times and Gazette.]

SIR,—An article which appears in the last number of your influential Journal requires some correction. Miss Nightingale is well able to defend her own views against all comers, as she has shown on many occasions; so I do not write in her defence, but to vindicate an important principle, which has been very ingeniously misunderstood by the writer. One or two of his heresies are too dangerous to pass entirely unnoticed; and it appears to me that they are opposed to the doctrines which the *Medical Times and Gazette* has always advocated.

Miss Nightingale, in the first section of her "Notes on Hospitals," lays it down, the writer asserts, "as an axiom, that the sanitary condition of Hospitals modifies the ultimate issue of cases which pass through the wards." This does not appear to be very unreasonable, and is placed beyond doubt by the observations in the Scutari Hospital, and by others equally conclusive. But the London Hospitals are referred to; and one of the subtlest Physicians of the day had ventured to assert, that the high rate of mortality in a Hospital, of which he is an ornament, "is mainly determined by the reputation of its Hospital staff." This is one of those explanations which dazzle us by their brilliancy, and is thus disposed of summarily by Miss Nightingale:—"A high and increasing death-rate has been actually put forward, not as the result of these causes [which she enumerates], but as the result of increasing celebrity; which can have no other practical meaning than this:—that a great many people go there to die next year, because so many have died there this year; a principle equally applicable in private practice, and according to which the Physician or Surgeon who loses the largest percentage of cases is the man most worthy of confidence."

We can scarcely wonder at our reviewer affirming that this telling extract "is incorrect, illogical, and impulsive;" but instead of a discharge of dialectic Roman candles, it would have been much more satisfactory to a plain person to see a correct statement of the actual cases treated and of the causes of death in the various Hospitals. We should then be able to judge of the value of the hypothetical cause which it is proposed to substitute for sanitary conditions, and for the two rows of beds in wards back to back.—(See figure, p. 39 of "Notes on Hospitals.") The Medical staff of the Hospital in question is equal to that of any Hospital in London; but how can the celebrity of the Surgeons contribute to the mortality? Very few patients die on the table; and if the worst cases are sent to the Surgeons, they will scarcely operate unless there be a fair chance of recovery. For the deaths by pyæmia and erysipelas the Hospital is answerable, and not the Surgeons. Then it is difficult to understand how acute diseases of unusual severity or fevers can be selected on account of the reputation of the Hospital staff. But we want facts to enable us to decide. We ask for light, and are open to conviction.

Another passage-at-arms arises on the question of "contagion and infection," of which the denunciation, "if not promulgated by a lady, would require rough treatment." Miss Nightingale says, that there are two or three diseases which can be propagated by inoculation. The word "infection," too, "expresses a fact, and does not involve a hypothesis" (pp. 9, 10, 11). An overcrowded fever ward poisons the blood of the sick, and also "of the Medical attendants and nurses, so that they also become subjects of fever."—(See "Notes on Hospitals," pp. 8—11). This is all that she admits, while affirming that "infection is not inevitable, but simply the result of carelessness and ignorance." Contagion in the Levantine sense she spurns, affording, as it does, "certain classes of minds, chiefly in the southern and less educated parts of Europe, a satisfactory reason for pestilence, and an adequate excuse for non-exertion to prevent its recurrence." It presupposes the existence of a certain germ, which can be conveyed any distance, attached to clothing, "especially to woollen stuffs, for which it is supposed to have a particular affection, and to feathers, which, of all articles, it especially loves, so much so, that, according to quarantine laws, a live goose may be safely introduced from a plague country, but if it happen to be eaten on the voyage, its feathers cannot be admitted without danger to the entire community. There is no end to the absurdity connected with this doctrine." This

is evidently drawn from the life, and is probably a quarantine study by the Miss Smith, who bore her eastern honours so meekly to Europe. Before his "rough treatment" of Miss Nightingale, the writer will, I trust, in justice to his cause, graduate in a Levantine lazaretto.

In a former number of the *Medical Times and Gazette* I gave the formula for determining the death-rate, which is obtained by dividing the deaths in a given time by the lifetime; thus, the deaths in a regiment during a year divided by the mean strength during the same time give the annual rate of mortality. The Hospitals, asylums, and workhouses contain the greatest number of inmates in winter and the fewest in summer; so, taken in the aggregate, the numbers on April 8, 1861—the census day—represent pretty accurately the average number of inmates in the year. The register books supplied the deaths for the year. The 57 lunatic asylums contained 21,909 inmates; the deaths in the year were 2425; and the mortality among these lunatics was at the rate of 11 per cent. annually. By the same method, the 22,785 deaths in workhouses, containing 119,984 inmates, implied that the annual mortality was at the rate of 19 per cent. But in the same year, 7227 deaths were registered in 106 Hospitals, which had 12,709 beds occupied by patients on the census day of that year, and consequently the mortality was at the rate of 57 deaths to every 100 occupied beds. Miss Nightingale (p. 3) calls attention to the fact that in 24 London Hospitals the mortality by the same method is at the rate of "90·84 per cent., very nearly every bed yielding a death in the course of the year." These are her precise words, admitting of no ambiguity. Next, we have 12 Hospitals in large provincial towns yielding a death-rate of 83 (a) per cent.; and there are 25 county Hospitals in country towns the mortality in which is no more than 39 per cent. "Here we have at once a Hospital problem demanding solution."—P. 4.

This is one method; there is another which is less correct, but more common. The deaths are divided by the mean number of cases admitted and discharged. By this method it is shown in M'Culloch's "Statistics of the British Empire" (vol. ii., p. 558, ed. 1839), that the case mortality in country Hospitals of moderate dimensions was about 4, in the London Hospitals about 9 deaths out of 100 cases treated. The defect of the method lies in this: it does not take the element of time into account, which is important, as it so happens that cases are scarcely ever admitted as in-patients of Hospitals at their origin, and that many cases are discharged from Hospital before they have terminated. The practice varies in different Hospitals. Thus, at St. Thomas's, London, the patients remained thirty-nine days on an average in 1861, while in two Dublin Hospitals the patients remained twenty-seven days. (b) It is incorrect to compare the cost of keeping patients in the two Hospitals, and it is equally incorrect to compare the mortality without noticing the variation in the time over which it extends (twenty-seven and thirty-nine days).

Miss Nightingale, with her usual conscientiousness, has taken care to understand both methods, and has explained them, so as to make them intelligible "to the meanest capacity." Either method might be employed; but the ratios of the two methods can only be confounded by inconceivable blundering. Such blundering, however, occurs in the inculcated article, and the writer exclaims,—"There is something audacious" in the table where twenty-four London Hospitals are accredited with a mortality per cent. on inmates [beds, as she explains, p. 4] of 90·84: it is a "simple piece of arithmetical legerdemain;" the problem as here put is exactly,—"What is the quotient of 100 apples divided by 15 red herrings?"—the patients dying in a Hospital having evidently no more relation to the average number sick in the beds, than "apples" have to "red herrings!"

Such is the licentiousness of a careless writer! "Anonymus" is naturally a much loftier being than "Anonyma," although he does mingle "audacity," "apples," "sins," "red herrings," and "Lord Dundreary," so lavishly in his vocabulary, as to give rise to a suspicion that he somewhat over-estimates the dignity of a certain reviewer of the sex to which the Latin grammar gives precedence, and who "could treat" "a lady" roughly "an he would."

What a refreshing contrast does the woman's book afford to the man's review! She has not walked through—she has lived

(a) I omit decimals.

(b) "Hospital Dietetics," by John Ch. Steele, M.D. *Trans. of Social Science Society*, 1862, p. 631.

in Hospitals during many of the fairest years of her life. She understands the whole economy of these institutions; she has watched thousands of patients enter their portals, and leave their wards after long illnesses, which she has softened by science and by kindness. Her observing powers are of as high an order as her opportunities, and her sagacity in drawing deductions has rarely been surpassed; yet, not satisfied with deduction only, she humbly seeks counsel from scientific induction. She makes herself thoroughly acquainted with the methods and resources of Medical statistics. She encounters great labour and incurs great expense to induce the Hospitals of this kingdom and of the continent to keep records and to publish analyses of the facts respecting the sick which take place within their walls. She probes all the defects which make Hospitals ways of death to their inmates. She collects plans; she consults engineers; and she brings the whole of the facts together in a clear, practical form, and holds out hopes that general Hospitals may yet benefit mankind directly, and not merely as pathological observatories and Medical schools. The third edition of "Notes on Hospitals" is, in my opinion, the most judicious, complete, and masterly treatise that has recently appeared on any subject.

February 6.

I am, &c.

W. FARR.

* * We thoroughly endorse every word of Dr. Farr's commendation of Miss Nightingale,—nay more, we hold her entitled to this special praise, that in undertaking the investigation of Hospital mortality, she is not only protecting the most poor and most helpless from falling into the very snares of death in the places whither they go for health, but she is consummating a reform, which the members of our Profession, to whom it rightly belongs, have not yet been able fully to carry out. We need not remind our readers, that spite of the demonstration of the fatality of crowded Hospitals thirty years ago or more, begun by the great military Surgeons, as Guthrie, with regard to military Hospitals;—continued by the obstetric Physicians, as R. Ferguson and Rigby, with regard to Lying-in Hospitals;—and confirmed by independent men, as Drs. G. Gregory and Copland, and by universal experience as regards all civil Hospitals,—yet that the real governing bodies, the committees, have not yet yielded to Medical influence, and that the demand for pure air, which has seemed like a crotchet in the mouths of the doctors, does at last seem likely to be enforced by the authority of practical, acute, and energetic workers—such as Miss Nightingale—out of the Profession.

But all this is no reason why our very acute and able reviewer should not point out such statements in her book as seem erroneous or exaggerated. Having read the book, and the review, and Dr. Farr's letter, we offer the following remarks:—

1. With regard to *death-rates*—let us accept what our distinguished correspondent tells us is the real mode of computing a death-rate for any given place or institution. But we add, that the use popularly made of a death-rate, viz., to take it as a test of the qualities of the *place* in which, omitting those of the *people* amongst whom the deaths occur, is unfair. To say that Cavendish-square is a "healthier place" than Lisson-grove, because the percentage of deaths amongst the English gentry who inhabit the one is less than that amongst the dirty Irishry in the other, is absurd; for we may be certain, that if the inhabitants were to change places they would not change their morals or their habits. In like manner we can point to two workhouses, belonging to one parish. In one the death-rate is 35, and in the other 8½ per cent. of the average number of the inmates per annum. Is it, then, fair to say that the first workhouse is "more unhealthy" than the other? Not a bit of it, no more than it is to compare apples with herrings. The first receives the poor in acute illness and acute distress, and keeps the dying, destitute wretches; whilst the chronic paupers are drafted off to the other.

But it appears to us that Miss Nightingale, spite of her own ample knowledge, and spite of her own admission of the influence of various diseases, ages, etc., etc., does yet, whilst admitting the worthlessness of Hospital statistics in page 2, deliberately use them as "startling facts," at pages 3 and 4, to prove what she has already confessed that they cannot prove.

She gives us, first, the twenty-four London Hospitals, with their mortality of 90·84 per cent.; secondly, twelve Hospitals in large provincial towns, with a death-rate of 83·16; thirdly, twenty-five country Hospitals, with a death-rate of 39·41 per cent. per annum. And she goes on to say:—

"Here we have at once a Hospital problem demanding solution. However the great differences in the death-rates may be explained, it cannot be denied that the most unhealthy Hospitals are those situated within the vast circuit of the metropolis; that the next lower death-rate takes place in Hospitals in densely-populated, large manufacturing and commercial towns, and that by far the most healthy Hospitals are those of the smaller country towns."

Of this extract we can only say that it seems to have been written in haste and left uncorrected; else we are sure that the acute and candid author would have seen that she is taking the mere mortality as a test of healthiness of a Hospital; and implying that certain Hospitals might be unjustly condemned as "unhealthy;" whereas the fact would be that they were doing good service by admitting the "most unhealthy" inmates. Any comparison which ignores the difference between the apple-cheeked farm-labourers who seek relief at Stoke Pogis (probably for rheumatism and sore legs), and the wizened, red-herring-like mechanics of Soho or Southwark, who come into a London Hospital, is fallacious. Whether or no Dr. Farr's method yield the absolutely correct formula for the death-rate, it does not—confessedly—give data for the inferences which Miss Nightingale allows herself to draw from it in the passage which our reviewer criticises.

2. With regard to the question of the "high and increasing death-rate" as a result of the celebrity of a Hospital, we have only to say that Miss Nightingale's observations are marked by a rhetorical artifice (that of drawing absurd conclusions from your adversary's argument, and fastening them on him), which was fairly dealt with by our reviewer. Certainly, the celebrity of some Practitioners brings them the worst cases, and an addition to the mortality of their practice. But an opinion on such a point cannot be proved by data, and, if wrong, is scarcely a "heresy."

3. With regard to Miss Nightingale's statements about contagion and infection, which our reviewer said deserved "rough treatment," we think they are scarcely warranted by Miss Nightingale's own admissions; they are contrary to the general experience of mankind; they would lead to hazardous practice; and they are marred by a rhetorical artifice, which we are sorry to see honoured by Dr. Farr's approbation. When the lawyers have a bad cause they throw dust into the eyes of the jury. Miss Nightingale throws feathers; and brings in a goose to show that absurdities are committed by the ignorant quarantineers of the Mediterranean, as if such an argument could disprove the existence of contagion or infection at home.

Miss Nightingale's opinions on these matters are accurately set forth by Dr. Farr. We may further abstract them thus—

a. She ridicules the existence of germs like sporules of fungi, capable of transportation, etc. *b.* She admits a specific virus in "two or three diseases," as small-pox, etc., which can be seen and tasted, and which propagates the disease by inoculation. *c.* By "infection," she means the effects of bad ventilation, air poisoned by emanations from breath, etc., shut up and allowed to decompose, etc. *d.* She admits that washerwomen may be poisoned by inhaled organic matter from foul linen, in badly-ventilated laundries. *e.* She ascribes "infection" to ignorance and bad management, and defective ventilation. *f.* Says that "no diseases ought to be considered infectious;" *g.* Denounces the notion of setting apart wards for diseases so reputed, and affirms that they may be safely treated in wards with the other sick, "with proper sanitary precautions." *h.* "No stronger condemnation of any Hospital or ward could be pronounced than the simple fact that any zymotic disease had originated in it," or had spread from the first patient. *i.* She speaks of fear of entering a cab

in which a case of fever or small-pox has been for half-an-hour as "morbid." "Nay," she says, "we have heard of a myth of scarlet fever being carried in a bed-side carpet."

It will appear by these extracts that Miss Nightingale has just that half-view of the truth which characterises the old "anti-contagionists," whose squabble with their equally absurd opponents, the "contagionists," created so much amusement to the readers of Captain Marryatt's novels. The fallacy of the one, reduced to strict terms, was this:—"Some diseases may be generated at home by filth; therefore no disease can be imported by contagion." That of the other: "A given disease is imported by contagion; therefore it cannot be generated at home by filth." Let any one take down an old book on Quarantine—say "Maclean"—and he will find throughout these assumptions, just as if a disease of local origin could not spread, or as if it might not spread into regions where there may be no local causes adequate to have originated it at first.

The view held by practical men at present is, that each side is true in its proper sphere. We have often had occasion to show, that there is a whole class of Hospital diseases which may be engendered almost at will, by over-crowding and want of ventilation—puerperal fever, erysipelas, pyæmia, Hospital gangrene, etc., etc. All these diseases are capable of spreading, both by contagion and by infection, even amongst the healthy and cleanly. Other diseases there are whose origin is doubtful (but whose favourite haunts are so like those of the last, that some believe them to originate under similar circumstances), and which, also, can and do spread in like manner—small-pox, scarlet fever, etc., etc. Each disease of these two classes is justly supposed by Dr. Farr to depend on some special poison, to which he has given names, as *typhine*, *scarlatinine*, etc., etc. These poisons have never been isolated, or seen, as Miss Nightingale seems to suppose, and their existence is inferred only from their effects. But as they exist, they must exist *somewhere*; and as it is not improbable that they are combined with vegetable spores or germs, or with minute animal atoms, pus globules, etc.—or else with organic particles in a state of chemical change—so they may not only be transported by the air, but may adhere to walls, carpets, etc., etc. Whilst the origin of some of the above diseases may probably be prevented with certainty, as the spread of all may be hindered, by free ventilation and cleanliness, yet sad experience shows that all precaution may fail. They may be "carried" into the houses of the healthiest, and may there spread, spite of "all sanitary care." Hence, without in the least decrying the powers of ventilation and the virtues of air, most sensible people practise "quarantine" as well. They keep "infected" persons and clothes at a distance; and if any person becomes ill, they separate him from the rest of the family, or send him out to a lodging.

Now, we leave it to Dr. Farr to decide how far Miss Nightingale's views are consistent with his own of the existence of specific zymotic poisons; and whether he will take the responsibility of advising Hospital committees to follow her dictum, and not to isolate "infectious" cases?

Let a Hospital be as well ventilated as possible, the patients can be no more secure from erysipelas or scarlatina there, than in their own homes. A patient may be admitted with the germs of either disease in his blood, which may break out next day. Shall the patient be kept in the same ward with others? Shall a barrel of gunpowder or of petroleum be kept in a town? Of course, with "proper precaution" it may be kept with safety. The worst of it is, that human carelessness—even if a thing be possible—can never be ignored in forecasting probable results. Suppose a dead calm in hot weather, what amount of air will pass through the Hospital wards? Most practical men agree with Dr. R. D. Thomson, in a recent report, in deploring the "want of sufficient means of isolating epidemic and contagious disease in the public Hospitals."

We thus independently affirm so much as was stated by our reviewer in deprecation of an unfair use of death-rates.

We object to Miss Nightingale's doctrines about contagion, as ignoring one truth in order to exalt another; and we ask Dr. Farr if it be fair to attribute to our reviewer the notions of a Levantine quarantine, merely because he contends for those palpable facts as to contagion and infection on which all practical men are agreed? Is it worth while to use that little sneer at anonymous writers? If our reviewer attacked Miss Nightingale he would sign his name; but what he attacks are the fallacies which disfigure a valuable work—fallacies which may lead to the loss of many a life, if any one shall be found rash enough to treat scarlet fever as not infectious, because Miss Nightingale has said that "no diseases ought to be considered infectious." We would further ask him, why he comes to us for an account of the mortality of the various Hospitals? We hold no brief for them. On the contrary, we shall be but too glad to make public any results which may arouse Hospital committees from that almost criminal apathy—from that Turkish, stolid fatalism which induces them to regard death after death as arising from "inevitable infection," or from any other cause which may cloak their want of fresh air.

All this fight has been about one or two incidental matters on which we conceive Miss Nightingale to be wrong, and to have been justly criticised. As regards the whole aim and scope of her labours, and the immense value of the "Notes on Hospitals," there cannot be two opinions. She is too plain-spoken herself to object to fair criticism of its few *macule*.—[ED. M. T. and G.]

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 19.

Mr. PRESCOTT HEWETT, President.

(Continued from page 131.)

Mr. HOLMES showed, for Mr. Nash, of Liverpool, a specimen of
WOUND OF THE SKULL.

A woman was brought drunk to the Hospital for what appeared to be a scalp wound only, but the probe was not used. She did not attend again for three days, having been drunk all the time. A probe was then passed through a fissure into the skull. It was then ascertained that her husband had thrown a poker at her, and that, being unusually worn and sharp at the end, it had stuck in the skull. She died of cerebral abscess. In reply to Mr. Sydney Jones, Mr. Holmes said that fragments of bone came away with the discharge.

Mr. SYDNEY JONES then related a case in which the skull was perforated by a shovel. The patient died, but of general pyæmia, having had no cerebral symptom whatever.

Mr. HICKS showed a specimen of

ANEURISM OF THE AORTA.

The patient had had a tumour for seventeen years, which at first was the size of a walnut. It grew slowly. She had no symptom connected with it, and died of some other disease. The sac from the transverse part of the arch of the aorta had perforated the manubrium, and was filled with clot. It began as a true aneurism. There had been no bruit, and all the valves were found to be competent.

Mr. CURLING then showed a specimen of

CARIES OF THE HEAD AND NECK OF THE FEMUR, AND NECROSIS OF THE SHAFT, FOR WHICH AMPUTATION WAS PERFORMED AT THE HIP-JOINT.

A child, five years of age, fell on his hip, but got up and walked home, but the same evening he had slight pain in the groin, and for weeks had inflammatory symptoms. Then an abscess formed in front of the thigh. This was opened, and a copious purulent discharge ensued. As, however, the child was suffering from the local disease, chloroform was given, an exploratory operation performed, but no diseased bone was found. The limb was not drawn up, and it was impossible to make out clearly disease of the hip-joint. Soon after, the child had measles, then troublesome diarrhœa, and the liver enlarged, and he was much reduced. The femur, too, enlarged. A second exploration was made, and yet no

exposed bone could be found. Now Mr. Curling wished to amputate, but the child was too reduced to bear it. He was sent to Ramsgate, and, having returned in better condition, Mr. Curling then removed the limb at the hip-joint. There was little loss of blood, and although at the time of operation the child was much reduced, yet he rallied, and lived upwards of four weeks. The stump was nearly healed. Miliary tubercle was found in the lungs. The liver was much enlarged. There was slight caries of the acetabulum. The upper half of the shaft of the femur was completely necrosed, and the whole head and neck destroyed by caries. As to how the disease of the hip arose from the injury, there might be two opinions; one, that the epiphysis was detached, and the other, the more probable, as the child walked after the accident, that periostitis of the shaft was the cause. That the joint was secondarily affected was an interesting feature; and in this respect the case resembled one brought before the notice of the Society by Mr. Maunder, in which acute necrosis of the tibia was followed by disease of the ankle-joint. It had been said (Mr. Curling added) that in nearly all cases of necrosis the limb could be saved; but he had witnessed several in which necrosis of the shaft had extended to the articulation, and caused its disorganisation, rendering amputation necessary.

Mr. HOLMES then related a case in which an injury to the wrist at first was thought by the House-Surgeon to be Colles' fracture. The patient died of pyæmia, and it was found that the local symptoms had been due to periostitis.

Mr. CURLING next showed a specimen of

RUPTURE OF THE RECTUS ABDOMINIS MUSCLE.

It was taken from a patient who died of tetanus, and the rupture was detected six days before death. This muscle (Mr. Curling said) was rarely ruptured except in tetanus. He related two other instances, and one in which the psoæ muscles were also ruptured. He had known rupture of the rectus muscle to occur in an epileptic fit, and also to result from the kick of a stallion.

Dr. BRISTOWE said that he had found rupture of the rectus in two patients who had died of phthisis.

Mr. WILLIAM ADAMS had seen one of the cases referred to by Dr. Bristowe.

The PRESIDENT had, some years ago, seen many cases of rupture of this muscle in patients who had died of what was then called "spotted fever."

Dr. PEACOCK said that the late Professor Reed had drawn attention to rupture of the rectus in typhus fever.

In reply to Dr. HARLEY, Mr. CURLING said that the muscular tissues had not been examined microscopically. One of the patients was only twenty-six years of age, and another of about the same age.

Dr. BRISTOWE had in one case made a microscopical examination, but had not found any disease.

Mr. SYDNEY JONES related a case of what appeared to be rupture of the rectus abdominis, by lifting a heavy weight. The patient was still under care.

Mr. LITTLE showed microscopical specimens of

ENCEPHALOID DISEASE OF THE TESTIS,

from a testicle in an advanced stage of encephaloid cancer. The specimens were taken from a part of the testicle still sound to the naked eye, but in which the tubes were distended with encephaloid matter, whilst the intervening and connecting tissue was free from disease. The commencement of the disease was intra- and not inter-tubular.

Some discussion then took place as to the microscopical signs of encephaloid and other tumours.

In reference to diagnosis of the malignancy of tumours, the PRESIDENT made some interesting observations. Some years ago, a patient, who had an enlarged testis, was admitted under the care of Mr. Cutler. Many thought the disease was not malignant, and that mercury ought to have been tried. Mr. Cutler, however, felt so certain that it was malignant, that he thought it safer not to wait. When removed and split down, he (the President) felt certain that it was not malignant; but Mr. Gray, who afterwards examined it by the microscope, said that it was. Being very much interested in the case, he sought further opinions. He called on Mr. Curling, but did not find him at home. One Surgeon said that, by the microscopical appearance, he should say it was not malignant, but by the naked eye he should say it was; another Surgeon, exactly the reverse. Brodie thought it was not malignant, but Stanley thought it was. The patient recovered, and went home, but in eight months returned with a tumour of the

other testis. This time mercury was used, and the man got well, and was, the President believed, still well.

Mr. CURLING said that, after so very varying opinions, any one must speak doubtfully; yet he had scarcely any doubt but that the tumour exhibited by Mr. Little was malignant. As a rule, a malignant tumour gives rise to secondary disease of the glands, but not always. Mr. Little's patient would be under observation, and the further progress would be communicated to the Society.

Dr. WILKS said that there was every degree between what was decidedly innocent and decidedly malignant. He should call the specimen semi-malignant.

Dr. BRISTOWE did not think highly of microscopical appearances as evidence of malignancy.

A specimen of

DISSECTING ANEURISM OF THE TRANSVERSE AND DESCENDING PORTIONS OF THE ARCH OF THE AORTA,

was exhibited by Dr. Peacock, which had been sent to him by Mr. C. Williams, the Resident Medical Officer of the Norfolk and Norwich Hospital. Mr. Williams stated that it was removed from the body of a man 59 years of age, a patient of Mr. J. Allen, who, while engaged in tolling a bell, gave himself a "wring," followed by pain so severe as to compel him to cease ringing. He suffered from symptoms of fever afterwards, and died suddenly on the sixth day. On examination after death, the pericardium was found distended with blood, which had escaped from a swelling of the coats of the aorta in front of the arch. On opening the vessel a rent was found in the internal coats situated immediately in front of the origins of the large vessels at the arch. From this point the blood was found to be extensively extravasated between the external and middle coats at the ascending and transverse portions of the arch, and between the layers of the middle coat in the descending portion. The separation of the coats of the vessel extended four inches down the descending aorta, and the newly-formed canal then reopened into the cavity of the vessel. The coats of the aorta were very slightly atheromatous, but the vessel was dilated; the heart was not materially diseased.

Mr. NUNN showed, for Mr. Worthington, a specimen of FATTY TUMOUR OF THE RECTUM, SURROUNDING THE GUT, AND OBSTRUCTING MICTURITION AND DEFECACTION.

The rectum, for about six inches from the anus upwards, appeared to be surrounded by, and growing from its muscular coat, a large, dense, circular, fatty tumour, the size of a child's head, which had so compressed the vagina and urethra against the symphysis pubis as almost to entirely obstruct the flow of urine, producing great dilatation of the bladder, ureters, and kidneys, the structure of which organs were much altered. This case was interesting as showing a rare form of tumour of the rectum, which had so mechanically obstructed the proper excretion of urine, as to dilate the bladder and ureters, destroy the kidneys, and end the patient's life, probably, by uræmic poisoning.

At a previous meeting, Mr. SAUL brought forward a man (living) who was the subject of

MULTIPLE TUMOURS.

The patient was a man of about 50. His arms presented all over irregular nodosities, caused by the development of subcutaneous growths. There are also numerous similar growths on almost all parts of his body, but not so numerous as on his fore-arms. The tumours had existed for two or three years; they had not been painful. There was no history of hereditary liability to tumours of any kind. None of the tumours had been excised.

The PRESIDENT expressed a decided opinion that the tumours were fatty; and in this most of the members present seemed to agree. Mr. Nunn, however, expressed a doubt as to whether in some of them there was not a venous element.

Dr. MURKISON stated that he had, some years ago, recorded a case somewhat similar of multiple fatty tumours. In this instance, three members of the same family were affected by them.

SCARCITY OF BODIES FOR DISSECTION IN PARIS.—There has been this winter a great scarcity of bodies for dissecting purposes, so that the Military Medical School at Val de Grace has been put to great straits to carry on the course of operations and lectures on anatomy. The opposition of the priesthood, who desire to secure the bodies for interment, has been assigned as a reason for the paucity.—*Allg. Wien. Med. Zeit.*

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen have passed their First Professional Examinations during the recent sittings of the Examiners:—

William Lawton Eames, Cork; Thomas Macdonald, Ross-shire; Joseph Jackson, Cumberland; James Simpson, Cumberland; Thomas Simpson, Yorkshire; James Hogg, Edinburgh; John N. O'Keefe, County Kerry.

And the following gentlemen have passed their final Examinations, and been admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh:—

Joseph Lindsay Kingston, County Cork; Latham Blacker M'Culloch, Drogheda; James Hinds, Notts; Patrick Callan Horan, County Cavan.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen have passed their First Professional Examinations during the recent sittings of the Examiners:—

Robert Anderson, Haddingtonshire; James Ingram, Orkney.

And the following gentlemen have passed the final Examinations, and obtained the Diploma of the College:—

John Middleton, Glasgow; James Godfrey, Glasgow; Robert Pearson Dunbar, Perthshire; William John Taggart, Antrim; Heinrich Frederik Lawatz Melladew, London; Frederick Montizambert, Quebec.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 4, 1864:—

Richard Wheeler Haines, Bromsgrove; Robert Wills Soper, Dartmouth, South Devon.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALSTON, J. MONTGOMERIE, M.D. Glasgow, has been appointed Surgeon to the Summerlee Collieries, Airdrie.

BANKS, JOHN T., M.D. T.C.D., has been re-elected King's Professor of the Practice of Medicine in the King and Queen's College of Physicians, Dublin.

BUTLER, FREDERICK J., M.D. St. And., has been appointed Surgeon to the County Prison, Winchester.

CULLINAN, WILLIAM, L.K.Q.C.P.I., has been elected Surgeon to the County of Clare Infirmary.

ELKINGTON, GEORGE, jun., M.R.C.S. Eng., has been elected Junior Resident Surgeon to the General Dispensary, Birmingham.

HALL, WILLIAM, M.R.C.S. Eng., has been appointed Assistant-Surgeon to the Hospital for Women and Children, Leeds.

MORRIS, J., M.R.C.S. Eng., has been elected House-Surgeon to the Warneford Hospital, Leamington.

REED, GEORGE, M.D., has been elected Resident Medical Officer to the Manchester Royal Infirmary and Dispensary.

STOKES, MR. WILLIAM, has been appointed Surgeon to the Meath Hospital, Dublin.

DEATHS.

GUNN, JOHN, L.R.C.S., Edin., Surgeon R.N., at Edinburgh, on February 8.

KENDALL, WALTER, L.S.A., of Budleigh Salterton, Devon, at West Lulworth, on January 27, aged 68.

PEARCE, SAMUEL, M.R.C.S. Eng., at 135, Bethnal-green-road, N.E., on February 3, aged 54.

TURNER, SAMUEL M., F.R.C.S. Eng., at Newcastle-under-Lyme, on January 5, aged 45.

WARD, ISAAC DUNLIN, M.R.C.S. Eng., at Lincoln, February 4, aged 28.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF DUBLIN.—At the Spring Commencements, held on Shrove Tuesday, in the Examination Hall of Trinity College, the following degrees in Medicine and Surgery were conferred:—*Baccalaurei in Medicinâ*:—Georgius O'Hanlon, Augustus Smith, Johannes Lyons, Alexander M'Clorg, Henricus Davy, and Johannes Knox Leet. *Magistri in Chirurgiâ*:—Alexander M'Clorg, Georgius O'Hanlon, and Augustus Smith. *Doctor in Medicinâ*:—Johannes Knox Leet.

THE UNIVERSITY OF DUBLIN v. THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.—We are informed that the Master of the Rolls will not give his decision in the University v. College question until next term, viz., in April.

SIR JOHN LIDDELL, K.C.B.—The *London Gazette* of Tuesday, February 9, contains the following announcement:—“WAR-OFFICE, Feb. 9.—The Queen has been graciously pleased to give orders for the appointment of Sir John Liddell, Knt., C.B., M.D., late Director-General of the Medical Department of the Navy, to be an Ordinary Member of the Military Division of the Second Class, or Knights Commanders of the Most Hon. Order of the Bath. We heartily congratulate Sir John Liddell on his well-deserved honours.

BENEFICENCE.—The late Mr. John Farnell, the head of the firm of Farnell and Watson, brewers, who has bequeathed upwards of £22,000 to charitable objects, has not forgotten those belonging to our Profession, having left £1000 to each of the following institutions:—The Hospital for Consumption at Brompton, the Royal Orthopædic Hospital, the Asylum for Idiots, and the Cancer Hospital. The late Miss Gale, of Andover and Cadogan-place, has bequeathed to the Middlesex Hospital, £1000; to the Royal Free Hospital, Gray's-inn-road, £500; the Fever Hospital, £100; the Deaf and Dumb Asylum, £500; the Indigent Blind, £500; and to the Winchester County Hospital, £500.

ANNUAL MEETING OF THE SUBSCRIBERS TO THE BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—On the 3rd inst. the stated annual meeting of the subscribers to the Belfast branch of the above Society was held in the rooms of the Ulster Medical Society, 33, High-street, Belfast. The attendance was large and influential. Among those present were—Dr. Patterson, Dr. Drennan, Dr. Cuming, Dr. Browne, R.N., Dr. Michael Magee, Dr. Keown, R.N., Dr. Whitaker, Dr. Stewart, and Dr. T. H. Purdon, the permanent president, who did not enter the room until the business of the day had commenced, and in whose absence Dr. Patterson, a warm and energetic friend of the Society, was unanimously requested to take the chair. From the statement made of the past year's proceedings, the working of the Belfast branch of this most useful Society presented much that was satisfactory, and evidenced that, as its objects became better known and understood, a larger amount of interest is being manifested on its behalf, both by the Profession and by friends outside of its pale. A number of subscriptions were announced, and the following gentlemen were elected a committee of management:—Dr. Patterson, Dr. Drennan, Dr. Moore, Dr. Thomas Reade, Dr. Cuming, Dr. Stronge, and Dr. H. S. Ferguson, for Belfast; Dr. Ross, Ballymena; Dr. Spearing, Antrim; Dr. John Moore, Glenarm; Dr. Musgrave, Lisburn; Dr. Filson, Portaferry; and Surgeon Patrick Carrickfergus, for the country.

THE MARISCHAL COLLEGE STUDENTS.—“And so, for four years, often in this public hall, but oftener still in the class-rooms where we were taught all that Marischal College had to teach, we wore the red gowns and red velvet collars which were the compulsory costume of the Students of Arts, till one early spring day we were ranged ceremoniously in the public hall, some eighteen or twenty of us who had completed the curriculum out of a class originally seventy strong, and there, clad all uncouthly in black silk gowns, which the college beadles had begged, borrowed, or stolen from the city clergy for the occasion, were made to repeat the words of a Latin oath, and, having been dabbed on the head individually by the Principal with a sacred bit of black velvet, were created and admitted Masters of Arts. When I think what *Magister Artium* implies according to the English standard, and then recollect what a flock of fledglings we were (the youngest of us exactly sixteen years and four months old) that flew off into the world from that northern nursery of learning, feathered legally with the fine designation, the thing does seem rather absurd.”—*D. Masson.*

CASE OF ALLEGED POISONING.—A prolonged inquiry has recently taken place at Hayle, Cornwall, into a charge against Mr. Richard Oke Millett, a Surgeon, residing at Penpol, of causing the death of Mr. Jacob C. Millett, his brother, by poison. It is sufficient to say that a more unfounded charge was never investigated in any court of law. It must be a matter of intense regret to the prosecutor that such an accusation was ever made. Mr. R. O. Millett is entitled to universal sympathy for having been made the subject of as severe a misfortune as could possibly fall upon an innocent man. The evidence clearly showed that the death of his brother was caused by apoplexy supervening on a condition of chronic hydrocephalus. A most careful investigation made by Professor Taylor completely proved the absence of any trace of poison in the viscera of the deceased. At the close of the

investigation, the chairman of the bench of magistrates, the Rev. Uriah Tonkin, addressed Mr. Millett as follows:—Mr. Millett, we are extremely sorry that we have been obliged to keep you so long in custody, but, sitting here as magistrates, we had no other alternative. It was our duty, as you were charged with a most sad and most grievous offence—one of the most grievous offences that human nature could be guilty of. In doing what we have done, we have done nothing but given a painstaking and earnest attention to this investigation, with continual regard to your position as well as to that of the prosecutor. The prosecutor, I may say, when he came to me, said that, even if no poison were found in the stomach, he had proof enough to authorise him to believe that the death of the deceased was occasioned by poison, and that he believed that that poison had been administered by you, and upon the faith of that statement I granted the warrant upon which you were apprehended. I am now very happy in having to say, Mr. Millett, that you are released from all further custody; and having investigated the case most minutely, and, I am sure, most fairly and with the strictest anxiety to do justice, my brother magistrates and myself have no longer anything further to do with the matter but to say that we are extremely happy that you are released from this charge. I need not, perhaps, say that the prosecutor has not made good his charge; the charge was made against Mr. Millett, and he was apprehended, but is now discharged. Mr. Millett was warmly congratulated by numerous friends, and was accompanied to his residence by a large concourse of persons; and the band of the Hale Foundry, to which establishment he was Surgeon, met in the evening in front of his house, and performed various pieces of music.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Bethnal-green.—The inquiry into Dr. Moore's conduct is not finished, and will doubtless end in the discomfiture of the Guardians.

Surditas.—It is said that the eminent aural Surgeon in question did visit an illustrious personage, and afford entire relief by his treatment of her ears.

A Commercial Traveller.—Consult the leading Physician or Surgeon in your town.

Errata.—In "First Impressions of the British Pharmacopœia," p. 155, par. 15, for magnesia, read magnesiae; par. 21, for cow read cocoa.

Infanticide without Intention.—"Murder has been classed among the fine arts, coarse as a good deal of it no doubt is in practice. There are many ways of getting rid of surplus infants. It is not merely by cutting the throats of the poor little innocents as if they were pigs, or by drowning them as if they were kittens, that thousands of murders are effected. In China they go about it in a more matter-of fact and business-like way than we do; but throwing them in heaps, alive, within the precincts of a 'devil's temple,' there to perish, does not come up to our more refined and civilized and varied modes of doing the Malthusianly needful work. And, in speaking of refined and civilised operations of the sort, it is not simply meant to refer to reiterated doses of 'quietness,' and such-like drugs; nor even to ingenious processes, such as those of the talented individual who got rid of five of his superfluous progeny by various artful dodges, such as setting a tub of water, like a trap, for the unprotected little one to roll into out of bed when all were asleep, and when no one, therefore, was to blame. Perhaps the method most entitling infanticide to be regarded as a branch (we wish we could call it a dead branch) of the fine arts, is to choke them by degrees from short supplies of vital air in close apartments. This is a much more safe and artful way of 'keeping down the population' than either smothering them in bed, dosing them with laudanum, or even stuffing them with 'strong meat' in the place of milk."—*Godwin's "Another Blow for Life."*

The *Elgin and Morayshire Courier*, for February 5, contains the following too true remarks:—

"The Medical Profession, while it is laborious above all others, and also the most indispensable, is at the same time thankless without a parallel, and most inadequately rewarded. It is notorious that the doctor, whose services are of the first importance, is paid among the last of all. He may be thankful, indeed, if his fee be forthcoming at any remote period of the future, since it is no unusual thing for him to be paid off not even with thanks, but the reverse. The doctor's laborious consecration to the salvation of the human body, his weary night work, his cold journeys, his severe and anxious study, demand a better reward than this; and the public good feeling and sense of justice, in addition to what is right and fair as to substantial requital, should provide also that his services shall meet with the appreciation and gratitude they deserve. While on this subject, we may direct the notice of our readers to the table of fees agreed upon at last week's meeting of the Medical Association, and which appears elsewhere in to-day's paper. No one will deny that the charges are reasonable; but while their statement in this form is useful

for the guidance of the community, it is out of the question to suppose that any market value can be put upon services which are of the kind that cannot be reckoned with money. There can be no fixed rate as to the remuneration due to superior skill and experience; but the Association have acted wisely in issuing a scale which the public conscience must acknowledge to be exceedingly moderate, and which no one can grudge for the smallest possible service rendered by the youngest member of the Profession. We observe that the Medical Practitioners of the northern districts of Aberdeenshire have also recently issued a table of fees, which, in all essential respects, is similar to that adopted by the members of the Banff and Moray Association:—

"BANFF, MORAY, AND NAIRN MEDICAL ASSOCIATION.

"Table of Fees.

"At a General Meeting of the Banff, Moray, and Nairn Medical Association, held at Elgin, on the 30th day of January, 1864, the following table was adopted, and ordered to be printed and circulated amongst the Members:—

"Visits.

The first Visit in Town, or Advice at Practitioner's Residence	From	To
Subsequent Attendance, to be according to its Length and the Social Position of the Patient.	£0 2 6	£0 10 6
Night Visit	0 5 0	1 1 0
Visit to the Country, at any distance not exceeding Two Miles	0 5 0	and upward
For every additional Mile, from	0 1 6	0 5 0
Night Visits to Country to be doubled.		
Every Hour that the Practitioner is detained, either from urgency of the case, or desire of the Patient or Friends	£0 2 6	0 5 0
It is understood that these fees should be paid at the time of visit, or when the attendance terminates.		
Ordinary Fee for Consultation	1 1 0	3 3 0
The Fee for Consultation, or other Medical attendance, when the Practitioner is not the one regularly employed by the Family, is expected to be paid at the time of visit.		
Ordinary Medical Certificate	£0 2 6	0 10 6
Lunacy Certificate	1 1 0	

"Surgical Operations and Midwifery.

Vaccination, Extraction of Teeth, Cupping, Bleeding, and other minor Operations	£0 2 6	£0 10 6
Operation of Hydrocele, Harelip, Tapping, Excision of Small Tumours, Amputation of Toes, Fingers, etc.	0 5 0	2 2 0
Reducing Fractures and Dislocations	0 10 6	3 3 0
Capital Operations, viz.:—Amputation, Trepanning, Aneurism, Extirpation of Mamma, Lithotomy, Lithotriety	2 2 0	21 0 0
Necessary Assistance at Operations	1 1 0	2 2 0
Delivery in Ordinary Cases	1 1 0	10 10 0
Do. in Difficult or Protracted Cases	1 11 6	10 10 0
In all cases of Operations and Midwifery, the Fee may be paid at the time, and to be independent of future visits.		
Post-mortem Examination, when requested by relatives, not less than	£2 2 0"	

RETIRING PENSIONS FOR POOR-LAW MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As the Government propose introducing a bill before Parliament this Session to enable Poor-law Medical officers whose health is broken down, or are above sixty years of age, and have served for twenty years, to retire on two-thirds of their salary, half to be paid out of the consolidated fund, and half out of the poor-rates, I think it would only be fair to all Medical officers who have served for twenty years and upwards, and who wish to resign their appointments, that they should be allowed this pension as a reward for their hard and ill-paid services, and that it should be given irrespectively of age, and paid entirely out of the consolidated fund.

It behoves, therefore, all Medical officers of Unions to address, either personally or by letter, both their county and borough representatives, to urge them to get this clause inserted in the bill.

Much, I am sure, may also be done by your powerful advocacy, through the medium of your valuable Journal, which has always been ready to aid this oppressed class of Medical Practitioners.

ALCOHOLIC STIMULANTS IN FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the controversy in your number of January 9, between Mr. Harding and Mr. Bayley, Mr. Harding, in mentioning my non-alcoholic treatment of fever, says, "Surely the experience of one man ought not to counterbalance that of the most eminent Physicians!" In answer, I would say, there are not usually two, but one, to make any great discovery. I claim being the one who has made the discovery of the non-alcoholic treatment of disease.

In the early part of my practice, half a century ago, if any Medical man had told me that wine or alcoholic stimulants were not necessary in typhoid or other fevers, I should have been much surprised, and as much inclined to discredit the assertion, as Mr. Harding himself; for at that period, so convinced was I of their absolute necessity in such cases, that I was wishful that the wealthy in the neighbourhood should form a wine dépôt for the poor who could not procure it for themselves. It is remarkable that the first disease which attracted my particular attention was typhoid fever, and which I treated without wine, in the year 1813. I have not once given alcoholic stimulants in fever since that time.

Mr. Harding states:—"It is quite possible that the type of fever which came under Mr. Higginbottom's notice was inflammatory, and not requiring stimulants."

During the last fifty years, at different periods, fevers have been epidemic in Nottingham and in the neighbourhood; indeed, we are rarely free from typhoid fever in lower parts of the town, and it is usually of a very low type indeed, many of those attacked being females, who worked

in overheated lace rooms, anæmic, of feeble constitutions. From my observation, the lower the type, the greater the danger in giving wine or any other alcoholic stimulant.

In the *Lancet* of August 15, 1857, I mention two epidemics. The first, in 1813, was extensive, and required half of each day to visit my fever patients, and it continued for four months. I lost no patient with my non-alcoholic treatment; two of them died, but they had wine given them by a family in the neighbourhood. The second was in 1848. Not one died under the same treatment. Other patients in the same locality, who took wine and brandy, died. There is no doubt patients often recover in fever in spite of the wine given; but it is my opinion, from long practice and observation, that the administration of alcoholic stimulants in typhoid or other fevers is always injurious, and often fatal in its effects.

I could relate detached cases, as the following:—Four patients with typhoid fever, three of them in a public-house in the lower part of the town, thickly inhabited—two daughters of the publican and their servant maid—and the other a female residing near the place. The daughters were treated on the non-alcoholic plan—both recovered; the servant was sent to the fever ward of the General Hospital—a healthy, open situation—and treated with alcoholic stimulants, and died. The neighbour was attended by a Medical man, who followed the same alcoholic treatment, and died. Such marked cases as the above occurred, and corroborated my opinion of the danger of administering in disease such an exhausting stimulant as alcohol.

I have entirely discontinued all alcoholic stimulants for the last thirty years in all diseases, being fully convinced of their insufficiency and dangerous qualities, and having proved, by abandoning their use, that patients suffering under acute disease were much more quickly restored to health, and chronic disease much more manageable. Indeed, I should consider myself criminal if I ever recommended alcohol in any form, either as food or as a medicine.

Very few of my Medical brethren have practised the non-alcoholic treatment of disease, and it is not right to condemn what they are ignorant of, not having given it a trial. I would remind such of the fit rebuke Sir Isaac Newton gave to Dr. Halley—"Sir, I have studied and practised these things; you have not."

I am, &c.

Nottingham, January 27.

JOHN HIGGINBOTTOM, F.R.S.

BOOKS RECEIVED.

The Church of England Temperance Magazine. London: Seeley and Co. New Series. Threepence, monthly.

** There is no doubt that "total abstainers" are useful in weaning drunkards from their vice, and that for most of the latter, Dr. Johnson's aphorism holds good, that "abstinence is easy, but temperance impossible." The clergy, therefore, may largely increase their influence amongst the intemperate by setting an example of abstinence from drink. Men in the prime of life do not need alcoholic liquors, if they possess the excellent appetites which usually distinguish our brethren the clergy. We will venture to say that they should not stop at drink; and we may endorse that counsel which has been given to the younger clergy by many fathers, and notably by St. Jerome and by the present Bishop of Fredericton. They never should forget, even in the most festive moments, that a something of abstinence, or, at least, of great moderation, is demanded by their sacred calling. It should never be whispered that a clergyman is a *bon vivant*, or epicure, or *nice in his eating*, as the vulgar say. What an excellent thing it will be for society when the clergy protest publicly against those wasteful luxuries which breed disease amongst the rich, whilst they raise the price of provisions for the poor! We are all familiar with the lines in the *New Bath Guide*—

"So, when they had wasted more meat at their breakfast,
Than the poor of the parish had had for a week past."

Such proceedings we may expect to see put down, when the clergy follow out the principles of true temperance to their logical end. They will protest against soups in which prodigious quantities of beef, and veal, and ham have been wastefully boiled down for "stock." These *entrées* will be silently rebuked, and pass untasted, on which the cook has lavished his truffles and condiments, and no *foies gras* will be extracted from the wretched geese of Strasbourg. In the higher ranks there are more victims to eating than to drinking; and if people did not eat of indigestible dishes, they would not be so much tempted to drink. We will not pursue what may be taken as sarcasm, although we affirm seriously that the principle of abstaining, for example sake, from the innocent enjoyment of things wherein others indulge to excess, is a principle which need not begin and end with alcoholic liquors. There is one manly and sensible paper in the magazine before us, by the Rev. Mr. Ellison, of Windsor; the rest are very poor, and more calculated to repel than to attract converts.

The Brown Book. A Book of Ready Reference to the Hotels, Lodging and Boarding Houses, Breakfast and Dining Rooms, Libraries, Public and Circulating, Amusements, Hospitals, Schools, and Charitable Institutions of London; and a Handy List, showing the nearest Post Office, Money Order Office, Cab Stand, Police Station, Fire Engine, Fire Escape, Hospital, to 1000 Principal Streets of the Metropolis. London: Saunders and Otley. 1864. Half-yearly. Price 2s. 6d.

** The detailed title is a sufficient explanation of this useful compilation. It is supplementary to "Red" and "Blue" books in its contents.

The Preparation and Mounting of Microscopic Objects. By Thomas Davics. London: R. Hardwicke.

** A good and practical little book, likely to be of value to working microscopists. It contains, for the most part, trustworthy formulæ and directions for preservative solutions, minute injections, and many other matters beyond the scope of systematic treatises.

Traité Theorique et Pratique des Maladies des Yeux. Par L. Wecker, etc. Tome premier. Deuxième fascicule. 8vo. Paris: Adrien Delahaye. 1863.

** This fasciculus contains diseases of the sclerotic, cornea, iris, and choroid. It will be easily understood how many moot points of modern practice occur in the course of it. Iridectomy is illustrated by some excellent woodcuts.

Homes without Hands. By the Rev. J. G. Wood, M.A., F.L.S. Part 2. London: Longman and Co.

** Completes the burrowing mammals and begins the birds. The illustrations are very good.

British and Foreign Medico-Chirurgical Review. January, 1864. London: John Churchill and Sons.

APPOINTMENTS FOR THE WEEK.

February 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Professor Frankland, "On the Metallic Elements."

15. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital 1½ p.m.; Samaritan Hospital, 2½ p.m. MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures on Physiology.—Lecture I.—The Rate of Pulsation under the Influence of numerous Agencies in Health and Disease. By Edward Smith, M.D., F.R.S., F.R.C.P.

16. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting. PATHOLOGICAL SOCIETY, 8 p.m. Meeting. ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."

17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m. JUNIOR MEDICAL SOCIETY OF LONDON (Whittington Club-house, Arundel-street, Strand), 8 p.m. Mr. J. Warrington Haward, "On the Treatment of Hernia."

18. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m. ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."

19. Friday.

Operations, Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 3 p.m. W. S. Savory, Esq., "On Dreaming and Somnambulism."

ORIGINAL LECTURES.

LECTURES ON
THE BRITISH PHARMACOPŒIA:
ITS CONSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,
AND THE
VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians: Physician to King's College Hospital.

LECTURE III.

Mr. PRESIDENT,—At my last Lecture, I endeavoured to give a short account of some of the more important remedies newly introduced into the British Pharmacopœia. I shall continue this subject to-day; and not only speak of the Medicines themselves, but likewise of any of their preparations which I think of importance to be known to the Practitioner, reserving for a future Lecture my remarks on many of the new preparations of drugs which have hitherto found a place in the Pharmacopœia of this College. As the substances of which I shall have to speak are somewhat numerous, and as the number of these Lectures is very limited, I shall be compelled to make my remarks upon them as terse and practical as possible, and not attempt to go into details as to their physical characters and composition.

First, of the Salts of Silver. The only novelty among the preparations of silver is the introduction of the oxide of the metal, and the transference of the crystallised nitrate from the appendix to the body of the work. Has the oxide of silver any properties which entitle it to be placed in the *Materia Medica*? Let us look at its characters and composition. It is simply a compound of one equivalent of silver and one of oxygen, and its symbol is Ag_2O ; the union of its elements is not very strong, a red heat being sufficient to cause the reduction of the silver to the metallic state. It is insoluble in water, but readily dissolved by acids; and, when introduced into the stomach, soon becomes absorbed into the system, probably as the chloride.

It differs from the nitrate in being much less caustic; and hence its topical action is by no means so energetic. Nevertheless, when taken internally, it exerts, in certain irritated conditions of the mucous membrane, a well-marked sedative influence; and, from my own experience, I can confidently assert that it is a remedy of great value in many forms of gastric disturbance. Furthermore, there can be little doubt that, in cases where the absorption of silver into the system is desirable, this preparation offers many advantages. It has been stated to have proved useful in some forms of hæmorrhage; and could not fail to be efficacious in those nervous affections in which the nitrate of silver has been ordinarily administered. It has been occasionally asserted that the oxide of silver possesses an advantage over the nitrate, in not causing the darkening of the skin. I certainly never heard of a case in which this symptom has manifested itself during the exhibition of this remedy; but I do not for a moment suppose but that the oxide, if continued for a lengthened period, would induce the same discoloration as the nitrate. We can hardly conceive the contrary, for both the nitrate and oxide are reduced to the same state in the stomach before absorption ensues. We must remember that the coloration of the skin, which is due to the reduction of the oxide and the deposition of metallic silver, is an effect which never ensues until the nitrate has been taken for several months; and I doubt if there are many instances on record of such a prolonged administration of the oxide of silver.

The dose of the oxide of silver is from a quarter to a half, or even one grain, and it is, perhaps, best given in a very simple form, as with crumb of bread. When united with certain organic substances, the silver becomes reduced, and there is one remedy with which it is peculiarly incompatible, and with which it is not unlikely to be prescribed in stomach affections. I allude to creosote. When these two bodies are mixed together, the

creosote becomes oxidised; great heat and even flame may be produced; and I am informed that pills thus composed have undergone combustion upon the druggist's counter.

A remedy under the name of Bael, or Bael, is contained in the *Materia Medica*, which consists of the dried, half-ripe fruit of the *Ægle Marmelos*, a tree belonging to the natural order *Aurantiaceæ*. The characters of this drug, which you will see in this specimen, I had occasion to mention in a former Lecture, when giving examples of the manner in which the first part of the Pharmacopœia is constructed.

One preparation only is introduced—a liquid extract, of which each fluid ounce is intended to contain the valuable properties of a solid ounce of the Bael.

Bael has been much used in India—in fact, it is commonly called Indian Bael. I believe it was introduced into this country chiefly by those who had employed it abroad.

Its chemical composition has by no means been accurately determined; it contains some astringent principle, probably more or less allied to tannic acid.

As to its use, I have only to remark, that in India its reputation stands high in the treatment of chronic diarrhœa and dysentery. My own experience of its powers is very slight, scarcely worth mentioning. I have, however, known it to fail, and gallic acid and opium to have been afterwards successful.

Of Belladonna I have but little to remark, excepting that the root of the plant has been introduced, and a liniment, termed "*Linimentum Belladonnæ*," ordered to be made from it, and that the sulphate of atropine is omitted. Perhaps, however, it may be well to say a few words concerning these changes.

That Belladonna and its alkaloid, atropine, possess the power of producing a topical influence, independent of any appreciable general symptoms, may be readily demonstrated from their effect when applied to the eye; for if such application be made with any moderate amount of the drug, the pupil of that eye only with which it comes into contact becomes affected. That its action is often simply local can be further shown from the fact that, although it usually requires as much as one-thirtieth of a grain of atropine administered internally to produce an appreciable effect upon the pupils of the eyes, yet, when applied topically, as I have repeatedly seen, the effect is produced by a millionth and even half a millionth of a grain. We have also abundant evidence, from clinical experience, that Belladonna acts topically in allaying pain, as frequently witnessed in cases of pleurodynia and other neuralgic affections.

As a topical agent, the tincture of the Pharmacopœia produces little effect, owing to its want of strength; the extract, to say the best of it, is a disagreeable and dirty preparation, and the alkaloid atropine very expensive. To remedy these evils, the Belladonna liniment has been introduced, made by percolating the dried root, and using such proportions of rectified spirit and powdered root, that each fluid part of the liniment represents the activity of the solid part of the drug from which it is prepared; a little camphor is added to give it the characters of a liniment rather than a tincture, and to increase its stimulant properties. Belladonna liniment has the colour of sherry wine, and forms a clean, and, I believe, efficacious local application in cases in which the topical influence of Belladonna is desired. It may be interesting to you that I should give some information as to the strength of this new liniment in comparison with the tincture of the Pharmacopœia. The method by which I ascertained this point was to observe the amount of dilution which the two preparations would bear before a drop applied to the eye began to show evidence of losing the power of dilating the pupil. In the case of the tincture, which is almost the same strength as the London preparation, I found it would bear dilution in the proportion of one part of the tincture to 200 of water; but when the liniment was made use of, one pint of it could be diluted with as much, or even more than 2000 parts of water, before it exhibited any want of dilating power; so that we may conclude that the latter compound is quite ten times more powerful than the former. Its elegance, strength, and inexpensiveness compared with atropine are the chief qualifications of *Linimentum Belladonnæ*, and it will doubtless become a favourite remedy for the alleviation of pain.

The Sulphate of Atropine has been omitted, partly from its not being required, partly from the salt not being a very satisfactory one in a pharmaceutical point of view, from the difficulty of crystallising it. Atropine itself forms very definite and beautiful crystals, and a solution of it, under the

name of *Liquor Atropiæ*, has been introduced, each fluid ounce containing four grains of the alkaloid; and the solution, more or less diluted, will form a convenient preparation for the ophthalmic Surgeon.

I may take the present opportunity of showing a fine specimen of the fresh *Belladonna* root, which has been procured and kindly sent me by Mr. Squire.

From the natural order *Gentianaceæ* a new bitter has been made officinal under the name of *Chirata*, and consisting of the entire plant of *Ophelia chirata*, which grows in the northern parts of India. The English name is *Chiretta*. Of this drug an infusion and tincture are ordered in the *Pharmacopœia*.

Of the value of *Chiretta* as a therapeutic agent I have little to remark: it contains a bitter principle, not unlike that contained in *Gentian* root, and but very little volatile oil; hence the taste of *Chiretta* has more of the simple intense bitter than the latter substance. It is a common remedy in India, and takes the place in that country of *Gentian*. It is a valuable stomachic, and is especially useful in forms of atonic dyspepsia, the result of too free living and indulgence in the use of alcoholic beverages. The dose of the tincture is from half a drachm to one drachm; of the infusion, from a fluid ounce to an ounce and a-half.

The dried fruit of a menisperm, the *Anamirta cocculus*, growing in Malabar and in the islands of the Eastern Archipelago, and commonly known by the name of *Cocculus Indicus*, has found a place in the *British Pharmacopœia* under the name of *Cocculus*.

The chemistry of this substance is not devoid of interest; the seed, which in good fruit should fill at least two-thirds of the shell, contains a non-nitrogenised, crystalline principle, picrotosine, $C_{10}H_6O_4$, and in the shell there is an alkaloid menispermine, $C_{18}H_{12}NO_2$, united with an acid.

There is but one preparation in the *Pharmacopœia*, *Unguentum Cocculi*, made by rubbing up 80 grains of the powdered seeds with an ounce of prepared lard. Picrotoxin is a principle possessing some considerable power, and appears to give to the seeds of the fruit their poisonous properties.

The action of *Cocculus* is evidently directed to some part of the nervous system, possibly the corpora quadrigemina and cerebellum; at any rate, animals under its influence lose the power of controlling their movements. Probably many of us have seen its action upon fish, how they turn on one side and are unable to swim; the higher classes of animals, as birds and mammals, are similarly influenced by *Cocculus*, or its principle, picrotoxin. The effect of the drug upon man has been but little studied, although from the large amount imported, and the small quantity which is used in a legitimate manner, it is more than probable that many are unconsciously affected by it. When in malt liquors, it appears to produce an unwillingness to move, perhaps a partial inability, without the ordinary symptoms of intoxication; so that the individual becomes desirous of remaining where he is, but still able to drink more. In large doses it is poisonous, not only to the vertebrate, but to the invertebrate animals also.

As to its therapeutics: I believe it has never been employed except as an external agent in obstinate cases of skin disease, as *tinea capitis*; it is also used for destroying pediculi. There is one precaution to be taken, which is never to use it to an abraded surface; death has resulted from absorption.

Considering that heavy penalties are imposed upon certain manufacturers for having the article in their possession, and upon the druggist for selling it to them, and, moreover, that as yet it has not been shown to be superior to many other external applications, it cannot but be regretted that it should have found a place in the *British Pharmacopœia*. It would, nevertheless, be interesting to examine the action of picrotoxin upon the nervous system, as possibly it may possess powers capable of being applied advantageously in practice.

Although introduced many years since into practice, and inserted in the last edition of the *Dublin Pharmacopœia*, *Cannabis Indica*, or *Indian Hemp*, is now for the first time made officinal in England. It consists of the flowering tops of the female plant, *Cannabis Sativa*, strongly imbued with a resinous exudation; and it is to this resin, which is only produced when the plant grows in warm climates, as India, that the *Hemp* owes its powers as a remedial agent. As you will observe in the specimens, the drug consists of the tops of the plant, including flowers, fruit, and smaller leaves matted together by a resinous substance, having a powerful and peculiar odour, and a dark green colour.

Of the composition of the resin nothing very definite is

known, saving that it possesses many of the properties of other resinous substances.

Two preparations are contained in the *Pharmacopœia*,—an alcoholic extract, and a tincture made by dissolving the extract in rectified spirit, in the proportion of nearly $2\frac{3}{4}$ grains to each fluid drachm.

Although *Indian Hemp* has been used in medicine for several years, a thorough investigation of its physiological action and therapeutic qualities is still a desideratum. That its effects are exerted upon the brain is manifest from the fact, that when given in large doses it causes delirium, and in smaller ones an exaltation of the mental faculties; and for this latter purpose it is so largely employed by Asiatics, under the form of hachish. In this respect it resembles somewhat closely the preparation of certain solanaceous plants, as *belladonna*, *stramonium*, and *hyoscyamus*. It, however, differs from these remedies in not causing dilatation of the pupil when administered internally or applied to the eye itself. Its action as an anodyne appears to be well established, and neuralgic pains are often greatly benefited by its exhibition; in some cases, when the dose is carried high, a sensation of numbness has been stated to be produced. Its powers as an antispasmodic are also pretty well made out. I have never found any direct soporific effects from *Indian Hemp*; although in some cases of wakefulness, arising from an over irritable state of the nervous system, it has allowed sleep to ensue. It would appear, then, that *Cannabis Indica* exerts its influence both on the brain and spinal cord; but of the nature of this influence, when compared with that of many other narcotics, we are at present ignorant. It differs in many important respects from opium, and most advantageously, in not causing the constipation, loss of appetite, and many of the other discomforts which arise from the use of that medicine.

The dose of the *Extract of Indian Hemp* is from a quarter to one grain, or more; of the *Tincture*, from $m\text{v}$. to $m\text{xxx}$. It is of great importance that it should be of good quality, and much that is comparatively inert has, at times, been sold. It should also be remembered that, when mixed with water, the resin is precipitated, and is apt to be slowly deposited on the sides of the bottle. A little spirits of ammonia causes it to be held in solution.

An uncrystallisable substance, considered to be the active principle of *Digitalis*, has been placed in the *Materia Medica*; it is called *Digitalinum*, or *Digitalin*; it occurs, as you will observe, in greyish white scales, is very sparingly soluble in water and ether, but readily dissolved by spirit. Although rendered soluble by acids, it has no power of neutralising them, and, chemically considered, is an indifferent or neutral body.

Physiologically and therapeutically, *digitalin* appears to possess the powers of the plant itself, but it is stated to be 100 times more powerful than the dried leaf. I have no experience of its action; but, from its want of crystallising power, which renders it doubtful if it be a pure principle; from the readiness with which it may be adulterated, and the difficulty of detecting admixture; and, likewise, from its extreme activity when pure, I cannot look upon it as a remedial agent which it would be difficult to dispense with.

The dose of *Digitalin* which may be given with perfect safety is from one-fiftieth of a grain upwards.

I mention *upwards*, because you are aware that *Digitalis*, although looked upon as a very potent remedy, can be given in doses very much larger than is usually supposed. At the very commencement of my Medical studies,—now twenty-eight years since—I became familiar with the administration of *Tincture of Digitalis* in quarter, half, and even ounce doses, given at that time in phthisis with the view of diminishing the rapidity of the pulse; and also after operations, with the idea of preventing the supervention of inflammation. Within the last few years the use of large doses of *Digitalis* has been revived; and the late Mr. Jones, of Jersey, employed them successfully in the treatment of delirium tremens. To his paper I must refer you. In a few cases of that disease I have made trial of the remedy, and am convinced that, where the malady is uncomplicated with inflammation of the brain structures, it is a most potent and satisfactory mode of treatment. About two years since, I suggested to my friend, Dr. Lockhart Robertson, the probability of large doses of *Digitalis* proving of value in acute mania. He has acted upon the suggestion, and recently published his results, which appear to be highly satisfactory. The real value of *Digitalis* as a remedy requires and merits a further searching clinical inquiry.

(To be continued.)

COURSE OF
LECTURES
ON THE URINE AND DISEASES OF THE
URINARY ORGANS. (a)

By GEORGE HARLEY, M.D.,

Professor in University College, and Assistant-Physician to University College Hospital.

LECTURE II.

GENTLEMEN,—Having seen how the quantity of liquid excreted by the kidneys varies, not only relatively at each micturition, but absolutely during the whole twenty-four hours, I have next to point out to you how the relative and absolute amount of solids excreted also varies, and call attention to the causes which induce the variations.

The solids consist of all that remains behind when the aqueous part of the urine is driven off by evaporation. They appear in the form of a brown-coloured, strongly-scented, bitter-tasted mass, which, on analysis, is found to be composed of acids and bases, organic as well as inorganic. Normal human urine contains the following :—

	Acids.	Bases.
Inorganic .	Hydrochloric.	Ammonia.
	Sulphuric.	Soda.
	Nitric.	Potash.
	Carbonic.	Magnesia.
	Phosphoric.	Iron.
	Fluoric.	Lime.
Organic .	Uric.	Urea.
	Hippuric.	Urohæmatin.
	Oxalic.	Creatinin.
	Lactic.	Resin.
	Malic.	Fat.
	Phenylic.	Albumen.
		Mucus. (b)

It was previously said, that the kidneys act the part of safety-valves to the system, in regulating the amount of fluid in the circulation; they might with equal justice be called the "scavengers" of the frame, for not only do they eliminate the normally *effete* elements of the tissues, but also all foreign and noxious materials that chance to have found their way into the circulation. Hence it is, that we occasionally find a variety of substances in the urine, many of which cannot have played any part in the processes of life, as they are expelled from the circulation almost as rapidly as they are absorbed. Ferrocyanide of potassium, for example, has been detected in the urine within two minutes after it was taken into the stomach; and many mineral and vegetable poisons are to be found in the urine within a very brief period after their admission into the system.

As regards *Sediments*, I may here state, once for all, that no spontaneous deposit takes place in normal urine within twenty-four hours after being voided. The only thing which

FIG. 5.

is at all visible to the naked eye is a small quantity of mucus, which appears after six or seven hours as a white hazy cloud, suspended (not deposited) in the clear transparent urine.—Fig. 5. For the purpose of demonstration, the mucus cloud is here represented much more distinct than natural; it ought only to be visible, and nothing more.

Whenever, therefore, any kind of deposit spontaneously forms within twenty-four hours, the urine may be regarded as abnormal. Either the proportion of some one or other of its solids is too great, or the proportion of its water is too little.

The effect of a mere diminution of the aqueous particles of the urine is easily rendered apparent, by simply concentrating a little of a perfectly healthy specimen. If, as soon as it is reduced to about one half of its bulk, it be placed aside to cool, a number of its solids will be precipitated in a crystalline form, the characters of which can be readily recognised

by the aid of a microscope. This fact we occasionally turn to practical account when searching for substances which, like leucin and tyrosin, are only crystallisable in concentrated solutions.

PHYSIOLOGICAL AND PATHOLOGICAL CONDITIONS INFLUENCING THE EXCRETION OF URINARY SOLIDS.

There are several physiological as well as pathological conditions which cause the absolute quantity of solids passed in the twenty-four hours to vary in different individuals, and even at different times, in the same individual. In consulting books on the urine, you will be struck with the apparent discrepancies of French, English, and German writers as regards the quantity of solids passed by healthy individuals. Thus, an adult male on a mixed diet is said to pass on an average the following amounts :

	Amount of Solids in Twenty-four Hours.	
	grammes.	grains.
Frenchman (Becquerel)	39.52 =	612.56
Englishman (myself)	53.00 =	821.50
German (Lehmann)	67.82 =	1051.21

Paradoxical though it appears, each of these statements is in itself correct, the variance being simply due to the national peculiarity of the individual; not that the French, German, and English constitutions are essentially different, but on account of the modes of life, and especially the diet of the individuals, being different. For example, Frenchmen take much vegetable, and little animal food, and what animal food they take is not of the most nourishing kind; first, because it is originally inferior; and secondly, because, in order to make it palatable, it is submitted to a complicated process of cookery, which still further decreases its nutritive value. Englishmen, on the other hand, eat moderately of both vegetable and animal diet; while our German *confrères*, on whom the experiments have mostly been made, contrary to their own opinions, eat largely of all foods. (c) In order to show you that this is no imaginary statement, and that diet does exert the influence here attributed to it, I shall quote to you the results of an experiment made by a German (Lehmann) on himself :—

	Diet.	Solids in Twenty-four Hours' Urine.	
		grammes.	grains.
	Animal	87.44 =	1355.32
	Mixed	67.82 =	1051.21
	Vegetable	59.23 =	918.06
	Non-nitrogenised	41.68 =	646.04

Here is at once seen the immense influence diet exerts over the amount of solids excreted by the kidneys. They are, it will be observed, increased by an animal, diminished by a vegetable, and still further reduced by a non-nitrogenised diet; and this, you will remember, is a precisely similar result to that noticed regarding the effect of diet on the quantity of liquid voided in the twenty-four hours. Curiously enough, the same rule holds good regarding the effect of drink on the solids; for, just as the amount of solids taken into the stomach influences the quantity of water eliminated by the kidneys, so the amount of water taken into the stomach influences the amount of solids excreted by the kidneys.

For a long time, Lecanu denied that with an excess of drink there was an augmentation of solid matter passed with the urine; but the researches of Winter, Vogel, and others, have placed the fact beyond a doubt. To me it appears quite natural that it should be so; not because I imagine that the fluids drunk augment to any great extent the metamorphosis of the tissues, but because, by increasing the quantity of fluid in the intestines, more food is dissolved, and consequently more solid matter absorbed into the circulation, and the excess beyond what the wants of the system require is excreted by the kidneys.

This view is founded on the result of an experiment made by Kierulf, who found that, after injecting water directly into the circulation, the solid matters of the urine were very little increased, although the urine became albuminous. Whereas, had the water which was injected directly into the blood been administered by the stomach, the urinary solids would have been proportionally augmented. Of course, no one would seek to deny that an excess of water in the circulation accelerates, to some extent, the metamorphosis of the tissues; all that it is desired to prove is, that this is neither the only nor the chief cause of the augmentation of the urinary solids after the free use of liquids.

(c) As a nation, the Germans are much worse fed than the English; but the students and Professors, on whom the experiments on healthy urine have been made, are a striking exception to this rule, as any one who has sat at a German *table d'hôte* must have observed.

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

(b) Some authors add to these bases manganese and creatin, and, to the acids, taurylic, damolic, and damaluric; but they are so rarely found in healthy urine, that they scarcely deserve being noticed.

It must be borne in mind that the foregoing remarks have only reference to the amount of solids eliminated in the twenty-four hours; for the proportion of solid matter excreted at each micturition is, in reality, reduced after free drinking. This is easily understood when we remember that there are three kinds of urine passed during the day,—the *urina sanguinis*, *urina potûs*, and *urina cibi*,—and that these differ in specific gravity; the difference being due to the variable amount of solids they contain. For example, if there are 46.6 grammes of solids in every 1000 cubic centimetres of the twenty-four hours' urine, possessing a specific gravity of 1020, there will be in every

Cubic Centimetres.	Specific Gravity.	Grammes.	Grains.
1000 of <i>urina cibi</i>	1025	58.25 =	902.87
„ „ <i>sanguinis</i>	1017	39.61 =	613.95
„ „ <i>potûs</i>	1009	20.97 =	325.03

Mother, aged 27; weight, 140 lbs.

	First Analysis.		Second Analysis.		Third Analysis.		Total Average.		Solids per lb. of bodily weight.	
	grammes.	grains.	grammes.	grains.	grammes.	grains.	grammes.	grains.	grammes.	grains.
Total solids in twenty-four hours	45.64 =	707.42	43.94 =	681.07	43.66 =	676.73	44.41 =	688.35	0.31 =	4.80
Organic substance	31.73 =	491.81	32.04 =	496.62	33.78 =	523.59	32.51 =	503.90	0.23 =	3.56
Inorganic salts	13.91 =	215.60	11.89 =	184.29	9.87 =	111.98	11.89 =	184.29	0.08 =	1.24

Female Child, aged 1½ year; weight, 21 lbs.

	Average of First and Second Analysis, calculated on Forty-eight Hours' Urine.		Third Analysis.		Total Average.		Solids per lb. of bodily weight.	
	grammes.	grains.	grammes.	grains.	grammes.	grains.	grammes.	grains.
Total solids in twenty-four hours	12.40 =	192.20	12.04 =	186.62	12.22 =	189.41	0.58 =	8.99
Organic substance	7.42 =	115.01	6.59 =	102.14	7.00 =	108.59	0.33 =	5.11
Inorganic salts	4.98 =	77.19	5.44 =	84.32	5.21 =	80.75	0.24 =	3.72

The influence of sex is no less remarkable than the influence of age, as is seen by the subjoined table, representing the average relative proportion of organic and inorganic salts daily eliminated by an adult English man and woman. The table is made from an average of four analyses:—

In Twenty-four Hours' Urine. Average weight, 140 lbs.; age, 25 years.

	Males.		Females.	
	grms.	grains.	grms.	grains.
Total solids	53.00 =	821.50	44.50 =	689.75
Organic	36.60 =	567.30	31.00 =	480.50
Inorganic	16.40 =	248.70	13.50 =	209.25
Solids per lb. of bodily weight	0.37 =	5.73	0.35 =	5.42

Women, it appears, therefore, excrete, both absolutely and relatively, less solid matter than men. (d)

INFLUENCE OF PREGNANCY.

Of all physiological conditions, that of pregnancy has the greatest effect upon the daily excretion of solid matter by the kidneys. The following observations were made on a *prima-para*, aged 26 years:—

Period of Gestation.	Total Solids.		Organic.		Inorganic.	
	grms.	grains.	grms.	grains.	grms.	grains.
Two months and a-half	57.99 =	898.84	42.88 =	664.64	15.11 =	234.20
Fifth month, ten days after quickening	57.61 =	892.95	40.55 =	628.52	17.06 =	264.43
Seventh month	45.64 =	707.42	31.73 =	491.81	13.90 =	215.45
Ninth month, three days before delivery	43.94 =	681.07	32.04 =	496.62	11.89 =	184.29

Here it is clearly seen, that the nearer we approach delivery the less solids are excreted, and there can be little doubt but that this arises from the fact, that the more developed the foetus the more nutritive material it withdraws from its mother's circulation, and consequently the less remains to be excreted by the kidneys. It is to be remembered, too, that the effete products of the foetal tissues are not directly returned to the maternal blood to be excreted along with her own, but are eliminated by the foetal kidneys in the shape of urine, which is expelled from its bladder into the liquor amnii. This is, in fact, the true explanation why urea is so often detected in the amniotic fluid.

(To be continued.)

(d) Parkes gives the mean solids at 61.14 grammes, 945 grains; but this arises from his including the high average of the Germans.

So that when we speak of the drink augmenting the urinary solids, we mean augmenting the total quantity excreted in the twenty-four hours.

INFLUENCE OF AGE AND SEX ON THE URINARY SOLIDS.

Age has evidently an important influence on the urinary solids; and although as yet few observations have been made on this point, they, nevertheless, all tend to one conclusion, namely, that children excrete, proportionally, more solid matter than adults. For instance, I found that, while a female child, aged 18 months, excreted 0.58 grammes (8.99 grains) for every pound of her weight, the mother, aged 27 years, living under the same conditions, excreted little more than half that amount (0.31 grammes = 4.80 grains) for every pound of hers.

ORIGINAL COMMUNICATIONS.

CASES OF EPILEPSY, CONVULSIONS, GIDDINESS, ETC.

PART OF A SERIES ILLUSTRATING AFFECTIONS OF THE NERVOUS SYSTEM, OF ORGANIC AND INORGANIC ORIGIN, WITH CLINICAL AND PATHOLOGICAL OBSERVATIONS.

By JOHN W. OGLE, M.D., F.R.C.P.,
Assistant-Physician to, and Lecturer on Medical Pathology at, St. George's Hospital.

(Continued from page 641, vol. ii., 1863.)

Case 82.—Jane C. A. A., aged 1½ year, a previously healthy child, who had never been the subject of any convulsive attacks, had been severely scalded about the upper part of her body, and was admitted into the Hospital in a state of collapse. Wine and ammoniated salines were ordered. In the course of the following night a convulsive "fit" occurred; but on the morning following the child appeared quite free from its effects, and was without pain. She continued in all respects to go on well for some days. On the 23rd, however, a second convulsive attack took place during the night, and again the child went on well. On the 27th, several convulsive attacks occurred, and on the 28th she was in a semi-comatose state. She swallowed food from time to time, but gradually sank and died, without any special symptoms referable to disease in the cranium or any internal organ showing themselves. (a)

On post-mortem examination the cranial veins and sinuses were found to be very full of blood, and a large quantity of serous fluid existed beneath the arachnoid membrane generally. Moreover, a considerable amount of extravasated blood was found among the subarachnoid tissues covering the upper and outer side of the right cerebral hemisphere. The same was found, though to a slighter degree, at a corresponding part of the left hemisphere. Again, numbers of minute dots of extravasated blood were found in the subarachnoid textures covering the whole surface of the cerebellum. On dividing the substance of the brain it was found that the grey matter of both cerebral hemispheres, where corresponding with the extravasated blood before described, was unusually

(a) See "Hospital Post-mortem Book," 1853, page 48.

pink, and much softened. This softening extended half an inch in depth from the surface of the brain. The right hemisphere of the brain was, throughout, more vascular than the left one. The heart was healthy, and also the lungs. A slight quantity of muco-purulent fluid was found in the bronchial tubes. All the abdominal organs were quite healthy.

Case 83.—James K., aged 10, with dark eyes and hair, irregular decayed teeth, and head somewhat large (measuring twelve inches over the vertex from ear to ear, and twenty and a-quarter round the head over the occipital and frontal protuberances), became an out-patient under my care on February 17, 1862. He was intelligent, and had talked at 2 years of age, and walked at 5 years; but when teething at 2 years of age had had "some sort of a convulsion." No more attacks had appeared until 1860. Moreover, in 1859, he had measles and sore-throat, followed by a discharge from both ears, which left off after four months' continuance. In 1860 he began to have frequent fits, which mostly occurred during the day. During the attacks he became very dark in the face, or very pale, and foamed at the mouth, but did not bite the tongue; and lost consciousness for several minutes. He generally stiffened all the limbs, clenched the hands, and firmly closed the teeth, the face and eyes being drawn to the left side, and the right leg and arm being drawn upwards. Immediately before the fits occurred he would often make half a circle backwards (always from left to right), and then stagger and fall. On some occasions, his mother said, he had "turned three times on his right leg" before falling. After the attacks he would generally sleep soundly, and subsequently feel great lassitude. He never had any distinct warning or premonitory symptom of the attacks, such as pain, etc. The bowels were generally costive. No intestinal worms were known to exist. When first seen as a patient, the pupils were dilated, acting tolerably well, and equal in size. The tongue was clean. There was slight congestion of the conjunctivæ. The pulse was feeble. Urine free from albumen. Ordered the syrup of iodide of iron and cod-liver oil twice a-day, and the "mistura gentian co." from time to time. Subsequently he took the "mist. ferri co." and "extract belladonnæ" for two months. For several weeks he had a number of strong fits, often many in one day, and complained of being always worse when he was prevented going out to take exercise. He never suffered pain either before or after the attacks. At the beginning of May, his mother said that during the attacks the "face would sink" on to the chest, and he would "subside on to the ground" whilst in a sitting posture. After the sleep which followed the attacks he would get all right again. His mother also in May stated again, that before falling on his face in the attacks, as he often did, he would "go round three times." At this period he took the "liquor gallii alb." for a month. In June, the attacks in the night were bad, and it was noticed that the evacuations were very light in colour. Small doses of hyd. c. creta, followed by senna wine, were given, and also the nitrate of potash and extract of taraxacum. The attacks were still, however, very frequent and severe, and he discontinued attendance at the Hospital, and was attended by Mr. C. Hunter, of Wilton-place, at his own house, owing to pain in the head and coma which came on. Mr. Hunter has informed me that when he was called to attend him in June he had "fits" every half hour, that the eyes were red, the head hot, and the pulse very rapid, and that he was treated with calomel and opium, then with calomel alone, leeches to the temples, cold to the head, which was shaved, and aperients. Subsequently the muscular spasms became more restricted to the neck and face, and gradually ceased, so that on July 8 there had been no fits for eight days, and none recurred afterwards. Ever since he has remained quite free from anything like epilepsy, or other symptoms of any affection of the nervous system. I saw him at the end of October last, and ascertained that he had remained perfectly well since July, 1862, and was apparently in rude health and good spirits, having grown much.

Case 84.—Elizabeth M., aged 6 years, always a delicate child, for five days previously had been affected by short attacks, in which she turned quite pale, as if fainting, and lay insensible, with slight jerking of the whole frame. There had been about three attacks each day. She had never had any of them before. Two years previously she had had whooping cough.

Thinking that possibly intestinal worms, or other irritation of the stomach or bowels, might exist, I cleared out the bowels by calomel and scammony powder, and gave her small doses of bicarbonate of potash and chloric ether in the infusion of orange peel.

No ascarides were passed, though the bowels were emptied

several times, and in such a way as to show that fecal matter had been long accumulating.

Subsequently, small doses of the ammonio-citrate of iron and the aromatic spirits of ammonia were given, and the aperient powders occasionally. At the end of three or four days' treatment the seizures complained of had quite disappeared, and at the end of one month the child was discharged as quite well.

Case 85.—Henry J. D., aged 11 months, during the period that he was "cutting his teeth," was affected by a dry cough, attended by "spasmodic inspiration." This had been going on for some weeks. He was somewhat delicate in look, but of healthy family. Ordered the syrup of iodide of iron, twenty drops, along with a teaspoonful of cod-liver oil twice a-day, and, with the expectation that possibly there might be ascarides in the bowels, a dose of the compound scammony powder.

No worms were voided; and at the end of three weeks, during which time the remedies were continued, it was reported that the spasmodic inspiration was very greatly diminished both as regarded frequency and intensity, and this was especially so at night. It continued, however, in some degree. At the end of seven weeks the report was that all spasm had entirely ceased. The medicine was continued, and another of the scammony powders given, but without the effect of evacuating any worms. Two weeks later there was a slight return of spasm, the steel wine was given three times a-day, and the bowels kept gently open with castor oil. He was discharged as being quite well after a short time.

Case 86.—John P., aged 3 years, had a cough for seven days, and was cutting the lower molar teeth on the right side. Some days previously he had vomited his food, and this vomiting was followed by fever and thirst; on the next day he had several severe attacks of convulsions, with intervals of great drowsiness; he had also pain in the chest and dyspnoea. He had taken "powders" of some kind or other.

He was admitted into the Hospital (b) in a comatose state, with closed eyes, the face very pale, and the pulse weak. Leeches were applied to the temples. On the following day the eyes were opened, and he was conscious, complaining of great pain in the chest, and his breathing was "short and laboured." There was much thirst, and the pulse was weak. The gums were ordered to be lanced. He went on tolerably well for four days, when he again became comatose, and was constantly moaning.

Two days later he was again sensible, but much weaker. He gradually sank, and died on the thirteenth day after admission.

On post-mortem examination, the lower parts of the lungs were found in a state of grey hepatisation, and to contain several small abscesses. The brain was found to be quite healthy, and the other organs of the body free from any disease.

Case 87.—James B., aged 45, a wheelwright, otherwise healthy, had been for two years subject to frequent headaches, and a confused, giddy feeling about the head, which made him constantly think that he was "about to have a fit." The bowels were regular; the urine clear, and free from albumen. The pulse was 68, and regular, but feeble. There was nothing observable about the muscles of the face, the eyes, etc., and there was no symptom of defective sensibility or motion in any of the limbs. Various modes of treatment had, apparently, been resorted to without success.

Ordered, emplast. lyttæ nuchæ; and the liquor hyd. bichl., ʒss; liquor potassæ, mxx.; tinct. cinch. co., ʒj.; decoct. cinchonæ, ad ʒiss. bis die.

At the end of two weeks the patient said that he had experienced great relief from the blister. The pulse was still very weak.

He continued taking the medicine for six weeks, only varied by occasional aperients of colocyth and calomel, and of rhubarb and magnesia, as he complained of irregular action of the bowels, and of symptoms which he termed "bilious;" but throughout his attendance the tongue remained clean. At the end of six weeks the patient was discharged as free from headache, and also from any unpleasant, giddy, or other sensations.

Case 88.—Henry P., aged 36, an irregular and intemperate man, was admitted into St. George's Hospital August 1, 1849, affected by jaundice, which had been preceded by sickness and vomiting. For two or three days before admission he had been "wandering" in his mind. He had not been the

(b) See "Post-mortem and Red Book," 1847, p. 96.

subject of any spasmodic affection up to 12 years of age (excepting certain convulsions as an infant), until a few days before his admission, when he had an attack of epilepsy, during which he bit his tongue, and lost consciousness for a period of several hours. Before admission into the Hospital leeches had been applied, and he had been salivated.

On admission it was found that a large tumour of the liver existed, and that blood was being passed by the bowels. The urine contained a quantity of yellow colouring matter; the bowels were much confined, etc.

Salines and purgatives were given, and leeches applied to relieve pain and feeling of tension over the region of the liver.

He had a second epileptic fit in a few days, from which he recovered well; but a third one came on, and he sank and died August 8.

On post-mortem examination, (c) the left side of his liver was found to be the seat of a large hydatid cyst. The heart's cavities were dilated; the lining of the heart and of the pulmonary vessels was much blood-tinged. The cranial bones were thickened, but the brain was quite healthy in structure; the cerebral vessels somewhat congested. The dura mater was tinged of a yellow colour. The other organs were natural.

Case 89.—Elizabeth H., subject to epileptic attacks for nine years, an elderly woman, whose mother and father and three brothers had died of fits, and whose grandson had fits, which began when he was 18 years of age. The attacks were generally at night, and were preceded by a feeling as if she was standing on her head, which lasted about a minute or two. Latterly she had been insensible for some time during the fits, and once or twice for some days afterwards. During the attacks there was no screaming and no struggling, merely a slight "catching" of the limbs, and some rattling in the throat. The intellect was generally good, but at times there was a degree of "wandering." Occasional deafness existed, but the senses of smell and taste were natural. There had been a degree of dysphagia at times ever since the first fit happened. Quinine, bark, and aperients were persisted in for three months, during which time the patient complained of giddiness, noises in the head, etc., and was subject to attacks of "catching" of the left side and face during the night. I then lost sight of the patient.

Case 90.—George W., aged 38, a cook, had for two years been subject to a feeling of "numbness" at the back of the head, also in both hands (especially the right one) and in the fingers, and in the left leg, beginning with headache. He had never had a regular "fit," but at times the "weakness" and numbness, and partial loss of senses, had been so great, that he was obliged to lay hold of chairs, etc., to prevent himself falling down. The power of motion of all the limbs was unaffected, as also the sensibility of the skin. The pulse was feeble, but regular; the skin cool; the tongue creamy; the conjunctivæ of the eyes somewhat vascular; the bowels were regular; there was no cough and no anasæra; the urine was free from albumen.

Ordered the tinct. ferri sesquichl., ℥xx.; sp. æther. chloric, ℥xv.; infus. quassia, ter. die.

At the end of one week the tongue was much better, but the pains in the head said to be much "sharper."

Quinine and iron were then given, and occasionally the haust. sennæ of the Hospital. Afterwards the mist. gentian co. of the Pharmacopœia was given, but the increased action of the bowels produced was said to make the patient worse. Fifteen drops of the tincture of foxglove were then given, along with twenty drops of the aromatic spirits of ammonia, in camphor mixture thrice a-day, and continued for a month. Eventually the giddiness ceased to trouble him, except on walking much; and the numbness gradually ceased, until at last he was discharged as "feeling well," ten weeks after his first application to the Hospital.

Case 91.—Thomas D., aged 61, had been subject to epileptic attacks for five years more or less, but for nine months had had none until three weeks previous to his application. They were originally caused, apparently, by fright, in connexion with some punishment in the army when living in the West Indies. The attacks were generally preceded by a painful feeling of swelling about the lower costal cartilages on the left side. Potatoes, if half cooked, would always cause the attacks, as he thought. He was in the habit of vomiting his food, and was evidently dyspeptic.

Ordered the hydrocyanic acid, with bicarb. of soda and tincture of columba, to which was added subsequently the ammon. cit. of iron. During the next two weeks five fits had

occurred; but vomiting had ceased. The pulse was very weak. Quinine and iron, with chloric ether, were then given. During the next week there were two fits.

After that I lost sight of the patient.

Case 92.—Richard D., aged 27, was admitted into St. George's Hospital, July 11, 1858, for irritability of the bladder and stricture of the urethra. Pneumonia came on, and eventually delirium and epileptic attacks; coma supervened before death.

After death no cause was found for the epileptic attack and delirium, etc. The kidneys were quite healthy.

Case 93.—In the number for December 18, 1852, of this Journal, (d) I published "a case of epilepsy," independent of the present series of observations. I propose to give some particulars of the progress of the case, which, I think, was one of considerable interest. It was that of a gentleman of delicate health, H. F. S., aged 21, whose symptoms were decidedly of an apoplectic as well as of an epileptic nature. He had had seizures in 1850, 1851, and 1852, for the most part following heavy, indigestible meals. Subsequently to the account given as above, the patient continued to have attacks even more frequently, and consulted Dr. Marshall Hall and others. They then occurred much oftener than before, and, indeed, came on every three or four months, retaining on the whole their former character. The patient, however, gained general power and tone—more, according to his own opinion, from the use of strychnia than from anything else, which he took pretty regularly for nearly a year. The attacks continued until his marriage in 1856 or 1857, and afterwards until the summer of 1859, when he was attacked by pneumonia on the left side, and abscess of the same lung, as evidenced by the sudden expectoration of a quantity of pus, sometimes with, at others without blood admixed. During this illness he burnt one of his feet extremely, owing to some accident with a hot-water bottle which was applied in bed. The burn caused a sore, which "festered" and formed an abscess in the sole of the foot, which remained unhealed for several months, partly, no doubt, owing to its position. At last, however, it healed; but as far as the present time, February, 1864, there has been no return whatever of epileptic attacks, and no positive threatenings of such ever since the attack of pneumonia in 1859, up to which time they had occurred very frequently— even every three or four months.

I ought to have previously stated that tonics of all kinds, and also the belladonna, had in this case been tried ineffectually as regards arresting the fits, although the general health had improved.

(To be continued.)

NOTICE OF ÆGLE MARMELOS. CORR. (NAT. ORD. AURANTIACEÆ.)

THE BELA, OR BAEL OF THE NEW BRITISH PHARMACOPŒIA.

By EDWARD J. WARING, Esq., F.L.S.,
Her Majesty's Indian Medical Service.

Ægle Marmelos.—Correa in Linn. Trans., vol. xxii., D.C., Prod. i., p. 538; Wight. Icones, i., t. 16; Roxb. Coromandel, pl. ii., t. 143; *Cratava marmelos*, Linn., sp. pl. 637; *Feronia pellucida*, Roth. Nov. Spec., p. 384; *Cydonia quæ marmelos*, *Arbor dicta*, Burm. Thes. Zeylan, p. 84; *Bilva*, or *Mahura*, Sir W. Jones, Asiat. Res., p. 348; *Bilacus*, or *Bilanus*, Rump. Herb. Amb., i., p. 197, t. 348; *Covalum*, Rheede Hort. Malab., iii., p. 37, t. 87; *Marmelos de Bengala*, seu *Mala Cydonia e Bengala*, Garcia ab Horto, Aromat. (Ed. Clusius, 1585), p. 199.

Botanical Description.—A small tree, trunk pretty erect, bark ash-coloured; branches few and irregular; thorns axillary, in pairs, single or none, very sharp and strong; leaves ternate; leaflets oblong or oblongo-lanceolate, attenuated to a bent point, crenulate, differing much in size, but the exterior one is always the largest; panicles small, terminal, and axillary; flowers large and white, hermaphrodite; calyx four or five-toothed; petals four to five; filaments about forty, short; anthers linear, erect; fruit large, spheroidal, smooth with a hard shell, and ten to fifteen cells filled with a tenacious, transparent gluten; seeds six to ten in each cell, oblong, a little compressed, woolly, attached to the inner angle of their cell.—(Lindley.)

Vernac. Synonyms.—The Bael, or Bengal Quince Tree (Eng.); Bivalva, Bilva, Mahura (Sans.); Seferjel-hindee

(Persian); Bilwa, Bêl, Bael, (Hindústani); Bela (Beng.); Mârèdu (Telegu); Vilva-marum (Tamul); Bel-puttrie (Canarese); Oo-sheet (Burmese); Covalum (Malabar); Beli, Belighas (Cingalese); Tanghula (Malay); Modjo, or Modsho (Javanese.)

Habitat.—Common in most parts of Bengal, extending down the whole of the western side of the Bay of Bengal, the Tenasserim Provinces, and Malayan Peninsular; also in Coromandel, Malabar, and other parts of Southern India, and Ceylon. It is generally found near temples, being one of the sacred trees of the Hindoos. Cultivated in the Mauritius.

Medical Properties and Uses.—This tree has apparently from the earliest ages enjoyed a high repute amongst the natives of India for its medicinal properties. All parts of it have been employed, as a summary of its uses, published some years since, by Baboo Ramcomol Gher (*Med. and Phys. Trans. of Calcutta*, vol. iv., p. 110), would indicate. According to this writer, the bark of the root in decoction (ʒj., aq. Oj., boiled to ʒiv.) is administered in bilious fevers; the bark of the stem is employed in similar cases, but generally in conjunction with other articles; the expressed juice of the leaves, which is slightly pungent and bitter, causes diaphoresis, and is given in colds and incipient fevers; the young leaves made warm are applied to the eyes in ophthalmia, to allay pain and inflammation; the unripe fruit in decoction is highly valued in dysentery and diarrhoea, especially when they occur in children, and the ripe fruit is employed in the same cases; and in the form of sherbet with tamarinds proves serviceable in febrile attacks, to allay thirst, heat, etc. The fruit is the part which chiefly merits attention, possessing, as it apparently does, the valuable property of establishing a healthy tone in the stomach and bowels, arresting diarrhoea when present, and acting as a mild aperient when constipation exists.

The dried fruit imported into England was analysed by Mr. H. Pollock (*Lancet*, July, 1853). He found that the pulp and dried shell of the fruit did not differ chemically in any respect, except as to quantity. They both contained—1, tannic acid; 2, a concrete essential oil; 3, a bitter principle; and 4, a vegetable acid. The pulp also contained a considerable quantity of sugar. Professor Macnamara, of Calcutta (*Indian Ann. of Med. Science*, vol. 2, p. 233), chemically examined the fruit, both in its mature and immature state: he found the ripe to contain more tannin than the unripe fruit, in the proportion of five to three; it likewise contained more sugar, also more of the bitter principle and vegetable acid. After extracting from the fruit the matters soluble in water, there was obtained, by means of ether, a balsam having a strong odour, like that of Peruvian balsam; this was found to exist in much larger quantities in the ripe than in the unripe fruit. The comparative deficiencies in these substances in the unripe fruit were compensated for by the gummy extractive and fibrous matters. The astringent action of the bael is due to the tannin; but Dr. Macnamara suggests that to the balsam is due the tone which this fruit gives to the coats of the intestines, rendering the secretions of the mucous membrane more healthy. It may advantageously be given in the form of sherbet. Thus, take of the soft gummy substance from the interior of the fruit, ʒij.; mix with ʒiij. to ʒiv. of water; sweeten with sugar to the taste; and add, if procurable, a lump of ice. This agreeable drink possesses the aroma of the fruit, and may be repeated twice or thrice daily. When prepared from the ripe fruit, it is not only astringent, but possesses the singular property of being aperient if the bowels are irregular and costive. When the patient is debilitated, and the stomach weak, it sometimes disagrees; it ought then to be given in small repeated doses, and if these also are rejected, the extract may be tried. The dose of the extract is, ʒss. to ʒj., twice or thrice daily. Another good mode of administration is that of marmalade, prepared in the same manner as orange marmalade; it is usually taken like it, spread upon bread. It has the great advantage of keeping well for a long period.

Therapeutic Applications.—In various forms of intestinal derangement, bael exercises a marked and valuable influence. Its use in diarrhoea and dysentery was first noticed in 1563 by Garcia, ab Horto, and subsequently by Rheede ("Hort. Mal.," iii., p. 37), Burman ("Flor. Ind. Ed.," 1768, p. 109), Bontius, and other early writers on the botany of the East; but it is only of late that European Practitioners in India became fully aware of its value in this class of diseases. In 1853, Sir Ranald Martin called attention to its use (*Lancet*, 1853, vol. ii., p. 53); and in the following year Dr. Alexander Grant, of the Bengal Medical Service, published a most excellent paper on this fruit (*Ind. Annals of Med.*, ii., p. 225), bringing

together all that had hitherto been known on the subject, and recording his own experience and that of others in its use. With regard to his own experience, he states, that he has been in the habit of recommending the sherbet (ante) as an aperient to persons subject to habitual constipation; a small tumblerful, taken early in the morning, producing generally one evacuation daily. In cases of dyspepsia, with obscure symptoms of land scurvy, it seemed also to act very favourably, and to possess alterative as well as antiscorbutic qualities. Many persons in Bengal (continues Dr. Grant) suffer, especially during the rainy season, from attacks of irregularity of the bowels, periods of looseness alternating with others of constipation. In such states of the system, the sherbet acts admirably; in the first instance as an astringent, and in the second as an aperient. It seems, in both these opposite conditions, to stimulate the mucous membrane to more natural and regular action, combining with the ingesta, and aiding healthy assimilation. It has been given, with very satisfactory results, to persons of delicate and weakly habits, subject to excessive mucous diarrhoea; it has been chiefly employed in cases of chronic dysentery and diarrhoea among native prisoners in the Bengal jails; most of such patients are in a condition of greatly depressed vitality, either anæmic, scorbutic, or debilitated and anasarous. Here mercury cannot be given in any form, for it acts as a poison, and opium checks the secretions of the liver. The bael fruit generally fails, as every other medicine would fail, to effect a cure; but it often does more good than any other remedy, and is always of temporary benefit. When stimulants were indicated, a small quantity of palm wine was allowed. Dr. Grant also quotes the experience of Drs. Stewart and Jackson, of Calcutta. The former states that, for years past, he has employed the bael, and that he never uses any other form than a sherbet of the ripe fruit, and he prescribes it, not only as an astringent in disease, but as a preventive of diarrhoea in persons subject to that complaint. According to Dr. Jackson, the bael is most successful in the chronic forms of dysentery, when the stools are frequent and bloody, mixed with mucus. When there is much heat of skin, it does not agree so well, and he has often been obliged to discontinue it, in consequence of the flatulence and indigestion it causes. He adds that, as a regulator of the bowels, half a tumbler of the sherbet, with a little sugar, will act in producing one healthy evacuation, and that he has known many people take it in this way as an aperient. In the diarrhoea after cholera, he has used the sherbet very beneficially.

Dr. Grant likewise adduces the experience of Dr. E. Good- eve, Dr. R. Moir, and Dr. Chuckerbutty, all of whom speak more or less favourably of its operation. Dr. Cleghorn, in his paper on the bael (*Ind. Ann. of Med.*, ii., p. 223), also quotes Dr. Sanderson, of Madras, and others, in favour of its efficacy. Dr. Kirkpatrick (*Madras Exh. Cat.*, No. 381, "Remarks") states that several cases of intermittent fever, accompanied with chronic dysentery, have been cured, under his own observation, by this remedy alone. He employs the following formula:—Two fruits, shells and all, bruised, are to be boiled in a quart of water till reduced to ʒxij.; of this, ʒvj. a day, in divided doses, should be taken, the dose to be diminished as the disease yields to the remedy. In some cases of dysentery, in the advanced stages, and in the diarrhoea of natives, I have seen unequivocal benefit from its use; it must be regarded as a remedy of very great value in this class of cases.

ATROCIOUS AND BASELESS CHARGE AGAINST A MEDICAL MAN.—On Tuesday, February 2, in the Belfast Police-court, a woman, named Rose Drummond, brought a charge of indecent assault against Dr. Charles Stewart Corry. After a long investigation, which lasted two days, the magistrates dismissed the case as utterly groundless, and unsupported by a shadow of evidence. Dr. Corry is a Dispensary Surgeon, and was engaged to attend the woman Drummond in her confinement. The *Northern Whig*, in a leading article on the subject, expresses the strongest sympathy with Dr. Corry, in having been made the victim of a trumped-up charge, and animadverts on the conduct of the magistrates, who adjourned the case to suit the convenience of the plaintiff's lawyer. It is said that Dr. Corry will not allow the matter to rest, but will prosecute the plaintiff and others on a charge of conspiracy.

CATTLE DISEASE IN VIENNA.—Disease of cattle is committing terrible ravages in Vienna, especially among the dairy cows.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

CASE OF DISLOCATION OF THE RIGHT FEMUR ON THE DORSUM OF THE ILIUM—REDUCTION WITHOUT PULLEYS ON THE TENTH DAY—FRACTURE OF THE LEFT FEMUR.

(Under the care of Mr. HULKE.)

A LABOURER, aged 36, working in a pit at Finchley, was struck down by a mass of falling gravel. The Surgeon who was called found his left femur broken, and suspected dislocation at the right hip; but there was already so much swelling that an accurate examination was not possible. On the fifth day, the swelling having lessened, a dislocation was recognised, and reduction was attempted with pulleys and chloroform; but without success. When he had somewhat recovered, he was sent to the Hospital, which he reached, much exhausted by the jolting of the cart.

The right thigh was slightly flexed, adducted, and rotated inwards, its axis making an angle of 20° with that of the trunk. The patella rested against the inner side of the other thigh, just above the knee. The upper border of the great trochanter was distant four and a-half inches from the anterior superior spine of the ilium; and the head of the femur could be distinctly felt (at this time) on the dorsum of this bone.

The fracture of the left femur, and overlapping of the fragments, prevented a satisfactory comparison of the length of the right with that of the left limb.

Next day, the tenth after the accident, the patient having been laid on a mattress placed on the floor, and brought fully under the influence of chloroform, Mr. Hulke, who was seeing Mr. Moore's patients, made an attempt to reduce the dislocation by extension in the direction of the axis of the thigh, with a jack-towel fastened above the knee, and counter-pressure with the foot resting on the tuber ischii. This brought the head of the bone lower down on the dorsum ilii; but failing, after seven minutes' trial, to bring it into the acetabulum, the plan was changed. The pelvis was held firmly against the mattress, the thigh was flexed on the belly and adducted, and upward traction was made with the towel across the axis of the trunk. The thigh was next adducted and rotated outwards, when reduction immediately occurred, with a slight snap. The legs were tied together, and a bag of ice was kept on the hip during several days. In the fourth week, the plaster bandage was removed from the left femur; the fracture was apparently consolidated; but, as considerable shortening was found on comparing the limbs, Mr. Moore, under whose charge the patient then was, reapplied the long splint, making extension with an India-rubber accelerator attached to the foot. This reduced the shortening to three-quarters of an inch. The man left the Hospital, ten weeks after his admission, with the fracture firm, and the complete restoration of the natural movement of the hip.

SUB-CORACOID DISLOCATION OF THE HUMERUS—REDUCTION, WITHOUT PULLEYS, TEN WEEKS AFTERWARDS.

(Under the care of Mr. HULKE.)

A stout, healthy young woman, in falling, struck her shoulder against a step; much swelling followed. A Surgeon thought that the humerus was broken near the joint, and applied splints. Ten weeks afterwards, by which time the fracture was thought to have firmly knit, the arm remaining very stiff, she was brought under Mr. Hulke's notice. The shoulder was angular. There was a hollow under the acromion, and an unnatural, rounded prominence, visible through the greater pectoral muscle, which rotated with the humerus. Flexion, extension, and adduction were possible in a limited extent, but abduction was not possible. The elbow pointed slightly backwards and from the side. The deltoid was much wasted. She complained of severe pain darting from under the collar-bone to the shoulder-blade. The distance between the tip of the acromion and the outer condyle of the humerus was nearly three quarters of an inch greater than in the uninjured arm. There

was evidently a sub-coracoid luxation of the head of the humerus.

Chloroform was given. The arm was abducted and forcibly rotated in order to break up adhesions. These gave way with loud cracking, and rotation became free. The arm was then adducted, extension was made with a round towel, fixed with a clovehitch above the elbow, and, with the foot in the axilla, the head of the bone returned to the glenoid cavity with a jerk and snap.

NOTES ON THE USE OF TINCTURE OF LARCH IN CHRONIC BRONCHIAL AFFECTIONS.

By Dr. HEADLAM GREENHOW, Assistant-Physician to the Hospital.

THERE is a certain stage of chronic bronchitis in which expectorants cease to be useful. More or less copious expectoration, indeed, still continues, but the acute symptoms have subsided, and the secretion from the bronchial membrane may be regarded rather in the light of a passive flux than as the immediate result of irritation. In such cases, the object of the Physician must, therefore, be rather to check than to encourage the continuance of the expectoration. In patients who have suffered from repeated attacks of bronchitis, this stage of the disease often persists for a lengthened period, and may even ultimately become the habitual condition of the patient. A somewhat analogous condition of the bronchial membrane is frequently met with in cases in which there has been no previous attack of acute or sub-acute bronchitis, but in which the ailment, having begun with a slight increase of bronchial secretion, has gradually merged into a chronic cough attended by expectoration. This latter form of bronchial affection is especially apt to occur in patients of gouty constitution, and also in persons exposed to breathe either the over-dried atmosphere of artificially-warmed and ill-ventilated apartments, or air charged with mechanical, gaseous, or other irritants. In whichever of these forms the chronic flux from the bronchial membrane may present itself, its tendency, even in slight cases, is to impair the general health and vigour of the patient, and to render him more especially liable to suffer from catarrhal attacks, each repetition of which further aggravates, and tends to render permanent the bronchial affection. Various remedies have long been in use for the treatment of this class of cases, especially balsamic medicines—such as balsam of copaiba, ammoniacum, and compound tincture of benzoin. Of these, balsam of copaiba is undoubtedly the most efficacious; but its nauseous taste and smell, for the most part, forbid its employment. Moreover, in many of such cases, there is a feeble condition of the digestive powers in which these balsamic medicines are apt to disagree with the stomach, and a want of general tone and vigour, requiring the administration of tonics. I have now, during some five or six years, been using, with much success, the tincture of larch in the treatment of these forms of bronchial affection. The tincture is made from the inner bark of the larch tree, and its taste is much less unpleasant than that of any of the above-named remedies. I have rarely found it disorder the stomach, and it is capable of being given in combination with tonics, or any other remedies the case may require. I most frequently prescribe it, in Hospital practice, in doses of from twenty to thirty minims, in a mixture consisting of tincture of gentian, nitro-muriatic acid, and water, with or without ipecacuanha wine, and either tincture of hyoscyamus or compound tincture of camphor, according to the more or less frequency and severity of the cough. When desirable, the mixture may be rendered more agreeable to the taste by the substitution of syrup of orange peel for tincture of gentian. Of the value of the tincture of larch as a remedy in the large class of cases above described, I entertain no doubt, having tested its efficacy very carefully, and having repeatedly found that patients improved greatly under its use when other medicines had failed. I have in a few cases tried an extract of larch bark, but have found it less decidedly useful than the tincture, which is also the most convenient form for administration. It will be inferred from the tenor of the foregoing observations, that tincture of larch will be found useful only in chronic forms of bronchial disease, attended by considerable expectoration. Its employment is contraindicated in acute bronchitis, or during the intercurrent catarrhal attacks, to which patients suffering from chronic bronchitis of long standing are so liable. Its effect as a remedy is gradually to lessen the amount of expectoration, and with it the cough and dyspnoea, and at the same time to render patients much less subject to catarrhal attacks at particular seasons or changes of weather.

ROYAL PORTSMOUTH AND PORTSEA AND GOSPORT HOSPITAL.

INJURY TO SPINE FOLLOWED BY COMPLETE PARAPLEGIA—RECOVERY.

(Under the care of Dr. J. W. MOORE MILLER.)

M. R., aged 22, jumped out of window in a drunken fit about nine months since. Paralysis of the legs instantly followed, and complete anæsthesia as high as the crests of the ilia. She suffered extreme pain in her back. Her bowels were very obstinate, and the bladder had to be emptied by the catheter.

The patient was admitted into the Hospital on June 9, 1863, nine months after the accident; she then stated that the pain had gradually subsided during the last four months, and that she had gained slight power over her legs. She could only stand with assistance. The bladder acted feebly, and the bowels were very costive. The sensibility of the skin was dull over both legs, but there was marked anæsthesia over left calf, right gluteal region, and right side of vulva. On examining the spine, a posterior curvature was discovered involving the lower dorsal vertebræ. The treatment consisted in iodide of potassium internally with the occasional use of mild aperients. She was directed to rest on the abdomen, and the muscles were regularly stimulated by Faradisation.

At the end of one month she had made considerable improvement; she could stand alone for some minutes, and with assistance walk along the ward. There was, however, much more power over the right than the left foot, the flexor muscles of the toes acting very feebly, while the extensors continued completely paralysed.

When discharged, September 1, her general health was good. Sensibility had everywhere completely returned, and although she could walk firmly, there was still only partial power over the left foot—it was raised, and then flapped down awkwardly.

Remarks.—This case is interesting because it is an illustration of recovery after a very severe injury of the spinal cord. The injury sustained by the fall appears to have been partial dislocation of one or more of the vertebræ backwards, at the same time the spinal canal was broken and the cord compressed. Nature's adapting processes were assisted by remedies to improve the nutrition of the cord; rest and position to relieve congestion; while the paralysed muscles were artificially exercised to preserve them from degeneration. The cure unfortunately was not quite complete; the flexors and extensors of the left foot remain permanently injured, and voluntary control over them is lost. This is not the result, however, of any change in the substance of these muscles or their nerves, but is due, in all probability, to defective nutrition and wasting of some nerve-tubes of the anterior columns or anterior roots belonging to them; and thus their communications with the brain have been severed at the seat of injury.

ACUTE MYELITIS—RECOVERY—REMARKS.

(Under the care of Dr. JOHN WARD COUSINS.)

J. H., aged 36, a gardener, was taken ill after watching in his field during a wet night. I saw him on November 14, 1862, and he then complained of pain in all his limbs and over the chest, together with a sensation like a cord tied round his body. His sleep was disturbed by "spasms" in his legs. He looked flushed and anxious; pulse 100; skin hot; and tongue coated. The next day the following notes were taken:—General hyperæsthesia is now present (especially over left side of body), and loss of power over both legs, which are frequently drawn up by spasmodic reflex movements. The left side of the body is still very painful, and his left arm and both legs are the seat of uneasy sensations, which he compares "to the gnawing of dogs." A warm sponge applied over the spine, from the dorsal region downwards, excites an intense sensation of burning, and the spinous processes are tender on percussion. There is no loss of power over the arms, and the control over the bladder is natural. The treatment commenced with a quarter of a grain of extract of belladonna every six hours, and the patient was placed on milk diet.

November 20.—The febrile symptoms have all subsided, and he is able to stand. Reflex movements of the legs much diminished. The belladonna was now combined with ergot of rye; blistering fluid was applied on each side of the spine, and a better diet ordered.

25th.—Slight hyperæsthesia still remains over left arm and leg. He can move his legs now freely when lying down. To-day he attempted to walk, but his gait is characteristically

myelitic. His general health is improving. The pills were now prescribed twice a-day, with a mixture of iodide of potassium and decoction of bark.

29th.—Patient now walks much better. Hyperæsthesia only slight over left leg. He continued daily to improve until the middle of December, when he was discharged cured.

Remarks.—On reviewing this case, the prominent symptoms—hyperæsthesia and loss of voluntary movement—plainly indicate, that the posterior columns were the portions of the spinal cord chiefly involved. The morbid action appears to have extended through a considerable portion of their length and thickness, because (1st) the sensibility of the four limbs was increased, and (2nd) had the alteration been limited to a small part of their length, there would have been but little loss of voluntary movement. The cord, however, was not much affected below the middle of the dorso-lumbar swelling, otherwise the sphincters of the bladder and rectum could not have escaped. The patient complained of a great deal of pain and "spasm" in the limbs, which suggests the probability that the case was complicated with some spinal meningitis. Had the anterior columns been the chief seat of the disorder, the power of motion would not have been greater in the recumbent position, but the limbs would have been paralysed, sensibility diminished, and the symptoms of myelitis less marked. On the other hand, we must admit that there was some inflammatory change in the grey matter, as the patient suffered from uneasy sensations at the periphery; but this part of the cord could have only been slightly involved, without diminution or loss of sensibility replacing the marked hyperæsthesia.

CHRONIC MYELITIS LIMITED TO CERVICO-BRANCHIAL REGION.

(Under the care of Dr. JOHN WARD COUSINS.)

M. D., aged 49, a widow, came under my care in April, 1862, suffering from severe neuralgic pain over right shoulder and down the arm. She continued under treatment some weeks, and was discharged relieved. She was admitted again into the Hospital on May 8, 1863, when the following symptoms were present:—Intense hyperæsthesia down the right arm, especially over biceps and dorsum of the thumb; the left is only very slightly affected. There is also increased sensibility of right cheek, without any change in the pupil. Hyperæsthesia, too, is marked on the right side of the spine, as low down as the middle of the back, and over the left leg. The lower cervical spinous processes are tender on percussion, and a warm sponge applied over them excites intense pain. The patient complains of a feeling resembling a cord tied round the chest, and of pain in the cervical and occipital regions. Her pulse was small and feeble, and lately her strength had much declined. She said "her arms were weak," but there was no perceptible alteration in voluntary control or reflex movement of either the upper or lower extremities. The treatment consisted in the internal administration of belladonna and ergot of rye, and the application of blistering fluid to each side of the spine in the cervical region. Her improvement was very satisfactory; the hyperæsthesia slowly subsided, and on June 26 she was discharged "quite well." Lately she has had a slight return of the old neuralgic pains in the left arm and shoulder.

Remarks.—This case is an illustration of the fact, that "hyperæsthesia, contrary to anæsthesia, may exist alone." Some vascular changes probably occurred in the posterior columns of the cervico-branchial swelling of the cord, too limited to produce any distinct loss of voluntary control over the upper limbs. For the same reason there were no increased reflex movements of the legs, and standing and walking could be performed without any apparent difficulty. Some fibres of the sympathetic, however, appear to have been involved, which caused the hyperæsthesia of the cheek; and the occipital pain the patient suffered had likewise a spinal origin.

DEATH OF DR. ELFINGER.—Dr. Elfinger, so celebrated in Germany as a painter of pathological objects, died suddenly last month in Vienna from an attack of hæmoptysis, having been only an hour before engaged in taking some laryngoscopic views for Dr. Türk, in the Vienna General Hospital. Our readers must be well aware of his powers as a faithful pathological artist, through the plates of skin diseases he has brought out in co-operation with Hebra, several of which have been republished by the New Sydenham Society.

Medical Times and Gazette.

SATURDAY, FEBRUARY 20.

ARMY MEDICAL DEPARTMENT.

ON the 9th inst. the Army Medical Department recruited its ranks from the candidates at the Competitive Examination. That the official net has been cast in many waters to catch young fish we have no doubt, but very considerable doubts about the vessel of the Department sinking under the weight of the draught. It would be an affectation in us to express sympathy with the official fishers at the limited supply of Medical candidates, or at their inferior quality, under the present regulations, government, and position of the Medical element in the army. It appears, moreover, that the Department is losing its hold upon those already within its bonds, for we have noticed, within as many weeks, the retirement of three senior Assistant-Surgeons.

We need not go far to seek the causes of this unpopularity. The aspect of things has altered in the world. Science now holds a place in our universities and in public opinion, which was once occupied by the cultivators of letters only. The men of mere learning and scholastic acquirements no longer fill the places, as they fail to respond to the wants of this generation. That these possessions will always bring honour, and never fail to confer benefit, may be true enough; but classical acquirements are no longer everything, and a man may win his spurs in the field of the physical sciences as well as literature. The Medical student of this day is a very different, as well as a rarer animal than of yore. His education is twice as good, and the expense of attaining it has equally increased. Commensurately with these advances has there been a progressive change in the social position and feelings of the Profession, both as a body and as individuals. There are a larger number of men of good birth and means, as well as of excellent general education, aspiring to Medicine as a profession than formerly. Men enter the arena of our Medical Schools better disciplined for the race before them—better prepared to pursue the study of a special science, and to practise it afterwards, as members of a liberal Profession. Necessarily, therefore, men like these look forward to filling positions which may enable them to pursue their functions with a due amount of independence and self-respect, and with corresponding honours and emolument.

A few changes in our services would bring numerous votaries to the Government shrines. But what do we find? Have any of the reforms with which the Medical press has been teeming of late been introduced? We fear not. Nothing has been done to diminish the congestion, arising from arrested circulation, in the lower ranks of the Department. Is it likely that an expensively educated man will enter a service where the steps of his promotion are under fifteen per annum, and where Assistant-Surgeons of some eight or nine years' service have 150 names above them. The Government, sooner or later—and the sooner the better, for the interests of everybody—must yield, and permit an earlier retirement than the

present. But it has been said, that men do not live by bread alone. Are there, then, no other causes operating to deter men from entering H.M.'s army? We have alluded to the regulations affecting the branding of soldiers, which still continue in force. Of late years, to add to the uncertainty and cloudiness which surround a Medical officer's position, we learn that they are tied down in the most stringent manner, in all cases, to the diets as laid down in the regulations. Not only is the hand of an attendant on the sick made to perform a large amount of writing for every—even the simplest—extra that may be given, but he cannot prescribe the cheapest drinks or certain diets without performing a sickening amount of writing, or paying for them himself. We have forgotten in how many ways the diet of a sick man has to be rendered, so numerous are they. We are perfectly aware that restraints must be imposed, but the restrictions are so many as to become irksome and irritating, and, in the cases of indolent, unconscientious men, can only operate banefully upon the sick soldier. It is ridiculous to suppose that a patient, on the eve of dying or the advent of recovery from a severe disease, should have to wait for a piece of fowl until the day after he asks for it, in order that he should be placed on a chicken diet, or that a sick man, on any diet, should not be allowed an inexpensive drink without the sanction of the Director-General being first had and obtained. Take, again, the subject of recruiting. It is not exactly logical that the most responsible duty in the passing of recruits should fall to the lot of one who does not receive the recompense for the individual so passed into the service, but whose pocket is placed in jeopardy if he be rejected. Still, Medical officers would have no great cause of complaint if they had to pay for cases of a negligent and defective exercise of their senses; but they declare that no latitude is allowed them for exercising the discretion indicated by the opening paragraphs in the regulations on this head, and they, therefore, think it safer to consider a healthy man with the cicatrix of a leech-bite ineligible.

All this kind of thing is very short-sighted; and we regret that the Medical officials in high places appear to have no power, or no desire, to remove, at any rate, these ridiculous sources of discontent.

THE CENSUS.

A THIRD volume, recently presented to Parliament on the subject of the Census in 1861, contains the general report of results arrived at in that important inquiry. - Seventy-six pages are devoted specially to this document, which is signed by the Registrar-general, Dr. W. Farr, and Mr. F. T. Hammick. It is followed by an appendix of great length, and very varied contents, which swells the size of the volume to 248 pages in all.

It is unnecessary to point out the immense and incalculable value of such a work, nor need expressions of a complimentary character be wasted on gentlemen who already rank among the highest authorities in their own branch of scientific research. It may better serve more practical purposes if we suggest the danger there is of investigations like this, pursued with ardor and ability, at an enormous expense of thought and labour, being lost sight of, and, as it were, overlaid by the very Government patronage which gives them their origin and encouragement. Bluebooks are proverbially, though unjustly, held to be dull reading. It is our pleasant duty to state that this report is not a blue, but rather a slate-coloured or neutral-tint book, and that, far from being dull, it is most attractive and enlivening. One advantage it borrows from its blue predecessors, and that is cheapness. George Edward Eyre and William Spottiswoode, no less excellent as men than distinguished as Royal printers, append to their title-page a pregnant statement—price 2s. 10d. Let us impress on our readers that thirty-four pence could not be

better spent than in procuring this handsome folio. Although results of honest scientific work such as these are like the old satirist's verses—

“Nec Scombros metuentia carmina, nec Thus”—

still we entertain no doubt that an economical purchaser might to a large extent *recoup* himself the expenditure in the household value of the very paper on which they are printed.

There is obviously more material than can be done justice to in a single notice. Nor need the accusation of tediousness be feared if we recur to the subject once and again. The report of this, the seventh, census of England opens by an account of local machinery for its management—the formation of districts, appointment of enumerators, and the like. England and Wales formed 30,329 enumeration districts; islands in the British seas, 300; and 533 public institutions had their own enumerator. Floating population, whether literally in vessels, docks, boats, and barges, or metaphorically “in barns, sheds, caravans, tents, etc., or in the open air,” required special arrangements. This and the subsequent collection of schedules, with collateral army returns and similar administrative points, are very briefly told. The total population of the United Kingdom was 29,321,288, and the increase in England and Wales since last census 2,174,327. Females exceeded males. “The nomadic race” numbered above 10,000. Inmates of public institutions, quaintly divided into voluntary and involuntary, numbered 26,096 criminals, 24,345 lunatics, 10,414 patients, 125,722 poor and infirm in workhouses, 23,598 in charitable asylums. Houses, families, towns, parishes, and militia districts are in turn noticed. Then paragraphs follow on age and conjugal condition, the law of population, occupations of the people; migrations come next, and are succeeded by facts as to the blind, deaf, and dumb. The tenth section is devoted to workhouses, prisons, asylums, and Hospitals, and to it we may recur hereafter. Short passages relating to the islands in the British seas, and the area and population of the British empire, including colonies and possessions, bring the report itself to a termination.

When we add that there is an appendix treating specially of the Medical Profession, enough has already been shown of its contents to justify the inference, that this work, if not in every Medical Practitioner's private library, should at least be accessible through the instrumentality of Medical book clubs and on the table of public libraries.

THE WEEK.

DR. TURNBULL AND THE HORSEGUARDS.

WE are happy to state that the announcement which appeared in the *Lancet*, to the effect that Dr. Turnbull, of the 6th Dragoons, has been placed on half-pay, is incorrect. Dr. Turnbull's contradiction of the statement is published in the *Daily Telegraph* of Wednesday, Feb. 17.

GALLANT CONDUCT OF NAVAL AND MILITARY SURGEONS.

COMMODORE SIR WM. WISEMAN, in his despatch, dated November 30, speaks in high commendation of the intrepid conduct of the two Assistant-Surgeons who landed with the party of seamen and marines, sent to act in concert with the troops in the recent attack on the Maori works at Rangariri. We are happy to see that the *Gazette*, in which the Commodore's despatch appears, contains the announcement of the promotion of Dr. Messer to the rank of Surgeon. The Commodore writes:—

“17. I would also bring to their Lordships' notice the admirable conduct of Assistant-Surgeons A. B. Messer, of the *Curaçoa*, and Duncan Hilston, of the *Harrier*; they were landed with the seamen and marines, and were indefatigable in their attention to the wounded, dressing them under fire.

“Mr. Messer, when he heard of Mr. Watkins', midshipman of the *Curaçoa*, fall, went up to the body, which was

lying in the ditch, close under the parapet of the enemy's work, to ascertain if he was alive or not; finding he was dead, he returned to attend to the other wounded; he was accompanied both on his going and returning by William Fox, ordinary seaman, of her Majesty's ship *Curaçoa*, and on both occasions exposed to heavy fire.

“The wounded, both naval and military, were brought on board the *Pioneer* and *Avon*, and remained on board till landed at the Naval Camp on Sunday, the 22nd; during the period Doctors Messer and Hilston were unremitting in their attention to them.”

The *Gazette* of Tuesday, February 16, contains the appointment of a successor to Assistant-Surgeon Pile, who lost his life at the Umbeyla Pass.

“101st Foot.—Staff Assistant-Surgeon Acheson George Bartley, M.D., to be Assistant-Surgeon, vice William Pile, M.B., killed in action.”

In the face of such facts as these, no amount of prejudice will suffice to establish the damaging distinction which certain authorities affect to draw between “combatant” and “non-combatant” officers.

PROFESSOR HUXLEY'S LECTURES ON “THE STRUCTURE AND CLASSIFICATION OF THE MAMMALIA,” DELIVERED AT THE ROYAL COLLEGE OF SURGEONS.—LECTURE III.—FEBRUARY 6.

PROFESSOR HUXLEY commenced by quoting a statement of Vic d'Azyr to the effect that, besides the comparative anatomy which aims at comparing the same parts in different animals, there is another comparative anatomy, which has for its object the comparison of the resemblances and differences between corresponding parts of the same individual. Last year, Professor Huxley stated, he had taken up one part of this great subject, and had instituted an examination of the skull and vertebral column, with a view to ascertain how far they were constructed upon the same plan, the result having been that the supposed resemblance did not exist; it was, however, otherwise with the anterior and posterior extremities, which, as is universally admitted, present a remarkable accordance throughout their construction. To point out the details of this accordance is by no means an easy problem, and consequently has received many different solutions. None of these, not even the one now proposed, can be considered as thoroughly satisfactory, as they have not been checked by the aid of a complete study of the development of the parts in question, the only method by which any morphological problem can be absolutely determined. Vic d'Azyr, who took up this subject in the latter part of the last century, thought that the comparison could only be carried out by taking the anterior and posterior limbs of opposite sides, the right upper with the left lower, and *vice versa*, a theory which has met with little or no support. Bourguery and Cruvielhier, seeing that the thumb corresponded with the great toe, and the lower ends of the radius and ulna with those of the tibia and fibula respectively, thought that it was the reverse with the upper ends of these bones, a crossing taking place in the middle of the forearm. Flourens and Martins accounted for the difficulty of the different direction of the articular surfaces of the femur and humerus by supposing that, while the former was a straight and unmodified bone, the latter was twisted on itself to the extent of 180° in man and the higher mammals.

Regarding these theories, and some minor ones which were alluded to, as more or less untenable, Professor Huxley instituted a new comparison of the limbs, placed, not in the position which they assume in adult life, but in the only one in which they really correspond with each other, viz., that which they first exhibit in the embryo. In this condition they stand out at right angles from the body, the extensor surface being placed dorsally, and the flexor surface ventrally, the same for both pair of limbs. They then gradually become bent, and afterwards acquire the modified position which suits them for their functions in life, and to which the various articulations become adapted. The embryonic position continues through-

out life in many Amphibia and Reptiles, and without much change in *Galeopithecus* among Mammals.

The special homotypes of the bones of the extremities were then shown; the division of the bones of the hand and foot into the previously-mentioned tridigital and bidigital series, greatly aiding the comparison. The correspondence of the pollex and hallux and of the other digits, has been admitted by every one. The unciform, magnum, trapezoid, and trapezium of the hand correspond very well with the cuboid and the cuneiform bones of the foot. About the remaining bones there is more difficulty; but there can be little doubt but that the cuneiform and pisiform of the hand correspond to the calcaneum, the lunar to the astragalus and the scaphoid, together with the ninth bone which appears in the carpus of most Apes and many inferior Mammals, to the navicular. The radius was then shown to be homotypical with the tibia, and the ulna with the fibula, all having, however, undergone remarkable adaptive changes in their upper extremities, the ulna being enlarged in this part in the arm, and the tibia in the leg. The correspondences of the humerus and femur were then pointed out, and especially the change that their articular heads have undergone in direction in accordance with the requirements of the position of the body; and it was shown that, owing to the alterations from the original position of the limbs, the fore-part of the arm corresponds morphologically with the hind part of the leg, and the outside of the one with the inside of the other.

The pectoral and pelvic arch offer, at first sight, some difficulties, but by no means of an insuperable nature. The scapula can readily be shown to correspond to the iliac bone, its upper border to the "linea arcuata interna," forming the brim of the pelvis, the spine and acromion to the upper portion of the ilium, the supra-spinous fossa to the iliac fossa. A comparison of the scapula and ilium of the *Ornithorhynchus* shows this relation very clearly. It is generally considered that the pubis and clavicle are homotypes, but there are several strong objections to this view; the attachment of the muscles and the relation of the great vessels are entirely different in each, and, what is more important, the pubis is developed in a pre-existing cartilage, which the clavicle is not. That which corresponds to the clavicle in the lower limb appears to be Poupert's ligament, which, if ossified, would agree well with it in the attachment of muscles and relations of the large vessels and nerves. The coracoid represents the pubis, or the pubis and the ischium, in Man and the higher Mammalia. This resemblance is strengthened by the fact, that in monotremes and reptiles there are two coracoids, with occasionally an aperture between them corresponding to the obturator foramen of the pelvis.

The correspondence that may be traced between the muscles of the anterior and posterior extremities, although not so exact as that existing between the bones, is so well marked that it cannot be regarded as accidental. Many of these have been already alluded to in the preceding lecture, as the mode of insertion of the extensor and the perforating and perforated flexor tendons into the phalanges. The following are the principal muscles of the leg, which clearly correspond to others in the hand:—The tibialis anticus, with its double insertion into the entocuneiform and base of first metatarsal bone to the extensor ossis metacarpi pollicis, inserted into the trapezium and the base of the first metacarpal bone; the difference between them being, that in the first case the larger insertion is into the proximal bone—in the latter, into the distal bone. The peroneus brevis with the gastromenius and soleus, correspond with the extensor carpi ulnaris, being functionally enlarged in the lower extremity; the tibialis posticus with the flexor carpi radialis; the flexor longus digitorum of the foot with the flexor digitorum profundus of the hand; the flexor brevis digitorum of the foot with the flexor digitorum sublimis of the hand; the extensor longus digitorum of the foot with the extensor communis of the hand; the popliteus with the pronator teres; the

gracilis and sartorius with the biceps flexor cubiti; the great adductors with the coraco-brachialis; the iliocubitus with the supra-spinatus; the glutei with the infra-spinatus and teres, etc.

Among the principal differences between the muscular arrangements of the two extremities may be noticed the absence of an opponens to the first metatarsal bone of the foot; this seems an important character, as it is pretty constant in the lower groups of Mammalia. There is a slight difference in the origin of the interossei in the space between the second and third metacarpal and the corresponding metatarsal bones, but without any alteration of their function. In the front limb there is no flexor or extensor arising in the hand, and in the posterior limb there is no flexor or extensor arising from the femur. In the arm the long flexors of the thumb and other digits each arise on the same side of the limb as that to which they are finally distributed. In the leg they arise from opposite sides, and their tendons cross each other. In the hand there is no interweaving of these tendons together, as in the foot. In the hand there is no muscle corresponding to the flexor accessorius. In the arm the extensor muscles cross each other, but in the leg they do not. The quadriceps extensor muscle of the leg has generally been supposed to correspond with the triceps of the arm, but this can scarcely be the case,—the former is situated both in its origin and insertion on the tibial side of the limb, the latter, on the ulnar side; so, though agreeing in function, they differ in homological structure. After leaving the bones and muscles, it becomes a very difficult matter to trace the homotypes among the nerves and vessels, and one which can only be made out by a careful study of development.

PARLIAMENTARY.

On Thursday, February 11, in the House of Commons, in answer to a question by Colonel Gilpin, the Under Secretary for War stated that the Government had decided that—

"All such expenses incurred by Colonel Crawley as were ever paid should in this instance be defrayed by the country. Colonel Crawley's passage from India and back had been paid; he had been in receipt of Indian pay and allowances during the whole time that he was in this country, and quarters had been provided for him at Aldershot. The expenses of all witnesses whom he desired to bring over from India had been paid; and, in fact, no greater expense had fallen upon him than he would have been subject to if his regiment had been in this country instead of India. Everything which in such cases had ever been paid for anybody had been paid for Colonel Crawley. The only expenses which had not been repaid to him were those connected with legal advice. No application had been made by Colonel Crawley for the payment of these expenses, nor could the Government accede to such an application if it was made. The position and status of legal gentlemen were not recognised at courts-martial, and the Government would have no means of checking their charges."

On Friday, February 12, Sir G. Grey, in answer to an inquiry from Mr. R. Long, stated that the Under Secretary for the Home Department would shortly give notice of the introduction of a bill, or rather of two bills, intended to remedy the evils arising from the importation of diseased cattle and sheep.

Sir W. Fraser called attention to the insufficiency of the means of egress from theatres in the case of fire or sudden alarm. He limited his observations to theatres, because churches were under the control of the churchwardens, and other public metropolitan buildings were subject to the regulations of the magistrates. Theatres were under the authority of the Lord Chamberlain. One million five hundred thousand persons visited the London theatres in the course of the year.

The Home Secretary stated that the Lord Chamberlain, previous to granting the annual license, required a report from an architect and surveyor, in which the means of egress and the precautions taken against fire were especially noticed. If the report were not satisfactory the managers received an official communication. The effect of these communications and the precautions taken was, that a great improvement had taken place. He believed that at the present moment the means of egress provided in theatres were much more com-

plete than in any other public buildings. In the case of new theatres, the place was always submitted to the Lord Chamberlain before the license was granted, and one of the chief requisites laid down in such cases was the provision of adequate means of egress.

On Monday, February 15, in the House of Commons, Mr. Bruce, in reply to a question from Lord Enfield, said that the report of the Children Employment Commissioners had been under the consideration of the Government during the recess. A measure was in preparation, and he hoped very shortly to ask leave to introduce it.

The Marquis of Hartington, in reply to Lord Hotham, stated that Colonel Crawley's expenses in the late court-martial would be spread over several of the votes taken last year. It would not be necessary to lay upon the table any supplementary estimate for the purpose. There would be no objection on the part of the Government to furnishing a return showing the total expenses incurred upon the trial of Colonel Crawley.

Sir G. Grey moved the second reading of the Insane Prisoners Act Amendment Bill. We have to correct an error which crept into our last parliamentary report with respect to a clause of this bill. "The whole of the visiting justices of the gaol collectively" are not to be substituted for the "any two justices" who have, under the 3rd and 4th of Victoria, the power of signing the certificate of insanity, but "two or more of the visiting justices," if the prison is one to which visiting justices are appointed.

Mr. G. Hardy said that the bill before the House did not provide an adequate remedy for such cases as Townley's. The case of persons sentenced to death ought, he thought, to be kept separate, and dealt with in a different manner from those of other prisoners. The new species of insanity which had been spoken of in Townley's case was never brought forward, except when prisoners were sentenced to death; although, if Townley was really believed to be irresponsible for his actions, it was as great a cruelty to put him on the public works as to take his life. The justices might be allowed to take the initiative in the case of persons only sentenced to imprisonment or transportation; but if a prisoner under sentence of death was once sent to an asylum, it was impossible for the Secretary of State to carry out the original sentence. In the case of a prisoner under sentence of death there was an opportunity before trial and at the trial to inquire into the state of his mind. The verdict should, he thought, be conclusive as to the state of his mind up to the period of the verdict, and the inquiry should only refer to the state of his mind after the verdict and up to the period of his proposed execution. The question then arose how the friends of such a prisoner would be able to bring a certificate under the notice of the Secretary of State. He suggested that the bill should be left as it now stood in respect to persons under sentence of imprisonment or penal servitude. The words of the clause were—"If any person shall appear to be insane;" but did not say to whom. He would suggest that the words should run, "If any person shall appear to the visiting justices to be insane." The visiting justices should represent the insanity to the Secretary of State, who ought thereupon to issue a commission. The inquiry need not be public, but it should be of a solemn and judicial character, and the proceedings should be published. The report of the commission as to the sanity of the prisoner should be binding on the Secretary of State, but would by no means affect the Royal prerogative of pardon or commutation of sentence. It was casting an unwarrantable and unfair burden on the Secretary of State to say that the certificate of two visiting justices and two Medical men was to be compulsory, and that he was to use his discretion notwithstanding. Much dissatisfaction would be felt if the Home Secretary allowed a man to be executed in spite of a certificate of his insanity. The Secretary of State would have the power to appoint a commission; and he (Mr. Hardy) would be sorry to see the commission composed wholly of Doctors; for when one took up those papers and read them through, it was clear there must be lay persons to decide where Doctors differed. For, in the first place, they had a Surgeon who decided when the prisoner was committed that he was sane, and made an entry in the prison-book to that effect; and afterwards the same Surgeon said that the man was mad, though he believed him to be then in the same state as he was in before, but that when he made the entry in the book the man was not legally insane. Then the Com-

missioners of Lunacy drew a distinction most dangerous to society; for they thought the man was of an unsound mind, but that he was in such a state that he ought to be responsible for his actions. Finally, they had a commission issued, composed of most eminent men, who seemed to have conducted their inquiry with a good sense which contrasted strongly with the previous mode of inquiry; and they came to the conclusion that he was not insane when they examined him. In the old times, when an inquiry was made, it was always as to the motive; but now, when they got the very strongest motive, jealousy, it was said the man was mad, because he had been actuated to commit a crime by the most violent of passions. If the visiting justices represented to the Secretary of State that the man was insane, and ought not to be hanged in that state, then the Secretary of State ought to appoint a commission, an independent tribunal, who should publish openly what they had heard, and the result at which they had arrived; and the Secretary of State, as far as his statutory capacity was concerned, should be bound by that decision; but if he chose afterwards to advise her Majesty to take another course, he should be responsible for that advice, as he was now.

Mr. Macdonogh reiterated his argument that the words, "it shall be lawful," in the Act of the 3rd and 4th Victoria were not imperative, but permissive, and objected that this bill was founded upon a wrong principle; that it should be declaratory only of the construction to be put upon the words of the particular Act.

Sir C. O'Loghlen regretted that the Secretary for the Home Department had thought proper to confine the operation of the bill to England alone. If the present bill passed there would be one law for England, another for Scotland, and another for Ireland. By the Scotch law the sheriff and two Medical men might forward to the Home Secretary their opinion of the insanity of a prisoner, and the moment that opinion was given it was final and conclusive; and the very same mischief which the present bill was brought in to remedy in respect of England might still occur in the case of Scotland. It was proposed by the present bill that the certificate of the visiting justices should be backed by Physicians or Surgeons; but in Scotland the certificate of the sheriff might be backed by an Apothecary. In Ireland the law in regard to these certificates applied only to persons under sentence of imprisonment. It was not applicable to persons under sentence of death; so that a prisoner there under sentence of death, becoming insane, must, if the Act were strictly to be carried out, be hanged, because no power was given to send him to a lunatic asylum, or else he must receive a free pardon. That difficulty was got over by the Lord-Lieutenant commuting the sentence to penal servitude, and then the convict, being under sentence of imprisonment, was sent to a lunatic asylum. He contended that such differences should not be allowed to exist, but that the same law should extend to the whole of the United Kingdom.

Mr. Scourfield supported the provisions of the Bill, although he thought some of them did not go far enough. He said:—

"It had been suggested that a commission should be issued, composed of legal and Medical men, to determine the question of the insanity of a prisoner. The result of such an arrangement would be, that the obscurity which now enwrapped the subject would be as the noontide sun compared with the darkness and chaos which would then ensue. The Medical man and the lawyer necessarily looked at the question of insanity in different lights. The Doctor was bound to consider the welfare of the patient, and the mode of curing him. The lawyer, on the other hand, was bound to consider the interests of the community at large, and the safety of the public. It was most important, in his opinion, that in determining who was and who was not insane, the legal opinion should not be subordinated to the Medical. The report clearly showed that, unless the opinions there laid down by Medical men were closely watched, they would be attended with the most dangerous consequences. For example, it was alleged that unconsciousness of guilt was a symptom of insanity. No doubt it might be one of the symptoms, but it was too much to say broadly that the criminal who was contrite and repentant was sane, and deserving of the full penalty of the law; while another who justified his misdeeds, and would not express any compunction for them, should be deemed insane, and allowed to escape with impunity.

Mr. Hunt called attention to, and reiterated some of the objections urged by Mr. Hardy. He thought the bill, so far as it went, would not place the law in a satisfactory state.

Mr. M. Smith, having considered the defects of the law and the provisions of the bill, had come to the same conclusion as Mr. Hardy. He urged that the question of the supervening insanity of a prisoner should be determined by the old constitutional form of inquiry by a jury.

Sir G. Bowyer, having explained that he had not recommended but deprecated the adoption of the scheme of a congress of Doctors and lawyers, said that he wished to call the attention of the House to a question which had excited considerable interest in Medical circles. The certificate in Townley's case was signed by a gentleman named Harwood, who was not a Practitioner registered under the Medical Act. A doubt having occurred to the right hon. baronet the Home Secretary, whether, under those circumstances, the certificate was valid, he had consulted the Lord Chancellor, who had given it as his opinion that, although Mr. Harwood was not registered under the Medical Act, the certificate signed by him was perfectly good. Now, it so happened that the 27th section of the Medical Act contemplated this very case, and it enacted that "no certificate required by an Act now in force, or that may hereafter be passed, from any Physician, Surgeon, Licentiate in Medicine or Surgery, or other Medical Practitioner, shall be valid unless the person signing the same be registered under this Act." There was clearly a conflict between the opinion of the Lord Chancellor and the words of this section, and he should like to hear what the right hon. baronet thought upon the subject. The proper time to discuss the details of this bill would be when it got into committee. All he could say upon the second reading was, that a change of the law was undoubtedly necessary, and, therefore, they were bound to support a measure which was brought forward by the Government for the purpose of remedying notorious and undoubted evils. He objected to the joint commission composed of Physicians and lawyers, because he thought the two classes of men would, to a certain extent, act at cross purposes. The legal and Medical ideas of insanity were quite different. Physicians would examine a man's sanity with reference to the condition of his brain; while the only question which would present itself to the mind of judges or commissioners in deciding whether a man was sane would be, was his state of mind such that he was responsible for his actions? A man might have something morbid in the recesses of his brain, and still be sane for all practical purposes, and amenable to criminal law. A man, on the contrary, who after sentence fell into a state in which he became unconscious of his actions, was justly exempted from punishment, being, in the words of a great authority, "sufficiently punished by the insanity with which he was visited by Providence." The only constitutional method of testing whether a man had become insane after his conviction was, in his opinion, trial by jury. (Hear, hear.) But whether the fact was established by the decision of a jury or of a commission, Medical men ought to appear as experts, and not as judges. The great defect of the present day was, that Medical men appeared not as witnesses, but as advocates; if set in motion for the prisoner, their object, disguise it as they might, was really "to get him off." The question of sanity, if raised at all, ought to be treated by parties having no interest in the case other than the elucidation of truth; and he thought it might be worth considering whether the Crown ought not to appoint Professional gentlemen of high standing, who would deliver their opinions officially—of course receiving a proper remuneration.

Sir F. Kelly, after reviewing the state of the common and statute laws upon this subject, and showing the imperfections of the Act 3rd and 4th Victoria, pointed out what he regarded as defects in the bill, which provided, he said, no remedy for an important error in that Act. It made no distinction between one kind of unsoundness of mind which exempts an offender from responsibility for his actions, and another kind which leaves him responsible. Referring to the case of Townley, he insisted upon the unconstitutional character of the jurisdiction exercised by the Secretary of State. He urged this upon the House, not for the purpose of imputing a shadow of blame to the Secretary of State, but of showing the unconstitutional and mischievous character of the Home-office jurisdiction. He trusted that jurisdiction would soon be put an end to, and with that object he should shortly ask leave to introduce a measure, by which the great question of life or death should be referred to the true constitutional and legal tribunal—a judge and jury. In order to avoid the absurdity of acting on the certificate sent up from the country, the right hon. gentleman was obliged to send four Medical men to examine Townley in the asylum, and they reported, not that

the prisoner had become sane, which was what the Act of Parliament required, but that Townley was then sane. It was never intended by the Act of Parliament to confer such a power on the visiting justices, but it was left open to the right hon. gentleman to act as he thought fit. By the bill as now proposed, it was again to be left to two justices and any Medical men they might select to set aside the verdict of a jury where sentence of death had been pronounced. He should object to this clause; and he trusted that when the House went into committee the provisions of his own measure would be before the committee. It would then be for the House to say whether the duty of deciding in such cases should rest with the Secretary of State, or whether it should be decided by a judge and jury. He was aware that not until capital punishments were abolished would unseemly questions of this nature cease to arise. If the time had come for abolishing capital punishments—and, if not, he trusted it would soon arrive—no one would rejoice more than himself at the substitution of some life-long and effective punishment. Until then, he hoped that the Government would not perpetuate the fundamental error of applying to capital cases the law which was enacted in cases of ordinary felonies and misdemeanours, and which had been productive in Townley's case of so much confusion, mischief, and dissatisfaction.

Sir G. Grey discussed the suggestions which had been thrown out in the course of the debate (as to some of which, he said, he should not express a decided opinion), especially the main suggestion of Mr. Hardy, that cases of prisoners under a capital sentence should be dealt with in a separate manner. There was nothing in the bill, he said, to prevent the capital sentence in a case similar to Townley's being legally carried into execution. He remarked, with reference to that case, that the inquiry after conviction was no revision of the verdict of the jury, but was consequent upon alleged insanity supervening after conviction. With regard to the non-registration of the Medical man who signed Townley's certificate, he reiterated the Lord Chancellor's opinion, that as Mr. Harwood had acted as Surgeon for forty-three years, and had frequently signed certificates of lunacy, his signature was valid. Admitting that the law respecting criminal lunatics in Scotland and Ireland was not satisfactory, he stated that the delay which would have arisen from the necessity of consolidating numerous statutes rendered it inexpedient to extend the bill to those parts of the United Kingdom. He added that he should be happy to receive suggestions from hon. members in committee.

The bill was then read a second time.

The discussion which followed on the motion, that the Malt for Cattle bill be read a second time, turned principally on the amount of benefit which would accrue to the agricultural interest, and upon the general question of the malt duty.

In answer to Mr. Bass's objection, that the admixture of ten per cent. of linseed would not spoil the malt for brewing purposes, the Chancellor of the Exchequer said he relied on the results of experiments made by the Chemical Staff of the Inland Revenue Board. He instanced the satisfactory results which had ensued on adopting the recommendations of the chemists attached to that Board in the case of methylated spirit and tobacco. He said that since Baron Liebig's report, which was read in the previous debate, he had received a similar one from Dr. Lyon Playfair. Dr. Playfair takes the same view of the matter as Liebig. He admits that, while the effect of malting barley is to diminish the sanguifying ingredients, on the other hand it makes them more soluble and accessible; and therefore, either with reference to feeding as a whole, or with reference to feeding in certain states of the animal, or in combination with other articles of food, this process may produce, if not a primary, at least a very important secondary article of diet for cattle.

On Tuesday, February 16, Mr. Adair (for the Hon. D. Fortescue) gave notice of the intention of the hon. member for Andover, on March 15, to bring under the notice of the House the case of the court-martial on Colonel Crawley, and to move for further papers.

FROM ABROAD—THE TRICHINA-PANIC IN GERMANY—LIGATURE OF THE COMMON CAROTID IN A CHILD—THE FRENCH RAILWAYS.

WHEN Mr. Hilton, many years since, discovered, in human muscle, the small encapsulated body which Professor Owen afterwards showed to contain a microscopic worm, named by him *trichina spiralis*, little did either *savant* anticipate the

important part this apparently mere scientific curiosity was destined to play. At the present day, the frequency with which it has been found in the muscles and intestines of the pig, and the fatal and serious results which have attended the consumption of flesh so contaminated, has spread a true panic throughout Germany. Pig-eaters in every form, *par excellence*, the Germans have now forsworn this description of food, and herds of swine wander about marketless, to the ruin of their owners. Great exaggeration, we do not doubt, prevails in the accounts which have reached this country as to the number of deaths that have been produced; but enough is certain to render the case a very alarming one, as Professor Virchow admits, who has just published a popular account of the *trichina*, in order to allay popular alarm by representing the truth as it really exists. A committee has also been appointed by the Berlin Medical Society, consisting of Virchow, Remak, Gurlt, and others, to examine into and report upon the whole subject. We fear that neither Virchow's pamphlet, nor anything else that has been written, will tend much to allay alarm; for all fail in pointing out the cause of the affection, or why it should have become so prevalent at the present time, and more especially in Saxony. The mode of feeding the pigs is pretty much the same now that it has always been; and, although cases of sausage-poisoning have long been familiarly known in Germany, the present prevalence is something quite new. Virchow, indeed, seems to think that the swine flesh must have always been, more or less, infected with *trichinae*, and that its frequent communication to man at the present time is much to be attributed to the rapid and imperfect smoking which the hams and sausages undergo, at the present day, compared with former times. Thus far, the disease has not been met with in any animal that is a vegetable feeder; and Dr. Langenbeck says that *trichinae* have been found in extraordinary numbers last year in earth-worms (as many as 500 or 600 having been seen in a worm of middling size), which form part of the food of the animals which swine feed upon when left at liberty. He advises the swine to be always fed in styes, and debarred access to localities where worms are numerous. It is not reassuring to find that there is no symptom indicative of *trichiniasis* in the pig, which, to all appearance, may be a highly healthy animal, the microscope being, indeed, the only means of detecting the presence of the worm. Effectual cooking seems the only means of assuring against ill-consequences; and when poisoning does occur from *trichinae*, beyond the mere use of emetics or purgatives in the earliest stages, there is at present no remedy known, a natural cure of the disease taking place, however, in many cases, by the encapsulation of the *trichinae* in the muscles. Seeing that a large importation of German hams and sausages takes place into this country, it behoves our sanitarians to turn their attention to this matter, as one also practically concerning ourselves. Moreover, what assurance have we that our own swine are free from the disease?

An interesting case of ligature of the common carotid in a child was related by Dr. Weinlechner at a recent meeting of the Vienna Medical Society. A girl, aged 3 years, in the middle of last November, fell ill with measles, which became complicated with diphtheritis. In the course of the disease, an abscess formed in the right side of the neck, below the mastoid process, and this was opened. Soon afterwards a tumour arose in the same region, which rapidly increased, displacing the larynx, lower jaw, tongue, and cervical muscles from their normal positions, and, on December 1, burst externally, causing hæmorrhage to about twelve ounces, which was arrested by pressure. On the 15th, arterial bleeding to about four ounces recurred. Dr. Weinlechner saw the child then for the first time, and was disposed to regard the tumour as a highly vascular, medullary carcinoma; but strong pulsations in its centre, and the large jets of arterial blood, convinced him that he had to do with a spurious aneurism of the carotid, arising from rupture of the arterial parietes. The child being

very anæmic, and rupture of the aneurism at another point threatening to take place, it was resolved to tie the common carotid below the tumour. The limited space, and the distortion of the parts caused by the tumour, rendered this a matter of difficulty, but it was accomplished with only slight loss of blood. The wound soon healed, the ligatures coming away on the second day, and the tumour had diminished, on the child's presentation to the Society on January 15, to a third of its former size. The collateral circulation had then also become so far established as to allow of pulsation being felt in the right submaxillary and temporal.

Dr. De Pietra Santa published, in 1859 and 1861, an account of the advantages which the public health has derived from railways, as evidenced by the experience derived from the French lines. In a recent communication he brings the communication down to the present time, his sources of information being elaborate Government reports, and the reports of the Medical officers attached to the great lines. In respect to these latter, we may observe that the French lines, from the earliest times of their formation, have been placed under organised Medical *surveillance*. The Medical officers, constituting now a numerous and somewhat united body, are charged with the duty of supplying speedy assistance in the case of accidents, with attending to the sick and convalescent among the *employés*, the superintending all hygienic appliances, and forwarding periodical reports to the directors. The general conclusion which M. Pietra Santa arrives at is, that railway travelling, some exceptional cases apart, exerts a highly beneficial influence upon the health; and his investigations do not seem to corroborate the somewhat highly-drawn pictures of the mischief resulting from it which have had some currency amongst ourselves. With respect to accidents, he enters into an examination of the official returns; and from these it appears that between the years 1856—62, the number of travellers amounted to 314,186,161, and among these there occurred 72 deaths and 894 injuries, 55 of the deaths and 280 of the injuries not being the fault of the railway administration. Thus, there was only 1 person killed in 4,363,696, and 1 injured in 351,438 travellers; and by a comparison with the accidents produced by the old diligence travelling, M. Pietra Santa finds that there are fourteen chances to one in favour of making a safe journey in a railway carriage compared to a diligence. The reports of the Medical officers of the various railway lines concur in affirming the superior condition of health enjoyed by the various *employés* as compared with that of persons of their own age elsewhere; and this improvement has been found continually progressing, a fact due no doubt to the various hygienic measures which are put into force and insisted upon. The French lines now in operation measure more than 10,000 kilometres.

POGONOTROPHY.—Dr. Belcher, in December last, read a paper before the College of Physicians in Ireland on "The Hygienic Aspect of *Pogonotrophy*." Under this sounding title, he made a forcible appeal in favour of wearing beards. Ancient history, Scripture, and mediæval records were put under contribution, the physiological use of the beard was considered, and the hygienic results of its free growth. Strong disapprobation was expressed at the arbitrary rules enforced in the army and navy, by which sailors are required to shave, and soldiers to leave a space of two inches between the moustache and whiskers. The writer concluded with some humour:—"The jolly shaven head and face of a century ago asserted a clear principle, that art was better than nature; the bearded man of this day asserts that nature is better than art. But the whole set of *compromisers*—inch-whisker men, jaw-whisker men, donkey-eared-whisker men, Newgate-frill men, Frenchified, moustached, or would-be-military men—have no reasonable ground on which to rest their opposition to the constitution and course of nature. They are alike opposed by the conclusions of anatomy, physiology, hygienic medicine, and by every principle of sound physiology." Dr. Belcher is evidently no barber-Surgeon.

REVIEWS.

Topics of the Day: Medical, Social, and Scientific. By J. A. HINGESTON, M.R.C.S., etc., etc. London: John Churchill and Sons. 1863.

THE title of this collection of essays is fairly explanatory of the contents. About 400 pages are well occupied with a varied list of subjects, which it would appear have previously come before the world in a periodical manner. As they mostly bear the character proper to such compositions, and aim at a concise review of the materials before them, it is difficult to furnish a short *resumé* of their peculiarities, and, by so doing, to submit, as it were, the *defruta* of a practised pen to a still further concentration.

In a first part, atmospheric phenomena are viewed in relation to cholera, and to health generally. Solar eclipses and vaccination, the latter topic followed by some rather stormy correspondence between the author and the late Dr. Lever, of Guy's Hospital, bring the purely scientific section to a close.

The second part deals mainly with mental and psychological subjects. Hypochondriacism; ethnological psychology; the human brain; duality of mind; deformities of infantile crania; the deformed, and their mental characteristics, form its substance, followed by two brief notices of Cleopatra's death, and Horace's death. This topic, perhaps, might receive advantageous expansion. Cleopatra is supposed to have died from the bite of a cobra, or some congener; Horace, from diabetes, the latter diagnosis being in part derived, and with some humour, from the "Intermissa Venus diu, rursus bella moves" of the poet.

The third probably represents the social portion of the title. In the first essay, named "The Wear and Tear of Medical Life," occurs much that may be read with profit by all members of our Profession, from the youngest student upwards. From this we have already laid an extract before our readers. "Three Thousand a-year: a Soliloquy," is not in the best taste. "Homœopathic Triumph" is a good ironical groan at its ephemeral success. Six articles on general topics, entitled severally "The War of 1854," "The Peace of 1856," "The Indian Rebellion in its Moral and Psychological Aspects," "Orientalism," "Ancient and Modern Civilisation," and "Change of Scene," conclude the work.

A short preface recapitulates certain points in which the author had preceded public opinion in his views and observations. It reads in places rather oddly; but, on the whole, Mr. Hingeston writes like a scholar and a gentleman, and has brought forth a somewhat heterogeneous, but readable and interesting volume.

The Medical Mirror: a Monthly Magazine of Current Medical Literature and News. Nos. 1 and 2, Jan. and Feb., 1864. Price 1s.; or 10s. per annum. London: H. K. Lewis, 15, Gower-street North, W.C. Pp. 64.

WE give the most cordial reception to this new member of the English Medical periodicals. Truly, there is no lack of materials to fill its pages. Never was there a time when the Medical mind and pen were more active, and when the already-established periodicals groaned more heavily under press of matter, and authors were more clamorous for *immediate* insertion. There can be no doubt, then, that the pages of the *Medical Mirror* will be filled easily enough. We hope that the number of Medical readers is also increasing in proportion to that of the writers, and that the publisher will reap the just reward of his enterprise. Amongst the contributors are Mr. J. Z. Laurence, Dr. Meadows, Mr. Maunder, Mr. Napper, Mr. H. Smith, Dr. Hillier, Mr. Power, and Dr. Drysdale.

Another Blow for Life. By GEORGE GODWIN, F.R.S., Editor of the *Builder*, etc., etc.; assisted by Mr. JOHN BROWN. With forty-one illustrations. London: W. H. Allen and Co. 1864.

THIS is a capital book, in spite of its odd title and the occasional vehemence into which the writer is betrayed. Mr. Godwin's knowledge and experience in construction, added to his literary standing as editor of one of the very best "special" newspapers extant, qualify him to speak authoritatively on the subjects with which he deals. The title, being interpreted, means a detail of facts as to the homes of the lower orders in the east of London, the neglect of drainage, over-crowding,

bad water supply, and disregard of ordinary precautions for health in cellars, shops, ships, hotels, and yards. Suggestions are made for good cookery, window-gardens, and many other valuable points.

Sanitary reform is the key-note of the work, and on this subject Mr. Godwin writes better than most sanitarians, because more precisely and by rule. The mind of an architect and builder seems trained to look at social evils of a material kind with more materialism, and therefore less vagueness, than some who proffer higher claims on our attention. With him, damp is damp, stinks are stinks; and drains or cesspools, visible, tangible enemies to health. This is vastly more satisfactory than zymotic, miasmatic, enthetic, dietic, and other learned but intangible causes of disease, where we half suspect, while we admire, the erudite statements of our philanthropic advisers.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

JANUARY 26.

THE effect of the few days of severe cold upon the mortality of our town has been terribly distinct. Dr. Trench reported to the last meeting of the Health Committee, that the deaths in the week ending January 16 amounted to 439, being 155 in excess of the corrected average of the last ten years, and 79 more than those of the worst week of the cholera epidemic of 1854. Pulmonary diseases, including phthisis, accounted for 208 of the deaths. Unhappily, it is evident that the cold has not been the only cause of this frightful mortality, since persons of middle age appear to have suffered in equal proportion to the very old or very young, 177 between the ages of 30 and 60 years having died during that week; and it can hardly be doubted that insufficient food and clothing have occasioned a sadly large proportion of these latter cases, especially though only one death was registered as due to "cold and destitution." Another and more important report was presented to the same committee by Dr. Trench for the whole of the past year, 1863. It seems that we can claim no exemption from the generally high rate of mortality prevalent over all England, and especially in the manufacturing districts. The deaths registered in the borough were 15,266, a number greater than in any year since 1849, and 524 above the corrected average of the last ten years. There were no epidemics, no sudden elevations in the numbers of deaths, but a constant increase from January to December, to which every disease contributed its quota. In the prosperous years 1859 and 1860, the death-rate amounted to 27.5 and 25.7 per thousand, which may be regarded as the standard death-rate; but in 1861, 1862, and 1863, the proportion was 29.1, 29.9, and 33 per thousand; yet in these years the same sanitary regulations were enforced, and there were no atmospheric conditions evident to which the augmentation in the mortality could be ascribed. Dr. Trench believes that the "type" of prevalent diseases has been modified, and that the tendency to death from all diseases was, in these three years, above the average. Zymotic diseases in 1863 caused 29.2 per cent. of all deaths, the average of the past ten years being 25.9; and, estimating the probable number of persons who have suffered from typhus, from Dr. Murchison's average of one death in every ten cases, it appears likely that there were about 11,650 cases of typhus in the borough last year. An analysis of the localities in which the deaths from this cause took place, brings out with startling clearness the old fact, that unventilated courts and alleys are the native habitations of this abominable pest. Thus, 691 deaths occurred in private houses, and of these 201 were in "courts"—an enormous proportion, when their area is compared to that of the rest of the town; but then we must add to this tale of victims 468 who died in workhouses, and, as these were all paupers, we may safely assume that more than three-fourths of them came from similar places.

Only six deaths are recorded as having occurred in Hospitals. This is due to the fact, that the Royal Infirmary, the Northern, and the Southern Hospitals, do not admit these diseases, so that all pauper fever patients go to one or other of the workhouses; those, not paupers, who cannot be nursed at home, go to the Institution for Infectious Diseases in Everton.

It is a lamentable fact, that, in spite of all the efforts of the parochial authorities to enforce vaccination, there were 100 deaths from small-pox last year. Deaths from tubercular

diseases were within the average—being 14·2 per cent. of the whole mortality of the borough—thus carrying out the curious rule, that when the mortality from zymotic diseases becomes high, that from tubercular diseases diminishes.

The deaths among children are frightfully high, in proportion to the general mortality. 7601 of them died under 5 years of age (only 64 less than half of all the deaths), and of these 6346 were under 2 years, and 4496 under 1 year. Dr. Trench very truly says, that these deaths may, “under certain restrictions, be regarded as equally just tests of the moral characteristics of the people, as of the sanitary conditions of their homes”—an assertion supported by the fact, that 108 infants were found suffocated in bed during the year, and that 70 of these cases occurred between Saturdays and Mondays. All things have a bright side, however, as well as a dark one. Only think how gratifying it must be to the publicans and their friends to have such conclusive evidence as that afforded by the fact just mentioned, that, whatever depression exists in other trades, their own at least is flourishing!

At a recent meeting of the Medical Society, the account of three consecutive successful cases of ovariectomy was read by Dr. Grimsdale:—

Case 1, aged 35, had been married ten years, and had had six children, the youngest being, when first seen (January, 1863), sixteen months old. When about four months advanced in pregnancy with this child she noticed that she was much larger than might have been expected. She had a somewhat tedious labour, and four days after suffered severe pain in the side, for which leeches were applied. She kept her bed six weeks; at the end of that time her abdomen was about as large as that of an ordinary woman at the full term of gestation. The tumour increased up to the time of her seeing Dr. Grimsdale, when the measurements were,—circumference at umbilicus, forty-seven inches; from scrobiculus cordis to umbilicus, fourteen inches; from scrobiculus cordis to pubis, twenty-four and a-half inches. Abdominal parietes thin, not very tense; superficial veins much enlarged; no solid to be felt; frictional fremitus on left side below umbilicus. There was evidence of scattered adhesions over the anterior surface. Uterus movable; os open. By the middle of June the circumference at the umbilicus had increased to fifty-one inches, the length from the scrobiculus cordis to the pubis to twenty-nine inches. On June 22 she was tapped, and sixty-three pints of thick fluid, like porter, removed. The cyst refilled, and on September 2 the operation was performed. An incision of four or five inches in length exposed the tumour; some adhesions were easily broken down, the cyst was tapped, forty pints of porter-like fluid drawn off, and it was then easily brought through the incision. The peduncle was found rather short and broad, and there were several small cysts at the base of the large one. No adhesions to omentum or intestines. The opposite ovary was healthy. The clamp was applied, and left at the lower end of the wound, which was closed by four interrupted silver sutures, carried through the abdominal parietes, including the peritoneum. A few superficial wire sutures and some strips of plaster, a layer of cotton wool and a bandage, completed the dressing of the wound. At 11 p.m. pulse 92 (it was 90 before the operation), once sick, no pain. September 3, 8 a.m.—Vomited three times in the night; no pain; some sleep; pulse 72. To take arrowroot and half an ounce of brandy every two hours. 12·50 midnight.—Pulse 66. 4th.—Restless night; nausea, but no vomiting and no pain. Wound looks well. 5th.—Bad night; pain in abdomen. Ordered enema with mxx . tinct. opii, after which she was relieved and she slept. 6th.—A good night; pulse 80; upper part of wound healed; very little discharge around the clamp. 8th.—Still doing well; clamp removed. 10th.—Four wire sutures removed. From this time she progressed well, and left the Lying-in Hospital on the 24th.

Case 2 came to the Hospital on February 5, 1863. She was then 21 years of age, had been married three years, and had one child two years since. Menstruation regular, but scanty. Two months after delivery had severe pain low in the right of abdomen, which continued with scarcely an intermission for about ten months. In March, 1862, first noticed a swelling, which continued to increase, though the pain decreased. On examination, the whole cavity, from the pelvis to the ribs and epigastrium, was found filled with an irregular tumour, consisting of separate cysts with much solid matter, and extensively adherent to the abdominal walls; os uteri drawn up almost out of reach of the finger; no tumour to be felt per vaginam. In November the tumour had not increased much, but she was getting weak and thin. She was,

therefore, admitted into the Hospital; and after a preliminary tapping of the most prominent cyst (to lessen some œdema which existed below the umbilicus), and a few days' rest in bed, the operation was performed on December 1. An incision about six inches long from the umbilicus downwards exposed the most prominent part of the tumour. Its adhesions were broken down, and it was punctured with the large trocar, but nothing flowed. It was, therefore, laid freely open, and through its cavity several others were opened, thus reducing the bulk of the tumour. After separating some very firm adhesions at the upper part of the tumour, and enlarging the incision, the mass was drawn through the wound. A large piece of omentum was found adherent. This was separated, one bleeding point tied, and it was returned. The peduncle, which was thick and of fair length, was secured by the clamp, as in the last case. The wound was closed by thirteen deep silk sutures and some superficial ones. The other dressing as in the former case. 10·45 p.m.—Pulse 136, skin moist, tongue dry, no pain, once sick. December 2.—Passed a good night. Skin moist, but tongue dry, pulse 132. Slight oozing around the clamp. Some portions of the stump removed. To have tea, arrowroot, and barley water. 11·10 p.m.—No pain, sick three times. 3rd.—Pulse 110; doing well. Two deep sutures removed. 4th.—Nine deep sutures removed, no suppuration around them. 5th.—Clamp removed. 6th.—One more deep suture removed. 8th.—Some griping pain. 9th.—Some swelling above left groin, much relieved by an enema of gruel and castor oil. She went on favourably, and was discharged cured on December 28.

Case 3.—A lady, aged 35, unmarried, had suffered from pain low on left of abdomen and vomiting, especially after meals, for the last two months of 1862. In January, 1863, first noticed abdominal swelling; menstruation regular. On examination, a small globular, movable tumour was found in the site of the left ovary. By the middle of July she suffered so much from pain, vomiting, and tympanitic distension, that it was decided to tap her, and on July 28 eleven pints of viscid, straw-coloured fluid were thus removed. The sac refilled, and on December 2 the operation was performed. An incision of about four inches was made; some adhesions on the left side, extensive but not strong, were broken down; the cyst was tapped, and eleven pints of fluid drawn off. The sac was brought easily through the wound, and its peduncle (which was thick, broad, and long) was secured, as in the others, by the clamp. The right ovary was healthy. Five deep silk sutures, and three superficial ones, were used. The other dressings as before. For twenty four hours after the operation there was almost constant vomiting, and for about eight hours bearing down pain, requiring three opiate enemata for its relief. Pulse 120; tongue moist, but raw looking. Ice, barley-water, champagne, brandy, oxalate of cerium, and effervescent mixture gave no relief. Fomentations did good, both for the pain and the vomiting. The matter vomited was so acrid as to excoriate the side of the mouth. Thirty-four hours after the operation there was less sickness; pulse 96. December 4.—Has slept some hours; not vomited since 1 a.m.; pulse 86; takes only ice and water, and uses warm fomentations. 5th.—Some flatulence and colicky pains; four deep sutures removed. 6th.—One more suture removed; wound irritable in places. Very free discharge from the peduncle; pulse 100; skin rather hot and dry; some more vomiting. 7th.—Restless night; some pain; pulse 100; some suppuration in the track of the wound; clamp removed; more abdominal pain, relieved by opiate enema and fomentations. 8th.—No pain or sickness; wound looks well; pulse 96; she begins to take nourishment. From this period she went on uninterruptedly to complete restoration to health.

HONOURS TO MEDICAL MEN.—Dr. Peter Stoffella has been made a Knight of the Austrian Order of the Iron Crown. By the comments of the Vienna press on the appointment, we conclude that Doctors, with respect to the higher honours, stand there pretty much in the same position with ourselves. This is the first occasion, it is said, that this order has been conferred upon a mere Medical Practitioner. That which after some years' service is no uncommon reward for the soldier or statesman, and is conferred for special services upon a bank-director, a railway-contractor, or an army-purveyor, is thought too much for the man who devotes his life and strength to suffering humanity. Even Dr. Stoffella probably owes the honour to the high position he has long enjoyed as Court Physician, first at Modena and now at Vienna.

GENERAL CORRESPONDENCE.

ON THE ISOLATION OF INFECTIOUS DISEASES.

LETTER FROM DR. MURCHISON.

[To the Editor of the Medical Times and Gazette.]

SIR,—In some excellent remarks on the subject of contagion, in the last number of the *Medical Times and Gazette*, you have called attention to the want of sufficient means of isolating infectious diseases in public Hospitals. There are few subjects on which more difference of opinion exists, and none more deserving of discussion.

The establishment of fever Hospitals and fever wards dates from the commencement of the present century; and they were established because it was found that, when patients suffering from an infectious fever were admitted into wards occupied by other patients, "the disease was apt to spread to an alarming degree, so as to require a general dismissal of the patients." The circumstance that most of the nurses and other officials of fever Hospitals contracted fever, coupled with the fact that, in certain fever Hospitals, the mortality was unusually high, produced a reaction in favour of mixing the patients, although the evils referred to were unquestionably due, in a great measure, to the buildings devoted to fever being overcrowded and badly ventilated.

At the present day, Professional opinion is divided on the subject. From an extensive inquiry which I made several years ago, I ascertained that the prevalent practice in the Hospitals of the United Kingdom was to isolate cases of contagious fever. The general Hospitals of London constituted an exception. Here the custom was, and still is, to treat them in the same wards with other patients, notwithstanding that the history of many of these Hospitals demonstrates the dire results which have too often resulted from the practice in question.

It is in this phase of the matter that certain non-professional sanitary reformers come forward, and dogmatically assert that contagion is a myth, and that all cases of infectious disease ought to be distributed through the wards of general Hospitals, and who denounce fever Hospitals and fever wards as at all times a crime against humanity, and a disgrace to the age in which we live. Before proceeding to institute a comparison between the results of isolation and of mixing, I may be permitted to remark, that the most strenuous upholders, in the Medical Profession, of the system of mixing utterly condemn such an extreme view as visionary and impracticable. Take typhus fever, for example: it is universally admitted that there is danger of its spreading in a general ward, if the proportion of cases at any one time be greater than 1 in 5 or 1 in 6. Now, in the year 1862, the number of patients suffering from true typhus, admitted into all the general Hospitals of London, probably did not exceed 400; whereas in the same year 1827 typhus patients were admitted into the London Fever Hospital, and a still larger number were probably treated in the fever wards attached to several of the parish infirmaries. When we consider the results which followed the admission of a few hundred typhus patients into the general Hospitals, some of which results are mentioned below, it is not difficult to picture the consequences which would certainly have ensued if there had been no fever Hospital and no fever wards in London, and if the thousands of typhus patients treated in them had been distributed through the general Hospitals of the metropolis. Although the abolition of the London Fever Hospital was actually advocated as a sanitary measure in this very year 1862, there are few members of the Profession, whatever be their views as to isolation or mixing, who refuse to concede that fever Hospitals and fever wards are necessary for the surplus number of patients in all large towns liable to be visited by typhus.

I now proceed to draw a comparison between the results of isolating cases of infectious fevers, and the plan of mixing them at present followed in the general Hospitals of London. And first I would remark that, whatever plan be adopted, the attendants upon patients sick of certain diseases, even in the best ventilated Hospitals, must run a certain amount of risk. No Medical man endowed with common sense, and with any experience of small-pox, scarlet fever, or typhus, believes for a moment that these diseases are not eminently infectious. The question to be decided is, by which of the two plans a given number of cases can be treated with the least risk of the diseases spreading. The objections urged against fever

Hospitals and fever wards are two—viz.: 1. That the concentration of the poison increases the mortality among the patients themselves; and 2, that the concentration of the poison increases the danger to the attendants. The validity of these objections, which are too often made without reflecting on what would be the alternative if all cases of infectious fever were admitted into general Hospitals, may be tested by comparing the results of the treatment of typhus in the London Fever Hospital with those in six of the principal general Hospitals of the metropolis in the year 1862.

During the first six months of 1862, 1107 cases of true typhus were under treatment in the London Fever Hospital, of which number 232 died, or the mortality was 20·95 per cent. In the same period, 343 cases of typhus were under treatment in six of the general Hospitals of London, of which number 80 died, or 23·32 per cent. It may be added that nothing contributes more to a fatal termination in typhus than advanced age, and that the proportion of aged typhus patients is much larger in the London Fever Hospital than in the other Hospitals of London, because a large proportion of them are the aged and decayed inmates of the metropolitan workhouses, and also that a much larger proportion of them are moribund and beyond all hope at the time of admission; 56 of the 232 cases mentioned above dying within forty-eight hours of their arrival at the Hospital. But leaving these elements out of the calculation, inasmuch as we do not possess the actual figures, on the other side, the bare fact remains that the rate of mortality from typhus was greater in the general Hospitals than in the Hospital specially devoted to fever. The result, however, is insignificant in comparison to what follows. The 1080 (1107 — 27) cases admitted into the Fever Hospital communicated the disease to 27 persons, of whom 8 died. In other words, only 1 person took the fever for every 40 admitted, and only 1 died for every 135. But the 272 cases admitted into the six general Hospitals communicated the disease to 71 persons, of whom 21 died; or 1 person caught the fever for every 3·8 cases admitted, and 1 life was lost for every 12·9 cases admitted.

The actual data upon which this calculation is founded are as follows:—

Hospitals.	No. of Admissions contracted of Typhus. in Hospital.	Cases Total.	Deaths.	
St. Mary's, January 1 to June 30, 1862	16	1	17	3
St. Bartholomew's " " " "	89	23	112	30
St. Thomas's " " " "	92	12	104	16
Guy's " " " "	40	21	61	21
Middlesex, January 1 to Sept. 30 " "	25	6	31	8
German, Dec. 1, 1861, to Feb. 28, 1862	10	8	18	2
Total	272	71	343	80

It is possible that the above comparison may be objected to, on the ground that the time selected was unfavourable to the general Hospitals. It is certainly not a common occurrence for typhus to spread in so many of the general Hospitals at one time, but this circumstance was due entirely to the unusual prevalence of typhus in all parts of the metropolis. It would not be difficult to cite many instances of an older date, where typhus has spread in general Hospitals, even to a greater extent than that indicated above; while, since the comparison was made, the admission of two or three patients suffering from typhus into three general Hospitals of London (two of which are not included in the above list), has been followed by an alarming and fatal spread of the disease. Moreover, the time selected was far from being the most favourable to the London Fever Hospital. In the first place, the rate of mortality was considerably above the average; during last year (1863) the rate of mortality among upwards of 1300 cases of true typhus was only 16 per cent., including cases moribund on admission. In the second place, owing to the small prevalence of fever during the years 1858—61, the staff of the Hospital had been reduced to a minimum; and on the sudden outbreak of typhus at the beginning of 1862, it was necessary to engage a large number of unseasoned nurses. During the fourteen years immediately preceding the date of the comparison, 3680 cases of typhus fever were treated in the Fever Hospital; but the disease was communicated to only 53 persons (nurses and patients), of whom 14 died. In other words, only 1 person caught the fever for every 70 under treatment, and only 1 died for every 263 under treatment. Moreover, many of the persons who caught fever in the Hospital were patients admitted with other diseases, and who were formerly treated in the same wards with the typhus patients; many, in fact, caught typhus in consequence of the principle of isolation not being sufficiently carried out.

Since June, 1862, the typhus and scarlet fever patients have been isolated from the other patients, and from one another, and the result has been, that only two or three patients have contracted either of these diseases in the Hospital since the change was made.

Again, some, no doubt, will be inclined to refer the spread of typhus in the general Hospitals to deficient ventilation, or to carelessness on the part of the attendants. If the ventilation of the principal general Hospitals of London, notwithstanding the amount of skill and science brought to bear upon them, be so defective as such an argument would lead us to infer, then I have only to say that we must take the Hospitals as we find them; and that, until we can build Hospitals in which such occurrences cannot take place, we ought not to put cases of infectious disease in the same wards with other patients. As regards carelessness on the part of the attendants, it may be said that, make what regulations you will, *humanum est errare*. As you justly observe, human carelessness can never be ignored in forecasting the probabilities of the spread of fever under the circumstances in question. Valuable lives ought not to hang upon the absolute perfection of Hospital nurses. That much may be done towards preventing the spread of fevers by thorough ventilation, I contend for as boldly as any man; but I am sure of this, that the amount of ventilation necessary for the purpose would be absolutely fatal to many of the patients in the wards of a general Hospital—to patients, for example, suffering from bronchitis or acute renal anasarca.

The question then resolves itself into this. A certain number of cases of infectious fever having to be treated, how can this be done with most advantage to the patients and with least danger to the attendants? From what has been stated, I think it is legitimate to infer that, on the plan of isolation, provided there be ample ventilation, they can be treated with equal advantage to themselves, and with far less danger to the attendants, in proportion to the number of cases treated. That the attendants, even in a well-ventilated fever Hospital, run a greater risk than the attendants in a general Hospital, there can be no doubt; but this is not due (or, at all events, need not be) to a concentration of the poison, but to the sources of infection being more numerous. In fact, if 2000 cubic feet of space be allowed to each patient, and if there be at the same time thorough ventilation, there need be no more concentration of the poison in a fever Hospital or in a fever ward, than in a general Hospital or in a general ward with a sprinkling of fever cases.

The arguments which I have now endeavoured to adduce in favour of the plan of isolating cases of infectious disease, refer mainly to typhus, which is certainly far from being the most infectious of the class of the diseases, the proper mode of dealing with which is under dispute.

But if my remarks apply to typhus, what are we to say respecting small-pox and scarlet fever, both of which certain theorists on sanitary matters would also have us treat in the wards of general Hospitals? Small-pox is happily at present excluded from the wards of most general Hospitals by the almost unanimous voice of Professional and public opinion; but scarlet fever, whose poison is scarcely, if at all, less active, is not so. There are few Professional men who will accept the dictum, that the poison of scarlet fever is a myth. Too many of them have reasons for a contrary belief, founded on bitter experience in their own families. Let the ventilation of a Hospital be as perfect as it is possible to make it, small-pox and scarlet fever will spread in it among persons not protected.

Medical students ought unquestionably to have the means of studying all infectious diseases, even small-pox, at our general Hospitals; but the patients suffering from these diseases ought not to be treated in the same wards with the ordinary patients. Wards ought to be provided for them, either in a separate building, or having a means of access not through the main building. Moreover, separate wards ought to be provided for small-pox, scarlet fever, and typhus; for experience has shown that patients suffering from, or convalescent from, any of these diseases, are liable to contract the others. I ask, Sir, is it charity, or is it not rather a barbarous practice, to admit a patient suffering from some trifling disease, such as indigestion or rheumatism, into the wards of a Hospital, and to make him, or his friends who visit him, run the risk of contracting typhus or scarlet fever, and perhaps dying of these diseases; and is it right that those charitable members of the community who visit the sick, to minister comfort and consolation, should unknowingly run a similar risk? Yet, these are risks almost daily incurred, and too often with the disastrous

effects detailed in this letter. It seems to me, indeed, extraordinary that a practice open to such grave objections should find advocates in the middle of this nineteenth century.

I am, &c. CHARLES MURCHISON, M.D.,
Physician to the London Fever Hospital.
79, Wimpole-street, W., February 15.

MISS NIGHTINGALE ON HOSPITALS.

LETTER FROM DR. J. S. BRISTOWE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Farr, in his letter, contained in your last week's number, enumerates, among Miss Nightingale's merits, that "she probes all the defects which make Hospitals ways of death to their inmates. She collects plans; she consults engineers; and she brings the whole of the facts together in a clear, practical form, and holds out hopes that general Hospitals may yet benefit mankind directly, and not merely as pathological observatories and Medical schools."

The words which I have put in italics do not so much state, as they do insinuate, a very grave charge indeed against existing Hospitals. Such a charge, brought even indirectly by a man in Dr. Farr's position, is a very serious matter, and demands, in the interest both of the Profession and of the public, the fullest investigation. Of course, Dr. Farr has in his possession the facts on which it is based, and is prepared to make them public.

I am, &c.,

J. S. BRISTOWE.

2, Queen-square, Westminster, Feb. 17.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Farr's confused and violent letter is so fully answered by your clear and temperate remarks, that I need interfere no further than to assure you of my hearty concurrence in them.

In the absence of anything to the contrary, I conclude that gentleman to be of opinion that a fair percentage of mortality can be struck between patients in Hospital on a single given day, and the deaths for a whole year. He is, of course, at liberty to amuse himself by this or any other arithmetical flights of fancy; but he must not complain if I, in common with most Hospital officers, look upon it as a gross misuse of figures, and utterly disbelieve any conclusions resting on it.

As I have not the honour of knowing "Anonyma," who unexpectedly turns up in Dr. Farr's queer composition, I may be excused in asking what possible connexion there can be between her and "Notes on Hospitals," and how on earth she came to be mixed up with

Yours, &c.

THE REVIEWER OF "NOTES ON HOSPITALS."

THE NEW COUNTY HOSPITAL AT WINCHESTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—Permit me to call your attention to what is now being done at Winchester. The old county Hospital having been very reasonably judged to be behind the requirements of the age, a new one is to be put up. The plans for the new building have been concocted by the following personages:—1. Miss Nightingale. 2. An architect named Butterfield, only known to me as a defacer of fine old churches, and a builder of ugly new ones. 3. A domineering baronet of the neighbourhood, who has put a ring in the nose of the Hampshire hog, and leads him about as he will.

It is interesting to remark that the proposed building is to stand on the top of a bleak hill: that it has five stories, including the basement; that it consists of one block only, the long axis of which lies east and west; and that every ward has a row of large windows facing the north. You will be able to judge how far these peculiarities agree with Miss Nightingale's published opinions. It is true that the architect has never built a Hospital before, and probable that he never saw the inside of one until he began this work. But surely any slight defect in the sanitary arrangements of the place will be amply atoned for by the strictly ecclesiastical character of the design, the impressiveness of the roofs, and the traceried window of the operating room. The penitential tone, too, given to the venereal wards, the windows of which are provided with blinkers, is very pleasing. A charmingly conventual effect is also obtained by putting the nurses to sleep in a room, fitted with little horse-boxes like a stable. No doubt the same beautiful feeling will be preserved in all

the fittings of the establishment, down to the humblest of its utensils.

The streaky-bacon style in which the building is designed is of course intended as a delicate compliment to the subscribers.

As the success or failure of the project is a matter of perfect indifference to any one but those immediately concerned in it, others may be content to draw amusement and instruction from the vagaries of these amateur Hospital builders. As one of these careless ones I beg to sign myself

I am, &c. EPICURI DE GREGE PORCUS.

DIGITALIS IN CARDIAC DISEASE.

LETTER FROM DR. JOHN C. THOROWGOOD.

[To the Editor of the Medical Times and Gazette.]

SIR,—I read with much interest your "Hospital Notes" on the "Action of Digitalis in Cardiac Disease;" and, as I have found this remedy a very useful one in a certain class of cases, I have thought it right to send you, in brief form, a few notes on the subject, especially as they will, I believe, bear out the correctness of the opinions of those able Physicians whose names and observations are recorded in your paper.

Some years ago I saw a poor woman who had been brought very low by uterine hæmorrhage. Palpitation of the heart, to which she had been always very subject, was now very distressing; she complained much of faintness and giddiness; there was œdema of the extremities, with some amount of ascites; the urine was scanty, and not albuminous. She had, moreover, a cough, and frequent attacks of watery diarrhœa; face pale and puffed. For ten days or so this patient got tinct. ferri, with opiates; then tr. scillæ, with nitric ether. A temporary and slight improvement resulted, but I see, by the notes now before me, that soon the dropsy and other symptoms returned as badly as ever, and the faintness and prostration were most distressing. The cardiac impulse was quick over an extensive space, and the first sound weak; murmur was doubtful. At this juncture the patient got tinct. digitalis, $\text{m} \times$, ter. die., ex mist. camphor; and this acted moderately as a diuretic, removing all the dropsy and other bad symptoms; so that, in six months' time, I saw her up and about her work as well as ever she was in her life.

In this case there was dropsy, to a pretty large extent, dependent on a weak and somewhat dilated heart,—just that form of dropsy which Dr. Withering, in the year 1785, said was so soon cured by digitalis.

In July, 1862, I had an opportunity of seeing the beneficial effect of digitalis, prescribed by Dr. Gull for a gentleman in the country who had been long ill with dropsy, mitral regurgitant disease, and renal degeneration. He was growing rapidly worse till he got pulv. digitalis, pulv. scillæ, $\bar{a}\bar{a}$ gr. j.; con. rosæ, q. s., ft. pil. bis die. A dozen of these pills materially improved the state of things; and then it was that Dr. Gull drew my attention to the great value of digitalis in mitral disease, and the danger of employing it in aortic disease.

Last August I was attending a case of severe cardiac disease from organic change in the aortic valves: mindful of the point to which my attention had so lately been drawn, I tried every medicine that held out hope of relief—digitalis alone excepted. The patient, a woman somewhat advanced in life, got no real and permanent benefit, and Dr. Peacock was good enough to see her with me. He confirmed my evil prognosis, and, on my mentioning digitalis, told me, as I expected, that it was no remedy for such a case as the present, and we gave tinct. ferri, with tr. hyoscy. and chloric æther.

The patient lingered on for weeks; there was no dropsy, but the attacks of dyspnœa were most severe and alarming, and gradually a faint mitral murmur became audible. It now struck me that, perhaps, digitalis might relieve this dyspnœa, and with some misgivings I tried the tincture in five-drop doses three times in the day. I went in at night to see how the patient was, and was amazed to find that even this small dose had made her more faint and worse generally, so that she detected that some change had been made in the medicine. I was satisfied, and gave her no more digitalis; eventually she sank and died.

It seems that Withering, in his memoir on "Digitalis," published in 1785, describes as cases of dropsy likely to be relieved by digitalis just such cases as we now know to be dependent on dilated heart with probably mitral disease also.

Sir H. Holland, in his "Medical Notes and Reflections," tells how that in his experience digitalis suits best the enlarged and flaccid heart, though at first sight it might seem otherwise;

and the experience of good practical Physicians of these days evidently confirms these observations.

I may just add, in conclusion, that it has seemed to me, that when digitalis is not likely to suit the system, it quickly causes disturbance of the stomach. I have never seen any serious symptoms caused by its administration, nor anything approaching to a manifestation of its so-called cumulative effect.

I am, &c.

JOHN C. THOROWGOOD, M.D., M.R.C.P. Lond.,
Assistant-Physician City of London Hospital
for Diseases of the Chest.

Finsbury-circus, January.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 9.

Mr. PARTRIDGE, President.

GEORGE WILLIAM CALLENDER, Esq., gave

SOME ACCOUNT OF THE AMPUTATIONS PERFORMED AT ST. BARTHOLOMEW'S HOSPITAL FROM THE 1ST OF JANUARY, 1853, TO THE 1ST OF OCTOBER, 1863.

These amputations are so arranged in a series of tables as to show, for a number of consecutive years, the totals of deaths and of recoveries in male and female patients. The operations comprise all the principal amputations, arranged as primary and secondary, and as amputations for disease. After some general remarks, certain deductions from the several tables are detailed. Of 93 primary amputations, 78 recovered, and 15 died; thus 16.1 per cent. of all these amputations prove fatal, or 1 in 6.2; and if the age of the fatal cases, which averages 47 years, be taken into consideration, it appears, for children and for adults under 40, that an unfavourable result after these amputations is an exceptional occurrence. The secondary amputations number 37, and of these 24 recovered and 13 died; so that 35.1 per cent., or 1 in 2.8 of all these operations, prove fatal. Taking primary and secondary amputations together, 7.1 per cent. of those of the upper extremity, and 32.4 of those of the lower extremity, prove fatal; and 21.5 per cent., 1 in 4.6, of the total of traumatic amputations. There are 228 amputations for disease or for malformations: 182 recovered, and 46 died, or 20.1 per cent. Of those performed at the upper extremity, 18.5 per cent. died; whilst of those which involved the lower, 20.3 per cent. ended fatally. It follows that, of the total 358 amputations, the ratio of mortality are: after all primary amputations, 16.1 per cent.; after all secondary, 35.1; after all amputations for disease, 20.1; after all amputations at the upper extremity, 10.8; after all those at the lower, 23.6; and after all amputations, 20.6 per cent. *Causes of Death.*—Old people are little able to resist the shock of the more severe amputations, the influence of age being most marked with primary operations. Females do not rally so easily as males after the severe shocks which precede and accompany primary amputations, nor after the depression consequent upon amputation at the thigh. The rate of mortality on the totals of cases is 18.9 per cent. for males, and 21.6 per cent. for females. The totals of deaths and of recoveries, as influenced by the age and sex of the patients, are shown in a separate table. After primary amputations, traumatic complications prove fatal at the rate of 40 per cent., and exhaustion at the rate of 20 per cent. of the total number of deaths. After secondary amputations, exhaustion is the chief cause of death, 38.4 per cent. sinking in this way; 23 per cent. die from secondary hæmorrhage. Of the total of traumatic amputations ending fatally, 28.5 per cent. sink from exhaustion, 25 per cent. from traumatic complications, 21.4 per cent. from hæmorrhage, and 7.1 per cent. from pyæmia. After amputations for disease ending fatally, exhaustion is the cause of death in 28.2 per cent.; pyæmia in 39.1 per cent.; and visceral complications in 15.2 per cent. Taking the four chief causes of death after all amputations, we obtain the following rates of mortality in the totals of fatal cases:—

Amputations.	Hæmorrhage.	Pyæmia.	Exhaustion.	Visceral
	Per cent.	Per cent.	Per cent.	Complication.
Primary	20.0	—	20.0	6.6
Secondary	23.0	15.3	38.4	15.3
All traumatic	21.4	7.1	28.5	10.7
For disease	4.3	39.1	28.2	15.2

Of the total 74 fatal cases, 24.3 per cent. die from exhaustion, 27 per cent. from pyæmia, 12.1 per cent. from hæmorrhage, 16.1 per cent. from visceral complications. After giving the particulars of the cause of death in each fatal case, and the injury or the disease for which the operation was performed, the days in which 74 cases terminated fatally are shown in a tabular form. From this it appears that deaths from shock, or from other injuries, or from both combined, take place within the first twenty-four hours, and within forty-eight hours the deaths from recurrent hæmorrhage occur. Exhaustion is most fatal about the fourth day; secondary hæmorrhage is a cause of death from the fifth to the twelfth day; pyæmia from the seventh to the twenty-fourth. Three cases of amputation are referred to, in which death was not accelerated by the operation, the patients dying on the 109th, the 102nd, and 93rd day respectively; and the paper concludes with an account of certain cases, and of certain sequences of fatal cases and recoveries, showing how necessary it is to mass together a considerable number of consecutive operations before we have a chance of arriving at tolerably just conclusions.

Mr. BRYANT, after remarking on the value of Mr. Callender's paper, said that he was surprised to find some startling difference in the results he had obtained, and in those he (Mr. Bryant) had deduced from a similar kind of analysis of the cases at Guy's Hospital. As regards numbers, his and Mr. Callender's statistics were pretty much alike, but the rate of mortality was very different—in the former 20 per cent., in the latter 25; when, for injuries, the difference was greater still, the mortality at Guy's being nearly double. In amputation for disease, however, it was the reverse. Mr. Bryant asked if it were possible that a difference of practice at the two Hospitals could reconcile these differences? At Guy's, conservative Surgery was carried to an extreme degree, and possibly too far. Then, perhaps, at St. Bartholomew's the practice might run a little towards the other extreme. He spoke, however, on this subject with great diffidence. Mr. Bryant then alluded to the very marked difference in the mortality after amputation of the upper extremity, in his and in Mr. Callender's series. Mr. Bryant then asked for the simple results as regards amputation of the thigh for disease of the knee-joint, as he wished to compare the mortality of this operation and that of excision of the knee-joint. The mortality of the latter was about one in five; whilst at Guy's and St. George's that of amputation of the thigh was one in eight.

Mr. SOLLY suggested that, as regards the discrepancy in the gross results of amputation for traumatic injuries, the difference in severity of the injuries should be taken into account. At the Borough Hospitals there were many severe railway accidents.

Mr. SPENCER WELLS said that the Surgeons of St. Bartholomew's and Guy's Hospitals might very justly cite the facts brought before the Society by Mr. Callender and Mr. Bryant, to prove that the mortality after amputations was very much less in these London Hospitals than in the large Hospitals of Paris and other continental cities. There the mortality ranged from 40 to 50 per cent., while here it was 20 to 25 per cent. The Surgeons of our Hospitals might regard this comparison with great satisfaction, but it might still be true that the mortality here was excessive. He (Mr. Wells) believed that it was excessive, and that it ought to be and would be reduced. A mortality of one in four or five after amputations, including those of the fore-arm and leg, must be very much larger than it would be if Hospital patients were placed more nearly in the condition of those who were operated on in private houses. It might be difficult or impossible to prove this by statistics, because any conclusions drawn from the few cases of amputation which any one Surgeon could bring forward from his experience in naval, or military, or private practice, would be met by some such curious facts as those just adduced by Mr. Callender. If he (Mr. Wells), or any one else, were to say, that of ten, or twenty, or thirty amputations, not one had died within six months after operation, the answer would be, that such a result was as purely accidental as the fact that all the women who underwent amputation in St. Bartholomew's in one year died, and all in the next year recovered; and it would not be easy to reply to this argument, however firmly a Surgeon might be convinced that his success was due to the care which he bestowed upon his patients, and that many of the causes of the excessive mortality in Hospital practice might be avoided. A private patient clearly escaped any contagious influence from other patients in the same ward, and arrangements might perhaps be made to give greater protection against contagion to Hos-

pital patients. First year's students, acting as dressers and dissecting on the same day, might explain a portion of the avoidable mortality in Hospitals from erysipelas and pyæmia. By attention to such matters as these, and by careful study of all those minor details in the mode of operating and in after treatment, which, though apparently trivial, might assist in turning the scale one way or the other, it was well known that some important operations had been performed much more successfully in small than in large Hospitals; and it was to be expected that similar care would also lead to greater success in all operations. The different sanitary condition of the Hospitals of London and Paris was accompanied by a death-rate of 20 to 25 per cent. in one city, and 40 to 50 per cent. in the other. A great deal had been gained already, but a great deal more might be done; and when it is done, he (Mr. Wells) felt certain that the mortality after amputations would fall very far indeed below the present proportion of 20 per cent.

The AUTHOR said that the great discrepancy Mr. Bryant had alluded to, was accounted for by the difference in the ages of the patients in his own and in Mr. Bryant's series. Many of the traumatic cases were lads from printing offices in the neighbourhood, and the injuries were less severe than those from railway accidents. Then as regards the great mortality after amputation of the upper extremity, several of the cases were exceptional. Two died of erysipelas, and two were at death's door when the operation was done. He had not made an analysis as to the mortality from amputation above the knee, but would add a note on this point to his paper. In reference to the remarks by Mr. Spencer Wells, he said that, at St. Bartholomew's, great pains had been taken to improve the condition of the wards; and, moreover, a Surgical registrar had been appointed, not merely to take notes of the cases of individual patients, but to watch the general health of the patients in the wards, to report upon any epidemics that might appear, and generally to supervise the hygienic arrangements, under the direction of the Surgical staff.

In reply to the President, the AUTHOR said that the gentleman appointed was not a student. He had been House-Surgeon, and was highly qualified for the registrarship.

The PRESIDENT thought that, from the want of such registration, a vast amount of Medical and Surgical scientific material was utterly wasted. He should have thought, speaking in reference to Mr. Spencer Wells' suggestion, that dressers were not appointed from first year's students.

The AUTHOR said they were not at St. Bartholomew's.

Mr. SPENCER WELLS said that second and third years' students dissected as well as the first, and he had not heard of any restriction upon dressing by students who were dissecting.

Mr. J. W. HULKE read a

MEMORANDUM OF A CASE OF STRANGULATED FEMORAL HERNIA WHERE, ON A FORMER OCCASION, THE NECK HAD BEEN TORN FROM THE BODY OF THE SAC IN THE TAXIS, AND THE EXTRUDING BOWEL HAD FORMED A LARGE POUCH OUTSIDE THE PERITONEUM.

A woman, aged 70, was admitted into the Middlesex Hospital on October 12, 1863, with a strangulated femoral hernia of moderate size. The strangulation was relieved by herniotomy, but the bowel could not be fairly put back into the belly. Death occurred about seventeen hours after the operation. At the post-mortem examination, the body of the sac was found *in situ*. The femoral ring opened into a large sub-peritoneal pouch, which contained eight feet of gut, and communicated by a round aperture, the original neck of the sac, with the peritoneal cavity.

THE LATE CAPTAIN PHELPS.—Captain Phelps, of the 2nd Battalion of the 14th Regiment, who was mortally wounded in the late action in New Zealand, entered the army originally as a Medical officer. Before relinquishing the Medical for the combatant branch of the service, he served as an Assistant-Surgeon in the Crimea. The following notice of this gentleman appeared in the New Zealand correspondence of the *Times* of February 12:—"Captain Phelps, an officer and a gentleman of whom New South Wales—his native country—may well feel proud, was hit in the abdomen, the bullet being supposed to have lodged in the kidneys. Having entered the army as a Medical officer—in which capacity he greatly distinguished himself in the Crimea—he at once pronounced his wound to be fatal. We write of him not only as an officer, a gentleman, and an artist of conspicuous merit, but as an estimable acquaintance whom it was our privilege to call friend."

LEGAL INTELLIGENCE.

ROLLS' COURT, CHANCERY-LANE, FEB. 11.

*(Before the MASTER OF THE ROLLS.)*THE ATTORNEY-GENERAL *v.* WALLACE.—JUDGMENT.

HIS HONOUR gave judgment in this case, which involved a question of the topographical extent of "London," under the following circumstances:—Lord Henry Seymour, by his will, dated in 1858, gave the residue of his personal property to be divided between "the Hospitals of Paris and London," and the Court was called upon to fix, as far as "London" was concerned, the limits of such a bequest. On the present occasion, the Hospitals of four districts, or limits, so to speak, put in their claims, on behalf of which it was contended—first, that the gift was confined to the Hospitals of the "city" of London; secondly, that it extended to all the Hospitals within the limits of the old bills of mortality; thirdly, that it included only the Hospitals of the metropolitan boroughs; and lastly, that it meant the Hospitals within the limits of the Registrar-General's report. The Court considered all these suggested limits or districts open to great objection. It was quite evident, from the context of the testator's will, that he did not mean "London" in its restricted sense, as embracing the city of London only; but that he used the words in its ordinary or popular sense, which meant not only the city of London, but Westminster, Southwark, etc. None of the other limits suggested would meet the difficulty any more than that of the city of London, inasmuch as in all of such limitations, if adopted, many populous districts would be altogether excluded, and many sparsely-populated districts, such as Plumstead-common, for instance, would be embraced. Then it had been suggested that the limits of the bequest might be taken to include London and Westminster, or the grounds covered by the metropolitan postal districts. But here, again, the first definition would be too limited; the latter too large. The best way of construing the gift would be to hold it as not being confined to any particular metropolitan limits, but to apply it to each particular case or claim as it might arise. The word "London" was a fluctuating term; and in the present instance the London Hospitals, or Hospitals of London, must be taken to mean the Hospitals existing in London in its widest sense in the year 1858, when the testator's will was made. Sir William Petty had spoken of "London" in the year 1686 as meaning not only the heart or city of London, but as London and its continuous streets and districts "within call." This must be the construction put upon the word as used in the testator's will; and "London" must be taken to mean not only the cities of London and Westminster and the boroughs of Southwark, etc., but all of these districts and their continuous streets. For instance, the Consumption Hospital at Brompton must be included as in the bequest. Acting on the principle thus laid down, the Court would deal with each case separately as it arose; and where any doubts existed in respect to any claim put forth, the merits of such claim would be dealt with and sifted in chambers.

COURT OF QUEEN'S BENCH, FEB. 13.

*(Sittings in Banco before Mr. Justice CROMPTON, Mr. Justice BLACKBURN, and Mr. Justice MELLOR.)*BECK *v.* FAREY.

This was one of two actions brought by Dr. T. Snow Beck against two persons, one named Sterne and the other Farey, to recover fees for attendances upon their families some years ago. Both actions were tried at the last Surrey assizes, one (the present case) before Mr. Baron Channell and a common jury, the other before Mr. Baron Bramwell and a special jury. The present case was tried first, and resulted in a verdict for the plaintiff; the other case was then tried, and resulted in a verdict for the defendant. In the latter case the learned judge was satisfied with the verdict, and the Court refused to disturb it. In the present case, in which the plaintiff got a verdict, the learned judge declared himself decidedly dissatisfied with the verdict, and the Court had granted a rule to set it aside.

Mr. Serjeant Petersdorff (with him Mr. Griffiths) appeared in support of the rule; Mr. Serjeant Parry appeared to show cause on the part of the plaintiff, and to support the verdict; but

The Court, finding the opinion of the learned judge who tried the case so decidedly against it, made the rule absolute to set it aside, without hearing the learned counsel for the defendant.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held on Monday, February 15, 1864, the following gentleman, having undergone the necessary Examination, was duly admitted a Member of the College:—

Scholes Butler Bireh, M.D. St. Andrews, Gore-lodge, Upper Kensington Gore.

At the same meeting, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

William Gill, Truro, Cornwall; Henry Biretzeke, Deptford; Arthur George Mickley, Buntingford; Cosby William Morgan, Newcastle, New South Wales; Henry Hitchcock Parry, Allington, Devizes; Kenrick Henry Bold Williams, Llansaintffraid, Conway; George Frederick Thomas, Taranaki, New Zealand; Charles Cameron, H.M. Bengal Army; Duncan Maclachlan Maclure, 16, Harley-street.

The following gentlemen were reported by the Examiners to have passed the First Part of their Professional Examination:—

George William Rigden, University College; Samuel Freeman Bagnall, King's College; Thomas Collier, Guy's Hospital; Frederick John Burge, King's College; William Bell, King's College; Benjamin Lamb Powne, St. Bartholomew's Hospital.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 11, 1864:—

William Burt Shorto, Charing-cross Hospital; Henry Osborn Fawcett Butcher, Ware, Herts; Jabez Bunting Jackson, Leicester.

The following gentleman, also on the same day, passed his First Examination:—

Frederick John Burge, King's College Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BOOTH, CHARLES, M.D. Edin., has been elected Surgeon to the Chesterfield and North Derbyshire Hospital and Dispensary.

CANDLISH, HENRY, M.D. Glasg., has been elected Surgeon to the Alnwick Infirmary.

DIXON, JOHN, M.D. St. And., has been elected Surgeon to the Surrey Dispensary, Great Dover-street, S.E.

EASTON, GEORGE F., M.D. Edin., has been appointed Physician to the Alnwick Infirmary.

JACOB, ARTHUR, M.D. Edin., has been elected Vice-President of the Royal College of Surgeons of Ireland.

JEPSON, OCTAVIUS, M.D. St. And., has been appointed Medical Superintendent of the City of London Lunatic Asylum, in course of erection at Stone, near Dartford, Kent.

LEISHMAN, WILLIAM, M.D. Glasg., has been elected Lecturer on Clinical Medicine, and one of the Ordinary Physicians to the Royal Infirmary, Glasgow.

MOORE, H. G., L.R.C.P. Lond., has been appointed House-Surgeon and Secretary to the East Suffolk Hospital, Ipswich.

RENFREW, ROBERT, M.D. Glasg., has been appointed Surgeon to the Police and Assistant Medical Officer of Health, Northern District of the City of Glasgow.

RINGER, SYDNEY, M.B. Lond., has been appointed Assistant-Physician to the Hospital for Sick Children, Great Ormond-street, W.C.

ROBERTSON, ROBERT, M.D., has been appointed Assistant House-Surgeon to the Liverpool North Dispensary.

WATSON, J., M.D., has been elected Resident Medical Officer to the Chorlton Union Workhouse, Withington, Lancashire.

DEATHS.

BRIERLEY, JOHN, M.R.C.S. Eng., at Davenport-house, Stalybridge, Cheshire, on January 7, aged 55.

BULL, JOSHUA, M.D. Edin., at Cittadella, Cork, on January 30.

GARDNER, C., M.D., at Toronto, Canada West, on December 27, aged 40.

JONES, JOHN, M.R.C.S. Eng., at 5, Seymour-place, Wandsworth-road, on February 10.

JONES, W. VAUGHAN, M.R.C.S. Eng., at Festiniog, Merionethshire, on February 3, aged 41.

LAWSON, JOSEPH A., M.D. Edin., at Horbury-crescent, Notting-hill, W., on February 11, aged 57, Deputy-Inspector-General of Hospitals.

MUSTON, EDWARD, late Surgeon in the Bengal H.E.I.C.S., at Bordeaux, on January 5, aged 76.

PARTRIDGE, WILLIAM S., L.S.A., at High-street, Bordesley, Birmingham, on February 6, aged 44.

ROSS, ANDREW, M.D., at 10, Pembroke-crescent, Bayswater, on Feb. 12, late of the H.E.I.C. Service.

ALLOWANCE OF FORAGE TO ARMY MEDICAL OFFICERS.—By a Warrant lately issued from the War Office, all Medical officers above the rank of Assistant-Surgeon will be henceforth entitled to horse forage, or an equivalent allowance, according to relative rank. An Assistant-Surgeon will be allowed forage for a horse if his duty oblige him to keep one. This is a restoration of one of the clauses of the Medical Warrant of 1858.

THE PROPOSED SPANISH MEDICAL CONGRESS.—The period for the assembling of this congress at Madrid is fixed for September 24 next. It will be held during six days, the two first being devoted to verbal or written communications, and the others to discussions. Foreigners must speak either in Spanish or French. A written communication must not occupy more than twenty minutes in duration, and a verbal one half that time. In the discussion, the speakers are to be allowed a quarter of an hour, and must only address the congress once upon the same subject. The following are the questions proposed for discussion:—1. The importance of quarantine and lazarettos. 2. The value of Surgery in the treatment of cancer. 3. The causes of pulmonary consumption, and the means of preventing or diminishing its ravages. 4. The criterium of moral liberty in the perpetration of crime. Any one possessed of a diploma in Medicine or Surgery or the accessory sciences may take part in the congress on the subscription of 60 reals (12s. 6d.), for which a copy of the proceedings will be furnished. All communications upon the subject are to be addressed, post free, to Dr. De Lague, 8, Calle Atochia, Madrid.

THE ARMY MEDICAL DEPARTMENT.—List of the candidates who were successful at the competitive examination in August last, and who have passed through a course at the Army Medical School:—

Names.	Studied at	Number of marks.
R. W. Troup	Aberdeen	5210
W. R. Kynsey	Dublin	5100
R. W. Lawless	Dublin	4946
J. F. Beattie	Aberdeen	4572
R. B. Cunynghame	Edinburgh	4492
A. Thomson	Aberdeen	4192
A. Turner	Aberdeen	4015
A. F. Preston	Dublin	3926
R. W. Forsageth	Dublin	3776
J. Delmege	Dublin	3756
C. McD. Cuffe	Dublin	3743
S. S. Gouldsbury	Galway	3729
J. A. Shaw	Dublin	3710
Charles Haines	Cork	3707
F. Dick	Edinburgh	3693
H. C. Collier	Edinburgh	3622
J. E. Barker	Dublin	3619
J. R. Greenhill	London	3572
H. R. Greene	Dublin	3511
R. H. Bolton	Dublin	3315
Henry Morris	London	3289
P. P. Lyons	Dublin	3259
E. H. Condon	Dublin	3251
James Barker	Dublin	3224
James Barry	Cork	3100
C. A. Atkins	London	3092
W. P. Smith	Dublin	3052
George Fearon	Dublin	3032
C. J. Weir	Dublin	3029
Francis Howard	Dublin	2989
Frederick T. Byrne	Dublin	2983
William Elger	Dublin	2784
Thomas White	Dublin	2573

THE BURNING OF QUEEN'S COLLEGE, CORK.—The Report of the President of the Queen's College, Cork, contains some extraordinary statements and correspondence respecting the burning of the College. It appears that one of the Professors in the Medical Faculty has charged the President, Sir R. Kane, with having set fire to the College. The Dublin correspondent of the *Times* writes that—"On June 5 last, Mr. Pope Hennessy stated in the House of Commons, on the authority of a Professor of Queen's College, Cork, that the building was set fire to by one of the officers of that institution. Sir Robert Kane wrote four times to the hon. gentleman, demanding the name of the Professor who made the statement. That gentleman, however, refused to allow his name to be mentioned, but at length he agreed that a copy of his letter might be

privately communicated to Sir Robert Kane. He had in the meantime made depositions upon the subject of the fire to the Irish Government. The authority in question was Dr. Dennis Bullen, Professor of Surgery. On July 2, Sir Robert Kane wrote to Major-General Sir Thomas Larcom, Under-Secretary, stating that great injury had been caused to the character of the officers of the College and of the Government by the persistent circulation and repetition of Dr. Bullen's statement. The Government was accused of screening the incendiary from justice, and of attempting to defraud the citizens of Cork of £7000 by seeking to recover that sum from the city, while suppressing the information they had received from Dr. Bullen; the officials of the College of all classes, from the President down to the humblest porter, being placed under vague but most injurious imputations. Sir Robert Kane, therefore, urgently requested to be furnished with a copy for publication of all the documents that Dr. Bullen had sent to the Government on the subject. This request was refused as inconsistent with official usage. About a fortnight after, however, Sir Thomas Larcom was directed to transmit to Sir Robert Kane, then in Switzerland, a copy of an extraordinary document received from Dr. Bullen, containing the gravest charges against the President of the College." These charges were contained in what purported to be memoranda of conversations held between Sir Robert Kane and Dr. Bullen. The former denies that such conversations ever took place. "The documents were all laid before the Council of the Cork College by Dr. Bullen, at the request of the President. The Council declined to take any action upon them. They simply resolved that they be handed to the President without investigating their contents, as they had already been under the consideration of the Government. The President then sent them back to Dublin Castle. There, on October 13, the Lords Justices directed the Under-Secretary to state that—"Their Excellencies, having referred to your explicit denial of their contents in your letter of July 27 last, so far as they purported to detail the particulars of private conversations between you and Dr. Bullen, are of opinion that no further consideration on the part of the Government would lead to a solution of the difficulties raised by statements so conflicting; nor are their Excellencies aware of any course of inquiry which could be instituted by them with the probability of a satisfactory result." Sir Robert Kane then asked and obtained the documents, in order that he might use them as circumstances should require, and in the concluding paragraph of his report he submits them to the judgment of the Queen in the following terms:—"From the above statement and the appended documents a judgment can be formed as to the validity of the grounds upon which Dr. Bullen has thought proper to prefer such charges against the officers of the College and against me. I am quite satisfied to leave to the wisdom of your Majesty, and to the impartial opinion of the public, the decision as to his conduct, and the notice which it may be considered to deserve." A difficult task is thus imposed;—first, Sir Robert Kane charges Dr. Bullen with making false statements in his sworn depositions; secondly, Dr. Bullen says:—"It is my conviction there is no evidence whatever to connect the crime with any person or party outside the College, and the conduct of Sir R. Kane with reference thereto demands inquiry."

ETHNOLOGICAL SOCIETY.—At a meeting on February 9—J. Crawford, Esq., F.R.S., Vice-President, in the chair—Mr. A. Oldfield read a paper "On the Ethnology of Australia." The author considered the New Hollanders to be mainly of Malay descent, which people he supposes colonised the northern shores of Australia, and thence their descendants have spread eastward over the continent, following, to a great extent, the lines marking the distribution of edible plants. The familiar customs of the various tribes evince a community of origin; but as the migrations have rarely been directly south, the migratory bands have crossed each other's lines, leaving their traces at the points of transit. It is estimated that, at the time of its settlement, the island of Tasmania contained a native population of 4000, consisting of four distinct tribes, each possessing a peculiar language, and diverse customs. Of this number not half a dozen survive, and in a few years the Tasmanian race will become extinct, there being no females capable of child-bearing among them. Although this proximate disappearance of the Alfouras is to be deplored, still, as it is not to be avoided by any means, it would be useless to waste time and labour in the hopeless task of endeavouring to avert the fate impending over them: the utmost that can be done is to make some effort to mitigate the rigors of the lot of those whose territories remain yet to be invaded. This hope-

lessness of averting the extinction of the native races arises from their utter inaptitude to receive, or, if they receive, to retain any amount of education; hence change in their mode of existence is impossible. The experiment has been made repeatedly; and although some proficiency has been attained in those branches of learning which depend altogether on the memory, all efforts to educate the reason have signally failed; even the effects of this lowest kind of education are soon effaced when once they are removed from the schools. The author has met with several adult natives who, in their youth, had acquired the arts of reading and writing, and though but a few years had elapsed since they had quitted their instructors, all traces of such powers had entirely disappeared. The education of their morals is as impossible as is that of their reason, the old savage nature eventually breaking forth even in individuals in whom it was imagined to have been totally subdued. The following instances, out of very many similar ones which have come under the author's observation, will serve to show how futile is the attempt to raise these people in the social scale. Many years ago, a settler in Western Australia received into his family an aboriginal child aged only a few days, the mother having been killed while it was of that tender age. The infant (a girl) was brought up with the children of her protector, and in after years received the same education as they did, in which she made great apparent progress, while at the same time she was most sedulously guarded from contact with any of her own race. As she grew up, she was esteemed a model of virtue, and great hopes were entertained that, through her, much might be done to ameliorate the condition of her people. At the proper age, and of her own free choice, she was given in marriage to an Englishman, and for some time all went on well. At length her savage instincts prevailed, and, casting off her civilised dress, she eloped with an aboriginal man, submitting to all the customs of savage life. Her husband followed the pair in hopes of reclaiming his wife, who, when he overtook them, incited her paramour to kill him. Even the half-caste breed evince much of this savage instinct. The author has seen a child of this class, who had never been in contact with any natives, greedily devour raw kangaroo-flesh, while, in other respects, she was remarkably dainty in her diet, preferring nicely-cooked made dishes to solid meat. This inclination was checked as much as possible; but if opportunity offered she was unable to withstand the temptation, even going the length of robbing the dogs of their half-gnawed, half-putrid bones when they had been fed on that meat. As was discovered by Dampier 200 years ago, so is it at the present day. The New Hollanders are incapable of anything like steady, persevering labour, the reward of which is in futurity. Short tasks, the reward of which is speedy, they will certainly perform; but the work done and the pay secured, it is not until again pressed by hunger that they willingly betake themselves to labour. Even when hired as permanent servants the settlers are never certain how long they will continue to work; for after becoming surfeited with the white man's food, their innate propensities resume their sway, and, doffing their civilised costume, they are constrained to lead for a time their former vagabond life. The President, J. Lubbock, Esq., F.R.S., communicated a notice of a stone celt found in the boulder-clay of the Island of Lewis. The new Fellows elected were—T. F. Wade, Esq., C.B., Secretary of H.M. Legation, Pekin; W. W. Shaw, Esq.; and A. M. Aitkin, Esq.

INSANE PRISONERS.—Sir George Grey's bill provides that the inquiry by two or more justices into the insanity of a prisoner is to be conducted by visiting justices, "if the prison is one to which visiting justices are appointed." Also, instead of the enactment, that the two justices are to inquire "with the aid of" two Medical men, this bill directs the two justices "to call to their assistance" two Medical men, thus making the justices responsible for the selection of the Medical men. The Medical men are to be persons registered under the Medical Registration Act. On receiving from the justices and the Medical men a certificate that a prisoner is insane, the Secretary of State "may, if he shall think fit," direct that the prisoner be removed to a lunatic asylum. In regard to the very important subject of the release of a prisoner who has been insane, the bill proposes that if two registered Medical men shall "duly certify" to the Secretary of State that the prisoner "is sane," the Secretary of State shall be "authorised" to direct that he be discharged out of custody if his sentence has expired by efflux of time.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Will "A Subscriber" authenticate his letter?

We shall be happy to receive Mr. F. A. Bulley's papers.

An Old Subscriber and a Union Officer of Twenty Years' Standing.—The first move in any such matter is to secure the services of some independent Member of Parliament, and to concert with him the terms of the proposed memorial, of course taking care not to ask what is not likely to be got. It is of no use to begin making such a claim in a manner which might seem unreasonable, and defeat itself. Can our correspondent tell us what the gross total of the entire charge on the Consolidated Fund will be?

A General Practitioner.—There can be little doubt that, were the amendments proposed by the Committee of the General Council of Medical Education and Registration to be carried into effect, the result would be to introduce the entire trade of chemists and druggists into the Medical Profession. This result seems inevitable when the new section (No. LVI.) is taken in connection with the change the Committee proposes to make in the preamble of the Act. The original preamble ran thus:—

"Whereas it is expedient that persons requiring Medical aid should be enabled to distinguish qualified from unqualified Practitioners: Be it therefore enacted," etc.

The following is the amendment:—

"Whereas it is expedient that persons requiring Medical aid should be enabled to distinguish qualified from unqualified Practitioners; and whereas it is, moreover, necessary, for the safety and protection of the public, towards securing adequately educated Practitioners in the several departments of Medicine, Surgery, and Pharmacy: Be it therefore enacted," etc.

Who will say that a chemist, licensed by the Apothecaries' Hall or the Pharmaceutical Society, and definitely recognised by the Medical Council, is not an adequately educated Practitioner in Pharmacy? And what distinction will the public draw between him and his next-door neighbour, the M.R.C.S. and L.S.A., who keeps an open Surgery?

Candler v. Peat.—We have been requested by the Honorary Secretary to the Peat Defence Fund to publish the following circular and subscription list. We need not add that the object of the movement should command the hearty co-operation of the Profession:—

"An action was brought against Mr. Thomas Peat, Surgeon, of Manningtree, Essex, before Mr. Justice Blackburn, in the Court of Queen's Bench, in December last, by James Candler, of Mistley, for ill-treatment of an injury to the ankle-joint, and after a careful trial, a verdict was given in favour of Mr. Peat, who, nevertheless, was put to great expense, and, by the bankruptcy of the plaintiff, is now left to pay from £150 to £160, the whole costs of the defence. A very general feeling arose among the Medical men of this district that they ought to show their sense of the injustice of the action by uniting to raise a sum sufficient to bear their friend, Mr. Peat, harmless of the costs of the trial.

"A meeting was held at the house of Dr. Bree on January 26th, and it was resolved, 'That a subscription be now entered into to defray the expenses incurred in the defence of Mr. Peat, in the action of Candler v. Peat; that the subscriptions in the first instance should not exceed £1 ls.; and that the case should be brought before the Medical public in the journals.' A Committee was formed to carry out the above object. (Names below.)

"The Committee invite your co-operation in raising the above sum, and feel confident, from the evidence in the late trial, that they have only to make an appeal to secure your sympathy.

"They feel this to be a favourable opportunity for expressing their deep indignation that the members of the Medical Profession are so frequently subjected to groundless or vexatious prosecutions, and that the present state of the law leaves vindication of character, at a ruinous expense, often, as in this instance, their only alternative.

"They rejoice that in this case the testimony of the Surgeons examined on both sides in the trial agreed so fully.

"The Committee request your donation, which may sent to any of their number.

"Signed by the Committee,

C. R. BREE, M.D., Treasurer, Colchester.

ALEX. WALLACE, M.D., Colchester.

R. S. NUNN, Colchester.

J. H. PARTRIDGE, Colchester.

C. P. MINGAYE, Dedham.

D. P. MORRIS, Secretary, Colchester.

COLCHESTER MEDICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—An extraordinary meeting of this Society was held on Tuesday, February 9, convened by a requisition "to take into consideration matters connected with the welfare of the Profession arising out of the trial of Candler v. Peat, and involving the interests and reputation of two of our members."

Mr. Peat brought a series of charges against Mr. Smith, of Manningtree, and evidence was heard in support of them; and I am directed to forward to you, and to request the publication of, the verdict of the Society thereupon.

"Resolved unanimously:—

"That the members of this Society have heard the charges of Mr. Peat against Mr. Smith, and the answers thereto.

"That they find Mr. Peat has so far proved his charges against Mr. Smith as to cause them to express with deep regret their opinion that Mr. Smith's conduct has been improper and unprofessional."

A copy of this resolution was to be sent to Mr. Smith, to Mr. Peat, to the *Lancet*, and to the *Medical Gazette*.

I am, &c. DAVID P. MORRIS, Hon. Sec.

Colchester, February 16.

The following were the charges brought by Mr. Peat against Mr. Smith:

"To the Members of the Colchester Medical Society.

"I hereby allege against Mr. Smith that he has been guilty of grossly unprofessional conduct towards me, and I pray the voice of the Society in my favour in the matter.

"I allege that he has acted unprofessionally in the case of James Candler, of Mistley, a former patient of mine, who sustained an injury of the ankle-joint, the tibia being thrown forwards, and the fibula fractured at its lower end. This case became the subject of an action in the Court of Queen's Bench at Guildhall, in the sittings before Hilary term, and a verdict was given in my favour.

"I allege that this action was brought by Candler against me, after communication with Mr. Smith; that Mr. Smith told Candler it was a good case for an action, and repeated the same thing to another party or parties, adding, the man was certain of a verdict, and would get hundreds out of me, as I had been wrong in my treatment all the way through.

"That he sent a letter to Mr. Bryant, of Guy's Hospital, accusing me of having mistaken the accident, and treated the injury as a simple sprain.

"That he did these things to injure, annoy, and damage me in Professional character and pocket; and I again pray your voice in my behalf.

"Manningtree, January 19, 1864." "THOMAS PEAT.

CAN A PHYSICIAN SUE FOR HIS FEES?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It is not the first time by any means that your pages have been honourably distinguished among your contemporaries for maintaining the dignity of the Profession. Others, alas! can see nothing but £ s. d. in a question of "fees" and "advic gratis." The Profession is, to them, a trading vessel—nothing more; and so it founders on these rocks. All honour to the *Medical Times*, which can recognise the Professional merits of a question when they are being sacrificed by other Professional organs.

I refer to the criticism of two of your contemporaries upon your remarks on *Gibbon v. Budd*. So far from being in "error," you are entitled to the thanks of the whole Profession for the statement that the decision in that case lowered the status of a Physician; and I thank you also for your hint to the College upon the subject. That a Physician should, under circumstances of peculiar aggravation, have appeared as plaintiff in the county court, is explicable; but that the College of Physicians should sanction this procedure, even by an act of omission, and those who affect to be directors of Professional conduct—the *Medical press*—should be silent, or speaking, should give such an uncertain, nay, derogatory sound, is significant of a widespread degeneracy. Would that the College had read the fable of the man and the goose with the golden eggs ere it passed this, and perhaps other of its recent bye-laws. Would that this protest might find favour with a certain editor, coming from
 Yours, &c.

A MEMBER OF THE BRITISH MEDICAL ASSOCIATION.

MR. HOLMES ON COUNTRY HOSPITALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have just seen a letter by Mr. Holmes, in your impression of Saturday, the 16th ult., in which, amongst other statements, he, in a separate sentence, makes this one in particular:—

"The fact is, that the Hospitals of London receive a different and a far more acute class of cases from that of country towns, and treat these cases with a success very little inferior to that obtained in the milder cases treated in country Hospitals."

There are two distinct propositions laid down in this sentence; and as they affect country Hospitals and country Surgeons, will you permit me, as a country Surgeon attached to a country Hospital, to ask Mr. Holmes what is the meaning of the first half of his sentence?—"The fact is, that the Hospitals of London receive a different and a far more acute class of cases from those of country towns."

Mr. Holmes cannot mean that the Hospitals of London receive, in the aggregate, a larger number of acute cases than those of the country, as this proposition is self-evident, and does not require to be enunciated even by him, for London has a far greater population than any country town, and the greater the population, the greater the number of acute cases absolutely. But is the proportion per cent. of acute cases larger in London than in a country town?—or does Mr. Holmes mean to assert that an acute case in London is "different" from an acute case in the country? If a man gets his skull fractured in London, or his leg smashed by a railway accident, or is the subject of a strangulated hernia, is the case "different and more acute" simply because it happens in London?—or does

Mr. Holmes imply that it is the custom of London Hospitals to take in all "acute cases," and that the Hospitals of country towns take in only the "milder" forms of injury and disease? If he does not mean any of these things, what on earth does he mean? Take my own country town, Leeds, for instance. We have relatively as many acute cases in our Hospitals as any in London, and how does Mr. Holmes make out what he calls "a fact," when he states that the cases in the London Hospitals are "different and more acute" than they are here? How has he got his fact? By what process of induction has he arrived at it, and how can he prove it? It seems to me that an acute case is an acute case all the world over, and that a case of compound fracture or dislocation, a case of ruptured perineum and urethra, a case of bowel obstruction, or peritonitis, or pneumonia, is the same, no matter where it occurs. How these cases can be more "acute" in London than in a country town, and why they should be so, I cannot understand at all, except upon the supposition that a Londoner is more obnoxious to grave disease and accident than a provincial, simply because he is a Londoner.

Mr. Holmes' second proposition, that the London Hospitals "treat these cases with a success very little inferior to that obtained in the milder cases treated in country Hospitals," admits of no manner of doubt as to meaning. It is singularly clear and explicit, and the "country Hospitals" and their Medical staffs ought to be extremely obliged to Mr. Holmes, and feel themselves much flattered for the very high estimate he has formed of their capabilities and Professional skill. But will Mr. Holmes be good enough to inform his "country" brethren where he has got his second "fact," which he asserts with so much self-complacency? Will Mr. Holmes be good enough to adduce any statistics which prove that the success of the "different and far more acute" case of amputation of the thigh, for instance, in London, is "very little inferior" in success to the "milder" case of amputation of the leg in the provinces?

I am afraid that Mr. Holmes' zeal for his Metropolitan brethren's good repute has outrun his discretion. Instead of lecturing Dr. Richardson on his "enormous errors," Mr. Holmes would do well to look after errors of his own, which are not less enormous. As Mr. Holmes seems to have a liking for uttering general propositions, perhaps he will not be offended if I quote, for his own advantage, the one with which he closes his letter in your columns:—

"Nothing but harm can be done by rash and exaggerated conclusions from imaginary facts."

I am, &c., M.D.

BRAXY: A MORSEL FOR PROFESSOR GAMGEE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I perceive, by an article in the *Lancet* of last week, that Professor Gamgee believes he has demonstrated the "dangers of slaughtering diseased cattle." The evidence he brings forward is, that an ox was ill with pleuro-pneumonia, or, as the Professor intimates, "with something worse; and that he was slaughtered by a drunken fellow on the farm, who, shortly before, had inflicted a severe ragged wound on his hand by a chop from a spade. This man died in a few days of diffuse inflammation of the arm; and, besides, four pigs and two dogs who feasted on the bull's viscera were seriously ill in consequence.

We may ask, when will Medical men and sanitarians learn a little of the value of logic, and of the laws of evidence, and refuse to bring forward defective instances like this? If Professor Gamgee were not so absorbed by the search for facts to suit his special purpose,—a most excellent and laudable purpose, no doubt—he would remember that the archives of Surgery are full of cases of drunken men who die of diffuse inflammation after even more trivial injuries than this, and that, therefore, the case before us proves absolutely nothing.

Don't let it be supposed that I am blind to the filth and indecency of eating diseased meat. Only in this, as in every other case, every exaggeration, and every doctrine sought to be proved without due evidence, does but recoil on our heads and weaken our cause.

There is no doubt but that large quantities of *braxy*—i.e., mutton which has died of disease—are consumed in Scotland; some of it, too, finds its way southwards, in the shape of *mutton hams*,—a food relished by Cockney tourists, but which the *callidus viator*,—your knowing man—rejects with disgust. Being desirous of knowing something more about the popular use of it (I had read of it in Hugh Miller's *Autobiography*), I wrote to a philosophical, but non-Medical, friend who lives in the Highlands, and forward his answer to your valuable Journal. There are one or two personal matters in it which I don't leave out, because they may show the more forcibly the intense horror with which the subject is regarded by my friend. Will Professor Gamgee take up the tale, and tell us whether any, and if so, what symptoms are observed amongst the shepherds who dissect and eat this horrid stuff?
 I am, &c.

May-fair, February 15.

D.

"... I am going to make a very abrupt transition to your grand question, the subject of which, however (*horreo dicendo*), don't smell of the perfumes emanating from 'Macassar.' You ask, What is *braxy*? Well, Doctor, to tell the truth, I would as soon have expected the Archbishop of Canterbury to put the question as you. You were previously wandering among the highest regions of art, squinting here and there at architecture, hymnology, cathedrals, and church service, and now you come down pat with—"What is *braxy*?" It reminds me of a person enveloped in a delicious cloud of incense, and then going away to have his olfactory nerves regaled with the strong effluvia of a dissecting-room. Well, I am not particular about smells, but certainly my mind made an inward protest against your rapid descent from 'the beautiful and sublime' to Scotch *braxy*. Here goes, then. After having deeply pondered upon the many questions which you proposed about dead sheep, and having called in shepherds and farmers to aid me with their counsel and experience, I find myself vastly illuminated, and quite prepared to treat you to '*braxy*' scientifically.

"*Braxy*" is a word whose etymology is nowhere to be found; it still lies among the '*recondita et obscura*.' In Gaelic it is spelt thus: '*bragsaid*;' the word approaching nearest to it is '*braghad*,'—a throat, windpipe, etc. The disease known under this name is an accumulation of water between the flesh and the skin, a swelling at the throat, and the bowels very much constipated. If the carcase of a sheep, defunct of '*braxy*,' be not found by the shepherd at least fifteen hours after its exit from the cares of this life, no mortal ingenuity can convert it into an article of food; but if it be found within the fifteen hours, it is first bled, then skinned; but the stench is horrible—it penetrates the tightest doors, and any quantity of them. It is not only loathsome, but its strength overpowers and makes you fly to windward instant. When the flesh is cut up in the midst of these horrible effluvia, the parts are washed, then buried in a barrel, with salt and water heaped about them. After this process they are withdrawn, with a much less offensive smell, then salted and pickled, and

hung up in a kitchen to be smoked. When a few weeks have passed, braxy ham is equal, if not superior to any other hams. The change is most wonderful; in fact I have partaken of it, and fancied that it was choice morsels of dried beef ham that I was devouring. But you may be sure that shepherds have not the patience to wait until braxy reach this stage of perfection; they bolt down whole masses of it, with its virgin smells pretty strong yet. The causes of 'braxy' disease have not yet been accurately determined by the knowing ones in the sheep line; at most we can only give negative causes. Thus, sheep never or seldom die of this complaint if fed upon turnips, or upon the low grounds lying close to the seashore tide marks. They never die of it in summer; winter and spring are the fatal seasons. Some imagine that it is brought on by the hard, crisp, and dry grass which they are compelled to eat at these periods; others, etc., etc.—but there are innumerable theories—for sheep science would not be worth anything unless it split men into a multitude of opinions and conflicting theories."

THE PRINTING-PRESS AND ITS INK.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am induced to address you on the above subject in reference to the discomforts and strain of vision I feel with many other elderly people in reading the newspapers and periodicals of the day—I allude particularly to the pale ink print. A good black print, even small, can be readily read by daylight, or at night, with ordinary light, using, as may be, spectacles; but the pale print, under the best circumstances, and especially at night, is a most trying and disagreeable task. Our ancestors rejoiced in a good black letter, but modern refinement seems to associate our vision with that of the owl and the pale moonshine. A good black type can be read well by old or young on the usual paper, and as we grow older we need a print legible as to colour as well as size. I shall be glad, Sir, if you can endorse this opinion, for even the great paper of the time, the "mighty Times," comes to us more and more in this moonshine garb.

I am, &c.

Nailsworth, February 15.

T. S.

THE NEW PHARMACOPEIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Some of the "first impressions," by a Chemist, of the British Pharmacopœia which appeared in your impression of last week will, I think, be somewhat modified on reflection. I cannot agree with him when he says that the abolishment of drachms and scruples "seems to be frivolous." The Council having adopted the avoirdupois weights, how is it possible to retain the drachms and scruples, belonging as they do to Troy weight?

He says the process given for making Hydrochloric Acid will not produce it. Of course it will not, because it has been omitted to be stated that heat should be applied to the retort. I ask, who, in his senses, would proceed to make this body who had not received a chemical education; and, having that knowledge, would he not apply heat?

The form for Linsced Poultice directs the ground seed from which the oil has been expressed, olive oil, and boiling water, to be used. I conceive it to be a great improvement—this substitution of sweet olive oil for the strong smelling oil of the linsced, especially when required to be applied to sensitive patients.

Crude Commercial Scammony or Resin of Scammony to be used indifferently. He says, "Surely this allows of two very different results." Has it not been proved by numerous experiments that the action of resin of scammony (the method for the preparation of which from scammony root was invented by Professor Williamson) is precisely the same as that of the best scammony gum?

Extract of Taraxacum. "Not an extract, but an inspissated juice." I say, call it what you will—extract, or inspissated juice—it is a great improvement on the form of the London Pharmacopœia. Instead of macerating the root in boiling water for twenty-four hours, boiling, and evaporating, and consequently converting the *inulin* into sugar, the expressed juice is simply heated to coagulate the albuminous matter, strained and evaporated, at a temperature not higher than 160° Fahr., to a proper consistence.

Lozenges are summarily dismissed as "frivolous." Patients can now get a definite amount of White Bismuth for a dose by using the Bismuth Lozenges of the Pharmacopœia, which was an impossibility when prescribed in the manner very commonly ordered.

If I may be permitted, Sir, I will endeavour to point out a few other improvements to be met with in the British Pharmacopœia.

The directions, that, in the preparation of the Waters, they are to be distilled either from the seed, fruit, leaves, or oil, as the case may be, instead of rubbing down the oil with sand, and adding the water, which was permitted by the London Pharmacopœia. The Decoction of Sarsaparilla can now be prepared in one hour and ten minutes, instead of four hours and a quarter, and with a better result. The introduction of a prescription for the preparation of Digitalin is a step in the right direction. The Extract of Calumba, prepared according to the British Pharmacopœia, is excellent. The Liquid Extract of Ergot will, I dare say, be found useful, although I should have preferred it prepared by percolating, firstly, with spirit, distilling off the excess of alcohol, afterwards exhausting with distilled water, evaporating, and subsequently combining the two extracts. I have for some time prepared it in this manner, and have been assured by Medical men that its effects are admirable.

Purified Ox-bile is infinitely superior to the simply evaporated ox-gall in present use.

Formulæ for Citrate of Iron and Ammonia and Citrate of Iron and Quinia are of first-rate importance. We shall now have definite quantities of iron and quinia in these extensively used preparations, instead of the present variable proportions of each of these important tonics met with. I once tested some so-called citrate of iron and quinia, which did not precipitate anything on the addition of an excess of ammonia; it was innocent of quinia.

The Granulated Sulphate of Iron is a very beautiful preparation, and easily prepared.

The Mercury with Chalk is not quite so strong as that of the London Pharmacopœia; but the directions that the mercury and chalk are to be rubbed in a porcelain mortar until metallic globules cease to be visible to the naked eye, and the mixture acquires an uniform grey colour, is more precise than those of the Ph. L., which directs to rub them together until globules are no longer visible. It is well known that it is prepared on the large scale by machinery, by which means the friction is carried too far, and the result is a dark grey compound, in which chemical combination has taken place. It contains the oxide of mercury, corresponding to

corrosive sublimate, and, when so prepared, its effect upon children is most alarming.

Compound Infusion of Gentian is very much improved. The maceration of the ingredients in spirit for two hours extracts the aroma of the orange and coriander, whilst the subsequent maceration for two more hours in water exhausts the gentian. The result is an extremely palatable preparation, which keeps well.

Infusion of Quassia is now prepared with cold water in half an hour. Solution of Acetate of Ammonia is superior to that of the Ph. L.; it is stronger, and will keep good.

Aromatic Spirit of Ammonia is stronger of carbonate of ammonia and spirit, and, what is of some consequence to the retail chemist, cannot become brown by keeping; its flavour is superior, and it is completely saturated with carbonate of ammonia.

Spirit of Chloroform is evidently intended to supersede chloric ether. The chloroform will not now be precipitated when mixed with water or infusions, as is the case with the so-called "chloric ether."

The Syrup of Poppies is a better preparation than that of the London Pharmacopœia. The spirit separates the albuminous matter, the presence of which, in the old preparation, made it so prone to ferment.

I consider the method by which the Tinctures are directed to be prepared—maceration and percolation—to be a most important improvement; the ingredients are more completely exhausted, and the making up the product to a given measure yields tinctures of a definite and uniform strength.

I am, &c.

Knightsbridge, Feb. 9.

J. B. BARNES, Pharmaceutical Chemist.

MIDWIFERY FEES TO POOR-LAW MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR—Will you do me the favour to insert in your valuable Journal the enclosed account of a trial that took place before J. B. Parry, Esq., Q. C., in the Thame County Court, on the 30th ult.?

I, in common with most district Medical officers, have always believed that we had a claim upon the board of guardians for attendance upon midwifery cases when ordered to attend by an overseer. (See Articles 206, No. 1., and 182 of the Consolidated Order, supplied by the Poor-law Commissioners for our guidance.) It appears, however, that it must not only be an order, but a "lawful" order; and that if, after the Medical officer has done his work, the guardians choose to question the legality of all the orders (as in my case), we have no remedy.

To constitute a "lawful" order, the case must be "sudden and urgent;" and, according to Mr. Parry, "no ordinary confinement can be sudden and urgent." Nothing short of a poor creature being taken in the pangs of labour "in the street or in the middle of a field" can justify an overseer in giving an order, though the "destitution" be of the most abject description (as in some of my cases).

I shall be very grateful to you or any of your readers for information as to whether this is really the "law," and whether there is no appeal against a decision so inhuman and (as it appears to me) unjust.

I have been a "Union Surgeon" for twenty years (four in the Thame Union), and have always been paid similar orders till within the last three quarters of a year.

I am, &c.

Brill, Bucks, February 15.

W. GAMBIER WALKER.

WALKER v. GUARDIANS OF THE THAME UNION.

This was a claim of £3 10s. for Medical attendance in seven cases of child-birth. Mr. Sawyer, instructed by Mr. Parker, appeared for the defendants. The plaintiff represented his own case, and in opening which said—My case is very simple, so far as I understand. I reside at Brill, and am a Medical district officer in the Thame Union. In that capacity I am called on to attend cases of midwifery. I have done so in accordance with instructions issued by the Poor-law Commissioners. I have now been kept out of my claim for three quarters of a year; my charge is 10s. per case, contract with the board of guardians, and as their Medical officer I am bound to attend cases upon receiving an order to that effect from an overseer. Brill, with a population of 1400 inhabitants, has no resident midwife, and the relieving officer lives at Thame, a distance of seven miles. I have been at great trouble and expense coming over to the board, endeavouring to get what is due to me, and the last time I attended I was told by the board that I had no claim upon them. If I have no claim upon them, am I bound to attend to the orders of overseers?

The Judge: Did the overseer give the orders in these several cases?

Plaintiff: Yes, these are the orders I now produce, and I attended the cases in accordance with instructions contained in articles supplied to Medical district officers by the Poor-law Commission. Mr. Walker, after requesting permission, read two articles, in which it was stated that Medical officers must attend cases of childbirth upon receipt of an order from a guardian, relieving officer, or overseer.

The overseer's orders to plaintiff were then examined by the Judge, and afterwards by Mr. Sawyer.

The Judge: The question is, whether an overseer is a proper person to give an order in cases of midwifery.

Mr. Walker (referring to the articles he had just read) replied—It there says so.

The Judge: As a magistrate for the county of Oxford, in case of an accident to a boy, I once gave an order to a Medical man to attend him, and the guardians afterwards refused to pay the claim.

Mr. Walker: What I have read are instructions supplied to us, are they not, in accordance with the Act of Parliament?

Mr. Sawyer referred his Honour to the latter part of article 48, where it stated that orders issued by overseers must be in cases of sudden and urgent necessity.

The Judge: Do you consider that ordinary cases of confinement are those of a sudden and urgent necessity?

Mr. Walker: If I receive an order from an overseer I am bound to attend.

The Judge: What I should term cases of sudden and urgent necessity would be, supposing that a woman was taken ill with childbirth on the road or in a field. I should then have no difficulty in coming to a conclusion for the plaintiff. Are these cases so?

Mr. Walker: They are not of that class. I simply want the case settled, to know how I am to proceed for the future. Medical men do not want these cases; we are subject to be called upon at all times, and under all circumstances; and when we receive an order from the overseer we are bound to attend to it, and the board of guardians tell me they are not bound to pay.

Mr. Joseph Dodwell, chairman of the board, rose to contradict that statement.

Mr. Walker, in reply: The brother of the chairman to the guardians, Mr. John Dodwell, told me I must attend as their Medical officer, but that I should not be paid by them.

The Judge: The question is, who is to pay you? I am clearly of opinion that an ordinary case of midwifery is not one of sudden and urgent necessity, and therefore not one to which the guardians would be liable to pay.

Mr. Walker: How am I to act after this, when I receive an order to attend a case? How is it possible for me to ascertain if it is a case that I may get paid for, or one I am bound to attend at my own expense?

The Judge: You must understand that the board are not, in this instance, guardians of their own purse, but of the public purse.

Mr. Walker: Oh yes, they are certainly guardians of the public purse. The Judge: Judgment will be for defendant. Plaintiff is unsuited.

Mr. Walker: But your Honour will hear what the overseers have to say? I have attended numbers of these cases before, and have been paid for them by the board. My cause has a precedent. Mr. Smith, a former overseer, is in the room now, who has given me orders like those disputed, which were paid when presented.

His Honour: But I understood you, Mr. Walker, to acknowledge these were not cases of sudden, urgent necessity.

Mr. Walker: What I said was, that they were not cases of women being taken with labour suddenly in the field or on the road.

Mr. Sawyer, addressing his Honour, said these orders express nothing of an urgent character; they merely request attendance.

The overseers were then called; and Mr. Home, in reply to plaintiff, said, as overseer, he was applied to for the orders; and he considered they were cases of necessity. Once or twice the births took place in a few minutes after Mr. Walker arrived there. He (the overseer) considered they were all cases requiring immediate assistance; that some of the poor had not means to pay; and, in one or two instances, the parties for whom the orders were given were really in distressed circumstances.

Mr. Walker applied that the case might be adjourned to get the advice of counsel upon it, observing that he thought his case was so clear that it would not be required.

The Judge, however, declined to grant an adjournment, observing that he sat there to act upon the matter to the best of his knowledge, and that judgment would be given for the defendants. If it were not so, Brill would soon become a lying-in district; persons would go there in cases of childbirth to have attendance free. Upon that principle, any one, by giving notice to the overseer at the last moment, would be able to get an order, and the expense would be charged to the Union.

Judgment for the defendants.

Mr. Sawyer told his Honour that the guardians would not press for costs.

** We think Mr. Parry's judgment in this matter clearly wrong. If the overseer considers a case sufficiently urgent to give an order on the Medical man, the latter is clearly not in a position to dispute it. The persons employing the overseer—i.e., the board of guardians—are, then, clearly responsible for payment. We recommend our correspondent to write to the Poor-law Commissioners.

COMMUNICATIONS have been received from—

APPOINTMENTS FOR THE WEEK.

February 20. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Professor Frankland, "On the Metallic Elements."

22. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital 1½ p.m.; Samaritan Hospital, 2½ p.m. MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures on Physiology.—Lecture II.—The Evolution of Carbonic Acid by the Lungs and Skiu, and other Phenomena of Expiration and Excretion, under the Influence of various Agencies. By Edward Smith, M.D., F.R.S., F.R.C.P.

23. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. Rev. T. W. Farrar, "On Ethnological Traditions." Mutu Cumara Swamy, "On the Ethnology of Ceylon." ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Savory, "On the Absorption of Dead Bone." Mr. Naylor, "Observations upon Alopecia." ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics." ST. MARY'S HOSPITAL MEDICAL SCHOOL, 8 p.m. Dr. Graily Hewitt, "Clinical-Conference in Midwifery."

24. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Middlesex, 1 p.m.; London, 2 p.m. HUNTERIAN SOCIETY, 8 p.m. Dr. Barnes, "On Cases of Ovarian Cystic Disease terminating in an unusual Manner."

25. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m., Great-Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m. ROYAL INSTITUTION, 3 p.m. Professor Tyndall, F.R.S., "On Experimental Optics."

26. Friday.

Operations, Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 8 p.m. J. Prestwich, Esq., "On the Quarternary Flint Implements of Abbeville, &c."

CHLORODYNE CHANCERY SUIT.

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

"It was fully proved and established in Court, before Vice-Chancellor Sir W. P. Wood, that Dr. John Collis Browne was the Discoverer of Chlorodyne.

"The Vice-Chancellor observed that Dr. J. Collis Browne's Chlorodyne was known before the Defendant 'Freeman' had ever thought of using the word; that the Defendant's conduct led to a very strong suspicion that there was a gradual course of proceeding on his part to mislead people into the belief that, when they bought his medicine, they were purchasing Dr. J. Collis Browne's Chlorodyne; and that, if the Plaintiffs could show that any one had actually been deceived, an Injunction would be granted."—*Times*, January 12.

Affidavits from eminent Physicians and Surgeons of the Metropolitan Hospitals proved, beyond doubt, that Dr. J. Collis Browne was the discoverer of Chlorodyne; that they prescribe it largely, and invariably mean the original Chlorodyne of Dr. J. Collis Browne.

An Affidavit by Mr. Warrington, Chemical Operator to the Apothecaries' Company of London, also established the fact, that Dr. Browne was the inventor of Chlorodyne; that the Company receive large orders for the supply of Chlorodyne for the Public Service, Hospitals, Merchants, and the Profession; and that, when Chlorodyne is ordered, they invariably supply Dr. J. C. Browne's.

Affidavits from Messrs. John Bell, Pharmaceutical Chemists, 338, Oxford-street, and several leading Wholesale Druggists of London, to the same effect, and that, when Chlorodyne is ordered, they invariably supply Dr. J. Collis Browne's.

Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury, London.

P.B.—In Chancery: Browne and Davenport versus Freeman.

J. T. DAVENPORT will thank any Member of the Medical Profession who will forward information that he has been misled by the Defendant Freeman's Advertisement into the belief that he was purchasing genuine Chlorodyne.

The observations of the Vice-Chancellor, as reported in the "*Times*," speak for themselves.

Each Affidavit from Physicians, Surgeons, and Chemists affirms that Dr. Browne's Chlorodyne was known to them in 1855; whereas the Defendant "Freeman's" Compound was not heard of until 1859, after the Genuine and Original Chlorodyne had obtained world-wide fame.

CHLORODYNE CHANCERY SUIT,

JANUARY 11th, 1864.

BROWNE AND DAVENPORT versus FREEMAN.

NOTICE.

Advertisements have appeared in the "*Lancet*," "*Medical Times*," and "*Chemist and Druggist*," apparently inserted by the Plaintiffs in this Suit, containing unfounded and perverted statements of the effects of the Affidavits made by various persons on their behalf, which might tend to mislead the public, were they permitted to remain unanswered.

Mr. FREEMAN deprecates most strongly any notice being taken of a Suit until its termination, but he is driven by the unfair acts of the Plaintiffs to set himself right.

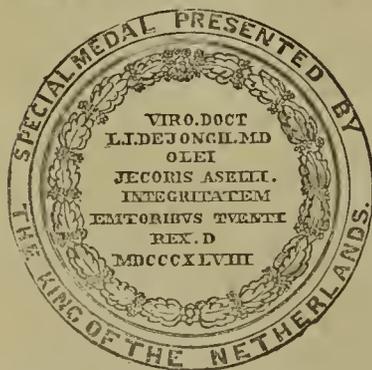

It is not true that it was in any way proved that Dr. John Collis Browne was the inventor of Chlorodyne; it is still in issue; and the effects of the Affidavits filed on behalf of Plaintiffs tend to show that Freeman's Chlorodyne is becoming the preferred Medicine.

Affidavits from eminent Physicians and Surgeons, on Mr. Freeman's part, proved clearly that the Plaintiffs had no case, and so the Vice-Chancellor considered, or he would have granted the injunction.

As Mr. FREEMAN is most anxious that the world should know his Chlorodyne, and not be deceived by any other, he intends to make his Bottles, Labels, and Wrappers still more unlike any other makers as he possibly can. He also intends to continue to publish to the world the fact, that he is the Inventor of this valuable Medicine.

In Bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 8s. 6d.

Manufactured by the Inventor, RICHARD FREEMAN, Pharmaceutist, Kennington-road, London, S.

DR. DE JONGH'S (Knight of the Order of Leopold of Belgium) LIGHT-BROWN COD-LIVER OIL.

SELECT MEDICAL OPINIONS.

Sir HENRY MARSH, Bart., M.D., Physician in Ordinary to the Queen in Ireland:—"I consider Dr. de Jongh's Cod-liver Oil to be a very pure Oil, not likely to create disgust, and a therapeutic agent of great value."

Dr. BARLOW, Senior Physician to Guy's Hospital:—"I have been well satisfied with the effects of Dr. de Jongh's Cod-liver Oil, and believe it to be a very pure Oil, well fitted for those cases in which the use of that substance is indicated."

Dr. ANKESTER, F.R.S., late Lecturer on the Practice of Medicine, St. George's School of Medicine:—"I consider that the purity and genuineness of

this Oil are secured in its preparation by the personal attention of so good a Chemist and intelligent a Physician as Dr. de Jongh, who has also written the best Medical Treatise on the Oil with which I am acquainted. Hence I deem the Cod-liver Oil sold under his guarantee to be preferable to any other kind as regards genuineness and medicinal efficacy."

SOLE CONSIGNEES AND AGENTS,
ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

ORIGINAL LECTURES.

LECTURES ON

THE BRITISH PHARMACOPŒIA:

ITS INSTRUCTION, ITS COMPARISON WITH THE
LONDON PHARMACOPŒIA,

AND THE

VALUE OF ITS NEW REMEDIES IN THE
TREATMENT OF DISEASE.

DELIVERED AT

The Royal College of Physicians,

By A. B. GARROD, M.D., F.R.S.,

Fellow of the Royal College of Physicians: Physician to King's College
Hospital.

LECTURE III.

(Continued from page 194.)

We must now refer to a most important class of remedies—a class of which the number of members is large, and the changes effected in the British Pharmacopœia by no means inconsiderable. I will endeavour shortly, but I trust clearly, to bring this subject under your consideration to-day.

In the London Pharmacopœia, Iron in its metallic form has never been introduced as a remedial agent. It is true that Iron wire was placed in the *Materia Medica*, but only as a material for the preparation of some of its compounds. Now, however, in the British Pharmacopœia, it is inserted as a medicine, under the head of *Ferrum Redactum*, or Reduced Iron—a preparation which has been for some years employed abroad as *Fer Réduit*, and also to a limited extent in this country.

The name Reduced Iron is applied on account of the manner in which it is made. It is, in fact, iron which has been reduced to a metallic state from its oxide by means of hydrogen gas. If, for example, the red oxide of iron, brought to a bright red heat in a gun barrel, has hydrogen gas passed over or through it, the oxygen of the iron unites with this hydrogen, water is formed, which passes off in vapours, and metallic iron in the state of fine division remains, which forms the *Ferrum Redactum* under consideration.

There are many difficulties in its preparation which I need not allude to here; but I may remark that, rightly prepared, it has a steel grey colour, is strongly attracted by the magnet, scintillates beautifully in the flame of a spirit lamp, and to a great extent is soluble in very weak acid solutions, with the evolution of bubbles of hydrogen. I say to a great extent, because a certain amount of magnetic oxide is always present, even when the preparation is most carefully made. When exposed to the air, it is liable to become oxidised, losing its steel grey colour, and assuming a duller appearance, and after a time it acquires a reddish-brown colour. It should, therefore, be preserved in carefully closed bottles. Having had a somewhat extensive experience of this remedy during the last ten or twelve years, I feel some confidence in stating my opinion of its value as a therapeutic agent.

In the first place, Reduced Iron is very easily dissolved in the stomach. This is made evident at times, when the medicine is taken fasting, from the slight eructation of hydrogen gas.

Secondly, it appears to produce little or no topical influence on the mucous membrane of the stomach, more especially when taken with the food. As long as it remains undissolved, it is probably inert, and as it gradually becomes dissolved it is absorbed, and hence at no one time is there any amount of an active remedy in contact with the stomach.

Thirdly, From the result of a great number of observations carefully conducted during the course of many years, and compared with those obtained with various other preparations of Iron, I can unhesitatingly affirm that Reduced Iron is one of the most potent, and for the amount given, the most powerful remedy in restoring the condition of the blood in all anæmic states of the system. It is in cases in which we require the hæmatinic effects of iron, and these only, that the preparation is peculiarly adapted. I should question if it possesses the astringent properties of many of the ferruginous compounds, and, therefore, should prefer these latter in the treatment of passive hæmorrhages, and in very relaxed conditions of the habit.

In administering Reduced Iron we must remember that we

are giving the metal in an almost pure state, and, therefore, as it is readily absorbed, the dose need not be large; one grain, for example, of pure iron should be equivalent to more than five grains of the citrate of iron and ammonia. It follows from this that even a single grain, repeated two or three times a day, produces, when continued for some period, a marked influence upon the constitution of the blood, when this fluid is impoverished in respect to its red corpuscles.

In my own practice I have invariably made it a point to give this medicine at meal times, and a few grains between two pieces of bread or bread and butter are scarcely detectable by the patient, whether young or old. Iron in this state is most valuable when we desire a long perseverance in the remedy, as many will thus continue its use who would object to take the ordinary form of medicine. In many cases of cardiac debility I have found essential advantage from this plan of treatment.

We next come to the Oxides of this metal; and we find one that is new to an English Pharmacopœia, namely, the Magnetic Oxide, and there is likewise a hydrated state of the Peroxide of Iron under the name of *Ferri Oxidum Hydratum*. With regard to the first of these, I have only to remark that the preparation ordered in the Pharmacopœia is not the common scale iron reduced to powder, but a precipitated oxide most carefully dried over sulphuric acid, and without the aid of artificial heat; so that it is in a condition most favourable for solution in the stomach and subsequent absorption into the system. In some respects this Magnetic Oxide resembles the Reduced Iron, for example, in being attracted by the magnet; but it gives no bright scintillation when sprinkled over a flame, and is certainly less soluble in weak acid solutions. As far as the value of the Magnetic Oxide is concerned, I do not feel justified in speaking with so much confidence as in the case of the Reduced Iron. That it is a useful hæmatinic I do not doubt, and it has also the advantage of being cheap. In the few clinical trials I have made with this substance in comparison with the metallic or Reduced Iron, the results were certainly in favour of the latter preparation. I should, however, desire more extended experience before giving a decided opinion on this point. It may, perhaps, be well to mention the composition of this salt; its formula is Fe_3O_4 , but there is every reason to suppose that it is more correctly represented by the following— $\text{FeO}, \text{Fe}_2\text{O}_3$, a mixed oxide, or rather salt, in which the protoxide of iron plays the part of base, and the sesquioxide acts as the acid. As prepared according to the process of the British Pharmacopœia, it retains about 22 per cent. of water. The dose may be from three to five grains, or even more, and it may be administered with the food.

The Hydrated Peroxide of Iron has been used as an antidote to arsenic in cases of poisoning, from its power of forming an insoluble compound with that acid. It has no peculiar virtues as a remedial agent.

The Iodide of Iron, formerly in the London Pharmacopœia, has been put into the list of the present work; there is likewise a pill containing this salt in the second part. The solid Iodide is very liable to become oxidised on exposure to the air, and hence the syrup is more frequently prescribed than the salt itself; in the pilular form change is, to a considerable extent, retarded.

The Phosphate of Iron will likewise be found in the *Materia Medica*; it is a medicine which has been long employed, but of late much neglected. It is blue, from partial oxidation; but, when freshly precipitated, it is almost white, but becomes coloured in drying. A syrup of the Phosphate is ordered to be made containing one grain of the Iron Salt to each drachm of syrup.

I know of no clinical facts proving that the Salts of Iron with Phosphoric Acid possess any powers superior to other ferruginous preparations; but, as part of the iron in the system probably exists in this condition, there appears to be a widespread opinion that the Phosphates of Iron must be efficacious remedies. The Blue Phosphate was largely used by the late Dr. Prout in the treatment of diabetes, and that it is a useful remedy I have had ample proof. Some years since I was in the habit of prescribing an Iron mixture made according to the formula of the London College, but containing the Phosphate of Iron in place of the Carbonate, and with such a mixture I was enabled to treat successfully anæmic conditions of the system. Lastly, there are contained in the British Pharmacopœia three persalts of Iron—namely, the Persulphate, the Perchloride, and the Pernitrate.

The Persulphate of Iron is contained in the appendix in the

form of solution, and from it several of the ferruginous salts are prepared; it can, of course, be employed as a remedy for internal or external use. Symbol $\text{Fe}_2\text{O}_3, 3\text{SO}_3$.

The Perchloride of Iron is introduced as a saturated solution, *Liquor Ferri Perchloridi*, each fluid ounce yielding nearly 125 grains of peroxide of iron; from this solution the tincture is ordered to be made, by the addition of three times its volume of rectified spirit, and in each fluid ounce contains about 31 grains of iron, measured as the old oxide. You will, therefore, perceive that, in ferruginous strength, it differs but little from the Tincture of the Sesquichloride of Iron of the London Pharmacopœia. It is, however, a very superior preparation, uniform in strength, which the old tincture was not, and free from the large amount of acidity contained in the former preparation, which was frequently a bar to its administration in large doses.

The symbol of its contained salt is Fe_2Cl_3 .

The Pernitrate of Iron, $\text{Fe}_2\text{O}_3, 3\text{NO}_5$, is also in the form of solution, which is an orange-brown liquid, intensely astringent and somewhat acid. It has been used, more especially in Ireland, as a powerful astringent acid.

It will be seen that the British Pharmacopœia is rich in these salts of Iron; and an extensive choice is, therefore, at the option of the Practitioner.

Before concluding my remarks on the Iron preparations, I may state that the ammonio-chloride, which was simply a mixture of hydrochlorate of ammonia and the perchloride of iron, has been omitted, as likewise, of necessity, the tincture of the same; and it will be observed, that not only is the crystallised greensulphate of iron present, but likewise the dried salt, *Ferri Sulphas Exsiccata*, from which six of the seven equivalents of water have been expelled by heat, and which is a very convenient form for exhibition of the salt as a pill—but it should be remembered that four and a-half grains of the dried salt is equivalent to nearly seven grains of the crystals; and, lastly, a second form of the crystallised sulphate, *Ferri Sulphas Granulata*, brought to the finer division by means of rectified spirit. This last preparation is much less readily oxidised by exposure than the ordinary form of the crystals, and may be used either as a medicine or employed as a test.

Of the Arseniate of Iron, as likewise of the double Salt of Iron and Quinine, I shall have occasion to speak in a future Lecture.

Since the publication of the British Pharmacopœia, I have seen a remark expressive of surprise, that some of the salts of manganese have not been made officinal, seeing that they are largely employed in medicine; and I may, perhaps, be allowed, having made many clinical observations upon their properties, to occupy your time in giving the results of my inquiries; and I do so, at the present period of our course, from their supposed relation to the ferruginous preparations we have just discussed.

The Black or Binoxide of Manganese is contained in the appendix, but is only used in the preparation of medicines, as *Liquor Chlori*, for example.

Some few years since, the *Sulphate of Manganese* was proposed as a purgative, and was considered to be useful as a cholagogue. In doses, of from an eighth to a quarter of an ounce, it purges somewhat like the sulphate of magnesia, and bilious actions are often the result; but I am not certain whether it influences the biliary organs more than other cathartics; it can scarcely be said to be used for this purpose at the present day.

Lately, however, first in France and afterwards in this country, some of the salts of manganese, more especially the carbonate, have been introduced as remedial agents; and it has been argued that the blood corpuscle contains manganese as well as iron, and that a variety of anæmia may exist, dependent not upon any deficiency of the ferruginous compounds, but from the want of manganese; and that when such is the case, the exhibition of the salts of this metal prove curative, even when iron has been previously administered without advantage. About five years since I had an opportunity of trying the action of manganese salts in several cases of well-marked anæmia, accompanied with amenorrhœa, and the mode in which the observations were conducted was as follows:—

After admission into the Hospital, the patients were placed for a week or two upon a generous diet, without medicine, and the influence of this treatment noted. This precaution was necessary, especially in Hospital patients, as anæmia may be kept up, if not produced, by bad air, hard work, and insufficient food. If no marked amelioration ensued, the

manganese was administered, to some, in the form of the crystallised sulphate in doses of about five grains. This salt, it may be observed, corresponds exactly with the green sulphate of iron, and is isomorphous with it, as seen in the table—

$\text{FeO}, \text{SO}_3 + 7 \text{HO}$, Sulphate of Iron.

$\text{MnO}, \text{SO}_3 + 7 \text{HO}$, Sulphate of Manganese.

To others a mixture was exhibited, made as *Mistura Ferri*, or Griffiths' Mixture, with the substitution of sulphate of manganese in place of sulphate of iron; and to a third set, the carbonate of manganese was ordered in the form of powder. In no single case could the hæmatinic powers of manganese be discovered, although the use of the preparations was continued for some weeks; but in every instance where iron salts were afterwards administered, speedy recovery ensued.

It is a somewhat remarkable and suspicious circumstance, that when manganese was first proposed as a remedy in anæmia it was given alone; but after a time, double salts of manganese and iron were substituted. These are, doubtless, of value, if only from the iron contained in them. I have no experience of the use of the manganese salts in other forms of disease, and, with regard to their power in restoring the condition of the blood in anæmia, can only say that as yet it has not fallen to my lot to find any case that has been cured by them; and I think I have had sufficient experience in their use to justify my feeling some considerable doubt of their hæmatinic properties.

Fel Bovinum Purificatum, or Purified Ox Bile, is made officinal, and a process given for its preparation from perfectly fresh bile by means of rectified spirit, by which the albuminous and mucus substances are removed, and the drug rendered altogether more pure and less liable to undergo decomposition. Ox gall is supposed to be of value in those forms of dyspepsia in which the secretion or excretion of bile is deficient; given in doses of a few grains it is said to aid intestinal assimilation, and promote the peristaltic action which the absence of bile impedes. It is desirable that it should not come in contact with the stomach, and hence it has been proposed to give it in capsules or well-covered pills. A few grains only of the Pharmacopœia preparation would represent a somewhat large amount of liquid bile.

I must confess I am not a convert to the use of the products of the digestive apparatus of animals in the treatment of disease: without denying their influence, as my insufficient experience would not allow me to do, I cannot help thinking that our endeavour in diseases of these organs should rather be directed to the restoration of their functions than to the supplying them with the products obtained from other animals, which, at the best, must be looked upon as but a very temporary method of relief. Pepsine has not been introduced into the Pharmacopœia, although, I believe, much used in practice.

The sweet principle obtained either from the saponification of fatty substances, or from their decomposition by the agency of superheated steam, and termed *Glycerina*, is now made officinal. Glycerine, $\text{C}_6\text{H}_5\text{O}_3 + 3\text{HO}$, when pure, forms a colourless liquid, sp. gr. about 1.5, soluble in water and spirit, and itself a most powerful solvent of many medicinal substances, as arsenious acid, borax, and so on. It has also the property of not becoming dry when exposed to the air, nor of undergoing any very appreciable change. These qualities render it valuable both as a pharmaceutical and medicinal agent.

As an external remedy, it may be added to lotions, to prevent their drying; it may likewise be applied, either alone or united with other substances, to any surface for the purpose of lubrication or protection from the air. Glycerine has been proposed and frequently given as a substitute for cod-liver oil. Even as far back as 1848, when this principle was little known, I made many trials of its value, employing it in cases where I should otherwise have ordered cod-liver oil; the results of these observations may be thus summed up: although in phthisis it not unfrequently allayed the irritation of the cough, probably in the same manner as syrups and mucilaginous fluids would do, yet it exerted no marked influence over the progress of the tubercular disease, and in no way could it be looked upon as a substitute for cod-liver oil.

Within the last few years I have not only verified the general truth of this statement, but have likewise been able to make some definite clinical observations upon its action. A patient was selected with a small amount of tubercular deposition, one in whom the activity of the disease appeared to be arrested, but who had not regained flesh; his weight was

accurately determined, and he was then placed on cod-liver oil; a steady increase of weight ensued, averaging a pound each four days; after a short time the use of the oil was discontinued, and with this a check to increase of weight. Glycerine in the same doses was next given, but with no further increase of weight during a week or so. Cod-liver oil was afterwards again administered, and the same result followed as on the first occasion.

Observations of a similar kind upon several patients have convinced me that glycerine possesses none of the therapeutic properties for which cod-liver oil is so highly prized—no power, in fact, of arresting waste in the system. Glycerine may be made use of for the purpose of sweetening articles of diet when sugar is objectionable, for example, in diabetes.

ORIGINAL COMMUNICATIONS.

ON RUPTURE.

By JOHN WOOD, F.R.C.S.,

Demonstrator of Anatomy, King's College, London, and Assistant-Surgeon to the Hospital.

No. IV.

TRUSS-PRESSURE IN INGUINAL HERNIA.

WHEN the abdominal contents first protrude, in a case of oblique hernia, an enlargement of the small pouch or digital impression in the peritoneum, at the side of the deep ring, is effected by the yielding of the peritoneum at its attachment to the fascia transversalis. In some cases this is owing, no doubt, in a great measure, to the yielding or weakened condition of the peritoneal structure itself. In most cases, and especially in those before referred to, as having a congenital origin, the protrusion of peritoneum through the deep ring is promoted, or entirely brought about, by the open condition of this aperture in the fascia transversalis, and its want of due support from the internal oblique muscle. When the bowel or omentum has once obtained a lodgment in the canal, the process of dilatation is carried on with greater advantage and celerity. The aponeurosis of the external oblique, at that part of the outer pillar which is placed over the deep ring, is propelled outwards. Its yielding is favoured by a relaxed condition of Poupart's ligament. But the chief dilatation of the canal is accomplished at the expense of the posterior and superior boundaries; the latter, especially, formed chiefly by the arched border of the internal oblique (in these cases, less efficient than normal), gives way easily.

In adult cases, the influence of the rectus muscle, also, is greatly felt upon the posterior wall, formed by the same conjoined tendon which gives this muscle its sheath. Contraction of the rectus draws backward the abdominal wall and conjoined tendon towards the spine, while, at the same time, the bowels are pressed outward, so as to bulge into the groins. By this means a double action of dilatation is effected, one of backward traction of the posterior wall, and one of forward impulsion upon the hernial contents. Under these influences a "bubonocoele," or hernia remaining entirely in the canal, may attain a large size if the resistance of the superficial pillars be great, without showing much externally. Lastly, the pillars of the superficial ring are separated, first, by yielding of the intercolumnar fascia and arciform fibres, and then, by the bulging outwards or elongation of the fibres of the pillars themselves. Finally, the bowel passes into and distends the coverings of the cord in the scrotum, and the valve-action of the canal is, for the time, destroyed.

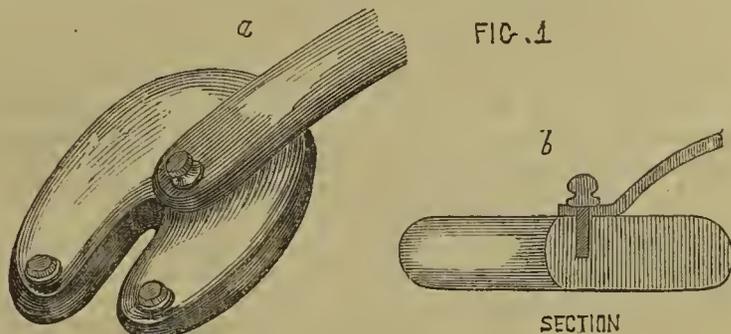

In many of the smaller cases, the sides of the canal resume their valve action for a while when the protrusion has been some time reduced, so that the rupture does not descend at once, and may remain in abeyance for days until a portion of bowel or omentum is again forced in. In the direct variety of hernia, the fascia transversalis and generally more or less of the conjoined tendon, yield before the pressure, the peritoneum being at this point (opposite the triangle of Hesselbach) so loose and movable (forming the superior false ligament of the bladder), as to supply readily almost any extent of hernial sac. Sometimes the fibres of the conjoined tendon are split, and give no covering to the sac. More rarely, a direct hernia, while still internal to the epigastric artery, yet escapes at the outer border of the conjoined tendon, and may obtain a small covering of cremaster fibres, and assume a slight obliquity of direction.

On dissecting the coverings of a hernia of whatever size, it will be found that their weakest part, both behind and in front, is that opposite to the long axis of the hernia or inguinal canal. If, consequently, it is attempted to prevent the entrance of the bowel into the sac by the pressure of a convex surface, such as is found in most trusses in common use, the effect is simply to reverse the action of the bowel on the front walls of the sac, and invert its convexity into the canal, and, at the same time, to perpetuate or increase the injurious backward pressure upon the already weakened posterior wall of the inguinal valve.

The theoretic perfection of a truss pad would be one which would fulfil four indications—viz., 1st. To oppose resistance to the first egress of the bowel through the deep ring by flat pressure over its site. 2nd. To press firmly upon the outer pillar and Poupart's ligament, so as to prevent their yielding before the tumour. 3rd. To press firmly and independently upon the upper wall of the canal, lying behind and above the inner pillar; and, lastly, to leave the axis of the canal and the superficial opening uninvaginated and not stuffed out by the front coverings of the rupture.

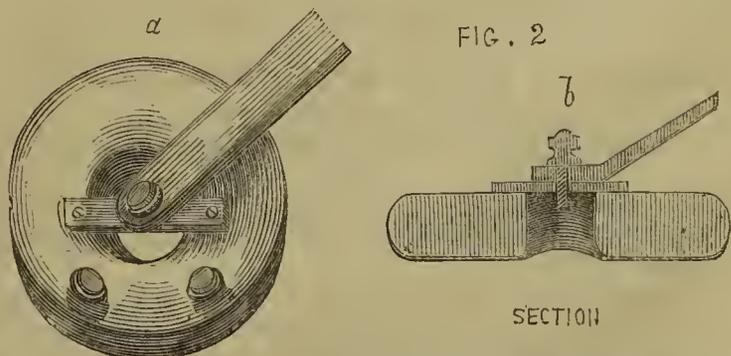

The ordinary neglect of these indications has led to the practice of putting on convex truss pads, under the use of which the hernial openings are continually widened by invagination of the skin and front coverings of the hernia, giving rise to a gradual increase of the rupture in size, as noticed each time it is suffered to come down. The constant wearing of the truss, with the view of producing a cure by gradually lessening the rupture and closing its openings, thus produces the very opposite effect of enlarging them. This effect is much increased by the constant boring or lateral motion of the side spring during walking in those trusses which have no joint between it and the pad.

To meet these requirements, I devised a truss-pad for oblique hernia, having a perfectly flat surface, rounded off at the edges, and arranged in the shape of an oblique horse-shoe, with one end longer than the other (see Fig. 1). The bow of

the bend is placed over the deep opening of the rupture, and the two ends over the two pillars of the ring, respectively following their several directions and obliquities. The cleft or fissure is placed over the axis of the canal and superficial ring. This truss-pad has the additional advantages of permitting the cord to emerge over the pubis without being subjected to pressure, by placing it within or under the cleft. The ends of the pad are also placed on each side of the pubic spine, so as to avoid a source of annoyance resulting from chafing of the skin over this bony projection, which is so commonly experienced in wearing the ordinary pads.

For direct hernia, also, I have devised an ovoid ring pad, with a flat bearing margin, intended to surround the margins of the direct opening, and to prevent their dilatation without invaginating the front coverings of the rupture into the hernial aperture (see Fig. 2). The hole in this pad (like the cleft in

the horse-shoe) permits of a certain degree of projection of the skin into it, sufficient to fix and hold it from shifting under

the pressure of the side spring or belt, without at the same time permitting the sac or bowel to project, for which a much wider interval would be necessary. These pads, in fact, effect, as nearly as mechanical appliances can do, what the fingers of the Surgeon do when he is holding up the rupture of a patient without invaginating the sac. For ordinary purposes, these pads may be made of boxwood well smoothed off. I have now a great many such in use, both upon patients who have been operated on for the radical cure (after which I consider their temporary use to be essential to support the newly-formed adhesions, without causing their absorption), and upon others who have objected to an operation, or in whom I have considered it inadvisable. They keep their places quite as well as the common pads, and have kept up ruptures which no other truss has been able to accomplish.

An India-rubber water cushion may be fitted to the surface of these pads, which will relieve the skin under their immediate pressure in cases where this is necessary. Mr. Matthews, of Portugal-street, has fitted some for me latterly, which have been very satisfactory. In infants, the pad so protected may be fastened to the body and thigh by an elastic figure of 8 band, of sufficient power to retain the rupture without being liable to shift or to interfere with cleanliness or the movements of the child.

In special cases I have had recourse to a lever spring within the pad itself, acting by two movable ends at the lower part upon a joint at the upper part, in conjunction with the pressure of the side spring or belt. By means of these pad springs we obtain an increased pressure at the lower end of the pad, which enables us to overcome some of the difficulties arising from a protuberant abdomen or projecting hips, as well as those resulting from a peculiar direction of force in the rupture itself. These pads have been worn in many very difficult cases with the best possible results. In some adult cases I have watched, a decided diminution of the size of the rupture has ensued.

It is, however, a matter of common remark, that few cases of cure, comparatively with the number of cases and trusses worn, have resulted from treatment by pressure only, even in the young, and how very rarely such a result ensues in the adult ruptures. In difficult and large cases I have employed a truss-pad split into two halves for independent pressure upon the two pillars. Each half is acted upon by the separate ends of a spring going round the hips like a double truss. The twin halves are connected with each other by an elastic or leather strap.

It has, therefore, long been a desideratum in Surgery to obtain a method of procedure at once safe and efficient to effect a radical cure of this very common and serious deformity. If by a radical cure is meant such a closure of the groin as to render the production of a rupture on that side ever afterwards impossible, then such an effect is no more within our reach than that the cure of an aneurism guarantees against any more aneurisms on the artery operated on; or an operation for urinary calculi against the formation of more stones; or amputation or excision for diseased bone against any more diseased bone; or dividing tendons for deformities against the return, in a certain percentage of cases, of the same, or a like distortion. But if it is meant by a radical cure, that the parts shall be rendered more secure against rupture than the same parts were before the rupture, in a proportion of cases quite as great as the success in most Surgical operations, then I conclude (from the experience of nearly 100 cases during the last six years) that, by the operations which I propose to describe in future papers, this great desideratum may be arrived at with as little or less risk to life or limb as in any Surgical procedure of like importance.

CLINICAL NOTES AND OBSERVATIONS.

By Mr. F. A. BULLEY, F.R.C.S.,

Senior Surgeon to the Royal Berkshire Hospital, Reading.

RUPTURE OF THE LIGAMENTUM PATELLÆ OCCURRING SOME TIME AFTER A FRACTURE OF THE BONE.

A short time ago, while inspecting some prisoners brought into the County Gaol at Reading, I was struck by the peculiar appearance of the knee-joint of one of them, a carpenter, who told me he had received a fracture of the knee-pan about three years previously.

On examining the joint more particularly, I found the patella drawn completely out of its natural position, and lying above the condyles of the femur, with the remains of its ligament, shrunk and contracted, attached to its lower portion. It had been entirely separated from its connection with the tibia, and its absence caused a deep transverse hollow in front of the joint.

On examining the retracted patella itself, I found that it had been broken across at about the line of junction of its lower third, the fragments having been united by a short intervening ligament of about half an inch in thickness, which allowed of a very slight lateral movement of the fractured portions. Flexion of the joint was performed but imperfectly, by reason, probably, of the limb having been kept constantly in nearly a straight position by means of a jointed steel instrument, with a stop, which allowed only a very limited movement of the joint in walking. Extension was equally difficult, on account of the extensor muscles having lost their attachment to the tibia, and he was obliged to give the leg a kind of swing to bring it into the straight position in getting along.

He stated that, about three years before, while playing at cricket, he slipped down, and broke the patella, which, being treated by the elevated straight position, resulted in a ligamentous union with a limited power of flexing the joint. He does not recollect having worn any particular apparatus after this accident. About twelve months after this, in coming downstairs, he again fell, receiving a fresh injury to the part, for which it was thought necessary again to adopt the straight position in bed; and, after a time, he became again able to resume his usual occupations, an instrument having been provided to guard against any great or sudden flexure of the joint. Some time after this, having neglected to put on the instrument, he slipped up for the third time, by which, he says, the parts were torn asunder, but being unwilling to undergo any further methodical treatment, he contented himself with reapplying the instrument, and, as the effects of this accident were not by any means so severe as the former ones, he soon regained his usual limited power of walking upon the limb.

I am not aware that any case precisely similar to the above has ever been recorded by Surgical writers. Mr. Fergusson mentions a remarkable instance of a patient who broke the patella five years before, the fragments remaining separated about an inch. On being brought into King's College Hospital for an injury of the same knee, it was found that the lower fragment had been broken transversely, while the newly-formed ligament above remained uninjured. It is difficult, in this latter case, to suppose that the small portion of bone below the ligament had been fractured, in the ordinary manner of such accidents, through its pulley-like position on the condyles; but it goes to show the great power of resistance of the intervening ligament which would thus allow the tearing apart of structures apparently much more capable of resisting the effects of muscular force, than the comparatively recent connecting tissue of the fracture—a fact which is strongly illustrated by the case I have related.

PRACTICE OF MEDICINE AT ROME.—Dr. Moriarty, of Dieppe, in a communication to a French journal, states that it is at the Pharmacies, indicated by the single word "Farmacia," that the Doctors hold their consultations every day at fixed hours, at the modest sum of a franc per head. It is there, and not to their own houses, that all communications are addressed to them. "Our confrères at Rome, who are modest, polite, and communicative, seem to lead a kind of nomad life. When you ask them their address, the great probability is, that they will give you that of a Pharmacien; and I recollect the astonishment with which a young Physician regarded the announcement of my intention of paying him a visit at his own house. The usual mode of remunerating the Profession is by annual contract, the sum of 200 francs per annum being the sum generally paid by a prince for attendance upon himself, family, and servants. When there is a vacancy in a commune for a Doctor, one is engaged, with emoluments of from 500 to 1000 francs per annum. It is not very long since that a meeting took place in a commune, with the object of presenting to a Doctor a testimonial for the zeal, skill, and humanity which he had constantly exhibited during twenty years. The proceedings were published; and after a whole column had been devoted to the recital of the praises of this worthy man, it was announced that a sum of about fifty francs had been allotted to him."

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

EXTENSIVE SUBCUTANEOUS MELANOSIS; THE TUBERCULAR SARCOMA OF ABERNETHY—DEATH—AUTOPSY—SIMILAR DISEASE IN THE CHEST AND ABDOMEN.

(Under the care of Mr. LAWRENCE.)

For the report of this very interesting case we are indebted to Mr. Lawrence's House-Surgeon, Mr. Eccles.

The patient, J. F., aged 33, was admitted in a very emaciated, low condition, and with a peculiarly anxious expression, on January 28, 1864. He said that, eighteen months ago, he first perceived a lump in each groin about the size of a hazelnut, for which he could not account. Six months after this, another one appeared, just below the umbilicus, which, according to his brother, was at first very like an ordinary wart, and, after rapidly increasing in size, was tightly ligatured, and separated at the end of a month, leaving only a black mark to indicate its original situation. He then stated that, until two months ago, no fresh nodules appeared, up to which period he had felt quite strong and well; but that at this time the hundreds which were scattered all over him now made their appearance, and that he had gradually been reduced to the condition he was in on admission. For eleven years he had been a railway porter; was married, and had two healthy children. His parents were alive, but he had lost a brother some time ago, but did not know of what he died.

When admitted, the original lumps in the groin were about the size of a small egg, hard, nodular, very movable, and apparently an enlargement of the glands of this situation. Scattered over the trunk, lower and left upper extremities, were innumerable nodules, which varied in size from a millet seed to a full-sized pea, and were apparently, for the most part, situated in the subcutaneous tissue. They were thickest over the abdomen and back, but, in the thighs, laid chiefly in the course of the vein. Similar nodules were felt in the situation of the lymphatic glands in the neck. He complained of some pain in the right lumbar region, but otherwise did not suffer much, save from a continual sensation of sinking. No blood was detected in the urine, although he said that of late he had passed blood in his water.

Good nourishment was given him, and palliative treatment followed, but he gradually sank, and died on February 8, eleven days after admission.

On February 9, Mr. Eccles made a post-mortem examination at the patient's own house. On reflecting the abdominal integument, the nodules were proved to be, with few exceptions, entirely subcutaneous. They were easily separable from their connexions, were very uniform in consistence, which was that of soft putty, and quite black. One rib, just at its junction with the costal cartilage, was infiltrated, and the bone softened, so as to be easily cut through with a scalpel. Somewhat larger nodules were scattered over the interior of the thorax, beneath the pleura; and a like condition existed in the pericardium, the cavity of which was filled with a dark serous fluid. Similar deposits were found beneath the visceral layer of the pleura, especially between the lobes, and some of smaller size in the substance of the lower lobes of each lung. The bronchial glands were apparently wholly infiltrated. The heart was studded on its exterior with numerous nodules (very like ordinary dry black currants), which here and there seemed to involve the muscular tissue of the heart. Similar deposits were situated beneath the endocardium, but the valves were unaffected. The liver was only slightly affected, the disease seemingly extending from the surface into the substance of the viscus. The capsules of the kidneys were greatly affected, especially the right, only a very little of the structure of these organs being apparently implicated. The spleen was very firm and small. No deposit could be detected. Attached to the omentum were several masses of disease, of which the largest were two lying in the cavity of the pelvis, each somewhat larger than a man's fist. On cutting through these, they were apparently uniform in structure throughout. The intestines were seemingly natural, save that the rectum contained some pinkish-coloured faeces. The brain, orbits, etc., could not be examined, unfortunately, especially so as the

man gradually became blind a few days before his death. The mesenteric glands were affected in the same way as the bronchial, and there were numerous nodules beneath the peritoneum in the sub-peritoneal tissue.

The almost exclusive distribution of the disease in the areolar tissue of the body was remarkable, and perhaps will account for the slight amount of continued or severe pain that the patient at any period suffered.

Mr. Lawrence remarked, at the bedside of the patient, that it was a case which Mr. Abernethy would have classed under his "tubercular sarcoma" division of disease.

HOSPITAL NOTES.

MERCURY IN SYPHILIS.

ANY one who is in the habit of going about from Hospital to Hospital will, we think, find that Physicians differ not less as to their facts, than they do as to their theories. In nothing more than in the treatment of disease. A plan that is lauded by one Physician is said by another to be highly unphilosophical. At one Hospital a patient with rheumatic fever is wrapped up in a blanket, and when the heart is examined, a stethoscope, "first warmed," is cautiously inserted between the folds; in another we are told that it is very important to keep the patient cool. We are told in the morning that some new drug is an excellent remedy in chorea, and in the afternoon a case is pointed out to us which has been successfully treated by syrup and water. We can thus only collect personal opinions. Perhaps there is no drug which is so much relied on by some, and so much deprecated by others, as mercury. Some give mercury in all cases of syphilis, and yet we have seen a patient who had indurated chancre and the usual sequelæ, well a year after the last symptom, although he had never taken a grain of it. Mr. Hutchinson has long taught the doctrine, that it does not cure syphilis by any specific action, but that its value is, that it absorbs lymph. For instance, in iritis its use is, that it can clear the iris and the choroid from lymph, so that the pupil is kept free and the retina uninjured.

Now this view is important; for if the influence of mercury in syphilis is simply that it absorbs lymph, we may, one would think, reason as to its effects from what we can see in the iris to what we can hear in pericarditis. Not long ago we mentioned this view to one of our most eminent Physicians, who deprecated the use of mercury in pericarditis, and asked how it happened that mercury absorbed a nodule of lymph in the iris, and had no effect on lymph elsewhere? We were somewhat astonished, when he rolled the question back, by asking if we really believed that mercury did absorb lymph. We know that several Physicians, as Dr. Hughes Bennett, never give mercury in iritis, nor, we believe, does Dr. Bennett give it under any circumstances; yet we know of but one ophthalmic Surgeon in London, Mr. Zachariah Laurence, who does not use it, except a few who give very large doses of the iodide of potassium in its stead, as ten or fifteen grains three times a-day. It must be admitted, that now and then a patient during salivation for iritis in one eye, will have an attack in the other. We have seen this several times, and it is especially mentioned in Mr. Hutchinson's work on "Syphilitic Affections of the Eye." Dr. Walshe has known pericarditis come on in a patient who was under treatment for ptyalism. At our last visit to Guy's, Dr. Gull remarked, in the clinical wards, that he never gave mercury in either pericarditis, pleurisy, or even iritis. He said that he did not believe that it absorbed lymph, but that, on the contrary, it tended to prevent its absorption.

It seems to us that the most positive proof of the power of mercury in procuring the absorption of syphilitic lymph may be obtained in the case of indurated chancres. Probably there is not a single Surgeon who enjoys adequate opportunities for observing the course of well-characterised induration under treatment who doubts on this point. A disc, almost as hard as cartilage, will soften and melt away in the most conclusive manner under its influence. If the mercury be suspended prematurely, the induration will relapse; if it be resumed, it will again diminish. In some cases of iritis with free effusion, its effect is, we think, scarcely less positive.

This view as to the action of mercury in syphilitic disease harmonises with what is now generally taught as to the treatment of soft chancres. It is said by many that soft chancres are never followed by secondary symptoms, but this is still disputed. At all events, it is generally held that, in this form

of primary disease, mercury can do no good, and may do much harm. Mercury should only be used when the chancre is indurated; yet, probably, many Medical men treat all cases of primary syphilis by mercury, but those who do so as a mere matter of routine, without investigating the validity of the opinions strongly urged against the indiscriminate use of this drug, incur a grave responsibility.

We recently heard Dr. Wilks remark that he had not given up his faith in the efficacy of mercury in many diseases, especially syphilis, although he felt doubt as to its value in arresting the inflammatory process. His views on this subject we give below.

The case which suggested the remarks was that of a girl with secondary symptoms. She was being treated with the biniodide of mercury with excess of iodide of potassium, in the form of a drachm of the solution of bichloride of mercury to three grains of the iodide of potassium, a mixture which he had often found to be beneficial when iodide of potassium alone had failed.

In this mixture there is double decomposition, biniodide of mercury and a little chloride of potassium being found. The red biniodide is soluble in the iodide of potassium, which is in excess. The green protoiodide was a favourite remedy with Dr. Brown-Séquard in the treatment of epilepsy and paralysis, when it appeared to be due to syphilis. He would give one-third to one-eighth of a grain, along with four, five, to ten grains of the iodide of potassium, three times a-day. Mercurial inunction is considered by many Surgeons to be by far less deleterious than administration of the drug by the mouth. This is especially a favourite plan with Mr. Wornald. We saw under Dr. Wilks' care a man with an excavated syphilitic ulcer in the throat, involving the soft palate and uvula. He was making no progress towards cure until mercury was used by inunction, when, in a few days, the healing process commenced.

We need scarcely mention that one of Dr. Wilks' colleagues has written a book to draw the attention of the Profession to the deleterious nature of this drug. Again, Mr. Cock, the Senior Surgeon, as did also the late Senior Physician, Dr. Addison, holds that diseases of bone generally ascribed to syphilis are due rather to the mercury used, or rather abused, in the treatment of it.

It seems to us that nothing is given by some more confidently than mercury to "correct the secretions," to act as an "alterative," or, to use a common and rotund phrase, to "unload the portal system." Then, in the other extreme, some will not give it in pericarditis, nor even in acute iritis, when they can see a nodule of lymph on the iris.

MERCURY IN INFLAMMATION.

Next to its employment in syphilis comes the use of mercury in inflammatory disease. Dr. Wilks considered that, although it did not arrest inflammation, yet that after the deposition had occurred, either in the lung, pleura, or elsewhere, that its absorptive power could scarcely be denied. He also differed from those who thought mercury of no use in inflammations of mucous membranes, for he had no doubt of its occasional very great value in bronchitis, especially in the acuter forms attacking the smaller tubes. We suppose a great deal would depend on the condition of the kidney. In diphtheria or croup, with albuminous urine, mercury would probably not be considered advisable. And yet, not very long ago, in one of our hospitals, we saw a child treated with mercury for croup, although the urine at the time was known to contain a good deal of albumen.

MERCURY IN BRIGHT'S DISEASE.

We suppose, however, that no one would give a course of mercury for any local affection, if the patient had chronic Bright's disease. It is more the fashion now to treat the patient than his disease, or at least to study the disease in relation to the general tissue-health of the patient. Not very long ago, if a patient's sight failed, either gradually or suddenly, and there were no external defects (in a case, for instance, which would have been called "amaurosis"), it was a very common practice to give mercury to salivation. Now-a-days, no one would be justified in doing this, without first making an ophthalmoscopic examination, to see on what actual disease the amaurosis depends. "If," says Dixon, "the ophthalmoscope had done nothing else than limit the wholesale administration of mercury in eye diseases, it would have conferred an immense boon on mankind." If the so-called amaurosis depended on syphilitic choroiditis, mercury would do good, but if it were merely a local manifestation of tissue degeneration in Bright's disease, it could do nothing

but harm. If the ophthalmoscope be not used, the urine should, at all events, be examined before giving mercury, and the presence of albumen, if indicative of renal disease, would, to most Physicians, be a bar to the administration of mercury. Dr. T. K. Chambers writes:—"There is no physical agent capable of doing so much harm in albuminuria as mercury."

As further proof of the danger of using mercury in renal diseases, we may mention that the excessive use of this drug seems to damage a healthy kidney. A young man, lately under the care of Dr. Wilks, was seized with albuminuria after a course of mercury. Dr. Blackhall, in his treatise on "Dropsy," published in 1814, gives several examples of dropsy, with albuminous urine, in persons who were mercurialised. In cases of poisoning by mercury, the kidneys are found gorged with blood, and the urine albuminous, but then lead and other substances produce the same effect.

DR. WILKS ON MERCURY.

In further illustration of this subject, we add the following, recently gathered from Dr. Wilks' observations at the bed-side. It will be seen that he agrees with Mr. Hutchinson in his view as to the mode of action of mercury as a remedy.

The beneficial effects of mercury and some other medicines in syphilis have caused them to be regarded as anti-syphilitic remedies, as if they had some counteraction on the venereal virus. This has been the view of those who have long had faith in their value; for, it must be admitted, there are those who have discarded their use from observing cases progress favourably without them. It is probable that the latter class of Practitioners have not sufficiently discriminated as to the cases in which a good result may be looked for.

Dr. Wilks has long thought that remedies of the kind mentioned are anti-syphilitic, inasmuch as they are absorbent; for it has been shown of late years that the great peculiarity of the venereal disease is exhibited in the exudation of an albuminous matter into the tissues. Why they should be peculiarly useful in syphilis arises simply from the fact, that in no other disease do we see such a disposition to the production of new albuminous matters; but, should new products arise under any circumstances, these same medicines are seen to have the same effect—a sufficient proof that their action is not limited to syphilis alone. In enlargement of the lymphatic glands, in bronchocele, various dropsies, etc., these remedies are eminently useful.

All observers are agreed that mercury, iodine, and some other medicines, if long persevered in, produce an atrophy of the tissues, shown externally by a wasting of the mammæ, testes, etc.; but that if any morbid material exist in the body, and which is always of a much lower formation than the tissues themselves, these will be destroyed in a very short time by such remedies, and long before any effect be discerned on the vital structures of the body. The medicines pick out, as it were, the new and morbid materials. Dr. Wilks has always acted on this principle in administering mercury in syphilis (constitutional or so-called secondary syphilis), and has been able to explain its advantages in certain cases and its failure in others. He has observed a disposition in many Practitioners to administer it in early stages of syphilis and ignore it in the latter, especially if the patient has become cachectic, and by so doing have often failed to relieve either. If one of the first symptoms of venereal taint be a roseolous or lichenous rash, such medicines may produce not the slightest benefit, whereas some saline or antimony may effect much more. Again, if a person long suffering from syphilis fall into a cachectic condition, the habit has been to give tonics, etc., on the supposition that the cachexia is a mere tertiary stage, whereas mercury may often be administered with the greatest success. Dr. Wilks has treated many cases of patients very cachectic, with enlargement of the bones, lymphatic glands, and large ulcers in the throat, where cod liver oil, quinine, and such remedies, produced no good, but a few days of mercurial inunction sufficed to heal the ulcer and benefit the patient more than months of the tonic plan had done.

Dr. Wilks, therefore, holds to the opinion, which, if true, is important from its simplicity and its application to practice, that mercury, iodine, potash, and such remedies, are anti-syphilitic, because in the venereal disease more than in any other affection is there a production of a low, organisable material, which is easily absorbable by such remedies, whose action is seen elsewhere. The rule of treatment, therefore, is to give them where such disposition appears to exist. The proof lies in the fact that, if such a secondary symptom as a node be removed, the disease still remains in the system, and

is ready to show itself again in the same manner as before. The remedies are constantly removing the effects without touching the cause.

THE MAJOR OPERATIONS OF MEDICINE.

We have long been in the habit of collecting statistics of the major operations of Surgery. The Physician, who stands by the bedside of a young patient, ill with rheumatic fever (before the attack, in robust health, and having to look forward to a life of hard work), has the same kind of responsibility as the Surgeon has who decides whether a limb should be amputated or not; and this responsibility, not only as to the case then the subject of treatment, but as to the influence his practice will have on the minds of students who will afterwards practise, more or less, on the model of their teacher. In the present prevailing scepticism as to old-established remedial agents, might it not then be well to collect statistical records of Operative Medicine? The proportion of cases submitted to really active drug-treatment is but small; and it would be very valuable to ascertain, if practicable, whether in these benefit or the reverse is obtained. Perhaps the number of patients under Dr. Jeaffreson's care in St. Bartholomew's who, during the last twelve months, have been freely salivated, is not larger than could be easily comprised in a detailed tabular statement. It would be very instructive to know what were the special circumstances in each case, and what were the results obtained. Again, we should like to record in tolerable fulness all the cases in which, during 1863, Dr. Gull ordered for his patients in Guy's the use of the lancet; the reasons for its employment, and the results. The treatment of delirium tremens, by heroic doses of digitalis, the employment of belladonna, to its full physiological effect, in certain diseases of the spinal cord, might also rank as major Medical operations. A few years ago, cinchonism, in the treatment of fever, might have held a similar place; but, thanks to the collection and publication of evidence of the kind we speak of, tolerably unanimous opinions are now held respecting it. Before the use of the ophthalmoscope, Mr. Travers, Mr. Tyrrell, and other Surgeons, who paid special attention to eye diseases, were in the habit of obtaining most brilliant results in amaurosis by the use of mercury. In how many cases, during last year, did their successors at Moorfields prescribe mercury for anaurotic diseases, exclusive of those of syphilitic origin, and with what degree of benefit? In recommending statistics, we do not mean the coarse methods sometimes allowed to assume that name, but the discriminative grouping of really similar cases. The plan of lumping together all that can by any possibility be made to come under one name, and then attempting to strike averages, is much like that of the celebrated F.S.S., who persisted in always weighing his letters for the post by the half-dozen together, and can only lead to like annoyance and disappointment. The fallacy of the inductive method is often rather a fallacy in collecting facts for induction.

IMPORTANCE OF KNOWLEDGE OF NATURAL COURSE OF DISEASE.
