The decline of the cattle industry has been in the main due to range lands having been settled up and put to more intensive use and the inability of the industry to compete with other agricultural pursuits on tillable lands. Production can be increased only at increasing costs. The demand for beef in the United States is distinctly elastic, and there is a marked tendency to use substitutes when prices rise. Duties on cattle and beef in the past have not had an appreciable effect on domestic prices and have been a negligible factor in the evolution of the industry. Neither Canada nor Mexico has been able to compete with the United States in fat animals, and the importation of lean animals from those countries has not been sufficient to have any marked effect on prices. The demand in the United States for beef of the type that would have to be imported from overseas is small, and it is doubtful whether the amount excluded by duties has appreciably affected prices.

The conclusions are reached that the domestic cattle industry in its present state is dependent very little, if at all, upon duties on cattle and beef; that the conditions under which future duties can increase prices and stimulate production are peculiarly difficult; and that protective duties for the cattle industry will eventually impose a burden on the public out of proportion to any gains that may accrue.

Studies of the production of cattle in the United States and Argentina and statistical tables are given in the appendixes. A bibliography is included.

American importation of Canadian wheat, A. E. TAYLOR and E. M. BRAND (*Wheat Studies, Food Research Inst. [Stanford Univ.], 3 (1926), No. 1, pp. 76*).—From 1921–22 to 1925–26 the United States imported an average of 9,728,000 bu. of wheat from Canada annually in bond to be ground and the flour exported, and an average of 6,313,000 bu. for domestic consumption, the latter paying a duty of 30 to 42 cts. per bushel. The production and classes of wheat produced in the two countries, the manufacturing considerations, transportation, relative prices, and other factors affecting the importation for domestic consumption and for export of flour are discussed. A table is included showing the daily prices of comparable grades of dark northern spring wheat in Minneapolis and of Manitoba northern wheat in Winnipeg from July 2, 1923, to June 30, 1926.

Survey of the wheat situation, August to November, 1926, M. K. BENNETT, J. S. DAVIS, ET AL. (*Wheat Studies, Food Research Inst. [Stanford Univ.], 3 (1927), No. 3, pp. 141–175, figs. 8; Sup., pp. 2*).—A continuation of the studies previously noted (*E. S. R.*, 55, p. 786), including a study of the crop developments, price movements, rate of marketing, international trade, the effect of the advance in ocean freight rates, and the international position and outlook.

The world wheat situation, 1925–26: A review of the crop year, J. S. DAVIS ET AL. (*Wheat Studies, Food Research Inst. [Stanford Univ.], 3 (1926), No. 2, pp. 77–140, figs. 12*).—This is the third of the series previously noted (*E. S. R.*, 54, p. 884) and reviews the production, consumption, stocks and carryovers, price movements, and the milling of, and the international trade in, wheat during the crop year 1925–26. Relevant statistical data are pre-

sented in appendix tables. The progress and workings of the Canadian Wheat Pool, returns to wheat growers in different countries, and the developments in future trading markets are discussed.

The Producers' and Consumers' Conference, held at Bathurst, New South Wales, September, 1926 (*Sydney: Govt., 1926, pp. VI+105, pls. 35, fig. 1*).—This is the report of the conference convened at Bathurst by the Minister for Lands of New South Wales to trace the causes of the disparity in prices and the waste of foodstuffs and to make proposals for improvements and reforms. The conference was attended by 139 producers' representatives, 61 consumers' representatives, and 19 special official representatives. The reports of the 13 producers' committees, each dealing with the marketing problems of particular industries or branches or groups of industries, of the 4 consumers' committees dealing with the questions of distribution of different groups of commodities, of the special committees on transportation, marketing facilities, finances, and weights and measures, and of the executive committee are given.

Statistics and graphs on production, consumption, prices, exports, imports, etc., for the several commodities, and other matter pertaining to agricultural organization, legislation, and production, and the assistance given by the Commonwealth to production and export of primary products are included in part 2.

The rural industries of England and Wales.—I, Timber and underwood industries and some village workshops, H. E. FITZRANDOLPH and M. D. HAY (*Oxford: Clarendon Press; New York: Oxford Univ. Press, Amer. Branch, 1926, vol. 1, pp. XIV+239, pls. 11*).—This is the first of a series of four volumes giving the results of a survey made on behalf of the Agricultural Economics Research Institute of Oxford University to determine (1) the existing rural industries and the causes of their establishment in particular localities; (2) the various types of organization in these industries; (3) the economic and social factors of rural industries, the conditions of labor attendant on them, the connection between such industries and agricultural employment, and how far such industries tend to depress or ameliorate the lot of the agricultural worker; and (4) the prospects of development of existing industries, the introduction of new enterprises, and the reviving of former industries.

Handbook of rural social resources, H. ISRAEL and B. Y. LANDIS (*Chicago: Univ. Chicago Press, 1926, pp. X+204*).—Part 1 consists of 14 articles by specialists on different phases of recent achievements and developments in rural life. Part 2 comprises statements of the programs and present services of the national agencies that are members of the National Council of Agencies Engaged in Rural Social Work.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Tenth annual report to Congress of the Federal Board for Vocational Education, 1926 (*Fed. Bd. Vocat. Ed. Ann. Rpt., 10 (1926), pp. XI+171, figs. 12*).—This report presents a general report of the work of the board, a statistical report, and special reports of the different services, among which are the following:

Home economic education service (pp. 15-43).—The growth and developments during the three years ended June 30, 1926, in enrollments, programs of instruction, methods of handling the work, etc., in school and class; teacher training, and negro education are reviewed, and the aims of the next three years outlined.

Agricultural education service (pp. 44-83).—The enrollment, types of schools, and distribution of expenditures to Federally aided agricultural schools are

discussed. The progress and developments during the past three years in State programs, part-time evening schools, methods of teaching, supervised practice, and the improvement of teachers are reviewed.

Suggestive course outlines for vocational agriculture, J. E. HILL, A. W. NOLAN, and C. S. ANDERSON (*Ill. Bd. Vocat. Ed. Bul. 37 (1926), pp. 110, figs. 8*).—This bulletin is planned as a guide to aid boards of education and administrators in establishing and conducting departments of vocational agriculture and to help teachers in organizing and teaching the various courses. Suggestive course outlines, with reference books, are given for crops and soils, animal husbandry, and farm-mechanic enterprises. The method of planning and organizing material for teaching each job in the various enterprises is illustrated by a lesson plan or a "teaching layout" of a particular job, and a stenographic report of a class recitation. An appendix gives suggestions relative to supervised farm practice of students, special activities for agricultural departments of schools, and plans, equipment, and apparatus, and the plan of the Illinois Board for Vocational Education for vocational agriculture.

Make extension work more effective, M. C. WILSON and W. W. CLARK (*Wisconsin Sta. Bul. 387 (1926), pp. 32, figs. 12*).—This study was made to ascertain the effect of service in materials upon the value of service in information in extension work, to what extent farmers adopt practices advocated by extension workers, and the effectiveness of different types of extension teaching. It is based upon 715 records collected by survey parties in a detailed survey of an alfalfa introduction project, and represents 93 per cent of the farms in 3 areas of 1 to 2 townships in size located in Clark, Winnebago, and Waushara Counties, Wis.

In Waushara County alfalfa requires lime, inoculation, hardy strains of seed, and careful culture. Although there was no county agent in this county, considerable extension work had been done by the agricultural college and lime and other materials could be had, yet up to 1923 only 15 per cent of the 240 farmers interviewed had started alfalfa. Following the establishment of satisfactory service in materials in 1923, the number of growers increased to 63 per cent in 1925. In Clark County before 1924, lime and seed had been available, but there was no local extension information and only 5 or 6 farmers grew alfalfa. In the two years following the first extension work more than 20 per cent of the farmers started growing alfalfa. In Winnebago County, where materials are not essential for alfalfa growing, the practice had been gradually adopted during the previous 20 years, and in 1925, 93 per cent of the farmers were growing alfalfa.

Eighty-six per cent of the growers attending extension activities or making contacts with extension workers regarding alfalfa reported that they had been influenced by such work. Meetings, particularly farmers' institutes, influenced 76 per cent of those attending and 47 per cent of all growers; news stories and bulletins influenced 81 per cent of those reached and 41 per cent of all growers; and adult demonstrations and farm visits, 61 and 46 per cent, respectively, of those reached, and 10 and 4 per cent, respectively, of all growers.

Data regarding other phases of extension work, as well as alfalfa, in the 3 areas show that of the practices influenced, 65 per cent were influenced by propaganda methods, 13 by personal service, 14 by object lessons, and 22 per cent indirectly. Condition of land occupancy, size of farm, and character of roads were found to have had but little effect on the adoption of better practices due to extension efforts.

The teaching of science and the science teacher, H. BROWNELL and F. B. WADE (*New York and London: Century Co., 1925, pp. XI+322, pls. 4, figs. 2*).—A textbook for teacher-training institutions and teachers desiring suggestions in science teaching. It is prepared with special reference to the relationship

of science teaching to education in general, particularly in secondary schools and the upper elementary grades.

Marketing of farm products, A. H. BENTON (*Chicago and London: A. W. Shaw Co., 1926, pp. XVIII+427, figs. 50*).—This book is intended for students beginning the study of marketing agricultural products, for farmers, and for business men. An analysis is made of the scope of marketing, its mechanical make-up, the methods used, and the services rendered, both under the old established private marketing system and the producers' cooperative marketing organization. The most important agricultural products of the United States and the less important ones presenting distinctive features are taken up in separate chapters. Other chapters review legislation relating to marketing agricultural products and the essential factors and difficulties involved in cooperative marketing. The appendix includes statistics of regional marketing associations, Federal classification standards for different products, and other information as to marketing and marketing organizations. References and self-test questions are included for each chapter.

Farm accounting: Principles and problems, K. F. McMURRY and P. E. McNALL (*Chicago and London: A. W. Shaw Co., 1926, pp. XIII+329, figs. 12*).—A textbook for college and high school classes in farm accounting. Part 1 covers the general principles of bookkeeping and accounting and special features and problems of farm accounting. Part 2 deals with additional records necessary to obtain cost records, the methods of determining valuation, the types of entries for different items, the use of farm cost accounts, etc.

Principles and practice of farm book-keeping, L. F. FOSTER (*London: Gee & Co., pp. VIII+476*).—A textbook of the principles and practice of farm book-keeping covering the knowledge necessary in the subject for degree and diploma in universities and colleges of England teaching agricultural and allied subjects.

Controlling expense by standards, S. A. DONHAM (*Jour. Home Econ., 19 (1927), No. 1, pp. 1-7*).—The procedure for making a household budget is outlined. The items of expense are grouped under savings, shelter, food, operating, clothing, and development, with each group subdivided into fixed charges, charges possible to estimate, and charges necessary to limit.

Rural sociology, C. C. TAYLOR (*New York and London: Harper & Bros., 1926, pp. [7]+509*).—This textbook is a study of rural problems and brings together a consideration of outstanding specific problems of rural life and the general principles of the science of sociology. Part 1 considers the foundations of rural society; part 2 the problems of rural isolation, tenancy and ownership, the rural home and family, the rural church, rural education, rural health, rural recreation, and rural art, and adequate rural religious and educational programs; and part 3 the farmer and his community, his town, his government, and civilization, and rural social psychology.

How to do research work, W. C. SCHLUTER (*New York: Prentice-Hall, 1926, pp. VII+137, figs. 4*).—This book attempts to explain "in understandable terms the fundamental tool of research, method, in relation to the actual procedure of discovering and solving research problems."

Research is stated to include (1) discovery of the problem and (2) methods of its solution. The steps in research procedure which are discussed in different chapters of the book are as follows: (1) Selecting the field, topic, or subject for research; (2) surveying the field to apprehend the research problem; (3) developing a bibliography; (4) formulating or defining the problem; (5) differentiating the elements in the problem and outlining; (6) classifying the elements in the problem on the basis of their relation to data or evidence (direct or indirect); (7) determining the data or evidence required on the basis of the elements in the problem; (8) ascertaining the availability of the

data required; (9) testing the solvability of the problem; (10) collecting the data and information; (11) systematizing and arranging the data preparatory to their analysis; (12) analyzing and interpreting the data and evidence; (13) arranging the data for presentation; (14) selecting and using citations, references, and footnotes; and (15) developing the form and style of the research exposition.

The author recognizes that it is not possible "to formulate any rigid theory of procedure which shall be correct regardless of actual conditions in practical fields of research," and that "methodology, because of its dynamic nature, being a means, not an end, defies portrayal in terms of formula or standardization." Nevertheless, it seems to him possible "to describe and explain the dynamic elements in research method in such a way that their validity and their soundness as guiding principles in the conduct of actual research in all fields may be attested by the consensus of informed opinion on research methods."

The book is addressed to and should be of service to directors of research and teachers and students of research methods, as well as to those actually engaged in organizing and conducting research. It deals with "the fundamentals of all research method," but "with their particular application in the field of business and social economy." The subject is presented in a concise, lucid, and orderly manner.

FOODS—HUMAN NUTRITION

The bacteriology of food, C. DUKES (*London: H. K. Lewis & Co., 1925, pp. IX+180, figs. 25*).—A text for college use written particularly for students of public health, but "of interest to bacteriologists, of whatever class, who are curious about the behavior and significance of microbes which do not belong to the special groups of which they have expert knowledge, and who seek to gain a wider outlook than is given them by their own specialized department."

Food from grains, A. MAURIZIO (*Die Nahrungsmittel aus Getreide. Berlin: Paul Parey, 2. ed., rev., 1924, vol. 1, pp. XII+461, pls. 2, figs. 180; 1926, vol. 2, pp. VIII+226, pl. 1, figs. 5*).—A revision of the volumes previously noted (E. S. R., 42, p. 456).

The chemical composition of the food grains, vegetables, and fruits of western India, D. L. SAHASRABUDDHE (*Bombay Dept. Agr. Bul. 124 (1925), pp. 38*).—A compilation of data for the most part obtained in the chemical laboratory of the Department of Agriculture, Bombay, India. The data include proximate analyses of various native food grains and vegetables, and acidity and total reducing and nonreducing sugars of various fruits, including plantains, pomegranates, grapes, figs, guavas, citrus fruits, mangoes, and dried dates and figs.

The energy value of milk as related to composition, O. R. OVERMAN and F. P. SANMANN (*Illinois Sta. Bul. 282 (1926), pp. 207-218, fig. 1*).—This publication includes details of the statistical methods by which the formulas given in a progress report (E. S. R., 56, p. 392) were derived and a discussion of the application of the formulas.

Fat soluble vitamins.—XXII, The comparative amounts of vitamin A and antirachitic factor in butter fat and cod liver oil, J. H. JONES, H. STEENBOCK, and M. T. NELSON (*Jour. Metabolic Research, 6 (1924), No. 1-6, pp. 169-187, pls. 2, figs. 4*).—This part of the investigation previously noted (E. S. R., 53, p. 264; 54, p. 489) consists of a comparative study of the potency of the same samples of butter and of cod-liver oil as sources of vitamin A and vitamin D. The vitamin A studies were conducted on rats and the vitamin D on dogs. The butterfat was obtained from the Wisconsin University creamery in November as a representative sample of a day's churning, and the cod-liver oil was a well-known commercial product.

Using the time of incidence as well as the cure of ophthalmia as criteria, the vitamin A content of the cod-liver oil was estimated to be from 10 to 20 times as high as that of the butterfat. As a source of vitamin D, or antirachitic vitamin, 0.05 gm. of the cod-liver oil proved more effective than 10 gm. of butterfat in preventive experiments, indicating that the oil is about 200 times as potent as the butterfat.

"The above values, of course, are not to be taken as absolute figures. They are bound to vary with the seasonal conditions under which the butterfat and cod-liver oil are produced and the method of preparation of the latter. In the light of knowledge that under certain conditions the antirachitic factor as well as vitamin A is required for normal growth, the statement that cod-liver oil may be 250 times as potent as butter may be taken to refer more to the antirachitic factor than to vitamin A."

Vitamin B in commercial meat residue and commercial egg albumen, G. R. COWGILL (*Amer. Jour. Physiol.*, 79 (1927), No. 2, pp. 341-345, fig. 1).—Commercial meat residue (the insoluble residue obtained in the manufacture of commercial beef extract) and cooked commercial egg albumin were found to be markedly deficient in vitamin B as tested by feeding as the sole source of this vitamin to rats in amounts constituting 44 and 35 per cent, respectively, of a ration having a caloric value of approximately 5.2 calories per gram.

Foods and cookery: A handbook for homemakers and teachers of home economics, compiled by M. H. HAGGART ([Ames]: *Iowa Homemaker*, 1926, pp. 254, pl. 1, figs. 26).—This practical handbook on food selection, preparation, and service, is a contribution from the foods and nutrition staff of the Iowa State College. As stated in the foreword by A. E. Richardson, "it is not only a compilation of the best of Iowa's recipes, but it has valuable dietetic information simply told, suggestions as to how to plan and serve meals, chapters on marketing, selection of foods, and table service."

Better homes recipe book, M. MILLS (*Boston: Boston Herald-Traveler*, 1926, pp. VIII+493).—A collection of tested recipes "essentially true to New England and New England traditions," with supplementary chapters on garnishes; temperatures, weights, and measures; suggestions for the diet of children; and selected menus for each month of the year and for special occasions.

The physiology of taste, J. A. BRILLAT-SAVARIN (*London: Peter Davies*, 1925, pp. XX+326, illus. 41).—To commemorate the centenary of the death of Brillat-Savarin his famous *Physiologie du Goût* has been translated into English, this volume being one of a special limited edition of 750 copies. The volume contains an introduction by A. Machen and a short biographical sketch in which it is noted that, with the exception of a translation appearing in 1883 in a small limited edition under the title of *A Handbook of Gastronomy*, no other complete translation has been published in England.

The physiology of taste (*Jour. Home Econ.*, 18 (1926), No. 9, pp. 520-522).—An editorial comment on the above with a plea for greater attention in meal planning to the sense of taste and its influence upon nutrition. "We think of meal-planning so much in terms of vitamin and minerals, protein and calories, that we forget it may also mean a skillful combination of flavors and textures by which the appetite is whetted and satisfied without danger of overeating."

The value of cocoa and chocolate as sources of protein in the diet, H. H. MITCHELL, J. R. BEADLES, and M. H. KEITH (*Jour. Biol. Chem.*, 71 (1926), No. 1, pp. 15-31).—As determined by the method employed in previous studies (E. S. R., 56, p. 188), the nitrogen of cocoa was found to have an average coefficient of digestibility (corrected for metabolic nitrogen in the feces) of 38 and an

average biological value of 37. A mixture of cocoa and milk containing equal parts of nitrogen and fed at a crude protein level of approximately 8 per cent gave a digestibility figure of 63 and a biological value of 70. These values are not far from the estimated values on the assumption that there is no supplementing action between cocoa and milk.

Since cocoa has an average crude protein content of 21.5 per cent, it would contain 8.2 per cent of digestible crude protein and only 3 per cent of net protein, showing that cocoa must be classed as an unimportant protein food. Chocolate containing a smaller percentage of crude protein would be even less important as a source of protein.

In the course of the investigation evidence was obtained that cocoa contains 0.55 per cent of creatinine and 0.24 per cent of creatine.

The effect on reproduction and lactation of differing proportions of meat in a mixed diet, F. L. MACLEOD (*Amer. Jour. Physiol.*, 79 (1927), No. 2, pp. 316-320).—The experiments reported in this study are regarded by the author as only preliminary in that they were continued for only a year. "For such experiments to be conclusive the number of animals studied should be much larger, each experimental animal should be continued on the diet at least through the entire reproductive life, and the diet should be studied through several generations."

In the first series of experiments the meat was fed fresh and raw in amounts of 10 and 40 gm. per rat per week as a supplement to a dry diet consisting of whole milk powder 12, powdered lemon juice and corn sirup 5, butterfat 5, dried spinach 2, dried carrot 5, patent flour 30, and starch 41 per cent. Four lots containing 2 males and 3 females each were placed on this diet at the age of 5 or 6 weeks, two lots receiving the small and two the liberal meat allowance, and were continued on the diet until they were slightly more than a year old. The adult animals ate an average of 70 gm. of dry food per week, thus making the intake of protein about 9.9 and 17.5 per cent of the food solids in the two diets.

The growth records in both groups were normal. To the 3 females continued on the low meat diet until the end of the experiment 6 young were born and none were raised, whereas 78 were born to the 3 females on the high meat diet and 30 of these were raised to the standard age of weaning. The average weight of the young on weaning was 29.1 gm., which is below the average normal weight at this age. One male and 2 females from every litter born on the meat diet were continued on this diet. All grew at a sub-normal rate and were extremely nervous, and although there was considerable breeding only one litter of 5 was raised.

In a second series the meat was dried and incorporated in the dry diet, which was the same as that of the first series except that the meat replaced an equivalent amount of starch. Two lots, one on the high and the other the low meat, were started when the animals were 5 or 6 weeks old and two other lots at from 3 to 4 months of age.

There was less breeding on the dry than on the fresh meat diet and not so marked a difference between the low and high feeding. Two of the 4 females on the low meat diet bred, and one litter of four was raised. Of the 6 females on the high meat diet only 2 bred, one of these producing 35 young, of which 32 were raised to weaning. There was no breeding in the second generation.

An additional series of experiments was run on the dried meat diet, with an increase in the amount of dried milk from 12 to 16 per cent. This increase, while producing no significant change in the rate of growth, made possible successful rearing of the young on the diet containing only 3 per cent of dried meat and a still better record on the higher proportion of meat.

"Although, in general, these experiments seemed to show improvement in reproduction when the proportion of meat in the diet was increased, it must be pointed out that the results are not conclusive. Nearly all of the animals were unusually nervous and somewhat below the general average of our colony in vigor. Further experiments of this type are needed to determine whether the use of other vegetables or the same vegetables in different proportions would give better results."

Infant feeding in the Tropics, R. BROOKE (*Amer. Jour. Trop. Med.*, 6 (1926), No. 6, pp. 403-419).—In the opinion of the author, the problem of infant feeding in the Tropics differs from that of temperate zones in two respects only—quantity and substitutes. Owing to the continuously hot and humid climate the caloric requirements are considered to be lower and the dangers from overfeeding higher than in temperate zones. The difficulty in securing fresh milk and preventing spoilage makes it necessary to use substitutes for artificial feeding. For this purpose powdered milk is considered more satisfactory than condensed milk. Since 1923 powdered milk (Klim) has gradually replaced condensed milk for infant feeding in the Canal Zone. Coincident with this change has been a decrease of over 50 per cent in the incidence of malnutrition and nonspecific diarrhea among the infants under 2 years of age at the Ancon Hospital.

Tables are given of formulas for children from 2 days to 12 months of age, using fresh milk and Klim, with Karo as the sugar. A table of lactogen formulas is also given. Suggestions are included for the dietary treatment of fat constipation, dyspepsia, marasmus, cholera infantum, and diarrhea.

The phosphorus intake of pre-school children as shown by a dietary study made by the individual method, H. MCKAY (*Ohio Sta. Bul.* 400 (1926), pp. 387-425, figs. 10).—Although the primary purpose of this study was to determine the phosphorus intake of normal healthy children, calculations were also made of the intake of protein, fat, carbohydrate, calcium, and iron during the period under investigation, which in all cases consisted of four consecutive days. The subjects included 25 children from private homes and 30 from an orphanage, all selected as being in normal physical condition and within 4 per cent of the "commonly accepted standard of weight for height." The ages of the children ranged from 2 years to 5 years 11 months. The calculations were made on the daily consumption of food by each child and averaged for the four days of the experiment.

The amount of food eaten varied greatly for children of the same age and even from day to day for the same child. The average daily caloric intake of the entire group was 1,418 for the boys and 1,363 for the girls and the intake per kilogram of body weight 91 and 88 calories, respectively. The average caloric intake increased with age, but no significant differences were noted in calories per kilogram body weight for the different age groups.

The average daily protein consumption was 44 gm. for the boys and 41 for the girls, with per kilogram intake of 2.79 and 2.66 gm., respectively. With 32 of the children the amount of protein per kilogram body weight was below most of the standards except that of Sherman. There was a slight tendency toward a decrease in protein consumption per kilogram with increase in age. An average of 69.2 per cent of the total protein was derived from animal sources in the children from private homes as compared with 48 per cent in the institution children.

The average fat consumption was 54 gm. daily for the boys and 53 for the girls, with an average per kilogram intake of 3.44 and 3.39 gm., respectively. For the entire group 35 per cent of the total calories came from fat. The fat intake for each group of the private home children exceeded that for

the corresponding age group of the institution children. The average total carbohydrate consumption was 190 gm. daily for the boys and 182. for the girls, with an average per kilogram intake of 12.07 and 11.73 gm., respectively. For the entire group an average of 53 per cent of the calories came from carbohydrate, with an average of 49 per cent for the private home children and 57 per cent for the institution children.

The average figures for mineral consumption for the entire group, the private home group, and the institution group were calcium 0.921, 1.026, and 0.834 gm. daily; phosphorus 0.974, 1.086, and 0.882 gm.; and iron 0.0061, 0.0082, and 0.0044 gm., respectively.

A further study of 8 of the children who were markedly in advance of standards of height and weight for age showed that their total consumption of food was larger than the other children of the same age groups and that this was also true of protein, phosphorus, calcium, and iron. The chief source of calcium and phosphorus in the diet was milk, with cereals ranking next in importance for phosphorus. Cereals and vegetables appeared to be the principal sources of iron, with milk and fruits providing smaller amounts. For the private home children meat and eggs were important sources of iron.

The relation of iron from various sources to nutritional anemia, H. S. MITCHELL and L. SCHMIDT (*Jour. Biol. Chem.*, 70 (1926), No. 2, pp. 471-486, figs. 3).—In this study extremely anemic second generation rats on a basal diet of whole milk, supplemented by salts of manganese, fluorine, silicon, aluminum, and iodine in the amounts recommended by Daniels and Hutton (E. S. R., 53, p. 564), were given soon after weaning daily supplements of various iron-containing foods and iron salts in amounts calculated to contain 0.4 mg. of iron. The effect of these iron-containing compounds on blood regeneration was tested by weekly hemoglobin determinations.

As thus tested, molasses, meat, and ovoferrin were ranked as very good in the availability of their iron, egg yolk and spinach good, and raisins and dates uncertain because of incomplete consumption. Of the inorganic sources of iron the readily soluble ferric chloride and ferric ammonium citrate brought about a prompt increase in the hemoglobin count, while the response to the insoluble compounds ferric oxide and ferric carbonate was decidedly slower, more irregular, and less marked. Contrary to the findings of Hart, Steenbock, et al. (E. S. R., 54, p. 293), the presence of chlorophyll did not increase the availability of the iron from the oxide or carbonate.

"In view of these observations it is suggested that a new line of differentiation be drawn as regards availability of iron in the animal organism, namely, soluble v. insoluble rather than merely organic v. inorganic."

Blood regeneration in severe anemia.—V-VII (*Amer. Jour. Physiol.*, 79 (1927), No. 2, pp. 260-288).—In these three papers the results are reported of a continuation of the studies on the influence of various types of feeding upon severe secondary anemia produced in dogs by bleeding (E. S. R., 53, p. 866).

V. Influence of striated and smooth muscle feeding, G. H. Whipple and F. S. Robscheit-Robbins (pp. 260-270).—The materials tested, arranged in order of increasing potency for hemoglobin production, were beef skeletal muscle, beef stomach, pig heart, beef heart, pig skeletal muscle, pig uterus, and chicken gizzard. The chicken gizzard, which was the purest form of smooth muscle tested, was far superior to the other materials, being almost as active as beef or pig liver. When fed cooked in amounts from 200 to 300 gm. daily, it increased the production of hemoglobin over that of the control period by from 60 to 100 gm. in two weeks.

The favorable results obtained in the dietary treatment of anemia reported in this and previous studies are considered by the authors to point to the

probability that many types of human anemia may be treated to advantage by diet control rather than by other methods, and in this connection the reports of Minot and Murphy (E. S. R., 56, p. 294) are cited. "It is to be hoped that other types of human anemia may be subjected to similar study. One of the difficulties encountered in human and animal experiments is related to appetite and ingestion of requisite amounts of food. Careful preparation and slight modifications of the diet mixtures will do much to overcome these difficulties, and it should be borne in mind that a few grams of any potent food are not sufficient but abundant intake of sufficient calories is a necessity."

VI. *Influence of kidney, chicken and fish livers, and whole fish*, F. S. Robscheit-Robbins and G. H. Whipple (pp. 271-279).—Cooked pig and beef kidney brought about as prompt and extensive regeneration of hemoglobin as did the chicken gizzard of the previous study. Chicken liver proved even more satisfactory, but fish liver was almost inert. Whole fish produced a very slight increase. Broth from the cooked chicken liver was without appreciable effect. The favorable results obtained with kidney, together with its high content of iron as reported by Forbes and Swift (E. S. R., 55, p. 591), are thought to suggest the possibility that the kidney is concerned with pigment conservation and storage.

VII. *Influence of dairy products on hemoglobin production*, G. H. Whipple and F. S. Robscheit-Robbins (pp. 280-288).—The dairy products tested included milk, cream, American cheese, and butter. Milk did not increase the hemoglobin production to the slightest extent. The other dairy products brought about a very slight increase (from 5 to 20 gm. in two weeks). "Whole milk stands at the foot of the class of diet factors which bring about rapid hemoglobin regeneration in severe anemia. . . . Physicians should keep this in mind in diet control of anemia, especially in young children or infants where milk is apt to be the main diet constituent."

The prevention of rickets.—The influence of the routine administration of cod liver oil in the prevention of rickets in infants, M. G. WILSON (*Amer. Jour. Diseases Children*, 31 (1926), No. 5, pp. 603-630, figs. 5).—In one preliminary survey and two detailed studies of the effect of the routine administration of cod-liver oil for the prevention of infantile rickets there were no striking differences in the incidence or severity of rickets in infants receiving and not receiving cod-liver oil, and apparently no relation between the degree of rickets observed and the amount of cod-liver oil administered. In those receiving the oil healing of rickets took place more promptly, however, than in those not receiving it.

Rickets was observed in all cases earlier by Röntgen-ray than by clinical examination. In the present studies it was observed in 4 per cent at 1 month and in 23 per cent at 2 months by Röntgen-ray, as compared with a total of 4 per cent at 2 months by clinical examination alone. By the fourth month rickets was present in the majority of the infants under examination, and after 6 months healing rickets was most frequently encountered.

The early age incidence of rickets is thought to indicate the necessity of applying control or preventive measures in the first month, particularly for babies born in the winter. Cod-liver oil would seem to be of greater value for control than prevention.

A tuberculosis survey of extremely underweight children, K. H. K. WOLFE (*Amer. Rev. Tuberc.*, 13 (1926), No. 6, pp. 506-523, figs. 8).—While this survey was undertaken primarily to determine the extent of tuberculosis among chronically underweight children in elementary, junior high, and high school classes, the data reported are of interest in pointing to malnutrition as laying the foundation not only for tuberculosis but other serious pathological conditions.

Of 105 children 15 per cent or more underweight who were given chest examinations, 64 were found to have tuberculosis, sinus, and tonsil infections. Organic heart defects and digestive disturbances were present in a relatively high percentage of the total number of 146 children examined. The group of tuberculous children had a much higher percentage of those who had insufficient sleep and who drank coffee daily, and the nontuberculous suffering from other infections of those who ate an excessive amount of sweets and white bread, with small amounts of vegetables and almost no milk. These observations are thought to point to overfatigue as an important factor in causing latent tuberculosis to become active, and to a causal relationship between a deficiency of minerals and vitamins in the diet and resistance to infection.

TEXTILES AND CLOTHING

A new mechanical method for determining the length of cotton fibers, E. E. CHANDLER (*U. S. Dept. Agr., Bur. Agr. Econ., 1926, pp. 38, figs. 11; abs. in Textile World, 70 (1926), No. 24, p. 51, fig. 1*).—The method described, developed by this Department in cooperation with Clemson College, consists in cutting a middle portion or section from several pulls of cotton and determining the ratio by weight of the two ends to the middle.

A new method for determining the strength of cotton, E. E. CHANDLER (*U. S. Dept. Agr., Bur. Agr. Econ., 1926, pp. 16, figs. 4*).—This preliminary report of experiments in cooperation with Clemson College describes the development of a simple method to determine the strength of cotton fiber.

The action of ammonia on wool, H. E. FARRAR and P. E. KING (*Jour. Textile Inst., 17 (1926), No. 11, pp. T588-T590*).—The action of aqueous and alcoholic ammonia on wool under various conditions of temperature, time, and concentration is described, and a new method for estimating the amount of sulfur on woolen cloth is outlined.

The testing of yarns and fabrics, H. P. CURTIS (*London and New York: Isaac Pitman & Sons, 1926, pp. XII+168, figs. 60*).—This is a practical manual designed for manufacturers, warehousemen, operatives, drapers, laundrymen, and clothiers. Chapters deal with analysis and dissection of woven fabrics, determining warp and weft, ends and picks per inch, identification of fibers, estimation of counts from cloth, examination of cloth, sizing, rayon, silk, color fastness tests, yarn and cloth testing, and watch calculators.

Thread take-up in the seaming of knitted fabrics, H. S. BELL (*Jour. Textile Inst., 17 (1926), No. 11, pp. T583-T587, figs. 4*).—Measurements were recorded at University College, Nottingham, for a typical range of stitches under working conditions of the amount of thread exclusive of waste used in the seaming of knitted fabrics. The work deals with chain stitch, lock stitch, 2 and 3-thread overlock, cup seaming, double chain stitch, double and triple interlock stitch, and flat lock.

The chemistry of dyeing, J. K. WOOD (*London: Gurney & Jackson, 1926, [2. ed.], rev., pp. VII+104*).—A revision of a brief monograph originally issued in 1913 on the chemical composition and properties of the textile fibers, dyes and their properties, and the nature of the dyeing process.

NOTES

Alaska Stations.—Dr. H. W. Alberts, senior agronomist at Sitka, has been appointed director beginning April 1. Dr. C. C. Georgeson is to continue in the service of the station as senior agronomist to complete the results of his 30 years' work.

Arkansas Station.—An appropriation of \$150,000 has been made by the legislature for the work of the three substations at Marianna, Hope, and Stuttgart for the ensuing biennium.

Kansas College and Station.—The legislature has appropriated \$2,800,632 for the support of the institution, including the branch stations and the extension service, during the biennium beginning July 1. The appropriations include \$315,000 for a new heating and power plant, a new item of \$40,000 for laboratory equipment and improvements, \$45,000 for equipment for the new library, \$24,000 for remodeling the old library building for classroom and laboratory uses, \$2,000 for the purchase of additional land for use in plant breeding, \$89,950 for the support of the four branch stations, and \$203,682 for duplicating Federal funds for extension work in agriculture and home economics. The total amount appropriated is \$160,732 greater than the regular appropriations made two years ago, but \$356,500 less than the amount requested for the ensuing biennium by the State Board of Regents. The principal cuts in the recommendations of the regents were made in the items for salaries, general maintenance, and improvements and repairs, the appropriations for these three items being the same as were made in 1925. As a partial offset to the inadequacy in the amounts of these items, the regents have ordered an increase in the incidental fee paid by students from \$15 to \$25 a semester for residents of Kansas and from \$22.50 to \$37 a semester for nonresidents.

A 4-year course in agricultural administration and a 6-year course in general science and veterinary medicine are to be offered beginning with the fall semester. The agricultural administration course is designed to provide opportunity for special preparation in the fields of land economics, rural banking, grain industries, agricultural journalism, agricultural engineering, and agricultural education. The 6-year course will provide four years of general science combined with subjects fundamental to veterinary medicine and leading to the B. S. degree, while the remaining two years will be given almost exclusively to professional veterinary subjects and complete the requirements for the degree of doctor of veterinary medicine.

The herbarium of the late B. B. Smyth, at the time of his death in 1919 curator of the Goss Collection at Topeka, consisting of approximately 7,000 sheets, has recently been donated to the college by Mrs. Smyth.

The third annual conference of substation workers was held at Manhattan March 4 and 5. The conference was devoted to a consideration of current problems in wheat production demanding experimental attention, especially the aspects of the wheat production problem resulting from the advent of the combined harvester thresher.

H. B. Walker, head of the department of agricultural engineering, has been given a year's leave of absence to become director of research in mechanical farm equipment with the U. S. Department of Agriculture. R. H. Driftmier will be in charge of agricultural engineering work during the year. V. R.

Hellman, assistant professor of agricultural engineering, has been succeeded by Roy Bainer as instructor and he in turn by E. D. Gordon. R. P. White, assistant plant pathologist, has resigned, effective May 1, to accept a similar position with the New Jersey Stations.

Kentucky University and Station.—The resignations are noted of Nellie A. Gard, assistant professor of home economics, on February 1 and Carrie Lee Hathaway, seed analyst, on March 1. The former has been succeeded by Gertrude Wade and the latter by Jessie Terry. R. E. Proctor has been appointed assistant in farm management beginning February 1.

New Hampshire Station.—The nutrition laboratory for the studies of basal metabolism with livestock has been enlarged to include a section to be devoted to work in human nutrition. Investigations in this project are being started by Mary E. A. Pillsbury in cooperation with Dr. F. G. Benedict, director of the Nutrition Research Laboratory of the Carnegie Institute of Washington.

E. H. Rinear, who specialized in marketing studies at the University of Wisconsin, has been appointed assistant agricultural economist to conduct special studies in marketing.

New Mexico College and Station.—Under legislation signed by President Coolidge March 2, the college is granted public lands aggregating about 55,000 acres for the purpose of conducting "educational, demonstrative, and experimental development with livestock, grazing methods, and range forage plants." The tract is located near Fort Selden in Dona Ana County, and some lands, watering places, and fences on the area are already owned or controlled by the college. The acquisition of the entire area, however, will permit of large scale experiments in range management, including work with range sheep and goats.

On February 1, K. K. Henness, formerly connected with the extension division of the University of Arizona, began work as field investigator under a project dealing with range sheep and goat production in eastern Arizona and western New Mexico. The Bureaus of Agricultural Economics and Animal Industry of the U. S. Department of Agriculture and the Arizona and New Mexico Experiment Stations are cooperating in the project, which is to continue at least three years.

New York State Station.—A new variety of kidney bean, named Geneva Red Kidney and said to surpass in many respects Wells Red Kidney, the standard red kidney bean of New York, has been originated by the plant disease specialist of the station, and is being introduced to bean growers, small quantities of seed being available for testing. The new bean originated from a cross between a white kidney bean of marked vigor and disease resistance, discovered in 1918, and Wells Red Kidney, in an effort to develop a bean more resistant to disease than the latter. Its chief advantages are said to be its greater disease resistance, vigor, and productiveness, an improved habit of growth, and better cooking qualities.

R. B. Dayton, assistant in research (chemistry) has resigned to accept a commercial position. Dr. Bernhard Nebel of the University of Halle is spending six months at the station in a study of its fruit breeding methods. Dr. Nebel is in this country under a fellowship from the International Education Board and will later study citrus fruits at the California Station.

North Dakota Station.—The legislature has appropriated \$288,195 for the station for the biennium beginning July 1, an increase from \$265,400. A special act was also passed which appropriates \$15,000 additional for certification and registration of pure seed. For animal diseases \$9,000 is provided, and \$15,000 is granted for a greenhouse for work in plant pathology. The appropriation for the substations was materially increased.

Pennsylvania College and Station.—R. G. Bressler, vice dean and director of instruction in the School of Agriculture, resigned February 1, and H. F. Farnsworth, assistant in animal husbandry, effective March 15. Carl A. M. Sorg has been appointed assistant professor of ornamental horticulture, effective September 1.

South Carolina College and Station.—The Pendleton Farmers' Society, organized in 1815, has deposited many of its oldest and most valuable books with the college library, including *Gardeners' Dictionary*, by Philip Miller, two volumes, published in 1733; *Young's Experimental Agriculture*, four volumes, and *Annals of Agriculture*; and Volumes 2 and 3 of the *Memoirs of the Philadelphia Society for Promoting Agriculture*.

The station has recently acquired approximately 800 acres of land near Columbia in Richland County to be used as the Sand Hill Substation. The soil here is typical of a wide range of Sand Hill soil traversing the Southeast, and extensive experiments will be conducted under the direction of the station.

An agronomy laboratory has just been completed at the agronomy experimental farm. This building provides room for offices, small gins, scales, etc., as well as storage space for seeds and fertilizers.

A station greenhouse is nearing completion. It will be equipped with an automatic heat regulator and temperature control and will be used among other things to facilitate experiments on the influence of temperature on the germination, growth, and development of plants.

Tennessee University.—An act passed by the last legislature authorizes a \$2,000,000 bond issue for additional buildings. This will enable certain necessary enlargements at Memphis and Knoxville and the taking over of the Hall-Moody properties at Martin, where it is expected to establish a junior agricultural college.

Wyoming Station.—Dr. C. B. Clevenger, assistant research chemist, has resigned to accept a commercial position in Honduras.

Agricultural College and Model Farm in the Ukraine.—A note in *School and Society* announces that a combined agricultural college and model farm is to be opened in the Ukraine next October. A former monastery on the River Dnieper, about 60 miles from Krivtoyrov, is to be available for the institution. This monastery has been run in recent years as a state farm and contains 7,000 acres of excellent soil and buildings sufficient to house 500 students. The plan is to provide four hours' work daily on the land and four hours in school, with the expectation that the enterprise will thus be self-supporting. The college will be coeducational and self-governing to the extent that students will be represented on the governing board as well as manage their own activities, including a radio transmitting station, a newspaper, etc. Special prominence is to be given to the "mechanization of agriculture" and also to its industrialization by the installation of a cannery and similar equipment. The course will occupy four years, and it is expected that the third and fourth year students will hold classes and give demonstrations throughout the countryside in modern agricultural methods and related questions.

German National Tobacco Research Institute.—Plans have been approved for the early establishment of this institution. A grant of 150,000 marks from the National German Government and 50,000 marks from the State of Baden has been contributed for its construction during 1927. The Baden Chamber of Agriculture has agreed to supply a building site and eight acres for an experimental field, to be located in the chamber's experimental and instruction grounds at Forchheim near Karlsruhe. Among the problems to be studied are those relating to cultural methods, fertilizers, and the introduction of foreign tobacco strains.

Ohara Institute for Agricultural Research.—A recent issue of *Berichte des Ōhara Instituts für Landwirtschaftliche Forschungen* contains a brief illustrated account of this institution, founded in 1914 by Magosaburo Ōhara in commemoration of the Ōhara family and located at Kurashiki, Okayama-Ken, Japan. The institute is supported mainly from the proceeds of the farm, but the deficit as well as emergency expenses, including the acquisition of a library of 40,000 volumes and considerable special equipment, has been made up by Mr. Ōhara. At the present time there are four departments, farm crops and plant genetics, agricultural chemistry and microbiology, entomology, and plant pathology.

North Manchuria Botanical Garden and Museum.—This garden was founded in Harbin in 1924 by the Manchuria Research Society in conjunction with the Manchuria Agricultural Society and is managed jointly by the two societies. One section is allotted to local food plants, another to ornamentals, a third to field and leguminous plants, and a fourth to weeds.

A subsection of the museum of the Manchuria Research Society is devoted to agriculture, including implements, grains, horticultural plants, apiculture, and fiber plants.

New Journals.—*The Journal of Textile Science* is being published monthly, and has absorbed *The Journal of the Leeds University Textile Association*. The initial number contains several technical articles, including Top Analysis; The Testing of Single Yarns; An Investigation into the Nature of British Pedigree Wools, Their Spinning and Their Weaving Qualities; and A Graphic Key to the Study of the Effects of Free Trade, Tariffs, and Preferential and Export Duties on Agriculture and Industry.

Mitteilungen der Gesellschaft für Vorratsschutz E. V. is being issued as an aid to the solution of problems related to storage losses. The initial number contains articles entitled Theory and Practice in the Control of Losses in Trade and Industry, by F. Zacher; Is the Saw-toothed Grain Beetle a Storage Pest? by M. Schmidt; and Destruction of Poles for Power Transmission by the Hausbock (*Hylotrupes bajulus*), by Zillig.

The Proceedings of the Entomological Society of London are to be issued separately from the Transactions of the society. Vol. 1, No. 1, of the proceedings, which will appear in three parts annually, has just been issued. The transactions will continue the former volume number and will appear in two parts annually.

Revista Argentina de Botánica is being issued quarterly, the initial number consisting mainly of an article entitled Floral Heteromorphism in *Solanum atropurpureum* and a description and key to 41 species of *Stipa*.

Revista de Veterinaria is being published monthly at Saragossa, Spain. It contains both original and translated articles, notes, abstracts, etc.

Prospective Congresses.—On invitation of the American Association of Economic Entomologists and the Entomological Society of America, the Fourth International Congress of Entomology will be held at Ithaca, N. Y., probably in the third week of August, 1928.

Following an invitation from the Netherlands East Indies, the Fourth Pan Pacific Science Congress is to be held in Java in 1929.

Recent researches on root respiration, Cerighelli.....	516
Growth and permeability of century-old cells, MacDougal.....	516
The effect of light of different wave-lengths on the rate of reproduction of <i>Volvox aureus</i> and <i>Closterium acerosum</i> , Klugh.....	517
Virescence in <i>Delphinium</i> , Gates and Cook.....	517
The mitogenetic rays, Gurwitsch.....	517
Sexual dimorphism in <i>Mercurialis annua</i> , Souville.....	517
Twining in darkness, Teodoresco.....	518
Effect of lightning on trunk of <i>Platanus occidentalis</i> , Schaffner.....	518
Bacteriophagy, Von Preisz.....	518

GENETICS

Heritable characters of maize, XXV-XXVIII.....	518
Factors for color of aleurone and endosperm, Hayes and Brewbaker.....	519
Cytological study of two types of variegated pericarp in maize, Randolph.....	519
Inheritance in crosses of dent and sweet corn, Lindstrom and Gerhardt.....	519
Method employed in testing F ₁ corn hybrids at Cornell Station, Wiggins.....	519
Correlated inheritance of characters in oats, Quisenberry.....	519
Correlated inheritance in wheat, Stewart.....	520
[Anomalies in certain wheat hybrids], Blaringhem.....	521
Inheritance of deformed leaves in <i>Pharbitis nil</i> , Imai.....	521
Meiosis in the pollen mother cells of <i>Oenothera</i> , Cleland.....	521
"Old-gold" flower color in <i>Oenothera</i> , Shull.....	521
Brittle races of <i>Oenothera lamarckiana</i> , Vries.....	521
Mendelian inheritance in hybrid warblers, Morss.....	521
The inheritance of acquired characters in modern genetics, Blanco.....	521
A method for calculating linkage values, Alberts.....	521
Sex-linked balanced lethal factors in <i>Drosophila</i> , Timoféeff-Ressovsky.....	521
Hybrid vigor and tumors in mice, Jones.....	522
The activity of displaced testes, Moore.....	522
The relation of the scrotum to germ cell differentiation, Moore.....	522
Injection of testis material and its effect on spermatogenesis, Quick.....	522
Duration of potency of spermatozoa of mammals in epididymis, Iwanow.....	522
The relation of the male to the hatchability of hens' eggs, Hays.....	523

FIELD CROPS

[Field crops work at the Georgia Coastal Plain Station, 1925], Starr.....	523
[Field crops experiments at Crookston, Minn., 1925], Selvig.....	524
[Field crops experiments at the Morris, Minn., Substation, 1925], Miller.....	524
[Field crops work at Porto Rico Insular Station], López Domínguez et al.....	524
[Field crops experiments in South Carolina].....	525
[Agronomic experiments in Utah], Stewart et al.....	525
[Field crops investigations in Washington], Schafer et al.....	525
[Agronomic work in Wyoming].....	526
Root nodule bacteria of Leguminosae, Fred et al.....	526
Winter hardiness in alfalfa varieties, Steinmetz.....	527
Irrigated alfalfa in Washington, Singleton.....	528
Bean growing in Idaho, Washington, and Oregon, Hunter.....	528
Red clover experiments, Wolfe and Kipps.....	528
[Cotton investigations in South Carolina].....	528
Growth of cotton plants at Greenville, Tex., McNamara et al.....	529
The use of first generation crosses for improving southern corn, Brown.....	530
The oat crop, Mooers.....	530
Experiments with certified Irish Cobbler potatoes, Musser.....	531
Rules for seed testing.....	531
Inspection of agricultural seeds, Roberts et al.....	531
Commercial agricultural seeds, 1926, Bartlett et al.....	531

HORTICULTURE

[Horticultural investigations at the Georgia Coastal Plain Station].....	531
[Variety testing at the Crookston, Minn., Substation], Selvig.....	531
[Variety testing at the Morris, Minn., Substation], Miller.....	532

	Page
Annual report of the plant breeder, Griffith-----	532
[Horticultural investigations at the South Carolina Station]-----	532
[Plant breeding at the South Dakota Station], Hansen-----	532
[Horticultural investigations at the Utah Station], Abell and Wilson-----	533
[Horticultural investigations at the Washington Station]-----	533
Insecticides and fungicides, 1926, Bartlett et al-----	534
Analyses of insecticides and fungicides during 1926, Cathcart and Willis-----	534
Insecticides and fungicides, Shutt-----	534
Seasonal factors and quality in sweet corn, Magoon and Culpepper-----	534
Planting and thinning distances for deciduous fruit trees, Allen-----	534
Germination and storage of apple seeds, Bakke et al-----	535
Fertilization of apple orchards, II, Dorsey and Knowlton-----	535
Sod-nitrate v. cultivation in the apple orchard, Shaw-----	536
The distribution of carbohydrate foods in the apricot tree, Bennett-----	536
Notes on the dropping of immature sour cherry fruits, Bradbury-----	536
The functions of paper mulch in pineapple culture, Hartung-----	537
Palms of Florida, Mowry-----	538

FORESTRY

Manual of forestry for northeastern United States, Hawley and Hawes-----	538
National forest resources of Utah-----	538
Foundations of silviculture upon an ecological basis, Toumey-----	538
Mixed v. pure forest plantations, Paton-----	538
Effect of spacing and root pruning on transplants, Janouch-----	538
Season for sowing red and white pine seed, Petheram-----	538
Loblolly pine primer, Mattoon-----	538
The seedling structure of <i>Tilia vulgaris</i> Heyne, Holden and Clarke-----	538
The Hevea rubber tree in the Amazon Valley, La Rue-----	539
Gum arabic, with special reference to its production in the Sudan, Blunt-----	539
The water-retaining capacity of certain woods, Bews and Aitken-----	539

DISEASES OF PLANTS

Plant diseases-----	539
Plant pathology-----	540
Division of plant pathology-----	540
Forage crop diseases, Bisby-----	541
Plant diseases and pests in Denmark, 1924, Gram and Rostrup-----	541
Annual report of the mycologist for 1924, Sharples-----	541
Tumor formation in Bryophyllum, Smith-----	541
Parasitism of <i>Cuscuta reflexa</i> (Roxb.), Thomson-----	542
Fusarium as a cause of plantlet diseases, Appel-----	542
The relations of Fusarium to other fruiting forms, Fuchs-----	542
Some protein analogies of the mycelium of <i>Fusarium lycopersici</i> , Scott-----	542
Culture studies with rust fungi, Klebahn-----	542
Holcus bacterial spot of <i>Zea mays</i> and Holcus species, Kendrick-----	542
Terminology of the Uredinales, Arthur-----	543
[Studies on the fungicidal activity of sulfur], Vogt-----	543
Chemotherapeutic tests of Kalimat and Fungolit, Esdorn-----	543
Inheritance studies in cereals-----	543
Recent studies on the life history and control of oat loose smut, Zade-----	543
Stinking smut control in Uruguay, Fischer-----	543
Smut-control test-----	543
[Acidity and rust resistance], Arrhenius-----	544
The inheritance of resistance to black stem rust in wheat, Harrington-----	544
Sulphur dust for rust control, Selvig-----	544
Montana's barberry campaign, Morris and Popham-----	544
Influence of high temperatures during and after seed treatments, Nagel-----	544
Stamping out the koleroga of areca, Narasimhan-----	544
[A bean fusariosis], Benloch and Del Cañizo-----	545
The relation of black rot to the storage of carrots, Lauritzen-----	545
Means by which the cotton-wilt fungus induces wilting, Rosen-----	545
[Occurrence of corn ear rots in given areas], Hume-----	545
The influence of plant injury on the composition of corn grain, Dungan-----	546
[Peppermint and peppermint rust], Ross-----	547

	Page
Potato diseases and their control, Barrus and Chupp.....	547
Tuber disease control, Selvig.....	547
Bordeaux spraying test [with potatoes], Selvig.....	547
Phytophthora tuber rot of seed potatoes, Zimmermann.....	547
Potato and tomato diseases, Gardner.....	547
<i>Striga lutea</i> on rice in Sumatra, Palm and Heusser.....	548
Control of sugar-beet nematode by crop rotation, Thorne.....	548
[Sweet potato diseases at the Prosser (Wash.) Substation].....	548
Strain of Yellow Jersey sweet potato resistant to surface rot, Lauritzen.....	548
Two important tomato diseases and their control, Essary.....	549
Tomato diseases in Florida, Weber and Ramsey.....	549
A stem-end and center rot of tomato, Brown.....	549
A tomato fruit rot caused by <i>Bacterium lycopersici</i> n. sp., Burgwitz.....	549
Tomato late blight and its relation to late blight of potato, Berg.....	549

ECONOMIC ZOOLOGY—ENTOMOLOGY

The Manchurian wapiti (<i>Cervus xanthopygus</i> Milne-Edwards), Baikov.....	551
The fauna of British India.—Birds, Baker, edited by Shipley.....	551
A natural history of the ducks, Phillips.....	551
The pheasants of Japan, including Korea and Formosa, Kuroda.....	552
The snakes of Iowa, Guthrie.....	552
Annual report of the division of entomology, Dozier.....	552
Insect pests.....	552
Entomology.....	553
Insect pests.....	553
[Report of entomology and apiculture department of Wyoming Station].....	553
Directory of field activities of the Bureau of Entomology.....	553
[Report of the] entomological branch.....	553
Report of the entomologist, Smee.....	553
Insects of western North America, Essig.....	553
How insects live: An elementary entomology, Wellhouse.....	553
Effect of arsenicals on the respiratory metabolism of insects, Fink.....	553
The insecticidal property of carbon disulphide, Simmons and Ellington.....	554
Toxicity of sodium silicofluoride and arsenical mixtures, Kerr and Smith.....	554
A new group of ultramicroscopic parasites: The <i>Borrellina</i> , Paillot.....	554
Soil treatment for subterranean insects, Melander et al.....	554
Tests of insecticides for potato insects, Selvig.....	554
Some important insects attacking nut trees in Illinois, Flint.....	555
Handbook of citrus insect control for 1926, Woglum.....	555
The common field cricket, <i>Gryllus assimilis</i> Fab., Severin.....	555
Notes on the biology of the leafhopper <i>Eutettia strobi</i> Fitch, Fenton.....	555
The chinch bug on St. Augustine grass lawns, Watson.....	555
Chinch bug control on St. Augustine grass, Beyer.....	555
New species of Triphleps preying on eggs of <i>Heliothis obsoleta</i> , China.....	555
Plum aphid and brown rot control, Lees and Briton-Jones.....	555
The aphids of <i>Myzocallis</i> infesting the bamboo, Takahashi.....	555
Factors influencing citrus aphid outbreak, Watson.....	555
<i>Lepidosaphes destefanii</i> Leon, a new enemy of the olive, Herce.....	555
Studies on potato tuber moth during winter of 1925-1926, Underhill.....	556
The European corn borer in Ohio, Huber and Neiswander.....	556
Learning to live with the European corn borer, Flint et al.....	556
Codling-moth in apricots, Pettey and Joubert.....	556
The sugar cane moth stalkborer, Van Dine.....	557
Spraying tests in controlling sugar beet webworm, Selvig.....	557
<i>Psara phoeopteralis</i> as a pest on grasses in India, Cherian and George.....	557
A revision of the adult anopheline mosquitoes of Japan, II, Yamada.....	557
The mosquitoes of the Lower Fraser Valley, British Columbia, Hearle.....	557

	Page
House flies and manuring operations in Ceylon, Jepson.....	557
Some experiences in control of fly-breeding, Allnut.....	557
Biology of the red-tailed Tachina-fly, Allen.....	557
Weevil biological work.....	558
Senses of the cotton boll weevil, McIndoo.....	558
Boll weevil control tests.....	558
Bee diseases in United States, Sturtevant.....	558
The Brazilian beekeeper, Schenk.....	558
New chemical for beekeepers, Corkins.....	558
The control of big bud mite in the field, Hatton et al.....	558

ANIMAL PRODUCTION

Fertility and the composition of the diet, Hogan and Harshaw.....	559
Commercial feeding stuffs, Kraybill et al.....	559
Inspection of commercial feedstuffs, Smith, Kokoski, et al.....	559
Izze, the most expensive steer in North Dakota, Shepperd.....	559
[Cattle feeding experiments at the Crookston Substation], Selvig.....	559
[Experiments in beef production at the South Carolina Station].....	560
Roughage rations for two year old steers, Hackedorn et al.....	560
Fattening calves in Arizona, Stanley and Scott.....	560
Sheep breeding and feeding trial, Selvig.....	560
Sheep breeding to eliminate the tail, Wilson.....	561
[Experiments in sheep production at the South Carolina Station].....	561
Nutritive value of first, second, and third cuttings of alfalfa, Sotola.....	561
Sheep feeding.—XIV, Fattening western lambs, 1925–1926, Harper.....	562
Lamb feeding experiments in the sugar beet growing districts, Holden.....	562
Effect of feeding and management of sheep on the wool, Joseph.....	563
Pork production at the North Platte Substation, Snyder.....	564
[Feeding experiments with swine at the South Carolina Station].....	565
[Feeding pigs on pasture in South Dakota], Wilson.....	565
Tankage for spring pigs on legume pasture, Vestal.....	566
Fattening hogs on squashes and pumpkins, Smith and Sotola.....	566
[Experiments with poultry at the Crookston Substation], Selvig.....	566
[Experiments with poultry at the South Dakota Station], Stevenson.....	567
[Experiments with poultry at the Washington Station].....	567
Report of egg-laying contests for 1925 and 1926, Allen.....	568
Warm water for winter layers, Kennard.....	568
English poultry keepers, Thompson.....	568

DAIRY FARMING—DAIRYING

[Feeding demonstrations in Porto Rico], López Domínguez and Ellison....	568
[Dairy production at the South Carolina Station].....	568
[Feeding dairy cattle at the Vermont Station].....	568
[Cattle experiments at the Washington Station], Ellington and Knott.....	569
Feeding dairy cows, Henderson and Hopkins.....	569
Report of the creamery license division for 1926, Goss.....	569
Producing cream on the farm, Hopkins and Trout.....	569
[Factors affecting the quality of dairy products].....	570
[Factors influencing the quality of butter], Olson.....	570
Effect of processing on dispersion of fat in ice cream, Reid and Moseley....	570
Concentrated sour skim milk, Rogers et al.....	571
Classification of the <i>Streptococcus lactis</i> group, Hammer and Baker.....	571

VETERINARY MEDICINE

Some recent advances in veterinary helminthology, Cameron.....	571
Veterinary science, Frederick.....	571
Reports of the official veterinarians of Prussia for 1920–1922, Wieman....	571
Reports of Civil Veterinary Department in British Baluchistan, Vacha....	571
Poisonous plants.....	572
Plant poisoning, Craig and Kehoe.....	572
Acidosis, trembles, and milk sickness, Couch.....	572
Effects of sugar, magnesium sulphate, sodium citrate, and dilute acid on the liver damage done by carbon tetrachloride, Chandler and Chopra....	572

Page

Relation between the chemical constitution and germicidal activity of the monohydric alcohols and phenols, Tilley and Schaffer.....	572
The exudate from nutrient agar slants, Healy.....	573
An epidemiological study of endemic typhus (Brill's disease), Maxcy....	573
Division of veterinary science, Kalkus.....	573
<i>Bacterium abortus</i> infection in udder of bovine, Runnells and Huddleson..	573
Bovine abortion—prevention and control—further remarks, Barnes....	574
[Report of zoology department of Wyoming Station].....	574
Experiments with mixtures of anti-hog cholera serum and virus, Benner..	574
[Surra experiments], Singh.....	574
Effect of chemicals in control of poultry diseases, I, May and Segelin....	574
The control of bacillary white diarrhea, Bushnell and Hinshaw.....	575
The bacteriophage of fowl cholera, Broudin.....	575
The bacteriophage in relation to <i>Salmonella pullora</i> infection, Pyle....	575
Fowl plague, Brunett and Kondo.....	575
New method for removing parasites from poultry, Ireland and Lamb....	575

AGRICULTURAL ENGINEERING

[Irrigation, drainage, and soil physics studies at the Utah Station]....	576
[Irrigation investigations at the Irrigation Substation], Wright.....	576
Surface water supply of the Great Basin, 1921.....	576
Surface water supply of Hudson Bay and upper Mississippi basins, 1923..	576
United States Government master specification for varnish.....	576
Synthetic motor spirit from carbon monoxide and hydrogen, Audibert....	576
Lubricating value as related to properties of oils, Parsons and Taylor...	577
The rôle of oiliness in industrial lubrication, Wilharm.....	577
Surface action and fluid film lubrication, Becker.....	577
The rôle of graphite in lubrication, Koethen.....	577
Some little understood factors affecting lubrication, Gilson.....	578
Oil flow in plain bearings, Barnard.....	578
Power and the viscosity of oil, Parish.....	578
Lubrication data from coöperative fuel research, Sparrow and Eisinger..	578
Principles underlying the use of equilibrium oils, Wilson and Wilkin....	578
Motor carbon deposits from typical automobile oils, Livingstone et al...	579
The tractor on California farms, Fletcher and Kinsman.....	579
Electricity in Oregon agriculture, Kable.....	579
Electric development as an aid to agriculture, Tripp.....	580
Farm lighting systems, Jones.....	580

RURAL ECONOMICS AND SOCIOLOGY

[Rural economics investigations at the Ohio Station], Falconer.....	580
[Investigations in agricultural economics at South Carolina Station]....	581
Comparison of profitable and unprofitable farms in Lincoln County, Long..	581
Farming changes in southwestern North Dakota, 1922 to 1925, Willard...	582
Conditions in Lexington-Batesburg section of South Carolina, Russell...	582
A survey of the cattle industry in the Nebraska sand hills, Hedges.....	582
Citrus-fruit growing in Polk County, Fla., Swinson and Funk.....	583
Harvesting and marketing cantaloupes and honey dew melons, Sanborn..	583
Operations of fruit and vegetable shippers in western New York, Corbett..	584
Great Lakes-St. Lawrence deep waterway, Fuller and Benton.....	584
Federal aid as a part of a long-time agricultural policy, Englund.....	584
Taxation of farms in Missouri, Brannen and Gromer.....	585
Some tax problems of North Dakota farmers, Newton and Benton.....	586
Cotton prices and markets, Cox.....	586
Monthly Supplement to Crops and Markets, [December, 1926].....	586
Membership relations of cooperative associations, Jones and Jesness....	587

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Proceedings of the fortieth annual convention of the Association of Land-Grant Colleges and Universities, edited by Haskell.....	587
First report of New York State College of Home Economics, Betten et al...	588
Ten years of successful institutes, Luther.....	588
Chemistry for agricultural students, Adie.....	588

FOODS—HUMAN NUTRITION

	Page
Nutrition and health, Sherman.....	588
The present and the future of the food supply, Forbes.....	588
A bacteriological study of canned salmon, Fellers.....	589
Home demonstration work, 1923, Malcolm.....	589
Baking qualities of Wyoming flour.....	589
Peas in the diet, Marlatt.....	589
Effect of fruit acids on flavors in jellies and jams, Lathrop and Walde.....	589
Bonbons, Rousset.....	590
Development of the food color industry in the United States, Bainbridge.....	590
Effect of the luxus consumption of meat upon the albino rat, Hitchcock.....	590
Effect of meat feeding on nursing rats and their litters, Hitchcock.....	590
Effect on the kidney of the long continued administration of diets containing an excess of certain food elements, I, II, Addis et al.....	591
The effect of an excess of vitamins A and B in the ration on basal metabolism and the specific dynamic effect of food, Årvay.....	592
On the growth-promoting property of irradiated fat in the diet, of direct irradiation, and cod-liver oil, Goldblatt and Moritz.....	592
Irradiated milk: Its effect on the blood, Dawkins and Pattison.....	593
Antirachitic properties in milk on irradiating the mother, Hess et al.....	593
Glass screens for the transmission of light radiations, Luce.....	593
Vitamins in their relation to medical supplies, Carr.....	593
Factors influencing calcification in the rabbit, Mellanby and Killick.....	593
The use of national foods in treating diabetic patients, Stern and Reyner.....	594

TEXTILES AND CLOTHING

Viscosity of cuprammonium solutions of cotton cellulose, Hahn and Bradshaw.....	594
The steeping process, I, Fargher et al.....	594
The effect of humidity on cotton yarn, Peirce and Stephenson.....	595
The moisture relations of cotton, VI, Urquhart.....	595
Mildew in cotton goods, IV, Morris.....	595
Winter damage of wet wash, Allyn.....	595
Overall shrinkage.....	595
The chlorination of wool, Speakman and Goodings.....	596
Difficulties in handling rayon, Johnson.....	596
The finishing of textile fabrics, Beaumont, rev. by Yewdall.....	596
Census of dyes and other synthetic chemicals, Marvin et al.....	596
Rabbit skins for fur, Green.....	597
Score cards for clothing selection and construction, O'Brien et al.....	597
Historic costume in western Europe, 1490-1790, Kelly and Schwabe.....	597

HOME MANAGEMENT AND EQUIPMENT

The use of time by farm women, Crawford.....	597
Farmhouse kitchen arrangement and household management, Gray.....	597
The domestic oil burner, Senner.....	598
Touching up the old furniture, Miller.....	598

MISCELLANEOUS

Sixth Annual Report [of Georgia Coastal Plain Station], 1925, Starr.....	598
Report of the Kentucky Station for 1924, Part II.....	598
Report of Northwest Experiment Station, Crookston, 1925, Selvig et al.....	598
Report of West Central Experiment Station, Morris, 1925, Miller.....	598
Report of [Porto Rico Insular Station, 1925], López Domínguez et al.....	598
Report of the South Carolina Station, [1926], Barre.....	599
Annual Report of [South Dakota Station, 1925], Wilson et al.....	599
Report of the [Utah Station], June 30, 1926, Peterson et al.....	599
Thirty-ninth Annual Report [of the Vermont Station, 1926], Hills.....	599
Thirty-sixth Report [of Washington Station], 1926, Johnson et al.....	599
Thirty-sixth Annual Report of [Wyoming Station, 1926], Hill.....	599

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

Stations in the United States

	Page
Arizona Station:	
Bul. 116.....	560
Tech. Bul. 11.....	512
California Station:	
Bul. 414.....	534
Bul. 415.....	579
Colorado Station:	
Bul. 312.....	583
Florida Station:	
Bul. 184.....	538
Bul. 185.....	549
Press Bul. 371.....	555
Georgia Coastal Plain Station:	
Bul. 6 (Sixth Ann. Rpt. 1925).....	523, 531, 558, 598
Idaho Station:	
Bul. 146.....	597
Illinois Station:	
Bul. 284.....	546
Circ. 313.....	556
Indiana Station:	
Bul. 300.....	566
Bul. 301.....	514
Bul. 302.....	531
Bul. 303.....	559
Bul. 304.....	562
Circ. 136.....	569
Iowa Station:	
Bul. 239.....	552
Research Bul. 97.....	535
Research Bul. 98.....	519
Research Bul. 99.....	571
Research Bul. 100.....	542
Kansas Station:	
Bul. 237.....	584
Kentucky Station:	
Thirty-seventh Ann. Rpt. 1924, pt. 2.....	598
Maine Station:	
Off. Insp. 122.....	531, 534
Massachusetts Station:	
Control Ser. Bul. 36.....	559
Control Ser. Bul. 37.....	514
Minnesota Station:	
Tech. Bul. 38.....	527
Crookston Substa. Rpt. 1925.....	507, 513, 524, 531, 544, 547, 554, 557, 559, 560, 566, 598
Morris Substa. Rpt. 1925.....	507, 513, 524, 532, 598
Mississippi Station:	
Bul. 236.....	530
Tech. Bul. 12.....	557
Circ. 67.....	581

Stations in the United States—Con.

APRIL ABSTRACT NUMBER

No. 6

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

New conceptions in colloidal chemistry, H. FREUNDLICH (*London: Methuen & Co., 1926, pp. VII+147, [pls. 5], figs. [38]*).—This small volume contains the subject matter of a series of lectures on the development of various aspects of colloidal chemistry delivered in the United States during the summer of 1925. Textbooks by the author on the same subject have been noted previously (E. S. R., 56, p. 201).

Practical colloid chemistry, W. OSTWALD, P. WOLSKI, and A. KUHN, trans. by I. N. KUGELMASS and T. K. CLEVELAND (*London: Methuen & Co., 1926, pp. XVI+191, figs. 22*).—An English translation of the fourth edition of this laboratory manual of colloid chemistry, the first German edition of which has been noted previously (E. S. R., 44, p. 409).

An introduction to surface chemistry, E. K. RIDEAL (*Cambridge, Eng.: Univ. Press, 1926, pp. [IX]+336, figs. 46*).—This monograph, the preface of which was contributed by F. G. Donnan, deals with the properties of surfaces and reactions at interfaces from the point of view of the theory of the molecular structure of surfaces, as advanced particularly by W. B. Hardy and by I. Langmuir.

Proceedings of the forty-first annual convention of the Association of Official Agricultural Chemists, 1925, (*Jour. Assoc. Off. Agr. Chem., 9 (1926), Nos. 1, pp. IV+124, pl. 1, fig. 1; 2, pp. VI+125-230, pl. 1, fig. 1; 3, pp. V+231-346, pl. 1; 4, pp. III+347-500+V, pl. 1*).—This is the complete report of the convention held at Washington, D. C., October 26-28, 1925 (E. S. R., 54, p. 98). Abstracts of some of the papers presented are given elsewhere in this section.

Factors affecting the distribution of electrolytes, water, and gases in the animal body, D. D. VAN SLYKE (*Philadelphia and London: J. B. Lippincott Co., 1926, pp. VII+62, figs. 16*).—These lectures on the general subject of the regulation of neutrality in the organism, which were delivered at Rutgers University under the Luther Laffin Kellogg Foundation, have been assembled as one of the series of monographs on experimental biology founded by J. Loeb.

The composition and characterization of the natural proteins [trans. title], S. P. L. SPØRENSEN (*Compt. Rend. Lab. Carlsberg, 16 (1926), No. 8, pp. 20*).—A critical summary of recent literature on the subject.

Chemical investigation of the amylases and related enzymes, H. C. SHERMAN (*Carnegie Inst. Wash. Yearbook 25 (1925-26), pp. 332-334*).—This progress report (E. S. R., 55, p. 110) deals chiefly with an investigation of the claims of Willstätter, Waldschmidt-Leitz, and Hesse regarding the separation of amylase and protease through the use of electro-osmotically purified kaolin.

A repetition of their entire process yielded a product with a final activity three or four times that of the original extract, but only about half that of the purified preparation obtained by the author's method. The results of the adsorption experiments are considered, however, to furnish added evidence that pancreatic amylase either is a protein or contains protein as an essential constituent.

Wheat and flour studies.—V, Plasticity of simple flour-in-water suspensions, P. F. SHARP (*Cereal Chem.*, 3 (1926), No. 1, pp. 40-56, figs. 3).—This paper includes a theoretical discussion, with references to the original literature, of the difference between viscosity and plasticity, a description of a comparatively simple apparatus devised to determine the plasticity of flour and water suspensions, and data on the use of this apparatus in determining the concentration at which flour and water suspensions become plastic.

Wheat and flour studies.—VI, Effect of yeast fermentation on the proteins of flour, P. F. SHARP and O. M. SCHREINER (*Cereal Chem.*, 3 (1926), No. 2, pp. 90-101, figs. 2).—In an effort to explain the effect of yeast upon the inhibitional properties of the glutenin of flour samples, as shown by Sharp and Gortner (*E. S. R.*, 52, p. 12), analyses of a dough containing 4 per cent of yeast were made during the progress of fermentation. No marked changes in the protein of the flour during the progress of fermentation could be detected by these analyses, which included moisture, crude protein, amino nitrogen, potassium sulfate-soluble and alcohol-soluble protein, and H-ion concentration.

Doughs were then prepared containing no yeast, 1 per cent, 2 per cent, and 4 per cent, respectively, and samples of these doughs were taken from time to time for measurements of their flow through a plastometer, using the method and apparatus described by Sharp as noted above. Both the consistency and the yield value of the glutenin suspensions were found to increase, the latter to a more marked extent, with the progress of fermentation.

Chemical composition of okra seed, J. O. HALVERSON and B. NAIMAN (*Jour. Oil and Fat Indus.*, 3 (1926), No. 11, pp. 386, 387).—Data are reported from the North Carolina Experiment Station on the composition of six samples of okra seed—two of tall green long pod, two of dwarf thick pod, and two of White Velvet white pod varieties, and of the separate meats and hulls of dwarf okra seed. The average composition of the six samples of whole seed on the moisture-free basis was ash 4.7, calcium 0.261, crude fat 21.72, crude fiber 31.37, and crude protein 27.28 per cent. These values are similar to reported values for cotton seed, the chief difference being the crude protein, which is 6.54 per cent higher in okra seed than in cotton seed.

“The mature seed of the okra plant possesses good feeding value in that it consists of one-fourth protein and one-fifth oil. This plant being prolific and a vigorous grower in the Cotton Belt has possibilities of economic importance due to its high oil content and to the feeding value for animals of the high protein meal remaining after the oil is extracted.”

The fatty oils of sweet clover seed.—I, Melilotus albus, B. A. DUNBAR and C. F. WELLS (*Jour. Oil and Fat Indus.*, 3 (1926), No. 11, pp. 382-385).—An analysis is reported of the seed of the sweet clover, *M. albus*, produced at Highmore, S. Dak., and of the oil extracted from the seed with ethyl ether in a specially constructed Soxhlet extractor. The proximate composition of the ground seed is moisture 6.58, ether extract 5.26, protein 35.17, crude fiber 11.15, ash 3.46, and nitrogen-free extract 48.38 per cent.

The oil was found to be a drying oil, having a specific gravity at 25° C. of 0.9513 and a refractive index of 1.4838 at the same temperature. Some of the

analytical constants reported are saponification number 203.3, iodine number (Hanus) 142.5, specific Maumené number 108.4, Reichert-Meissl number 3.45, and acetyl value 43.13. Corresponding values for the saturated and unsaturated fatty acids were neutralization number 216.3 and 198.9, iodine value (Hanus) 68.05 and 147.16, and mean molecular weight 259.75 and 282.1, respectively. The oil contained 4.08 per cent of free fatty acids, 3.05 per cent of unsaponifiable matter, 11.11 per cent of glycerol, and 86.90 per cent of total fatty acids.

Negative results were obtained with the Molisch test for carbohydrates, the ferric chloride test for phenol derivatives, and the phenylhydrazine reaction for ketones. The oil is thought to possess commercial value as a substitute for drying oils.

Inactivation of the antirachitic factor in cod-liver oil by ultra-violet irradiation [trans. title], A. ADAM (*Klin. Wchnschr.*, 5 (1926), No. 36, pp. 1648-1650).—Attempts to increase the antirachitic activity of cod-liver oil by irradiation in the same manner as cholesterol and other food materials are activated led to the destruction of the antirachitic vitamin already present as tested by the use of the irradiated oil as a preventive and curative measure in rat and infantile rickets. Chemical and physical studies conducted on the irradiated oil are reported, with the following results:

The absorption spectrum for ultra-violet light showed a greater permeability for the irradiated than for the nonirradiated oil. The irradiated oil blackened photographic plates, showed no fluorescence, was more readily emulsified with gum tragacanth, and blackened on heating to 250° C. The viscosity and the surface tension of the oil increased rapidly with irradiation, the iodine number decreased, and the acidity as measured by pH and also by titration increased.

The possible bearing of these changes on the chemical action involved in the inactivation of the oil is discussed, with the final suggestion that the sterols in cod-liver oil become inactivated by saturation.

Synthesis and indicator properties of some new sulfonphthaleins, B. COHEN (*Pub. Health Rpts. [U. S.]*, 41 (1926), No. 53, pp. 3051-3074, fig. 1).—This is the complete report on the synthesis and properties of several new sulfonphthalein indicators, five of which were noted in a preliminary report (*E. S. R.*, 48, p. 804). The present report includes a description of the synthesis of the new indicators and of their absorption curves in the visible spectrum, determinations of the apparent dissociation constants, and data on the salt and protein errors.

A new set of buffer solutions with a pH range of 2.2 to 6.0 [trans. title], J. M. KOLTHOFF and J. J. VLEESCHOUWER (*Biochem. Ztschr.*, 179 (1926) No. 4-6, pp. 410-413).—The new series of buffer solutions described is prepared with tenth-molar monocalcium citrate with $N/10$ hydrochloric acid and $N/10$ sodium hydroxide or with tenth-molar citric acid and twentieth-molar borax, respectively. The mixtures are recommended as a good substitute for the Clark biphthalic acid-base buffer solutions.

A modification of the Gillespie approximate method of determining hydrogen ion concentration, J. MCCRAE (*Analyst*, 51 (1926), No. 603, pp. 287-290, figs. 4).—An apparatus is described and illustrated for determining the H-ion concentration of solutions by the principle of the Gillespie drop method (*E. S. R.*, 46, p. 110) without having to make a large number of volume and drop measurements.

The device consists essentially of two right-angled triangular glass cells which can be placed together to form a divided rectangular cell over which is fitted a metal cover provided with lateral slots. A sliding holder carrying a small rectangular glass cell rests on the top of the metal cover and can be

moved along this for the color comparison. In use all three cells are filled with the solution to be tested, to which has been added a sufficient amount of the indicator found on trial to be the most appropriate. A few drops of acid are added to one of the triangular cells and a few drops of alkali to the other, and the solution is stirred to insure uniformity of color. After placing the cover on the triangular cells the small cell is moved along until its color matches the color immediately below it.

The nephelometer [trans. title], H. KLEINMANN (*Biochem. Ztschr.*, 179 (1926), No. 4-6, pp. 301-303, figs. 2).—Certain errors in the use of the author's nephelometer (*E. S. R.*, 50, p. 312) have been traced to inequalities in the thickness of the glass. To overcome this the nephelometer tubes are now made of glass not exceeding 2 mm. in thickness. Other slight modifications in the apparatus are described and illustrated.

A new colorimeter for small amounts of liquids (microcolorimeter) [trans. title], H. KLEINMANN (*Biochem. Ztschr.*, 179 (1926), No. 4-6, pp. 276-286, figs. 2).—A microcolorimeter of the Du Boscq type for use with as small an amount as 1 cc. of the liquid to be examined is described and illustrated by photograph and diagram.

Microcolorimetric nitrogen determination.—Total and rest nitrogen determination in a few drops of blood [trans. title], H. KLEINMANN (*Biochem. Ztschr.*, 179 (1926), No. 4-6, pp. 287-300, figs. 3).—Detailed directions are given for a micro method for the determination of nitrogen by an adaptation of the Kjeldahl method of ashing the material, distillation of the ammonia with steam, nesslerization, and final colorimetric determination in the microcolorimeter described in the previous paper. It is said to be possible to conduct the determination on 0.002 cc. of blood for total nitrogen and 0.1 cc. for residual nitrogen.

The determination of potassium in the presence and absence of sulphates, M. A. HAMID (*Analyst*, 51 (1926), No. 606, pp. 450-453).—A comparison is reported of the cobaltinitrite and perchloric acid methods of determining potassium, both in the presence and absence of sulfates. Attention is called to the demonstration that the precipitate formed in the cobaltinitrite method has the formula $K_2NaCo(NO_2)_6 \cdot H_2O$ instead of $K_3Co(NO_2)_6$ as suggested by some investigators. The data reported indicate that the cobaltinitrite method yields results comparable with those obtained by other methods, and has the further advantage of being satisfactory in the presence of sulfates where the perchlorate method is unsatisfactory.

A method for potash in mixed fertilizers, G. S. FRAPS (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 2, pp. 192, 193).—The method described, which is based on the De Roode method for potash in soils, is said to have the advantage of rendering the phosphoric acid insoluble before the extraction, of avoiding the precipitation with ammonia and ammonium oxalate which may cause absorption of potash, and of not requiring ignition.

On the determination of small quantities of phosphorus in proteins, M. SØRENSEN (*Compt. Rend. Lab. Carlsberg*, 15 (1925), No. 10, pp. 6).—A critical study of the reliability of various methods of determining phosphorus when applied to materials containing minute quantities of the phosphorus (0.02 to 1 mg.) in considerable quantities of organic matter has led to the adoption of a combination of various known methods essentially as follows:

The protein solution in question is dried in a long-necked Kjeldahl flask and digested carefully with 4 cc. of concentrated sulfuric acid and 4 cc. of concentrated nitric acid, followed if the liquid is not perfectly clear after the nitric acid has boiled away by more nitric acid but no more sulfuric acid.

After the digestion has been completed and the solution cooled, 25 cc. of water and 10 cc. of saturated ammonium nitrate solution are added, the flask is heated on a boiling water bath, 25 cc. of 5 per cent ammonium molybdate solution is added, the heating continued with repeated shaking for 5 minutes, and allowed to stand until the following day. The liquid is then poured off through a Berzelius filter (No. 0, diameter 7 cm.), care being taken to get as little as possible of the precipitate on the filter. This is washed four times with ice-cold water and eight times with ice-cold 50 per cent alcohol, and is then transferred to the Kjeldahl flask by pouring on the filter 5 cc. of 2 N ammonium hydroxide, followed by filling up the funnel three times with water. An accurately measured amount of N/10 sodium hydroxide calculated to be from 3 to 5 cc. in excess of the amount equivalent to the molybdate precipitate is added, together with a few pieces of pumice, and the solution boiled for about an hour or until it has been reduced from about 60 to from 10 to 15 cc.

The excess sodium hydroxide is titrated with N/10 sulfuric acid, from 1 to 2 cc. more of the acid is added, and the solution boiled for 8 or 10 minutes to expel carbon dioxide. After cooling, the sulfuric acid is titrated with N/10 sodium hydroxide, an excess of about 0.5 cc. of the sodium hydroxide is added, and the titration completed after standing for about half an hour. Two or three blank experiments are run with each determination. The total number of cubic centimeters of sodium hydroxide minus that of the blank multiplied by the factor 0.112 gives the amount of phosphorus in milligrams.

A new colorimetric method for the determination of sugar [trans. title], L. FÁBLÁN (*Biochem. Ztschr.*, 179 (1926), No. 1-3, pp. 59-61).—The new method described depends upon the reducing action of sugar solutions upon a solution of copper hydrogen carbonate and the measurement of the intensity of the color of the solution after the precipitation of cuprous oxide.

A comparison of the Folin-Wu and new Benedict methods for the estimation of blood sugar, A. E. OSTERBERG and J. STRUNK (*Jour. Lab. and Clin. Med.*, 12 (1926), No. 3, pp. 278-282).—The authors report, from a comparison of the Benedict modified method of determining blood sugar (E. S. R., 54, p. 10) with the original Folin-Wu method on four blood filtrates alone and with the addition of varying amounts of glucose, that the Benedict method yields results approximately 12 mg. per cent lower than the Folin-Wu procedure, and that the recovery of glucose added to blood filtrates is more satisfactory by the Benedict method.

Detection and determination of lactic acid in the presence of other organic acids, E. K. NELSON (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 3, pp. 331-333).—The method described, which is said to be satisfactory for the detection and determination of lactic acid in the presence of malic, tartaric, citric, acetic, and benzoic acids as in jams, jellies, or preserves, combines certain features of the Kunz method (E. S. R., 13, p. 524) and the Phelps and Palmer method (E. S. R., 36, p. 808). The lactic acid is finally determined as quinine lactate as in the latter method.

The separation of formic acid in food products by distillation with xylene, J. K. MORTON and G. C. SPENCER (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 2, pp. 221-224).—"The xylene distillation method for separating acetic acid from mixtures is adapted to the separation of formic acid from food products. In the absence of other volatile reducing substances the results obtained compare favorably with the results obtainable by the steam distillation method. The manipulation is simpler and less time is required."

The determination of copper in foodstuffs, L. H. LAMPITT, E. B. HUGHES, P. BILHAM, and C. H. F. FULLER (*Analyst*, 51 (1926), No. 604, pp. 327-335).—This is a critical discussion of various methods of determining copper in food-

stuffs, with the recommendation of a modified ferrocyanide method as the most satisfactory volumetric method and for a gravimetric procedure precipitation with the antiseptic quinosol, followed in case of large amounts of copper by electrolytic precipitation.

Detection of added pepper shells in pepper, E. R. SMITH, S. ALFEND, and L. C. MITCHELL (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 3, pp. 333-342).—From the analysis of 45 authentic samples of different varieties of whole pepper, pepper shells, and pepper siftings it has been determined that the most valuable criteria for detecting the addition of pepper shells to ground pepper are the figures for crude fiber, *d*-glucose, magnesium oxide, the ratio of magnesium oxide to *d*-glucose, and the product of magnesium oxide and crude fiber. By the use of these values it is said to be possible to detect with certainty the addition of 10 per cent or less of shells if the variety of pepper under examination is known. The use of pepper siftings is said to be readily detected by the abnormally high ash content without appreciable changes in the other values.

Method for the determination of acidity of highly colored fruit-type products, C. H. BADGER and J. W. SALE (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 3, pp. 342-346).—The method described depends upon the fact that in acidulated solutions containing the permitted coal tar colors soluble in water the color is readily transferred by boiling to woolen samples contained in them. Two of the permitted dyes, yellow A B and yellow O B, are insoluble in water, and erythrosine is precipitated on boiling. The error in the method, which is due chiefly to the difficulty of removing all of the acid from the cloth, is said not to exceed 2 per cent.

The analysis of butter, L. C. MITCHELL and S. ALFEND (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 2, pp. 209-220, fig. 1).—A critical study of the Official method for determining fat in butter is reported, together with a proposed modification of the method which is said to yield results in close agreement with those obtained by the Official method and to be much more rapid.

The proposed method is the so-called Gooch method modified by the use in place of asbestos of white sand of sufficient fineness to pass through a 100-mesh sieve. The sand is prepared for use by successive extractions with water, concentrated hydrochloric acid, water, 20 per cent sodium hydroxide, water, and concentrated hydrochloric acid, and finally by washing thoroughly with water and igniting. The extraction of the fat is conducted with chloroform, preferably in a simple form of continuous extraction apparatus, which is described and illustrated.

Determination of strychnine in poisoned grains, J. W. ELMORE (*Jour. Assoc. Off. Agr. Chem.*, 9 (1926), No. 2, pp. 224-230).—In connection with the enforcement of the California economic poison law, a method of determining the percentage of strychnine in the poison baits used in rodent control was developed, the technique of which is described in detail. The method is a modification of one for the assay of nux vomica described in Allen's Commercial Organic Analysis. The technique involves drying the sample at not over 60° C., grinding it to a powder, and after the extraction as in the method for nux vomica clarifying by the addition of a small amount of Karo, extracting with hydrochloric acid, purifying the solution with lead acetate and acetic acid, and finally precipitating the strychnine with saturated picric acid solution.

Starch-making and the manufacture of dextrin, starch sugar, syrup, and sugar colouring, F. REHWALD, trans. by C. SALTER (*London: Scott Greenwood & Son, 1926, pp. VIII+264, fig. 93*).—A translation of the fifth revised German edition of this handbook for starch, dextrin, and starch-sugar manufacturers.

The chemistry of organic dyes, P. CASTAN (*La Chimie des Matières Colorantes Organiques. Paris: Octave Doin, 1926, pp. 456, figs. 2*).—A volume in the series entitled The Library of Chemistry, edited by A. Pictet, this series being a part of the Scientific Encyclopedia published under the direction of Toulouse.

Volatile solvents and thinners used in the paint and varnish industries, N. HEATON (*London: Ernest Benn, 1925, pp. VIII+11-158*).—This handbook on the nature, preparation, and properties of volatile solvents used in the paint and allied industries is one of the series of oil and color chemistry monographs edited by R. S. Morrell. The more than 60 solvents included are classified by chemical composition in eight groups, the general characteristics of each group preceding the description of the individual solvents. The final chapter deals with some of the theoretical considerations involved in the use of solvents.

METEOROLOGY

An aerological survey of the United States, II, W. R. GREGG (*U. S. Mo. Weather Rev. Sup. 26 (1926), pp. V+60, figs. 14*).—This is part 2 of this survey and deals with results of observations by means of pilot balloons. Part 1, dealing with results of observations by means of kites, was noted (E. S. R., 48, p. 15). The data furnished by this survey are primarily of "practical usefulness in connection with aviation," but are considered of value for other theoretical and practical purposes.

Normals of daily temperature for the United States, C. F. MARVIN and P. C. DAY (*U. S. Mo. Weather Rev. Sup. 25 (1925), pp. II+87, figs. 13*).—Normals for the 46-year period July 3, 1875, to July 2, 1921, are given. "This series of means, unlike any previously used, . . . is practically homogeneous throughout the period of years considered, and the data from all parts of the country are placed upon a strictly comparable basis."

Weather conditions and crops, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 11-14*).—Data for precipitation, temperature, killing frosts, and cloudiness at the Northwest Experiment Station at Crookston, Minn., during 1925 are summarized, and general weather and crop conditions are briefly reviewed.

The total precipitation was 23.76 in. as compared with a 10-year average of 18.69 in. The mean annual temperature was 40.3° F. The minimum temperature was -36° February 2, the maximum 95° August 23. The frost-free period extended from May 17 to October 6. The snowfall of the winter 1924-25 was very light, and winterkilling of winter wheat was very severe. Winter rye and alfalfa suffered but little from this cause.

Weather of the season, P. E. MILLER (*Minnesota Sta., Morris Substa. Rpt. 1925, pp. 5-8*).—Observations on precipitation, temperature, and cloudiness at the West Central Experiment Station at Morris, Minn., during 1925 are summarized, and general weather and crop conditions are noted.

The total rainfall for the year was 21.6 in., 3.5 in. lower than the 17-year average. The temperature of the growing season was approximately 2° higher than the normal. "Weather conditions on the whole were favorable for all grain crops except wheat and corn. Early hay crops and the first cutting of alfalfa yielded well. Late hay crops and corn were seriously reduced in yield because of dry weather during the latter part of the growing season."

Meteorological report for 1925, F. E. HEPNER (*Wyoming Sta. Rpt. 1926, pp. 184-186*).—Observations at the University of Wyoming, Laramie, on pressure, temperature, precipitation, wind, and cloudiness are summarized as in previous years. The mean pressure for the year was 23.07 in. The maximum

temperature was 89° F. July 14, the minimum -17° December 15. The mean monthly temperature was 42°. The last killing frost in spring occurred May 9, the first in autumn September 20. The annual precipitation was 14.44 in.

Montezuma pyrhelimetry, 1920 to 1926, C. G. ABBOT (*U. S. Mo. Weather Rev. Sup.* 27 (1926), pp. 1+15, fig. 1).—Pyrhelimetric observations made at Montezuma, Chile, during the period named are tabulated, and the conditions under which they were obtained are briefly explained.

Meteorological factors affecting fertility in the sheep, J. E. NICHOLS (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 43 (1927), No. 3-4, pp. 313-329; also in [*Gt. Brit.*] *Min. Agr. and Fisheries and Bd. Agr. Scot., Agr. Met. Scheme, Mo. Crop Weather Rpts.*, 3 (1926), No. 1, pp. 12; abs. in *Scot. Jour. Agr.*, 10 (1927), No. 1, p. 108).—Tracing the influence of meteorological conditions in flocks of Cheviot and Blackface sheep kept under the same conditions of nutrition and environment over a period of about 14 years, there were found to be significant differences in fertility between the two breeds and a differential breed response to environmental conditions. While temperature conditions may have some effect, the number of rainy days was found to be the most important meteorological factor in influencing yield of lambs and proportion of dry ewes (eild) in both flocks, probably through effects on early post-natal mortality. The amount of rainfall appeared to be of no significance. On the other hand, "a high number of rainy days is associated with low lambs percentage and high eild and vice versa, but while this and other meteorological factors do influence lambs percentage in both breeds, there being differential responses, the reasons for differences in the yield of lambs in the two flocks are due chiefly to inherent breed characteristics."

SOILS—FERTILIZERS

[**Soil studies at the Utah Station**] (*Utah Sta. Bul.* 198 (1926), pp. 65-68).—Studies of calcium chloride and gypsum to increase the permeability of alkali soils are reported by M. D. Thomas and D. S. Jennings to have shown that calcium chloride yielded some very promising results, while gypsum acted similarly but much more slowly. It was found that the addition of sodium salts has two important effects, namely, (1) the concentration of the soil solution may be increased, producing a medium toxic to plants, and (2) the sodium enters the silicate complexes replacing calcium, magnesium, and potassium, and yields a soil which is more or less impermeable to water and alkaline in reaction when the amount of soluble salt is low enough to be nontoxic. Vapor pressure studies showed that the soil has the power of removing considerable quantities of sodium sulfate and sodium carbonate from solution, but has little or no action on sodium chloride.

Mechanical puddling and freezing of heavy clay soils was found to affect only the larger capillary spaces, whereas repeated treatment of these soils with strong solutions of the salts of mono- and divalent bases and the subsequent washing free of soluble salt produced more deep-seated changes. In wet soils saturation with sodium causes a remarkable state of deflocculation which has a direct bearing on the reclamation possibilities of alkali soils.

[**Soil studies at the Washington Station**], F. J. SIEVERS ET AL. (*Washington Col. Sta. Bul.* 208 (1926), pp. 38-40, 41).—The progress of studies on the maintenance of organic matter in eastern Washington soils, soil fertility, the fixation and distribution of nitrogen and organic matter by legumes in Palouse silt loams, and on plant composition as influenced by variation in soil type are briefly reported (*E. S. R.*, 54, p. 808).

[**Soil studies at the Adams Substation**], H. M. WANSEER and I. M. INGHAM (*Washington Col. Sta. Bul. 208 (1926), pp. 46-48*).—The progress results of experiments on tillage and soil moisture, permanent fertility, and on soil organic matter maintenance are briefly reported (E. S. R., 54, p. 809).

The outstanding results were that early spring plowing, which is the most common method of tillage, resulted in the second highest percentage of moisture in the soil at the beginning of the crop year. Fall disking, followed by early spring plowing, produced a slightly higher moisture content. The percentage of nitrogen in grain tended to decrease as the plowing was delayed. The same tendency was noticeable from shallow to deep plowing.

Chemical studies of soil and alkali (*Wyoming Sta. Rpt. 1926, p. 173*).—The progress results of these studies are briefly presented. The principal salts found by the method of separating alkali from soil solutions by natural crystallization were the simple sulfates of calcium, sodium, and magnesium. Slightly more nitrogen was found in soil growing alfalfa than in virgin soil.

[**Soil and soil fertility studies in India, 1924-25**] (*India [Dept. Agr.] Rev. Agr. Oper., 1924-25, pp. 50-57*).—A progress report is presented of work on soils and fertilizers (E. S. R., 54, p. 810).

In nitrogen fixation studies at Pusa it was found that fixation of nitrogen by algæ alone can take place in India in liquid culture media. The considerable increase of fixation shown in soils exposed to light as compared with darkened controls, accompanied by a correspondingly large growth of algae, suggested the independent action of the latter in this respect. Mannite was found to give the greatest increase in growth of *Azotobacter* and peptone the least of all the substances tried. Up to 30 per cent of moisture the larger the quantity of water in soils the higher was the amount of nitrogen fixed, and fixation and nitrification were higher at 40° C. (104° F.) than at lower temperatures. An increase in nitrogen took place both in the presence and absence of light. When a moistened soil was dried after fixing the highest quantity of nitrogen and was then moistened again, the amount of nitrogen fixed increased for four or five weeks more up to a certain limit. The addition of lime to a soil already containing enough lime did not increase nitrogen fixation but facilitated nitrification.

The loss of nitrogen as ammonia during the fermentation of urine was prevented by the addition of sulfur and appropriate oxidizing bacteria, the resulting ammonium sulfate being readily available as a nitrifiable source of nitrogen.

In Madras sulfur was found to be the most effective of the various chemicals tried for inhibiting the loss of nitrogen from barnyard manure. Laboratory experiments showed that as a rule nitrification in black cotton soil is greater than in red soil. The results from pot culture studies of the availability of organic fertilizers indicated that peanut cake with or without phosphates gives the best results of all, and is even distinctly superior to ammonium sulfate with or without phosphates.

A depression of nitrification in red soils treated with oil cake and lime was found in Bengal to occur in the beginning and continued for three weeks, after which nitrification progressed more rapidly in limed than in unlimed soils. After a lapse of about 12 weeks nearly 75 per cent of the added nitrogen was nitrified in limed soils and only 25 per cent in unlimed soils.

At Pusa it was found that the loss of nitrogen as ammonia during the preliminary stages of decomposition of bone meal in soil and in composts could be prevented by the addition of sulfur and appropriate oxidizing bacteria. Pot culture experiments at Madras demonstrated the superior value of the small amount of nitrogen in bone meal.

A successful method of preparing dicalcic phosphate from apatite was developed at Pusa, which involves the solution of the mineral in perchloric acid and the subsequent precipitation of the dissolved phosphoric acid as lime phosphate. The latter was found to contain about 35 per cent phosphoric acid, almost the whole of which is citrate soluble. It was found that by means of composting with sulfur the natural indigenous phosphate in the form of bones can be effectively utilized in place of imported superphosphate. The addition of a small quantity of charcoal to the compost was found to enhance the solubilization.

Pot experiments at Madras with cyanamide and barnyard manure alone and in combination showed that cyanamide alone gave as good results as when used in conjunction with organic manures, the yields in both cases being five times those obtained in the controls. Successive and increasing additions of cyanamide to a clayey soil, however, resulted in a gradual decrease in the yield of grain and an increase in the yield of straw.

Other data are given on the use of gypsum and lime and on the influence of manures on the quality of crops.

[Soil experiments at the Wellcome Tropical Research Laboratories, Khartoum, 1925], A. F. JOSEPH (*Wellcome Trop. Research Labs., Chem. Sect. Pub. 39 (1926), pp. 7-14, 15-20*).—The usual progress report on mechanical and chemical studies of the soils of the Sudan is presented (*E. S. R.*, 53, p. 722).

Investigations on moisture equivalent of soils showed that mixtures of pure clay and clean sand possess moisture equivalents which are a linear function of their composition. Two classes of soil, namely, aeolian and alluvial, were found to differ very greatly with reference to the silt fraction in relation to moisture equivalent, the silt of the aeolian being much more siliceous and presenting a much lower moisture equivalent than that from soils of alluvial origin. It is considered clear that silt fractions differ as much among themselves as clays, and where this fraction forms a considerable proportion of the soil the differences will have to be taken into account and will in some cases assist in explaining unusual moisture equivalents.

Efforts to separate clay into fractions differing in chemical composition or physical properties showed that the range of composition is much smaller than would have been expected from the imbibitional water, and that the process of supercentrifuging either separates the more physically active part of the colloid or alters the structure in some way.

A continuation of the studies of the action of alkalis on clay showed that the amounts of insoluble compounds of clay with base formed in the presence of an excess of the latter are in the order of calcium, barium, potassium, sodium, and ammonium. The total amounts of sodium and calcium hydroxide neutralized were the same. The addition of sodium and calcium chlorides to their respective hydroxides increased the amount of insoluble compounds formed. The most important differences between the behaviors of silica and clay toward alkalis are (1) that, weight for weight, the former possesses a much greater neutralizing power, and (2) that while the sodium and potassium silicates found are almost entirely soluble, in the case of clay, a large proportion of base is found in the solid phase.

Preliminary experiments showed that with the same clay nephelometer readings could be used to measure the strength of the suspension, but that the addition of neutral flocculants did not affect the turbidity even when the amount of electrolyte added was greatly in excess of that required to produce flocculation. The addition of alkalis, however, produced a very marked decrease in turbidity, the magnitude of which was apparently dependent only on the nature of the alkali and not on its concentration.

Clay which had been treated with calcium and sodium salts to bring about saturation showed quite considerable quantities of calcium and sodium introduced by such treatment, the properties of the products differing greatly in imbibitional water content. The sodium clay was much more slowly dialyzed than the calcium clay and never reached the degree of purification attained comparatively easily by the latter. It was also much more easily and rapidly deflocculated than calcium clay.

Data are also presented on the relation between salt content of soils and crop yield, classification of soil organic matter, humus content of good and bad soils, apparent variation of salt content on storage, and other subjects relating to alkali and the movement of irrigation water.

Application of the Robinson method to the determination of clay, E. B. ENGLE and D. R. YODER (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 1016-1025, fig. 1).—Studies conducted at the Nebraska Experiment Station are reported which showed that the Robinson method for the determination of clay is simple and accurate, more subject to standardization and more rapid than the centrifugal method, leads to more comparable results, and allows more extensive use of clay determinations in soil studies. The accuracy of the results obtained was found to depend more upon the completeness of deflocculation of the soil sample than upon any other feature of technique. The method is not recommended for alkali and highly calcareous soils, due to their tendency to reflocculate on standing.

Report of the sixth annual meeting of the American Soil Survey Association (*Amer. Soil Survey Assoc. Rpt.*, 7 (1926), pt. 1, pp. 143, figs. 2).—The proceedings of this meeting contain special papers on Profile Studies of Representative Soils in the Northern Prairie States, by T. D. Rice; Southern Soils, by W. E. Hearn; Some Profiles of Representative Western Soils, by M. H. Lapham; Mapping Soils in New York, by H. G. Lewis; Some Field Problems in Indiana, by W. E. Tharp; Field Problems of the Illinois Soil Survey, by R. S. Smith; Field Work in South Dakota, by W. I. Watkins; Field Work of the Soil Survey in Alberta, by F. A. Wyatt; Problems and Methods of Mapping Alkali Soils, by A. E. Kocher; Soil Maps in the Drafting Room and the Preparation of Copy, by J. W. McKericher and E. M. Eastwood; Some Important Cuban Soils and Their Relation to Agriculture, by H. H. Bennett; The Soils of Haiti, by A. T. Sweet; Classification of Organic Soils, by J. O. Veatch; Some Characteristic Soil Profiles in the North Central States, by M. Baldwin; Observations on Australia Including Soil, Economic, and Social Aspects, by C. F. Shaw; Copying Soil Survey Maps, by T. M. Bushnell; and Map Production, by A. B. Hoen.

Soil survey of Dooly County, Georgia, S. W. PHILLIPS ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1923, pp. III+271-305, fig. 1, map 1*).—This survey, made in cooperation with the Georgia State College of Agriculture, deals with the soils of an area of 258,560 acres in the Coastal Plain of south-central Georgia. The topography is gently rolling to rolling, and the upland ridge land is well drained. The surface over most of the county is marked by ponds, sinks, and depressions, and in the southeastern and east-central parts by poorly drained flats.

The soils of the county are dominantly low in organic matter and are light in color. Including swamp, 21 soil types of 14 series are mapped, of which the Norfolk and Tifton sandy loams cover 19.4 and 19 per cent of the area, respectively.

Soil survey of Dickson County, Tennessee, J. A. KERR ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1923, pp. III+307-329, pls. 3, fig. 1, map 1*).—This survey, made in cooperation with the Tennessee Geological Sur-

vey, deals with the soils of an area of 316,800 acres lying in the Highland Rim in north-central Tennessee. The county is predominantly hilly, consisting of dissected plateaus, with smooth land only on the ridges.

The soils of the county are typically deeply weathered, with the content of soluble minerals reduced by leaching. The formations are mainly of the lower Carboniferous. The higher formations are predominantly of deeply weathered clay and chert rock. The lower formations are largely limestone and calcareous shales. Including rough stony land and mine diggings, 14 soil types of 8 series are mapped, of which the Baxter gravelly silt loam and the Dickson silt loam cover 53.5 and 20.4 per cent of the area, respectively.

Study of the marsh lands of the north coast of Porto Rico, R. FERNÁNDEZ GARCÍA (*Porto Rico Dept. Agr. and Labor Sta. Ann. Rpt., 1925, p. 113; also in Spanish ed., pp. 118, 119*).—Pot studies of marsh soils are reported to have indicated that the high salt tolerance of cane plants is probably due to the antagonistic action of the high content of organic matter.

Alkali tolerance of plants considered as a phenomenon of adaptation, J. F. BREAZEALE (*Arizona Sta. Tech. Bul. 11 (1926), pp. 237-256, figs. 4*).—Studies are reported the results of which indicate that the limit of endurance of a plant for alkali salts is apparently determined by the amount of alkali that is required to kill the root enzymes concerned with growth. There appears to be a definite order of toxicity of alkali salts, and the position of each salt in this order depends upon the number of units of time that the plant has come into contact with the salt during its period of adaptation.

The presence of calcium, even in minute amounts, enormously increases the tolerance of wheat seedlings for sodium chloride and other alkalis. Plants are able to utilize calcium at one period, and this calcium may be effective in overcoming alkali at a later period. Plants may be inoculated against alkali with calcium.

Soil potassium, J. W. AMES (*Ohio Sta. Bimo. Bul., 12 (1927), No. 1, pp. 14-18*).—Data are summarized from a study of the availability of soil potassium as indicated by crop yields and soil analyses. It is estimated that the amount of potassium at the disposal of a crop during its growth represents a comparatively small proportion of the total reserve supply. Applications of calcium sulfate, ammonium sulfate, and sodium nitrate appeared to slightly increase the solubility of soil potassium in most of the soils experimented with.

Studies on some obligate thermophilic bacteria from soil, W. A. FEIBER (*Soil Sci., 23 (1927), No. 1, pp. 47-56*).—Studies conducted at Johns Hopkins University are reported in which the biological and cultural activities of 10 aerobic, spore-forming, motile, obligate thermophiles are described. The optimum temperature for growth was found to fall between 50 and 60° C. Growth does not take place below 40° and ceases when the temperature is raised to 80°. The thermal death point for a definite concentration of spores varied with each species. The limits lie between 125 and 155° for 15 minutes. One aerobic obligate thermophile was found which exhibits proteolytic action. The cultures are not pathogenic for guinea pigs.

Bacterial activities in an orchard soil, R. H. WALKER (*Iowa Acad. Sci. Proc., 32 (1925), pp. 77-80, fig. 1*).—Studies conducted at the Iowa Experiment Station are reported from which the conclusion is drawn that the nitrogen oxidizing power of a soil as determined by its average nitrate content throughout a long period of incubation, accompanied by knowledge of its physical and chemical nature, will serve as a criterion of its crop-producing power.

The occurrence of yeasts in soil, R. L. STARKEY and A. T. HENRICI (*Soil Sci., 23 (1927), No. 1, pp. 33-45, figs. 12*).—Studies conducted at the University of Minnesota are reported in which yeasts were found in small numbers in 39

out of 87 soil samples. There was no correlation between the occurrence of yeasts and the type of soil, the nature of the crop, or the season of the year. They were found in such small numbers and were so haphazard in distribution as to indicate that they play no important part in soil transformations. Forty-nine strains isolated fell naturally into 12 groups or species.

The viability of legume bacteria on stored inoculated seed, A. G. LOCHHEAD (*Canada Expt. Farms, Div. Bact. Rpt. 1925, pp. 7-9*).—The preliminary results of a series of experiments in which alfalfa and red clover seed were inoculated with cultures of the legume organism and kept for different periods of time under various storage conditions before planting are reported.

Storage in the barn was least favorable, indicating that alternate freezing and thawing temperatures work adversely. The moist, even cold of a refrigerator appeared to be somewhat favorable.

Tests with "Soil Vita" and "Vitamite," A. G. LOCHHEAD (*Canada Expt. Farms, Div. Bact. Rpt. 1925, pp. 16-19*).—Laboratory and greenhouse studies with these materials are briefly reported which indicate that so-called Soil Vita is of no practical benefit. In the case of Vitamite an apparent attempt has been made to include nitrifying organisms, *Azotobacter*, and the nodule organism, but the opinion is expressed that it is of practical value only so far as it is a legume culture.

Some factors in greenhouse soil sterilization, A. G. NEWHALL (*Ohio Sta. Bimo. Bul., 12 (1927), No. 1, pp. 21-25, fig. 1*).—Studies are reported in which variations of 40° F. or more were often found between points 6 in. apart but at the same depth in greenhouse soils after steaming for from 1 to 3 hours. The highest soil temperatures at the lowest depths were attained in the driest (26 per cent) sandy soils. Conversely, the poorest steam penetration was in the wettest clay soils (60 per cent moisture).

The results emphasized the importance of thoroughly loosening the soil and of breaking up all the lumps before sterilizing. Under strictly comparable conditions side by side in a heavy clay soil the harrow method proved much less effective than the pan. In one trial on a heavy, wet clay, doubling the time of application of the pan from 1.25 to 2.5 hours increased the depth of steam penetration nearly 50 per cent.

Future trends in soil conservation, J. G. LIPMAN (*Indus. and Engin. Chem., 18 (1926), No. 10, pp. 1034-1040*).—This is a contribution from the New Jersey Experiment Stations presenting statistical data bearing on the subject.

Soil fertility and soil management experiments, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 36-44*).—The progress results of experiments on the effect of continuous cropping of small grains without fertilization and a 4-year rotation without fertilization, phosphating and manuring, rate of manuring, the use of sweet clover for soil improvement, and on straw utilization are briefly reported (*E. S. R., 55, p. 320*).

[Soil fertility studies at the Morris, Minn., Substation], P. E. MILLER (*Minnesota Sta., Morris Substa. Rpt. 1925, pp. 9-22*).—The progress results of studies on phosphate and manuring rotations, rates of manuring, and on the use of wheat straw and corn stover as fertilizers are briefly reported.

[Soil studies at the Prosser Irrigation Substation], H. P. SINGLETON (*Washington Col. Sta. Bul. 208 (1926), pp. 58, 59*).—The progress results of studies on general soil fertility and on the general uses of sulfur and gypsum as fertilizers are briefly reported. It was found that the slight increases due to sulfur and gypsum during the time the experiment has been under way are insufficient to warrant the application of either to alfalfa on the fine sandy loam soils of the Yakima Valley.

Observations of some biological activities in manure composts, A. J. ENGLEHORN (*Iowa Acad. Sci. Proc.*, 32 (1925), pp. 85-94).—Studies conducted at the Iowa Experiment Station are reported which showed that aerobic bacteria are quite active in normal manure composts, especially if those composts are kept at one-half saturation. Sulfur in a manure compost was found to have a depressing effect on the numbers of bacteria due to the acid reaction produced. The presence of orthoclase, and especially the presence of raw rock phosphate, seemed to have a stimulating effect upon the numbers of bacteria. The activities of fungi in compost heaps were found to be markedly depressed by a moisture content of 150 per cent. The presence of sulfur had a stimulating effect on the growth of fungi, while the presence of orthoclase apparently had a depressing effect.

Activated sludge: Its production, composition, and value as a fertilizer, O. J. NOER (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 953-962).—Studies conducted at the Wisconsin Experiment Station showed that water-carriage methods of sewage disposal result in enormous losses of nitrogen, phosphoric acid, and potash. The activated sludge process of sewage purification produces a sludge of high nitrogen and phosphoric acid content. Dried activated sludge contains from 4.75 to 6.5 per cent of nitrogen and from 2.3 to 4 per cent of phosphoric acid.

In pot tests in the greenhouse with oats activated sludge as a source of nitrogen proved about equal to cottonseed meal and fertilizer tankage and was considerably better than digested leather.

Field trials with cabbage, tomatoes, corn, and potatoes indicated that activated sludge is a satisfactory source of organic nitrogen for use in mixed fertilizers. Activated sludge was found to exert a favorable influence upon the mechanical condition of mixed fertilizers, helping to prevent setting of the mixtures, making uniform distribution easier, and reducing the danger of injury to the young sprout.

The action of ammonium sulfate and ammonium nitrate on acid sand soils [trans. title], D. MEYER (*Mitt. Deut. Landw. Gesell.*, 41 (1926), No. 36, pp. 740-742).—Experiments conducted by the Agricultural Board of Breslau are reported which showed that ammonium sulfate is unfit as a nitrogenous fertilizer for strongly exchangeable light soils with a low humus content, and that sodium and calcium nitrates are best used for this purpose.

Commercial fertilizers, O. S. ROBERTS ET AL. (*Indiana Sta. Bul.* 301 (1926), pp. 69, fig. 1).—Guaranties and actual analyses of 1,442 samples of fertilizers and fertilizer materials collected for inspection in Indiana during 1925 are reported.

Inspection of commercial fertilizers for the season of 1926, H. D. HASKINS, L. S. WALKER, and M. W. GOODWIN (*Massachusetts Sta. Control Ser. Bul.* 37 (1926), pp. 40).—Guaranties and actual analyses of samples of fertilizers and fertilizer materials, representing 541 brands, collected for inspection in Massachusetts during 1926, are presented and discussed.

Analyses of commercial fertilizers, fertilizer supplies, and home mixtures for 1926, C. S. CATHCART ET AL. (*New Jersey Stas. Bul.* 440 (1926), pp. 39, fig. 1).—Actual analyses, and in some cases guaranties, of 244 samples of fertilizer materials, 27 home mixtures, 436 brands of commercial complete fertilizers, 3 brands containing phosphoric acid and potash, and 71 duplicate samples collected for inspection in New Jersey during 1926 are reported and discussed.

AGRICULTURAL BOTANY

Intermediate products in the metabolism of higher plants [trans. title], G. KLEIN (*Naturwissenschaften*, 13 (1925), No. 2, pp. 21-24).—Chiefly, a systematic review is given of hypotheses, researches, findings, and interpretations regarding carbon dioxide and nitrogen in assimilation and respiration.

Formation and distribution of inulin in stems of Jerusalem artichoke [trans. title], H. COLIN (*Rev. Gén. Bot.*, 37 (1925), No. 435, pp. 97-101).—The inulin content of Jerusalem artichoke is given in tabular form as determined early in August and about the middle of October at the top, middle, and base of the stem in bark, wood, and pith.

Physiological study of two varieties of Ipomoea batatas, G. R. JOHNSTONE (*Bot. Gaz.*, 80 (1925), No. 2, pp. 145-167, figs. 4).—Sweet potatoes, of the varieties Porto Rico and Triumph, increase their respiration rate from the date of harvest to a maximum, after which the rate falls to a nearly constant level. Cured sweet potatoes do not reach so high a level of respiration. Increase of respiration as a result of injury of the cortical layer is due rather to the facilitated gas exchange than to direct wound stimulation.

Curing sweet potatoes under carefully controlled conditions does not greatly reduce the moisture content. The variety Porto Rico shows more carbon dioxide than Triumph in the intercellular spaces. Respiration in both varieties responds to temperature rise between 15 and 25° C. in much the same way as between 25 and 35°, Porto Rico respiring, however, more than does Triumph.

Complete dormancy requires a temperature of not over 25° (77° F.). The H-ion concentrations of the expressed juices are slightly acid and about the same for the two varieties. Moisture and catalase activity are higher in Porto Rico. This variety shows also both laccase and peroxidase, which appear to be important in connection with discoloration on exposure to air. Enzyme behavior is indicated. A physiological distinction of the two varieties is evident. Porto Rico shows greater respiratory activity, greater enzymatic activity, and a higher moisture content.

Salt requirements of wheat at different growth phases, W. F. GERICKE (*Bot. Gaz.*, 80 (1925), No. 4, pp. 410-425, figs. 10).—Further but not yet complete presentation is made of the results of work previously in part reported (E. S. R., 52, p. 426). The plan of altering or renewing the medium in which wheat was grown at different developmental stages of the plant was continued.

The maximum development among all the cultures was shown by plants grown four weeks in a complete solution and then transferred to media lacking phosphorus for 104 days. Complete nutrient solution not renewed gave better results than did complete nutrient solution renewed three times during growth. Supra-optimal exposure of cultures to complete nutrient solution of plants transferred to media lacking potassium, magnesium, phosphorus, or sulfur prevented maximum development. The effect of excess was greatest in case of phosphorus and least in sulfur.

Iron and isolated nutrition [trans. title], SIDORINE (*Rev. Gén. Bot.*, 37 (1925), No. 440, pp. 337-359, fig. 1).—Development along lines similar to those of previous studies (E. S. R., 36, p. 633) is outlined. Partial absorption of iron and of sulfur is dependent upon three conditions, namely, structure of the vascular system, peculiarities in the circulation of liquids in the vascular system, and differences in the assimilation rates of iron and sulfur.

The enzymes of Stereum purpureum, J. K. MAYO (*New Phytol.*, 24 (1925), No. 3, pp. 162-171).—A survey has been made of the enzymes in *S. purpureum*, employing both fructifications and pure-culture mycelium, and the active extracts have been prepared from moist living tissues. Tests were made for

diastase, inulase, glycogenase, invertase, raffinase, maltase, emulsin, pectinase, protease, tyrosinase, oxidase, and reductase. Positive results were obtained for diastase, inulase, glycogenase, invertase, raffinase, emulsin, pectinase, tyrosinase, and oxidase.

The pectinase of *Sclerotinia cinerea*, G. W. MUHLEMAN (*Biol. Gaz.*, 80 (1925), No. 3, pp. 325-330).—Methods are described of growing *S. cinerea* on different media, and it is stated that one growth of the fungus on prune juice seems to unfit this medium for growing further crops. Methods of preparing culture media which give maximum growth are described, as well as three methods of preparing an active pectinase solution.

S. cinerea does not excrete pectinase into the culture media. It is claimed to have been shown that the color of the felts of *S. cinerea* furnishes a good index of the activity of the pectinase solution which may be prepared.

An injurious factor affecting the seeds of *Phaseolus vulgaris* soaked in water, P. TILFORD, C. F. ABEL, and R. P. HIBBARD (*Mich. Acad. Sci., Arts, and Letters, Papers*, 4 (1924), pt. 1, pp. 345-356, fig. 1).—Seeds of *P. vulgaris* under certain conditions, as soaking in stagnant water, rot without germinating. It is stated that bacterial products kill or weaken the embryo, and that soaking alone is not the injurious factor. Disinfected beans free from organisms germinate as high as 87 per cent even after prolonged soaking in running water at 20° C. (68° F.). Disinfected clean seeds soaked under sterile conditions germinate as high as 54 per cent at the end of 48 hours, and are capable of germination after 126 hours. Disinfected seeds soaked in sterile distilled water and vigorously aerated germinated as high as 97 per cent even after three days under water.

Comparative morphology of cytoplasm and chromatin, C. J. CHAMBERLAIN (*Bot. Gaz.*, 80 (1925), No. 2, pp. 203-212, pl. 1, figs. 3).—"It seems apparent that both cytoplasm and chromatin are vacuolated and of essentially the same structure."

Continuous respiration studies of dormant seeds of *Xanthium*, J. OTA (*Bot. Gaz.*, 80 (1925), No. 3, pp. 288-299, figs. 4).—A study was made of the respiration behavior of the upper seeds of *Xanthium* during the long period necessary to their germination. The experiments did not run long enough to indicate the natural rate of carbon loss from respiration under natural conditions. Respiratory activity and catalase activity run parallel throughout the period of dormancy of these seeds.

Recent researches on root respiration: Variations in respiratory quotient during development [trans. title], R. CERIGHELLI (*Rev. Gén. Bot.*, 37 (1925), Nos. 435, pp. 102-112; 436, pp. 157-166).—Traumatism exercises a variable influence on the respiratory quotient, $\frac{CO_2}{O_2}$, which tends to approach unity.

Temperature, at least between 12 and 24° C., influences the respiratory quotient only in case the roots, which are fleshy, are rich in reserve material. The value of the respiratory quotient is in close relation with the quantity of reserve material contained in the root. At the beginning of their development the roots usually show a respiratory quotient less than unity. They are at that time poor in reserve material, which they tend to give up rapidly. Roots in annual plants, which are poor in reserve material, have during their whole development a respiratory quotient less than unity. Roots which accumulate reserve material show, on the contrary, at any given stage of their development a quotient higher than unity.

Growth and permeability of century-old cells, D. T. MACDOUGAL (*Amer. Nat.*, 60 (1926), No. 670, pp. 393-415, figs. 10).—This paper deals with properties of parenchymatous and medullary cells of the tree cactus (*Carnegiea gigantea*),

which may persist and show activity individually during the century or more of the life of the plant.

Great numbers of parenchymatous cells of all ages are transformed into vascular bundles forming strands connecting with the woody cylinder. The estimated rate of enlargement of medullary cells is greater in the second than in the first half century, following the initial distention. Growth occurs within 150 days annually. Environmental conditions are favorable to activity except for a few periods of a few hours duration of low temperature each year. The abundant pentosans or mucilages diminish with age, while glucose and silica crystals increase. Plasmatic layers shrink and tend to granulate with age. Nuclei change but little. Cell walls thicken. H-ion concentration varies only between pH 5.3 and 5.7. Fatty substances, which are abundant in young cells, give place to starch. Immersion of young cells in acid or alkaline solutions increases permeability and diminishes water-holding capacity. Such immersion of old cells in graded concentrations is followed by maximum swelling in acid solutions at pH 3.0 to 3.5, and a secondary maximum in alkali at pH 9.0 to 11.0. Such nodes have been attributed to the influence of isoelectric regions of proteins in *Opuntia*.

The effect of light of different wave-lengths on the rate of reproduction of *Volvox aureus* and *Closterium acerosum*, A. B. KLUGH (*New Phytol.*, 24 (1925), No. 3, pp. 186-190, figs. 2).—"Five colonies of *V. aureus* were placed respectively in red, green, and blue light and their rate of reproduction was ascertained, and five individuals of *C. acerosum* were treated in the same way. If the rate of reproduction be taken as a criterion of photosynthetic activity, then photosynthesis is a wave-length phenomenon, red being most efficient, blue much less so, and green inefficient."

Virescence in *Delphinium*, R. R. GATES and W. R. I. COOK (*New Phytol.*, 24 (1925), No. 3, pp. 172-179, pl. 1).—A study was made of virescent inflorescence of *Delphinium*, which is described. This case is compared with other records of virescence and peloria, and particularly with various instances in which genetic experiments have been made. It is pointed out that many different kinds of change are included under the term "virescence," and that the same teratological condition may appear as the result of a germinal change or as an externally impressed modification.

The mitogenetic rays, A. GURWITZ (*Bot. Gaz.*, 80 (1925), No. 2, pp. 224-226, fig. 1).—The author claims to have demonstrated previously the possibility of inducing increase of mitosis in onion root tips through the proximity of similar root tips over a distance of 2 mm. Recent facts are said to have confirmed the existence of a factor, here called mitogenetic, and to have given some idea as to its nature.

Heteroinduction from a *Helianthus* root tip to an onion root is said to be possible. The induction is effected through water as well as through air. No apparent decrease of effectiveness is caused by distance so far as tested (up to 38 mm.). The effects of the induction are decreased, but not suspended, by the interposition of a glass cover slip. A glass plate 30 μ in thickness gives no sensible reduction. Considerable dispersion of the assumed ray beam is said to be caused by the interposition of a thin layer of plant tissue (onion skin). The ray beam apparently does not undergo diffraction when passed through a slit 30 μ in width. Preliminary experiments with the photographic plate have given only negative results.

Sexual dimorphism in *Mercurialis annua* [trans. title], G. SOUVILLE (*Rev. Gén. Bot.*, 37 (1925), No. 434, pp. 49-62).—It is claimed that in *M. annua* morphological dimorphism is evident and physiological dimorphism probable. The evidences are summarized.

Twining in darkness [trans. title], E. C. TEODORESCO (*Rev. Gén. Bot.*, 37 (1925), Nos. 437, pp. 212-232, figs. 14; 438, pp. 261-278, figs. 16; 439, p. 303-320, figs. 13; 440, pp. 360-368, figs. 6).—Twining movement in darkness was studied in 14 different plants, which are dealt with separately.

Effect of lightning on trunk of *Platanus occidentalis*, J. H. SCHAFFNER (*Bot. Gaz.*, 80 (1925), No. 2, pp. 226, 227, fig. 1).—In the spring of 1924 a large sycamore tree was struck by lightning, which removed some of the outer bark without visibly tearing or splitting the trunk or branches. At the opening of the growing period the trunk began to develop numerous buds all the way from the branches of the large crown to the ground, both on the lightning paths and on the undisturbed part of the bark, more than 200 twigs in all. It is thought that this may indicate methods of inducing active growth or rejuvenation of plant tissues which have been differentiated into a condition of stability.

Bacteriophagy, H. VON PREISZ (*Die Bakteriophagie*. Jena: Gustav Fischer, 1925, pp. [3]+110, pls. 3; rev. in *Naturwissenschaften*, 13 (1925), No. 20, pp. 438, 439).—This book, based principally on the author's own researches, presents in 14 sections the various phases of the phenomenon designated as bacteriophagy. The author's conception of the assumed agent apparently does not differ greatly from that of D'Herelle (*E. S. R.*, 48, p. 675).

GENETICS

Heritable characters of maize, XXV-XXVIII (*Jour. Heredity*, 17 (1926), Nos. 8, pp. 300-306, figs. 3; 9, pp. 326-329, figs. 2; 18 (1927), No. 1, pp. 41-44, fig. 1; 17 (1926), No. 11, pp. 405-411, figs. 4).—Four more parts of this series (*E. S. R.*, 54, p. 629) are given.

XXV, *Piebald seedlings*, M. Demerec.—This states that piebald corn seedlings are characterized by the usually large, irregular, white spots on their leaves. These spots may remain until maturity or disappear with age. In inheritance studies at Cornell University involving 6 different lines of piebald seedlings, 4 genetically different factors for piebalds were found, Pb_1 , Pb_2 and Pb_3 , Pb_4 being simple Mendelian recessives and Pb_2 , Pb_3 and Pb_4 , Pb_5 duplicate genes. Linkage tests indicated that piebald 1 is not linked with $R r$, $Su su$, $Lg lg$, $Y y$, and $D d$ factors; piebald 2 and 3 are not linked with $Y y$; and piebald 4 is not linked with $Wx wx$, $Su su$, $Lg lg$, $Y y$, and $Gl gl$ factors.

XXVI, *Concave*, J. B. Wentz.—A defective kernel type termed "concave" (cv), in this contribution from Iowa State College, somewhat resembles sugary corn but is more shrunken and lacks the glassy or translucent appearance of sugary seeds. The crown and the side of the seed as well present concave surfaces, and special care seems necessary in germination. Concave seeds were relatively high in sugar and low in starch. This defective is evidently caused by some factor which interferes with starch formation similar to the situation in sugary corn. Inheritance data suggested that concave is due to a single factor.

XXVII, *Colored scutellum*, G. F. Sprague.—From the ratios obtained in the investigations reported from the U. S. D. A. Bureau of Plant Industry it appeared that at least three factors are involved in the production of scutellum color (in Blue Flour corn) which are similar in their interaction to the A , C , and R factors for aleurone color (*E. S. R.*, 40, p. 436). At least one and possibly two factors different from these three may also be involved in producing scutellum color.

XXVIII, *Barren-sterile*, C. M. Woodworth.—Barren-sterile, a corn type found in several lines at the Illinois Experiment Station, bears no tassel and in most cases both cob and silk are absent. Barren-sterile plants occurring in selfed lines are much weaker and shorter and the stalks more slender than normal plants in the same lines, while in crosses between certain of

these lines barren-steriles appeared with as much vegetative vigor as any of the normals. Plants exhibiting this type of sterility are very susceptible to corn smut, and the root system is very weak or poorly developed. Although barren-sterile behaved as a simple Mendelian recessive, the appearance of intermediate types in hybrid progenies suggested that the inheritance of the barren-sterile condition is more complex than is indicated by the simple 3 : 1 ratio obtained.

Factors for color of aleurone and endosperm in maize, H. K. HAYES and H. E. BREWBAKER (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 9, pp. 761-767).—Genetic studies with corn at the Minnesota Experiment Station gave results indicating a linkage of the *Pr* factor with the *R* factor in linkage group II. One of two yellow endosperm types differing from the usual yellow color was somewhat darker than pale yellow and the other a very pale yellow endosperm. The factors conditioning the development of these endosperm colors appeared to be located in chromosome VIII.

A cytological study of two types of variegated pericarp in maize, F. R. RANDOLPH (*New York Cornell Sta. Mem.* 102 (1926), pp. 14, pls. 2, figs. 4).—Study was made of the morphology of the kernel and pistil, location of pigment, development of the epidermis, and color and structure of glumes of sporophytic variations in color, near self and dark crown, occurring in corn strains producing ears with kernels having variegated or striped pericarp. In general the supposed morphological foundation of the hypothesis, as stated by Emerson (E. S. R., 37, p. 737), that mutations occurring in epidermal and subepidermal tissues have produced, by causing the formation of pigments in the two distinct tissues, the dark crown and near self types kernels, respectively, has been found to be insecure, i. e., the color is not limited to the epidermis in one case and to subepidermal tissue in the other.

Inheritance of carbohydrates and fat in crosses of dent and sweet corn, E. W. LINDSTROM and F. GERHARDT (*Iowa Sta. Research Bul.* 98 (1926), pp. 257-277).—The inheritance of chemical characters in corn kernels was studied with the F_1 and F_2 of reciprocal hybrids between white and yellow dent and white and yellow sweet corns. Besides the observations noted earlier from other sources (E. S. R., 55, p. 526; 56, p. 29) it was noted that pollen mixtures did not consistently differentiate quantitatively the carbohydrate differences between the *SSS* and *SSs* genotypes borne on the same ear. While no consistent correlation or linkage was demonstrated between yellow and white endosperm color and sugar or starch values, some evidence of a very slight linkage between endosperm color and fat percentage was found. The inheritance of fat or oil content proved to be closely associated with the carbohydrate situation, high fat values being linked with high sugar percentage and vice versa. No evidence appeared of a cumulative effect of any fat values, dependent on the endosperm factors in the triple fusion of nuclei.

Method now employed in testing F_1 corn hybrids at the Cornell University Agricultural Experiment Station, R. G. WIGGANS (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 9, pp. 794-798).—Methods of testing F_1 corn hybrids and of interpreting the results are outlined.

Correlated inheritance of quantitative and qualitative characters in oats, K. S. QUISENBERRY (*West Virginia Sta. Bul.* 202 (1926), pp. 55, figs. 7).—The inheritance of length of grain and other differential characters was studied in a cross between Sparrowbill and Victor oats. The Victor had a length of the primary grain averaging 16.4 mm., black grain color, and open panicle, and each primary grain bore a rather strong, black, twisted, geniculate-awn. Sparrowbill had a mean grain length of 11.5 mm., white grain and side panicle, and no or few grains were awned. A sample of 10 grains selected from all

parts of the Victor panicle gave about as accurate measure of grain length for the panicle as did all of the grains therein. Grains at the panicle tip were found longer than at the base. Poor soil did not shorten grain length much, whereas height and yield of plant were reduced greatly, showing that grain length is less variable than such characters as plant yield and height.

The F_1 was intermediate for grain length, although tending to approach that of Victor. The variability for grain length in F_2 greatly exceeded those for either parent, ranging between their lengths. From a total of 150 F_2 families, two were recovered with a mean grain length as short as Sparrowbill and four with a mean length as long as Victor. Lines apparently homozygous for grain of intermediate length were found between these two extremes. The results seemed explainable by assuming that the parents differ by at least three main factors or groups of factors for grain length.

Color of grain was controlled by a single factor pair, black being dominant and panicle type by two duplicate factors, one or both present in the dominant condition giving open panicles. Inheritance of awns, more complex in nature, could not be explained by a single factor difference. No linkage was found between the factor for grain color and any factors for grain length. A factor or group of factors for grain length seemed probably linked with each factor for panicle type. At least one factor for awns appeared to be linked with a factor or factors for grain length, and linkage also existed between a factor for panicle type and one for awns. Color of grain and panicle type were not associated, and there was little or no relation between color and awns. The data indicated a linkage group containing a factor for color and possibly one for awns, a second group containing a factor for panicle type and a factor or factor group for grain length and awns, respectively, and a third group containing a factor for panicle type and a factor or factors for grain length.

Correlated inheritance in wheat, G. STEWART (*Jour. Agr. Research* [U. S.], 33 (1926), No. 12, pp. 1163-1192, figs. 4).—A varietal cross made at the Utah Experiment Station, Dicklow \times Sevier wheat, gave rise in subsequent generations to lines more compact of spike, more lax than the parents, outyielding the better parent, or exhibiting resistance to many forms of *Puccinia graminis tritici*. These results led to a genetic study of spike density, awns, and other characters in a cross between a pure line of Federation and one of Sevier wheat. Federation was awnless, intermediate in spike density, slightly square-headed, and had short culms, while Sevier was awned, slightly denser than Federation, not square-headed, and had long culms. The subsequent behavior into F_2 is described.

The F_2 genotypes as classified by the F_2 breeding behavior rather highly substantiated the presence of two factors for awns, both in the same chromosome, with crossing-over to the extent of about 35 per cent. One major factor and a series of minor factors appeared to be involved in the inheritance of spike density in the cross. The ratio of square-headedness was found to be distinctly different in the two parents, and the ranges in the individual rows of parents and in F_2 progeny showed an enormous variation in this character, due to environment. There was definite evidence that segregation occurred as regards height of plant, but its nature could not be determined accurately.

Correlation studies of F_2 plant characters revealed small but apparently significant correlations between spike density and (1) length of longest culm, (2) number of culms, (3) total culm length, (4) awn classes, and (5) thickness of neck and between awn classes and (1) length of longest culm and (2) number of culms. The odds were about 142 to 1 that the correlation between spike density and thickness of neck was nonlinear. In all other cases the rather small odds suggested that the other correlations reasonably approached lin-

earity. The rather large coefficients of correlation and correlation ratios between square-headedness and spike density did not seem of great genetic importance, and those found between length of longest culm and (1) total culm length and (2) number of culms seemed physiologic rather than genetic in nature. The data suggested linkage between the factors for the characters of spike density and awn classes.

[Anomalies in certain wheat hybrids], L. BLARINGHEM (*Bul. Soc. Bot. France*, 72 (1925), No. 3-4, pp. 341-350, pl. 1, figs. 2).—Seeds of wheat obtained by crossing varieties of *Triticum vulgare* among themselves or by crossing *T. vulgare* with *T. spelta* showed all the regular stages usual to such crossings, but all crossings of such species with *T. monococcum* showed anomalies, which are described.

Inheritance of deformed leaves in *Pharbitis nil*, Y. IMAI (*Bot. Gaz.*, 80 (1925), No. 3, pp. 276-287, fig. 1).—The Japanese morning-glory (*P. nil*) shows variegation (several types), deformation, and deficiency. The present account deals with the genetical behavior of the variegated and deficient leaves.

Meiosis in the pollen mother cells of *Oenothera biennis* and *Oenothera biennis sulfurea*, R. E. CLELAND (*Genetics*, 11 (1926), No. 2, pp. 127-162, figs. 42).—This is a contribution from Goucher College.

"Old-gold" flower color, the second case of independent inheritance in *Oenothera*, G. H. SHULL (*Genetics*, 11 (1926), No. 3, pp. 201-234, pl. 1, fig. 1).—This is a contribution from Princeton University.

Brittle races of *Oenothera lamarckiana*, H. DE VRIES (*Bot. Gaz.*, 80 (1925), No. 3, pp. 262-275).—This study originated with two races, one of which (*O. lamarckiana similis*) was found in the field at Hilversum, and the other (*O. lamarckiana scindens*) in the author's experimental garden at Amsterdam. The genetical constitution of the three races here studied is expressed, with discussion.

Mendelian inheritance in hybrid warblers, N. MORSS (*Amer. Nat.*, 60 (1926), No. 669, pp. 384-387).—Data are presented showing that two independent pairs of factors are mainly responsible for the differences in color between the golden-winged warbler (*Vermivora chrysoptera*) and the blue-winged warbler (*V. pinus*). Two intermediate forms, *V. laurencei* and *V. leucobronchialis*, are attributed to hybridization with segregation of the pairs so that one is dominant and the other recessive in these species.

The problem of the inheritance of acquired characters in modern genetics, R. BLANCO (*El Problema de la Herencia de los Caracteres Adquiridos en la Genética Moderna*. Lugo, Spain: Cons. Prov. Fomento, 1925, pp. 65).—A discussion.

A method for calculating linkage values, H. W. ALBERTS (*Genetics*, 11 (1926), No. 3, pp. 235-248, figs. 2).—A constant k which shows the relation of observed values in linkage studies to independent inheritance is obtained in this contribution from the Illinois Experiment Station. When $k=10$, independent inheritance is indicated; when k =more than 10 but less than 16, coupling; when k =less than 10 but more than 8, repulsion; and when k =less than 8, some factor other than chance resulting in marked deviations from theoretical ratios. Formulas given show the interrelations of members of theoretical gametic and zygotic series, the relationship between the extreme terms and middle terms of a distribution is shown, and formulas and tables for determining the percentage of crossing over are presented.

A case of sex-linked balanced lethal factors in *Drosophila melanogaster* [trans. title], N. W. TIMOFÉEFF-RESSOVSKY (*Ztschr. Wiss. Biol., Abt. D, Arch. Entwickl. Mech. Organ.*, 107 (1926), No. 4, pp. 651-671).—A female which was heterozygous for a sex-linked character described as abnormal abdomen was

found to have produced offspring in which the females were much in excess of the males, the ratio being 24:1. A genetic analysis of the X chromosomes of this female showed that one chromosome contained a lethal factor l^1 , while the other contained a second lethal factor l^2 . The appearance of such a female was only possible if a female heterozygous for the lethal factor l^2 was mated with a male having an abnormal abdomen and whose X chromosome also contained a gene for the lethal factor l^1 .

Hybrid vigor and tumors in mice, D. F. JONES (*Amer. Nat.*, 60 (1926), No. 670, pp. 482-484).—The author discusses hybrid vigor and concludes that it is due to the accumulation of numerous dominant factors as distinct from Castle's suggestion (*E. S. R.*, 55, p. 634) that it may be due to a physiological stimulus resulting from the interaction of different genetic factors.

The activity of displaced testes and its bearing on the problem of the function of the scrotum, C. R. MOORE (*Amer. Jour. Physiol.*, 77 (1926), No. 1, pp. 59-68, figs. 2).—Testes of the rat and guinea pig transplanted to a subcutaneous position continued their spermatogenetic function for from 3 to 9 months, though spermatozoa were not formed. Similar testicles located in the abdomen showed no activity of the germinal epithelium. The lower temperature under the skin is assumed to be more nearly like that of the scrotum.

These investigations were conducted at the University of Chicago and furnished evidence in support of the hypothesis of the temperature-regulating function of the scrotum (*E. S. R.*, 53, p. 428).

The relation of the scrotum to germ cell differentiation in gonad grafts in the guinea pig, C. R. MOORE (*Amer. Nat.*, 60 (1926), No. 669, pp. 324-333, fig. 1).—In continuing the studies of the temperature-regulating function of the scrotum at the University of Chicago, referred to above, a testicle from a 14-day-old male guinea pig grafted in the scrotum of a 60-day-old male guinea pig was found to show all grades of the spermatogenetic cycle, including the presence of spermatozoa, when removed 5.5 months after the operation. Subcutaneous or intraperitoneal grafts showed some activity but never the presence of spermatozoa.

Ovarian grafts in the scrotum of rats or guinea pigs did not show any effects which could be attributed to the lower scrotal temperature.

The injection of testis material into the rat and its effect on spermatogenesis, W. J. QUICK (*Amer. Jour. Physiol.*, 77 (1926), No. 1, pp. 51-58).—Subcutaneous or intraperitoneal injections of suspensions of spermatozoa or macerated testis material repeated for from 1 to 5 times have had no apparent effect on the production of normal spermatozoa in the 13 male rats so injected in experiments at the University of Chicago. Two of the males were not mated after the treatment, but 9 of the other 11 produced litters. Cysts present in some of the injected males as a result of the treatment tended to cause mechanical displacement of the testes, which resulted in degeneration.

The duration of the potency of the spermatozoa of mammals in the epididymis removed from the organism [trans. title], M. E. IWANOW (*Compt. Rend. Acad. Sci. [Paris]*, 183 (1926), No. 3, pp. 456-458).—Preliminary experiments have shown that the motility of spermatozoa could be conserved for several days, and even weeks, in certain cases when preserved in the epididymis removed from the animal, but when such sperms were used for the purpose of artificial insemination the results with rabbits and guinea pigs were negative in 1924. During 1925 some success was obtained, and in 1926 with the improved methods of technique fertilization occurred with sperms preserved in the epididymis for 7 days in a rabbit and 8 days in a guinea pig.

The relation of the male to the hatchability of hens' eggs, F. A. HAYS (*Science*, 64 (1926), No. 1660, p. 408).—Data are presented from the Massachusetts Experiment Station showing that almost no eggs hatched which were produced by 7 Rhode Island Red pullets when mated to the same cockerel, though many were fertile. When the same birds were mated to another cockerel in a second year the hatching percentages of fertile eggs varied from 0 to 82 per cent. It is pointed out that physical characters of the eggs appear to be of less importance in relation to the hatchability of fertile hens' eggs than the genetic make-up of the hen laying the egg or the male fertilizing the eggs.

FIELD CROPS

[Field crops work at the Georgia Coastal Plain Station, 1925], S. H. STARR (*Georgia Coastal Plain Sta. Bul.* 6 (1926), pp. 8-21, 23-40, 44-46, 53-56, figs. 8).—Varieties outstanding over periods in continued comparisons (E. S. R., 54, p. 130) included Georgia Red wheat, Hundred Bushel oats, Abruzzi and South Georgia rye, strains of Toole and Cleveland, Lightning Express, Cook, and Dixie Triumph cotton, Whatley and Hastings Prolific corn, North Carolina peanuts, Oootan and Laredo soy beans, Iron and Brabham cowpeas, barnyard millet, Tracy Early Black velvet bean, Austrian winter field pea, Monanthos, hairy, and purple vetch, Tifton bur clover, Red Bliss potatoes, McMillan Cluster, Hardshell, and Southern Queen sweet potatoes (for acre yields), and Yellow Prior tobacco. The yields of hay mixtures and the merits of miscellaneous legumes and grasses are set forth. Combination of the three was superior to seeding either carpet grass, Dallis grass, or lespedeza alone for pasture.

October 15 to November 1 appeared to be the optimum period for seeding small grains, with a 6-pk. rate for wheat. Fertilizer tests suggested for oats 400 lbs. of acid phosphate, 100 lbs. of sodium nitrate or its equivalent, applied as top-dressing, and 50 lbs. of potassium chloride or its equivalent.

For cotton on typical Tifton sandy loam a 9-3-5 fertilizer is indicated, with a slight increase in nitrogen and potash on lighter soils. On good soils 800 to 1,000 lbs. per acre seemed desirable, and quickly available sources of nitrogen were preferred. Top-dressing tests recommend 100 to 125 lbs. of sodium nitrate or its equivalent in ammonium sulfate applied at chopping. Spacing tests suggest 2 stalks per hill 12 to 15 in. apart in 3.5-ft. rows for good results. Liming was not economical, whereas green manure in combination with a complete fertilizer gave good results with both cotton and corn.

A 10-2-4 fertilizer was the best combination used for corn on Tifton sandy loam, with slight increases indicated for lighter soils. The fertilizer should be applied at planting on average soils. The type of husk seemed the major factor in weevil damage, a husk of fine texture which fits closely and extends well over the tip repelling the weevil markedly.

Fertilizer tests with peanuts recommend from 10 to 12 per cent of phosphoric acid, 2 to 3 of ammonia, and 2 to 4 per cent of potash, together with lime. Spacings of from 6 to 7 in. are indicated. In 1924 and 1925 no benefit accrued from the use of hulled nuts.

Commercial varieties of sweet potatoes fluctuated less in yield with extremes in seasonal conditions (rainfall) than did productive noncommercial sorts. April planting, late harvesting, and spacings between 8 and 20 in. in 3.5-ft. rows gave highest yields, and best results were also had from 8-6-2, 8-4-4, and 8-2-6 fertilizers, with from 600 to 800 lbs. the most profitable acre rate. Source of seed stock, northern- or southern-grown, seemed to influence yields little. Data for 4 years showed the average percentage of rot in storage of 16 varieties to

range from 5 to 43 per cent. Roots from well balanced fertilizer formulas have shown the least rot.

Experimental results with potatoes suggest planting March 15 to April 1 and using an 8-4-4 fertilizer at from 1,000 to 1,200 lbs. per acre. Overhead irrigation used less water and gave more marketable tubers than subirrigation. Both surpassed unirrigated potatoes.

Further tests continued to recommend not less than 1,000 lbs. per acre of an 8-3-5 fertilizer for tobacco, and a small addition of manure gave decided benefits. The nitrogen should be equally from organic and inorganic sources.

[Field crops experiments at the Crookston, Minn., Substation, 1925], C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 6-8, 15-33, 34-36, 45-51, 52-56, 72-76, 77-80, figs. 2*).—Experiments with field-crops (E. S. R., 55, p. 332) reported on comprised variety tests with spring and winter wheat, corn, oats, barley, rye, flax, alfalfa, sweet clover alone and with nurse crops, soy beans, potatoes, mangels, sugar beets, and annual hay crops; seeding tests with wheat and rye; trials of wheat-flax and oats-flax mixtures; studies on the longevity of scarified and unscarified seed of alfalfa and sweet clover; soil preparation, seed selection, varietal and seed stock, manuring and fertilizer tests, and experiments on the utilization of sweet clover and straw on potatoes; fertilizer, depth of plowing, date of planting, and spacing tests with sugar beets; and crop rotations. Agronomic information and the susceptibility to rust, scab, and glume spot are recorded for a number of wheat varieties and hybrids. Variety and fertilizer trials at Mahnomen and Gary are summarized, and an article entitled Potato Culture and Fertility Practices in the Red River Valley, by T. M. McCall, is appended.

[Field crops experiments at the Morris, Minn., Substation, 1925], P. E. MILLER (*Minnesota Sta., Morris Substa. Rpt. 1925, pp. 23-38*).—Experimental work (E. S. R., 55, p. 735) reported on in these pages includes variety tests with spring and winter wheat, oats, barley, rye, corn, flax, soy beans, field beans, alfalfa, and potatoes; trials of mixtures of flax with wheat and oats; and crop rotations.

[Field crops work at the Porto Rico Insular Station], F. A. LÓPEZ DOMÍNGUEZ, A. H. ROSENFELD, L. A. SERRANO, P. OSUNA, and R. FERNÁNDEZ GARCÍA (*Porto Rico Dept. Agr. and Labor Sta. Ann. Rpt., 1925, pp. 24-28, 29-31, 35, 36, 42, 43, 49-59, 70-74, 85-87, 88-96, 110-112, 114; also in Spanish ed., pp. 26-30, 31-33, 38, 39, 45, 46, 52-64, 74-77, 89, 90, 92-100, 115-118, 119*).—Experiments with sugar cane during the period of the report included trials of varieties and seedlings, comparisons for resistance to mosaic, fertilizer tests, breeding work, and a test of the effect of pruning the growing tip. Comment is made on a yellow striped sport of D. 1135 and adventitious buds of P. R. 417 and on production of seed (cuttings) by different varieties. Special activities by Rosenfeld included studies of varieties and seedlings, comparisons of the better varieties, reports on the Java P. O. J. canes (E. S. R., 54, p. 133) and on B. H. 10(12) and S. C. 12(4) canes (E. S. R., 55, p. 232), a study of the sugar industry in Vieques Island, and an investigation of the declining productivity of the older varieties in Louisiana and their replacement by P. O. J. 234.

Sugar cane fertilized with filter press mud produced 12.6 tons per acre, while untreated cane averaged 6.3 tons. In a test of the effect of nutrients on the rate of maturity of Uba cane, cane from unfertilized plats gave juices with the highest purities, and of the fertilized canes those treated with potash gave juices with higher purity than when no potash was used. The purity was in proportion to the potash application. Although as much as 0.25 per cent sodium chloride on the weight of dry soil was used on marsh-land soil,

no bad effect could be detected on sugar-cane plants. Analyses showed that for each ton of "Rayada" cane on a virgin alluvial soil there was removed 2.47 lbs. of ammonia, 0.93 of phosphoric acid, 5.93 of potash, and 0.9 lb. of lime. Varieties in greatest demand included B. H. 10(12), S. C. 12(4), P. R. 329, F. C. 306, P. R. 328, D. 117, and D. 1135.

Varietal trials were also made with cowpeas, yautia, tania, miscellaneous legumes, and forage grasses. The characteristics of the vines, flowers, and roots, and the yields are tabulated for 224 varieties of sweet potatoes.

[**Field crops experiments in South Carolina**] (*South Carolina Sta. Rpt. (1926)*, pp. 69-77, figs. 5).—Further studies (E. S. R., 54, p. 635) reported on from the station and substations included variety trials with corn, sweet potatoes, and peanuts, fertilizer tests with corn, oats, potatoes, and sweet potatoes, source of seed trials with potatoes, topping tests with tobacco, trials of legumes and cover crops, pasture studies, and crop rotations.

[**Agronomic experiments in Utah**], G. STEWART, A. F. BRACKEN, D. W. PITTMAN, J. W. CARLSON, and R. J. BECRAFT (*Utah Sta. Bul. 198 (1926)*, pp. 20-22, 23, 24, 25, 26, 28-31, 64, 65).—The outstanding results in varietal trials with spring and winter wheat, corn, and barley; a barnyard manure, green manure, and stubble disposal test with wheat; breeding work with wheat and potatoes; a test of time of plowing and manuring silage corn; irrigation tests with alfalfa, sugar beets, potatoes, field peas, and wheat; trials of forage and catch crops; seed production studies with alfalfa; control work with wild morning glory; and range reseeding tests are noted as heretofore (E. S. R., 52, p. 732).

No difference was observed between yields from fall and early spring plowing, whereas later spring plowings showed marked decreases. Seven to 8 in. seemed to be the depth for maximum net returns. Alternate fallow and crop appeared to be the safest and most efficient practice in comparison with continuous cropping, 2 crops and 1 fallow, and 1 crop with 2 years of fallow.

Seeding tests with Turkey wheat indicated not less than 5 pk. per acre not later than October. Ordinary drilling 7 in. apart gave higher wheat yields than where the rows were spaced further apart, and in most cases cultivation decreased yields. When wheat was cut as soon as ripe and at 10-day intervals over 2 months, the weight per bushel dropped from 61 to 57 lbs. but no change took place in the gluten content, loaf volume, and quality of bread from the delayed cuttings.

[**Field crops investigations in Washington**], E. G. SCHAFER ET AL. (*Washington Col. Sta. Bul. 208 (1926)*, pp. 23-25, 26, 30, 31, 40, 44-46, 48, 49, 50-53, 57, 58, 59, 60, 61).—Continued experimental activities (E. S. R., 54, p. 827) reported on from the station and substations embraced variety tests with winter and spring wheat, corn, oats, barley, rye, flax, alfalfa, sweet clover, and sweet potatoes; seeding tests with wheat and potatoes; breeding work with wheat, oats, and potatoes; weed control studies; tests of cover crops; and rotations.

The total yield of grain during equal periods was greater in rotations in which field peas replaced summer fallow. Wheat after peas yielded less than wheat following good summer fallow but more than after corn or sunflowers. Field peas after wheat in different rotations averaged 22.7 bu., while spring wheat following wheat in rotations averaged 21.9 bu. Spring wheat and oats and field peas gave much higher yields after fallow than after corn or wheat at Waterville.

From 40 to 45 cultivations with the knife of the weeder set 3 to 5 in. deep were required during the growing season to keep bindweed or wild morning glory below the surface. After 2 years of such cultivation about nine-tenths

of the original infested area was free from the weed. Results on the Irrigation Substation demonstrated that the chief value of corn cultivation on the fine sandy loam soils of central Washington is in weed eradication.

Four winter wheat varieties seeded on three dates on early and late fallow and on alfalfa sod gave indications that under the same date of seeding the variety producing the best yield or quality for conditions of early summer fallow may not be the best adapted to land summer fallowed late or where legumes are grown in rotation, nor may that same variety excel if the seeding date be changed. Spring and winter wheats were found of equal merit at the Adams Substation when the winter wheat did not complete emergence until spring and the spring wheat had been seeded early. An experiment on seed-bed cultivation at planting of spring wheat showed that the use of a harrow following a drill may add to the yields, and that the use of individual press wheels following a hoe drill can be substituted for the harrow without sacrificing yield. The use of press wheels is recommended for light soils subject to drifting. Harrowing winter wheat in the spring resulted in decreased stands and yield at the Waterville Substation.

Alfalfa and sweet clover seeded on ground cropped the previous year were unsatisfactory at Waterville, but seeded after a year of clean fallow they provided a limited green pasture in summer after the small grains dried up. Neither has yielded as much hay as the small grains. Biennial white was superior to biennial yellow sweet clover on the Irrigation Substation in carrying capacity of dairy cattle and sheep. Sheep found them equally palatable.

Close spacing of potato seed in the row gave the highest total yield and the most No. 1 tubers at the Irrigation Substation. Larger yields were obtained with increased application of water within the limits of the amounts used. Where water was applied according to the growth stage of potatoes the highest yields were obtained with enough water to maintain vigorous growth until blossom bud formation was evident, after which a more abundant supply was uniformly maintained until the tubers were ready to begin ripening.

Germination of seven legume crops was decidedly higher under two-thirds shade and one-third shade than in the open, apparently because surface moisture was maintained better under shade. However, all except spring vetch developed much more rapidly in the open. Designating the average growth of the crops in full sun by 100, the growth under one-third shade would be 80.5 and under two-thirds 43.9. Alfalfa seemed more sensitive to shade than Hubam or sweet clover.

[Agronomic work in Wyoming] (*Wyoming Sta. Rpt. 1926, pp. 162, 163, 179*).—Varietal leaders in continued comparisons (E. S. R., 54, p. 733) embraced Marquis, Red Bob, Kubanka, and Dicklow wheat, Markton and Iogren oats, and California Feed, Hannchen, and Charlottetown barley. Exceptional yields were obtained from a strain of Red McClure and a strain of Pearl potatoes. A rotation consisting of four years of alfalfa and two of crops seemed superior to a shorter sequence. In tests at Archer, in cooperation with the U. S. Department of Agriculture, use of the furrow drill resulted in a 20 per cent increase in the winter wheat yield, and together with late spring fallow, increased yields over 30 per cent in comparison with the common drill.

Root nodule bacteria of Leguminosae, E. B. FRED, A. L. WHITING, and E. G. HASTINGS (*Wisconsin Sta. Research Bul. 72 (1926), pp. 43, pls. 15, figs. 6*).—Investigations dealing with laboratory study of the root nodule bacteria of legumes and of growth conditions for cultures to prove effective in the field under favorable conditions and with field conditions influencing the bacteria in their relation to the host plant have been extensively noted from other sources. Experiments on factors influencing the entrance of the bacteria into

the plant concerned the rate of movement of nodule bacteria in the soil, effect of ground water on such movement, nitrates in plant tissue, and the influence of nitrates, moisture, temperature, reaction, and germinating seed on nodule bacteria. The effect of nodule bacteria on the host plant was shown by comparisons of nitrogen fixation with strains of alfalfa bacteria and soy bean bacteria and by tests of the effects of inoculation on yield and nitrogen content of alfalfa and soy beans, on the balance of nitrogen in the soil, and on the quality, yield, and pod production of peas, and of the relation of process to distribution of disease. Studies around the bacterial life in the soil in the absence of the host plant had to do with the longevity of bacteria in sterilized and unsterilized soil, influence of nitrates and carbonates, and nitrogen assimilation. Miscellaneous experiments involved the effect of freezing on nodule bacteria, distribution of nodule bacteria in manure, and the effect of inoculated and uninoculated legumes on subsequent crops of nonlegumes.

Winter hardiness in alfalfa varieties, F. H. STEINMETZ (*Minnesota Sta. Tech. Bul. 38 (1926)*, pp. 33, figs. 6).—The relative winter hardiness of Grimm and Kansas-grown common alfalfa was studied by using several available methods in an endeavor to ascertain ready means for distinguishing hardy and nonhardy types.

Alfalfa plants seemed to have no autonomous rest periods, as plants came into active growth within 3 days when brought into the greenhouse during every month in which growth was not possible in the field. The plants appeared to be forced into inactivity by unfavorable environmental conditions. The varieties studied have a critical period during early spring when the snow disappears and the soil thaws. Resistance to cold seemed to increase in the roots of both varieties as winter approaches and to disappear with the coming of spring. Temperatures at the soil surface beneath the snow indicated that the snow amply protects alfalfa plants against killing by low temperatures. Freezing injury resulted in the destruction of the central portion of the root, leaving it susceptible to infection by decay organisms. The crown buds are evidently hardier than the root tissues just below them.

The thermoelectric method used in determining the freezing point of root tissues was rapid but in general did not seem reliable for differentiating between hardy and nonhardy varieties. No absolute correlation was found between the degree of freezing point depression and resistance to killing by freezing. Physical determinations upon sap expressed from the roots showed that the quantity of press juice obtained from 100 gm. of material at the respective pressures bears no apparent relation to the hardiness of varieties. While viscosity was related to total solids in the sap, neither appeared to be connected with hardiness.

The alfalfa root seems to function as a storage structure for carbohydrates and possibly for small amounts of protein reserves. There appears to be a transformation of starch into sugar during the late autumn and early winter and apparently a partial reconversion in early spring, in accordance with the principle of Fischer. The Grimm was found to have more sugar, expressed in terms of total carbohydrates, than the Kansas-grown common. Considering that sugar acts as a protective colloid, Grimm appeared to have an advantage. No apparent quantitative relation existed between pentosan content and hardiness. The amino-nitrogen fluctuations did not indicate that protein cleavage is important in protecting proteins against precipitation.

As positive measures of differences between varieties studied, the freezing of potted plants or roots removed from the soil was found the most practical and reliable method.

Irrigated alfalfa in Washington, H. P. SINGLETON (*Washington Col. Sta. Bul. 209 (1926)*, pp. 15, figs. 5).—Varietal trials at the Irrigation Substation at Prosser, Wash., showed northern-grown strains of common alfalfa to average higher in yields than Grimm and other variegated strains as a group. The latter seem better adapted for localities where the former winterkill. Turkestan and the nonhardy Peruvian gave lower yields. Considering yield and quality, cutting test results recommend cutting alfalfa when one-half in bloom.

Bean growing in northern Idaho, eastern Washington, and eastern Oregon, B. HUNTER (*U. S. Dept. Agr., Farmers' Bul. 1509 (1927)*, pp. II+14, figs. 4).—This is a further revision of and supersedes Farmers' Bulletin 907 (E. S. R., 38, p. 434). It indicates suitable districts, favorable factors and advantages in bean production, describes cultural methods and field practices, and discusses varieties, improvement, marketing the crop, by-products, and production in competing areas.

Red clover experiments, T. K. WOLFE and M. S. KIPPS (*Virginia Sta. Bul. 252 (1926)*, pp. 24, figs. 13).—Experiments in cooperation with the U. S. Department of Agriculture were concerned with the hay yields and anthracnose resistance of red clover from different sources. The extent of red clover seed production in Virginia is described, with notes on a method for removing buckhorn plantain from red clover seed and on substitutes for red clover.

Fall and spring seedings of red clover from domestic and foreign sources agreed with results obtained elsewhere in showing that anthracnose infection is often less and the yields larger from fall than from spring seeding. Anthracnose appeared to be one of the chief reasons for death of spring-seeded clover during the following summer. Trials at the station and at Arlington, Va., showed the sources of red clover most resistant to anthracnose to include Tennessee (disease-resistant), Virginia, Maryland, Ohio, and Michigan, and these are indicated as best for the Virginia farmer. If foreign-grown seed must be used, the tests indicate that seed from Chile, France, and north European countries are best for Virginia conditions.

[**Cotton investigations in South Carolina**] (*South Carolina Sta. Rpt. 1926*, pp. 10-17, 19, 20, 42, 43, 44, 45, figs. 3).—The continuation of previously noted experiments (E. S. R., 54, p. 636) is reported on.

The differences noted in the resistance of the bolls of the Humco Cleveland, Dixie Triumph, and Webber varieties to needle puncture were found to be closely correlated with resistance to puncture by the boll weevil. As a rule, their bolls increased in hardness from day to day until from 3 to 4 weeks old, after which there was relatively little change in resistance to puncture. Preliminary indications are that hardness of the bolls is influenced by fertility conditions. Low fertility seemed to cause earlier hardening, especially for early-season bolls, whereas bolls developing from blooms after July 20 hardened as rapidly under high fertility conditions as on poorer soil. Soil moisture, air humidity, and temperature also seemed to have direct bearing on these qualities. Additional fruiting studies resulted similarly to those recorded earlier. Irrigation and shading of cotton gave indications that soil moisture is the most important factor in varying the length of the boll period of cotton, the period being curtailed by shortage of soil moisture.

In spacing experiments involving Cleveland, Dixie Triumph, and Carolina Foster the increased earliness due to close spacing was found about equal in the varieties, although they differed somewhat in their growth habits. The difference in earliness was also apparent in the acre yields of seed cotton. The maximum yields in practically every case were produced with 6-in. spacing, although yields from 6-, 9-, and 12-in. spacing differed little. Very little

weevil damage was observed on any plat. The 6- to 12-in. spacings gave similar yields whether two presquare poison applications were made or poison was applied as seemed necessary. In further hill-spacing tests an increase in earliness and generally an increased yield came from a larger number of plants per hill. Continued recommendations are that cotton should be spaced to average about 1 stalk every 6 in. in the 4-ft. row, providing for about 21,000 plants per acre. On the average, higher yields may be had from plantings at Florence between April 1 to 15 if conditions favor germination then.

Cleveland, Humco Cleveland, and Coker Cleveland 5 yielded highest on dusted plats and Coker Delta led the varieties given only two applications of poison. Piedmont Cleveland, Lone Star, Okra Leaf Acala, Miller, and Trice yielded high in adaptation tests, and Dixie Triumph was foremost in the wilt resistance trial on badly infected soil.

Spinning tests in cooperation with the U. S. Department of Agriculture indicated that cotton grown at the station and at other points in the State in 1925 produced lint of rather high spinning quality in spite of unfavorable seasonal conditions. While the staple in some cases was a little shorter than normally produced by the varieties the spinning quality was good for the length of staple.

In accord with previous results on the time of applying nitrogenous fertilizers the greatest yield increase occurred where 50 lbs. of sodium nitrate was supplied at chopping and 50 lbs. when the first squares formed. Addition of 100 lbs. of sodium nitrate when the first squares began to form was next in effectiveness. The fertilizer experiments as a whole recommend for cotton in the Coastal Plain of South Carolina 600 to 800 lbs. per acre of fertilizer containing 9 to 12 per cent of acid phosphate, 3 to 5 of ammonia, and 3 to 4 of potash, with 150 lbs. of sodium nitrate or 110 lbs. of ammonium sulfate as a side application. For the Piedmont 600 to 800 lbs. of fertilizer analyzing 10 to 12 per cent phosphoric acid, 3 to 5 of ammonia, and 2 to 3 per cent of potash is indicated with the same top dressing as for Coastal Plain soils. Cover crop experiments indicated that land can be rapidly improved and planted to cotton each year provided a good cover crop of rye or vetch is produced each winter and turned under. Where rotation is practiced and a legume follows small grain the land is improved more rapidly.

Growth and development of cotton plants at Greenville, Tex., H. C. McNAMARA, J. W. HUBBARD, and R. E. BECKETT (*U. S. Dept. Agr., Dept. Circ. 401 (1927), pp. 18*).—The growth and behavior of the cotton plant was observed under various cultural methods as affected by environmental conditions at Greenville, Tex. The effect of different planting dates at weekly and longer intervals and spacing 12 in. and unthinned upon the normal rate and sequence of production and the growth and development of fruiting parts was studied with Lone Star cotton. Comparative studies on growth and development were also made with Kasch, Mebane Latest Improved, Rowden, Truitt, Lone Star, Acala, and Kekchi.

Flowers appeared in ascending series along the main axis of the plant about three times as fast as in a horizontal series along the fruiting branches. The intervals between the appearance of flowers on the first nodes of successive fruiting branches averaged 2.4 days and between the appearance of successive flowers on the fruiting branches of the same plants 6.2 days. The germination and early growth of seedlings were more rapid in the late plantings. The period from planting to appearance of the first square ranged from 58 days on an April 2 planting to 19 days for plantings made July 24 and August 15. The

interval between appearance of successive fruiting branches was little affected by the planting date. For 1923 the means ranged from 2.28 to 2.93 days. In 1924 there was a slight tendency for the intervals between the appearance of successive fruiting branches to be longer on closer spacings. The intervals between the appearance of successive squares on fruiting branches were very irregular without significant differences between the different planting dates. The intervals between the appearance of successive squares on fruiting branches were longer in unthinned rows than in 12-in. spacings of each planting date.

The rate of square production appeared to be directly related to the vegetative vigor of the plants and not necessarily affected by the advance of the season. Long intervals between the appearance of squares may occur at any time during adverse weather conditions or when the plants are reaching maturity or bearing a heavy crop of bolls. The square period, the time from the appearance of a square until it flowers, tended to shorten on later plantings and was longer on unthinned cotton than on 12-in. spacing. The lengthening of the square period on the outer nodes of the branches appeared to be definitely related to the position on the plant or the slowing up of plant growth during the late season.

The maturation period of bolls was affected little by the planting date, lengthened with advance of season, and was also somewhat longer in unthinned rows, especially where the stand was very thick, than in 12-in. spacing. The period from planting to maturity was much longer on the earlier plantings, but most of this was in the seedling stage before the appearance of the first square.

No significant differences were found in the rate of growth and development of fruiting parts between any of the varieties studied when planted on the same date and subject to the same cultural treatment and weather conditions. No relation was shown between the number of locks per boll and the maturation period, the 4-lock and 5-lock bolls opening together in each variety.

The use of first generation crosses and other methods for improving southern varieties of corn, H. B. BROWN (*Mississippi Sta. Bul. 236 (1926)*, pp. 31, figs. 4).—The merits of several methods of corn improvement are discussed, with summaries of experiments involving them at the station.

Mass selection, which has brought forth good varieties, appears useful in maintaining their good qualities. Various modifications of the ear-to-row method during 10 years' tests did not result in significant gains. Crossing experiments during 9 years indicated that F_1 crosses of corn varieties, such as are grown in Mississippi and other southeastern States, will outyield the average of their parents. In a few cases the better yielding parent was surpassed. The gain of the F_1 crosses over the better parent was so slight that their use seemed hardly practicable. When plats of pure white and pure yellow corn were grown adjacent the data showed that there is considerable crossing between adjoining rows, but with separation the percentage falls rapidly. Selfed strains of southern corn varieties exhibited reduction in vigor, stalk size, and yields, and various abnormalities. Certain trial crosses between strains inbred for from one to three years yielded less than the original parent strains, while others made considerable gains.

The oat crop, C. A. MOOERS (*Tennessee Sta. Bul. 136 (1926)*, pp. 17, figs. 7).—Fall-sown or winter oats matured earlier and outyielded spring oats during a 10 years' test at the station, although spring oats fit better into the average cropping system. Fulghum as a spring oats decidedly surpassed Burt, and Kanota, a strain of Fulghum, seemed desirable in Tennessee. Fulghum is not recommended for fall seeding in the State. In prolonged trials at Knoxville and Jackson, Culberson oats was found 10 days earlier, less apt to lodge, and to yield equally with Virginia Gray Turf oats on good land. Comparisons of Tennessee, Texas, and Arkansas grown seed from the same original Red

Rust Proof strain did not reveal significant differences, except that contamination with smut reduced the yields from the Arkansas-grown seed.

Early March seemed to be the optimum time for seeding spring oats at the station and after March 15 on the Cumberland plateau and similar elevations. September was the best month for planting winter oats at the station and October at Jackson. For favorable conditions at Jackson 1 bu. of seed per acre sufficed for winter oats, 1.5 to 2 bu. being suggested for average or adverse conditions.

The merits of alfalfa, clover, grass, vetch, and rape seeded with winter and spring oats are shown, and fertilizers are indicated for oats under different regional and cultural conditions.

Experiments with certified Irish Cobbler potatoes, A. M. MUSSER (*South Carolina Sta. Bul. 232 (1926), pp. 20, figs. 4*).—In comparisons during 4 years certified potato seed averaged 57.1 bbls. per acre and noncertified seed 49.9 bbls. Certified seed generally excelled in the production of No. 1 tubers, stands, and comparative freedom from disease. Seed from Wisconsin and Vermont produced the highest average yields at the station, Florence, and Summerville for sources tested 5 years, and Michigan seed led the sources tested 4 years. Tests with stored seed suggested that with proper storage conditions seed stored from season to season might yield about as well as northern-grown seed for the first year. Subsequently the crop from stored seed might mature a few days later than that from northern seed.

Rules for seed testing (U. S. Dept. Agr., Dept. Circ. 406 (1927), pp. 13).—These rules, adopted by the Association of Official Seed Analysts of North America in August, 1926, outline procedure in sampling agricultural seed, in analyzing for purity and germination, evaluating results, and making reports.

Inspection of agricultural seeds, O. S. ROBERTS ET AL. (*Indiana Sta. Bul. 302 (1926), pp. 68, figs. 2*).—The tabulations presented show the purity, germination percentage, weed seed content, and for legumes hard seed content, for 745 official samples of agricultural seed obtained from seed merchants in Indiana in 1925.

Commercial agricultural seeds, 1926, J. M. BARTLETT ET AL. (*Maine Sta. Off. Insp. 122 (1926), pp. 74-83*).—Tables show the purity, germination, and weed seed content for 176 official samples of agricultural seed collected from dealers in Maine during 1926.

HORTICULTURE

[**Horticultural investigations at the Georgia Coastal Plain Station**] (*Georgia Coastal Plain Sta. Bul. 6 (1926), pp. 40-44, 46-52*).—Of 16 tomato varieties, New Stone produced the greatest number of marketable fruits over a 4-year period. Yield records taken on New Stone tomatoes planted at 15-day intervals from April 1 to July 1 showed that early planting is decidedly the best. Tomatoes responded to liberal fertilization with a formula high in all three principal ingredients. Overhead irrigation proved slightly more economical in water used in relation to yield than did subirrigation.

Thurmond Grey again proved (*E. S. R., 54, p. 136*) a superior watermelon. Watermelons thinned to one melon per vine produced the largest melons, but normal unthinned vines produced the greatest yield per acre.

Variety tests with beans, peas, peaches, grapes, strawberries, and dewberries are reported.

[**Variety testing at the Crookston, Minn., Substation**], C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 44, 45, 57-61*).—This comprises the usual brief notes upon the results of varietal tests with tree and bush fruits, vegetables, ornamentals, etc. (*E. S. R., 55, p. 339*).

[Variety testing at the Morris, Minn., Substation], P. E. MILLER (*Minnesota Sta., Morris Substa. Rpt. 1925, pp. 38-40*).—The usual brief report (E. S. R., 55, p. 742) upon variety tests with tree and small fruits.

Annual report of the plant breeder, J. P. GRIFFITH (*Porto Rico Dept. Agr. and Labor Sta. Ann. Rpt., 1925, pp. 75-83; also in Spanish ed., pp. 78-87*).—In the belief that the avocado has great possibilities in Porto Rico, improvement work was actively pursued with this fruit during the year. Many new varieties of Guatemalan, West Indian, and Mexican origin were introduced. A test of various avocados as stocks showed the native or West Indian to be by all means the most successful. The Puebla, a Mexican variety, proved generally unsuited to Porto Rican conditions. Tests with the mango, jack fruit, and cacao are briefly discussed.

Studies with numerous *Rubus* species, both introduced and native, show that tropical species are quite generally resistant to the types of disease that attack northern species. Crosses were made between *R. probus* and Cuthbert and between *R. probus* and *R. trivialis*, the manatee dewberry. The treatment of wild raspberry (*R. rosaeifolius*) seed with sulfuric acid (sp. gr. 1.84) for 45 minutes gave 95 per cent germination.

Of introduced grapes the Carman, a Texas variety, appears promising. A dwarf lemon known as the Meyer variety, obtained from the U. S. Department of Agriculture, gave promising results, one tree producing at 3 years of age over 300 fruits. It was found that this lemon could be quite easily propagated by hardwood cuttings buried in sand.

[Horticultural investigations at the South Carolina Station] (*South Carolina Sta. Rpt. 1926, pp. 46-49, fig. 1*).—Of 30 apple varieties tested for self-fruitfulness by covering the blossoms with glassene paper sacks, 5 only, namely, Golden Russet, Ozark, Bismark, Western Beauty, and Early Harvest, set fruits. Examination of the pollen placed in a 10 per cent sugar solution showed good germination in Golden Queen, Golden Delicious, Scotch Cluster, York Imperial, Apple of Commerce (Beach), Bismarck, Kansas, Coffelt, Payne, Simmons Red, Early Harvest, and Delicious. Winesap, Stayman Winesap, and Blacktwig pollen gave very poor results. Delicious, York Imperial, Golden Delicious, and Early Harvest proved satisfactory pollinizers for Winesap, Stayman Winesap, and Blacktwig.

As in the preceding year (E. S. R., 54, p. 642), fertilizer studies with the peach again showed the superior value of a high-grade fertilizer. At McBee, in the Sand Hill section, trees fertilized with an 8-8-4 material were most productive, and similar results were secured at Gramling, in the Piedmont region. Nitrogen fertilizers delayed the maturity of peaches as much as 10 days in 1925. The growing of a cover crop increased the yield of peaches the following season.

Cutting asparagus the first year after planting proved an injurious practice from the viewpoint of yields the succeeding season.

[Plant breeding at the South Dakota Station], N. E. HANSEN (*South Dakota Sta. Rpt. 1925, pp. 25-32*).—Attempts to breed hardy varieties from tender material have led to negative results, but it was pointed out that hardiness and desirable qualities may be obtained by hybridization. Crosses between hardy wild grapes of the Dakotas and nonhardy cultivated forms have yielded many promising seedlings, 32 of which are herein named and described, as are also 10 gooseberries resulting from crosses between the wild native and European forms. Four improved forms of wild black currants, a sand cherry, an apple, a plum, and a chokecherry are briefly discussed.

[**Horticultural investigations at the Utah Station**], T. H. ABELL and A. L. WILSON (*Utah Sta. Bul. 198 (1926)*, pp. 44-50).—The usual progress report (E. S. R., 52, p. 738).

Notes are presented upon the results of a strawberry variety test. Observations following severe winter injury to peaches in December, 1924, indicated that the severity of the injury was enhanced by lack of irrigation water in late summer, low soil fertility, unfavorable site, and peach borer injury. The testing of tomato stocks preparatory to breeding operations showed outstanding differences between strains within the same variety in type, yield, and time of ripening.

Tests of a large number of different Spanish types of onions showed a great confusion in nomenclature. The Riverside Sweet Spanish onion, a selected strain of Valencia, was found superior to all others because of its dark color, firmness, and spherical shape. Thinning tests with Riverside Sweet Spanish indicated the inadvisability of this operation when seeding was at the rate of from 2.5 to 3.5 lbs. per acre. Fall-planted mother bulbs yielded more seed per plant than spring-set bulbs, but the loss in stand in the fall bulbs was very large.

Thinning increased the proportion of large apples upon trees growing near Logan.

[**Horticultural investigations at the Washington Station**] (*Washington Col. Sta. Bul. 208 (1926)*, pp. 28-30, 61, 62, 65, 66, 68, 69).—The usual annual report (E. S. R., 54, p. 835). Nitrogen-bearing fertilizers were found by O. M. Morris, H. J. Jensen, and W. A. Luce to be of benefit in orchards of low vigor and yellow foliage. An exception was found in the case of orchards located on very thin or gravelly soils and suffering from insufficient soil and soil moisture. Phosphorus and potassium fertilizers gave no direct improvement to either tree or fruit, but did influence the ground cover between the trees. Low production was also found to be associated with insufficient water, improper pruning, imperfect pollination, and the crowding of the trees.

Studies by F. L. Overley showed that peaches harvested immaturely failed to develop full color or quality. Overley and Jensen found that apples also, in order to attain maximum quality, must be practically full sized and well colored at harvest. Morris found that preliminary holding in common storage prior to cold storage was very destructive to the storage quality of Winesap, Rome Beauty, and Delicious apples.

Results of pollination tests, conducted by Morris and Luce near Wenatchee, suggest that Winesap, Delicious, and Arkansas Black are either partially or fully self-sterile, and that Rome Beauty, Jonathan, Winter Banana, and Esopus are self-fruitful. Cross-pollinizers are suggested for the less favored kinds. Bartlett, Bosc, and Anjou pears were inclined to self-sterility, and Flemish Beauty was self-fruitful.

At the Irrigation Substation, at Prosser, Jensen found that a single thickness of burlap placed over the strawberry bed at sundown kept the soil from 8 to 12° F. warmer than that without such protection.

D. J. Crowley, working with cranberries in Pacific County, found that fruit buds continued to form until the middle of December in a year of no frosts. Unfortunately, the new growth of the following spring was caught by a heavy frost, which seriously reduced the crop. Certain plats sprinkled throughout the night of the frost suffered no injury, and young freshly sanded bogs suffered less than older ones covered with heavy vine growth. Little difference was found in the keeping quality of scooped and of hand picked McFarlin and Centennial berries. Berries dried before being placed in the warehouse kept

much better than those taken in wet. McFarlin and Centennial bogs suffered reduced yields from scooping, while Howe, Early Black, and Burgess bogs, owing to a different habit of growth, were not affected.

Work in blueberry propagation showed good success with cuttings planted 2 in. deep in a 50-50 mixture of well-pulverized peat and sand. Among weed killers tested in the cranberry bog, kerosene showed considerable promise, killing grass and at the same time injuring the cranberries but slightly.

Insecticides and fungicides, 1926, J. M. BARTLETT ET AL. (*Maine Sta. Off. Insp. 122 (1926)*, pp. 84-88).—In conformity with the usual report (E. S. R., 55, p. 138), the results of analyses of fungicidal and insecticidal materials collected by the commissioner of agriculture during 1926 are herein presented.

Analyses of materials sold as insecticides and fungicides during 1926, C. S. CATHCART and R. L. WILLIS (*New Jersey Stas. Bul. 441 (1926)*, pp. 16).—According to the usual procedure (E. S. R., 55, p. 38), this bulletin presents the results of analyses of samples of insecticides and fungicides collected during the inspection of 1926.

Insecticides and fungicides, F. T. SHUTT (*Canada Expt. Farms, Div. Chem. Rpt. 1925*, pp. 51-59).—This reports analyses made of insecticides and allied materials.

The relation of seasonal factors to quality in sweet corn, C. A. MAGOON and C. W. CULPEPPER (*Jour. Agr. Research [U. S.]*, 33 (1926), No. 11, pp. 1043-1072, figs. 12).—Studies upon Golden Bantam and Stowell Evergreen corn harvested from plantings made at approximately 10-day intervals from April 28 to August 19 at Arlington Farm, Va., show that temperature is the most important among the various seasonal factors influencing the growing and canning of sweet corn. Rainfall had a very marked effect on plant growth but little effect on the chemical composition of cut corn or the quality of the canned product. No specific effect of sunshine was determined. Light frost had no significant effect on composition or upon the canned product, and even a heavy freeze had no immediate significant influence.

According to time of planting the number of days from sowing to the time of silking ranged from 55 to 79 for Golden Bantam and 63 to 92 for Stowell Evergreen. The shortest period occurred in early summer. Temperature also affected the time from silking to canning maturity, the range being from 20 to 40 days. Toughness of the kernel as measured by resistance to puncture increased continuously during the period of development and was found an important index to quality, which progressively declined as toughness increased. The proportion of cut corn to the ear increased more rapidly in midsummer than in autumn. The percentage of moisture in the kernels decreased continuously during development and was especially rapid in midsummer.

Total sugars were constantly changing during the development and maturation of the kernel, increasing for a time and then declining as maturity approached. Sucrose showed a similar increase and decline. Reducing sugar was high in the early stages and decreased steadily as maturity came on. Polysaccharides at the stage when corn was in prime condition for canning consisted of approximately equal parts of water soluble and water insoluble portions, presumably dextrans and starches. All chemical changes were directly influenced in their rapidity by temperature.

Planting and thinning distances for deciduous fruit trees, F. W. ALLEN (*California Sta. Bul. 414 (1926)*, pp. 29, figs. 11).—A general discussion of planting plans and tree spacing, based upon studies in an experimental orchard at Davis and upon extended observations in various commercial orchards.

The author points out some of the outstanding evils of close planting and suggests proper distances for the principal fruits and nut species. Close planting was found especially precarious in nonirrigated orchards, where the water supply in the soil is a limiting factor.

Germination and storage of apple seeds, A. L. BAKKE, H. W. RICHEY, and K. REEVES (*Iowa Sta. Research Bul. 97 (1926)*, pp. 241-255, figs. 2).—Records taken upon freshly removed apple seeds having an initial moisture content of 84.79 per cent and stored in ordinary room temperature showed a drop to 56.44, 41.53, 25.42, 9.88, and 7.6 per cent on the fourth, fifth, seventh, eleventh, and twenty-first days, respectively. Germination tests in the greenhouse in late February with apple seeds which had been stored in different situations, (1) common fruit storage, 5 to 10° C. (41 to 50° F.), (2) fruit refrigeration, 1 to 3°, (3) below freezing, 0 to -2°, (4) at room temperature, and (5) outdoors at from 10 to -25°, showed no significant benefit in any of the lots from soaking in distilled water for 20 hours previous to planting. Seeds of treatments 4 and 5 failed to germinate at all.

A part of each of the five lots was kept moist and a part dry. Germination records on the various sublots were distinctly in favor of the moist seeds. In the moist portion of lot 2 a maximum germination of 91 per cent was reached. In respect to time of planting the data showed little difference in favor of any one date between November 3 and February 24. The highest germination again occurred in the moist section of lot 2. In general, seeds planted after January 1 did not take as long to germinate as those sown earlier. Apple seed which had been air dried and held for one year failed to germinate. Injury to the seed coat mechanically or with acids failed to influence germination.

Fertilization of apple orchards, II, M. J. DORSEY and H. E. KNOWLTON (*West Virginia Sta. Bul. 203 (1926)*, pp. 53, figs. 10).—This contribution is for the greater part a progress report upon long continued studies (E. S. R., 44, p. 638). One project, however, cultural studies at the station, is reported upon for the first time.

In the St. Marys experiment, started in 1911 in a run-down Rome Beauty orchard 20 years of age, nitrate applications consistently and significantly increased the bloom and the set of fruit, the growth of the tree, and the size of the crop. During the years 1918-1924, the greatest average annual growth was made on the complete fertilizer plot, and the maximum yield was obtained upon the nitrogen and phosphoric acid area. On account of soil erosion danger this orchard was maintained in sod after 1918.

In the Sleepy Creek experiment, started in 1913 with 9-year-old trees, nitrogen applications apparently benefited the trees, but when the results were analyzed statistically no consistent or significant differences in either growth or yield were shown between the several treatments; in fact there was as much variability within a single treatment as between treatments. This orchard was maintained in the cultivation and cover crop system of management.

The Rome experiment, started with 1-year-old trees in 1911 and maintained continuously in the tillage cover crop system, also failed to show any significant differences in growth or yield in favor of any treatment. The soil in this case was much more fertile than in the other orchards.

The cultural experiment at the station afforded comparison of different systems of orchard soil management. Among various treatments tested, sod without fertilizers resulted in the least growth, and either cultivation with stable manure and non-legume cover crop or cultivation with nitrate of soda and acid phosphate and a non-legume cover crop resulted in the greatest growth.

In general conclusion the authors suggest that growth and fruitfulness can be maintained in the average apple orchard of West Virginia by cultivation or by sod, if supplemented with early spring applications of nitrate of soda or ammonium sulfate, or stable manure if procurable in sufficient quantities.

Sod-nitrate v. cultivation in the apple orchard, J. K. SHAW (*Amer. Soc. Hort. Sci. Proc.*, 21 (1924), pp. 328-337, fig. 1).—In 1921 sod-nitrate and cultivation plats were established by the Massachusetts Experiment Station in an orchard which during the 10 years of its existence had been fertilized occasionally and managed on the tillage cover crop basis. Records taken from 1921 to 1924 showed a steady gain in yield in favor of the sod-nitrate plats. Variations in the yield of cultivated plats were traced to the turning under of an old sod on part of two of the plats. An estimate in 1923 of the size of the crowns of the trees in the several plats showed the nitrated trees to have developed considerably larger tops than the cultivated trees.

Measurements of trunk growth taken for several years before and during the present investigation showed considerable divergence in favor of the nitrated trees following the application of fertilizer. The Baldwin responded more vigorously to fertilizers than did McIntosh, Oldenburg, or Wealthy. Estimates of bloom were in favor of the nitrated trees. Counts made within 10 days after petal fall showed considerably higher set in the nitrated trees, especially in Baldwin and Wealthy. Grading of Oldenburg apples in 1924 showed a considerably larger proportion of large sizes in the fruit harvested from the nitrated trees.

The distribution of carbohydrate foods in the apricot tree, J. P. BENNETT (*Amer. Soc. Hort. Sci. Proc.*, 21 (1924), pp. 372-384).—Analyses, reported on the basis of the percentage of fresh weight, of the various parts of heavily and lightly pruned Royal apricot trees dug at monthly intervals following planting showed no significant seasonal changes in sugars, but large depletion in starch occurred during the growing season. Since hemicellulose content did not show seasonal fluctuations comparable with those of starch, the author feels that this material does not function as a reserve carbohydrate. No consistent differences were noted between lightly and heavily pruned trees in respect to the amount or the distribution of reserve food. During the season of accumulation (autumn), the heaviest deposition of starch was found in the roots, the percentage in the main and lateral roots being from two to three times that in the trunk and branches. In only 5 of 19 cases did the root system exceed 50 per cent of the total weight of the trees. The minimum was 35.2 and the maximum 62.3 per cent. At the end of the first growing season only from 9 to 17 per cent of the trees' reserves were contained in the branches, and at the close of the second season the new growth held but from 7 to 19 per cent of the reserve food. Hence pruning, when restricted to the new growth, would remove but a small percentage of the total reserves in the tree. Spurs were found to have the same percentage composition as the adjoining branches, and thus to comprise a very small fraction of the total reserve supply.

Notes on the dropping of immature sour cherry fruits, D. BRADBURY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 105-110).—Studies at the Wisconsin Experiment Station with Early Richmond and Montmorency cherries showed that, while both varieties are self and interfruitful, self-pollination gives a lower percentage set than cross-pollination. In general, nondeveloping fruits dropped in three distinct waves, the last of which is termed the June drop. An examination of fruits of the first drop showed in one instance as high as 99 per cent of pollination, with 98 per cent of fruits in which the pollen tubes had reached the ovarian cavity. In over four-fifths of the aborting fruits both ovules were shriveled, a condition obtaining apparently before the tubes had

entered the cavity in view of the random growth of the tubes in the ovaries of such fruits. There was no evidence that the rate of pollen tube growth was slower in aborting than in normal fruits.

A study of abscising fruits of the second drop showed embryos in 41 per cent and no evidence of apogamy. A total of 95 per cent of the fruits contained embryos or had pollen tubes in the ovarian cavities. The embryo sac contents of a large number of the aborting second drop fruits were completely disorganized. Of 250 third-drop cherries examined, all but two contained embryos or endosperm tissue.

Since dropping was apparently not associated with lack of pollination or failure of the pollen tubes to reach the ovaries, the author concludes that unfavorable nutritional conditions are the important controlling factor in the dropping of cherries. This assumption was supported by the fact that in years of light bloom the percentage of abscising fruits was considerably less.

The functions of paper mulch in pineapple culture, W. J. HARTUNG (*Honolulu: Hawaiian Pineapple Co., 1926, pp. 31, pls. 2, figs. 10*).—Nitrogen determinations made upon soil samples taken at the beginning and at frequent intervals throughout the 714 days of a study of the effect of paper mulch upon the pineapple show that applications of fertilizer containing 316 lbs. of nitrogen (65.2 per cent inorganic and 34.8 organic) per acre increased the total nitrogen of the soil from 0.2875 to 0.343 per cent. Ammoniacal nitrogen in the upper soil of the fertilized plat disappeared after 91 days, but in a fertilized and paper-mulched plat this form of nitrogen was present in conspicuous amounts one year after fertilization. Even 500 days after application of the fertilizer some of the introduced nitrogen was in ammoniacal form. Nitrate nitrogen increased rapidly in both fertilized plats with the advent of the heavy spring rains, which apparently greatly stimulated nitrification. In the mulched and fertilized plat, nitrate nitrogen reached a higher maximum and was retained much longer than in the fertilized plat, indicating that paper mulch not only stimulated the activity of nitrifying bacteria but also prevented rapid leaching of the resulting nitrates.

Observations upon pineapple slips planted in sealed pots containing soil of measured moisture content indicated that 22.5 per cent is the critical point, below which water becomes unavailable for the pineapple. Data obtained in the field showed that paper mulch raised the average soil moisture from 4 to 6 per cent during the experimental period. In the same period, temperature readings in the upper 3 in. of soil showed that paper mulch raised the mean temperature 3.5° F. during the 714 days. Computation toward the close of the experiment of the air-dry weight of roots showed those of the mulched and fertilized plats to be much heavier. On a basis of 100 for the control, those of the paper mulch, fertilizer and paper mulch, and fertilizer areas were 150, 179, and 176, respectively. Fertilized plants had from 40 to 50 per cent of their roots in the upper 4 in. of soil, as compared with from 25 to 35 per cent for the unfertilized. All plats had 90 per cent or more of the roots in the upper foot of soil. Determinations of dry and green weight in the above-ground portion of plants made at the end of 6, 12, and 18 months from planting showed the fertilizers to have had a marked stimulating effect. Paper-mulched plants made a greater proportion of their growth during the first year than the nonmulched plants.

In respect to total and average weight of fruit, the fertilized plants were markedly in the lead. The paper-mulched plants were almost twice as productive as the controls, but the difference was largely in the number of fruits produced. Estimated yields per acre for the several plats were 15.13, 18.93, 21.68, and 12.23 tons for paper, fertilizer, paper plus fertilizer, and con-

trol. No significant differences were found in the percentage of nematode infestation. Inconclusive results were obtained in comparing perforated and nonperforated paper. Paper mulch practically eliminated weeds and hence saved a great deal of labor.

Palms of Florida, H. MOWRY (*Florida Sta. Bul.* 184 (1926), pp. 54, figs. 57).—This paper, devoted principally to descriptions of the various species of palms, native and introduced, which are growing in Florida, also contains information upon the propagation, general culture, and temperature requirements of the family.

FORESTRY

Manual of forestry for the northeastern United States, R. C. HAWLEY and A. F. HAWES (*New York: John Wiley & Sons; London: Chapman & Hall, 1925, 2. ed., pp. XII+281, figs. 64*).—A second and corrected edition of this work (*E. S. R.*, 39, p. 50), which is volume 1 of Forestry in New England.

National forest resources of Utah (*U. S. Dept. Agr., Misc. Circ.* 71 (1926), pp. 27, figs. 16).—A general discussion upon the location, principal features, and resources of the national forests of Utah, with comments on administrative policies regarding the development of timber, grazing, water, and recreational uses.

Foundations of silviculture upon an ecological basis, J. W. TOUMEX (*Ann Arbor, Mich.: Edwards Bros., 1924, pt. 1, pp. 1-171; 1925, pt. 2, pp. 172-314; 1926, pt. 3, pp. 315-476, figs.-4*).—This contribution, prepared in mimeographed form, is presented in three parts, as follows: (1) The site factors, (2) the forest, and (3) methods of investigating the site factors and the forest vegetation and relating one to the other.

Mixed v. pure forest plantations, R. R. PATON (*Ohio Sta. Bimo. Bul.*, 12 (1927), No. 1, pp. 18-20).—A brief popular article pointing out the desirability of mixing forest species. Mixed plantings are considered less exacting on the soil in that the food demands are varied and the roots penetrate to different levels.

Effect of spacing and root pruning on the development of transplants, K. L. JANOUGH (*Jour. Forestry*, 25 (1927), No. 1, pp. 62-67).—Experiments in the Bessey Nursery, Nebraska, showed that a 6 by 1.5-in. spacing is very satisfactory in the transplant bed for both jack and yellow pine. Root pruning did not prove of any significant value in either species. Jack pine does not have a pronounced taproot, and severing the taproot of yellow pine caused a rather severe setback, lasting even to the first year in the field.

Season for sowing red and white pine seed, H. D. PETHERAM (*Jour. Forestry*, 25 (1927), No. 1, pp. 57-61).—Studies at the Cass Lake Nursery in Minnesota showed that although midsummer sowing gave the highest germination in both red and white pine, the resulting plants did not survive as well as those raised from late fall sowings. Very early spring sowings gave quite favorable results but not equal to late fall, the seedlings from which were larger and of better quality.

Loblolly pine primer, W. R. MATTOON (*U. S. Dept. Agr., Farmers' Bul.* 1517 (1926), pp. [2]+38, figs. 27).—In simple, nontechnical terms, aided by abundant illustrations, the author discusses the geographical distribution, economic importance, habits and rate of growth, establishment of seed beds and plantations, and the marketing of the timber of loblolly pine, a species of very important commercial value in the southeastern States.

On the seedling structure of *Tilia vulgaris* Heyne, H. S. HOLDEN and S. H. CLARKE (*Jour. Linn. Soc. [London], Bot.*, 47 (1926), No. 315, pp. 329-337, figs. 20).—Technical descriptions are offered of *T. vulgaris* seedlings, which as a rule

occur rarely in England but in 1924 were found in fair numbers, indicating that the preceding year had been a favorable one for ripening seed.

The Hevea rubber tree in the Amazon Valley, C. D. LA RUE (*U. S. Dept. Agr. Bul. 1422 (1926), pp. 70, figs. 14*).—A report based upon extended personal surveys of the rubber producing situation, present and prospective, in important producing regions of Brazil and Bolivia. At the present time all of the rubber produced in this area is obtained from jungle trees, but large tracts of land were noted which were apparently well suited for plantations. The wild trees contained a great reserve of rubber which could be harvested in case of necessity or were the prices sufficiently high to warrant. Methods of tapping, collecting, and preparing rubber now in vogue in this region are very incompletely known, but the plantation trees of the East Indies are believed to be identical with the white rubber trees found along the lower Amazon. In concluding, the author discusses the occurrence of diseases and gives a brief account of Castilla and Sapium, two other genera yielding rubber.

Gum arabic, with special reference to its production in the Sudan, H. S. BLUNT (*London: Humphrey Milford, 1926, pp. 47, pls. 22, figs. 4*).—A popular account, taking into consideration the distribution and botany of the tree, methods of gathering and marketing, chemical properties, and uses, with notes on the forest policy adopted by the Sudan Government for enlarging and protecting plantations and forests.

The water-retaining capacity of certain woods in relation to their microscopic structure, J. W. BEWS and R. D. AITKEN (*So. Africa [Dept. Agr.] Bot. Survey Mem. 8 (1925), pp. 34-41*).—Small blocks of the freshly cut older wood of 12 native Natal forest species and of 19 Australian eucalypts were dried in a steam oven to determine their water-containing capacity. In general the lighter, softer woods with a high initial water content lost water more rapidly and dried out more completely in a shorter time than did heavy, dense hardwoods having a lower original water content. Eucalypts lost water at a more uniform rate than did the native Natal species. Although the initial rate of water loss was slower in the Eucalyptus, the average total time required to dry out was approximately the same for woods of this genus as for the native species.

DISEASES OF PLANTS

Plant diseases (South Carolina Sta. Rpt. 1926, pp. 41, 42).—It is claimed that in 1926 corn smut was much more severe than usual, infection on the station plats amounting to from 6 to 36 per cent. The early varieties seemed to show less infection, but there did not appear to be any strong indication of resistance in any case. Ear rots are said to have been more abundant than usual, due possibly to a severe infestation of the corn earworm.

The stem blight of beans previously reported (*E. S. R., 54, p. 648*) is said to have been found in a number of places in the State, and also to have been reported from Georgia and Mississippi.

Angular leaf spot of cotton was more prevalent than usual and is said to have caused considerable damage where no control measures were used. Cotton wilt was also prevalent, and this resulted in a demand for seed of wilt-resistant varieties.

A rot of gladiolus caused by *Bacterium marginatum* was reported for the first time in the State, and it is said to have assumed serious proportions in two widely separated localities.

Plant pathology (*Utah Sta. Bul.* 198 (1926), pp. 56-62).—Investigations by B. L. Richards are reported on potato, canning crops, and miscellaneous diseases. Among the potato diseases particular attention was given to the virus diseases, mosaic, leaf roll, and spindling tuber having been studied. By the use of insect cages, greenhouse, and field plats the symptoms of mosaic and leaf roll were fairly well determined for each of the commercial potato varieties important in the State. Control methods, including tuber indexing, are said to have resulted in the complete elimination of rugose mosaic and leaf roll and to very definite reduction in spindling tuber.

In the canning crop studies, the work was confined to *Fusarium* wilt, mosaic, and western yellow blight of tomato. Selections for disease-resistant strains have resulted in obtaining four strains of the Stone variety which have a high degree of resistance to wilt. The study on mosaic was confined largely to cross-inoculation experiments, in which it was found that mosaic could be transferred from the potato to tomato and to the black nightshade, from *Physalis* sp. to tomato, and from tomato to *Physalis*, black nightshade, and yellow nightshade. Four types of mosaic of varying degrees of severity were obtained on the experiment farm in Davis County. Three of these continued true in type and have been carried through three generations. The western yellow blight, which practically ruined the tomato crop in 1905 and in 1924, appeared again in 1926 in a very severe form.

Notes are given on a number of diseases, all the data being obtained in the plant disease survey. The white spot of alfalfa is said to have occurred in a number of fields, in some cases seriously reducing the tonnage and quality of hay. The alfalfa stem nematode (*Tylenchus dipsaci*) was found present in practically half the fields surveyed in Salt Lake County. Crown wart (*Urophlyctis alfalfae*) was found in 16 per cent of the fields surveyed. There were also heavy infestations of leaf spot caused by *Pseudopeziza medicaginis*, and some evidence was obtained indicating heavy infestation of the bacterial stem blight (*Pseudomonas medicaginis*).

Two diseases observed in Utah for the first time were peach leaf curl caused by *Epoasculus deformans* and the yellow leaf blotch of alfalfa.

Division of plant pathology (*Washington Col. Sta. Bul.* 208 (1926), pp. 31-35).—In continuation of previous investigations on wheat smut (E. S. R., 54, p. 841) a report is given of tests by F. D. Heald of 58 different methods of seed treatment in which negative results were obtained, no smut appearing even when the seed was heavily inoculated with smut spores.

Studies were made by Heald of winter injury of fruit trees in connection with the prevalence of perennial canker (*Gloeosporium perennans*) and the wood-destroying fungus *Schizophyllum alneum*. Winter injury is considered the principal cause of the severe outbreak of canker, and the wood-destroying fungus invaded the injured wood and completed its destruction. The apple variety Spitzenberg is said to have shown most winter injury, and it was also the most susceptible to canker.

The same investigator made a study of the fungus flora of normal apples and also of the fungi responsible for storage rots. Normal sound apples taken from storage at various times during the season were found to carry from a few thousand to as many as 100,000 fungus spores. While many of the species were harmless forms, others of proved pathogenicity were invariably present. Isolations of fungi from rotten fruit were made, and in addition to isolations which had not been identified, the following genera were represented: *Alternaria*, *Acrostalagmus*, *Botrytis*, *Fusarium*, *Gloeosporium*, *Phomopsis*, *Penicillium*, *Rhizopus*, and *Stemphylium*.

In cooperation with the divisions of chemistry and horticulture, a study was made of the different types of fruit wipers to determine the efficiency of wiping fruit for the removal of arsenical residues. None of the dry wiping machines proved effective in reducing the arsenic load of heavily sprayed fruit to the tolerated amount of 0.01 grain per pound of fruit. Analyses seem to indicate that the wiping rubs most of the arsenical residue into the wax, rendering it inconspicuous. Promising results are said to have been obtained with other methods of handling the fruit.

The effect of shade on western yellow blight of tomatoes was investigated by B. F. Dana, and it was found that shaded plants contracted the disease as readily as plants not shaded.

Infection studies of mosaic and related diseases of potatoes are said to have shown positive results in the transmission of witches'-broom when potatoes were grown in the field from inoculated progeny grown under glass. Inconclusive results were obtained in attempts to transmit the disease by the green aphid, and negative results followed core-graft inoculation. Core grafts also failed to transmit chlorosis. During five seasons' work with the same stock all progeny have become infected with chlorosis. Giant hill was transmitted to Notted Gem stock by means of core grafts, and progeny of giant hill plants have shown 100 per cent infection during the two seasons that they have been under test. One season's field work with core grafts for the transmission of rugose mosaic gave negative results. Dana claims that the season's work demonstrated the possibility of maintaining a strain of stock in regions where virus disease symptoms are masked.

Notes are given of a number of diseases newly reported or imperfectly known in the State.

Forage crop diseases, G. R. BISBY (*West. Canad. Soc. Agron. Proc.*, 5 (1924), pp. 60-64).—The diseases here briefly discussed, primarily those occurring in Manitoba, include those affecting alfalfa, clovers, and other legumes, cereals, and a few other crop plants.

Plant diseases and pests in Denmark, 1924 [trans. title], E. GRAM and S. ROSTRUP (*Tidsskr. Planteavl*, 31 (1925), No. 3, pp. 353-417, figs. 2; *Eng. abs.*, pp. 414-417).—This report, which covers the year ended September 30, 1924, includes an account of some insect injuries, as well as a number of diseases of plants. The latter include barley stripe (*Pleospora graminea*), wheat naked smut (*Ustilago tritici*), and oat nematodes (*Heterodera schachtii avenae*); beet mosaic; swede and cauliflower bacteriosis (*Bacterium maculicolum*); potato wart (*Synchytrium endobioticum*) and late blight (*Phytophthora infestans*); clover (?) *Ascochyta trifolii* and clover nematode disease (*Tylenchus devastatrix*); grass snow mold (*Fusarium* spp.); apple and pear rot (*F. willkommii*); gooseberry mildew (*Sphaerotheca mors-uvae*), also a disease associated with *Gloeosporium ribis* and *G. curvatum*; and hyacinth diseases (*Phytomonas hyacinthi* and *Cephalosporium asteris*).

Annual report of the mycologist for 1924, A. SHARPLES (*Malayan Agr. Jour.*, 13 (1925), No. 7, pp. 214-219).—This report deals chiefly with major investigations on diseases of rubber and of oil palm and coconut palm, mention being made also of minor investigations on a few other plants.

Tumor formation in Bryophyllum, E. F. SMITH (*Jour. Heredity*, 16 (1925), No. 8, p. 272, fig. 1).—A photograph is submitted to show that one successful inoculation on *B. calycinum* with the hop strain of *Bacterium tumefaciens* does not protect from a second inoculation with the same strain. Both tumors were still free from necrosis, the older being nearly two years old and the younger over five months.

Parasitism of *Cuscuta reflexa* (Roxb.), J. THOMSON (*Nature* [London], 116 (1925), No. 2906, p. 66).—The hyphae of this dodder are differentiated into strands of tracheids when they meet the xylem vessels of the host. Those entering the host phloem are not modified; moreover, the shaft of the haustorium contains no sieve tubes. Irritation set up by the haustorium stimulates all the living cells in its neighborhood to active cell-division. In woody host stems the radius of the stem of the host on the side invaded by the parasite is increased. Connection with the host xylem is maintained by the differentiation into tracheids of young parenchyma cells at the tip of the haustorium. The dodder grown on peeled stems can live on material derived from the host's wood even when its chlorophyll is prevented from functioning by inclosure in a light-tight box. Haustoria then formed are perfectly normal although smaller.

Fusarium as a cause of plantlet diseases [trans. title], O. APPEL (*Angew. Bot.*, 6 (1924), No. 2, pp. 48-50).—Results of research credited to the elder Appel are briefly noted as having to do with stem diseases (principally near ground level), and their causal organisms, among which the so-called snow mold, *F. nivale*, is important.

The relations of *Fusarium* to other fruiting forms [trans. title], J. FUCHS (*Ztschr. Pflanzenkrankh.*, 34 (1924), No. 5-6, pp. 193-220, figs. 7).—Of the two *Fusarium*s here reported as studied, *Fusarium* α is said to be connected with *Volutella*, *Fusarium* β with *Verticillium*. The forms *Acrostalagmus*, *Spicaria*, and *Verticillium* are not separable as definite genera. *Fusarium*, as a genus, is regarded as not more definite.

Some protein analogies of the mycelium of *Fusarium lycopersici*, I. T. SCOTT (*Missouri Sta. Research Bul.* 92 (1926), pp. 44, figs. 9).—The author claims that "when the living mycelial mats of the fungus, *F. lycopersici*, are added to dilute buffered and unbuffered single-salt solutions at different reactions and the change in hydrogen-ion concentration is followed by means of electrometric or colorimetric methods the reaction is changed in every case to a final equilibrium point at or near a Sorensen value of 5.4. Dead mycelium does not give as consistent results as the living, but suggests that it possesses an equilibrium point different from that for the living mycelium. Spore germination studies indicate that the toxicity of certain deleterious ions like the cations, mercuric, cupric, and basic dye—methylene blue—is greater in solutions more alkaline than pH 5.4; while the anions, cyanide and acid dye-eosin—show greatest toxicity in solutions more acid than pH 5.4. The simplest explanation of the observed phenomena that might be offered is that the living tissue of *F. lycopersici* behaves in a manner analogous to an amphoteric protein colloid, like gelatin, with an isoelectric point in the neighborhood of pH 5.4."

Culture studies with rust fungi [trans. title], H. KLEBAHN (*Ztschr. Pflanzenkrankh.*, 34 (1924), No. 7-8, pp. 289-303).—Since the publication of reports previously noted (E. S. R., 45, p. 144), the author has continued his experimentation, and in the present article he contributes on the susceptibility of pines to *Peridermium pini*, *Cronartium asclepiadeum* on pine, teleutospore hosts and overwintering of *C. ribicola*, specialization of *Coleosporium tussilaginis*, habituation of gooseberry rust (*Aecidium grossulariae*) to *Ribes nigrum*, study of mallow rust (*Puccinia malvacearum*), certain wheat and grass rusts, *P. menthae*, and cultures of rust fungi on artificial media.

Holcus bacterial spot of *Zea mays* and *Holcus* species, J. B. KENDRICK (*Iowa Sta. Research Bul.* 100 (1926), pp. 301-334, figs. 5).—A description is given of a leaf-spot disease of sorghum, broomcorn, Sudan grass, Johnson grass, corn, pearl millet, and foxtail, caused by *Pseudomonas holci* n. sp., or *Bacterium holci* n. sp. The disease on the *Holcus* species is said to be character-

ized by light centered, red bordered, round, elliptical lesions on the leaves. The very small lesions are red throughout. It is said that often the spots are so numerous as to cause the death of the entire leaf. Field observations and greenhouse inoculations showed as hosts for the disease 22 varieties of sorghum and broomcorn, Sudan grass, Johnson grass, and pearl millet; 20 varieties of corn; and foxtail. The causal organism is said to be a white fluorescent, cylindrical, polar flagellate bacterium, a technical description of which is given. The organism is said to be carried over winter in or on sorghum seed, and some evidence was obtained which indicates that it may also overwinter in the soil. No evidence was found of the organism being carried over on the seed of corn, and the initial infection on this host is believed to come from the soil or from other hosts growing in close proximity.

As a control measure, the author recommends the selection of *Holcus* seeds from fields free from the disease, the destruction of volunteer plants growing in or near corn fields, and crop rotations.

Terminology of the Uredinales, J. C. ARTHUR (*Bot. Gaz.*, 80 (1925), No. 2, pp. 219-223).—"If the emphasis in thinking of the rusts is placed upon the mycelial body and the fruit forms or sori which it bears in unvarying order, instead of upon the spore forms and their accessories, there should be no difficulty in apprehending the simplicity of the new terms and their suitability for every possible situation, whatever bewildering likeness the spores and their accessories may suggest."

[**Studies on the fungicidal activity of sulfur**], E. VOET (*Angew. Bot.*, 6 (1924), No. 2, pp. 276-300, figs. 2).—Under conditions of light, air access, and humidity, elemental finely divided sulfur is not oxidized to SO_2 , nor is it reduced to H_2S . Vaporization of sulfur is very slight, even under conditions of very fine division and highest natural temperatures. The precise action of sulfur as a fungicide was not discovered in this experimentation.

Chemotherapeutic tests of Kalimat and Fungolit [trans. title], I. ESPORN (*Angew. Bot.*, 6 (1924), No. 2, pp. 105-112).—These experiments as tabulated and briefly discussed deal with the spreading, curative, and toxic effects.

Inheritance studies in cereals (*Washington Col. Sta. Bul.* 208 (1926), p. 26).—Tests are reported of inheritance studies by E. F. GAINES on the resistance of 238 varieties of wheat to bunt and 43 varieties of oats to covered smut, in which a large number of wheat varieties maintained their immunity and several oat varieties appeared immune. In the third generation cross between the oat varieties Markton and Banner 214 families were tested, and 144 of them produced no smut, the others showing from a trace up to 31 per cent infection.

Recent studies on the life history and control of oat loose smut [trans. title], ZADE (*Angew. Bot.*, 6 (1924), No. 2, pp. 113-125).—Noting certain inconsistencies among control experiments with loose smut (*Ustilago avenae*) of oats under laboratory and under field conditions, the author details with discussion observations on the behavior of this fungus toward other species of *Avena*.

Stinking smut control in Uruguay [trans. title], G. J. FISCHER (*Angew. Bot.*, 6 (1924), No. 2, pp. 125-140, fig. 1).—Formalin and copper sulfate were found to retard germination of oats, copper-lime less, and Uspulun not at all. Formalin kills about 25 per cent of the viable seeds, copper sulfate less, copper-lime still less, and Uspulun none. Other effects are detailed.

Smut-control test (*Utah Sta. Bul.* 198 (1926), p. 22).—In a comparison by A. F. BRACKEN it is claimed that for the control of smut formalin and copper sulfate were both slightly more efficient than copper carbonate. In the yield test, in which no treatment, copper carbonate, copper sulfate, and formalin

were compared, no significant differences were shown, since the wheat emerged soon after drilling.

[Acidity and rust resistance], O. ARRHENIUS (*Ztschr. Pflanzenkrank.*, 34 (1924), No. 3-4, pp. 97-101).—A study is reported regarding a possible relation between resistance to wheat yellow rust and the actual and potential acidity of cell sap and tissue, designating various summer and winter wheats as having been tested. No such relation was established.

The inheritance of resistance to black stem rust in crosses between varieties of durum wheat, J. B. HARRINGTON (*West. Canad. Soc. Agron. Proc.*, 5 (1924), pp. 20-35, figs. 5).—In this investigation, regarding which an account as to the greenhouse technique, the differential varieties, and the rust strains has been given in a paper previously noted (*E. S. R.*, 49, p. 840), a study was made of the parasitic capabilities of four biologic strains of *Puccinia graminis tritici* on F_3 , F_4 , and F_5 progeny from crosses between the three varieties of *Triticum durum*, Kubanka No. 8, Mindum, and Pentad, involving the inoculation of 23,620 hybrid seedlings and 3,680 seedlings of parental varieties. The varietal details are indicated.

Reaction to rust was inherited in the same manner as were other characters. Several factors appeared to have been involved, environmental influences modifying the expression of rust reaction. Fairly satisfactory agreement was found between the rust results in the greenhouse one year and those of the next year. It is considered necessary to use larger numbers of seedlings to determine accurately the genetic class of any particular family. No relation was found to exist between rust reaction and seed color. The nursery results indicated the presence of more than one genetic factor difference for each of the characters nursery rust reaction, erectness of plant, and earliness of heading. There seemed to be a slight linkage between the inherited factors governing resistance to rust under field conditions, plant height, erectness of plant, and time of heading. The hybrids that resembled Pentad in rust reaction also tended to show resemblance in other characters.

Sulphur dust for rust control, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, p. 33*).—A report is given of trials made to determine the value of sulfur for controlling black stem rust of wheat. The wheat was dusted with precipitated sulfur at 4-day intervals. Based on these and other trials, it is concluded that under certain conditions one dusting with precipitated sulfur will control stem rust, even in the presence of a severe epidemic. Several dustings at 4- or 5-day intervals, applied at the right time, are considered necessary to insure rust control. The dust seemed to have very little residual effect, and the best results were obtained when the first dusting was applied about flowering time and continued until the wheat had reached the hard dough stage.

Montana's barberry campaign, H. E. MORRIS and W. L. POPHAM (*Montana Sta. Bul. 196 (1926), pp. 24, pl. 1, figs. 7*).—After giving an account of the black stem rust of wheat and the relation between the barberry and wheat stem rust, a summary is given of the work done in the barberry eradication campaign in the State. The most satisfactory method of eradication is said to be the use of crushed rock salt or kerosene applied about the bushes.

The influence of high temperatures during and after seed grain treatments [trans. title], W. NAGEL (*Angew. Bot.*, 7 (1925), No. 5, pp. 304-319, fig. 1).—A detailed, tabular, and graphical account is given of trials with several much-used fungicides against *Tilletia tritici* on seed wheat at different elevated temperatures, and the apparently different influences of such temperatures.

Stamping out the koleroga of areca, M. J. NARASIMHAN (*Mysore Agr. Calendar, 1926, pp. 25, 28*).—Preventive measures against koleroga (*Phytoph-*

thora sp.) of areca nut as carried on for some years gave encouragement resulting in attempts to eradicate the disease. Lack of complete cooperation and the presence of field hosts (*Bryophyllum calycinum*) discouraged the hope of complete eradication, leaving, as the only practical alternative, spraying work as a regular routine operation.

[A bean fusariosis], M. BENLLOCH and J. DEL CAÑIZO (*Bol. Estac. Patol. Veg. [Inst. Agr. Alfonso XII, Madrid]*, 1 (1926), No. 1, pp. 2-7, figs. 5).—A disease affecting bean plants (*Phaseolus vulgaris*), which show on transverse section of base or root a clogging of the vessels, is said to be associated with the abundant occurrence of a fungus. The characters of this are described as relating it to the species *Fusarium martii*, possibly the variety *F. martii pisi* described as a new variety by Jones (*E. S. R.*, 50, p. 839).

The relation of black rot to the storage of carrots, J. I. LAURITZEN (*Jour. Agr. Research [U. S.]*, 33 (1926), No. 11, pp. 1025-1041, figs. 4).—A report is given of a study of a black rot of carrots caused by *Alternaria radicina*, especial attention having been given to the temperature relations of the fungus. The optimum temperature for infection and decay of carrots by *A. radicina* is said to be about 28° C., with an infection range of from -0.6 to 34°. For the control of black-rot disease, it is recommended that carrots be stored at temperatures of from 0 to 2°, thus reducing the amount of infection and decay to a minimum. Little varietal difference was observed in resistance to the fungus when inoculated into carrot roots, but there was some difference in susceptibility when the roots were dipped into suspensions of the spores.

Efforts to determine the means by which the cotton-wilt fungus, *Fusarium vasinfectum*, induces wilting, H. R. ROSEN (*Jour. Agr. Research [U. S.]*, 33 (1926), No. 12, pp. 1143-1162, figs. 3).—The claim that wilting of cotton, cowpeas, and watermelons was due to the plugging of the vascular system by the fungus (*E. S. R.*, 11, p. 944) having been questioned in the case of diseases of other plants caused by species of *Fusarium*, the author made a study of *F. vasinfectum* in relation to the wilting of cotton plants.

A report is given of a large number of experiments, in which pure cultures of different strains of the cotton-wilt fungus were grown on various liquid media, the fungus removed, and toxicity studies undertaken with the filtrates by placing cotton plants in them. When whole plants with root systems carefully handled were placed in filtrates of *F. vasinfectum*, wilting ensued as with plants that were freed from roots. Microscopic observations of the vascular elements of wilted cotton plants are said to have clearly indicated that wilting was not due to mechanical plugging of the vessels by the fungus. The author concludes that filtrates of *F. vasinfectum* growing on Richards' solution possess at least two substances poisonous to the cotton plant. One is said to be a volatile compound with an alkaline reaction and the other an inorganic salt in the form of nitrite. The wilting of cotton infected with *F. vasinfectum* is considered to be due to poisonous chemical substances formed by the fungus.

[Occurrence of corn ear rots in given areas and the effect which ear rots may have upon the constituents of affected ears], A. N. HUME (*South Dakota Sta. Rpt. 1925*, pp. 13, 14).—Numerous ears of seed corn selected on the basis of appearance of disease on the kernels and ears were studied, and as a result of the original inspection of these ears the presence of several apparently distinct diseases was discovered. Several correlations were established, one of which reveals the positive correlation between percentage of germination and yield in nursery rows of several seed ears, and another between the final stand of corn in the field with relation to yield per acre.

As a part of this investigation, P. Danielson made a detailed study of normal and abnormal corn plants, in which all nodes and internodes were analyzed

separately for total ash, nitrogen, phosphorus, potassium, calcium, iron, aluminum, and silica. Normal plants were found to have different selective powers for the various ash constituents, and no two plants seemed to have any correlation in the distribution of the elements absorbed. Normal plants were found to contain a higher average percentage of phosphorus, calcium, and silica than abnormal ones. Abnormal plants showed a marked difference in their selective powers and contained a much higher average percentage of ash than normal ones, being particularly higher in iron, aluminum, and potassium. When all abnormal plants were considered, no large accumulations of iron or aluminum or other elements were found in any particular portion of the plants. However, when individual abnormal plants were observed, large accumulations were found in certain nodes and internodes, which did not seem to be correlated with any particular character found in the plant. Discolored nodes and internodes in plants apparently affected with rots did not appear to be correlated with a higher percentage of iron or aluminum.

The influence of plant injury and the root rot diseases upon the physical and chemical composition of corn grain, G. H. DUNGAN (*Illinois Sta. Bul.* 284 (1926), pp. 253-281, figs. 9).—In a previous publication Trost called attention to the greater infection by root rots of seedlings from ears of corn, the grain of which was of a starchy nature, than from those with a horny endosperm (*E. S. R.*, 47, p. 447), and Holbert et al. reported upon correlations of certain seed characters of corn and susceptibility to root rot attack (*E. S. R.*, 52, p. 245).

No explanations of the reasons for this behavior having been offered, the author made a study of the influence of some environmental characters upon the quality of grain produced. In one series of experiments stalks and shanks of ears were broken but not severed when the grain was in the milk stage, and in another series when the grain was in the soft-dough stage. In other experiments seed of the same variety of corn, which had starchy and horny endosperms, was inoculated with *Diplodia zeae*, *Fusarium moniliforme*, *Gibberella saubinetii*, and *Rhizopus* spp. and the effect noted on the grain produced.

Constricting the ear shanks and stalks of corn by breaking the supporting tissue without completely severing the vascular elements was found to have the same effect upon the yield and composition of corn grain as premature harvesting. Breaking the shanks when the ears were in the soft-dough stage caused the greatest chaffiness in the grain. Chemical analyses showed that there was no definite correlation between kernel starchiness and quantity of starch in the grain, as has been commonly supposed. The percentage of total nitrogen, hemicellulose, and nonhydrolyzable material was distinctly higher in grain from ears produced on broken shanks than in grain from ears produced on sound shanks. The mutilation of the shanks, on the other hand, resulted in a greatly reduced proportion of ether extract and starch in the grain.

Inoculation of the seed at planting time with corn-root organisms resulted in the production of grain having a specific gravity of 0.027 lower than that from the adjoining uninoculated plants. Samples of grain produced by plants that grew in inoculated hills absorbed an average of 5.78 per cent more water than samples from plants growing in uninoculated hills. Chemical analyses did not show any significant differences between the grain produced in the inoculated and uninoculated hills. There was slightly more nitrogen, on the average, in the corn from inoculated seed and a little less ether extract and total sugar.

Analyses of two lots of horny and two lots of floury corn of the Leaming variety showed that there was no significant difference in the chemical composition between these two types of corn. Upon germination, however, the horny corn was found to contain a greater proportion of soluble starch and dextrins

than the flourey corn, and starch digestion in the horny corn was somewhat more rapid than in the flourey corn. This is believed to offer an explanation for the superior vigor of seedlings from horny corn.

[**Peppermint and peppermint rust**], H. ROSS (*Ztschr. Pflanzenkrankh.*, 34 (1924), No. 3-4, pp. 101-107).—A study is reported of peppermint as subject to attack by the rust fungus, *Puccinia menthae*, concluding with the claim that proper nutrient and moisture conditions, with correspondingly correct stand, lessen attacks of peppermint by *P. menthae*.

Potato diseases and their control, M. F. BARRUS and C. CHUPP (*N. Y. Agr. Col. (Cornell) Ext. Bul.* 135 (1926), pp. 3-123, figs. 36).—The authors describe and, so far as definite means are known, offer suggestions for the control of potato diseases.

Tuber disease control, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt.* 1925, p. 52).—Hot formaldehyde and corrosive sublimate were compared for the control of potato scab and Rhizoctonia, but the yields were so interfered with by water that no data were secured. However, in rotation experiments in which tubers were treated with hot formaldehyde, it was found that a 2-year rotation was too short to control black scurf and potato scab, and the large amount of manure applied appeared to be conducive to the development of scab.

Summarizing the results of experiments on seed treatment, the author claims that the treatment of seed potatoes proved profitable every year tried. For the years 1922-1924 the average annual increase in yield from the corrosive sublimate treated tubers was 44.1 bu. per acre, and from hot formaldehyde 41.4 bu. Tuber disease control was not absolute, but the percentage of disease-free seed in 1924 from the treated seed is said to average 90 per cent as compared with 65 per cent for untreated seed.

Bordeaux spraying test [with potatoes], C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt.* 1925, p. 51).—In an experiment designed to test the relative effectiveness of early summer and late summer spraying, so much injury was done to the plats by water that the project was abandoned and only the effect of three standard sprayings of Bordeaux mixture and calcium arsenate was noted.

Bordeaux mixture was effective in controlling early blight and potato flea beetles, and excellent results were obtained from sprayed plats uninjured by water. Potato vines were kept green and growing until the end of the season. The author states that the increase in yield of potatoes from the use of three applications of Bordeaux mixture has varied during a 5-year period from 7.35 to 32 bu. per acre, with an average of 25.08 bu. As a result of 15 years' experiments, three sprayings with Bordeaux mixture proved most profitable, except in two years when potato leafhoppers were very abundant. Additional late sprayings proved profitable under these conditions.

Phytophthora tuber rot of seed potatoes [trans. title], H. ZIMMERMANN (*Angew. Bot.*, 6 (1924), No. 2, pp. 51-53).—At the Rostock Experiment Station potato seed tubers all more or less affected with *P. infestans* were planted May 4 in soil of moderate fertility supplied with fertilizers named and kept moderately moist by weather conditions. The results are tabulated as to returns and disease on the crop tubers. From severely diseased plantings the crop tubers were nearly all sound, while from slightly infected plantings the crop tubers were disease-free with better (heavier) individual classified and total tubers. It is thought that keeping the seed tubers dry was a factor in keeping down *Phytophthora*.

Potato and tomato diseases, M. W. GARDNER (*Ind. Hort. Soc. Trans.*, 1924, pp. 124-132).—A brief account is given of Indiana potato diseases, including

Fusarium wilt, early blight, blackleg, black scurf, scab, mosaic, and leaf roll; also of tomato diseases, including Fusarium wilt, Septoria leaf spot, early blight, bacterial spot, mosaic, and leaf mold. Late blight of potatoes does not occur, but Bordeaux mixture is used to prevent hopperburn. Mosaic is the worst disease of early potatoes, spreading in the field and killing the plants. Leaf roll is the worst disease of the late potato crop. Both diseases can be avoided by the use of northern-grown certified seed. Tomato Fusarium wilt has been widely distributed by the use of southern-grown plants. Septoria leaf spot is very destructive in wet seasons, though controllable by the use of Bordeaux mixture on the plant bed and in the field. Seed disinfection is controlling bacterial leaf spot. Mosaic is not seed borne but persists perennially in certain weeds, which can easily be eradicated from the plant beds. A microscopic study of tomato mosaic shows that scattered groups of cells are killed, the surrounding cells being stimulated to grow and divide, producing tumorous growths, accompanied in the fruits by surface blisters and abnormal adhesions between the fruit wall and the seed pulp, with various forms of injury. The leaf mold fungus invades the stem end of the fruit, causing a black rot. This results in a much earlier infection of the sepals, torus, or pedicels. The seeds are invaded, and they transmit the fungus.

Striga lutea on rice in Sumatra [trans. title], B. T. PALM and C. HEUSSER (*Ztschr. Pflanzenkrankh.*, 34 (1924), No. 1-2, pp. 11-18, figs. 4).—*S. lutea*, here said to be one of the most widely distributed and injurious of parasitic plants, is discussed as to its root relations with rice plants, also as to its relations with numerous other hosts named.

Control of sugar-beet nematode by crop rotation, G. THORNE (*U. S. Dept. Agr., Farmers' Bul.* 1514 (1926), pp. II+21, figs. 15).—A popular summary is given of the results of seven years' field investigations of the sugar-beet nematode in the Western States. After a brief discussion of the distribution of the nematode, its life history, common sources of infestation, and host plants, practical methods of control are outlined. Where only a few fields are infested, it is recommended that these should be planted with other crops and beets not grown again on these infested areas. In sections where the infestation is general, suitable crop rotations are recommended.

[Sweet potato diseases at the Prosser (Wash.) Substation] (*Washington Col. Sta. Bul.* 208 (1926), pp. 60, 61).—Experiments with sweet potatoes, by H. Jensen, are said to have offered an opportunity to observe the effect of adverse climatic conditions on the susceptibility of sweet potato varieties to diseases. It was found that all slow growing and small, open foliated varieties were more susceptible to *Pythium* than the rapid growing, heavy foliated varieties. In the slow growing varieties in the experiment the disease almost checked plant growth, and extreme heat with a continuously dry atmosphere also affected the plants unfavorably. The rapid growing varieties were less injured by dry, hot weather. Stem rot is reported to have made its appearance in the State for the first time, and the variety Nancy Hall proved very susceptible to this disease, while Triumph, Strassburg, and some others were practically immune.

A strain of Yellow Jersey sweet potato resistant to surface rot (*Fusarium oxysporum*), J. I. LAURITZEN (*Jour. Agr. Research [U. S.]*, 33 (1926), No. 11, pp. 1091-1094).—A description is given of Improved Yellow Jersey, a variety of sweet potato of unknown origin that is said to be resistant to surface rot. In addition to its disease resistance, the roots do not shrivel as much in storage as the ordinary variety from which the strain was selected.

Two important tomato diseases and their control, S. H. ESSARY (*Tennessee Sta. Circ.* 8 (1927), pp. 4, figs. 2).—Popular accounts are given of the wilt, or blight, and leaf spot of tomatoes, and suggestions are given for their control. The use of resistant varieties of tomatoes for the prevention of wilt and spraying for the prevention of leaf spot are recommended.

Tomato diseases in Florida, G. F. WEBER and G. B. RAMSEY (*Florida Sta. Bul.* 185 (1926), pp. 57-138, figs. 42).—The author has brought together for the benefit of growers information regarding tomato diseases known to occur in Florida. About 30 diseases are described, their causes are indicated when known, and suggestions are given for their control so far as definite treatments can be recommended.

A stem-end and center rot of tomato caused by various unrelated organisms, N. A. BROWN (*Jour. Agr. Research [U. S.]*, 33 (1926), No. 11, pp. 1009-1024, figs. 5).—The author reports that a stem-end and center decay is responsible for heavy losses in shipments of green tomatoes. It is claimed that the disease can scarcely be detected on the outside of the fruit, while the central core, including portions of the seeds, is a mass of hard, dark tissue. The disease occurs usually during seasons of hot weather and abundant rain, or during weather in which the fruit expands too rapidly after a period of checked growth. It is claimed that there is always an organism present which is responsible for the decay. The organisms which produced the decay readily proved to be *Bacterium malvacearum*, *B. marginale*, *B. tumefaciens*, *B. savatanoi*, *B. campestre*, *B. viridilividum*, *Cladosporium* sp., *Septoria gladioli*, *Verticillium* spp., *Fusarium moniliforme*, and *Alternaria* sp. In addition, inoculation experiments showed the disease might be produced with difficulty by *B. citri*, *B. vitians*, *Bacillus coli communis*, and *B. mycoides*. The author claims that the blossom-end rot of tomatoes, considered by pathologists to be a physiological disease induced by irregularities in the water supply and not by parasites, was produced by inoculating tomatoes with some of the above organisms.

A tomato fruit rot caused by *Bacterium lycopersici* n. sp. [trans. title], G. BURGWITZ (*Zitschr. Pflanzenkrank.*, 34 (1924), No. 7-8, pp. 303-312).—A description is given of a hothouse tomato fruit rot observed during 1923 and of a study of the associated organism, which is considered as a new species and is named *B. lycopersici*. Varieties known to be attacked include, thus far, Earliana and Alice Roosevelt, Danish Export remaining entirely unaffected though exposed. Apparently, the organism can overwinter in outdoor soil.

Tomato late blight and its relation to late blight of potato, A. BERG (*West Virginia Sta. Bul.* 205 (1926), pp. 31, figs. 7).—From his investigation the author claims that the *Phytophthora infestans* which produces late blight of tomato differs biologically from the form which produces potato blight. The potato fungus was found to infect the tomato fruit and leaves under artificial conditions, but the fruit could not be infected with this strain unless the epidermis was ruptured. The period of incubation for the potato strain, when inoculated on tomato plants, proved to be shorter than that of the tomato strain on the same host, and vice versa. In all cases observed under natural conditions, potato late blight is said to have appeared earlier in the season than the tomato late blight, and wherever tomato late blight was found potato late blight also occurred in close proximity.

Disease resistant fruits and vegetables, C. T. GREGORY (*Ind. Hort. Soc. Trans.*, 1924, pp. 118-121).—A list is given of disease resistant varieties of bean, celery, asparagus, cabbage, radish, spinach, tomato, muskmelon, apple, peach, raspberry, and strawberry.

Studies of the epidemiology and control of apple scab, G. W. KEITT and L. K. JONES (*Wisconsin Sta. Research Bul.* 73 (1926), pp. 104, pls. 6, figs. 9).—In order to arrive at definite recommendations for the control of apple scab, the authors conducted field studies of the disease in relation to the natural environment and laboratory and greenhouse studies of the development and prevention of the disease under controlled conditions.

Field studies are said to have shown that moisture and temperature factors play a leading part in the severity of the disease and the difficulty of its control. Experiments on spore germination under controlled conditions indicate that infection occurs at temperatures ranging from 6 to 26° C., with the temperature most favorable for rapid development near 20° (68° F.) Abundant infection was found to occur following suitable periods of intermittent wetting. The investigations of the authors confirm previous reports that apple leaves and fruits were more susceptible to scab in the early stages of development than at later periods.

Under Wisconsin conditions, the apple scab fungus was found to overwinter to a significant extent only through the formation of the perithecial stage in dead leaves. Discharges of spores occurred only when the leaves bearing the ascocarps were wet. A severe drought in early spring delayed the discharge and reduced the quantity of ascospores produced. In the six seasons studied primary infection commonly occurred during the first sufficient rain period following the exposure of susceptible host tissue in the unfolding fruit buds. The most critical period for the development of apple scab epidemics was found to extend from the time the apical parts of the sepals were first exposed in the unfolding fruit buds until an indefinite time some two or four weeks after petal fall.

Control experiments conducted during the years 1919–1924, inclusive, in which Bordeaux mixture, liquid lime sulfur, dry lime sulfur, and various mixed programs of Bordeaux mixture and liquid lime sulfur were tested, showed that Bordeaux mixture or liquid lime sulfur, appropriately applied, ordinarily controlled the disease. Bordeaux mixture, however, was unsatisfactory commercially because of injury to fruit and foliage. Liquid lime sulfur, 1–40, appeared to be the most satisfactory spray tested. Data are given as to the time and number of applications of spray tentatively recommended under different climatic conditions.

[**Apple tree scab and weather**], H. BREMER (*Angew. Bot.*, 6 (1924), No. 2, pp. 77–97, figs. 2).—Observations credited to R. Aderhold and R. Ewert, as carried on during 10 years, of the severity of apple scab (*Fusicladium dendriticum*) show that the most influential factor is precipitation. The most critical month is May, particularly its first 10 days, the disease showing great severity in case of heavy rainfall during this short period.

Apple harvesting [in relation to internal browning] (*Utah Sta. Bul.* 198 (1926), pp. 50, 51).—Investigations by T. H. Abell are reported, in which an effort was made to determine whether or not delayed harvesting causes internal browning of the Jonathan apple. About 20 apples were picked from plats at weekly intervals, beginning two weeks before and continuing until three weeks after commercial harvest. The apples were stored in a cellar until May or later. The first year's results are said to indicate that internal browning is more abundant in Jonathan apples raised on well-drained bench soils, and is practically nonexistent on those grown in richer, more retentive soils. It was increased by leaving the fruit on the tree one week too long, and could have been avoided by harvesting one week earlier without sacrificing much in red color. Water core is said to have been serious in extremely late pickings, but the amount was not so clearly correlated with the time of earlier pickings.

Coryneum blight of stone fruits, C. S. PARKER (*Howard Rev.*, 2 (1925), No. 1, pp. 3-40, pls. 5).—Coryneum blight of stone fruits is said to have become important in the State of Washington, and to have been reported from a number of peach-growing sections of the United States east of the Rocky Mountains since its first appearance on the Pacific coast in 1900. The present paper reports several experiments with the organism (*C. beijerinckii*) responsible for the disease as studied on peach, apricot, and cherry. Blossom, leaf, and twig blight are dealt with.

Artificial inoculations and reisolutions reproduced all typical phases of the disease. No indication of any other than the summer or conidial stage was found. Infection occurs only through stomata or ruptured epidermal tissue. A supposedly separate strain of *C. beijerinckii* is noted. Spores were not killed by desiccation, and it is believed that they resist unfavorable conditions for a long period.

Heart rot of gladioli and its control [trans. title], H. PAPE (*Gartenwelt*, 29 (1925), No. 40, pp. 676-680, figs. 4).—Gladiolus heart rot (*Septoria gladioli*) is described as seen in bulbs of gladiolus sent in 1925 from Stuttgart and Bonn.

A leaf disease in *Primula obconica* [trans. title], H. PAPE (*Angew. Bot.*, 6 (1924), No. 2, pp. 255-275, pls. 2, figs. 2).—A leaf-blade disease affecting a few to all leaves of the plant *P. obconica* is described as to macroscopic and microscopic characters. Neither pest nor disease organism could be made out in this connection. Studies on causation as outlined included chemical soil constituents, temperature, and sulfuric acid (or SO₂) gas in the atmosphere, the presence of which, under certain conditions, is regarded as capable of causing such leaf injury.

Oak mildew [in Russia] [trans. title], A. BUCHHEIM (*Ztschr. Pflanzenkrankh.*, 34 (1924), No. 1-2, pp. 1-11, figs. 4).—Oak mildew, which was found in almost all European countries in 1907 and 1908, and which became widely distributed in Russia during 10 to 15 years preceding 1923, has been made the object of study as to both its morphology and its biological relations. The forms of the causal organism studied by the author have been referred to the comprehensive species *Microsphaera alni*, with comment on biological grounds regarding its inclusion under *M. quercina*. No morphological differences were distinguished between the conidia of the organism on oak and of those on beech.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The Manchurian wapiti (*Cervus xanthopygus* Milne-Edwards) [trans. title], N. A. BAIKOV (BAIKOFF) (*Obshch. Izuch. Man'chzhursk. Kraia Otd. Izd. (Manchuria Research Soc. Misc. Papers), Ser. A, No. 5 (1925), pp. 14, figs. 11; Eng. abs., p. 14*).—This is an account of the species of deer met with in Manchuria, Chosen, Transbaikalia, the Amur, and the Maritime Provinces.

The fauna of British India, including Ceylon and Burma.—Birds, E. C. S. BAKER, edited by A. E. SHIPLEY (*London: Taylor & Francis, 2. ed., 1922, vol. 1, pp. XXIII+479, pls. 8, figs. 98; 1924, vol. 2, pp. XXIII+561, pls. 8, figs. 86; 1926, vol. 3, pp. XX+489, pls. 8, figs. 90*).—This is a second edition of a work in four volumes, the first two of which, published in 1889 and 1890, were by Oates, under the editorship of W. T. Blanford, and the two last, published in 1895 and 1898, were by Blanford. The present three volumes are devoted to and complete the order Passeres, in which are included 33 families, 303 genera, and 1,336 forms.

A natural history of the ducks, J. C. PHILLIPS (*Boston: Houghton Mifflin Co., 1925, vol. 3, pp. IX+383, pls. 56*).—In this third volume of the work previously noted (E. S. R., 50, p. 355) the author concludes his account of the subfamily Anatinae and deals with Fuligulinae (in part).

A monograph of the pheasants of Japan, including Korea and Formosa, N. KURODA (*Tokyo: Author, 1926, pp. [3]+43, pls. 15*).—In this work the author deals with 12 forms belonging to the genera Phasianus, Graphophasianus, and Cyanophasis. A list of 72 references to the literature is included.

The snakes of Iowa, J. E. GUTHRIE (*Iowa Sta. Bul. 239 (1926), pp. 145-192, figs. 69*).—In this account the author deals with the classification, including a key for identification, of the snakes occurring in Iowa, their life histories and habits and economic importance. Descriptions are given of the 25 forms which occur in the State, of 2 additional species from nearby States, and of the banana boa, photographs of many of which are reproduced. It is pointed out that the bull snake, fox snake, milk snake, king snake, and blue racer are Iowa's most valuable snakes because their chief food consists of rats, mice, ground squirrels, and pocket gophers. The two species of rattlesnakes are the only poisonous forms occurring in Iowa.

Annual report of the division of entomology, H. L. DOZIER (*Porto Rico Dept. Agr. and Labor Sta. Ann. Rpt., 1925, pp. 115-124; also in Spanish ed., pp. 121-129*).—This is a report of observations of the occurrence of insects during the year, and of the work conducted.

In control work with white grubs third-instar larvae of *Lachnosterna portoricensis* placed in soil in cages were killed to the extent of 75 per cent through the application of a carbon disulfide emulsion, 75 cc. in 12.5 qt. of water, sprinkled over the soil. In a check cage adjoining, the natural mortality was 32 per cent. In studies of the sweet potato bug (*Corecoris (Spartocera) batata* Bbr.) it was found to be killed by a fungus, *Sporotrichum gloeosporoides*. The first nymphal instar of this bug required about eight days, in November, for its completion. Notes are presented on *C. fusca* Thumb., of which a number of nymphs in various instars were found on cundeamor vine in November. Reference is made to the rearing of the tachinid fly *Trichopoda pennipes* from the last nymphal instar of *C. batata*. Outbreaks of the striped grass looper (*Mocis (Remigia) repanda*) occurred in various sections of the island, causing damage to malojilla grass and young sugar cane in October and November, but it was eventually controlled by parasites. The yellow cane aphid (*Sipha flava*) caused serious injury to Uba cane, but was controlled by the use of a 3 per cent nicotine dust. The lesser corn stalk borer was a source of injury to 2-months-old Uba cane at Buena Vista. Scale insects were not prominent pests due to the natural control by parasites. The species mentioned include the purple scale, West Indian rufus scale (*Selanaspilus articulatus*), snow scale (*Chionaspis citri*), soft brown scale (*Coccus hesperidum*), pustule scale (*Asterolecanium pustulans*), tessellated scale (*Eucalymnatus tessellatus* (Sign.)), and black scale. *Pulvinaria iceryi* was a source of injury to sugar cane in one locality. The cloudy-winged whitefly was found infesting sour-orange foliage in private home gardens. An efficient parasite, *Encarsia* n. sp., was reared in abundance from *Metaleurodicus minimus* on *Cestrum diurnum* and guava, and from *Aleurodes variabilis* Quaint. on *Carica papaya*. Large numbers of the small chalcid parasite *Eretmocerus californicus* How. were reared from the woolly whitefly. The occurrence of this parasite is thought to account for the comparatively small damage caused by this whitefly. The red-banded thrips were abundant throughout the year, damaging many different host plants, including the grape, achote, mango, almendra, guava, etc. Reference is made to the rearing of some 7,000 silkworms during the year and the indication that they can be profitably raised on the island, particularly in view of the fact that the white mulberry is considered to be about the best shade tree for coffee.

Insect pests (South Carolina Sta. Rpt. 1926, pp. 31-41, figs. 4).—Brief reference is made to studies of cotton insects, including the boll weevil, cotton flea

hopper, leafhopper, and boll worm; corn billbug; insecticides; Mexican bean beetle; rice weevil; and tomato fruit worm. It is pointed out that the native persimmon is a host and reservoir for certain destructive insects, including the twig girdler, the persimmon psylla, and the flat and round-headed borers.

Entomology (*Utah Sta. Bul. 198 (1926), pp. 39-41*).—A brief reference is made to the several insect projects under way, particularly to tests of different baits for ants, by I. M. Hawley, and studies of the Chalcis fly in alfalfa seed, by C. J. Sorenson.

Insect pests (*Washington Col. Sta. Bul. 208 (1926), pp. 66, 67*).—Reporting upon cranberry investigations, D. J. Crowley refers to a number of insect pests of importance during the year, including the fruit worm, scale insects, weevils, and tussock moths. Volck's oil spray used for fireworm control at strengths of 2, 3, and 4 per cent was found to have some value as an ovicide, although it had little effect upon the fireworm larva.

[Report of entomology and apiculture department of Wyoming Station] (*Wyoming Sta. Rpt. 1926, pp. 174, 175*).—Brief reference is made to work under way with the alfalfa weevil, American foulbrood, selective breeding of bees, wintering bees, honey production in the higher mountains, and studies in the manipulation of bees.

Directory of field activities of the Bureau of Entomology (*U. S. Dept. Agr., Misc. Circ. 80 (1926), pp. II+35, pl. 1*).—This directory is arranged alphabetically, by States.

[Report of the] entomological branch (*Canada Min. Agr. Rpt., 1925, pp. 91-105*).—This is a general statement of the entomological work of the year.

Report of the entomologist, C. SMEE (*Nyasaland Dept. Agr. Ann. Rpt. 1925, pp. 9, 10*).—This brief report deals with insect pests of tobacco, cotton, coffee, and maize. The pink boll worm was discovered in the Mwaya-Ipiana plain of Tanganyika Territory and in North Nyasa. It was decided to prohibit the growing of cotton in the North Nyasa district for the future, and to delimit a quarantine area comprising Mombera, West Nyasa, and Kasungu districts and Kota-Kota district lying north of the Bua River, in which cotton growing is prohibited.

Insects of western North America, E. O. ESSIG (*New York: Macmillan Co., 1926, pp. XI+1035, figs. 766*).—This manual and textbook of insects of western North America is an outgrowth of the author's *Injurious and Beneficial Insects of California*, the second edition of which was published in 1915 (*E. S. R., 33, p. 652*). In the preparation of this work the author has reviewed all the available literature dealing with western insects, references to which are appended as footnotes. The data are presented systematically by orders, families, and subfamilies, and keys are given for the separation of the classes, orders, suborders, and families. The work includes indexes to the authors consulted (pp. 911-919), to host plants (pp. 920-934), and to the subject matter (pp. 935-1035).

How insects live: An elementary entomology, W. H. WELLHOUSE (*New York: Macmillan Co., 1926, pp. XV+435, figs. 333*).—This is an introduction to a course in economic entomology. Following brief general considerations, the subject is dealt with in systematic order, a chapter being devoted to each order and typical insects used to represent the orders and the various groups in the larger orders. This is followed by a list of the orders and families of insects, a chapter on the phylum Arthropoda, and a chapter presenting suggestions for collecting insects and illustrated keys for distinguishing the principal orders and families of adult insects and some common larvae.

Physiological studies of the effect of arsenicals on the respiratory metabolism of insects, D. E. FINK (*Jour. Agr. Research [U. S.], 33 (1926), No. 11,*

pp. 993-1007, figs. 8).—The author reports studies made of the effect upon the respiratory metabolism of the Colorado potato beetle (adults) produced by feeding foliage sprayed with various arsenicals. Similar experiments were also made upon wireworms fed grains of corn soaked in arsenical solutions. It was found that the metabolic activity of the potato beetle was reduced when the beetle was fed on lead arsenate, calcium arsenate, ferric arsenate, and manganese arsenate from 2 to 16 hours and increased when fed on realgar for the same period. The percentage depression of the oxygen consumption and the carbon dioxide production was found to vary with the arsenical employed. The respiratory metabolism of the insects was reduced when they were fed the oxide components of arsenical compounds, including lead oxide, manganese oxide, ferric oxide, and calcium oxide. With the concentration of arsenious and arsenic-acid solutions used, it was found that arsenious acid was 57 per cent more toxic than arsenic acid. Similarly it was found that sodium arsenite was 59 per cent more toxic than sodium arsenate.

The discovery of the insecticidal property of carbon disulphide, P. SIMMONS and G. W. ELLINGTON (*Science*, 64 (1926), No. 1657, pp. 326, 327).—It is pointed out that the insecticidal value of carbon disulfide was discovered by L. Garreau, who reported upon it in July, 1854.

Toxicity of sodium silicofluoride and arsenical mixtures to plant foliage, A. P. KERR and C. E. SMITH (*U. S. Dept. Agr., Off. Rec.*, 4 (1925), No. 48, p. 5).—In experimental control work with blister beetles (*Epicauta lemniscata*) in May and June, 1925, the application of a dust containing calcium arsenate and sodium silicofluoride caused much greater injury to the plant than where these insecticides were used separately. This led to investigations from which it was concluded that chemical reactions occur where either calcium arsenate or Paris green is mixed with sodium silicofluoride in the presence of moisture, and that high percentages of water-soluble arsenic are released as a result of the reaction.

Undiluted sodium silicofluoride in two grades (C. P. and a commercial product containing 98 per cent) caused only slight burning, whereas mixtures made up of equal parts of calcium arsenate and sodium silicofluoride completely killed the soy beans. The experiments indicate that great caution should be used in combining sodium silicofluoride with certain arsenicals for insecticidal use on plants, especially those containing metallic elements which combine readily with the silicofluorides.

Contribution to the study of diseases of insects caused by filtrable virus.—A new group of ultramicroscopic parasites: **The Borrellina** [trans. title], A. PAILLOT (*Ann. Inst. Pasteur*, 40 (1926), No. 4, pp. 314-352, figs. 9).—This is a more extended account than that previously noted (E. S. R., 55, p. 458) of the author's investigations of ultramicroscopic parasites which cause diseases in insects, and for which the genus *Borrellina* was erected. The account includes a list of 51 references to the literature.

Soil treatment for subterranean insects, A. L. MELANDER, R. L. WEBSTER, and A. SPULER (*Washington Col. Sta. Bul.* 208 (1926), pp. 21, 22).—Results obtained after the publication of Bulletin 199, previously noted (E. S. R., 55, p. 55), indicate that sodium fluosilicate is also an effective poison for use in the control of root weevils affecting strawberries.

Tests of insecticides for potato insects, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt.* 1925, pp. 51, 52).—Brief reference is made to tests of two lots of potato green A and B supplied by a chemical company, which were found to be equal in effectiveness to lead arsenate when applied at the rate of 2 lbs. and 4 lbs., respectively, to 50 gal. of water. Three compounds

of London purple from a white lead company were found effective against the beetles, and caused no injury to the foliage.

Some of the more important insects attacking nut trees in Illinois, W. P. FLINT (*North. Nut Growers Assoc. Proc.*, 16 (1925), pp. 108-114).—The insects here considered include the hickory tiger beetle or borer, flat-headed borer, hickory twig girdler, oak twig pruner, walnut caterpillar, nut weevils, and nut curculios. Control measures are given for each.

Handbook of citrus insect control for 1926, R. S. WOGLUM (*Calif. Fruit Growers Exch.*, Los Angeles, *Bul.* 3 (1926), pp. 17).—This is an analysis of the value of sprays as compared to fumigation for scale insect control, based on results obtained by the author and J. R. LaFollette during the season of 1925-26. The red scale, black scale, citricola scale, purple scale, and red spider are dealt with. The effect of "oil film" sprays on lemons from the packing house standpoint is considered by H. W. Nixon (pp. 15, 16).

Distribution, life history, economic importance, natural enemies, and control of the common field cricket, *Gryllus assimilis* Fab., H. C. SEVERIN (*South Dakota Sta. Rpt.* 1925, pp. 23, 24).—An account of this pest has been noted (E. S. R., 55, p. 355). In control work in alfalfa fields with the granular form of calcium cyanide the author failed to obtain satisfactory results.

Notes on the biology of the leafhopper *Eutettix strobi* Fitch, F. A. FENTON (*Iowa Acad. Sci. Proc.*, 31 (1924), pp. 437-440, figs. 3).—This is a brief account of a leafhopper which produces stigmose on the leaves of the common pigweed or lamb's-quarters (*Chenopodium album*).

The chinch bug on St. Augustine grass lawns, J. R. WATSON (*Florida Sta. Press Bul.* 371 (1925), pp. 2).—Attention is called to the injury caused by chinch bugs to this popular lawn grass in Florida and means of control through the use of calcium cyanide and nicotine sulfate lime dusts.

Chinch bug control on St. Augustine grass, A. H. BEYER (*Citrus Indus.*, 7 (1926), No. 8, pp. 13, 16, 17).—A practical account of this pest and means for its control in Florida.

A new species of *Triphleps* (Heteroptera, Anthocoridae) preying on the eggs of *Heliothis obsoleta* H. S. in Queensland, W. E. CHINA (*Bul. Ent. Research*, 16 (1926), No. 4, pp. 361, 362, fig. 1).—Under the name *T. australis* the author describes a new species which attacks the eggs of the boll worm in Queensland.

Plum aphid and brown rot control, A. H. LEES and H. R. BRITON-JONES (*Jour. Pomol. and Hort. Sci.*, 4 (1925), No. 3-4, pp. 196-199).—This has been noted from another source (E. S. R., 55, p. 662).

The aphids of *Myzocallis* infesting the bamboo, R. TAKAHASHI (*Ent. Soc. Wash. Proc.*, 28 (1926), No. 7, pp. 159-162, figs. 8).—Seven species of *Myzocallis* are recorded as known to infest the bamboo. *M. taiwanus*, which attacks the young leaf and shoot at Taihoku and Karenko, Taiwan, is described as new.

Factors influencing citrus aphid outbreak, J. R. WATSON (*Citrus Indus.*, 7 (1926), No. 9, pp. 10, 11, 33).—A discussion of the factors influencing the occurrence of *Aphis spiraecola* in Florida. It is pointed out that the aphid has recently been reported as seriously damaging citrus trees in Louisiana, and that specimens have been received from the Satsuma belt of Alabama. In Florida, Satsumas from Gainesville south are as severely infested as any other variety of citrus, but there are no signs of its presence on Satsumas in most of the Satsuma belt in the State.

***Lepidosaphes destefanii* Leon, a new enemy of the olive** [trans. title], P. HERCE (*Bol. Estac. Patol. Veg. [Inst. Agr. Alfonso XII, Madrid]*, 1 (1926), No. 2, pp. 53, 54, figs. 3).—The author records the infestation of the olive at Maella, Saragossa, Spain, by this scale.

Studies on the potato tuber moth during the winter of 1925-1926, G. W. UNDERHILL (*Virginia Sta. Bul.* 251 (1926), pp. 21, figs. 6).—This is an account of studies of the potato tuber worm in fields on the eastern shore of Virginia. It includes a discussion of the percentage that failed to survive the winter in the fields in which a fall crop of potatoes had been grown, with the death rate of prepupae and pupae; number of insects that failed to survive the winter when attached to cornstalks in fields in which a spring crop of potatoes had been produced; observations of the death rate of pupae in the soil; location of pupal cocoons in the field; observations of the different stages of the potato tuber worm during the winter; comparison of the temperature of the past winter with other years; and parasites and predators.

It was found that during the winter of 1925-26 only the pupal stage survived out of doors, while in the storage houses, where the temperatures remained above freezing, all stages remained alive throughout the winter. The infestation of the spring crop fields was traceable to culls and volunteers. The great reduction in number of insects during the winter seemed to be largely due to low temperatures, the work of parasites, and the habit of the moths of emerging during the winter. The fact that only about 5 per cent of the pupae survive until March is due to the combined effect of cold and the work of parasites. Six species of parasites were observed which, in order of importance, are: *Campoplex ferrugineipes* Ashm., *C. phthorimaeae* Cush., *Ephialtes aequalis* Prov., *Bracon gibbosus* Say, *Apanteles carpatus* Say, and *Itopectis conquisitor* Say. Two predators, namely, *Podisus spinosus* and *Lycocoris campestris* Fabr., were observed to attack and kill the larvae. With 1,872 cocoons from above ground examined, parasitism ranged from 3 to nearly 50 per cent, with an average of nearly 30 per cent.

The European corn borer in Ohio, L. L. HUBER and C. R. NEISWANDER (*Ohio Sta. Bimo. Bul.*, 12 (1927), No. 1, pp. 2-13, figs. 7).—This is a practical account arranged in the form of 53 questions and answers. The article concludes with a discussion of the corn borer control program.

Learning to live with the European corn borer, W. P. FLINT, J. C. HACKLEMAN, and F. C. BAUER (*Illinois Sta. Circ.* 313 (1927), pp. 16, figs. 11).—In this circular the author gives the latest information concerning the spread of the corn borer and methods for combating it.

Codling-moth in apricots, F. W. PETTEY and C. J. JOUBERT (*Union So. Africa Dept. Agr. Jour.*, 12 (1926), No. 5, pp. 461-483).—This is a further report of studies of the life history and control of the codling moth at Wellington during the 1925-26 fruit season (*E. S. R.*, 54, p. 156).

The insect continues to be a serious pest of apricots in many Wellington orchards, where practically no pear, apple, or quince orchards exist, and it appears to be slowly spreading to most orchards in the district. It has now been reared from loquats. The infestation was less than in the previous year, but it averaged from 10 to 15 per cent in orchards where no efforts were made to control the pest. It was found that 31 per cent of the infestations in Alphas and from 48 to 67 per cent of those in Royals did not become serious except for the exporter of fresh fruits, owing to the fact that either the larvae left these fruits soon after they burrowed through the skin, or died prematurely. One codling moth larva may infest or injure several apricots before it finally establishes itself in a fruit to develop to maturity. Spraying can not yet be recommended for the control of this pest in apricot orchards, and it is confidently expected that it will be unnecessary if the other measures of control, particularly banding, are thoroughly and properly practiced.

The sugar cane moth stalkborer (*Diatraea saccharalis saccharalis* Fab.), D. L. VAN DINE (*Trop. Plant Research Found. [Wash., D. C.] Bul. 2 (1926), pp. 11*).—A brief account of this pest in Cuba, its Cuban parasites, viz, *Trichogramma minutum* Riley, *Euzenillioopsis diatraea* Twins., *Sarcophaga sternodontis* Twins., *Apanteles diatraeae* Mues., *Bassus stigmaterus* Cress., and *Isaria (Cordyceps) barberi* Giard, and means of control.

Spraying tests in controlling sugar beet webworm, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 56, 57*).—The results obtained on August 15 with 8 different spraying treatments are reported in tabular form. Liquid sprays were found much more effective than dust sprays of the same poison due to their better sticking qualities.

On *Psara phoeopteralis* as a pest on grasses in south India, M. C. CHERIAN and C. J. GEORGE (*Jour. Bombay Nat. Hist. Soc., 31 (1926), No. 2, pp. 529, 530, pl. 1*).—A brief account is given of the life history of this enemy of fodder grasses in Malabar. It is known to occur on *Panicum javanicum*, *P. miliaceum*, *Andropogon annulatus*, and *Cynodon dactylon*, and probably feeds on any common grass, having in one instance been reared from wheat. It has also been found in Coimbatore, Bangalore, and Bellary. A single specimen of the ichneumon parasite *Syzeuctus annulipes* was reared from a larva.

A revision of the adult anopheline mosquitoes of Japan, II, S. YAMADA (*Tokyo Imp. Univ., Govt. Inst. Infect. Diseases Sci. Rpts., 4 (1925), pp. 447-493*).—This completes the paper previously noted (*E. S. R., 55, p. 459*), 14 forms having been recognized.

The mosquitoes of the Lower Fraser Valley, British Columbia, and their control, E. HEARLE (*Canada Natl. Research Council Rpt. 17 (1926), pp. 94, pl. 1, figs. 42*).—A discussion of the Lower Fraser Valley mosquito problem, with keys to Lower Fraser Valley mosquitoes, descriptions and accounts of species in habitat groups, a list of Lower Fraser Valley mosquitoes, and control measures.

House flies and their connection with manuring operations on estates in Ceylon, F. P. JEPSON (*Ceylon Dept. Agr. Bul. 74 (1926), pp. 16, pls. 7*).—The author records *Musca yerburyi*, *M. nebulo*, *Stomoxys calcitrans*, *Ophyra nigra*, and *Chrysomyia megacephala* as breeding in artificial manure. Of these *M. yerburyi* and *M. nebulo* are the only ones concerned in the swarms which invade bungalows, and the former is probably more commonly met with. The studies indicate that the swarms of flies which coincide with manurial operations on estates originate, in most cases, from eggs laid after the manure has been spread in the field, by flies which were already present on the estate in small numbers. Experiments conducted demonstrated that flies will neither oviposit nor breed in perfectly dry artificial manure, although they will readily do so when certain of these manures are moistened.

Some experiences in the control of fly-breeding, E. B. ALLNUTT (*Jour. Roy. Army Med. Corps, 47 (1926), No. 2, pp. 105-120, fig. 1*).—This deals with the method of treating stable litter in a two-stalled manure pit, practical points in working the method, experimental work in connection with fly breeding in manure, etc.

Biology of the red-tailed Tachina-fly, *Winthemia quadripustulata* Fabr., H. W. ALLEN (*Mississippi Sta. Tech. Bul. 12 [1925], pp. 32, figs. 10*).—This is a report of investigations commenced in 1923 and continued through 1924 and part of 1925. It is shown that this parasite occurs over the greater part of Europe and a large part of North America and has been reared from no less than 48 lepidopterous hosts in Europe and North America, and that Coleoptera may be occasionally attacked. The author considers it to be without question one of the most valuable native insect parasites. Following the presentation of a list of hosts and their habits and a discussion of its economic importance,

technical descriptions are given of its several stages, then an account of biologic studies, including duration of life stages, seasonal cycle, habits of the adult, food, habitat, oviposition, emergence from the egg, and habits of the larva. The author has found that in Mississippi this species hibernates as a full grown maggot in the soil, though it has been reported in Europe to pass the winter in the pupal stage. Three additional complete broods and a partial fourth are described. A bibliography of 48 titles is included.

Weevil biological work (*South Carolina Sta. Rpt. 1926, pp. 7-10, fig. 1*).—This is a brief reference to studies of the life history and habits of the boll weevil near Florence, conducted cooperatively by F. A. Fenton and E. W. Dunnam, of the U. S. D. A. Bureau of Entomology. In hibernation work with 12,425 weevils placed in cages, 54 per cent of the 102 survivors had emerged by April 28, and 99 per cent by June 7, when the first squares were developed. Cages located in the woods gave an average survival of 0.42 per cent as compared with 1.20 per cent for those placed in the open. There was a survival of 0.1 per cent from the cage stocked September 18, while no weevils issued from those stocked September 24 and October 1. It was found that 100 per cent of the weevils emerging from April 27 to May 28, and placed in cages over cotton in the field, were dead by June 7, when the cotton began to fruit. There were 4 generations of weevils during the year. The first-generation weevils emerged from July 5 to August 27, and the second from July 25 to September 24, the peak of weevil emergence being reached about August 2. The first migrating weevil was collected on July 7, with the greatest migration taking place between August 28 and September 14. Of the 6 parasites of the boll weevil reared in the vicinity of Florence, *Microbracon mellitor* was by far the most important.

Senses of the cotton boll weevil—an attempt to explain how plants attract insects by smell, N. E. McINDOO (*Jour. Agr. Research [U. S.], 33 (1926), No. 12, pp. 1095-1141, figs. 16*).—In this account the author deals with chemotropic experiments (pp. 1097-1102) and morphology of the sense organs of the adult stage (pp. 1102-1126) and of the larval stage (pp. 1126-1135) of the boll weevil, with illustrative drawings. The account concludes with a discussion of the manner in which plants attract insects by smell and a summary of the senses. A list of 60 titles of literature cited is included.

Boll weevil control tests (*Georgia Coastal Plain Sta. Bul. 6 (1926), pp. 21, 22*).—In a brief reference to control work conducted it is pointed out that the work has shown conclusively the benefits of early poisoning. Applications may be made with calcium arsenate dust or with the homemade mixture of molasses, calcium arsenate, and water, the latter being probably more practical since it does not require the use of dusting machinery. The applications should be begun a week to ten days before squaring, and two to three applications be made at weekly intervals.

Bee diseases in United States, A. P. STURTEVANT (*Gleanings Bee Cult., 54 (1926), No. 10, pp. 648-653, figs. 5*).—This is a report upon a study of records of samples received by the U. S. D. A. Bureau of Entomology bee culture laboratory during a period of 20 years.

The Brazilian beekeeper, E. SCHENK (*Der Brasilianische Bienenzüchter. Porto Alegre: Germano Gundlach & Co., 1925, 6. ed., pp. 250, pls. [40], figs. [155]*).—This is a textbook on beekeeping in Brazil.

New chemical for beekeepers, C. L. CORKINS (*Gleanings Bee Cult., 54 (1926), No. 10, pp. 644-646*).—It is pointed out that calcium cyanide is a new and most useful chemical for the beekeeper, being efficient in the destruction of diseased honey bees, wild bees, the wax moth, and ants without poisoning the honey.

The control of big bud mite in the field, R. G. HATTON, J. AMOS, and H. M. TYDEMAN (*Jour. Pomol. and Hort. Sci., 5 (1926), No. 2, pp. 124-130, pl. 1*).—The field experiments here reported led to the recommendation that black

currant bushes be sprayed with winter-strength lime sulfur (1.025 sp. gr.) just as the bloom trusses are appearing and before they open.

ANIMAL PRODUCTION

Some relations between fertility and the composition of the diet, A. G. HOGAN and H. M. HARSHAW (*Missouri Sta. Research Bul. 94 (1926), pp. 23, figs. 8*).—This is a further study along lines previously noted (E. S. R., 55, p. 90). Synthetic diets containing casein, starch, lard, cod-liver oil, yeast, cellulose, various salt mixtures, vitamin B, wheat germ and wheat-germ oil were used to determine whether there is a specific vitamin controlling reproduction.

When rations containing no known source of vitamin E were fed to rats sterility resulted. Females became pregnant, but in many cases the litters were resorbed and when young were produced they were either born dead or died in a short time. Sterility did not occur immediately, and females in some cases produced litters 7 months after being placed on the experimental diet. Using wheat germ or wheat-germ oil resulted in the birth of a normal number of litters. Observations did not indicate that sterility was due to anemia. When males were fed rations containing no vitamin E the testes showed lack of sperm and a typical condition of atrophy.

Commercial feeding stuffs, H. R. KRAYBILL ET AL. (*Indiana Sta. Bul. 303 (1926), pp. 20, fig. 1*).—A report of samples collected for official inspection during 1925, a list of the feed manufacturers, and the number of samples of their products examined, passed, not passed, and not tagged (E. S. R., 54, p. 357).

Inspection of commercial feedstuffs, P. H. SMITH, F. J. KOKOSKI, ET AL. (*Massachusetts Sta. Control Ser. Bul. 36 (1926), pp. 29*).—This publication consists of tables giving the results of chemical and microscopic analysis of 1,428 feeding-stuff samples collected for official inspection during the year ended September 1, 1926 (E. S. R., 54, p. 663).

Isze, the most expensive steer in North Dakota, J. H. SHEPPERD (*North Dakota Sta. Circ. 34 (1926), pp. 4, fig. 1*).—This circular indicates in a popular manner the difference between purebred and scrub cattle.

[**Cattle feeding experiments at the Crookston Substation**], C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 62-64*).—The results of two experiments on fattening cattle are briefly reported.

Pasture trials for cattle.—In continuing the pasture trials with yellow blossom sweet clover and brome grass (E. S. R., 55, p. 359), the cattle made average gains per head for the 112-day period of 98 and 105 lbs., respectively. After September 1 the cattle on the brome grass just maintained weight, while those on sweet clover were turned into a new growth and made an average daily gain during 28 days of 1.43 lbs.

Fattening two-year-old steers.—Four lots of six 2-year-old steers each were selected for comparing the value of ground wheat screenings when used as a portion of the grain ration with whole or ground barley and oil meal. As fed in the different lots the grain rations consisted of 45 per cent wheat screenings, 45 per cent ground barley, and 10 per cent oil meal; 90 per cent whole barley and 10 per cent oil meal; 90 per cent ground barley and 10 per cent oil meal; and 90 per cent ground barley and 10 per cent oil meal, the last being fed sweet clover hay and corn silage and the other lots alfalfa hay and corn silage as roughage. The lot receiving the wheat screenings made average daily gains of 3.13 lbs., while on whole barley there were produced average daily gains of only 2.13 lbs. and on ground barley with alfalfa hay 3.08 lbs. The average daily gain with ground barley and sweet clover hay was 2.86 lbs. The results showed that wheat screenings proved to be slightly more efficient when replacing half the barley than barley alone. Ground barley increased the rate of

gain and the resulting profit, and improved condition of the experimental animals as compared with whole barley. Sweet clover was inferior to alfalfa.

[Experiments in beef production at the South Carolina Station] (*South Carolina Sta. Rpt. 1926, pp. 57-59, figs. 3*).—Experimental work with beef cattle was continued as previously noted (*E. S. R., 54, p. 664*).

Steer feeding.—Twenty-four grade steers under 2 years of age, averaging 675 lbs., were divided into 3 lots. One lot receiving cottonseed meal and hulls made an average daily gain per head of 1.75 lbs. in a 112-day feeding period. A similar lot fed cottonseed meal and corn silage gained at the rate of 2.13 lbs. The third lot, receiving soy bean oil meal and corn silage, made 2.07 lbs. daily gain. The cost of 100 lbs. gain was \$15.84 in lot 1, \$12.39 in lot 2, and \$13.95 in lot 3.

Wintering feed cattle at the Coast Station.—A purebred Aberdeen Angus herd was fed from December 22 to March 30 on cottonseed meal, sorghum silage, and either hay or straw as additional roughage. The mature cows gained 112 lbs. per head at a cost of \$17.87, while the heifers gained 78 lbs., costing \$13.01 per head.

Roughage rations for two year old steers, H. HACKEDORN, J. SOTOLA, and R. P. BEAN (*Washington Col. Sta. Bul. 208 (1926), pp. 12, 13*).—Four groups of 10 steers each weighing from 850 to 900 lbs. per head were selected for comparing home-grown roughages. One lot receiving whole alfalfa hay made average daily gains of 1.22 lbs. per head, while lots receiving alfalfa hay and silage in equal parts, alfalfa hay and silage 1 : 2, and the waste alfalfa hay from the first lot made average daily gains of 1.52, 1.78, and 0.69 lbs. per head, respectively. The results of this 90-day experiment indicated that the feeding of corn silage with alfalfa hay was a much better practice than feeding alfalfa hay alone.

Fattening calves in Arizona, E. B. STANLEY and E. L. SCOTT (*Arizona Sta. Bul. 116 (1926), pp. 314-336, figs. 7*).—The experimental work reported in this bulletin is the first of a series of trials to determine the economical possibilities of fattening calves in Arizona. Sixty high-grade Hereford calves, averaging about 375 pounds in weight, were divided into 6 lots of 10 head each. Lots 1, 4, 5, and 6 were steer calves. Lot 3 was composed of heifer calves, and lot 2 was divided into 4 head of heifers and 6 head of steers. Lots 1, 2, 3, and 4 were fed corn silage, alfalfa hay, rolled barley, and cottonseed meal. In the first 3 lots the silage was fed in the proportion of 1 part hay to 2 parts silage. In lot 4 all the silage the calves would consume was fed. Lot 5 received the same ration except that no cottonseed meal was fed during the first 90 days. Lot 6 received alfalfa hay, rolled barley, and cottonseed meal.

The results indicate that heifer calves finished as well when fed in the pen with steers as when fed in separate lots. Heifer calves gained slower and required more feed per unit of gain than steer calves, but attained a market finish earlier. Limiting the silage received in proportion to the hay consumed gave somewhat higher gains, decreased the cost of gains, and the margin necessary to break even. Steers in the silage-fed group made more efficient use of their feed and more economical gains than those receiving no silage. Adding cottonseed meal to a ration of corn silage, alfalfa hay, and rolled barley did not effect an economical saving of rolled barley. The 10 smallest calves in the experiment made a daily gain of 2.13 lbs. as compared with 1.9 lbs. with the 10 largest calves.

Calves fed on the feeds grown in Salt River Valley attained a satisfactory finish, but were not good enough to bring the premium paid for baby beef, either because they were not large enough to begin with or the feeding period was too short.

Sheep breeding and feeding trial, C. G. SELVIG (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 64-69, fig. 1*).—In a study of the possibilities of economic sheep production in the Red River Valley region of Minnesota, four lots of 40

ewes were selected and wintered on various combinations of feed. One lot receiving alfalfa hay and ground barley produced 38 living lambs and lost an average of 1.19 lbs. per head from November 18 to May 26. Another receiving the alfalfa hay and ground wheat screenings produced 43 lambs and lost an average of 5.95 lbs. per head. The other two lots, receiving sweet clover hay and ground barley and sweet clover hay and ground screenings, produced 42 and 34 lambs, respectively, and the former gained 2.29 lbs. per head in live weight, while the latter lost 2.68 lbs. In the spring one-half of the lambs were turned on sweet clover pasture and the other half on native pasture. Beginning with August 26 they were fed in the sheep barn on a light grain ration of ground barley and ground oats with alfalfa hay, which was somewhat modified as the fattening period progressed. When sold on the Chicago market in November they brought practically top prices. Though the calculated profits for the enterprise were small, it is nevertheless concluded that this experiment shows that there is no reason why sheep production can not be carried on profitably on a Red River Valley farm.

Sheep breeding to eliminate the tail, J. W. WILSON (*South Dakota Sta. Rpt. 1925, p. 9, fig. 1*).—By crossing fat-rumped sheep with other breeds and selecting tailless nonfat-rumped offspring having desirable characteristics for several generations, 18 out of 21 lambs produced during the first year were short-tailed and the majority had good fleeces, while only a few showed any evidence of the fat rump.

[**Experiments in sheep production at the South Carolina Station**] (*South Carolina Sta. Rpt. 1926, pp. 59-61, fig. 1*).—A brief description of the work.

Sheep improvement by use of purebred rams.—Sixty native ewes from the coastal section were bred to a purebred Southdown ram. The first cross lambs sheared fleeces averaging 5.08 lbs., while the fleeces of the ewes averaged 4.15 lbs. The lambs showed marked improvement in mutton qualities over their dams. The ewes responded to good feed and care. In September, 1923, they averaged 65 lbs. in weight and in 2 years had increased to 80 lbs. The fleeces in 1923 averaged 1.8 lbs. and two years later weighed 4.15 lbs.

Cottonseed meal and hulls v. mixed soybean and grass hay for wintering ewes.—Forty ewes were divided into 2 lots and fed for 70 days. One lot received cottonseed meal and hulls and the other mixed soy bean and grass hay. After 28 days the ewes on hay had failed to gain so cottonseed meal was added to the ration. The ewes on cottonseed meal and hulls gained 18 lbs. per head at a cost of \$1.54, and those on hay gained 13 lbs. at a cost of \$2.09. A record of the weight of the lambs at birth showed that those from the cottonseed meal and hull ewes weighed 7.77 lbs. and those from ewes fed hay averaged 7.95 lbs.

The searing iron v. the knife for docking lambs.—Twenty grade lambs, 1 to 2 weeks old and docked with a sharp knife, gained faster and the wounds healed more rapidly than a similar lot docked with the searing iron.

The nutritive value of first, second, and third cuttings of alfalfa hay, J. SOROLA (*Washington Col. Sta. Bul. 208 (1926), pp. 13, 14*).—In 54 separate digestion and metabolism studies with ewe and wether lambs, it was found that sheep fed alfalfa hay excreted 44.79 per cent of the ingested organic matter in the feces. Two and one-third lbs. of water were consumed per pound of feed when receiving dry feed such as alfalfa hay, with some variation resulting from the environmental temperature. The largest yields of digestible matter per acre were obtained when the first and second cuttings were made in the one-half or three-fourths stages of bloom. The second cutting yielded the most digestible matter per acre when cut at the three-fourth to full bloom stage, though no differences were apparent in the first cutting. The third

cutting was best made at the half bloom stage for obtaining the maximum yield of digestible matter per acre. When the first and second cuttings were made in the three-fourth bloom stage and the third in the half bloom stage a total of 192.71 lbs. of calcium and 20.36 lbs. of phosphorus were removed per acre during the season.

Sheep feeding.—XIV, Fattening western lambs, 1925–1926, C. HARPER (*Indiana Sta. Bul. 304 (1926), pp. 12, fig. 1*).—In work done to check results of previous experiments, a comparison of hominy feed and shelled corn resulted in approximately the same gain and feed consumption. The corn-fed lambs made somewhat cheaper gains (E. S. R., 43, p. 375).

Lambs fed clover hay in comparison with soy-bean hay (E. S. R., 54, p. 363) gained 5.8 lbs. more per lamb in 60 days and cost \$2.12 less per 100 lbs. of gain.

When the amount of legume hay fed was varied (E. S. R., 41, p. 70), it was found that lambs fed hay each day gained faster but at no less cost than those fed hay every fifth day. The market finish was the same in both cases.

Lamb feeding experiments in the sugar beet growing districts, J. A. HOLDEN (*Nebraska Sta. Bul. 216 (1926), pp. 21, fig. 1*).—The data presented in this bulletin represent a continuation of a study of lamb feeding on irrigated farms in western Nebraska (E. S. R., 49, p. 670). The work reported was begun in the fall of 1922 and continued for three successive winters. The first winter there were 30 lambs per lot, averaging 48 lbs. initial weight, and the second and third winters 25 lambs per lot, averaging 45 and 59 lbs.

The objects of the experiment were to compare: (1) Corn, barley, and dry pulp when fed with alfalfa hay; (2) cottonseed cake and linseed cake when fed with either corn, barley, or dry pulp; and (3) corn silage, beet-top silage, beet tops, and cull potatoes when fed with a ration of corn, cottonseed cake, and alfalfa hay. The lambs in each lot were fed all the alfalfa hay they would eat without waste. When on full feed the lambs were fed corn, barley, and dry pulp at the rate of 1 lb. per lamb daily, cake at the rate of $\frac{1}{3}$ lb., and silage or potatoes at the rate of 1.6 lbs. Beet tops were fed in amounts that the lambs would clean up.

The following table gives the summary of the combined 3 years' work:

Summary of three years' comparative feeding tests in fattening lambs in western Nebraska

Lot	Average gain per lamb	Feed required per 100 pounds gain										Selling price per 100 pounds
		Corn	Barley	Dry pulp	Cottonseed cake	Linseed cake	Alfalfa hay	Corn silage	Beet-top silage	Beet tops	Cull potatoes	
		<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	
1	30.3	335					683					\$15.40
2	27.0		375				770					15.30
3	24.0			422			851					15.25
4	35.4	286			92		552					15.65
5	32.4		312		100		660					15.55
6	33.7			301	96		632					15.50
7	35.2	288				92	590					15.65
8	32.2		315			101	671					15.55
9	33.1			306		98	638					15.50
10	36.0	282			90		455	478				15.70
11	37.2	272			87		476		462			15.65
12	37.4	270			87		455			1.62		15.60
13	38.4	263			84		488				447	15.65

¹ Per ton of yield.

Effect of feeding and management of sheep on the tensile strength and elasticity of wool, W. E. JOSEPH (*Jour. Agr. Research [U. S.], 33 (1926),*

No. 11, pp. 1073-1089, figs. 7).—Wool fibers taken from the shoulders of Rambouillet ewes in several flocks wintered under range and semirange conditions were compared as to stretch by each increment of weight or stress, the elastic limit point, total stretch at the breaking point, breaking stress, and diameter, with the fibers of yearling wethers and ewes and mature ewes which were wintered under good farm conditions. The methods of testing the fibers were essentially described in earlier work at the Montana Experiment Station (E. S. R., 33, p. 762).

The average results of these tests indicated lower values for the range ewes for stretch, break, and diameter, but higher values for range ewes for average elongation, tensile strength, elastic limit on equal area, and Young's modulus, which is the relation between the product of length and stress divided by the product of stretch and area of the cross-section.

The data are presented in tables and graphs. These show a rather uniform tendency of a smaller diameter of fiber from the aged ewes as well as the yearling wethers and yearling ewes kept under range or semirange conditions, as compared with those kept under more favorable conditions. A greater strength of the small fibers per unit of area of cross-section was explained on the basis of the medulla making up a greater proportion of the cross-section than the cortex in case of the fibers having the greater diameter.

In a second experiment lots of wethers were fed for 5 to 6 months during the winter on rations of alfalfa hay, oats, and linseed oil meal, as compared with mixed hay in 1 year, and alfalfa as compared with oat straw and cottonseed cake in 2 other years for a study of the effect of such feeding on the quality of the wool of individual animals.

An analysis of these results showed no variation in the stretch, break, diameter, average elongation, tensile strength, Young's modulus, or elastic limit on equal area which could be ascribed to differences in the feed during the test period, notwithstanding the fact that the fleeces of the wethers in the lots fed straw and cottonseed cake were dry, harsh, and lifeless to the touch as compared with fleeces of the wethers fed a liberal ration of alfalfa hay, which were in every case quite satisfactory in condition.

The fleeces grown during the period in part of which hay was fed were uniformly heavier than those produced during the year represented by the test period on straw and cottonseed cake. With two exceptions the length of the staple showed a uniform tendency to decrease with the advancing age of the wethers for the first two fleeces, but in the third fleece there was no tendency for a decrease in the length of staple as compared with the second fleece. Age appears to be a greater factor in determining the length of staple than the rather marked differences in the level of feeding over a period of 5 to 6 months. Opposed tendencies on the length of staple and the weight of the fleece observed, as well as the lack of change in the diameter of the fiber or apparently in the quantitative relations of such structural parts of the fiber as influence its strength or elasticity, indicated that while the physical properties of the wool fiber itself are not easily changed either quantitatively or qualitatively, the yolk or grease and other factors that go to make up shrinkage are easily subject to influence by the level of feeding.

It is concluded from these experiments that the level of winter feeding should be determined according to the needs for other purposes than for wool production, because any additional weight of fleece produced by more liberal winter feeding of sheep in good physiological condition is concerned largely with the factors making up shrinkage and only slightly with the actual wool fibers.

Pork production at the North Platte Substation, W. P. SNYDER (Nebraska Sta. Bul. 214 (1926), pp. 27, fig. 1).—The results of several years' work with hogs at the North Platte Substation are summarized.

Comparison of the relative feeding values of white and yellow corn for fattening hogs.—The results of 3 winter and 1 summer test, involving 210 fattening pigs, are summarized. Nine lots of pigs fed white corn and various other feeds made an average daily gain of 1.35 lbs., as compared with 1.36 lbs. for similar lots fed yellow corn and other feeds. The feed required for 100 lbs. of gain for those fed white corn was 358 lbs., and for those fed yellow corn 377 lbs. When pigs had access to both white and yellow corn there was no appreciable difference in the rate of gain, economy of feed required to produce a unit of gain, or the amount of either kind of corn eaten. The feeding or not feeding of alfalfa and other supplements did not favor corn of either color.

Sudan grass pasture v. alfalfa pasture.—In 3 years' work, the first year the grazing period was 60 days, while the last two years the tests were continued until the pigs had reached a marketable weight.

The first year the 15 pigs on alfalfa pasture made an average daily gain of 1.51 lbs., as compared to 1.3 lbs. for those on Sudan grass. The feed required for 100 lbs. of gain was alfalfa 359 lbs. and Sudan grass 402 lbs.

The second year 3 lots of 20 hogs each were pastured on alfalfa and 3 lots on Sudan grass. One lot on each type of pasture received a 1 per cent corn ration, another a 2 per cent corn ration, and the third was self-fed corn. On Sudan grass the light-grain-ration group gained at the rate of 0.19 lb. per day and required 517 lbs. of corn for 100 lbs. of gain. The 2 per cent grain group gained 0.48 lb. and required 419 lbs. of corn, and the self-fed lot gained 1.11 lbs. and required 406 lbs. of corn. The pigs on alfalfa fed the same rations gained at the rate of 0.47, 0.91, and 1.29 lbs., respectively, and consumed 214, 222, and 388 lbs. of corn per 100 lbs. of gain. All lots were put into dry-lot on October 21 and self-fed corn and tankage. The two lots self-fed in summer were ready for market in 2 weeks. The medium-fed lot on alfalfa pasture required 35 days to attain market weight, and the similar lot on Sudan grass required 65 days. The light-fed alfalfa lot reached market weight in 65 days and the light-fed Sudan grass lot was 14 days behind the similar alfalfa pigs and 28.5 lbs. under market weight.

The third summer one lot of 15 pigs on each kind of pasture was self-fed corn and tankage, another lot was self-fed corn, and one lot received a 2 per cent corn ration. The self-fed corn and tankage lot went to market direct from pasture. Those self-fed corn on alfalfa went 2 weeks later, and the 2 per cent corn on alfalfa and self-fed corn on Sudan grass lots followed in 7 weeks. The 2 per cent corn on Sudan grass lot was not ready for 10 weeks after the first group. From these results it is very doubtful if light summer feeding is particularly economical in either rate or cheapness of gains.

Tankage.—The results of several trials showed that the addition of tankage to corn increased the rate of gain, decreased the feed required per unit of gain, and usually increased the net profit. The addition of shorts to a corn and tankage ration had little or no effect upon the rate of gain. Feeding alfalfa hay in addition to corn and tankage did not increase the rate of gain, but decreased the corn and tankage required per 100 lbs. of gain. Feeding tankage on Sudan grass pasture increased the rate of gain.

Self-feeding v. hand-feeding and self-watering v. hand-watering.—Self-feeding and self-watering gave much greater gains at a considerable saving of feed required per unit of gain than hand-feeding or hand-watering. Hand-feeding decreased the rate of gain 0.2 lb. per pig daily, the amount of tankage eaten slightly, the cost of 100 lbs. of gain by 18 cts., and the profit per pig by 31 cts.

Finishing fall pigs, 1924.—When fall pigs were kept through the winter and put on feed when they reached about 150 lbs. in weight, it was found that the 20 pigs confined to a dry lot gave more rapid gain, cheaper gain, and returned more profit than the 25 pigs receiving a similar ration but run on alfalfa pasture. The pigs on dry lot consumed nearly twice as much tankage as those on pasture. One pound of tankage was found to be equal to 3.75 lbs. of shorts when fed as a supplement to corn to 25 157-lb. pigs on alfalfa pasture.

[Feeding experiments with swine at the South Carolina Station] (*South Carolina Sta. Rpt. 1926, pp. 52-54, fig. 1.*)—A brief description of feeding work in continuance of experiments previously noted (E. S. R., 54, p. 665).

Comparison of green forage crops for hogs.—Fifty pigs averaging 40 lbs. in weight were divided into 5 lots. Lot 1 was full fed corn and tankage in dry lot; lot 2 a 2.5 per cent corn ration on green soy bean forage; lot 3 a 2.5 per cent corn and tankage ration on green soy bean forage; lot 4 a 2.5 per cent corn and tankage ration on Sudan grass; and lot 5 a 2.5 per cent corn and tankage ration on cowpea and sorghum forage. The average daily gains per pig were 0.54, 0.69, 0.77, 0.41, and 0.5 lb., respectively. Dry weather affected the growth of forage, especially the Sudan grass.

Hogging down peanuts, sweet potatoes, and corn at the Pee Dee Station.—Two series of tests were conducted; the second series was with later crops after the hogs had consumed the forage in the first series. Forty pigs averaging 118 lbs. were used in these tests. In the first series lot 1 was fed corn and tankage in dry lot. Lot 2 hogged down peanuts alone, lot 3 hogged down peanuts plus a 2 per cent corn ration, and lot 4 hogged down peanuts plus a 2 per cent corn and tankage ration. The average daily gains in this test were 1.66, 1.07, 1.58, and 1.79 lbs. per pig, respectively. The costs of gains were greatest for the dry lot pigs and cheapest in lot 3.

In the second series one lot of pigs on corn and tankage in dry lot made 1.88 lbs. average daily gain per pig. Lot 2 hogging down sweet potatoes plus tankage made 1.02 lbs. gain and lot 3 hogging down standing corn plus tankage made 1.64 lbs. The cost of gain was cheapest in lot 3 and most expensive in lot 1.

[Feeding pigs on pasture in South Dakota], J. W. WILSON (*South Dakota Sta. Rpt. 1925, p. 10.*)—The results of two experiments are briefly reported.

Summer feeding of market pigs.—The results of two experiments in comparing corn, barley, and oats supplemented with tankage for feeder pigs on alfalfa pasture have indicated that when limited grain rations were fed 115 and 118 lbs., respectively, of barley and 143 and 146 lbs., respectively, of whole oats produced the same gains as 100 lbs. of yellow corn. During the finishing period in dry lot on yellow corn and tankage which followed the grazing, the type of ration fed with the pasture greatly influenced the subsequent gains. Estimates of the amount of feed saved by alfalfa pasture showed that in addition to yielding approximately 1.5 tons of hay during the season, 1 acre of such pasture saved over 25 bu. of corn and 579 lbs. of tankage.

A limited corn and tankage ration fed in dry lot did not produce satisfactory returns, as the gains were slow and losses were greater than in lots fed on alfalfa pasture.

Tankage requirements of pigs fed barley on pasture.—Tests showed that 100 lbs. of gain were secured for each 378 lbs. of ground barley and 11 lbs. of tankage fed to pigs with an initial weight of 42 lbs. and carried to a final weight of 200 lbs. These results indicated that barley is a very good substitute for corn, especially when the saving in tankage in this ration is compared with the amount needed in a corn and tankage ration.

Tankage for spring pigs on legume pasture, C. M. VESTAL (Indiana Sta. Bul. 300 (1926), pp. 14, figs. 2).—Twelve trials begun in 1920 and carried on each year for six years have been completed, six with fattening pigs and six with growing pigs. March and April pigs, averaging 74, 62, 68, 76, 74, and 63 lbs. at the beginning of the several tests, were used in lots of 20. Clover pasture was used for 4 seasons and alfalfa pasture the other 2, together with yellow corn, 60 per cent protein tankage, and salt. The pastures were half-acre units. In case of shortage of pasture the pigs were removed to another unit until the original had made sufficient recovery to turn the pigs back on. In the fall when the pasture was gone the feeding was continued in dry lot until the pigs had reached the required market weight of 217 lbs.

In trials for fattening, the corn or corn and tankage was self-fed on legume pasture. In the trials for growth, the corn was limited to 2 lbs. daily for each 100 lbs. live weight. When corn and tankage were fed they were mixed 95 parts corn and 5 parts tankage by weight and fed at the rate of 2 lbs. for each 100 lbs. live weight. In these latter trials the pigs were kept on the growing ration until the close of the pasture season in September, when both groups were finished in dry lot on corn and tankage self-fed.

The following table gives the average returns for the 6 years' work:

Rate of gain and feed requirements of spring pigs

Kind of trial	Average daily gain per head		Feed required per 100 pounds gain				Extra time required by pigs without tankage
	With tankage	Without tankage	With tankage		Without tankage		
			Shelled corn	Tankage	Shelled corn	Tankage	
Fattening.....	1.72	1.38	326.6	24.2	375.5	-----	Days 22
Growing.....	0.72	0.67	263.8	14.5	292.0	-----	
Finishing.....	2.39	2.38	380.6	16.4	357.5	18.8	
Average of growing and finishing.....	1.20	1.18	331.2	15.6	332.0	11.5	

Fattening hogs on squashes and pumpkins, R. T. SMITH and J. SOTOLA (Washington Col. Sta. Bul. 208 (1926), p. 13).—In tests of the feeding value of squashes and pumpkins for hogs, one group of 10 head, averaging 120 lbs. in weight, made an average daily gain of 0.55 lb. per head on pumpkins alone, consuming 31.4 lbs. of the feed per head daily. Analyses of pumpkins and squashes showed that they contain 87 to 91 per cent water, 1.75 to 2.5 per cent crude protein, 1.06 to 0.65 per cent ether extract, 1.5 to 2.1 per cent crude fiber, and 3.77 to 8.92 per cent nitrogen-free extract. The feeding of the seeds alone was likely to cause indigestion as a result of the high fat content.

[Experiments with poultry at the Crookston Substation], C. G. SELVIG (Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 70, 71).—Studies of the effect of the age of hens on the hatchability of their eggs indicated that the hatchability was not as good from eggs laid by extremely old or very young breeding stock as from 2- or 3-year-old hens.

In another experiment no cases of leg weakness developed in a lot of chicks receiving cod-liver oil as a supplement to the dry mash, while in a lot not receiving the cod-liver oil several cases of leg weakness developed which disappeared when the affected chicks received cod-liver oil in the mash. In further tests 1 to 2 per cent of cod-liver oil gave as good results as 3, 4, or 5 per cent in the mash.

In comparing buttermilk and meat meal as protein supplements for laying pullets, a lot receiving buttermilk ad libitum laid an average of 101 eggs during the 212-day test, while another receiving 15 per cent of meat meal in the dry mash fed ad libitum laid an average of 112 eggs in the same period. The calculated cost per dozen was 1.3 cts. less in the buttermilk lot.

The second generation of mating of purebred cockerels and mongrel birds resulted in a marked improvement in the hatchability of the eggs and in the uniformity of the color and size of the chicks and pullets used for egg production. The practicability of special feeding and fattening of turkeys before marketing was demonstrated in another test.

[Experiments with poultry at the South Dakota Station], G. L. STEVENSON (*South Dakota Sta. Rpt. 1925, pp. 33, 34*).—In a test of the use of artificial lighting during January and February one lot of 150 birds lighted for the 2-months period produced an average of 31.25 eggs, while an unlighted lot of 100 birds produced an average of only 23.03 eggs.

In a test conducted to determine the effect of high-fiber-content grains on egg production, one lot of 25 birds receiving barley, oats, buckwheat, and emmer produced 21.72 eggs in 2 months, as compared with 36.56 eggs, the production of another lot of birds receiving a ration of corn, wheat, barley, and oats, with a 20 per cent tankage mash. It is pointed out that the birds receiving the high-fiber feed were overfat.

In another experiment one lot of 25 birds fed oats, corn, wheat, and barley laid an average of 23 eggs per bird, while another pen receiving the same feed plus a 20 per cent tankage mash laid an average of 36.6 eggs per bird in the same period.

In a ventilation experiment the best results were obtained with wind-baffler ventilators combined with straw lofts with gable vents or cupolas.

Eggs held for a period up to 10 days before incubation without turning hatched as well as eggs turned during this period. Holding eggs longer than 10 days caused a reduction in the hatchability, though some eggs held 21 days gave a 50 per cent hatch. The hatching percentages from clean and wiped eggs were 83.3 and 80 per cent, respectively, but only 40 per cent of eggs which had been washed hatched and only 16.6 per cent of dirty eggs.

[Experiments with poultry at the Washington Station] (*Washington Col. Sta. Bul. 208 (1926), pp. 35-38, figs. 3*).—The results are briefly reported.

Breeding and selection, J. S. Carver.—In continuing the pedigree breeding work (*E. S. R., 54, p. 864*), the 595 Single Comb White Leghorns hatched from dams producing over 200 eggs and sires whose dams produced over 250 eggs gave an average production of 235.2 eggs per bird for the year. The 80 Rhode Island Red hens from stock similarly selected produced an average of 217.5 eggs per bird. In studying the relation between conformation and production no correlation was found between different body measurements and production.

Watery whites, J. S. Carver and L. W. Cassel.—An examination of over 4,000 eggs by candling and after breaking showed that the temperature at which the eggs are kept and the length of the storage period had a decided influence on the firmness of the albumen, while feed was not an important factor. Collecting the eggs laid each hour and cooling them in an ice box did not prevent the appearance of watery whites. Eggs stored at a cellar temperature of 70° for three days rapidly became watery.

Feeding, J. S. Carver and L. W. Cassel.—In studies of the comparative value of yeast and diastase as supplements to the college standard laying ration, it was found that these supplements detracted from the ration rather than enhanced its feeding value for egg production. In another test, high egg production resulted from the use of the no-mash method of feeding sour skim milk

plus various scratch feeds, but the standard laying ration proved more profitable.

Report of egg-laying contests for 1925 and 1926, W. H. ALLEN (*New Jersey Stas. Hints to Poultrymen*, 15 (1926), No. 3, pp. 4, fig. 1).—A report of the tenth year of the Vineland international egg-laying contest and the Bergen County international egg-laying contest (E. S. R., 54, p. 766).

Warm water for winter layers, D. C. KENNARD (*Ohio Sta. Bimo. Bul.*, 12 (1927), No. 1, pp. 26, 27, fig. 1).—Directions for insulating a pail with straw or excelsior so that hot water will maintain its heat longer.

Viewing English poultry keepers as neighbors across the way, W. C. THOMPSON (*New Jersey Stas. Hints to Poultrymen*, 15 (1926), No. 2, pp. 4, fig. 1).—The author describes some of the principles and practices of English poultry raisers, particularly considering breeding for quality egg production and cross-breeding.

DAIRY FARMING—DAIRYING

[Feeding demonstrations at the Porto Rico Insular Station], F. A. LÓPEZ DOMÍNGUEZ and M. ELLISON (*Porto Rico Dept. Agr. and Labor Sta. Ann. Rpt.*, 1925, pp. 39, 127-129; also in *Spanish ed.*, pp. 41-43, 132-134).—The results of two feeding demonstrations with dairy cattle are briefly summarized.

Powdered skimmed milk for calves.—The cost of raising a calf on powdered skim milk to 180 days of age was \$10.80. Raising a similar calf to the same age on whole milk cost \$81.

Corn meal v. breadfruit in a dairy ration.—Two cows were fed a ration consisting of corn meal, wheat bran, ground oats, cottonseed meal, and linseed oil meal, 1:3:1:1:1. A second lot of 2 cows was fed a similar ration except that breadfruit meal in equal amounts was substituted for corn meal. Lot 1 produced 1,392.5 lbs. of milk, and lot 2 1,581.3 lbs. The cost of a pound of milk was 2.1 cts. in lot 1 and 2 cts. in lot 2.

[Dairy production at the South Carolina Station] (*South Carolina Sta. Rpt.* 1926, pp. 62-64).—Some of the current problems are noted.

The value of grinding hay for dairy cattle.—Two groups of cows were fed for 120 days by the double reversal method, the only difference in the ration being ground and unground alfalfa hay. The palatability of the hay was unaffected by grinding, and there was no marked effect upon the quantity and quality of the milk. The increased cost of 100 lbs. of milk and 1 lb. of butterfat with the ground alfalfa was 9 cts. and 2 cts., respectively.

A digestion trial with 4 cows in milk with an actual digestion period of 15 days and a 10-day preliminary period showed little difference in the digestibility of either ground or unground hay.

Wintering dairy heifers or roughage only.—Two lots of 8 dairy heifers, averaging about 381 days in age, were fed for a period of 90 days. One lot received roughage alone and was kept in an acre lot with an open shed for shelter. The other lot was fed grain and roughage and housed during the night in the barn. Weights and measurements were taken at regular intervals. The roughage consisted of soy bean hay and corn silage the first 60 days and oat hay and sorghum silage the last 30 days. The heifers receiving the grain ration gained 0.39 lb. per head more per day than those on roughage alone. The daily difference in height growth was 0.009 in. per lot in favor of the grain-fed heifers. The difference in weight was due apparently to storage of fatty tissue.

[Feeding dairy cattle at the Vermont Station] (*Vermont Sta. Bul.* 260 (1926), pp. 11, 12).—In continuing the studies of the protein requirements of dairy cattle (E. S. R., 48, p. 173), a series of nitrogen balances were determined

on four cows fed over a period of 12 months. The results indicated that milch cows are able to maintain satisfactory production on less protein than is required by some feeding standards. The coefficients of digestibility of all the nutrients except ether extract were lower than those calculated from average coefficients for the individual feeds included in the ration.

In the study of the maintenance requirements of dairy cows (E. S. R., 48, p. 374), the addition of steamed bone meal and ground limestone to a ration of timothy hay, corn silage, and a grain mixture changed negative calcium and phosphorus balances to positive. Dry cows on winter maintenance rations also assimilated calcium and phosphorus when so fed. The retention of calcium and phosphorus was reduced when the cows were not exercised.

In continuing the study of the effect of cocoa meal on dairy cattle (E. S. R., 52, p. 677), it was found that the bromine content of this feed was apparently mainly responsible for the increase in the fat content and the decrease in the milk flow which occurred when this product was fed. The average coefficients of digestibility of cocoa meal, as determined in 5 trials with cows, were dry matter, 27; crude protein, 37; cellulose, negative; nitrogen-free extract, 40; and ether extract, 89.

[Experiments with dairy cattle at the Washington Station], E. V. ELLINGTON and J. C. KNOTT (*Washington Col. Sta. Bul. 208 (1926), pp. 18-20*).—The results of two experiments are briefly reported.

A study of calf rations: Powdered buttermilk and semisolid buttermilk.—Eight calves raised on a mixture of 9 lbs. of water to 3 lbs. of semisolid buttermilk or 1 lb. of powdered buttermilk, together with alfalfa hay and a grain mixture, were compared as to their rate of gain in height and body weight with Eckles standards. It was concluded that these substances furnished satisfactory substitutes for skim milk when such was not available at reasonable prices.

Methods of stabling dairy cows.—Studies of the amount of bedding used, amount of labor required, and the cost of construction with steel swinging stanchions with steel stall partitions, wooden box stalls, stalls known as Hoard's Dairyman Model Cow Stall, and a modification of the model stall showed that there was no difference in the time required for feeding and very little difference in the time required for milking. The box stall was the most expensive in all respects, while the model and modified stalls were cheapest to build and required less bedding but a trifle more time for cleaning than did stanchions. The model and modified stalls were much more comfortable for the cows than the stanchions.

Feeding dairy cows, H. O. HENDERSON and J. V. HOPKINS (*West Virginia Sta. Circ. 42 (1926), pp. 22, figs. 2*).—This publication gives the important principles and accepted practices of feeding dairy cows in order to increase milk production. A brief description of the more common feeds and suggestions relating to making and balancing a dairy ration are included.

Twelfth annual report of the creamery license division for the year ending March 31, 1926, W. G. GOSS (*Indiana Sta. Circ. 136 (1926), pp. 24, figs. 2*).—This annual report (E. S. R., 54, p. 377) shows the production of dairy products in Indiana, the creameries inspected, the examination of distributors, revoked licenses, and prosecutions. The names of the licensed manufacturing plants in the State are appended.

Producing cream on the farm, J. V. HOPKINS and G. M. TROUT (*West Virginia Sta. Circ. 43 (1926), pp. 15, figs. 11*).—Methods of producing good milk and cream on farms of West Virginia are explained in this publication. The grades of cream and a list of the absorbed and developed flavors of cream are also given.

[Factors affecting the quality of dairy products] (*Vermont Sta. Bul.* 260 (1926), pp. 11, 12, 13).—In studies of methods of sampling and testing butter for moisture, opening the sample and stirring rapidly just before cooling and immediately before weighing out the portions for analysis has been found to give more accurate and more consistent results than the official method, but stirring with the container open during a considerable portion of the process was found to result in the loss of considerable moisture.

The use of unclean utensils or containers with rusty spots or exposing the cream to bare copper or iron was found to impart undesirable flavors to cream when frozen and stored, but well tinned or lacquered cans had little or no effect on the flavor.

Comparisons of the bacterial plate count and the methylene blue reduction test for determining the quality of milk showed that the latter consistently gave more reliable results.

Studies of the essential factors in the production and marketing of a satisfactory high-grade quality of milk indicated that the elimination of the fore milk tended to reduce the bacterial content, but because of the small quantity of the fore milk the relative effect was slight. Contamination from outside the udder appeared to cause milk to require less time for reduction in the reductase test than the fore milk itself.

Tests of the effect of acidity on the quality of ice cream indicated that the public is able to discriminate between ice cream of high, medium, and low acidity, and that the low acidity product is preferred.

[Factors influencing the quality of butter], T. M. OLSON (*South Dakota Sta. Rpt.* 1925, p. 21).—In studying the effect of a starter on the quality of fresh and storage butter, lots of cream were churned without the use of a starter, after ripening with a starter, and after washing the butter with a starter. Starter butter had a somewhat higher score when fresh and also after 6 months' storage. The variation was slight, and the storage period was short.

Frozen cream when thawed developed a flakiness resembling sour cream in appearance, but this had no effect on the length of time required for churning. The butter showed a short grain as soon as massed from the granular condition and after working was completed. The short-grained condition also prevailed in the storage butter.

The effect of processing on the dispersion of fat in an ice cream mixture, W. H. E. REID and W. K. MOSELEY (*Missouri Sta. Research Bul.* 91 (1926), pp. 25, figs. 11).—A study of different methods of processing ice cream mixes was made to determine the dispersion of fat. All mixes were pasteurized at 63° C. (145.4° F.) for 30 minutes. A 55-lb. batch was drawn off and cooled to 3° to be used as a check. Five 55-lb. batches were emulsified, one once, the others 2, 3, 4, and 5 times, respectively. Fifty-five-pound batches taken from the viscolized mixtures were processed at pressures of from 500 to 5,000 lbs., varying at intervals of 500 lbs. The pressures used on the two-stage homogenizer ranged as follows: 1,000, 1,500–500 and increased 500 lbs. on the first and second valves up to 5,000–4,000. Ten samples were taken to study viscosity and surface tension. Different samples were used each day for 10 days.

Microscopic studies were made the day the mixtures were processed. Bricks were taken from each sample for scoring, for making hardness determinations, and for determining of effect of temperature on stability.

Processing an ice cream mixture increased its viscosity by increasing the surface area of the fat and causing clumping of the fat globules. Clumping of fat globules was due to adsorption of the protein out of the liquid phase.

Processing increased the surface tension by decreasing the size of the fat globules, decreased the stability of the ice cream, increased the smoothness, and aided in the control of the freezing process.

Concentrated sour skim milk, L. A. ROGERS, W. T. JOHNSON, JR., and H. G. ALBERY (*U. S. Dept. Agr., Dept. Circ. 404* (1926), pp. 8).—This publication describes the concentration of sour skim milk under a process patented by the senior author for public use.

Since it is practically impossible to concentrate skim milk at ordinary acidity to a state where it may be preserved, the acidity must be increased. The skim milk to be concentrated should be pasteurized either in a continuous machine at 170 to 180° F. or by the holding method. When the milk is cooled to 115°, 2 per cent of mother starter is added and the agitation continued for several minutes. The mixture is allowed to stand overnight and the temperature kept between 105 and 110°, and at the end of an 18-hour ripening period the acidity should be between 1.7 and 2 per cent of lactic acid. The concentration is then carried on to about 28 per cent solids in the same manner as in concentrating buttermilk.

Wooden containers are recommended for the finished product, since the acid attacks metal. The concentrated skim milk, if the acidity is above 5 per cent, will keep indefinitely even at summer temperatures, except that when exposed to air molds appear on the surface.

Classification of the *Streptococcus lactis* group, B. W. HAMMER and M. P. BAKER (*Iowa Sta. Research Bul. 99* (1926), pp. 281-300).—This is a proposed classification of the lactic acid producing streptococci, including a general consideration of the *S. lactis* group and a description of the classes under this group, some of which have been previously noted (*E. S. R.*, 47, p. 382; 49, p. 376).

VETERINARY MEDICINE

Some recent advances in veterinary helminthology, T. W. M. CAMERON (In *National Veterinary Medical Association of Great Britain and Ireland, Annual Congress at Cambridge, 1925*. London, [1925] pp. 161-183).—This is a review of the more recent discoveries as to worm parasites of domestic animals, their prevention and elimination.

Veterinary science, H. J. FREDERICK (*Utah Sta. Bul. 198* (1926), pp. 68-72).—Feeding experiments to determine the injurious effects of sugar beets and their by-products on horses, sheep, hogs, and cattle are briefly referred to. The data obtained are considered sufficient to lead to the conclusion that beet top silage should not be used in any quantity for horses, but is safe for feeding to cattle, sheep, and hogs. Miscellaneous investigations mentioned include studies of poisonous plants on the range and diseases of dairy cattle, sheep, and poultry.

Annual reports of the official veterinarians of Prussia for 1920-1922 [trans. title], WIEMANN (*Veröffentl. Jahres-Vet. Ber. Tierärzte Preuss.*, 17 (1920-1922 [pub. 1926], pt. 1, pp. 3-164, pls. 21).—This report in continuation of those previously noted (*E. S. R.*, 51, p. 678) deals with and illustrates the occurrence of animal diseases from 1920 to 1922, inclusive, by the use of maps which are inserted.

Annual administration reports of the Civil Veterinary Department in British Baluchistan for the years 1924-25 and 1925-26, N. K. VACHA (*Baluchistan Civ. Vet. Dept. Ann. Admin. Rpts. 1924-25*, pp. 16; 1925-26, pp. 17).—Tabular data which show the occurrence of and control work with infectious diseases of livestock are included in these reports.

Poisonous plants (*Wyoming Sta. Rpt. 1926, pp. 172, 173*).—Studies of three new poisonous plants, a larkspur (*Delphinium venenosum*), a death camas (*Zygadenus washakie*), and the arrow grass *Triglochin maritima*, begun during the year are briefly referred to. The new larkspur was found to be very poisonous, as were the tops of the death camas. Reference is also made to work with the silvery lupine, a bulletin on which was issued during the year (E. S. R., 54, p. 772).

Plant poisoning, J. F. CRAIG and D. KEHOE (In *National Veterinary Medical Association of Great Britain and Ireland, Annual Congress at Cambridge, 1925. London, [1925], pp. 52-113*).—In this paper the authors give a general summary of the present status of knowledge of plant poisoning of livestock as it occurs in Great Britain and Ireland.

Acidosis, trembles, and milk sickness, J. F. COUCH (*Science, 64 (1926), No. 1662, pp. 456, 457*).—The author reports briefly on a biochemical study of animals poisoned by richweed (*Eupatorium urticaefolium* Reichard) and by the rayless goldenrod (*Aplopappus heterophyllus* Blake), the results of which indicate that the animals so poisoned suffer from an acidosis. It is pointed out that the fact that excretion of acetone does not begin until after the onset of the characteristic trembling suggests that the ketogenesis may be a secondary effect of the intoxication. It is considered probable that the toxic principles of these two plants are excreted in the milk of lactating animals, and that the suckling young of animals feeding on these plants may be poisoned and exhibit the characteristic symptoms, such as trembles and acidosis. Consequently, human beings who drink milk or eat butter obtained from cows that have grazed on either of these plants are in danger of being poisoned.

Effects of the administration of sugar, magnesium sulphate, sodium citrate, and dilute acid on the liver damage done by carbon tetrachloride, A. C. CHANDLER and R. N. CHOPRA (*Indian Jour. Med. Research, 14 (1926), No. 1, pp. 219-226, pls. 3*).—The authors have determined that carbon tetrachloride is extremely toxic to cats, very much more so than to dogs. The liver of cats is damaged in the same way as in dogs, but more severely, and in addition the kidney undergoes a profound degree of degeneration accompanied by copious albumin in the urine. Practically the same results were obtained from 0.25, 0.5, and 4 cc. per kilogram. The experiments indicate that administration of sugar simultaneously with carbon tetrachloride tends to delay death for a day or two. Sugar given a few hours before carbon tetrachloride without a second dose simultaneously with it does not appear to have any protective effect. Administration of sodium citrate, tending to increase the alkalinity of the intestines, somewhat reduces the toxicity, while administration of dilute hydrochloric acid increases it. A magnesium sulfate purge also tends to reduce toxicity. In dogs there was found a very considerable individual difference in susceptibility to carbon tetrachloride, but always much less than in cats. A dose of 2 cc. per kilogram caused a central necrosis of the liver lobules, usually amounting to 50 to 75 per cent liver destruction without obvious symptoms. No significant protection resulting from administration of sugar before or with carbon tetrachloride could be demonstrated.

Relation between the chemical constitution and germicidal activity of the monohydric alcohols and phenols, F. W. TILLEY and J. M. SCHAFER (*Jour. Bact., 12 (1926), No. 5, pp. 303-309*).—This is a contribution from the U. S. D. A. Bureau of Animal Industry, in which the authors report that phenol coefficients have been determined for a number of primary, secondary, and tertiary normal alcohols and paraphenols. "When these coefficients are converted from the original gram weight basis to a gram molecular basis the

coefficients of successive members of each series are found to increase almost uniformly, with an average ratio between coefficients of 3.36 for the primary normal alcohols and of approximately 3.0, 2.7, and 3.3 for the secondary normal alcohols, tertiary normal alcohols, and paraphenols, respectively."

The exudate from nutrient agar slants—the so-called water of condensation, D. J. HEALY (*Jour. Bact.*, 12 (1926), No. 3, pp. 179, 180).—This is a contribution from the Kentucky Experiment Station which led to the conclusion that the so-called water of condensation which collects in nutrient agar slant tubes is an exudate from the nutrient agar, possessing nutrient substances suitable for sustaining bacterial growth.

An epidemiological study of endemic typhus (Brill's disease) in the southeastern United States, K. F. MAXCY (*Pub. Health Rpts. [U. S.]*, 41 (1926), No. 52, pp. 2967-2995, figs. 5).—The author finds that a disease giving a positive Weil-Felix reaction, and clinically indistinguishable from typhus fever except with regard to its relative mildness and low fatality rate, is endemic in the southeastern United States.

"The epidemiology of this disease appears to differ significantly from that of Old World typhus. The epidemiological characteristics afford no evidence suggesting louse transmission and are interpreted as being at variance with man-to-man transfer by lice, unless it be assumed at the same time that the disease occurs mostly in unrecognizable form. It is suggested as an hypothesis which seems to afford a more probable explanation of the mode of transmission that a reservoir exists other than in man, and that this reservoir is in rodents, probably rats or mice, from which the disease is occasionally transmitted to man."

Division of veterinary science, J. W. KALKUS (*Washington Col. Sta. Bul.* 208 (1926), pp. 41-43).—Work with abortion of cattle is reported upon, the results from which still show that the presence of infection at the time of full-time calving in abortion-infected cows is the exception rather than the rule. An attempt made to infect two negative heifers during pregnancy by feeding milk per orum gave negative results. An attempt made to determine the tenacity of the organism under varying conditions has shown that cultures may be exposed in bright sunlight as long as 4 hours and still remain viable. Cultures kept at room temperature, varying from 55 to 85° F., in dark closets remained viable in some instances as long as 20 days. Cultures exposed to the elements with the temperature ranging from a few degrees below freezing to 80° remained alive in some instances as long as 87 days. Cultures kept in a refrigerator in a temperature of from 42 to 45° F. remained alive as long as 45 days, and those kept in a dairy barn as long as 26 days. It is pointed out that sterility in adult cows following abortion appears to be due to secondary infection rather than the specific abortion infection.

Red water experiments commenced January, 1924, with heifer calves in an attempt to produce artificial cases have given negative results.

The nature of Bacterium abortus infection in the udder of the bovine, R. A. RUNNELLS and I. F. HUDDLESON (*Cornell Vet.*, 15 (1925), No. 4, pp. 376-390, pls. 2).—This is a contribution from the Michigan Experiment Station. In summarizing the account, the authors point out that, while *B. abortus* was not observed in the histopathological sections, there is circumstantial evidence to incriminate it as being the agent which caused inflammatory foci in the tissues of the udder, and that this conclusion is strengthened by the fact that no other microorganism was isolated from the milk of these cows. A histopathological study of these udders confirms the findings of Cooledge (*E. S. R.*, 41, p. 578) and Tweed (*E. S. R.*, 51, p. 81) that there is a relation of high cellular counts to *B. abortus* infection of the udder.

Bovine abortion—prevention and control—further remarks, M. F. BARNES (*Jour. Amer. Vet. Med. Assoc.*, 68 (1926), No. 4, pp. 429-442).—The author here outlines the Pennsylvania plan for the prevention, repression, and eradication of bovine infectious abortion.

[**Report of zoology department of Wyoming Station**] (*Wyoming Sta. Rpt.* 1926, pp. 178, 179).—In work during the year with the tapeworm *Thysanosoma actinoides*, it was found that material from this parasite scattered over the grass and at the edge of a small pond failed to infect young lambs, and that but one lamb was infested with *Moniezia expansa*. In studies of the muscle-parasite of sheep, *Sarcocystis tenella*, it was found that rats can be infected directly when they eat the spores, and that during the time when they are migrating from the intestinal tract they have a very damaging effect on the health of the animal.

Experiments with mixtures of anti-hog cholera serum and hog cholera virus, J. W. BENNER (*N. Y. State Vet. Col. Rpt.* 1924-25, pp. 231-235).—In the experiments here reported the immunity produced by injecting serum and virus in tissues far enough apart to insure separate absorption proved to be of somewhat higher grade than that produced by the use of the mixture made in vitro and in vivo.

“No product as a result of a neutralization of virus by serum which would permit a decrease in dosage of the latter was observed in either the fresh or stock mixtures. Each entity seemed to retain its properties and action, regardless of the short period of contact as in the case of the fresh mixture, or the long period of contact as in the case of the stock mixture. The stock mixture in the experiment described conferred a desirable grade of immunity in animals vaccinated as long as two months after the mixture was made.”

[**Surra experiments**], K. SINGH ([*Punjab*] *Camel Specialist Ann. Rpt.* 1924-25, pp 3+3+12).—The author reports experimental treatment of surra in equines by intravenous administration of tartar emetic on alternate days with encouraging results. In the treatment of surra in camels and equines with Bayer 205, rapid improvement resulted. In the experimental work the first full dose of trypanamide, followed by a dose of tartar emetic, did not disperse trypanosomes from the peripheral circulation of the surra-affected animal for 6 days. In transmission experiments negative results were obtained with all but one of the three species of tabanids tested, namely, *Tabanus ditaeniatus*, with which in 2 of 11 experiments transmission took place. Further transmission experiments with *Ornithodoros crossii* (*E. S. R.*, 49, p. 157; 54, p. 872) have shown that this tick is capable of transmitting the disease up to 212 days after an infected meal.

The effect of chemicals in the control of poultry diseases.—I, Preliminary experiments with bacillary white diarrhea, H. G. MAY and H. E. SEGELIN (*Poultry Sci.*, 6 (1926), No. 1, pp. 36-41).—This is a contribution from the Rhode Island Experiment Station in which the authors deal with toxicity and infection experiments.

Potassium permanganate 1:1,000, hydrochloric acid 1:250, mercuric chloride-sulfocarbolate mixture 1:10,000, resorcin 1:250 and 1:400, and sulfuric acid 1:500 failed to show any effectiveness in reducing mortality of chicks artificially infected with *Salmonella pullorum*. Hypochlorite in a dilution containing 0.02 per cent free chlorine in four trials involving 80 chicks reduced the mortality over 50 per cent and is considered to warrant further investigation. With the exception of hydrochloric acid and the hypochlorite solution, which produced gains in the infected chicks equal to those of the uninfected controls, none of the chemicals showed any decided benefit to the surviving chicks and in some instances they were harmful rather than beneficial. Fifty per cent of

the mortality of infected chicks occurred from the fifth to the eighth day, the peak appearing on the fifth day. The agglutination test performed on surviving chicks about three weeks after infection revealed only a few sporadic reactors.

Problems arising in the control of bacillary white diarrhea, L. D. BUSHNELL and W. R. HINSHAW (*Poultry Sci.*, 5 (1926), No. 6, pp. 249-256).—This is a contribution from the Kansas Experiment Station, read at the annual meeting of the American Association of Instructors and Investigators in Poultry Husbandry, at Manhattan, Kansas, in August, 1925. A list is made of the facts which should be brought under very careful study, the status of which is briefly considered.

A preliminary note on the bacteriophage of fowl cholera [trans. title], L. BROUDIN (*Compt. Rend. Soc. Biol. [Paris]*, 95 (1926), No. 35, pp. 1332, 1333).—The author records the discovery in November, 1925, of the antifowl cholera bacteriophage in the bone marrow of the tarsus of a fowl that had succumbed to the disease. The investigation here reported upon was conducted at the laboratory of animal microbiology at the Pasteur Institute of Saigon.

The bacteriophage in relation to Salmonella pullora infection in the domestic fowl, N. J. PYLE (*Jour. Bact.*, 12 (1926), No. 4, pp. 245-260, pl. 1).—This is a contribution from the Massachusetts Experiment Station in which the author reports upon studies made of the intestinal contents, fluids, and tissues from the domestic fowl, with a view to locating and identifying a bacteriophage lytic for *S. pullora* in these materials. Methods were employed for increasing the lytic activity of the avian bacteriophage in vitro to the end of using it as a therapeutic reagent in avian therapeutics. The data presented and observations made have led the author to consider the following conclusions justified:

"Tissues of the domestic fowl do contain bacteriophages causing lysis of various strains of *S. pullora*. Up to the present time, although these avian 'phages' are lytic for *S. pullora*, it has not been demonstrated that they are specific only for this organism. When agar slant cultures of *S. pullora* are treated with liquid cultures of these avian bacteriophages which are lytic for *S. pullora*, watery, moth-eaten, or pellucid areas are demonstrated. This fact, together with the demonstration of the transmission of bacteriophagy for *S. pullora* in series would indicate that the transmissible bacteriolytic is a living ultramicroscopic entity. These reactions of the avian bacteriophage are characteristic of d'Herelle's 'bacteriophagum intestinale.' Although the bacteriophages isolated and studied have demonstrated marked bacteriolysis in vitro, the evidence from animal experiments does not indicate that as now prepared and used they have much therapeutic effect in freeing the bird's body of infection. Bacteriophages actively bacteriolytic for *S. pullora* have been isolated from domestic fowls showing a high agglutinative titre for this organism."

A list of 26 references to the literature is included.

Fowl plague, E. L. BRUNETT and S. KONDO (*N. Y. State Vet. Col. Rpt.* 1924-25, pp. 209-224).—Following a brief reference to the occurrence of this disease abroad, the authors report upon its occurrence in New York State, the nature of the disease and its etiological factor, the infecting dose of the virus blood, and the thermal resistance, longevity, and transmission of the virus. A list of 43 references to the literature is included.

A new and efficient method for removing intestinal parasites from poultry, J. W. IRELAND and A. R. LAMB (*Poultry Sci.*, 6 (1926), No. 1, pp. 42-49).—The authors point out that according to various estimates farm poultry are from 25 to 75 per cent infested with one or more of the three most common

varieties of intestinal worms, namely, the large roundworm (*Ascaris inflexa*), the common tapeworm (*Taenia fundibuliformis*), and the small round cecum worm (*Heterakis papillosa*), which cause tremendous losses to the poultry industry. They here describe a method that is considered very efficient in removing the large roundworm and the common tapeworm. The birds are treated individually by use of a syringe containing a mixture consisting of oil of chenopodium, thymol, turpentine, and cottonseed oil.

AGRICULTURAL ENGINEERING

[Irrigation, drainage, and soil physics studies at the Utah Station] (*Utah Sta. Bul. 198 (1926)*, pp. 51-56).—The progress results on snow surveys, on flood and gravel control, and on fundamental soil moisture constants are briefly reported.

It was found by W. Gardner and O. W. Israelsen that if the angle of contact of the surface of contact of water and soil grains is zero, a soil kept in a dark chamber can not be in equilibrium with saturated water vapor without becoming completely saturated with water. This leads to a new interpretation of the so-called hygroscopic coefficient, in that it becomes a measure of the moisture condition at equilibrium between soil and water in the presence of light, but this moisture condition changes with the intensity of the light.

Some experimental evidence has been accumulated indicating that the angle of contact involves the curvature of the surface of separation of the liquid and solid phases. It is suspected that the surface tension, heretofore regarded as a constant for a given liquid and a given solid, may itself vary over a slight range for varying curvature. Further conclusions indicate that heavy soils may be completely saturated at various levels above the water table.

[Irrigation investigations at the Irrigation Substation], C. C. WRIGHT (*Washington Col. Sta. Bul. 203 (1926)*, pp. 62-65, fig. 1).—The progress results of studies on the economical use of irrigation water and on alkali and the reclamation of alkali soils are briefly reported (*E. S. R.*, 54, p. 875).

Surface water supply of the Great Basin, 1921 (*U. S. Geol. Survey, Water-Supply Paper 530 (1926)*, pp. V+194, pls. 2).—This report, prepared in cooperation with the States of Idaho, Utah, Nevada, California, and Oregon, presents the results of measurements of flow made on streams of this basin during the year ended September 30, 1921.

Surface water supply of Hudson Bay and upper Mississippi River basins, 1923 (*U. S. Geol. Survey, Water-Supply Paper 565 (1926)*, pp. V+199, pls. 3).—This report, prepared in cooperation with the States of North Dakota, Minnesota, Wisconsin, Iowa, Illinois, and Missouri, presents the results of measurements of flow made on streams in these basins during the year ended September 30, 1923.

United States Government master specification for varnish, spar, water-resisting (*U. S. Dept. Com., Bur. Standards Circ. 103, 4. ed. (1926)*, pp. 6).—The text of the specification is given.

Synthetic motor spirit from mixtures of carbon monoxide and hydrogen [trans. title], E. AUDIBERT (*Chim. et Indus. [Paris]*, 13 (1925), No. 2, pp. 186-194; trans. in *Fuel*, 5 (1926), No. 4, pp. 170-177).—Experiments are reported which draw attention to the catalytic activity of binary compounds containing oxygen having sufficient reducing power to oxidize spontaneously in air. These unsaturated compounds bring about the hydrogenation of carbon monoxide. Mixtures of carbon monoxide and hydrogen were found to undergo with suboxides the change expressed by the equation $\text{CO}_2 + 2\text{H}_2 = \text{CH}_3\text{OH}$, from

which it is calculated that 82 per cent of the calorific value of the gas may be recovered in the form of liquid fuel.

Lubricating value as related to certain physical and chemical properties of oils, L. W. PARSONS and G. R. TAYLOR (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 493-496, figs. 5).—A brief review of the theory of lubrication is given, together with a discussion of the application of this theory to a few special cases, with particular reference to the value of certain tests.

The rôle of oiliness in industrial lubrication, W. C. WILHARM (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 463-467, figs. 3).—The importance of efficient lubrication is outlined, and the mechanism and possibilities for improving this factor, especially as it applies to electrical machinery and such other types as are not subjected to high temperatures, are discussed. The property of oiliness is considered as a means of improvement, and a modified inclined plane is described as a method of measuring this property.

A number of determinations were made with a brass plate and steel slider lubricated with several typical lubricants. The results showed a difference in the lubricating value of various lubricants that is not shown in the tests usually made.

A comparison of a Pennsylvania crude with a lubricating fraction of the same material showed that the process of refinement was not detrimental to the oiliness property of the oil.

The conclusion is drawn that the secret of good oiliness is to have a tenaciously adsorbed film of such thickness that the projecting asperities can not interlock. The friction would thus be a function of the attractive forces of the metals, the tensile strength of the metals, and the internal friction of the lubricant. It is thought that this may partly explain why soft bearing metals such as the babbitts give lower resistance than the harder metals.

Surface action and fluid film lubrication: Some film thickness measurements, A. E. BECKER (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 471-477, figs. 17).—Studies are reported which showed that to obtain fluid film lubrication there must be adequate adhesive forces between the lubricant and the bearing surfaces. This indicates four general types of bearing combinations. An apparatus for measuring the film thickness developed is described, and data for four oils and four bearing combinations are reported.

The general equation for film thickness in terms of load, speed, and viscosity is found to be

$$t = K \left(1 - \frac{\log P}{A} \right) \left(1 - \frac{\log S}{B} \right) \left(1 - \frac{\log \mu}{C} \right)$$

in which K , A , B , and C are constants depending upon surface action forces, P is the load, S is the speed, and μ is the absolute kinematic viscosity.

The rôle of graphite in lubrication, F. L. KOETHEN (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 497-499, figs. 6).—Tests on a Riehle machine to determine the amount of pressure required to rupture the fluid film in a 3-in. bearing rotating at constant speed and measurements of the coefficient of friction of weighted sliders, in each case using oil with and without suspended graphite, are reported.

Both methods of test showed that under conditions of ruptured film lubrication with some solid-to-solid contact the presence of graphite substantially reduced the friction. Graphite was found to be effective in prolonging the period of unbroken film lubrication and in the ruptured film stage reduced friction and minimized metallic contact. This is explained on the basis that it deposits to a certain extent in the low places of the metal, thus making a smoother surface, and that when solid-to-solid contact does take place it abrades more readily and with less friction and damage than would plain metal surfaces.

Some little understood factors affecting lubrication, E. G. GILSON (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 467-470, figs. 12).—Studies are reported which showed that changes in friction can not always be satisfactorily explained by changes in viscosity of the oil due to a change of its temperature. Oil film friction is shown to be influenced by a change of one of the metals between which the film is working and also by changing from an oxidizing to a non-oxidizing atmosphere. It is demonstrated by means of a complete bearing within an inclosure how the friction is affected by the atmosphere surrounding the bearing.

It is concluded that the facts shown can not be explained by the viscosity-temperature changes of the oil, and it is suggested that efficient lubrication may depend upon a reaction between the metals of the bearing and the oil, the nature of which is influenced by the atmosphere in which the bearing is operated. The reaction seems to be accelerated when both oxygen and moisture are present.

Oil flow in plain bearings, D. P. BARNARD, IV (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 460-462, figs. 6).—This paper describes a simple method of developing the approximate laws controlling oil flow through bearings, due both to the pressure developed in the film and to oil feed pressure, and presents some experimental data in substantiation of this method.

Power and the viscosity of oil, W. F. PARISH (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 525, 526, figs. 2).—Studies are briefly reported from which the conclusion is drawn that the value of the lubricant for use under modern conditions in continuous lubrication systems is not entirely indicated by the viscosity of the oil when new.

Lubrication data from coöperative fuel research, S. W. SPARROW and J. O. EISINGER (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 482-485, figs. 4).—A continuation of studies by the U. S. Bureau of Standards is reported which give data on crank case oil dilution, the effect of dilution on viscosity, and viscosity requirements. The data indicate that in general breakaway torque is not affected by changes in the viscosity of the oil upon the cylinder wall, regardless of whether these changes are produced by a change in temperature of the jacket water or by a change in the original viscosity of the oil in the crank case. Similar results were obtained when the engine was rotating very slowly. At higher speeds, however, a marked influence of viscosity upon engine friction was apparent.

These results are taken to indicate that when an engine is started, or when it is being rotated extremely slowly, practically all of the oil is squeezed out from between the rubbing surfaces and lubrication is dependent almost entirely upon the so-called oiliness film. This belief is supported by the fact that the addition of 5 per cent of lard oil containing 2.9 per cent oleic acid reduced the breakaway torque by about 25 per cent.

Principles underlying the use of equilibrium oils for automotive engines, R. E. WILSON and R. E. WILKIN (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 486-490, figs. 7).—This paper presents a theoretical analysis of crank case oil dilution and the development of the fundamental laws, assuming that dilution approaches an equilibrium condition in the crank case. Experimental data from road tests and dynamometer trials were obtained to determine the constants and to test the validity of these laws.

These data show that under average conditions the crank case oil loses about two-thirds of its viscosity in the first 150 miles of winter service, and thenceforth remains practically unchanged if operating conditions are constant. In order to make an oil which will give satisfactory starting and cold lubrication and will at the same time have sufficient viscosity at all times in the average

engine, it is suggested that a heavy oil of from 425 to 525 seconds viscosity at 100° F. be blended with from 10 to 12 per cent of a distillate having a boiling range substantially identical with that found in the average crank case at equilibrium. It is possible, by this means, to produce an oil with an initial viscosity of about 200 seconds which gives easy starting and adequate cold lubrication, and yet is so near the average equilibrium dilution that in general it maintains an optimum viscosity throughout its entire service. The results of extensive tests of such oils are presented.

Motor carbon deposits formed under controlled conditions from typical automobile oils, C. J. LIVINGSTONE, S. P. MARLEY, and W. A. GRUSE (*Indus. and Engin. Chem.*, 18 (1926), No. 5, pp. 502-504, figs. 3).—Apparatus developed at the Mellon Institute of Industrial Research is described which consists of a small single-cylinder motor provided with a special lubricating system, permitting circulation of a very small charge of lubricating oil, and with devices enabling the very close control of the head, oil, and intake temperatures, the amount of fuel, and the composition of the fuel mixture, as well as the load on the motor and its speed. The modified motor can be so operated as to permit close duplication of conditions, and, with a given lubricating oil, the carbon deposits in the combustion chamber can be checked very closely in a series of runs.

By use of this apparatus results are reported from which the belief is expressed that there is a close connection between the volatility of an oil and its carbon depositing tendency. If an oil contains a fair proportion of hydrocarbons nonvolatile at the prevailing temperature of the metal surface, such as a steam-refined cylinder stock, this residue will progressively crack and oxidize to sticky and asphaltic materials, which will gradually bake into dense, adherent deposits. If, on the other hand, the oil can distill off fairly cleanly it will probably take much longer to produce a deposit of equal thickness. In addition it appears that a deposit from such a volatile oil will contain a small amount of binding material, and will therefore be more friable than a deposit from a higher boiling oil.

The tractor on California farms, L. J. FLETCHER and C. D. KINSMAN (*California Sta. Bul.* 415 (1926), pp. 35, figs. 27).—The purpose of this bulletin is to aid the farmers of California in the choice and successful operation of their field power and to impress upon manufacturers and dealers the need of supplying tractors of the proper design and type to meet the special requirements for farming in California. The information presented is based on data obtained from replies to questionnaires sent to all known tractor owners in the State and from contact with tractor owners.

Electricity in Oregon agriculture, G. W. KABLE ([*Corvallis*]: *Oreg. Com. on Relation of Elect. to Agr.*, 1926, pp. 48, figs. 22).—This is the 1926 annual report of the Oregon Committee on the Relation of Electricity to Agriculture, the investigational work of which is conducted by the Oregon Experiment Station (E. S. R., 53, p. 891).

In the work with electricity in poultry raising the use of electric lights in laying houses during the short winter days has been found to result consistently in increased egg production. The cost of power for lights and extra feed consumed is relatively small compared with the increased returns, the cost of installing the lights being the more important item of expense. Electric brooders have been found satisfactory if properly operated. Electricity for brooding usually costs more than oil, but eliminates much of the labor and most of the hazard. See also a previous note (E. S. R., 56, p. 481).

Studies on the use of electricity in horticulture have shown that the capacity of a dehydrator is approximately doubled by recirculating part of the heated

air with a fan. The amount of fuel used per ton of dried product is decreased, the operation of the dehydrator is under better control, and the dried product is usually better and more uniform where the air is recirculated. The construction cost of dehydrators per ton capacity is less for the recirculation than for the natural draft type. The use of electric motors as sources of power for driving fans has been found to introduce greater reliability for continuous service, more uniform power, and lower cost for labor in operating and for repairs. Electricity for lights and for power to operate oil burners, water pumps, traying machines, graders, and washers in dehydration plants has been found to save labor and result in a better product.

The electric power required for grinding feed with mills now on the market has been found to average a little more than 0.5 kw. hour per 100 lbs. of grain. Feed can usually be ground in less time than it can be sacked, hauled to town, and returned.

Work with electric hay hoists showed that an electric hay hoist will replace a team and possibly an extra man and horse during haying. The power used in putting hay in the barn was less than 0.5 kw. hour per ton. It was found that a hay hoist should be simple, and the power required should be no more than 5 h. p. and preferably 3 h. p. A satisfactory hoisting speed is from 150 to 200 ft. per minute, and the pullback speed should be no greater than the hoisting speed. The drums should be not less than 6 in. in diameter and preferably larger. It is not essential to have a clutch on a single-drum hoist if there is a sliding gear to free the drum. Drums should always be provided with brakes and should be free running when the clutch or pinion is disengaged. In large barns and where large amounts of hay are handled, a double-drum hoist with cable speeds of 200 ft. per minute is desirable.

Other data are reported on electric pumping for irrigation, hoisting earth from a well, the operation of silage cutters, elevating grain and shavings, and shearing sheep.

Electric development as an aid to agriculture, G. E. TRIPP (*New York: Knickerbocker Press, 1926, pp. VII+78, pls. 6, figs. 2*).—This book contains chapters on power on the farm, the farm problem, restoring the balance between industry and agriculture, power and its distribution, and the future of national electric service.

Farm lighting systems, M. M. JONES (*Missouri Sta. Bul. 243 (1926), pp. 19, figs. 4*).—Three types of farm lighting systems are described, namely, the acetylene and individual electric types and the system receiving energy from the rural electric line. The results of a questionnaire to determine the degree of satisfaction that each of these types is giving in actual use are also presented.

The data on acetylene plants indicate that the greatest objections are time and trouble of recharging, high cost, and the fact that this system can not be used for power. The cost of light from this system is not high as compared to electric lights and is very little, if any, higher than light from kerosene lamps. The greatest disadvantages of individual electric plants are the expense, the time and trouble required to care for the plant, and the inability of the plant to operate large motors. It is stated that a rural electric line is the ideal source of electricity for the farm where it can be economically secured.

RURAL ECONOMICS AND SOCIOLOGY

[**Rural economics investigations at the Ohio Station**], J. I. FALCONER (*Ohio Sta. Bimo. Bul., 12 (1927), No. 1, pp. 28-32*).—The results of work in rural economics are given.

Less land area required to feed Ohio horses.—Based on the decrease in the number of horses in Ohio from 1910 to 1925 and on cost studies showing that horses on farms with tractors were fed 15 per cent less than those on non-tractor farms, it is estimated that 1,194,000 acres, or approximately 10 per cent of the total crop acreage, used to produce feed for horses within the State in 1910 are no longer necessary for that purpose.

Ohio farm and city valuation as shown by index numbers, 1915 to 1925.—Index numbers (1915 valuation=100) are given by years for city and farm real-estate values in Ohio as appraised for taxation from 1913 to 1925 and for farm land values as reported by the crop-reporting service. From 1915 to 1925 the value of real estate increased 187 per cent in Cleveland, 125 in Columbus, 90 in Cincinnati, and 115 per cent in all cities and incorporated villages, while that for farm land decreased 3 per cent.

Labor requirements for corn production in 1907-1912 v. 1920-1924.—The production of an acre of corn required 36 hours of man labor and 48 hours of horse labor in 1907-1912, and 25 hours of man labor and 38 hours of horse labor in 1920-1924. The distribution of man labor among various operations is shown for 1907-1912 and for 1920-1927.

Index numbers of production, wages, and prices.—Index numbers previously noted (E. S. R., 56, p. 285) are continued through October, 1926.

[*Investigations in agricultural economics at the South Carolina Station (South Carolina Sta. Rpt. 1926, pp. 21-31, figs. 2).*—The results obtained on a number of projects not previously noted (E. S. R., 55, p. 538; 56, pp. 84, 286) or noted from Bulletin 233 on page 582 are reported on.

Special farm management study of Seneca community.—The average capital per farm was about \$12,000, and the average acreage about 100 acres, of which approximately 30 acres were in cotton and 22 acres in corn, oats, and other grains. About 20 acres of crops were grown per man-equivalent and 19 acres per work animal. One hundred and seventy work units per man and 90 per mule were obtained annually. Nearly \$500 worth of food and other products for family use were produced per farm.

Production, supply, and demand study of Greenville trade area.—Cotton is the principal money enterprise. Farm organization could be improved by growing more feeds and foods for farm use and local sale. Dairying, poultry raising, and truck growing offer opportunities.

Cotton marketing study.—Considerable discrepancy was found between buyers' and government grades for identical cotton in the Orangeburg, Barnwell, and McCormick markets, and also between local prices and the prices in central markets at Augusta and Atlanta, Ga. A study of gin and seed conditions showed that not all farmers were using the best seed, and that proper precautions were not being taken at the gins to keep seed pure.

A comparison on the basis of net income of twenty profitable and twenty unprofitable farms of Lincoln County, L. E. LONG (Mississippi Sta. Circ. 67 (1926), pp. 6).—The 20 most profitable and 20 least profitable farms, selected on the basis of records of 80 farms collected for the year 1924, show a net cash income of \$1,298 and minus \$47, respectively. Tables are given comparing for the two groups the averages for the investment in real estate and working capital, utilization of land, acreage of different crops, cash sales of and prices received for different crops, items of farm expenses, amount and cost of fertilizers, cash sales of and expenses on livestock, numbers of different kinds of livestock, etc.

Some farming changes in southwestern North Dakota, 1922 to 1925, R. E. WILLARD (*North Dakota Sta. Bul. 201 (1926), pp. 19, fig. 1*).—The results obtained by the farm management survey of 159 farms made in 1923, previously noted (*E. S. R., 52, p. 291*), are compared with similar data from 130 of the same farms obtained by the 1925 agricultural census of the U. S. Bureau of the Census.

Size of farm varied from 160 to 3,600 acres in 1922 and from 160 to 8,080 acres in 1924, but the average size decreased from 817 to 770 acres. Farms less than 480 acres tended to increase in size and those over 480 acres to decrease, from 480 to 640 acres appearing to be considered the economic unit. The average number of acres per farm owned and rented decreased from 578 to 537 and from 239 to 233 acres, respectively.

The average value per farm of real estate decreased from \$17,270 in 1922 to \$11,315 in 1925, of livestock from \$2,186 to \$1,918, and of machinery from \$1,743 to \$1,375. The farms doing a small business maintained the value of their livestock, and those having current expenses of \$1,000 to \$2,000 increased their machinery investment.

The average acreage in crops increased from 276 to 279 acres, the change being due to increases of 1 acre each in alfalfa, oats, and barley, 26 acres in flax, 5 acres in corn, and 4 acres in sweet clover and decreases of 22 acres in wheat, 6 acres in rye, and 7 acres in other crops. Horses increased from 11.3 to 11.7 head per farm; milk cows decreased from 10.3 to 9.2, and other cattle increased from 20.6 to 26 head; and sows increased from 2.5 to 5.2, other hogs from 1.4 to 13.4, and poultry from 74 to 90 head. The percentage of farms operating tractors increased from 30 to 39.

The average assets and liabilities per farm both decreased approximately 29 per cent, being \$23,084 and \$3,468, and \$16,493 and \$2,473, respectively, for the two years. In 1922 full owners operated 29 per cent of the farms and owner tenants 71 per cent, and in 1924 full owners operated 36, owner tenants 60, and tenants 4 per cent.

A study of economic conditions in the Lexington-Batesburg section of South Carolina, B. A. RUSSELL (*South Carolina Sta. Bul. 233 (1926), pp. 36, figs. 12*).—This bulletin deals primarily with the organization of the farm business, the factors affecting income, and the cost of production of the more important crops of the section. It is based upon records gathered from 141 farms in 1924.

The average farm comprised 185 acres, of which 71 acres were in woods, 20 in pasture, 9 in tillable land lying out, 12 in waste land, and 73 acres in crops as follows—cotton 27.4 acres, corn 25.1, oats 11.3, wheat 3.4, rye 1, and miscellaneous patches, garden, and truck 4.8 acres. The cash crops were cotton, averaging 69.3 per cent of the gross receipts; asparagus and corn, each averaging 4.4 per cent of the receipts; and peaches. The average total investment per farm was \$13,708, distributed as follows: Land \$7,450, buildings \$3,426, cash \$1,237, livestock \$663, feed and supplies \$588, and machinery and equipment \$344. The farm receipts averaged \$2,747, expenses \$1,832, farm income \$915, labor income \$230, return on capital 4.9 per cent, and operator's earnings \$1,221. The net return on cotton was \$19.48 per acre, or 6.5 cts. per pound, and asparagus \$52.27 per acre. The cost of developing asparagus to 4 years of age was \$109.41 per acre, and of producing peaches 58 cts. per bushel at the orchard unpacked.

A survey of the cattle industry in the Nebraska sand hills, H. HEDGES (*Nebraska Sta. Bul. 215 (1926), pp. 22, figs. 2*).—The results are given of a survey made in 1925, in cooperation with the U. S. D. A. Bureaus of Agricul-

tural Economics and Animal Industry, of the operations from April 1, 1924, to March 31, 1925, of 71 ranches in the sand hill region of Nebraska. The average size of the ranches was 7,749 acres, the value of the ranch real estate \$47,813, and the ranch personal property \$29,078. The average total receipts were \$8,965, expenses \$5,288, and interest on borrowed money \$2,236. Allowing \$987 for wages for operator and family, the return on the operator's equity in capital invested was 0.99 per cent. Fifty of the ranches reported real estate mortgages and 51 chattel mortgages, only 15 per cent being free of both. Interest rates varied from 5 to 9 per cent for real estate and from 6 to 10 per cent for chattel mortgages. A comparison of the 15 best and 15 poorest ranches showed the following, respectively: Total investment \$62,140 and \$84,684; receipts \$9,654 and \$6,666; expenses \$3,890 and \$5,823; percentage of income to investment 9.28 and 1.0; number of cows 247 and 262; percentage of calves to cows 78.0 and 66.9; death losses among all cattle 0.77 and 0.86 per cent and among cows 0.76 and 1.20 per cent; labor cost per head \$4.21 and \$4.98; months of labor per 100 head 8.5 and 9.3; cattle cared for by one man 142 and 130; receipts from range cattle 84.7 and 88.2 per cent, from other livestock 5.4 and 9.0 per cent, from livestock products 3.4 and 1.2, and from crops and other sources 6.5 and 1.6; total receipts, percentage of total investment 14.3 and 6.8; cattle receipts, percentage of cattle investment 37.3 and 28.2. Pasture management, ownership v. leasing of land, age and quality of cattle for marketing, markets, etc., are discussed.

Economic aspects of citrus-fruit growing in Polk County, Fla., C. R. SWINSON and W. C. FUNK (*U. S. Dept. Agr. Bul. 1435 (1926), pp. 40, figs. 11*).—This report is based upon the study of the records of 100 citrus grove farms from 1917 to 1922. The farms averaged 41 acres, of which 9.7 acres was woodland, 3.7 waste land, and 27.6 acres tillable land, 26 acres of which was in crops, 7.6 being in bearing grapefruit, 9.7 in bearing oranges, 1.1 in other bearing citrus fruits, 1.5 in nonbearing grapefruit, 4 in nonbearing oranges, 0.4 in nonbearing tangerines, and 1.8 acres in hay and other crops. The citrus situation in the United States, the section studied, the selection of a grove site, the organization of citrus farms, and grove operations and practices of the section are described.

The average capitalization per farm in the section increased from \$20,656 in 1917 to \$41,776 in 1922, and the net return to capital and for supervision varied from \$1,213 to \$6,680, averaging \$4,192 per farm. The cost of developing an acre of citrus grove up to and including the fifth year, allowing \$125 for cost of land and charging interest at 8 per cent, was \$536.

Harvesting and marketing cantaloupes and honey dew melons in the Arkansas Valley of Colorado, seasons of 1924 and 1925, N. D. SANBORN (*Colorado Sta. Bul. 312 (1926), pp. 59, figs. 21*).—The harvesting, standardization and inspection, and marketing methods and practices in the Arkansas Valley district are described. The average cost per acre and per crate of harvesting and marketing and the average returns realized from the 1924 and 1925 crops are shown. The gross sales of cantaloupes in 1925 amounted to \$333.39 per acre, of which 10.5 per cent went for labor, 11.8 per cent for materials, 0.2 per cent for association dues, 0.4 per cent for inspection, 42 per cent for freight, and 15.1 per cent for commission. The gross sales of honey dew melons in 1925 were \$488.78 per acre, of which 6.7, 16, 0.15, 0.35, 43.4, and 15.4 per cent, respectively, went for the various items of expense. Gross sales per acre in 1924 were \$2.86 less for cantaloupes and \$8.84 for honey dew melons, but the expenses absorbed 5 and 4 per cent, respectively, less of the gross receipts.

An economic study concerning the operations of fruit and vegetable shippers in western New York, R. B. CORBETT (*New York Cornell Sta. Bul. 453 (1926), pp. 67, figs. 7*).—This bulletin presents the results of an investigation to ascertain the costs of the marketing services performed by fruit and vegetable shippers in western New York and the margins taken by them. The data were determined for apples in barrels, apples, peaches, and pears in bushels, and cabbage in bulk.

Of the amount returned to shippers for all products studied in 1922-23, 69.6 per cent was paid to growers, 27.6 per cent went for handling charges, 2.3 for allowances, and 3.1 for management costs, leaving a loss of 2.6 per cent, which was reduced to 1.6 per cent by the income from by-products. In 1923-24, 92.9 per cent of the return to shippers was paid to growers, the handling costs equaled 27.7 per cent, allowances 0.6, management cost 3.9, and income from by-products 0.9 per cent, leaving a loss of 24.2 per cent to the shippers. Of the city sale price of the total shipments on consignment in 1922-23, 28.6 per cent went to pay costs from the shipping point to the first sale in the city, leaving 71.4 per cent for the shipper. The grower received 55.9 per cent of the city sale price. In 1923-24, the costs from the shipping point to the first sale in the city absorbed 27.2 per cent of the city sale price, leaving 72.8 per cent for the shipper. The grower was paid 81 per cent of the city sale price, making a loss of 8.2 per cent for the shipper.

The average cost per barrel of storing 45,600 barrels of apples from October, 1923, to May, 1924, was 72.2 cts. and the shrinkage 3.8 per cent.

The products shipped were widely distributed, being sold in from 41 to 129 markets in from 13 to 27 States and countries in 1922-23, and in from 24 to 143 markets in from 9 to 24 States in 1923-24. An appendix includes a description of the method of calculating costs of handling each product and copies of the forms used in collecting the data.

Great Lakes—St. Lawrence deep waterway: Its value to North Dakota, O. M. FULLER and A. H. BENTON (*North Dakota Sta. Bul. 204 (1927), pp. 36, figs. 17*).—The need of North Dakota for cheaper transportation and the value of the proposed Great Lakes—St. Lawrence deep waterway to the State are discussed. It is estimated that the proposed waterway will increase farm prices, due to reduced freight costs, on exports to Europe by 5.6 to 12 cts. per bushel on grains and \$11 per short ton on pork and pork products, and that the estimated reduction on freight costs of poultry and eggs will be at least 50 per cent. Examples of the probable savings in costs of foods and raw materials for manufacture shipped into the State are given.

Federal aid as a part of a long-time agricultural policy, with special reference to the distribution of tax levies, E. ENGLUND (*Kansas Sta. Bul. 237 (1926), pp. 54, figs. 12*).—This is a general study of the present policy of Federal aid for research in agriculture and for agricultural extension, vocational education, and rural highway construction. Its purpose is to indicate the relation of this policy (1) to the general public welfare and (2) to the distribution of the tax levies, particularly in agricultural States such as Kansas. The precedents for, the constitutionality, and the principal criticisms of Federal aid are discussed. An analysis is made of the National and State relations in Federal aid as regards (1) the State and local initiative, (2) the diversion of funds to purposes of subordinate local importance, and (3) the fairness in the distribution of taxes among the States.

The acts of Congress providing Federal aid for research and education in agriculture and for road construction have given broad scope for State and local initiative, and the actual workings of such acts have stimulated such

initiative and afforded opportunity for cooperative self-help in local communities. That the people have shown their preference for the public services given Federal aid is evidenced by the fact that the State and local expenditures for each dollar of Federal funds averaged \$6.11 in 1924 for agricultural experiment stations, \$2.13 for agricultural extension in 1923, \$2.90 for vocational education in 1924, and \$13.79 for road construction in 1925, notwithstanding that the Federal acts require no matching of funds in the case of the agricultural experiment stations and only dollar for dollar matching in the case of the other funds. The opinion that Federal aid results in an unfair distribution of taxes among the States overlooks the facts (1) that the States as such pay no Federal taxes; (2) that taxes are not always paid where collected, i. e., are shifted; and (3) that the benefits of Federal aid are not confined to the State in which the money is expended.

Industrial and commercial development have brought about an enlargement of the economic unit—the territorial unit in which there is substantial economic interdependence, but the size of the local taxing units—counties, townships, school districts, etc.—in which the major share of the taxes (85 to 89 per cent in Kansas from 1910 to 1923) is levied, has remained the same. These small taxing units within large economic units probably result in an unfair distribution of tax levies, especially where, as in Kansas, tangible property is the main source of revenue. Federal aid partly offsets the disadvantages of the small taxing units, and it is probable in the future that public functions which are general in character will receive relatively more support from the larger taxing units than in the past.

Taxation of farms in Missouri, C. O. BRANNEN and S. D. GROMER (*Missouri Sta. Research Bul. 93 (1926), pp. 19*).—The investigation reported was made in cooperation with the U. S. Department of Agriculture. General property taxes, which form the bulk of farm taxes, constituted 85 per cent of the revenues from taxes in 1890 and 83.2 per cent in 1922. The average tax per acre on farm lands increased from 8 cts. in 1881 to 15 cts. in 1913, and from 23 cts. in 1919 to 40 cts. in 1923 and 1924. A survey of cash-rented farms in 23 counties in the northwestern part of the State showed that the average net cash rents were \$3.09 in 1913, \$3.83 in 1918, and \$4.26 in 1922, while the average taxes per acre were 35 cts., 36 cts., and 73 cts., respectively. On selected farms in Audrain, Boone, Gentry, and New Madrid Counties the average net rent per acre decreased from \$4.71 in 1919 to \$3.73 in 1923, while the average taxes per acre increased from 47 to 75 cts. The ratio of the assessed valuation to the owners' estimated valuation in these four counties increased from 14.6 per cent in 1919 to 105.1 per cent in 1923, as compared with an increase from 54.6 to 64.6 per cent for the values of from 19 to 68 pieces of city real estate in the same counties. The 5-year average percentage of capitalized net rent of owners' estimated value for the period 1919–1923 was 45.7 per cent for rural and 84.2 per cent for urban real estate. The assessed value of 246 pieces of rural real estate transferred in 1924 in 6 Missouri counties was 62.7 per cent, as compared with 55.4 per cent for 340 pieces of urban real estate transferred.

The farmer's taxes in Boone County in 1924 were distributed 9.9 per cent for State purposes, 45 for county purposes, and 45.1 for special district purposes, and 27.9 per cent was used for administrative and general expenses, 38.7 for education, 17.1 for highways, and 16.3 per cent for miscellaneous purposes. The actual contribution of the States to common school purposes decrease over \$1,378,000, or nearly 23 per cent, from 1921 to 1924.

The steps suggested to counteract the inequalities in taxation are (1) that property taxes be made to reflect more fully the variations in the earning capacity of different classes of property, (2) that a large proportion of all taxes be obtained from sources other than property, and (3) that the State assume a greater part of the cost of administration, schools, roads, and other government costs.

Some tax problems of North Dakota farmers, R. W. NEWTON and A. H. BENTON (*North Dakota Sta. Bul. 203 (1926)*, pp. 63, figs. 32).—The amount of taxes paid by farmers in North Dakota, how the money raised is spent, the causes of recent increases in taxes, and some of the methods of making farm taxes less burdensome were studied.

The tax on farm real estate is estimated to have increased from 23 cts. per acre in 1916 to 55 cts. in 1922, and then decreased to 48 cts. in 1924. More than 40 cts. per acre has been spent annually for local purposes since 1920. General property taxes, exclusive of the hail tax, on selected farms in Traill and Wells Counties in 1919 to 1924 and Hettinger County in 1921 to 1924 averaged from 14 to 18.3 per cent of the net rent in 1919, from 23.5 to 85.1 per cent in 1920 to 1923, and from 13.8 to 19.2 per cent in 1924. Four-fifths of the population of the State is rural. Rural land, livestock, farm implements, and agricultural products in 1922 represented 66.6 per cent of the taxable wealth of the State, railroads 14.1, and city real estate 8.6 per cent, consequently the possibility of transferring farm taxes to other property is limited. General property taxes levied in 1923 were distributed as follows: State 13.36 per cent; county 22.16; city, town, and village 8.49; township 8.18; and schools 47.81 per cent. The inequality between farm and other taxes resulted from a pronounced lack of stability in the value of farm products, and that between farm taxes in different sections to the variations in the assessed valuation per child and cost per child of maintaining schools up to the State requirements in different counties and districts in the same county, the lack of uniformity in the relation of assessed to actual valuation of property, and the variation in the benefits from roads received by different persons in proportion to the road taxes paid.

Some suggestions made for reducing and making more equitable distribution of taxes are as follows: (1) Levies should be fixed after harvest time, (2) industrial development should be encouraged, (3) distribution of State school funds should be on a basis of educational cost rather than per child basis, (4) school taxes should be more uniform throughout the county, (5) higher motor vehicle and higher gasoline taxes should be levied, (6) state-wide taxes should be levied to supplement motor taxes for primary roads, (7) local roads should be under county control, (8) county taxes should be lowered by using a shortened ballot and longer terms of office, (9) township assessments should be revised, and (10) township and school district treasurers abolished.

Cotton prices and markets, A. B. Cox (*U. S. Dept. Agr. Bul. 1444 (1926)*, pp. 78, figs. 16).—The fundamental factors involved in cotton price making are analyzed, and the character, organization, functions, etc., of the different types of cotton markets are described. Special attention is given to price making in the futures market and to problems involved in arriving at correct conversion ratios for spot and futures contracts.

Monthly Supplement to Crops and Markets, [December, 1926] (*U. S. Dept. Agr., Crops and Markets*, 3 (1926), Sup. 12, pp. 385-440, figs. 3).—The usual tabulations, summaries, and notes are given regarding crops, dairy products, cold-storage holdings, fruit and vegetable shipments, livestock and livestock products, prices and price movements of agricultural products, seeds,

exports of grain, and world agriculture. Special reports are included on the acreage sown and condition of winter wheat and rye December 1, the December 1 pig survey in the 11 Corn Belt States, and the tobacco production in 1926. Tables are given showing (1) the acreage, production, December 1 price, farm value, etc., by years and by States from 1924 to 1926 of cereal grains, forage crops, fruits and vegetables, tobacco, and cotton; (2) the estimated prices of farm products, November 15, 1925 and 1926, by States, with comparisons for the United States with previous years; (3) monthly farm prices, 1908-1926, of important farm products; (4) the yearly value per acre, 1866-1926, of the 10 leading field crops combined; and (5) the estimated aggregate value, 1919, 1924, 1925, and 1926, by States, of 22 leading crops.

Membership relations of cooperative associations (cotton and tobacco), J. W. JONES and O. B. JESNESS (*U. S. Dept. Agr., Dept. Circ. 407 (1927), pp. 29*).—This study, made in cooperation with the Kentucky Experiment Station, was undertaken to determine the causes of weak membership morale, dissatisfaction with associations, and contract violations in centralized cooperative marketing associations in the South. The answers to a schedule from approximately 150 to 460 members of two cotton and two tobacco associations with memberships of from 35,000 to 108,000 and operating over an entire State or parts of more than one State are tabulated and discussed. The schedule covered members' opinions and criticisms regarding their organization; reasons for joining; benefits obtained; members' ideas as to purposes, possibilities, and limitations of such associations; degree of satisfaction and anticipations realized; causes of dissatisfaction; members' knowledge of the association and its operation; etc.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Proceedings of the fortieth annual convention of the Association of Land-Grant Colleges and Universities, edited by S. B. HASKELL (*Assoc. Land-Grant Colls. and Univs. Proc., 40 (1926), pp. 432, figs. 8*).—Lists of the officers, committees, and delegates; the constitution of the association; the minutes of the general sessions and the several sections; and the reports of the officers and committees of the convention, held at Washington, D. C., November 16-18, 1926, and previously discussed (*E. S. R., 55, pp. 701, 798; 56, p. 1*), are published here. The following papers and addresses not hitherto referred to, together with discussions, are included: Report on behalf of the American Council of Education, by C. R. Mann; The Correlation of the Curricula of the Arts Colleges and the College of Agriculture, by A. Vivian; Freshman Week and Orientation, by R. G. Bressler; The Allocation of Subject Matter to Departments of Instruction, by C. Betten; Agricultural College Enrollment, by C. F. Curtiss; Some Factors Affecting Tenure in Extension Work, by W. A. Lloyd; Developing an Economic Background for an Extension Staff, by F. W. Peck; Factors to be Considered in Enlarging an Extension Organization, by R. McCann; Home Economics Extension, by M. Van Rensselaer; Engineering Degrees, by O. M. Leland; Engineering Teachers—General Discussion, by E. H. Rockwell; What Can Be Done to promote the Development of Engineering Teachers? by F. C. Bolton; Cooperation Among Deans for the Selection and Advancement of Teachers, by A. Marston; When Should Young Teachers Obtain Their Professional Practice? by J. W. Votey; Control of Service Courses of the Engineering Curricula, by D. S. Kimball, H. S. Boardman, O. J. Ferguson, E. A. Hitchcock, M. S. Ketchum, and E. J. McCaustland; Index to Programs and Papers of the Engineering Section, Association of Land-Grant

Colleges, 1913 to 1926, by O. M. Leland and D. R. Hyman; Placing Young Graduates in Suitable Positions, by C. R. Jones, G. W. Bissell, A. A. Potter, and R. L. Wales; Major Objectives in Home Economics Education, by F. D. Farrell; Major Objectives in Home Economics, by L. Bane; Present Status of Minimum Requirements for a Degree in Home Economics, by M. Van Rensselaer; Factors Affecting the Minimum Requirements for a Degree in Home Economics, by F. R. Lanman; Adjusting Home Economics Instruction to Changing Conditions in Home Life, by A. L. Marlatt; Our Responsibility for Offering Service Courses, by M. Fedde; Report on Child Development and Parental Education, by A. E. Richardson; and A Five Year Administrative Program in Home Economics Extension, by G. E. Frysinger.

First annual report of the New York State College of Home Economics at Cornell University, 1926, C. BETTEN ET AL. (*N. Y. State Col. Home Econ., Cornell Univ., Ann. Rpt., 1 (1926), pp. 28*).—This is the first annual report and includes a brief summary of the development of home economics work in Cornell University from 1900.

Ten years of successful institutes, E. L. LUTHER (*Wis. Agr. Col. Ext. Circ. 209 (1927), pp. 16, figs. 8*).—The developments in farmers' institute work are discussed. The most important developments were the increasing use of trained specialists of the College of Agriculture on institute programs; the unification of the work of the institute and the county agents; the combination of service in information with service in materials; the greater stress on farm business, especially cooperative marketing; and the development of specialized institutes devoted entirely to cooperative marketing of a single commodity. The program of the first cooperative marketing institute held in November, 1925, is included.

Chemistry for agricultural students, R. H. ADIE (*London: Univ. Tutorial Press, 1926, pp. VIII+357, figs. 99*).—A textbook designed to show students of agriculture how the fundamental facts and inferences of chemistry and physics have a bearing on practical work and observations.

FOODS—HUMAN NUTRITION

Nutrition and health, H. C. SHERMAN (*Indus. and Engin. Chem., 18 (1926), No. 12, pp. 1261-1263; also in Baking Technol., 6 (1927), No. 1, pp. 20-24*).—This and the following paper were presented at the Round Table Conference on The Rôle of Chemistry in the World's Future Affairs at the sixth session of the Institute of Politics, Williamstown, Mass., on August 24, 1926.

A concise discussion is given of the requirements for an adequate diet, the distinction between adequate and optimal nutrition, and the best means of improving the utilization of the primary crops now produced so as to make optimal nutrition possible. In the author's opinion this would consist in converting a larger share of grass and grain into milk and less into meat. "The energy and protein of the material eaten is much more economically converted into human food by the milch cow than by the animal which is fed merely for slaughter, and what is now seen with special force is that the conservation of the vitamins and mineral elements so important to the human food supply is incomparably more efficient in the conversion of feed into milk than into meat."

The present and the future of the food supply, E. B. FORBES (*Indus. and Engin. Chem., 18 (1926), No. 12, pp. 1263-1267*).—This paper consists chiefly of a discussion of the economics of food supply and demand, with emphasis upon the part played by chemistry in food production. In regard to the question of

dairy cattle v. beef cattle, the author states "at the present time there is no competition between man and the domestic animals for food in this country. The animals perform a definite and most important service of conservation of foods either unavailable or unwanted for human consumption. With the tightening of economic conditions, however, as we approach the limit of population, we shall have no choice but to increase the proportion of vegetable foods in the diet, and to discontinue the raising of cattle for beef alone; shall make increasing use of dual-purpose types of cattle; and eventually may have to depend for our beef solely upon that resulting as a by-product of the dairy industry."

A bacteriological study of canned salmon, C. R. FELLEES (*Jour. Bact.*, 12 (1926), No. 3, pp. 181-202).—The study reported covered a period of five years in which 7,674 cans of salmon, comprising 540 separate lots, were examined bacteriologically. Of these, 5,276 cans proved to be sound and normal and 2,398 of doubtful quality. Of the sound cans, 3.4 per cent were found to be nonsterile and 0.9 per cent were rejected on bacteriological grounds. Corresponding percentages for the cans of doubtful quality were 7.1 and 1.6 per cent. Among the bacterial groups isolated in decreasing order from the nonsterile cans were sporulating aerobes, cocci and nonsporulating rods, true thermophiles, obligate anaerobes, and molds.

Inoculation experiments showed that many sporulating aerobes grow well in canned salmon, producing a softening of texture, abnormal odor, and discoloration but no gas or marked spoilage. *Clostridium botulinum* grew vigorously in canned salmon even at low temperatures, but this organism has never been found in commercially canned salmon and no outbreaks of botulism have been attributed to this food. The Salmonella group was absent, and it is believed that food poisoning from this source is very rare with canned salmon.

Home demonstration work, 1923, O. P. MALCOLM (*U. S. Dept. Agr., Dept. Circ.* 399 (1926), pp. 48, figs. 18).—The reports on home demonstration work from the States in 1923 are reviewed and summarized.

Baking qualities of Wyoming flour (*Wyoming Sta. Rpt.* 1926, pp. 176).—In this preliminary report it is noted that higher temperatures are required to bake bread in a given time at high than at low altitudes. At an altitude of 7,150 ft. a temperature of 475° F. was required to bake a loaf weighing slightly more than 1 lb. in half an hour.

Peas in the diet, A. L. MARLATT (*Wis. Agr. Col. Ext. Spec. Circ.*, Oct., 1926, pp. 23).—In addition to a general discussion of the subject, this circular contains selected recipes for the use of canned peas in soups, salads, mixed vegetable dishes, and in combination with meats, cheese, eggs, and fish. Translations of French, Italian, and Armenian recipes and English recipes dating back to 1100 A. D. are included.

Effect of fruit acids on fruit flavors in jellies and jams, C. P. LATHROP and W. L. WALDE (*Canner*, 64 (1927), No. 2, pp. 40, 41; also in *Canning Age*, 8 (1927), No. 1, pp. 42, 43; *Fruit Prod. Jour. and Amer. Vinegar Indus.*, 6 (1927), No. 5, pp. 11, 12, 27).—The authors call attention to the fact that the technique of jam and jelly making is not limited merely to questions of pectin content and texture, but that the preservation of the original fruit flavor is of fundamental importance. This has been found to depend largely upon the kind and quantity of acid. Variations of from 0.02 to 0.05 per cent in the concentration of acids such as citric, tartaric, malic, and lactic were found to produce decided differences in the fruit flavor of jellies. The acid content required to bring out the maximum fruit flavor varied only slightly with the different fruit acids used (currant, raspberry, and pineapple). Citric acid in concen-

trations of from 0.5 to 0.55 per cent acid, calculated as anhydrous citric acid, gave the best results. About two-thirds as much by weight of tartaric, malic, or lactic acid was required to produce the optimum fruit flavor, but the flavors were not as good with these as with citric acid. When the correct acidity has been determined the pectin content can be adjusted to give the desired jelly texture under the established proportions of fruit juice, sugar, and fruit acid.

Bonbons, H. ROUSSET (*Bonbons. Paris: Desforges, Girardot & Co., 1926, pp. 268, figs. 29*).—This collection of recipes for candy making in the home has been compiled largely from American publications.

Development of the food color industry in the United States, W. C. BAINBRIDGE (*Indus. and Engin. Chem., 18 (1926), No. 12, pp. 1329-1331*).—A brief historical survey of the subject from 1880, when the first attempts at standardization of coloring matter for foods were made, to the present time.

The effect of the luxus consumption of meat upon the voluntary activity and growth of the albino rat, F. A. HITCHCOCK (*Amer. Jour. Physiol., 79 (1926), No. 1, pp. 206-217, figs. 4*).—This study deals with the effect upon the growth of white rats and upon their voluntary activity as measured by revolving wheels of the addition of a liberal quantity of meat to a diet already adequate. This diet, consisting of cakes prepared from whole wheat flour 62.5, dry casein 15, skim milk powder 15, calcium carbonate 1.5, sodium chloride 1, and cottonseed oil 5 per cent, with cod-liver oil in the proportion of 200 cc. to each 100 lbs. of the food, was fed with dry yellow corn ad libitum and cabbage or lettuce once a week. About half of the animals received this stock diet alone and half the same with the addition of 8 gm. daily of fresh lean meat cooked rare.

The total number of rats used consisted of 56 females and 35 males in four groups. The experiment was begun when the rats were 30 days old and continued for nearly a year. After 2½ months some of the rats were subjected to a 5 days' fast, after which the condition of feeding was reversed, the former controls now receiving the meat. During the first 10 months of the experiment no attempt was made to determine the food consumption. Daily weighings and calculations during the last 2 months showed that the control females consumed approximately 13.8 and the control males 15 gm. of the stock ration per day and the meat-fed females 11.4 and males 13.4 gm. in addition to the meat. This made the total intake of the meat-fed rats 61 and 67 calories per day as against 53 and 57 calories for the controls. The protein in the diet of the meat-fed group represented about 36 per cent of the total energy intake and of the control group 29 per cent.

Although the numbers were too small to warrant general conclusions, the data obtained appeared to indicate that luxus meat consumption promoted more rapid growth, with larger weight at maturity, and more rapid and complete recovery from starvation. The voluntary activity was changed only slightly and not consistently.

Although not emphasized in the author's conclusions, the fact that out of 8 females and 6 males dying of unknown causes during the experiment 6 of the females and 5 of the males belonged to the meat-fed series would suggest the possibility that high meat feeding may tend to shorten the life span.

The effect of meat feeding on nursing mother rats and the rate of growth of their litters, F. A. HITCHCOCK (*Amer. Jour. Physiol., 79 (1926), No. 1, pp. 218-220, fig. 1*).—The diets used in this study were the same as in the preceding except that the meat was not added until the birth of the first litter and was gradually increased in amount from the original 8 or 10 gm. daily

to an amount sufficient to furnish about 1 gm. daily to each of the young after they had begun to eat from the mother's diet. Four female rats mated with males from the same stock were used and the experiment was continued through three generations, 5 females being selected from the meat-fed group and the same number from the control to continue the experiment. In the third generation 2 meat-fed mothers with their litters were taken as controls, 2 control mothers with their litters for the meat feeding, and 2 were continued on the meat feeding.

No data are given as to the numbers in the various litters, but the composite growth curves show in the first two generations a decided advantage in the litters of the meat-fed mothers. In the third generation the total weight of the two control litters whose mothers had previously received meat was 739 gm., of the two meat-fed groups whose mothers had been controls 898, and of the two litters continuing on the meat 1,034 gm., again showing an advantage for the meat. It was also noted that the death rate among the control litters was much higher than among the meat-fed, largely through an epidemic of respiratory infection, which resulted in the death of 27 young of the control and only 5 of the meat-fed group, as well as one of the mothers of the control group and none of the meat-fed.

The effect on the kidney of the long continued administration of diets containing an excess of certain food elements.—I, Excess of protein and cystine. II, Excess of acid and of alkali, T. ADDIS and E. M. and L. L. MACKAY (*Jour. Biol. Chem.*, 71 (1926), No. 1, pp. 139-166, figs. 11).—In the studies reported in these two papers, special precautions were taken to control all variables except the one under consideration. The period of observation was made sufficiently long to cover what would correspond to 30 years of a man's life, and the control and experimental diets were fully adequate for growth and maintenance and as closely comparable as possible. The control diet in both studies consisted of cornstarch cooked, dried, and powdered 44, powdered casein 16, lard 14, cod-liver oil 10, Osborne and Mendel's salt mixture 4, Harris yeast powder 10, and dried and powdered alfalfa 2 per cent. The food intake was determined every 5 days and the body weights every 10 days. The rats were placed on the experimental diet at 30 days of age and continued to ages of 330 and 360 days.

In the first study the high protein diet used contained casein in place of the cornstarch and lard of the basal diet, making the protein content 69.5 per cent in place of 17.3 per cent. In the cystine experiment 1 gm. of cystine was mixed with 99 gm. of the control diet.

The rats on the high protein diet did not reach the weight of the controls or the cystine group. The average rate of excretion of protein in the urine was higher on the high protein than on the other two diets and higher in the males than in the females. Red blood cells were occasionally found in the urine in all three groups with but slight differences in the different groups. Occasional hyaline casts were found, but no more frequently on the high protein than on the other diets. There was but little variation in the blood urea. On post-mortem examination the principal cause of the relatively low body weight of the high protein rats was found to be an almost complete absence of fat. No difference could be detected microscopically between the kidneys of the three groups, but the weight of the kidneys was higher and of the livers lower in the high protein group.

This study is thought to prove decisively that "rats can live for a third of their life span on a diet very high in casein or with added cystine and yet

escape any damage to their kidneys. This fact leads us to reject the hypothesis that a large consumption of protein is in and by itself necessarily harmful to the kidneys."

In the second study the acid diet was made by mixing 2 gm. of CaCl_2 with every 98 gm. of the control diet and the alkaline by mixing 4 gm. NaHCO_3 with 96 gm. of the control. On such diets the average H-ion concentration of the urine had previously been found to be pH 6.4 in the control, 5.2 in the acid, and 6.9 in the alkaline group.

The rats on the acid diet, although eating more than the controls, ceased to gain at about the one hundred and twentieth day and lost in weight gradually from then on. The ones on the alkaline diet grew but at a somewhat slower rate than the controls. The most pronounced effect of the diets was a difference in the amount of blood in the urine. There was no blood at all in the acid group, a little in the control, and a large amount in the alkaline, particularly in the male rats. The protein excretion in the urine was much less in the acid group. Blood urea concentrations were within normal. Hydro-nephrosis of one or both kidneys was present in 7 of 24 rats on the alkaline diet. In the rats on the acid diet the body weight and the weight of the heart per 100 mm. of body length were much less than in the controls. The liver weights were lower on both the acid and the alkaline diets than on the control, but the kidney weights were not appreciably different.

The effect of an excess of vitamins A and B in the ration on basal metabolism and the specific dynamic effect of food [trans. title], A. V. ÁRVAY (*Pflüger's Arch. Physiol.*, 214 (1926), No. 4, pp. 421-438).—Data are reported from experiments on rats leading to the conclusion that although the basal metabolism is lowered by a deficiency of vitamin B, an excess of this vitamin does not increase the basal metabolic rate nor does it have any effect on the specific dynamic action of the food. Cod-liver oil as a source of vitamin A was found to increase the basal metabolic rate of rats not only on a vitamin-poor or vitamin-free diet, but also on a vitamin-rich diet. Cod-liver oil also brought about an increase in the specific dynamic action of the food. Butter was without effect. These results are rendered less conclusive from the fact that in no case was the vitamin in question the sole limiting factor in the diet.

On the growth-promoting property of irradiated fat in the diet, of direct irradiation, and of cod-liver oil, H. GOLDBLATT and A. R. MORITZ (*Jour. Biol. Chem.*, 71 (1926), No. 1, pp. 127-137, figs. 5).—The experimental data reported in this paper demonstrate the growth-promoting properties of vitamin D, as well as vitamin A, and the ineffectiveness of irradiation in synthesizing vitamin A or mobilizing its reserves in the tissues.

Four groups of rats receiving the same basal diet free from both vitamins A and D were continued on this diet after growth had ceased, group 1 receiving no addition, group 2 being irradiated daily, group 3 receiving irradiated cottonseed oil in place of the untreated cottonseed oil of the basal diet, and group 4 receiving 7 drops (150 mg.) daily of cod-liver oil. Growth was immediately resumed in groups 2 to 4, but after 4 weeks groups 2 and 3 had ceased to gain and were for the most part losing in weight, while most of the rats in group 4 were continuing to gain. The experiment was continued until all the rats in groups 1 to 3, inclusive, had died (20 weeks). At this time 5 out of 8 of group 4 were still living and gaining weight.

A practical conclusion drawn from this study is that neither irradiation nor the feeding of irradiated oil can act as a complete substitute for cod-liver oil in growth promotion experiments unless vitamin A is also given.

Irradiated milk: Its effect on the blood, V. DAWKINS and C. L. PATTISON (*Lancet [London], 1926, II, No. 26, pp. 1314, 1315, fig. 1*).—The effect of irradiated milk on the blood of 5 children, suffering from acute bone tuberculosis and who had failed to show any improvement after about 4 months on a hospital diet which included cod-liver oil and $1\frac{1}{4}$ pints of milk daily, was tested by determinations of the red cell count and the hemoglobin percentage of the blood at the beginning of the experiment and at the end of two successive periods of 4 weeks each in which $\frac{1}{2}$ pint of the daily allowance of milk had been irradiated for half an hour at a distance of 2 ft., followed by a period of the same length on ordinary milk and a final period of 3 weeks on the irradiated milk.

The blood count increased steadily during the periods in which irradiated milk was fed and decreased sharply in the one period on ordinary milk. The hemoglobin rose slightly in the first period, remained at about the same level during the second, fell sharply in the third, and was only slightly altered in the fourth period. The red cell counts were in all but one case slightly over 4,000,000 per cubic millimeter at the beginning and considerably over 5,000,000 at the end of the experiment, but the percentage of hemoglobin in all but one case was lower at the end than at the beginning, averaging 76.6 and 70 per cent, respectively. For purposes of comparison, similar analyses were made of the blood of 6 other children between the ages of 2 and 14 years who had received irradiated milk daily for an average of 10 months. The minimum, maximum, and average values for the red cell count were 4,390,000, 5,970,000, and 5,030,000, respectively, and for the hemoglobin 74, 84, and 78 per cent. These figures are thought to indicate that the fall in hemoglobin and rise in red blood cells noted in the first group do not continue indefinitely.

It is noted that there was a marked improvement in the general health and well-being of the children and in the condition of the local lesions after 8 weeks on irradiated milk.

Antirachitic properties developed in human milk by irradiating the mother, A. F. HESS, M. WEINSTOCK, and E. SHERMAN (*Jour. Amer. Med. Assoc., 88 (1927), No. 1, pp. 24-26*).—In this complete report of the study previously noted from a preliminary account (*E. S. R., 56, p. 295*), attention is also called to the probable beneficial effect of irradiation on the mother, as well as the child, through preventing the excessive drain of calcium and phosphorus involved in pregnancy and lactation.

Glass screens for the transmission of the light radiations curative of rickets, E. M. LUCE (*Jour. Biol. Chem., 71 (1926), No. 1, pp. 187-190*).—This is a preliminary report to the effect that rats on a rickets-producing diet, when irradiated by sunlight for 6 to 7 hours daily through Corning glass filters No. G86B transmitting only 0.5 per cent light of wave length between 300 and $305\mu\mu$, received no protection against rickets, while in similar experiments with filters Nos. G980A and G986A, transmitting 80 and 77 per cent, respectively, of light of wave length $300\mu\mu$, there was complete protection against rickets.

Vitamins in their relation to medical supplies, F. H. CARR (*Pharm. Jour. and Pharm. [London], 4 ser., 63 (1926), No. 3294, pp. 729-734*).—A concise summary of present knowledge concerning vitamins A, B, C, D, and E, including their distribution in nature, the most generally used methods for their determination, their physical and chemical properties, and theories concerning their function.

A preliminary study of factors influencing calcification processes in the rabbit, M. MELLANBY and E. M. KILLICK (*Biochem. Jour., 20 (1926), No. 5, pp. 902-926, pls. 3, figs. 7*).—This paper deals chiefly with the use of the rabbit as an experimental animal for studying calcification processes. After trial

of a number of experimental diets, the one adopted as the most satisfactory for securing a moderate rate of growth and at the same time poor calcification consisted of 4 parts of oats to 1 of bran, with 1.5 per cent calcium carbonate fed ad libitum and 6 cc. of decitrated lemon juice daily for each animal. Of 22 rabbits fed this diet, 19 developed definite rickets within 7 weeks and 2 osteoporosis, while 1 remained well with normal bones and teeth. In the authors' opinion the effect of rate of growth upon calcification is of greater importance than the ratio of calcium to phosphorus.

Various supplements to this basal diet were tested. The rabbits were unable to take as much as 2 cc. daily of cod-liver oil for a prolonged period, but with the unsaponifiable fraction from 1 cc. of oil growth was somewhat better than on the basal diet and the general health was improved. With the same amount of cod-liver oil and 20 gm. or more of cabbage daily there was good growth and normal calcification of the teeth and bones. With egg yolk, failure of growth and death resulted after several weeks of improvement except when the diet was further supplemented with cabbage. Of the other materials tested, green grass, especially summer grass, was effective, dandelion leaves fairly so, and cabbage ineffective without cod-liver oil. Of the root vegetables tested, swedes and carrots gave rather variable results, while turnips had no antirachitic effect. The rabbits responded as other animals to irradiation or to the use of irradiated foods.

The use of national foods in treating diabetic patients of foreign birth, F. STERN and J. REYNER (*Jour. Amer. Med. Assoc.*, 88 (1927), No. 5, pp. 316-322).—From the authors' experience as dietitians at the food clinic of the Boston Dispensary, suggestions are given for the adaptation of diabetic diets to racial food habits. Two sets of typical American, Jewish, Italian, and Armenian diabetic menus are given, including a low tolerance diet furnishing approximately 75 gm. of carbohydrate, 70 of protein, and 130 gm. of fat, with a total of 1,750 calories, and the Joslin maintenance diet furnishing 159 gm. of carbohydrate, 84 of protein, and 135 gm. of fat, with a total of 2,187 calories.

Specific practical applications of the adaptation of general principles to widely differing racial food habits are given for the principal groups of foods, together with suggestions for the task of teaching foreign patients, many of whom can not read, how to measure their foods. In the scheme which has been found to work most satisfactorily a lump of sugar weighing approximately 5 gm. is used as the unit for the amount of carbohydrate in a 100-gm. portion of a 5 per cent vegetable, and other food quantities are demonstrated in multiples of this unit.

TEXTILES AND CLOTHING

The viscosity of cuprammonium solutions of cotton cellulose, F. C. HAHN and H. BRADSHAW (*Indus. and Engin. Chem.*, 18 (1926), No. 12, pp. 1259, 1260, figs. 3).—In viscosity studies made with solutions derived from a representative series of different grades of linters and from four distinct samples of long staple cotton, the figures for the linters samples exceeded those for the long staple cotton. There also seemed to be a progressive rise in viscosity from low grade second cut to high grade mill run linters, and then a drop to first cut linters and a further drop to long staple cotton.

The steeping process.—I, The constituents of cotton soluble in water or dilute mineral acids and the effect of their removal on subsequent scouring, R. G. FARGHER, L. R. HART, and M. E. PROBERT (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 5 (1926), No. 21, pp. 257-273).—The investi-

gation reported dealt with the amount of material in cottons of different origin which dissolves in water or in dilute mineral acids; its reducing, nitrogenous, and mineral constituents; and the effect of its removal on subsequent scouring. The effects of dilute sulfuric acid on gray and scoured yarns were compared to ascertain the applicability of the copper number determination as a measure of tendering during a gray sour. Typical enzyme preparations used in the desizing of cotton goods were examined for their effects on the constituents of the cotton itself.

The effect of humidity on cotton yarn: The strength and extensibility of sized and unsized warp yarns in equilibrium with steady atmospheric conditions, F. T. PEIRCE and R. J. STEPHENSON (*Jour. Textile Inst.*, 17 (1926), No. 12, pp. T645-T660, figs. 6).—Material including warp yarns, spun to a twist factor about 3.8, 4 about 33's count, 1 50's count, 2 being also pure sized and 2 heavy sized, representative of common trade products and spanning a wide range of quality, was tested at humidities from dryness to saturation for single thread breaking load and extension and for ballistic work of rupture. The data obtained appear to have yielded considerable information on the nature of the influence of humidity and of sizing on the yarn properties.

The moisture relations of cotton.—VI, The absorption of water by cotton mercerized with and without tension, A. R. URQUHART (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 5 (1926), No. 24, pp. 303-320, figs. 2; also in *Jour. Textile Inst.*, 18 (1927), No. 2, pp. T55-T72, figs. 2).—The present research on yarns mercerized with and without tension has confirmed previous findings with loose cotton (E. S. R., 54, p. 93) in that the curves showing the relation between the hygroscopicity of mercerized cotton and the concentration of the mercerizing solution resembled those representing the swelling of cotton fibers in solutions of sodium hydroxide. The changes in the absorptive capacity of cotton caused by mercerization were found to be very similar for all cotton varieties examined. The applied tension acts in opposition to the swelling force, so that the absorptive capacity of cotton mercerized with tension is considerably less than that of cotton mercerized loose.

Mildew in cotton goods.—IV, Antiseptics and the growth of mould fungi on sizing and finishing materials, L. E. MORRIS (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 5 (1926), No. 25, pp. 321-349, pl. 1, figs. 17).—A preliminary account is given of the progress of inquiry toward the prevention of mildew growth in manufactured cotton goods by the use of antiseptics. The properties of an antiseptic that are essential to satisfactory use in sizing and finishing are chiefly lacks of color, odor, danger to the operative, or of action upon the size, cloth, or machinery. The necessity is emphasized of considering a number of species in determining the efficiency of an antiseptic. The action of some antiseptics varies with the acidity of the medium, some being more and others less effective in fermented than fresh flour.

Winter damage of wet wash, L. B. ALLYN (*Starchroom Laundry Jour.*, 33 (1926), No. 11, pp. 132, 134, 136, figs. 7).—Winter damage, usually met with between December and April and more prevalent in middle and eastern United States than in other sections of the country, is found only in cotton goods, and shirts appear to suffer most from this cause. Bacterial infection seems to be the principal source, and laundrymen troubled with this type of damage are urged to leave the wet wash slightly acid rather than neutral or alkaline.

Overall shrinkage (*Starchroom Laundry Jour.*, 34 (1927), No. 1, pp. 90, 92, 94, fig. 1).—Tests were made on overalls and overall materials to determine the

shrinkage under various conditions of temperature, "strength" (amount of alkalinity in the detergent) of washing powders, and methods of laundering.

The shrinkage of overalls seemed to be independent of the detergent used. Boiling water did not cause more shrinkage than water of 120° F. The average loss in tensile strength appeared to vary slightly with the detergent used, yet not with the temperature. Excessive pounding due to low water in the wash-wheel did not cause an increase in shrinkage. Ninety-one per cent of the shrinkage occurred in the first wash. Overalls shrunk as much when washed by a home method as when washed in a commercial laundry.

The chlorination of wool, J. B. SPEAKMAN and A. C. GOODINGS (*Jour. Textile Inst.*, 17 (1926), No. 12, pp. T617-T614, pl. 1, figs. 2).—The cause of unshrinkability of wool and the amounts of chlorine needed to produce this condition were studied at the University of Leeds.

The reduction of shrinkage obtained by chlorination of wool seemed due to the formation of a jelly layer between the unattacked cortex and the cuticle of wool by the consecutive actions of chlorine and soap or soda. The bad wearing properties of unshrinkable wool are attributed to the ease with which the jelly layer and its surrounding scales are removable by friction. A process, applicable only to dyed goods, has been devised for shrinking and hardening the jelly layer to the unattacked part of the cortex and thereby improving the wearing properties of the wool. Absolute unshrinkability appears to be attainable under particular conditions, the limiting factor in this respect being the difficulty of insuring even chlorination of all fibers, especially where yarns are concerned, on account of the preferential absorption of chlorine by the outside fibers.

Difficulties in handling rayon, G. H. JOHNSON (*Starchroom Laundry Jour.*, 34 (1927), No. 2, pp. 102, 104, 106).—The research department of the Laundry-owners' National Association found that the damages to rayon most frequently met with in the laundry include loss of luster after the first washing due to removal of soluble sizing or mechanical finish, dissolving or disappearance of rayon fibers when laundered the first time, shrinkage troubles, distortion of the design caused by employment of a loose weave, poor laundering qualities, damages due to misuse, and tears from faulty handling in the laundry.

The finishing of textile fabrics, R. BEAUMONT, rev. by A. YEWDALE (*London: Scott, Greenwood & Son; New York: D. Van Nostrand Co.*, 1926, 2. enl. ed., rev., pp. XV+368, figs. 188).—In its successive chapters this book deals with woolen, worsted, and union fabrics; processes of finishing and their effects; materials used for cloth scouring; scouring machines and the process of scouring; theory of felting-milling agents, fiber and yarn structure, fabric structure, and compound fabrics; fulling and milling machinery; drying processes and machinery; raising and its application to different types of fabrics; raising processes and machinery; cutting machinery; setting and lustering processes and machinery; miscellaneous processes and machinery; and methods of finishing.

Census of dyes and other synthetic organic chemicals, 1925, T. O. MARVIN ET AL. (*U. S. Tariff Comm., Tariff Inform. Ser. No. 34 (1926)*, pp. IX+224, figs. 3).—"This report is a survey of the domestic dye and synthetic organic chemical industry in 1925. It presents the results of a special investigation made by the U. S. Tariff Commission with respect to the production in the United States of coal-tar dyes and synthetic organic chemicals, both of coal-tar and of noncoal-tar origin. It includes a detailed tabulation of coal-tar dyes imported into the United States and official statistics of imports and exports of coal-tar dyes by the large consuming and producing nations of the world.

There is also included a chapter on the cost of dye in representative fabrics and garments."

Rabbit skins for fur, D. M. GREEN (*U. S. Dept. Agr., Farmers' Bul. 1519 (1927), pp. II+14, figs. 7*).—Directions are given for killing and skinning rabbits and for handling the skins from the time the pelt is removed until it reaches the raw fur market. For those who wish to prepare the skins for home use, directions are given for tanning the skins by the salt-acid and salt-alum processes. It is emphasized, however, that home tanned skins do not compare favorably with the commercially tanned skins. A list of 57 different trade names applied to rabbit and hare pelts after they have been prepared for fur manufacturing purposes indicates the extensive use of rabbit fur under different names. It is estimated that more than 100,000,000 rabbit skins are utilized annually in the United States, about 98 per cent of which, valued at approximately \$25,000,000, are imported from Australia, New Zealand, Belgium, France, and other foreign countries.

Score cards for judging clothing selection and construction, R. O'BRIEN, M. CAMPBELL, and M. A. DAVIS (*U. S. Dept. Agr., Misc. Circ. 90 (1927), pp. II+13*).—These score cards have been compiled by the Bureau of Home Economics from a study of cards submitted by various State clothing specialists. While issued for the special purpose of furnishing uniform standards in clothing contests, they should also serve as useful guides for the construction and selection of clothing. Several references on the construction, design, and economics of clothing and on textile fabrics are included.

Historic costume: A chronicle of fashion in western Europe, 1490-1790, F. M. KELLY and R. SCHWABE (*New York: Charles Scribner's Sons, 1925, pp. XV+284, pls. 63, figs. 139*).—This history of costume design in the field of fashionable civil apparel of both men and women covers the years 1490 to 1790, or, roughly speaking, from the time of transatlantic exploration to the French Revolution. Considerable attention is paid to headgear and footgear and to changing modes of dressing the hair. The book is illustrated by reproductions, some in color, of paintings of the period, supplemented by sketches of details of the costumes. Selected costumes of the six periods covered are illustrated further by patterns drawn to scale. An annotated bibliography is appended.

HOME MANAGEMENT AND EQUIPMENT

The use of time by farm women, I. Z. CRAWFORD (*Idaho Sta. Bul. 146 (1927), pp. 14, figs. 4*).—A survey of the present use of time by 49 Idaho farm and 32 town home makers was made by having each report on a special blank her activities in 5-minute units throughout a period of 7 days. The percentages of time spent on the several activities were, respectively, food 15.3 and 13.2, house 10.1 and 8.4, clothing 7.7 and 7.0, family 3.1 and 4.5, management 1.1 and 1.7, sleep and rest 33 and 37.9, self 3.1 and 3.8, leisure 16.8 and 21.8, other work 5.8 and 0.1, and miscellaneous 1.0 and 1.6. Sixty-three of the 81 preferred the work of home making to any other work. Of the town women 28 had running water in the house and 24 used baker's bread entirely, as compared with 19 and 14, respectively, of the farm women. Thirty-five of the farm women had hand-run washing machines. A smaller percentage of the town women had washing machines, but practically all were run by electricity.

Farmhouse kitchen arrangement from the standpoint of household management, G. GRAY (*Agr. Engin., 8 (1927), No. 1, pp. 11, 12, fig. 1*).—This is a

contribution from the Nebraska Experiment Station which was presented at the meeting of the American Society of Agricultural Engineers at Lake Tahoe, Calif., in June, 1926. It is based largely on a study of nearly 400 rural Nebraska kitchens.

The results of this study indicated that architects and builders should pay greater attention to storage space and illumination, as well as to the arrangement of equipment. More than half of the kitchens studied did not have enough storage space, most of them being short of room for staples and cleaning supplies. More than half of them did not have adequate artificial illumination, and only a little over half received sufficient daylight.

The domestic oil burner, A. H. SENNER (*U. S. Dept. Agr., Dept. Circ. 405* (1927), pp. 30, figs. 23).—On the basis of the results of tests of a number of oil burners of different design, an attempt is made to give the information necessary for the home owner to select an oil burner.

The results indicate that oil burners are well suited to the requirements of many home owners on account of their convenience and ease of heat control if the prospective purchaser is willing to pay the cost of the change and possibly an increased operating cost. It is stated that several types of burners now on the market afford good combustion of oil fuels, and the tests indicate that there is no material difference in the efficiency of the better makes. Any burner which will burn the fuel without giving off soot or smoke and does not require a great excess of air is considered as satisfactory with regard to combustion. It is stated further that if the present plant when burning coal does not give sufficient heat very probably an oil burner will not improve this condition. In general warm air heaters are less suited to oil burner installations than are hot water or steam plants.

Touching up the old furniture, M. M. MILLER (*Ky. Agr. Col. Ext. Circ. 199* (1926), pp. 12).—Practical information on the retouching and refinishing of old furniture is presented.

MISCELLANEOUS

Sixth Annual Report [of Georgia Coastal Plain Station], 1925, S. H. STARR (*Georgia Coastal Plain Sta. Bul. 6* (1926), pp. 57, figs. 10).—This contains the organization list and a report of the director on the work of the station. The experimental work reported is for the most part abstracted elsewhere in this issue.

Thirty-seventh Annual Report of the Kentucky Agricultural Experiment Station for the year 1924, Part II (*Kentucky Sta. Rpt. 1924, pt. 2, pp. [2]+281+58+[2], figs. 42*).—This contains reprints of Bulletins 252-256 and of Circulars 32-34, all of which have been previously noted.

Report of Northwest Experiment Station, Crookston, 1925, C. G. SELVIG ET AL. (*Minnesota Sta., Crookston Substa. Rpt. 1925, pp. 84, figs. 4*).—The experimental work reported is for the most part abstracted elsewhere in this issue.

Report of West Central Experiment Station, Morris, 1925, P. E. MILLER (*Minnesota Sta., Morris Substa. Rpt. 1925, pp. 46*).—The experimental work reported is for the most part abstracted elsewhere in this issue.

Annual Report of [Porto Rico Insular Station, 1925], F. A. LÓPEZ DOMÍNGUEZ ET AL. (*Porto Rico Dept. Agr. and Labor Sta. Ann. Rpt., 1925, pp. 140, fig. 1; also Spanish ed., pp. 141, fig. 1*).—This contains the organization list, a report of the director for the fiscal year ended June 30, 1925, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Thirty-ninth Annual Report of the South Carolina Experiment Station, [1926], H. W. BARRE (*South Carolina Sta. Rpt. 1926, pp. 86, figs. 30*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1926, and a report of the work of the station during the year. The experimental features reported are for the most part abstracted elsewhere in this issue.

Annual Report of [South Dakota Station, 1925], J. W. WILSON ET AL. (*South Dakota Sta. Rpt. 1925, pp. 38, fig. 1*).—This contains a report by the director on the work of the station, a financial statement for the fiscal year ended June 30, 1925, and departmental reports. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Report of the director [of the Utah Station] for the 18-month period from January 1, 1925, to June 30, 1926, W. PETERSON ET AL. (*Utah Sta. Bul. 198 (1926), pp. 72*).—This contains the organization list and a report on the work and publications of the station during the 18-month period ended June 30, 1926. The experimental work reported is for the most part abstracted elsewhere in this issue.

Thirty-ninth Annual Report [of the Vermont Station, 1926], J. L. HILLS (*Vermont Sta. Bul. 260 (1926), pp. 15*).—This report contains the organization list, a financial statement for the fiscal year ended June 30, 1926, and a report of the director on the work of the station. The experimental work reported is for the most part abstracted elsewhere in this issue.

Thirty-sixth Annual Report [of Washington College Station], 1926, E. C. JOHNSON ET AL. (*Washington Col Sta. Bul. 208 (1926), pp. 76, figs. 4*).—This contains the organization list, a report on the work of the station, and a financial statement for the fiscal year ended June 30, 1926. The experimental work reported is for the most part abstracted elsewhere in this issue.

Thirty-sixth Annual Report of [Wyoming Station, 1926], J. A. HILL (*Wyoming Sta. Rpt. 1926, pp. 153-186*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1926, a report of the director on the work of the station, and meteorological observations by F. E. Hepner (see p. 507). The experimental work reported is for the most part abstracted elsewhere in this issue.

NOTES

Michigan College and Station.—The winter radio program, operating from January 10 to April 29, included 320 lectures given by 124 members of the staff and representing 20 departments. The 32 courses were divided between agriculture, home economics, science, liberal arts, and engineering. The agricultural courses included poultry husbandry, forestry, production of quality dairy products, soils, fertilizers and manures, much farming, soil preparation and fertilization for spring and summer crops, feeds and feeding, farm crops, horticulture, power and its applications, farm explosives, and landscape improvement of the farm home grounds.

The estimated attendance at Farmers' Week, January 31 to February 4, was 7,000. The group conferences, including breeders' associations, press associations, and various crop promotion meetings, were larger than in any previous year.

Dr. Edward D. Devereux has been appointed assistant professor of bacteriology and research worker in the station.

Missouri University.—The degree of doctor of agriculture was recently conferred on Dean F. B. Mumford by the University of Nebraska in recognition of his services to agriculture and agricultural research.

Cornell University.—Attendance at the twentieth annual Farmers' Week reached a total of 5,000 registrants, over 1,000 more than in any previous year.

Ohio State University.—The new animal husbandry building has now been occupied. It is a combined administration, teaching, and laboratory building, with a meat cutting laboratory, a judging arena seating 750 persons, and two livestock classrooms.

The departments of animal husbandry and rural economics, cooperating with the New York Central Lines and various local and national agencies, operated a meat production and marketing train through 16 counties in northwestern Ohio from February 14 to 25. The train included three exhibit and demonstration cars, one of pens of livestock, a second of refrigerated meats, and the third for lecture purposes and motion pictures. The total attendance is estimated at over 5,000 persons.

Washington College.—An attempt to raise the tuition fee from \$10 to \$25 a semester has been defeated by the State Legislature.

Wisconsin University and Station.—Forty-six representatives of the various service bureaus of the public utility companies of the State attended the three-day course on tree trimming work, with special reference to roadside plantings. At the conclusion of the course, the entire group signed a petition for the continuation and expansion of the work the ensuing year and asked that its opportunities be extended to park boards and commissioners.

The average number of farm visits made annually by Wisconsin county agents increased in the last decade from 381 in 1916 to 587 in 1926. The average number of office calls per year increased in the same period from 1,477 to 1,744. The county agents also used the press much more than ever before, preparing almost six times as many articles per man as 10 years ago.

CONTENTS OF VOL. 56, NO. 7

Editorial notes:	Page
The passing of five pioneers.....	601
Recent work in agricultural science.....	610
Notes.....	699

SUBJECT LIST OF ABSTRACTS

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The composition of milk, I, II, Cranfield, Griffiths, and Ling.....	610
The proteolytic action of certain specific organisms on milk proteins in milk and synthetic butter, Spitzer et al.....	610
The effect of heating on the hydrogen-ion concentration and on the titratable acidity of milk, Whittier and Benton.....	611
Variations in susceptibility of fat in dry milks to oxidation, Holm et al.....	611
The effect of separating, or clarifying, and pasteurizing of a milk upon the keeping quality of its milk powder, Holm et al.....	611
Sweetened condensed milk, V, VI, Rice.....	611
Peroxidase as a factor in butter deterioration, Palmer and Miller.....	612
Lactose solubility and crystal formation, I, Hunziker and Nissen.....	612
The insoluble pectic substances in vegetables, Conrad.....	613
The solidification point of food fats, Meyer.....	613
Determination of Na, K, and Cl in foodstuffs, Husband and Godden.....	614
Testing wheat for protein, Coleman, Fellows, and Dixon.....	614
Examination of mixtures of coconut and palm oil, Elsdon and Smith.....	615
A rapid method for the sorting of butters and margarines, Manley.....	615
A Babcock-Gerber method for fat in ice cream, Moore and Morse.....	615

METEOROLOGY

	Page
Popular long-range weather forecasts, Cave.....	616
Popular long-range weather forecasts, Butler and Cave.....	616
Observations at the Massachusetts Station, Ostrander and Parkin.....	616
Oklahoma climographs and biotic regions, Weese.....	616
Preliminary division of Oklahoma on basis of rainfall adequacy, Bollinger.....	616
Aerological code, 1926.....	617

SOILS—FERTILIZERS

Soil characteristics: A field and laboratory guide, Emerson.....	617
A study of soil types in relation to utilization and management, Weir.....	617
Soil survey of Greene County, Alabama, Stroud et al.....	617
Soil survey of Gibson County, Indiana, Bushnell et al.....	617
Soil survey of Coleman County, Texas, Hawker et al.....	618
Minnesota glacial soil studies, II, III.....	618
On the permeability of clay soils, Wityn.....	618
Treatise on sedimentation, Twenhofel.....	619
Aluminum hydroxide and "freezing up" of alkali soils, McGeorge et al.....	619
Interrelations between temperature of soil and atmosphere, Smith.....	620
Origin and nature of the soil organic matter, V, Waksman.....	620
The degree of humification of the dead covering of forest soils, Nemece.....	621
The function of organic matter in the soil, Thorne.....	621
Nitrate production under field conditions in Alberta, Wyatt et al.....	621
Handling sweet clover with reference to nitrates, Whiting and Richmond.....	622
Crop and soil management for eastern Canada, Hopkins and Hopper.....	622
The effect of lime and fertilisers on the potash content, Lipman et al.....	622
Lime and phosphate, Waterman and Thomas.....	623
Soil investigations, Hume.....	623
Tests comparing sulphate of ammonia and nitrate of soda as fertilizers.....	623
The fixation of atmospheric nitrogen, Brahm.....	623
Some phenomena in the electric arc process of nitrogen fixation, Karrer.....	623
The fixation of nitrogen as aluminum nitride, Krase et al.....	623
The assimilation of phosphorus from phytin by oats, Whiting and Heck.....	624
Availability of Tennessee raw rock phosphate, Conner and Adams.....	624
Volatilization methods for the manufacture of phosphoric acid, Jacob.....	624
Lime in agriculture, Corrie.....	624
Some effects of limestone and hydrated lime in acid soils, Dorsey.....	624
Synthetic calcium silicates as a source of lime, III, Barnette.....	625
Inspection of lime products used in agriculture, Haskins et al.....	625
Commercial fertilizers, 1926, Bartlett.....	625
The American fertilizer hand book.....	625
International trade in fertilizers, 1925-26.....	626

AGRICULTURAL BOTANY

Manual of botanical microtechnique, Kisser.....	626
Life of plants, Keeble.....	626
Photosynthesis, Spoehr.....	626
The nature of the growth rate in plants, Hanna.....	626
Ripening processes in seeds of Pharbitis, Yoshii.....	627
Problems in the physiology of germination, Merckenschlager.....	627
A method for determining seed viability, Fick and Hibbard.....	627
The relative light requirements of some coniferous seedlings, Bates.....	627
Carbohydrate variations [in corn], Hume.....	627
The first sugar of photosynthesis and the rôle of cane sugar, Priestley.....	627
Carbon dioxide assimilation, Warburg.....	628
Calcium oxalate monohydrate and trihydrate in plants, Frey.....	628
Relation of salt concentration to transpiration and respiration, Newton.....	628
On the root system as an osmotic apparatus, Sabinin.....	628
The effects of an artificially controlled hydric concentration upon wound healing in the potato, Herklots.....	628
[Leaf variegation and bacteria], Mattei.....	629
Foliar anomalies in <i>Medicago sativa</i> , Draghetti.....	629
Floral abortion in the olive, Melis.....	629
Effects of X-rays on plant tumors, Rivera.....	629

	Page
Transformations induced by X-rays in plant tumor tissue, Rivera.....	629
Bacterial symbiosis in plants other than the legumes, Wilson.....	629
On the occurrences of a species of <i>Colletotrichum</i> , Small.....	629
Polyporaceae in Bulgaria, B'rzakov (Barsakow).....	630

GENETICS

Genetics.....	630
Gigantism and genetic constitution in tetraploid genera, Artom.....	630
Linkage and synthetic lethality in barley, Hallqvist.....	630
Inheritance of characters in a barley cross, Neatby.....	630
A genetical interpretation of ecological adaptation, Sax.....	630
Effect of environment on variegation patterns in maize pericarp, Eyster.....	630
Genetic factors for yellow endosperm color in maize, Anderson.....	631
A botanical study of the flax plant, VII, Searle.....	631
The extent of natural cross-fertilization in jowar, Patel.....	631
Inheritance in <i>Nicotiana tabacum</i> , VII, Clausen and Goodspeed.....	631
Interspecific hybridization in <i>Nicotiana</i> , III-V.....	632
A cytological study on the pollen sterility in <i>Solanum tuberosum</i> , Stow.....	632
A recessive glabrous character in soybeans, Stewart and Wentz.....	632
Natural crossing in soybeans, Garber and Odland.....	633
Practical sugar cane genetics, Poole.....	633
Genetics and its relation to cane production, Krauss.....	633
Chromosome behaviour in triploid wheat hybrids, Thompson.....	633
Some hybrids of <i>Aegilops ovata</i> L. ♀ × wheats ♂, Percival.....	633
A study of wheat-rye hybrids, Meister.....	633
Segregation in fertile hybrids between wheat and rye, Blaringhem.....	634
Chromosome behavior in a cross between wheat and rye, Thompson.....	634
Heteroploidy and somatic variation in Dutch flowering bulbs, De Mol.....	634

FIELD CROPS

Crop returns in the Wisconsin drift soil area, Stevenson et al.....	634
Fixation of nitrogen by legume nodule bacteria in pure culture, Barthel.....	635
Fleshy annual pastures in Canada, McRostie et al.....	635
Bagging cotton flowers to prevent cross-pollination, Kearney and Porter.....	635
Experimental error of field trials with cotton, Bailey and Trought.....	635
The cotton growing countries present and potential.....	635
Johnson grass in Texas, Pollock.....	635
Breeding winter oats for the South, Stanton.....	636
[Potato experiments in New Brunswick], MacLeod.....	636
Potato growing in Colorado, Sandsten.....	636
A method of crossing sorghums, Vinal.....	637
Report on the sugar beet experiments [in Ireland], 1925.....	637
Effect of increased sodium nitrate on quality of sugar beets, Souček.....	637
White sweet clover as related to soil enrichment, Whiting and Richmond.....	637
[Tobacco investigations in Canada in 1925], Slagg et al.....	638
On the biology of tobacco fermentation, Schmidt.....	639
Spring wheat production in Illinois, Stark.....	639
Influence of certain soil amendments on winter wheat in Ohio, Thatcher.....	639
[The Swedish State Seed Testing Station], Witte.....	640
Recent Indiana weeds, 1925, Hansen.....	640
Weed control, Groh.....	640
Weed rye (<i>Secale cereale</i>) in the mountains of central Asia, Balabaev.....	640

HORTICULTURE

Methods of interpreting results of horticultural experiments, Anthony.....	640
Effect of various lengths of day, Aughter and Harley.....	640
[Breeding work at the South Dakota Station], Hansen.....	641
Fertilizer experiments with greenhouse lettuce and tomatoes, Lloyd.....	641
A case of arsenical injury to tomato plants, Fenton.....	641
Trials with commercial varieties of canning peas, Hume.....	641
Watermelon culture, Wharton.....	642
Essentials to successful fruit culture in Arizona, Crider.....	642
Fruit bud formation and growth, Hooker.....	642

	Page
Comparative rates of imbibition in apple wood tissue, Rogers.....	642
The chemical composition of developing flowers and young fruits from weak and vigorous spurs of the apple, Howlett.....	642
The effect of inbreeding on the vigor of apple seedlings, Lantz.....	642
Apple stock variation and its relation to scion growth, Bregger.....	643
Relation of temperature to pollen tube growth, Knowlton and Sevy.....	643
Causes and results of partial pollen sterility in apples and pears, Kobel.....	643
Pectic constituents of peaches, Appleman and Conrad.....	644
The influence of potash upon grapes, Dusserre and Godet.....	644
Correlation of chemical composition with hardiness in brambles, Lott.....	644
The avocado stock problem, Webber.....	645
Results of pollination and other experiments on avocados, Clark.....	645
The citrus industry in South Africa, Webber.....	645
Orange cincturing and root pruning tests, Savage.....	645
Studies in the Kao Pan Siamese seedless pomelo, Tanaka.....	645
Pollination of feijoas, Clark.....	646
The effective use of flowering plants, Ernst.....	646
Improving small home grounds in Illinois.....	646

FORESTRY

The new book of trees, Woodward.....	646
Acacia seedlings, Part XI, Cambage.....	646
Forestry legislative survey.....	646
Some aspects of forestry in South Australia, Mawson.....	646
The line-plot system: Its use and application, Robertson.....	646
Accuracy of methods in estimating timber, Candy.....	646
A new growth per cent formula, Gevorkiantz.....	646
Air seasoning lumber in the Douglas fir region, Johnson and Gibbons.....	647
Waste kauri wood as a source of paper pulp and resin.....	647

DISEASES OF PLANTS

The relation of environment to disease in plants, Jones.....	647
Bibliography of the literature of plant protection, Morstatt.....	647
Indiana plant diseases, 1923, Gardner.....	647
The disease susceptibility of cereals and wild grasses, Mains.....	648
Conditions for heat canker and sunscald in plants, Harvey.....	648
Mosaic and related diseases, Kunkel.....	648
Spore characters and histology of <i>Puccinia graminis</i> , Mehta.....	648
Studies in the life history and physiology of certain smuts, Sartoris.....	648
The toxicity of the spores of <i>Tilletia tritici</i> to animals, Dobson.....	648
The relation of stinking smut virulence to soil character, Gassner.....	648
Values in pickling media, Gassner.....	648
Biological testing of seed treatments, Friedrichs.....	649
Dust fungicides in Hungary, 1921-1924, Kern.....	649
Preliminary studies on <i>Pleosphaerulina briosiana</i> , Miller.....	649
Cabbage diseases in Indiana, Gregory.....	649
Corn ear rot, Hume.....	649
Transmission of streak disease of maize by <i>Balclutha mbila</i> , Storey.....	649
The testing of new varieties of hops, Hatton and Amos.....	650
Physiologic races of oat smuts, Reed.....	650
The conditions of infection in potato wart, Weiss.....	650
The Helminthosporium disease of rice, Ocfemia.....	650
Relation of soil temperature to germination of rice and infection by the Helminthosporium disease, Ocfemia.....	651
A note on the sterilization of rice-grains, Bose.....	651
<i>Puccinia coronifera</i> on winter rye, Russakow.....	651
Solanaceae as hosts for <i>Synchytrium endobioticum</i> , Esmarch.....	651
Influence of enviroinal factors on the infection of sorghums and oats by smuts, I, II, Reed and Faris.....	651
Cytological studies of the mosaic disease of tobacco, Rawlins and Johnson.....	652
Acidity and varietal resistance of wheat to <i>Tilletia tritici</i> , Hurd-Karrer.....	652
Breeding for control of loose and stinking smut of wheat, Sessous.....	653
The loose and stinking smuts in Indiana, Gregory.....	653

	Page
Field observations on crown-gall of nursery stocks, Wormald and Grubb.....	653
The incidence of leaf scorch upon the apple, Hatton and Grubb.....	653
An unusual form of pear canker, Harris.....	654
The mulberry "blight" in Britain, Wormald.....	654
Mulberry bacterial blight, Wormald.....	654
The blue stripe wilt of the raspberry, Harris.....	654
<i>Erysiphaceae croatiae</i> , Škorić.....	654
The cause of spike disease in sandal (<i>Santalum album L.</i>), Jivanna Rao.....	654
Biology and pathology of hardwood heart-rotting fungi, I, II, Baxter.....	654
Studies in wood decay, III, Schmitz.....	655
Studies in wood decay, IV, V, Schmitz.....	655

ECONOMIC ZOOLOGY—ENTOMOLOGY

A biological survey of North Dakota, I, II, Bailey.....	656
Some habits of mountain lions in Arizona, Musgrave.....	656
Anatomy of the wood rat, Howell.....	656
A disease in wild rats, Meyer and Batchelder.....	656
The storing habit of the Columbian ground squirrel, Shaw.....	657
Records of birds bred in captivity, Hopkinson.....	657
The distribution of bird-life in Ecuador, Chapman.....	657
Protozoology, Wenyon.....	657
Marine borers on the Atlantic coast of Canada, M'Gonigle.....	657
Studies on insect metamorphosis, III, Singh-Pruthi.....	657
New method for comparing the efficiency of stomach insecticides, Janisch.....	657
Fish oil, an efficient adhesive in arsenate-of-lead sprays, Hood.....	658
Tar-distillate washes: Their comparative effectiveness, Goodwin et al.....	658
Injury to glasshouse plants from hydrocyanic acid gas following the application of copper fungicides, Guba.....	658
[Report of South Dakota] department of entomology-zoology, Severin.....	659
Insect and other invertebrate pests of 1925, MacDougall.....	659
The principal enemies of alfalfa in Argentina.....	659
[The animal enemies of rice], Winkler.....	659
Notes on some unusual insect pests on fruit, Theobald.....	659
Citrus insects and their control, Watson.....	659
Insects affecting coffee in Trinidad and Tobago, Ulrich.....	659
Fumigating olives with calcium cyanide for <i>Phloeothrips oleae</i> , Benloch.....	659
Heteroptera or true bugs of eastern North America, Blatchley.....	659
Experiments on the control of the apple capsid bug, Staniland.....	660

The work-day of the bee, Hover and Lord.....	662
The first successful attempt to control the mating of queen bees, Cale.....	662
Beekeeping up to date, Flower.....	662
Seventh International Congress of Beekeepers, 1924.....	662
Infestation of flax seed by mites, Davin.....	662
Etiology of Oroya fever, V, Noguchi.....	662

ANIMAL PRODUCTION

	Page
Natural history of the races of domestic mammals, Hilzheimer.....	662
The physiology of the morphogenesis.—I, Cryptorch rams, Zavadovskii.....	662
Influence of castration on the horns in Merino sheep, Zavadovskii.....	663
Bilateral and unilateral castration in Cervus, Zavadovskii.....	663
Investigations of experimental hermaphroditism, Krause.....	663
Observations on the oestrous cycle of the albino mouse, Parkes.....	663
The properties of the gonads.—IX, Testis graft reactions, Moore.....	664
Phosphorus metabolism and influence of testes upon it, Blakher.....	664
Histological changes in the testis of the guinea-pig, Lindsay and Medes.....	664
The metabolism of animals suffering from dietary sterility, Anderson.....	664
Vitamin E and reproduction, Mattill and Clayton.....	664
Increased food consumption in pseudopregnancy, Goss.....	665
The feeding value of different grades of barley, Honcamp and Schramm.....	665
Investigations on barley and its milled products, Honcamp and Schramm.....	665
Silage experiments at Nagpur, Annett and Padmanabha Aiyer.....	666
Swedish fish meal, its composition and feeding value, Hansson.....	666
Does the addition of sodium chloride increase the value of a corn ration for growing animals? Mitchell and Carman.....	666
The value of green corn stacked as a feed for cattle, Wilson.....	667
A comparison of white and yellow corn for swine, Rice et al.....	667
[Feeding experiments with swine at the South Dakota Station], Wilson.....	667
The hog: Its use as a domestic animal, Stegmann von Pritzwald.....	668
Fertility in sheep, Nichols.....	668
Conformation and appointments of the horse, Timmis.....	668
Fragment of skull of a horse from the interglacial deposits near Puławy (Poland), Kączkowski and Prawocheński.....	668
Report of the committee on research in poultry husbandry, Jull et al.....	668
Biometrical measurements of domestic fowl, Saller.....	669
The growth of the skeleton of the White Leghorn chicken, Latimer.....	669
Standard breeds and varieties of chickens, II, Jull.....	669
The Sussex fowl, Outram.....	669
Poultry in Arizona, Embleton.....	669
[Experiments with poultry at the South Dakota Station], Stevenson.....	669
Poultry feeding experiments, Hoh and Kam.....	670
Effect of cod liver oil upon flavor in poultry meat, Carrick and Hauge.....	670
Application of "protozyme" to poultry feeding, Clickner and Follwell.....	670
Brooding and pullet development, Moore and Lewis.....	670
Hatching and raising chicks, Smyth.....	671
Hatching quality of eggs with relation to management, Goodale.....	671
Report of the committee on egg-laying contest standardization, Jones.....	671
The Missouri plan of certified breeding, Winton.....	671

THE HISTORY OF THE UNITED STATES OF AMERICA
FROM 1763 TO 1876

The history of the United States of America from 1763 to 1876 is a story of growth, struggle, and achievement. It begins with the early years of settlement and the fight for independence, leading to the formation of a new nation. The period is marked by significant events such as the American Revolution, the War of 1812, and the Civil War. The text details the political, social, and economic changes that shaped the country during this time, including the expansion of territory and the development of a unique American identity. The author provides a comprehensive overview of the nation's history, highlighting the challenges and triumphs of the early republic.

EXPERIMENT STATION RECORD

VOL. 56

MAY, 1927

No. 7

The winter's toll of the ever dwindling number of surviving pioneers in the promotion of education and research in agriculture and related lines in this country has been unusually heavy. Since the beginning of 1927 at least five men and women widely known for their services in developing their respective fields have passed away. Three of these—Dr. Erwin F. Smith, Dr. Frederick B. Power, and Miss Caroline L. Hunt—had been associated for many years with the Federal Department of Agriculture. The remaining pair, Drs. Charles E. Marshall of Massachusetts and Thomas Forsyth Hunt of California, had been practically throughout their entire careers actively identified with the agricultural colleges and experiment stations. In their several specialties of plant pathology, phytochemistry, home economics, microbiology, and agricultural education, each of the five had served long and contributed much.

The death of Dr. Erwin F. Smith occurred April 6, 1927, a few days' sickness ending a scientific career of over 40 years spent entirely in the service of the Federal Department of Agriculture. Graduating from the University of Michigan in 1886 when 32 years of age, Dr. Smith was immediately appointed an assistant in mycology in the Department and eventually was given charge of the laboratory of plant pathology of the Bureau of Plant Industry. It was his fortune to be associated with the Department almost from the very beginning of its activities in this field and from a time when little work was being done anywhere in the United States on the economic side of plant pathology. In the words of a recent biographical note in the *Official Record* of the Department, "he and his associates blazed the trail for this new science, furnishing the initial impetus for nation-wide phytopathological research with such ability and dynamic energy that to-day this branch of science exceeds in the number of its workers any other branch of botanical endeavor in this country."

Much of his early work dealt with peach yellows, one of the most baffling problems of phytopathology. He studied this troublesome disease for about 5 years, clearing away much of the prevailing uncertainty regarding its cause and development through laboratory studies and comprehensive and extensive field experimentation.

From 1888 to 1891 he published a number of papers summarizing his findings, and as these constituted the first comprehensive description and discussion of the disease they attracted wide attention among investigators and practical fruit growers. He differentiated and named the southern contagious peach rosette as distinct from peach yellows but belonging to its general type, and he established the practicability of the control of yellows by the eradication from orchards of diseased trees.

A later and more immediately fruitful study was his work on *Fusarium* diseases and the fungus infestations of the soil. Previously all members of the form genus *Fusarium* had been considered to be pure saprophytes, and his studies consequently opened up a new vista of plant parasitism. He also discovered that the *Fusarium* spores are capable of retaining their virulence for several years in the soil, with the result that the breeding of resistant strains of susceptible crops was successfully undertaken.

In 1893 Dr. Smith entered upon a study of bacterial diseases of plants, one consequence of which was the development of the modern science of plant bacteriology. In 1905 he issued the first volume of a monograph entitled *Bacteria in Relation to Plant Diseases*, followed by a second volume in 1911 and a third volume in 1914, while his textbook in 1920 entitled *An Introduction to Bacterial Diseases of Plants* brought the subject into concrete pedagogical form.

No complete account of Dr. Smith's accomplishments can be here attempted, but reference must be made to the phase of his research with which his name is most generally associated—his work on crown gall and its resemblance to cancer in men and animals. His findings of numerous analogies between the tumors of plants and animals attracted world-wide attention and led to numerous honors at home and abroad, including the presidency of the American Society for Cancer Research in 1924 and election to the National Academy of Sciences. He had previously served as president of the Society of Plant Morphology and Physiology in 1902, Section G of the American Association for the Advancement of Science and the Society of American Bacteriologists in 1906, the Botanical Society of America in 1910, and the American Phytopathological Society in 1916, and had received the degrees of doctors of science and laws from the University of Michigan and that of laws from the University of Wisconsin.

Dr. Smith was a prolific writer, a survey of his publications indicating no fewer than 167 titles, exclusive of many reviews, and many of his works were of outstanding importance. Most of his papers were published by the Department of Agriculture, but he was also a frequent contributor to outside journals. One of his final addresses was given at the International Congress of Plant Sciences at Cornell

University last August on the subject of Fifty Years of Phytopathology. This was notable not only as an epitome of the striking scientific accomplishments of the half century, but also as revealing inevitably the large part which Dr. Smith himself had played in developing the field by his personal service and the inspiration of his leadership.

The career of Dr. Frederick B. Power, senior chemist in charge of the phytochemical investigations of the Department, paralleled that of Dr. Smith in several interesting particulars. Both were born in New York State, Dr. Power in 1853 and Dr. Smith in 1854, and to both was accorded the opportunity of active service substantially to the end. Both were resourceful and productive investigators and both were indefatigable writers of much literary ability. Explorers alike of little-known byways of science, both found fame and their best-known opportunity for service when their trails unexpectedly led to a common interest in diseases threatening mankind.

Unlike Dr. Smith, much of Dr. Power's life was spent abroad. In 1880 he received the degree of doctor of philosophy from the University of Strassburg. Returning to this country he was for 3 years in charge of the chemical laboratory of his Alma Mater, the Philadelphia College of Pharmacy, resigning to organize the School of Pharmacy at the University of Wisconsin, and for 4 years he was engaged in commercial work. In 1900, however, he was appointed director of the Wellcome Chemical Laboratories of London and continued in that position for 14 years. From 1916 until his death, which occurred March 26, 1927, he was in charge of the phytochemical laboratory of the Bureau of Chemistry.

Dr. Power thus looked back upon an experience of over 50 years. Most of this time he devoted to a study of the chemical constituents of plants. As Dr. Alsberg, a former chief of the Bureau of Chemistry, has well said, "only those who have themselves cultivated this field know how difficult, how time consuming, how patience taxing is such work." A measure of his success is seen in the fact that he was the author of 129 scientific papers, and that his last year had been spent in the preparation of what was to be an exhaustive monograph, covering the whole field of phytochemistry and which would have summarized his many notable contributions.

Outstanding among his accomplishments in popular interest was his study of the chemical constituents of chaulmoogra oil and his determination of the structural formulas of chaulmoogric and hydrocarpic acids. Chaulmoogra oil has long been known to be of value for the treatment of leprosy, but it remained for Dr. Power by his work on the constituents of the chaulmoogra seeds and the con-

stitution of chaulmoogra acid to lay the foundation on which rests the present-day treatment of leprosy which has been so encouraging.

The decade of his connection with the Department of Agriculture was devoted largely to research on the odorous principles of the apple, peach, and grape. Not long before his death, he completed a study of the odorous and nonvolatile constituents of the cotton plant, isolating a number of odorous principles which it is thought may be utilized by entomologists and others in the preparation of baits for combating the boll weevil. Not the least valuable of his services, however, was his relations with his associates. To quote Dr. Alsberg again, "he soon became one of the strongest influences in the bureau for fostering that sound scholarship and research spirit, which, under pressure for immediate and practical results, so easily perishes in industrial and research organizations."

The value of Dr. Power's work was widely recognized, and he was the recipient of many honors, including the degree of doctor of laws by the University of Wisconsin, the granting of several gold medals abroad, and election as a fellow of the Chemical Society of London and as a member of the National Academy of Sciences, the last-named a distinction said to have been shared only with Dr. Smith and one other member of the Department. Yet as Dr. Browne, the present chief of the Bureau of Chemistry, has said, "notwithstanding the great eminence which he had attained in the fields of pharmacy and chemistry, Dr. Power was exceedingly modest in manner and showed a strong dislike of the exaggerated publicity which is sometimes given to scientific investigations. . . . In the fields of pharmacy and phytochemistry the results of his work will long remain as outstanding accomplishments of the present era of chemistry. The world of science is much poorer with his passing. There is no one left to take his place."

The death of Miss Caroline L. Hunt on January 27, 1927, removed from the ranks of home economics workers at the age of 62 years not merely one of the pioneers in this relatively new field but a prominent member of that small but farseeing group of women under whose leadership home economics developed from an exposition of cooking and sewing into the broader aspects of to-day. Her sound educational equipment, her restless energy and enthusiasm, and her characteristic idealism and wide sympathies combined to give her a position of influence which was as unique as it was helpful.

A graduate of Northwestern University in 1888, Miss Hunt later carried on graduate work in chemistry both there and at the University of Chicago. In 1895 and 1896 she collaborated with Miss Jane Addams of Hull House in some of the earliest dietary studies made in this country, embracing families in the congested district of Chicago and undertaken under the auspices of the nutrition inves-

tigations of the U. S. Department of Agriculture. The next decade she spent in teaching home economics, five years at Lewis Institute in Chicago and a like period as professor of home economics in the University of Wisconsin. In 1909 she joined the nutrition staff of the Department, continuing with this work throughout its administration in turn by the Office of Experiment Stations, the States Relations Service, and the Bureau of Home Economics until her death.

Miss Hunt came to the Department as one of the comparatively few college women of that time who had received some definite training in home economics and the sciences related thereto. She had specially studied dietetics and thus supplemented the knowledge of the other members of the force engaged in nutrition investigations. One specific accomplishment was her devising of a system which simplified the former elaborate calculations of the results of dietary studies.

Her chief work with the Department, and that for which she became most widely known, was the application of scientific facts about nutrition to everyday food problems. She wrote clearly in comparatively nontechnical language and had unusual ability in graphic and pictorial presentation of subjects relating to food and diet. Her work was incorporated in a number of semipopular bulletins which had a wide circulation and were particularly useful to teachers and students of home economics. Such, for example, were the numerous farmers' bulletins on the economic use of meat and other foods in the home and those portraying the group system of selecting foods for a balanced menu without definite calculation of calories. She was also the author of similar bulletins on good proportions in the diet, food for young children, school lunches, and fresh fruits and vegetables in relation to other staple foods. Publications of this type are now quite common, but when she began her writings the application of the principles of nutrition to practical meal planning in the home was virtually pioneering, and its accomplishment was productive of widespread benefit. As a recent tribute in the *Journal of Home Economics* states, "it is impossible to estimate the influence of her bulletins on the popular literature of nutrition or their share in the progress of health education."

Miss Hunt's activities and influence were by no means restricted, however, to matters of food and nutrition. Not the least of her services to her own and later generations was her biography of Mrs. Ellen H. Richards, which traced with intimate touch and sympathetic insight the history of the whole home economics movement. Such a task she was well qualified to perform, for in addition to technical knowledge she had broad vision and understanding and a far-reaching social philosophy. This is illustrated by the following

passage from a paper entitled Revaluations, originally prepared in 1901 and which typifies the dominant motive of her life: "That which is necessary for good home making can be determined only by holding fast to the highest ideal of home and by having a clear understanding of changing social conditions. . . . The final test of the teaching of home economics is freedom. If we have unnecessarily complicated a single life by perpetuating useless conventions or by carrying the values of one age over into the next, just so far have we failed. If we have simplified one life and released in it energy for its own expression, just so far have we succeeded."

The youngest member of the group was Dr. Charles E. Marshall, who died very suddenly at Amherst, Mass., on March 20, 1927, in his sixty-first year. Although born on an Ohio farm, Dr. Marshall like Dr. Smith was a graduate of the University of Michigan, receiving the degree of bachelor of philosophy in 1895 and that of doctor of philosophy in 1902, while like Dr. Power he had also supplemented his studies in this country by work abroad, spending considerable time in bacteriological laboratories of Copenhagen, Paris, and Berlin. After serving for 3 years as instructor in bacteriology and hygiene at the University of Michigan he was appointed assistant in bacteriology in the Michigan Experiment Station in 1896. Two years later he became bacteriologist and in 1902 professor of bacteriology and hygiene in the Michigan Agricultural College, while in 1908 he was also made vice director of the Michigan Station. In 1912 he resigned to become professor of microbiology in the Massachusetts Agricultural College and dean of its Graduate School, and was in active service in these capacities at the time of his death.

Dr. Marshall was the author of many articles on bacteriology and microbiology, mostly issued under the auspices of the Michigan Station, but including the well-known college text on Microbiology, which appeared in 1911. His own research work was of a high order, notably his studies of the associative action of bacteria in milk and on a number of animal diseases. It was largely because of his high ideals and thorough understanding of research principles and methods that he was placed in charge of the scientific work of the Michigan Station. For this supervision he was well equipped, both by temperament and conviction. A firm believer that in individuality is to be found the very essence of creative work, he none the less steadfastly maintained, as at the 1912 meeting of the Association of the American Agricultural Colleges and Experiment Stations, that "an organization effected to foster research work requires someone in sympathy with it to push it forward." He had much to do with the outlining and conduct of the early work under the Adams

Act, exerting a strong influence in maintaining high standards and otherwise improving the quality of the station work.

Doubtless the same attributes, together with his sound scholarship and special pedagogic training, contributed toward his selection to organize the Graduate School at the Massachusetts Agricultural College. In this undertaking he had been very successful, converting the relatively undeveloped graduate instruction which had been offered for about 18 years to a handful of students to an efficient educational unit with a greatly enlarged enrollment, an adequate and well-organized curriculum, and a deserved national reputation. Important as have been his personal contributions to science, it is perhaps through the work of the many students whom he had assisted on the pathway to a research career that his ideas and ideals will be longest perpetuated.

The death of Dr. Thomas Forsyth Hunt occurred somewhat unexpectedly on April 25, 1927. Dr. Hunt was on shipboard, nearing San Francisco from a trip to Honolulu, where he had represented the University of California at the Pan Pacific Conference on Education, Reclamation, Rehabilitation, and Recreation. He was in his sixty-sixth year.

Dr. Hunt was a native of Illinois and received his collegiate training entirely at that university, obtaining the bachelor's degree in 1884 and the master's degree in 1892. The honorary degree of doctor of agriculture was conferred upon him in 1903 and that of doctor of science by the Michigan Agricultural College in 1907.

Unlike most of the group herein discussed, Dr. Hunt's experience included a wide range of institutions from the East through the Middle West to the Pacific coast. Starting his career as an assistant to the State entomologist of Illinois in 1885, he served in turn as assistant in agriculture in the University of Illinois and its experiment station from 1886 to 1891, as professor of agriculture in the Pennsylvania State College in 1891-92, and as professor of agriculture and later dean of the College of Agriculture and Domestic Science at Ohio State University from 1896 to 1903. From there he was called to the College of Agriculture at Cornell University as professor of agronomy, serving 4 years, and then going back to Pennsylvania as dean of the School of Agriculture and director of the station from 1907 to 1912. In the latter year he was made dean of the College of Agriculture of the University of California, being likewise director of the station till 1917.

In 1923 he relinquished the duties of dean but continued as dean emeritus and also as professor of agriculture. Much of his time since that date had been spent on a survey of agricultural conditions in

California. A comprehensive report of his findings which he had projected was in process of preparation, and it is hoped may be brought to completion by others.

Dr. Hunt's extended service was noteworthy for his participation in a number of pioneer undertakings. While at the Ohio State University, as well as subsequently, he did much to popularize the cause of agricultural education, and his success in securing the erection in 1898 of Townshend Hall, the first of the so-called modern agricultural buildings now to be expected as a matter of course on every campus, was significant of the belated but eventually emphatic acceptance of the new form of education. It was also while he was serving as dean of the Ohio College of Agriculture, and largely through his influence, that the first session of the Graduate School of Agriculture, fostered by the Association of American Agricultural Colleges and Experiment Stations, was held in 1902.

Dr. Hunt was long a familiar figure at the meetings of the association. He will be particularly remembered for his service on its committee on instruction in agriculture. The subject of methods of instruction was one in which he was much interested, and he was a vigorous champion of the movement to introduce courses more closely related to the farm and farm life than was the prevailing trend of the day. He was the author or co-author of numerous texts, one of which, *Soils and Crops*, was issued in 1896. Another early work in a little-cultivated field was his *History of Agriculture and Rural Economics*, which appeared in 1899.

While Dr. Hunt's reputation was largely as a teacher, administrative officer, and writer, he was a firm believer in the need of research in the advancement of agriculture and the development of agricultural instruction, and his periods of service as a station director in Pennsylvania and California were years of steady development and encouragement. He was quite successful even in the face of discouraging circumstances in drawing together a large group of research workers, many of them of national reputation, and in furthering their efforts by securing appropriations and otherwise affording opportunity and facilities for their work under favorable conditions.

Dr. Hunt was broadly interested in agriculture as a whole rather than in its localized or narrowly specialized forms. He was zealous in the upbuilding of the Society for the Promotion of Agricultural Science as a means to this end, serving as its president in 1907-1909. During the war he was selected as one of the members of the Agricultural Commission and sent abroad by the Federal Government, and in 1920-21 he served as resident delegate of the United States to the International Institute of Agriculture at Rome. Presumably because of this relationship he was given last December the decora-

tion of Cavalier of the Order of the Crown of Italy. This honor, it is said, he consistently refused to make public during his lifetime. However this may be, it is certain that many other evidences of the value of his unique services to the cause of agricultural education have long been apparent to observers of the last half century's progress. His death will be especially mourned in the many institutions for whose upbuilding he had so ardently labored.

So diverse were the five men and women here considered in heritage, environment, and choice of work that they could hardly have been expected to possess many relationships in common. Yet likenesses are not hard to find. All were broadly educated, with more than the usual command of the English language, and most of them were firm believers in the efficacy of the written word. All were earnest advocates of research and the thorough preparation of research workers. In a large sense, all were educators, though their contacts with the educational world differed widely.

More characteristic and more fundamental than any of these attributes, however, was their zeal for the betterment of mankind, a zeal so concrete and personal as to lead one and all into more or less unexpected paths for the promotion of the cause. With Dr. Hunt, the agronomist, the road ran quite directly into the domain of agricultural education and subsequently to explorations in the then little-known realm of agricultural economics and sociology. For Miss Hunt, also, the new science of home economics was a logical selection, but with her temperament and ideals it was inevitable that her work could not be limited to the affairs of the kitchen but would embrace the whole field of social philosophy. It was more than a coincidence, however, that the remainder of the group should have so applied their respective specialties of microbiology, phytochemistry, and phytopathology as to make substantial contributions to the knowledge of three serious human diseases—tuberculosis, leprosy, and cancer. Yet while Drs. Marshall, Power, and Smith in this work touched humanity at these points more directly, this phase was merely typical of the whole dominating motives of their lives. Likewise it was no accident that the services of the entire five were recognized repeatedly by associations of workers in their own and related fields, by foreign Governments, by great universities, and by scientific institutions. As a group their lives well exemplify the spirit of applied science, irrespective of its manifold divisions, of contributing the utmost possible service to the world.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The composition of milk, I, II, H. T. CRANFIELD, D. G. GRIFFITHS, and E. R. LING (*Jour. Agr. Sci. [England]*, 17 (1927), No. 1, pp. 62-93, figs. 13).—Two series of analytical investigations are reported.

I. *Variation in the solids-not-fat, fat, and protein content of cow's milk, and their relationship.*—Over 700 mixed milks from 15 herds were examined during 1925-26 for percentages of fat, solids-not-fat, and protein. The herds were selected to include the greatest variation possible in size of herd, climate, soil types, and general management. The report includes frequency distributions, standard deviations, mean percentages with probable errors, and correlation tables and graphs for the three constituents determined. Certain seasonal variations of some ratios are discussed.

II. *Variation in the percentage of mineral constituents in cow's milk, and their relationship with the solids-not-fat and protein content.*—Determinations were made of total ash, soluble ash, insoluble ash, lime, and phosphoric acid in 670 mixed milks from 15 herds. Frequency distributions, standard deviations, mean and probable error of mean are reported for each constituent named. Correlations of these constituents with solids-not-fat and with protein are shown in tables and curves. Total ash was found to fall with solids-not-fat until low values of the latter constituent were reached, when the ash appeared to rise. Soluble ash rises, insoluble ash falls, with falling solids-not-fat; and lime and phosphoric acid fall with nonfatty solids. Seasonal variations were noted.

A study of the proteolytic action of certain specific organisms on milk proteins in milk and synthetic butter, G. SPITZER, E. H. PARFITT, and W. F. EPPLE (*Jour. Dairy Sci.*, 10 (1927), No. 1, pp. 15-32).—In experiments reported from the Indiana Experiment Station, sterile skim milk samples were inoculated in pure culture with 13 species of microorganisms and incubated at from 20 to 21° C. Analyses were made each 15 days for ammonia, for nitrogen not precipitated by phosphotungstic acid, and for nitrogen not precipitated in a saturated solution of zinc sulfate. The synthetic butter experiments were made by sterilizing 50-gm. lots of skim milk, inoculating with the specific organism to be studied, and adding to each 100 gm. of sterilized butterfat, the mixtures being rendered homogeneous by shaking. Synthetic butters were held at room temperature and at from 0 to 4°. Analyses of these two series were made each 15 days and each 30 days, respectively.

In 45 days the various organisms produced ammonia increases in milk of from 0.06 to more than 25 per cent; the nitrogen not precipitated by phosphotungstic acid showed increases of from 0.18 to 50 per cent; and peptone increases were from 0.56 to nearly 21 per cent. In the butter experiments, after 120 days at 0 to 4°, the ammonia increases ranged from 0.17 to 1.16 per cent, the nonprecipitated nitrogen from 0.17 to 20.8 per cent, and the peptone from 1.72 to over 25 per cent. Held at room temperature for 60 days, the synthetic butters showed, with the various organisms, ammonia increases of from 0.50 to 2.14 per

cent, nonprecipitated nitrogen increases of from 6.15 to 18.75 per cent, and pepsone increases of from 0.08 to 18.66 per cent.

The effect of heating on the hydrogen-ion concentration and on the titratable acidity of milk, E. O. WHITTIER and A. G. BENTON (*Jour. Dairy Sci.*, 9 (1926), No. 5, pp. 481-488, figs. 2).—The effect on H-ion concentration and on the titratable acidity of milks produced by heating them continuously at 95 and at 100° C. for from 14 to 16 hours was studied. The H-ion concentration increases continuously after an initial drop attributed to loss of carbon dioxide from the milk. The titratable acidity rises somewhat more sharply than the H-ion concentration. During coagulation the rate of change of H-ion concentration is considerably lessened, due to buffer readjustments which can not yet be explained. At the same time there is apparently some adsorption of the acid by the curd. The amount of acid production is dependent upon both time and temperature of heating.

Variations in the susceptibility of the fat in dry whole milks to oxidation when stored at various temperatures and in various atmospheres, G. E. HOLM, P. A. WRIGHT, and G. R. GREENBANK (*Jour. Dairy Sci.*, 10 (1927), No. 1, pp. 33-40, figs. 4).—Free acid catalyzes the oxidation of the fat. The initial change appears to be favored by certain enzymes which are largely removed by clarification. Results with dry whole milks of low and of relatively high moisture content indicate that free moisture has a retarding effect on oxidation, confirming the former observation of Greenbank and Holm (*E. S. R.*, 52, p. 10). A small amount of free moisture is, therefore, necessary to optimum keeping quality. Since powders vary in water adsorption capacities, each powder would have its own optimum. For spray powders of good solubility an optimum moisture content of between 2 and 3 per cent has been found. Plots of induction period against time of storage are given to indicate the effect of storage time, storage temperature, and moisture content upon susceptibility to oxidation.

Results of preliminary experiments upon the effect of separating, or clarifying, and pasteurizing of a milk upon the keeping quality of its milk powder, G. E. HOLM, G. R. GREENBANK, and E. F. DEYSHER (*Jour. Dairy Sci.*, 9 (1926), No. 6, pp. 512-516, figs. 2).—Preliminary results of a study in continuation of that previously noted (*E. S. R.*, 54, p. 711) indicate that the keeping quality of whole milk powders can be materially improved by clarification of the milk, preferably as soon as possible after it is drawn. Higher pasteurization temperatures than are ordinarily used (63° C. for 30 minutes) also seem desirable, but too high a pasteurization temperature appears to render the fat more readily oxidizable. Plots of induction period against time of storage are given to show the effects of clarification and of varying temperatures of pasteurization on the resistance to oxidation of the fat of milks after drying.

Sweetened condensed milk, V, VI, F. E. RICE (*Jour. Dairy Sci.*, 9 (1926), Nos. 3, pp. 293-305; 5, pp. 459-468).—In continuation of experiments previously noted (*E. S. R.*, 55, p. 613), rancidity is defined in part 5 as a flavor resembling that of butyric acid. Rancid commercial condensed milks showed a high titratable acidity, increasing with the degree of rancidity. The viscosity also increased, some of the samples becoming solid. However, this is not to be confused with bacterial thickening (*E. S. R.*, 51, p. 380). The peroxidase test was usually positive. Two general forms of experiment were used: (1) Small scale manufacture in an experimental vacuum pan; (2) addition of raw milk or other substances to factory-made condensed milks.

Rancidity is apparently due to a lipase contained in the raw milk. The admission of a little raw milk into the pan while a batch of milk was being condensed invariably caused rancidity. As little as 0.75 per cent of raw milk

added to normal condensed milk had the same effect. The lipase present in an addition of 0.2 per cent of commercial pancreatin was also effective. The lipatic activity of raw milk was destroyed by momentary heating to 150° F., but in the presence of 35 per cent of sucrose higher temperatures were required. The bacteria of the raw milks productive of rancidity, together with other bacteria and many molds, were tested for capacity to produce rancidity, with negative results. Excessive heat before or during the condensation, the use of neutralized sour milk, the freezing of the milk, the addition of oxidation and hydrolysis products of fat, and the addition of iron, copper, tin, zinc, and hypochlorous acid salts were all eliminated as causes of rancidity, and lipase appears to be the sole cause.

Factory control methods for preventing rancidity are suggested.

Tallowiness in condensed milk, taken up in part 6, results from an atmospheric oxidation in the container (usually catalyzed by small amounts of copper) of the butterfat of the milk. Iron is a much feebler catalyst in the reaction and is not of practical importance, and tin appears to be without effect. Tallowiness increases with the copper content, much more air space being necessary to produce the flavor when the copper content is low.

The time of holding the milk in open pasteurizers, holding tanks, and hot-wells should be as short as is practicable. Copper equipment should be eliminated wherever possible. Copper apparatus that has not been used for some time should be cleaned with especial care, since milk dissolves copper much more readily from an oxidized than from a bright copper surface. As little as 2.5 mg. of copper per kilogram of condensed milk, added as lactate, produced distinct tallowiness in 70 days in samples having some air space over the milk and held in cold storage. The addition of clean, bright copper strips had the same effect of distinct tallowiness in 70 days, fairly strong tallowiness in 100 days.

Peroxidase as a factor in butter deterioration, L. S. PALMER and M. M. MILLER (*Jour. Dairy Sci.*, 9 (1926), No. 3, pp. 272-275).—In experiments at the Minnesota Experiment Station, peroxidase concentrated from horse-radish roots according to the method of Willstätter was added to cream which had been rendered free from enzymes by heating to determine whether the presence of peroxidase is in itself detrimental to the keeping quality of butter. The butter made from the cream was packed in 1-pint glass jars having glass tops, rubber seals, and metal clamps. Aseptic conditions were maintained as far as possible throughout, all utensils, jars, etc., being sterilized. One-half of each lot of butter was stored at room temperature and the other half at 0° C. The examination included a study of the organic and amino acids in the aqueous phase of the butter, peroxidase tests on the aqueous phase of the butter, the Kreis test on the butterfat, and a determination of the amount of oxidized fatty acids in the fat. The general quality of the stored samples was also noted.

It was concluded that peroxidase in itself is not a factor in the deterioration of stored butter. The improved keeping quality of butter made from cream pasteurized at a high temperature appeared to be due to the elimination of deteriorative agencies other than peroxidase.

Lactose solubility and lactose crystal formation.—I, **Lactose solubility**, O. F. HUNZIKER and B. H. NISSEN (*Jour. Dairy Sci.*, 9 (1926), No. 6, pp. 517-537).—The colloids in milk do not appear to have any material influence on the solubility of lactose or the form of the lactose crystals. The presence of sucrose diminishes the solubility of lactose somewhat, this effect being very slight in sucrose solutions below 14 per cent, and affects the form of the crystals. Lactose solubility was determined by direct observation of the saturation

point, by determinations of total solids, and by gravimetric determinations according to Fehling's method with Munson and Walker's tables. Close agreement with Hudson¹ was obtained with respect to the solubility of lactose in water.

A biochemical study of the insoluble pectic substances in vegetables, C. M. CONRAD (*Amer. Jour. Bot.*, 13 (1926), No. 9, pp. 531-547, figs. 3).—The nomenclature and definition of pectic substances is confused. The three insoluble pectic substances considered in this paper, from the Maryland Experiment Station, are designated protopectin, pectic acid, and insoluble pectates, pectin being defined, in accordance with Fellenberg's results,² as a more or less methylated pectic acid, the solubility increasing with the number of carboxyl groups methylated.

Carré's method³ for protopectin in apples was studied with respect both to concentration of acid and to time and temperature of heating, for the purpose of adapting the method to various vegetable materials. Hydrochloric acid from N/30 to N/50, heated with the tissues for 1 hour, gave the best results. These conditions apply to vegetable materials containing only protopectin. The pectin resulting from this hydrolysis of protopectin was converted into calcium pectate and weighed according to the Carré and Haynes method (*E. S. R.*, 47, p. 610). Difficulties in filtration due to starch, to proteins, and in onions to a substance apparently soluble in alcohol were encountered. Malt solutions and diastase could not be used for removing starch, as they destroyed the pectin, but ptyalin (saliva) was effective. In the case of potatoes, the protein was estimated by the Kjeldahl method and its weight deducted from that of calcium pectate precipitated.

Materials containing pectic acid as well as protopectin did not yield all their pectic substances when handled according to the above method. A combined method in which protopectin and pectic acid were determined together was, therefore, devised, the protopectin being hydrolyzed with N/30 hydrochloric acid as before, while the pectic acid was dissolved by adding ammonia citrate up to 1 per cent to the neutralized hydrolyzate and again boiling for 30 minutes. It was found that pectic acid may be formed in drying the samples. This was prevented by boiling the sliced material in 95 per cent alcohol and subsequently drying at 80° C.

Protopectin, pectin, and pectic acid were determined in a variety of plant tissues. The two former substances were found in all the tissues studied, but free pectic acid was found only in radishes.

The solidification point of food fats [trans. title], T. MEYER (*Ztschr. Untersuch. Lebensmtl.*, 52 (1926), No. 6, pp. 461-465, figs. 3).—The solidification point determination is liable to error in that the solidification is often only a crystallization of an insoluble fat fraction from a still liquid portion, in which point the author confirms Rahn.⁴ The drop and subsequent rise of the temperature is not comparable with that occurring in a freezing point determination and will only give consistent results if all the conditions of every determination are strictly the same. Good results were obtained with the fats of the margarine industry by Mohr's method. The greatest discrepancy found was $\pm 0.2^\circ$ C., the average being less than $\pm 0.1^\circ$. The solidification curves of various fats are characteristic. Good margarines have solidification curves similar to those of butterfats.

The determination of sodium, potassium, and chlorine in foodstuffs, A. D. HUSBAND and W. GODDEN (*Analyst*, 52 (1927), No. 611, pp. 72-75).—Kramer's method for sodium and potassium in blood (*E. S. R.*, 42, p. 506) was modified for the determination of sodium and potassium in foodstuffs to avoid the inclusion of magnesium and of phosphates in weighing the mixed potassium and sodium salts. The modified procedure was carried out as follows:

"A suitable quantity of the material is ashed at a low temperature, and the ash is twice extracted with hot N hydrochloric acid (about 100 cc. in all being used). The residue is washed with hot water, and the filtrate and washings are made up to 200 cc. Of this extract, 100 cc. are heated to boiling, and 5 cc. of a 10 per cent solution of barium chloride are added. The mixture is evaporated to about 25 cc., and then, while hot, made alkaline with strong ammonia and allowed to cool. When cold, the precipitate is filtered off and washed with 2 per cent ammonia. The filtrate and washings are evaporated just to dryness in a 250-cc. beaker. To it, when cold, 30 to 35 cc. of alcoholic ammonium carbonate solution are added, and the whole is vigorously stirred for about 5 minutes. The contents of the beaker are transferred to a 100-cc. flask and the beaker rinsed with more alcoholic ammonium carbonate solution. After thorough shaking, the solution is made up to the mark with the reagent. The mixture is allowed to stand at least 2 hours, preferably overnight, and then filtered into a dry flask. Fifty cc. of the filtrate are evaporated to dryness in a weighed vitreosil basin, and the cold residue treated with 5 cc. of redistilled sulfuric acid. The excess of acid is evaporated off on a sand bath, and the residue is heated over a naked flame until quite dry. During this stage it is advisable to scatter on to the residue a little powdered ammonium carbonate, which facilitates the removal of the last traces of sulfuric acid. The dish is then heated in the muffle at a bright red heat for 10 minutes, cooled, and weighed. From this weight of mixed sulfates and the percentage of potassium the percentage of sodium can be calculated."

The potassium may be satisfactorily determined volumetrically, by means of cobaltinitrite.

Chlorine is extremely likely to be lost in ashing the sample. Treating the sample with from 10 to 25 per cent of its weight of calcium oxide, mixing to a paste with water, and ashing the mixture at a low temperature greatly reduces the loss. The Official method gave very low results. These findings confirm those of Weitzel (*E. S. R.*, 46, p. 311).

Testing wheat for protein with a recommended method for making the test, D. A. COLEMAN, H. C. FELLOWS, and H. B. DIXON (*U. S. Dept. Agr. Bul.* 1460 (1926), pp. 32, figs. 3).—The growing importance of crude protein in the valuation of wheat is noted. At present hard red spring and hard red winter wheats are marketed on a protein basis.

Current methods for the protein test were subjected to collaborative study at experimental, mill, commercial, and grain testing laboratories in the central Northwest and Southwest. A minimum difference between duplicates of 0.58 per cent was found, the maximum difference being 1.22 per cent. An exhaustive laboratory study was made of many of the outstanding methods. A direction for a standard method is given, including detailed notes on sampling, removing dockage, dividing and grinding the sample, preparing reagents, and selecting apparatus, digesting, and distilling.

Great care is needed to prevent loss of moisture from samples. Not less than 30 gm. should be ground. The Gunning method is as economical as any if optimum heat conditions are provided, but the Kjeldahl is the only method by which wheat samples are completely oxidized in less than an hour at all intensi-

ties of heat tested. Yellow and red oxides of mercury are equivalent, 0.5 gm. giving best results; mercuric sulfate gives slightly lower results. Copper sulfate is of little value at low intensities of heat. Ten gm. of either sodium or potassium sulfate gave satisfactory results with 20 cc. of sulfuric acid. The caking of sodium sulfate can be prevented by using 60 per cent potassium sulfate with 40 per cent sodium sulfate. Electric heat is to be preferred. The slightly higher results obtained with 2 gm. samples do not warrant the extra digestion time required. Traps and blank determinations are important. At least 150 cc. of distillate should be collected in acid capable of holding the ammonia equivalent to from 35 to 70 mg. of nitrogen for samples of from 1 to 2 gm. Sulfuric and hydrochloric acids are equally good for receiving the ammonia. Contrary to some statements in the literature, boric acid solution does not hold ammonia quantitatively at temperatures of 40° C. and above.

The examination of mixtures of coconut oil and palm kernel oil.—The determination of butter fat in margarine, C. D. ELSDON and P. SMITH (*Analyst*, 52 (1927), No. 611, pp. 63–66).—Tables for determining butterfat in margarines from the Polenske and the Kirschner values and for calculating coconut and palm kernel oils from the Reichert and Polenske values are given.

A comment by H. D. Richmond on the limitations of the method indicates that when coconut oil and palm kernel oil "exist in the same mixture and the percentage of coconut oil is well under 50 per cent, an approximate idea of the relative proportions of the two oils can be deduced within about 15 or 20 per cent either way."

A rapid method for the sorting of butters and margarines, C. H. MANLEY (*Analyst*, 52 (1927), No. 611, pp. 67–72, figs. 2).—The following procedure is substituted for the Reichert method:

"Five gm. of the filtered fat are saponified with 20 cc. of glycerol soda solution (made by mixing 900 cc. of pure glycerol with 100 cc. of a 50 per cent aqueous solution of sodium hydroxide) and the soap dissolved in 100 cc. of boiled distilled water. Into the cooled solution 4 drops of 0.5 per cent methyl orange solution are introduced and sulfuric acid (25 per cent by volume) added from a burette until the solution is faintly pink. The total volume of the solution and precipitated fatty acids is taken and 100 cc. filtered off, nearly neutralized with 10 per cent sodium hydroxide solution, and the neutralization completed with N/10 sodium hydroxide solution. In this way the sulfuric acid is neutralized, leaving only the soluble fatty acid, which is then titrated with N/10 sodium hydroxide, after the addition of 0.5 cc. of 0.5 per cent phenolphthalein solution. The number of cubic centimeters of N/10 sodium hydroxide solution taken, less the number required for a blank, is represented as the M value.

"The blank is carried out upon 20 cc. of glycerol soda solution dissolved in 100 cc. of distilled water (free from carbon dioxide). In measuring the glycerol soda solution, 20 cc. are poured into a 25-cc. cylinder, and after the bulk has been transferred to the flask, 4 drops are allowed to enter, after which the cylinder is removed. In this way a reasonably uniform quantity is used in each case."

The neutral filtrate may be used for a determination of the Kirschner value. The method can not claim the accuracy of the Polenske process, but it can be used advantageously for margarines, in which the probability of a butterfat content in excess of 10 per cent is extremely small. The presence of boric acid was not found to interfere.

A Babcock-Gerber method for determining the percentage of fat in ice cream, H. C. MOORE and P. A. MORSE (*Jour. Dairy Sci.*, 9 (1926), No. 3, pp.

276-285).—Using Babcock test bottles, the Troy-Fucoma modification of the Gerber method for butterfat was compared experimentally with the Mojonnier and the Troy-Fucoma methods, and found to be quicker, simpler, and more accurate than the Troy-Fucoma method. It is recommended for factory control, but for more accurate work the Mojonnier method is preferred. A slight modification of the method of Fisher and Walts (E. S. R., 53, p. 809) was found superior to the Troy-Fucoma method in accuracy.

METEOROLOGY

Popular long-range weather forecasts, C. J. P. CAVE (*Nature [London]*, 119 (1927), No. 2984, pp. 52-55, figs. 3).—The 50-day rainfall forecasts prepared by Lord Dunboyne and published in the London *Daily Mail* are discussed and certain tests of their reliability are applied, from which it is concluded that “the forecasts, even for one week ahead, have not any success” and are no better than “purely fortuitous predictions.” It is stated that no account of the methods used in preparing the forecasts has been published.

Popular long-range weather forecasts, R. P. BUTLER and C. J. P. CAVE (*Nature [London]*, 119 (1927), No. 2987, pp. 164-167, figs. 2).—The question of accuracy of the forecasts referred to above is further discussed.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and W. H. PARKIN (*Massachusetts Sta. Met. Buls.* 457-458 (1927), pp. 4 each).—The usual summaries and notes are given of observations at Amherst, Mass., during January and February, 1927.

Oklahoma climagraphs and biotic regions, A. O. WEESE (*Okla. Acad. Sci. Proc. [Okla. Univ.]*, 5 (1925), pp. 91-95, figs. 3).—Climagraphs, or more accurately, as the author claims, hythergraphs, portraying graphically the climatic rhythm to which the biota of a given region is adjusted, were made “for all Weather Bureau stations in the State for which records covering 15 years or more were available,” and an attempt is made “to divide the area into climatic regions as indicated by the climagraph types.” There was found to be a close agreement between the map so constructed and the various vegetation maps which have been published. It is suggested that “further studies should take into account not only averages but critical years, which have a very great influence in delimiting the distribution of species at or near the borders of their range.”

A preliminary division of Oklahoma into major and minor provinces on the basis of rainfall adequacy, C. J. BOLLINGER (*Okla. Acad. Sci. Proc. [Okla. Univ.]*, 5 (1925), pp. 119-123, fig. 1).—The paramount importance of rainfall in Oklahoma agriculture is indicated, other climatic elements being generally favorable but failing of full efficiency “because there is not a corresponding abundance of soil moisture to meet the requirements of growing plants.” On the basis of rainfall during the 10 years 1911-1920, the State is divided into three major divisions as regards rainfall, namely, humid, semihumid, and semiarid. These major divisions, “based on the frequency of occurrence of months between February and November with an amount of rainfall which it is believed will give adequate moisture for the average crop growing on the average soil,” are subdivided into “districts based on the percentages of months rated ‘adequate’ during spring and early summer, March to June, inclusive, which is, with the possible exception of the ‘Panhandle,’ the chief period of crop growth in Oklahoma.” The percentages of months having adequate rainfall during the 10-year period were, for the different districts, as follows: Humid, 62.5; semihumid, 37.5 to 62.5; semiarid, less than 37.5.

Aerological code, 1926 (*U. S. Dept. Agr., Weather Bur., 1926, pp. 22, fig. 1*).—This is the revised code for transmission of free-air observations, effective January 1, 1927.

SOILS—FERTILIZERS

Soil characteristics: A field and laboratory guide, P. EMERSON (*New York and London: McGraw-Hill Book Co., 1925, pp. X+222, pls. 2, figs. 5*).—This manual contains chapters on a general study of soils, soil physics, soil fertility, and soil microbiology.

A study of soil types in relation to utilization and management, W. W. WEIR (*Jour. Amer. Soc. Agron., 18 (1926), No. 12, pp. 1067-1075, fig. 1*).—In a contribution from the U. S. D. A. Bureau of Soils the results of a field survey covering six counties in north-central Indiana are reported. This survey was made for the primary purpose of studying the relation of soil types to crop production.

The facts collected showed that when the dominant soils within the area surveyed are classified according to the natural characteristics observed within their profiles, such soils correspond to the soils to which the farmers have given recognition (1) in local descriptive names, (2) in their soil management practices, (3) in their estimates of average yields per acre, and (4) in their estimates of relative land values as based on their farming experiences.

Soil survey of Greene County, Alabama, J. F. STROUD ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1923, pp. III+357-399, fig. 1, map 1*).—This survey, made in cooperation with the Alabama Department of Agriculture and Industries, deals with an area of 412,800 acres situated in western Alabama and included in the geological division of the Gulf Coastal Plain. The elevation is from 100 to 400 ft. above sea level. The surface features consist of flat stream bottoms and terraces, undulating prairie, and gently rolling to hilly land in the northern part. Upland drainage is good, but that of the stream bottoms is poor.

The two main soil groups noted are prairies or limestone lands, especially adapted to alfalfa, grasses, and clovers, and rolling uplands with light sandy surface soils over reddish yellow to red subsoils, principally utilized for cotton, trucking, and fruit growing. The calcareous first and second bottom soils are suited to grasses and corn and are among the most productive soils of the county. The areas under the various soils are classified into 4 types in 14 series, the Ruston and Cahaba fine sandy loams leading in proportionate area covered, with 15.1 and 8.3 per cent, respectively. Fine sandy loams constitute the most frequently represented soil type found in the survey.

Soil survey of Gibson County, Indiana, T. M. BUSHNELL ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1922, pp. IV+1159-1216, pl. 1, figs. 2, map 1*).—This report is presented in two parts:

I. [*Soil survey*], T. M. Bushnell and W. E. Tharp (pp. 1159-1201).—A survey made in cooperation with the Indiana Experiment Station, of an area of 316,800 acres of the "Wabash Lowland Region," in the southwest corner of Indiana is described. About one-fourth of the area is bottom land, with a smaller proportion of glacial-lake and outwash plains, the remainder consisting of gently to steeply rolling, well-drained uplands, from 400 to 650 ft. above sea level. The bottoms are somewhat subject to overflow and are poorly drained.

The soils may be grouped according to conditions of development as (1) well drained, (2) water saturated, (3) alternately saturated and aerated, and (4) alluvial. Areas of 7 soil types in 24 series are tabulated and mapped, the largest areas being those of Gibson and Tilsit silt loams, which constitute 16.9 and 11.8 per cent, respectively, of the total area surveyed.

II. *The management of Gibson County soils*, A. T. Wiancko and S. D. Conner (pp. 1203-1216).—The soils of the county are grouped according to their needs as indicated by chemical composition, physical properties, and drainage conditions, with indications as to proper treatment of the soils of each of the groups.

Soil survey of Coleman County, Texas, H. W. HAWKER ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1922, pp. III+1217-1256, fig. 1, map 1*).—This survey, made in cooperation with the Texas Experiment Station, deals with an area of about 800,000 acres situated at about the geographic center of the State. The original upland, undoubtedly nearly level with a slight east and southeast slope, has been largely removed by erosion. The present surface consists of a series of low ridges and plateau-like areas, with broad terraces and valleys. The average surface level of both terraces and uplands rises toward the west and northwest. The elevation varies from 1,400 to 2,250 ft. above sea level. The mean annual rainfall is 27.8 in.

The soils are of 3 main classes: Residual, outwash or terrace plain, and recent alluvial or first bottom soils. Silty clay loam, clay loam, and clay soils predominate. Including rough stony land, 6 types of 10 series are mapped, of which Abilene clay and Valera stony clay cover, respectively, 42.8 and 27.4 per cent of the area. The Abilene soils are productive, and, with a rainfall well distributed during the growing season, give good yields of crops adapted to the region.

Minnesota glacial soil studies, II, III (*Soil Sci., 23 (1927), No. 1, pp. 57-80, figs. 6*).—Two further contributions from the University of Minnesota are presented (E. S. R., 45, p. 19).

II. *The forest floor on the late Wisconsin drift*, F. J. Alway and P. M. Harmer.—The forest floor was sampled in 9 virgin or nearly virgin Minnesota woods, 6 being remnants of the original southeastern deciduous forest and 3 being in the northern coniferous forest.

The weight per acre was found to vary from 13 to 97 tons and the content of nitrogen from 1.47 to 1.89 per cent and of volatile matter from 52 to 81 per cent. The nitrogen in the volatile matter varied from 2.02 to 2.99 per cent, the organic carbon from 31 to 39 per cent, and the ratio of organic carbon to nitrogen from 18 to 24 per cent. The samples showed little or no acidity, carried about 0.3 per cent phosphoric acid, and had moisture equivalents of from 97 to 120.

A comparison of the weight per acre of nitrogen in the forest floor with that in the underlying 6 in. of soil showed the one extreme to be in a hard maple wood, in which the floor carried only one-sixth as much as the surface soil, and the other in a spruce-balsam-birch forest, in which the floor carried more than three times as much nitrogen as the surface 6 in. of soil.

III. *Density of the surface foot in forest and prairie on the late Wisconsin drift*, P. M. Harmer.—The density of the soil in place was determined in the four 3-in. sections of the surface foot of 12 Minnesota virgin fields developed on the till plains of the Des Moines lobe of the late Wisconsin drift. Six of these fields were in the deciduous forest and 6 on the open prairie. In the surface section the density of the soil was much the same in prairie and forest, but below that it increased gradually in the former and rapidly in the latter, being one-third higher in the lower two sections of the forest soil.

On the permeability of clay soils, J. WITYN (*Internatl. Rev. Sci. and Pract. Agr. [Rome], n. ser., 4 (1926), No. 3, pp. 554-588, figs. 17*).—Studies conducted at the Department of Agriculture in Latvia are reported.

Great fluctuations were observed in the permeability of soils, and the mechanical composition of the soil was found to offer only a small clue. The

fluctuations were greater in sandy soils than in loam and clay soils, and greater in the loam soils as the content of fine particles not capable of sedimentation in three weeks increased. Permeability fluctuations were small in those soils which contained few particles of this size.

The permeability of marl loam soil was considerably reduced by distilled water, and acid soils and neutral humus were made completely impermeable after a few months. Soils were more permeable to water containing carbon dioxide, and the permeability of marl loam was considerably increased. The effect was not so noticeable in acid soils.

The permeability of soils for a 0.02 N solution of calcium bicarbonate was quite different from the permeability for water saturated with carbon dioxide. This solution passed through marl loam quite readily if it contained no podsol formations. It did not pass readily through acid podsol soil but passed through the subsoil of the podsol. Large differences in the permeability for this solution were also observed in the clay loams, and this was very greatly influenced by the absorbed sodium content of the soil. The permeability of clay loam with a high content of absorbed sodium was very small for the bicarbonate solution, but there was an improvement on partial removal of the sodium content.

The permeability of soils for gypsum was similar to that for calcium bicarbonate except in the case of marl loam containing podsol and clay loam containing considerable quantities of absorbed sodium. Solutions containing both calcium sulfate and calcium bicarbonate increased the permeability of very acid clay loam soil.

The permeability of neutral soils was considerably increased by calcium hydroxide, and the effect of this treatment remained for several months. The permeability of very acid soils was quickly reduced by this treatment, which was followed in a short time by almost complete impermeability. Sodium bicarbonate solution even in very weak concentrations considerably reduced the permeability of soils, and if the soils contained no calcium carbonate the finest constituents were leached out to a considerable extent. The influence of sodium bicarbonate was found to be greatest in clay soils, even in the lowest concentration used.

Even very dilute solutions of ammonia decreased the permeability of soils, especially marl loams and clays. The degree of dispersion of marl loams was increased by very dilute ammonia solutions, and the decomposition of the calcium carbonate content was reduced.

Treatise on sedimentation, W. H. TWENHOFEL (*Baltimore: Williams & Wilkins Co., 1926, pp. XXV+661, pls. 33, figs. 14*).—This book contains chapters on sources and production of sediments; the transportation, deposition, diagenesis, and lithification of sediments; important conditions modifying sedimentary processes; sediments and organisms; products of sedimentation; structures, textures, and colors of sediments; environments or realms of sedimentation; and field and laboratory studies of sediments.

Aluminum hydroxide and the "freezing up" of alkali soils during reclamation, W. T. McGEORGE, J. F. BEEZEALE, and P. S. BURGESS (*Science, 64 (1926), No. 1664, pp. 504, 505*).—In a contribution from the Arizona Experiment Station it is reported that the so-called freezing up phenomenon of alkali soils during the reclamation process is due to the precipitation of colloidal aluminum hydroxide within the washed soil complex simultaneously with the almost complete dispersion of the clay fraction, as the alkalinity is progressively reduced below pH 9.5 to 10. Where black alkali soils are being reclaimed by leaching the freezing up occurs as soon as the excessive alkalinity is reduced to the precipitation point of aluminum hydroxide.

It has been found that if pure aluminum hydroxide is allowed to become perfectly dry it loses many of its colloidal properties, which can not be fully restored by wetting or by pulverizing. It was shown that if a black alkali soil is leached with pure water until it becomes impermeable and is then dried out and cultivated, it takes water much more readily.

A contribution to the study of interrelations between the temperature of the soil and of the atmosphere and a new type of thermometer for such study, A. SMITH (*Soil Sci.*, 22 (1926), No. 6, pp. 447-457, figs. 3).—In studies conducted at the University of Wisconsin air temperatures taken at heights varying from 6 to 60 in. above the soil surface were higher during the day in cropped areas, such as sugar beets and corn, than in uncropped areas. With a crop such as hemp, where there was a heavy stand, lower temperatures were obtained during the day at the 6- and 12-in. heights and higher temperatures at the 36- and 60-in. heights, as compared with adjoining uncropped areas. The night air temperatures taken immediately preceding sunrise, when the atmosphere was calm, were higher in the cropped than in the uncropped areas. The greatest differences were found in the hemp. Inversions of temperature were greatest over the uncropped plats.

By the use of an enlarged bulb thermometer the temperature of the surface soil was found to be lower than that of the air in contact with it just before sunrise on calm nights. Mineral soils where the drainage conditions were good showed differences as high as 4.55° , whereas on poorly drained areas, such as peat soils, the temperature of the surface was seldom more than 1.5° cooler than the air in contact with it. During calm weather the temperature of the air in contact with the soil was found to be higher by the use of the copper bulb as well as by the electric resistance thermometer.

On the origin and nature of the soil organic matter or soil "humus"—V, The rôle of microorganisms in the formation of "humus" in the soil, S. A. WAKSMAN (*Soil Sci.*, 22 (1926), No. 6, pp. 421-436).—This is the fifth contribution to the subject by the New Jersey Experiment Stations (E. S. R., 56, p. 421).

It was found that by the use of dilute sodium hydroxide the soil organic matter can be separated into four distinct groups (1) the part insoluble in dilute alkali even under pressure, (2) the part soluble in alkali and precipitated by an excess of hot hydrochloric acid, (3) the part soluble in alkali and in acid but precipitated at a definite isoelectric point, namely, at pH 4.8 to 5, and (4) the part made soluble in water as a result of treatment of the soil with alkali. The third fraction may be absent in peat soils but it is present abundantly in mineral soils, consisting of from 50 to 70 per cent of aluminum and other bases and from 25 to 40 per cent of organic matter. The presence and absence of this fraction allows a differentiation between peat and mineral soils. The second fraction, equivalent to the so-called humic acids, is practically free from ash and contains from 2 to 4 per cent of nitrogen.

When organic matter is added to the soil the various sugars, starches, hemicelluloses, celluloses, and proteins are rapidly decomposed. The lignins, and to a lesser extent the fats and waxes, resist decomposition under anaerobic conditions, as in peat soils, and are slowly decomposed under aerobic conditions by certain groups of organisms.

Pure or mixed cultures of soil fungi and bacteria rapidly attack the various constituents of the natural organic materials added to the soil, converting a part of the carbon into microbial protoplasm. A definite amount of nitrogen is thereby assimilated and changed from an inorganic into an organic form or from plant proteins into microbial protoplasm. A part of this protoplasm gives all the reactions characteristic of humus and is rather rich in nitrogen.

The soil humus is a result of the accumulation of substances of plant origin, on the one hand, largely the lignins and to some extent the fats and waxes and perhaps certain nitrogenous substances, and on the other hand nitrogenous substances synthesized by microorganisms.

On the degree of humification of the dead covering of forest soils, A. NEMEC (*Internatl. Rev. Sci. and Pract. Agr. [Rome], n. ser., 4 (1926), No. 3, pp. 600-603*).—Studies conducted by the Ministry of Agriculture of Czechoslovakia are briefly reported which showed that the proportion of humified matter contained in organic matter increases in the humus of spruce, Scots pine, and pedunculate oak, with decreasing acidity of the vegetable mold. The strongly acid layers of the dead covering under close growing conifers and pedunculate oak produced practically no nitric nitrogen. The layers of humus in broad leaved forests were found to show generally a very considerable degree of humification and a high intensity of nitrification. The acid humus of conifers exposed to the action of sunlight was more easily rendered soluble than that in the dense shade of standing trees. In high forests of Scots pine the favorable influence of the beech undergrowth was indicated by the greater degree of humification of the superficial layer of humus.

The function of organic matter in the soil, C. E. THORNE (*Jour. Amer. Soc. Agron., 18 (1926), No. 9, pp. 767-793*).—In a contribution from the Ohio Experiment Station data from a large number of sources bearing on the subject are summarized.

Nitrate production under field conditions in soils of central Alberta, F. A. WYATT, A. S. WARD, and J. D. NEWTON (*Sci. Agr., 7 (1926), No. 1, pp. 1-24, figs. 7*).—The studies indicate that the climate of the black earth belt of Alberta has been largely responsible for the fertile condition of the virgin soils as indicated by their nitrate content. It has been found that the soil temperatures from May to September, inclusive, are never too high to inhibit nitrification and are seldom sufficiently low to retard this process. The soils of this district as well as those of the prairie belt of Alberta are said to be also well supplied with microorganisms.

The analytical data showed that the soils contain an abundance of mineral nutrients and a comparatively large amount of organic matter. It is considered apparent that nitrification proceeds relatively rapidly in these virgin soils under field conditions.

The results obtained also confirm those of others in showing that the production of nitrates in field soils is influenced by the crop growing, the crop sequence, the method of tillage, and the moisture and temperature factors. It was found, for instance, that the perennial crops such as timothy and alfalfa keep the nitrates at a lower level than do the annual crops such as wheat, barley, corn, and potatoes. The nontilled annual crops such as wheat and barley keep the nitrates slightly lower than the intertilled crops such as corn and potatoes. It was found further that the plant residues from legumes promoted nitrification more vigorously and at an earlier date in these soils than did residues from nonlegumes.

A distinct relationship was established between the moisture and nitrate contents of the soil especially during the early part of the summer and until the rapid rate of plant growth disturbed this relationship. In the case of summer fallow this relationship persists later into the season than when the soil is cropped, and becomes disturbed only when the soil moisture becomes sufficiently great to leach some of the nitrates into the lower layers of the soil. In general the nitrate production was found to show a slight lag behind moisture and temperature. There is a major maximum in the nitrate production during the

latter part of spring and the early part of summer, and a minor maximum during the early part of the fall. However, when crops are occupying the soil the high point in nitrate accumulation seldom extends into the summer season.

It was found that in general the soil temperatures are inversely proportional to the soil moisture. There is a great accumulation of nitrates in fallow soil and a great disappearance when fallow soil supports a crop. Soils cropped continuously were found capable of producing sufficient nitrate nitrogen for the production of maximum crop yields.

Experiments in handling sweet clover with reference to the accumulation and conservation of nitrates in the soil, A. L. WHITING and T. E. RICHMOND (*Illinois Sta. Bul.* 285 (1927), pp. 287-307).—An account of experiments to determine the optimum time and conditions for the plowing under of sweet clover with reference to the nitrification and the physical condition of the soil and to the conservation of the nitrate produced is presented.

Nitrification was found to be rapid with both fall- and spring-plowed clover, the accumulation of nitrate being in one case in excess of the requirements of a large corn crop. Spring plowing resulted in a better physical condition of the soil than did fall plowing, however, and less labor was needed in the preparation of the land for subsequent crops. Moreover, a greater proportion of active organic matter was plowed under in the spring plowing. Summer-plowed sweet clover nitrifies rapidly and with a large accumulation, but subsequent losses of nitrogen are large unless a cover crop is planted. Both oats and rye proved effective as cover crops, oats being the more so on account of a greater fall growth and because this crop was dry when plowed in. There is no advantage with respect to nitrate production in the summer plowing, and it wastes a year. The date of spring plowing under is to be decided by the nature of the soil, light, sandy, open soils and those deficient in organic matter benefiting by as late a plowing as is consistent with a proper preparation for corn, whereas clays and loams, and soils in general which have grown one or more sweet clover crops, are not likely to be much affected with respect to corn production by the date of the spring plowing of the clover.

Under certain conditions nitrates appear to rise from the lower into the surface layers, the surface soil nitrate content increasing under surface soil moisture conditions which would inhibit nitrification. Even in the presence of a 50- to 65-bu. corn crop at its period of heavy nitrate absorption, the surface soil was frequently found to contain over 100 lbs. of nitrate nitrogen. Such a concentration should be converted into a fixed form for conservation. Weeds in the corn, volunteer grains, and late summer and fall crop growth serve to convert much nitrate. A legume will lead to more rapid nitrification in the following year.

In general, the investigations showed that sweet clover was effective in conserving soil nitrogen, and that the method of handling it plays an important part in the securing of its fertility value.

Crop rotations and soil management for eastern Canada, E. S. HOPKINS and W. C. HOPPER (*Canada Dept. Agr. Bul.* 72, n. ser. (1926), pp. 57, figs. 19).—A large amount of practical information on the subject is presented.

The effect of lime and fertilisers on the potash content of soil and crop, J. G. LIPMAN, A. W. BLAIB, and A. L. PRINCE (*Internatl. Rev. Sci. and Pract. Agr.* [Rome], n. ser., 4 (1926), No. 3, pp. 546-553).—Studies conducted at the New Jersey Experiment Stations are reported in which the potash content was determined in soils from a number of plats which had received definite fertilizer and lime treatment for a period of 15 years. It was also determined in several crops grown on the experimental plats.

The percentage of potash in the soil of plats having parallel fertilizer treatment was slightly lower in nearly all cases for the limed than for the unlimed sections. The fertilizer treatment did not appear to have had much influence on the potash content of the soil. Such variations as were noted were attributed mainly to natural variations in the soil or to limitations in the methods of sampling. There was a consistently lower percentage of potash in the cornstalks grown on the limed than on the unlimed sections.

Lime and phosphate, S. WATERMAN and N. J. THOMAS (*Ontario Dept. Agr. Bul. 321 (1926), pp. 20, figs. 5*).—The practical results of experiments on the effect of lime and phosphate on the yield of fall wheat and clover in Ontario are presented.

Soil investigations, A. N. HUME (*South Dakota Sta. Rpt. 1926, pp. 11, 12*).—Field experiments at Brookings show the possibility of increasing cereal crops by an average of 30 per cent through the use of phosphatic fertilizers. Similar indications were obtained in briefer field trials at Vermilion, Groton, and Highmore.

Summary of experiment station field plot tests comparing sulphate of ammonia and nitrate of soda as fertilizers (*Barrett Co. [New York] Agr. Dept. [Pub.] 33, [n. ser.], [1925], pp. 64*).—The results of a large number of experiments that have been conducted by the various agricultural colleges and experiment stations and by the U. S. Department of Agriculture comparing ammonium sulfate and sodium nitrate as nitrogenous fertilizers are summarized. While most of these experiments have included experiments with other fertilizer ingredients, it is apparently the intention of this publication to present the data comparing the two nitrogen carriers mentioned as the ones most important to the fertilizer trade.

The fixation of atmospheric nitrogen, J. M. BRAHAM (*Amer. Electrochem. Soc. Trans., 48 (1925), pp. 205-219, figs. 4*).—In a contribution from the U. S. D. A. Fixed Nitrogen Research Laboratory the growth and present trend in nitrogen fixation are discussed, together with some of the newer developments in the industry and the kind of nitrogen products being made available to agriculture from air nitrogen processes.

Three processes are now producing nitrogen compounds for fertilizer use. The synthetic ammonia process is considered to be the most important at present, and is used for over two-thirds of the total nitrogen fixed. The process is dependent upon a large supply of cheap hydrogen, and the catalyst is a very important factor. The arc process is dependent upon large quantities of cheap electrical power, and produces only 6.4 per cent of the total nitrogen fixed.

Some phenomena in the electric arc process of nitrogen fixation, S. KARRER (*Amer. Electrochem. Soc. Trans., 48 (1925), pp. 223-230*).—In a contribution from the U. S. D. A. Fixed Nitrogen Research Laboratory a discussion is given of the phenomena of dissociation of oxygen and nitrogen molecules into neutral atoms, ionization within the arc, excitation, radiation, and energy transfer.

The fixation of nitrogen as aluminum nitride, H. J. KRASE, J. G. THOMPSON, and J. Y. YEE (*Indus. and Engin. Chem., 18 (1926), No. 12, pp. 1287-1290*).—In a contribution from the U. S. D. A. Fixed Nitrogen Research Laboratory the history of the aluminum nitride process is briefly reviewed. Experiments on the reduction of low-grade bauxite in the electric furnace are reported to have given sufficiently encouraging results to warrant further investigation with larger equipment.

Nitrification experiments on the ferro-aluminum alloys showed that practically all the aluminum in the alloys could be nitrified if small amounts of such substances as cryolite, magnesium, aluminum, calcium fluoride, or chloride were added to the pulverized alloy before nitrification.

Since in the process approximately 4 lbs. of aluminum oxide are produced for each pound of nitrogen fixed, it was found that the value of the aluminum oxide is nearly twice that of the nitrogen. Hence it is considered evident that the process is primarily one for the production of alumina and not a nitrogen fixation process.

The assimilation of phosphorus from phytin by oats, A. L. WHITING and A. F. HECK (*Soil Sci.*, 22 (1926), No. 6, pp. 477-493, figs. 5).—Studies conducted at the University of Illinois are reported which showed that the phosphorus supplied in phytin was more readily assimilated by growing plants than that in the inorganic form. An increase in the rate of application increased the phosphorus content of both the grain and straw of oats but to a greater extent of the straw. This was true with both organic and inorganic phosphates. A marked toleration of phosphorus was found in the straw of the oats and an indication of some tolerance of that element in the grain. Large amounts of phosphorus as phytin were found to be deleterious to the growing plant. Oats planted 23 days after the addition of alfalfa and leached alfalfa to sand were injured or killed, whereas those planted 14 days later in the same treatments grew normally.

Availability of Tennessee raw rock phosphate in relation to fineness and other factors, S. D. CONNER and J. E. ADAMS (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 12, pp. 1103-1107).—Studies conducted at the Indiana Experiment Station are reported in which commercial fine ground raw Tennessee phosphate was compared in pot cultures with the same material reground in a ball mill. The reground phosphate was only 7.7 per cent more effective than the commercial phosphate. The finest mechanical separate in the phosphate was 10 per cent more effective than the commercial phosphate. The pot tests with two soils deficient in phosphorus did not indicate that it would pay to grind such phosphate finer for use as a fertilizer in the raw form. The addition of sulfur to the raw phosphate caused an increase on one soil and a decrease on the other. Calcium carbonate reduced the availability of the raw phosphate on both soils.

The development of volatilization methods for the manufacture of phosphoric acid, K. D. JACOB (*Amer. Electrochem. Soc. Trans.*, 48 (1925), pp. 277-285).—In a contribution from the U. S. D. A. Bureau of Soils a brief discussion is given of work by the bureau on the development of volatilization methods for the manufacture of phosphoric acid. A recent modification of the process consists in the substitution of an oil-fired furnace in the place of the electric furnace. While it is difficult to attain a temperature of 1,600° C. in fuel-fired furnaces, recent tests have shown that the phosphate rock-coke-silica mixture will react at as low a temperature as 1,200°.

Lime in agriculture, F. E. CORRIE (*London: Chapman & Hall, 1926, pp. IX+100*).—This is a practical handbook containing information on the use of lime in plant and animal nutrition.

Some effects of limestone and hydrated lime on biochemical activities in acid soils, H. DORSEY (*Connecticut Storrs Sta. Bul.* 141 (1926), pp. 113-163, figs. 7).—The experiments reported in part 1 of this bulletin (pp. 118-148) report comparative results with the Jones, Iowa, Truog, and Soiltex lime requirement tests, together with the colorimetric determination of the H-ions as applied at various regular intervals after the laboratory treatment of four

acid soils with equivalent quantities of ground limestone and hydrated lime. Part 2 (pp. 149-154) describes a brief study of the effect of the limes used upon the ammonifying and upon the nitrifying powers of the soils. In part 3 (pp. 155-162) the effect of field applications of the two limes is shown, together with comparative notes on the field and laboratory results.

Hydrated lime was found more effective in neutralizing soil acidity than ground limestone, but the difference lessened progressively after treatment. The effectiveness of ground limestone is also dependent both upon the degree of fineness and upon the base content. It reduced acidity gradually for from 6 to 8 weeks, the acidity rising a little in some cases at the end of about 6 or 7 weeks. With hydrated lime minimum soil acidity was reached rapidly, the acidity rising gradually after about from 2 to 3 weeks for a period of 8 weeks. Treated and untreated soils showed fluctuations in acidity during an 8-week period, though the treated-soil fluctuations were on a lower plane of acidity.

Both the ammonifying power and the nitrifying power of acid soils were increased by either limestone or hydrated lime.

Of the tests used in determining the lime requirements, the Jones test was found the most valuable because the most sensitive to small changes in lime requirements. The Truog and Iowa tests lack sharpness of color change for small variations in soil acidity. The pH determination correlated rather well with the Jones test. Changes caused in field soils by lime, limestone, and hydrated lime can be measured by any of the tests tried, but most accurately by the Jones test and by the pH determination. The temperature of the water used greatly influences the resultant indication of limestone requirement in the Jones test, and should be standardized.

Synthetic calcium silicates as a source of agricultural lime.—III, A comparison of the influence of synthetic calcium silicates with other forms of lime on the soil reaction, R. M. BARNETTE (*Soil Sci.*, 22 (1926), No. 6, pp. 459-466, figs. 3).—A third contribution to the subject from the New Jersey Experiment Stations is presented (E. S. R., 56, p. 215).

Chemically equivalent and practical applications of calcium carbonate, hydrated lime, dicalcium silicate, and limosil, which is a mixture of monocalcium silicate and calcium oxide, produced, within the limits of experimental error, equal changes in the H-ion concentration of soil to which they were added. There was a progressive increase in the H-ion concentration of soils treated with liming materials following the date of application. The measurement of the pH values for two acid loam soils treated with increasing applications of limosil showed typical buffer curves for loam soils, whereas the pH values for a well-limed Penn loam free from humus showed little increase with increased applications.

Inspection of lime products used in agriculture, H. D. HASKINS, L. S. WALKER, and M. W. GOODWIN (*Massachusetts Sta. Control Ser. Bul.* 38 (1926), pp. 6, fig. 1).—Analyses of 23 samples of agricultural lime and 2 samples of gypsum registered in 1926 are reported, together with a chart showing the relative fineness of ground limestone from various sources. The purchase of agricultural lime on the basis of actual cost of 100 lbs. of effective oxides delivered at point of use is urged, the f. o. b. cost being given for the various samples.

Commercial fertilizers, 1926, J. M. BARTLETT (*Maine Sta. Off. Insp.* 121 (1926), pp. 53-72).—The usual analyses and guaranties of 302 samples collected in 1926 are reported.

The American fertilizer hand book (*Philadelphia: Ware Bros. Co., 1926, 19. ed., pp. [480], figs. 10).*—This number contains the usual standard reference material and directory of the commercial fertilizer industry and allied trades.

International trade in fertilizers and chemical products useful in agriculture—16th review, year 1925–26 ([Rome]: *Internatl. Inst. Agr., Bur. Gen. Statis.*, [1926], pp. 32).—Data on the subject are presented for the year 1925–26. Special mention is made of such materials as natural phosphates, superphosphate of lime, basic slag, natural and artificial guano, bones and bone manure, potash fertilizers, sodium nitrate, ammonium sulfate, synthetic nitrogenous fertilizers, and other fertilizers.

It is stated that the upward trend of the world production of natural phosphates, which was noticeable in 1924, continued in 1925. A considerable increase in this respect was observed in the United States. International trade in phosphates developed in a corresponding degree.

The potash industry in 1925 showed a marked tendency to regain the ground lost during the two previous years in Germany, the most important center of production. The price of potash advanced steadily in the United States from the beginning of the second quarter of 1925, and especially toward the end of the first half of 1926. There was also a similar increase on the French market, while prices in Germany, after a rise at the end of April, 1925, remained steady until the end of June, 1926.

The increase in the production of Chilean nitrate was less marked in 1925 than during the previous year. A slight increase was observed in the production and export of Norwegian nitrate of lime, while the production of cyanamide of calcium also increased in France, Poland, and the United States. An increase in the production of ammonium sulfate occurred in Belgium, France, Italy, and the United States.

AGRICULTURAL BOTANY

Manual of botanical microtechnique, J. KISSER (*Leitfaden der Botanischen Mikrotechnik*. Jena: *Gustav Fischer*, 1926, pp. VII+145, figs. 51).—Instruments, manipulations, and related processes are detailed.

Life of plants, F. KEEBLE (*Oxford: Clarendon Press*, 1926, pp. XII+256, figs. 52).—The mode of treatment adopted presents in a popularized way the essential botanical facts.

Photosynthesis, H. A. SPOEHR (*New York: Chemical Catalog Co.*, 1926, pp. 393, figs. 16).—This volume, one of the American Chemical Society monograph series, discusses the manner in which the green plant utilizes solar energy, stressing the results of experimental observations rather than the conclusions arrived at by field observations or empirical methods. Experimental methods have demonstrated the complexity of the subject and emphasized the need for great experimental skill. An endeavor has been made to discuss the salient features of the subject with some consideration of those theoretical aspects which offer promise of fruitful development on the basis of experimental study.

The chapters deal severally with the origin of organic matter and the cosmic function of green plants, the nature of photosynthesis as determined by observations of gaseous interchange and the formation of organic matter, the products of photosynthesis, the methods of measuring photosynthetic activity, the chemistry of photosynthesis, the energy relations in photosynthesis, and chlorophyll and the chloroplasts.

The nature of the growth rate in plants, W. F. HANNA (*Sci. Agr.*, 5 (1925), No. 5, pp. 133–138).—This brief bibliographical review (28 references), which constitutes the introductory portion of a thesis noted previously (E. S. R., 52, p. 632), is concerned chiefly with growth measurements, internal factors, and external factors in plant growth.

Ripening processes in seeds of *Pharbitis* [trans. title], Y. YOSHII (*Jour. Faculty Sci., Imp. Univ. Tokyo, Sect. III, 1 (1925), No. 1, pp. 139, pl. 1, figs. 20*).—A study on the ripening processes of seeds of *P. nil* deals more particularly with the germinability of the unripe seeds.

Problems in the physiology of germination, F. MERKENSCHLAGER (*Keimungs-physiologische Probleme. Freising: F. P. Datterer & Co., 1924, pp. 57, figs. 8*).—The greater portion of this contribution deals with reactions (resistance or responses) of seeds to various ions, alkaloids, temperatures, illuminations, irradiations, electrical currents, gases, inanition, narcotics, senescence, auto-toxins, and infections.

A method for determining seed viability by electrical conductivity measurements, G. L. FICK and R. P. HIBBARD (*Mich. Acad. Sci., Arts, and Letters, Papers, 5 (1925), pp. 95-103*).—This account presents results of studies attempting to determine seed viability by using an electrical conductivity method, the fundamental principle of which is credited to Osterhout (E. S. R., 41, p. 819) as having demonstrated a difference between the conductivity of living and that of dead tissues.

The material used included seed of timothy, having a large endosperm, and seed of red clover, having no endosperm. Three methods were studied, the first measuring the resistance of the seeds themselves, the second comparing the relative absorption and excretion of salts, and the third measuring the relative outward diffusion of electrolytes as indicated by conductivity readings. The third method was adopted. The data indicate a correlation between electrical conductivity and seed viability, which with further improvement may be capable of practical application.

The relative light requirements of some coniferous seedlings, C. G. BATES (*Jour. Forestry, 23 (1925), No. 11, pp. 869-879, figs. 2*).—Seedlings of eight species of conifers were grown under artificial light containing many of the longer wave lengths of the visible spectrum and varying in intensity from 53.5 to 1.2 per cent during the first six months, and from 16.6 to 0.4 per cent during the last five months of the exposure. The results as studied suggest that in the forest light is not often likely to be the limiting factor in the survival of seedlings. In most instances in which light in the forest is a presumed limiting factor, it is not so in the absolute sense, though the variations in photosynthetic capacity between species give rise to long-term struggles for supremacy, in which rooting vigor and domination of root space, or ability to make good use of a small moisture supply, are almost certainly the determining characters. A study by Bates (E. S. R., 49, p. 535) is mentioned as leading to essentially the same conclusion, namely, that the struggle between species involves the ability of the species to make growth with a minimum use of water, and that the relative photosynthetic capacities of the species constitute an important element in the struggle.

Carbohydrate variations [in corn], A. N. HUME (*South Dakota Sta. Rpt. 1926, pp. 9, 10*).—A brief report is given of a study of carbohydrate variations in leaves and husks in early and late maturing varieties of corn. Samples of leaves from plants grown in the greenhouse were removed and determinations made of starch, pentosans, and sugars, and an examination of the results is said to show decided variations in photosynthesis between different plants. These differences are believed to be correlated not only with the arranged variations in temperature and light but also with the stage of development of the corn plants.

The first sugar of photosynthesis and the rôle of cane sugar in the plant, J. H. PRIESTLEY (*New Phytol., 23 (1924), No. 5, pp. 255-265; abs. in Bot. Gaz.,*

80 (1925), No. 2, p. 228).—Though available data are frequently interpreted to indicate that cane sugar is the primary product of photosynthesis, grounds are herein given for concluding that these data really support the formation of hexoses as the primary photosynthetic sugars. A consideration of the data as to the occurrence of cane sugar and hexoses in the vascular system indicates that cane sugar frequently appears in such a system upon its release from the differentiating protoplast. If this view be correct, cane sugar would not be directly connected with either the synthesis or hydrolysis of starch, but starch or other carbohydrate reserves or photosynthetic products would be used in the synthetic metabolism in the meristematic protoplast, and cane sugar would appear as a secondary product in the metabolism of this cell, being subsequently released occasionally from these cells as they vacuolate and differentiate.

Carbon dioxide assimilation [trans. title], O. WARBURG (*Naturwissenschaften*, 13 (1925), No. 49–50, pp. 985–993, figs. 5).—Studies during 1922–1925 on *Chlorella* in Knop solution are outlined with results in tabular, graphical, and descriptive detail.

Calcium oxalate monohydrate and trihydrate in plants [trans. title], A. FREY (*Vrtljschr. Naturf. Gesell. Zürich*, 70 (1925), No. 1–2, pp. 1–65, pls. 2, figs. 16).—This is a physiological study principally regarding phases of calcium oxalate compounds.

The relation of the salt concentration of the culture solution to transpiration and root respiration, J. D. NEWTON (*Sci. Agr.*, 5 (1925), No. 10, pp. 318–320).—It is claimed to have been shown that the rate of plant-root respiration, as related to transpiration, increases when the salt concentration of the culture solution is increased, this fact indicating that as the concentration of the culture solution increases, the plant roots must expend more energy in absorbing a given volume of solution. It is shown also that the rate of transpiration is decreased when the concentration of the culture solution is increased, and it is pointed out that the concentration of the soil solution is one of the factors governing water requirements of crops. This is regarded as a matter of practical importance, as the concentration of the soil solution may be modified to some extent by cultural and manurial treatments.

On the root system as an osmotic apparatus [trans. title], D. A. SABININ (*Izv. Biol. Nauch. Issledov. Inst. Permsk. Gosud. Univ. (Bul. Inst. Recherches Biol. Univ. Perm)*, 4 (1925), Sup. 2, pp. 136, figs. 2; *Eng. abs.*, pp. 129–136).—Methods claimed to embody somewhat widely applicable new features are described, and results are detailed as regards movements of water and solutes in plant roots.

Osmotic pressure was perceptible in all saps examined. It appears that the root is not a passive conductor of solutions into the upper parts of the plant, but an organ performing important work in the concentration of ions in the sap current. Such a concentration is thought to be possible on a basis of Donnan membrane equilibriums. Permeability of protoplasm did not appear to be a factor limiting the concentration of a given ion in the sap current, as it is the concentration of substances on which the Donnan equilibriums in the root systems depend which determines the concentration of ions in the sap. This conclusion places the problem of studying the osmotic processes in the root systems on a somewhat special basis, the problem of osmotic penetration of electrolytes into the root systems becoming one which is not biophysical but biochemical. The task which is indicated by the facts established in this work is that of determining which sap electrolytes are influential in concentrating the ions in the external solution.

The effects of an artificially controlled hydrion concentration upon wound healing in the potato, G. A. C. HERKLOTS (*New Phytol.*, 23 (1924),

No. 5, pp. 240-255, pl. 1, figs. 2).—A study of healing in cut potatoes shows the necessity for the presence of atmospheric oxygen for both suberization and meristematic activity. Acetates alone in acid buffer solutions proved toxic to potato tissues. All buffer jellies, regardless of salts employed, kill at acid and not at alkaline pH. The range of toxic effect has its maximum at pH 4.2 and its minimum at pH 7. Disintegration of the pectic substances of the middle lamella never occurs with buffers more acid than pH 5. The fats released by the potato are in the form of unsaturated fatty acids. Alkalinity (especially from pH 7.5) promotes suberization but retards meristematic activity. After a suberized block has been formed acidity (at least up to pH 4.6) promotes phellogen activity, but retards its subsequent suberization.

[**Leaf variegation and bacteria**], G. E. MATTEI (*Riv. Biol.*, 8 (1926), No. 1, pp. 41-61, figs. 4).—Evidence, with discussion, is presented, bearing upon the question whether leaf variegation may be due to bacteria.

Foliar anomalies in *Medicago sativa* [trans. title], A. DRAGHETTI (*Staz. Sper. Agr. Ital.*, 56 (1923), No. 4-6, pp. 153-177, figs. 22).—Alfalfa leaf anomalies are systematically discussed.

Floral abortion in the olive [trans. title], A. MELIS (*Staz. Sper. Agr. Ital.*, 56 (1923), No. 7-9, pp. 302-312, figs. 5).—Weather and other conditions, and probably not heredity, are responsible for floral anomalies indicated as conditioning barrenness.

Effects of X rays on plant tumors [trans. title], V. RIVERA (*Riv. Biol.*, 7 (1925), No. 4-5, pp. 449-465, figs. 4).—It is stated that in several plants studied experimentally the effects of X-ray treatments on tumors caused by *Bacterium tumefaciens* was positive. The tumors, after a period of continued growth following inoculation (regarded as a latent period), cease growth and become yellowed and dry, the surrounding tissue of the plant remaining normal.

Transformations induced by X rays in plant tumor tissue [trans. title], V. RIVERA (*Riv. Biol.*, 8 (1926), No. 1, pp. 1-15, figs. 4).—In tumor tissue that had appeared after exposure to X-rays in *Pelargonium*, one of the genera mentioned in the article noted above, it was found that the treatment had determined in the body of the tumor the formation of a globular region which had undergone a differentiation and detachment from the rest of the tumor formation. The characters and the mode of formation of this portion are discussed.

Bacterial symbiosis in plants other than the legumes, J. K. WILSON (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 6, pp. 373-381).—It is stated to be the purpose of this review to point out some of the probable symbiotic relations existing between certain plant families other than the Leguminosae and bacteria. It is stated that bacteria may be found not only in the tissues of many plants but also in the buds, flowers, and seeds. In certain instances, designated as cases of hereditary symbiosis, the bacteria which are found in the seed may pass through the tissue of the growing plantlet and subsequently appear in the leaves and bloom and finally enter the growing seed and there remain. This condition has been observed in the Myrsinaceae and the Rubiaceae. In the latter of these the bacteria enable the plant to secure free nitrogen from the air for its own use. These bacteria from the plants of the Rubiaceae and possibly from the Myrsinaceae, when grown under suitable conditions in culture media, increase the nitrogen content. Plants of the Rubiaceae, when deprived of bacteria and grown in a nitrogen-poor substratum, fail to increase their nitrogen content and show nitrogen starvation. Myrsinaceae plants, when deprived of their bacterial symbiont, show inferior growth and nitrogen starvation.

On the occurrences of a species of *Colletotrichum*, W. SMALL (*Brit. Mycol. Soc. Trans.*, 11 (1926), pt. 1-2, pp. 112-137).—As a result of studies on strains

of a *Colletotrichum* which the author has found convenient to refer collectively to *C. coffeanum*, these strains appear not to be genetically stable and not distinguishable as physiological entities. Suggestions are offered as to the naming of certain forms.

Polyporaceae in Bulgaria [trans. title], B. B'RZAKOV (BABSACOW) (*Izv. B'lgarsk. Bot. Druzh. (Bul. Soc. Bot. Bulgarie)*, 1 (1926), pp. 21-36; *Ger. abs.*, p. 36).—The study here outlined of Bulgarian Polyporaceae includes *Polyporus* (25 species), *Boletus* (15 species), *Physisporus* (2 species), *Merulius* (1 species), *Trametes* (1 species), *Daedalea* (2 species), and *Lenzites* (2 species).

GENETICS

Genetics [trans. title] (*Ann. Sci. Agron. Franç. et Étrang.*, 43 (1926), No. 3, pp. 230-256).—Breeding work with field crops under the direction of the Institute of Agronomic Research in France during 1925 supplemented and continued the studies already recorded (*E. S. R.*, 55, p. 223).

Gigantism and genetic constitution in tetraploid genera and species [trans. title], C. ARTOM (*Riv. Biol.*, 7 (1925), No. 4-5, pp. 533-555).—This is largely a synthetic review dealing with genetic relations in plants showing gigantism and other anomalies.

Linkage and synthetic lethality among the chlorophyll factors of barley [trans. title], C. HALLQVIST (*Hereditas*, 8 (1926), No. 1-2, pp. 229-254, figs. 2).—Forty-two of 78 possible combinations between 13 factors were studied in some detail. Three strong linkages were found, the remainder of the cases showing free combination. The data did not permit the author to draw parallels between chromosome number and linkage groups in barley.

Inheritance of quantitative and other characters in a barley cross, K. W. NEATBY (*Sci. Agr.*, 7 (1926), No. 3, pp. 77-84, figs. 8).—The inheritance of a number of characters was studied in the F_2 of Guy Mayle \times Canadian Thorpe barley at the University of Saskatchewan. The two varieties involved differ widely in earliness, height, density, and outer glume length, and Guy Mayle is 6-rowed and hull-less and Canadian Thorpe 2-rowed and hulled.

Time of maturity, height, and density seemed to depend on two or more independently inherited factors, while length of outer glume depended upon two factors, one of which is not expressed in the presence of the factor for hulled seed. A single main factor difference was apparent between 2-rowed and 6-rowed varieties. The hull-less condition behaved as a simple recessive to the hulled condition. The quantitative characters, maturity, height, and density were all shown to be linked with lateral floret fertility. Two-rowed forms tend to be late, tall, and dense, whereas 6-rowed forms have the reverse tendency.

A genetical interpretation of ecological adaptation, K. SAX (*Bot. Gaz.*, 82 (1926), No. 2, pp. 223-227).—In a cross of Improved Yellow Eye \times Small White beans at the Maine Experiment Station there was a simple 3:1 segregation for pigmented v. white and for mottled v. self-colored in F_2 . These differences in seed coat pattern are associated with differences in yield per plant, indicating linkage between these qualitative factors and factors for plant yield. In F_3 , under unfavorable conditions, mottled segregates outyielded self-colored or white segregates, while in F_4 , when all classes were relatively productive, the white segregates excelled. This behavior seemed to suggest that the yield factors depend on environmental conditions for their expression, and that ecological adaptation and distribution of economic plant varieties depend on genetic factors.

The effect of environment on variegation patterns in maize pericarp, W. H. EYSTER (*Genetics*, 11 (1926), No. 4, pp. 372-386, figs. 6).—Strains of corn

with variegated pericarp and strains with orange pericarp were grown by the Missouri Experiment Station under strikingly different environmental conditions at Chula Vista, Calif., and at Sacaton, Ariz., as a preliminary study of the relation of environmental factors on the somatic expression and genetic changes of these pericarp color patterns. The higher and more variable temperature and the greater transpiration at Sacaton were apparently the chief environmental differences between the two localities. Consequently, the pericarp at Sacaton matured fully a month sooner than at Chula Vista.

In every case of the eight variegated strains grown at each locality a definite and consistent difference was noted in the variegation pattern. The California-grown variegations consistently had more red markings, covering one-fourth the surface of a kernel, and larger areas than the Arizona-grown variegations. The significance of this difference seemed to be that under the California conditions more of the color changes extended into the germ plasm and thus became genetic. Changes from orange to variegation and from orange to red also occurred more frequently under the California conditions.

Genetic factors for yellow endosperm color in maize, E. G. ANDERSON (*Mich. Acad. Sci., Arts, and Letters, Papers, 4 (1924), pt. 1, pp. 51-54*).—Experiments reported and cited concerning yellow endosperm factors in corn indicate that three factors are known well enough to be used in linkage tests and other studies. *Y*—yellow, a dominant factor, gives the deep yellow to orange-yellow endosperm color found in nearly all yellow varieties of corn. Dominance is incomplete, the heterozygous forms being lighter in color than the homozygous dominant. *Y* has been shown to be linked with *Pl*, *sm*, *pm*, *W_s*, *W_c*, and *W₁*. *Yp*—pale yellow, also dominant, gives a pale or light yellow color and is known to be linked with a factor for pale green seedling color. *Wh*—dominant white endosperm color, is dominant to both deep and pale yellow, but dominance is incomplete. Chief among modifying factors are those factors affecting endosperm texture.

A botanical study of the flax plant.—VII, A preliminary account of the genetics of flower colour and other related characters, G. O. SEARLE (*Linen Indus. Research Assoc., Research Inst. Mem. 35 (1926), pp. 115-134, pl. 1*).—Four flax varieties with white, violet, pink, and dark violet flowers, respectively, were involved in the breeding experiments (E. S. R., 53, p. 522) described. The interaction of these four types agreed fairly closely with the Mendelian hypothesis of segregation, and all forms arising from crosses of these types were explainable by using four factors. The possibility of obtaining 16 homozygous forms is indicated. The relationship between color and other flower characters is discussed, and it is shown how the flower characteristics may be related to other characters of the flax plant.

The extent of natural cross-fertilization in jowar (*Andropogon sorghum*) at Surat, G. B. PATEL (*Agr. Jour. India, 21 (1926), No. 5, pp. 366-370*).—Under prevailing conditions, natural cross-fertilization occurred to the extent of 25 per cent on the average in sorghum in rows 3 ft. apart, and every plant examined up to 6 ft. away showed contamination. The progression of flowering in sorghums of the Surat District is traced.

Inheritance in *Nicotiana tabacum*.—VII, The monosomic character, "fluted," R. E. CLAUSEN and T. H. GOODSPEED (*Calif. Univ. Pubs., Bot., 11 (1926), No. 3, pp. 61-82, pls. 3, figs. 2*).—The seventh number of this series (E. S. R., 55, p. 328) describes a form, fluted, occurring spontaneously in *N. tabacum* cultures in about 1:150 in frequency and characterized by distinct morphological features, which on cytological examination was found to be a monosomic ($2n-1$). About 60 per cent of the functioning ovules and 2 per

cent of the functioning pollen grains were ($n-1$). Selfing fluted seemed to give a somewhat lower rate of transmission than expected. Fluted involved a different chromosome set than trisomic enlarged and was independent of five other linkage groups. Crosses of fluted tabacum \times sylvestris give fluted and normal F_1 sylvestris-tabacum hybrids with more pronounced morphological differences than those between fluted and normal tabacum, particularly in flower color.

Interspecific hybridization in *Nicotiana*, III-V (*Calif. Univ. Pubs., Bot.*, 11 (1926), Nos. 4, pp. 83-101, figs. [2]; 5, pp. 103-115, figs. 6; 11 (1927), No. 6, pp. 117-125, figs. 8).—Three studies are reported on.

III. *The monosomic tabacum derivative, "corrugated," from the sylvestris-tabacum hybrid*, R. E. Clausen and T. H. Goodspeed.—An inconstant derivative termed "corrugated," on account of its distinct leaf type, was established by selfing a partially fertile individual from the back cross of the F_1 *N. tabacum macrophylla-N. sylvestris* hybrid to *N. tabacum macrophylla*. Although character differences between corrugated and normal are complex, they seem to behave as a unit in heredity. Cytological examination showed that corrugated is a monosomic ($2n-1$) tabacum derivative.

The behavior of corrugated, selfed and in crosses with *N. sylvestris* and *N. tabacum*, is described. Crosses of corrugated with white tabacum showed that the chromosome set involved in the production of corrugated bears the factors *Ww* for colored v. white flowers. Applied to the problem of the return of tabacum derivatives from the sylvestris-tabacum hybrid to the pure parental condition, the results seemed to indicate that selective functioning of pollen grains is largely responsible for doubling up of unpaired tabacum chromosomes.

IV. *Some cytological features of the paniculata-rustica hybrid and its derivatives*, T. H. Goodspeed, R. E. Clausen, and R. H. Chipman.—This paper is primarily concerned with cytological phenomena observed in the *N. paniculata-N. rustica* hybrid and its derivatives.

V. *Cytological features of two F_1 hybrids made with *Nicotiana bigelovii* as a parent*, T. H. Goodspeed and R. E. Clausen.—The cytological features of F_1 of *N. bigelovii* \times *N. suaveolens* and of *N. bigelovii* \times *N. glutinosa* are described and discussed.

A cytological study on the pollen sterility in *Solanum tuberosum* L., I. Stow (*Imp. Acad. [Japan], Proc.*, 2 (1926), No. 8, pp. 426-430, figs. 7).—Experiments at Hokkaido University involving 16 varieties of potatoes showed the haploid number of chromosomes to be 24. The reduction division of the pollen mother cells proceeds normally at 15 to 20° C. (59 to 68° F.) and normal tetrad cells, later developing to fertile pollen grains, are produced. Abnormalities occurred at higher (25-30°) temperatures, and the degree of abnormality in the meiotic division appeared to vary according to the potato variety.

A recessive glabrous character in soybeans, R. T. STEWART and J. B. WENTZ (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 997-1009, figs. 3).—In a new type of soy bean designated as p_2 in this contribution from the Iowa State College, pubescence seems to be absent, but a small hand lens reveals short, fine hairs. Glabrous plants are much smaller than the pubescent, produce few pods, and their leaves are much smaller than leaves of normal plants and exhibit a crinkled and dwarfed condition. The glabrous character perhaps arose from a mutation in the germ cells of one of the parents in the cross Soysota \times Ogemaw. The inheritance seems to be controlled by a single pair of Mendelian factors, glabrousness being recessive. It is yet doubtful whether this character differs from that (P_1) reported by Nagai and Saito (*E. S. R.*, 54, p. 825), or whether an inhibitor (P_2) causes the same

character (P_1) to behave differently. More natural cross pollination was observed between normal and glabrous plants than apparently has been reported in previous soy bean studies.

Natural crossing in soybeans, R. J. GARBER and T. E. ODLAND (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 967-970).—In the soy bean varietal experiments at the West Virginia Experiment Station where each variety was grown in 4-row plats with rows 30 in. apart, natural crossing between varieties in adjacent rows was determined to be 0.14 per cent in 1922 and 0.36 per cent in 1923.

Practical sugar cane genetics, C. F. POOLE (*Assoc. Hawaii. Sugar Technol. Rpts.*, 4 (1925), pp. 150-159).—A discussion of sexual and asexual improvement of sugar cane and of factor relations in quantitative inheritance.

Genetics and its relation to cane production, F. G. KRAUSS (*Assoc. Hawaii. Sugar Technol. Rpts.*, 4 (1925), pp. 177-194, fig. 1).—A summary is given of replies to a questionnaire on problems, methods, and results of sugar cane breeding work in Hawaii.

Chromosome behaviour in triploid wheat hybrids, W. P. THOMPSON (*Jour. Genetics*, 17 (1926), No. 1, pp. 43-48, figs. 8).—Cytological studies at the University of Saskatchewan showed 3 to 7 bivalent and 15, 13, 11, 9, or 7 univalent chromosomes to appear at the heterotype division of the hybrid between *Triticum monococcum* and a variety of *T. turgidum*. After the bivalents divided the univalents all arranged themselves on the plate and divided equationally. At the homotype division some chromosomes lagged, failed to divide, and wandered at random to the poles, their number corresponding to that of the univalents of the first division. This behavior resembles that in pentaploid hybrids except in regard to the variable amount of mating. It is similar to that in *T. monococcum* × *T. dicoccum*, except that in the latter a number of univalents fail to divide at the heterotype division.

The morphology and cytology of some hybrids of *Aegilops ovata* L. ♀ × wheats ♂, J. PERCIVAL (*Jour. Genetics*, 17 (1926), No. 1, pp. 49-68, pls. 6).—The characteristics of hybrids obtained between *A. ovata* and several forms of *Triticum dicoccoides*, *T. dicoccum*, *T. durum*, and *T. vulgare* are set forth. It is noted that the reciprocal crosses were unsuccessful and that all the hybrids were sterile. While the hybrids were intermediate in quite a number of characters, empty glumes of the hybrids were longer than in either parent. The only dominant characters observed were fragility of the rachis of the wild emmer and the mode of disarticulation of the inflorescence of the *Aegilops* parent.

The basic chromosome number in *Triticum* and *Aegilops* is 7, with similar polyploid species, $2x$, $4x$, and $6x$. In both the pentaploid and the tetraploid hybrids investigated pairing of the chromosomes in metaphase of the heterotype division was loose, and longitudinal division of the chromosomes frequently occurred soon after the univalents began their movement toward the poles of the heterotype spindle. In these *Aegilops* × wheat hybrids the chromosomes passed to poles of the spindle in both the heterotype and homotype divisions in two groups, one of them lagging behind the other. Tetrad formation was generally very irregular, and microspores of several different sizes were produced, some of which when fully developed were empty and others containing two or more nuclei with variable numbers of chromosomes. Twin microspores were also produced. Sterility of the hybrids seemed connected with these irregularities.

A study of wheat-rye hybrids [trans. title], N. MEISTER (*Zhur. Opytn. Agron. Iugo-Vostoka (Jour. Expt. Landw. Südost. Eur.-Russlands)*, 3 (1926),

No. 1, pp. 121-130, fig. 1; Eng. abs., p. 130).—Continued studies of the progenies of wheat-rye hybrids (E. S. R., 48, p. 735) revealed forms beyond the ranges of the *Triticum vulgare* parents, some resembling "wild wheat," *T. spelta*, and *T. dicoccum*, and still others approaching *T. durum*. Certain segregates surpassed the winter-wheat parents in winter hardiness and quality of grain.

Segregation in fertile hybrids between wheat and rye, L. BLARINGHEM (*Compt. Rend. Acad. Sci. [Paris], 183 (1926), No. 22, pp. 1049-1051*).—Observations on the behavior of different characters in F_1 and subsequent generations in *Triticum spelta* × *Secale* sp. and *T. turgidum* × *Secale* sp. are recorded and discussed.

Chromosome behavior in a cross between wheat and rye, W. P. THOMPSON (*Genetics, 11 (1926), No. 2, pp. 317-332, figs. 9*).—Investigations reported on from the University of Saskatchewan dealt with chromosome behavior in the parental and subsequent generations of a cross between a spring wheat of Chinese origin (*Triticum vulgare albidum*), having 21 haploid chromosomes, and Prolific spring rye with 7 chromosomes. The proportion of successful crossings was as high as in crosses between wheat varieties, and the F_1 was very vigorous and not wholly sterile.

Heteroploidy and somatic variation in the Dutch flowering bulbs, W. E. DE MOL (*Amer. Nat., 60 (1926), No. 669, pp. 334-339*).—Among the hundreds of bud variations (some of which are described in this paper) occurring in the principal varieties of flowering bulbs, there are only a few rare cases of concomitant changes of chromosome number or of nuclear structure. Heteroploidy, manifested so strongly in hyacinth and narcissus, is not considered by the author to be correlated with the process of somatic variation. The gametophyte rather than the sporophyte has a mutable nuclear structure.

FIELD CROPS

Crop returns under various rotations in the Wisconsin drift soil area, W. H. STEVENSON, P. E. BROWN, and L. W. FORMAN (*Iowa Sta. Bul. 241 (1926), pp. 225-263, figs. 10*).—Crop rotations were compared with continuous culture on a typical field in the Wisconsin drift soil area of Iowa, and the merits of various fertilizer treatments were studied under the different cropping methods. The tests involved a 5-year rotation of corn, oats, clover, wheat, and alfalfa, keeping the alfalfa on the same plats 5 years; a 4-year rotation of corn, corn, oats, and clover; a 3-year rotation of corn, oats, and clover; a 2-year alternation of corn and oats; and continuous corn. The treatments, employed in amounts of ordinary practice, centered around the use of farm manure, which represented the livestock system of farming, and the turning under of crop residues, which represented the grain system. Lime was applied as shown to be needed. In the 2-year and 3-year experiments rock phosphate was also tested with the manure and lime or with the crop residues and lime. In the 4-year and 5-year rotations rock phosphate and acid phosphate were both used, either with manure and lime or with crop residues and lime.

The value of crops grown over a 10-year period appeared to be greater under the 4- or 5-year rotations than under the 3-year system or from the 2-year alternation or continuous corn. In this respect the 4-year rotation surpassed or equaled the 5-year system in all cases, except that the 5-year rotation showed greater values of crop increases where acid phosphate, manure, and lime were applied. The crop values under the 5-year system exceeded those under the 3-year rotation except where manure, lime, and rock phosphate were applied and also where crop residues and lime were used.

In general, the longer rotation of 4 or 5 years probably may be more valuable over a period than the shorter 3-year rotation, which in turn is definitely preferred to the 2-year system or to continuous cropping. The value of applications of manure, lime, and a phosphate fertilizer to soils in this area under various rotations was definitely shown. It seemed that in many cases acid phosphate may be more profitable than rock phosphate on these soils.

Fixation of nitrogen by legume nodule bacteria grown in pure culture [trans. title], C. BARTHEL (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden]*, No. 308 (1926), pp. 16, fig. 1; *Eng. abs.*, p. 16).—Experiments with a strain of *Bacterium radicicola* gave negative results regarding its ability to fix atmospheric nitrogen when grown in pure culture. Addition of 0.1 per cent of caffeine to the nutrient solution did not influence the result positively.

Fleshy annual pastures in Canada, G. P. McROSTIE ET AL. (*Canada Dept. Agr. Pamphlet 73, n. ser.* (1926), pp. 8, figs. 7).—General information is presented on the culture of rape, kale, and cabbage in Canada, and the results of tests on these crops at some of the Dominion Experimental Farms and stations are summarized.

Bagging cotton flowers to prevent accidental cross-pollination, T. H. KEARNEY and D. D. PORTER (*Jour. Heredity*, 17 (1926), No. 8, pp. 273-279, pl. 1, figs. 3).—The technique used in bagging Egyptian cotton flowers to prevent cross-pollination (*E. S. R.*, 49, p. 226) is described, and data are cited regarding cross-pollination, the effectiveness of bagging, and local insect carriers of pollen. Unless artificially pollinated, bagged flowers produce fewer seeds per boll, doubtless because pollen reaches only that part of the stigmas in contact with or immediately above the uppermost anthers. White bags were found more efficient than colored bags.

An account of experiments carried out to determine the experimental error of field trials with cotton in Egypt, M. A. BAILEY and T. TROUGHT (*Egypt Min. Agr., Tech. and Sci. Serv. Bul.* 63 (1926), pp. [2]+29, pls. 23).—Experiments to determine the amount of variability to be expected in field trials with cotton led the authors to recommend that no paths be left between beds, but that ridges bordering the bed should be uprooted at picking time, tenfold repetition of variety beds, and continuation of trials for at least 3 years. Beds should be in the form of long strips (up to 16 times as long as wide), sited along the length of the ridges to facilitate planting, and where possible $\frac{1}{2}$ feddan (about $\frac{1}{5}$ acre) in area. Where sufficient land or seed is not available, fewer replications should be used and the strips divided into two or even three equal parts at harvest to maintain the required number of comparisons between adjacent beds. Results should be computed by the method of differences.

Ninety references are given concerning experimental procedure, and a method is suggested by U. Yule for obtaining the standard error of a difference between two means in a chessboard variety experiment.

The cotton growing countries present and potential: Production, trade, consumption (*Rome: Internatl. Inst. Agr., Bur. Gen. Statist.*; London: P. S. King & Son, 1926, pp. XXXVI+317).—The production of cotton in important political divisions of the world is described briefly as in an earlier note (*E. S. R.*, 49, p. 529), with statistics of yields, acreages, commercial movement, and prices.

Johnson grass in Texas, E. O. POLLOCK (*Texas Sta. Circ.* 43 (1927), pp. 15, fig. 1).—Designed to aid in the better management of fields on which Johnson grass is already established, this circular indicates the adaptation and distribution of the plant, and describes production methods for hay and seed, its

value for pasture, its place in the cropping system, and means for its eradication. Brief abstracts are given of laws affecting the production and shipping of Johnson grass hay.

Breeding winter oats for the South, T. R. STANTON (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 9, pp. 804-814, fig. 1).—Breeding work with winter oats at the Arlington, Va., Experiment Farm developed two strains of Winter Turf which during the period 1916-1925 outyielded unselected stock by about 8 bu. per acre. Definite winter types isolated from Fulghum seem more cold-resistant and yield better than the original Fulghum. Several high-yielding strains of winter oats developed from Winter Turf×Aurora satisfactorily combine the earliness and kernel characters of Aurora with the winter resistance of Winter Turf. Other winter oats breeding activities of the U. S. Department of Agriculture are outlined briefly. The maintenance of varietal identity is indicated as an important problem confronting southern oats growers.

[**Potato experiments in New Brunswick**], D. J. MACLEOD (*Canada Expt. Farms, Div. Bot. Rpt. 1925, pp. 43-45, 48-50*).—In the production of certified seed close spacing appeared superior to thin planting because of the smaller number of large tubers in the former. Growers of Irish Cobbler and Green Mountain seed potatoes might adopt the practice of planting as close as is consistent with roguing. Selected Green Mountain seed grown on seven types of soil revealed tendencies for soils such as coarse sand and black muck to product short round tubers and heavier soils such as ordinary sandy loam and clay to yield longer types.

Potatoes were stored under dry and damp conditions in burlap containers in contact with certain salts, fertilizer ingredients, fungicides, and commodities of general consumption such as are shipped in bags often used subsequently by potato shippers. Salts, particularly when brought in contact with the moistened surface of tubers, readily dissolve and entering through the lenticels infiltrate the surrounding tissues, producing necrosis.

Epsom salts, sodium nitrate, potassium nitrate, and coarse common salt appeared similar in severity of action, and ammonium sulfate, while slightly slower, ultimately produces like conditions. Bordeaux dust and acid phosphate produced restricted necrotic sunken areas involving only the tissues adjacent to the lenticels, leaving the rest of the tuber otherwise firm and normal. The former under dry conditions produced no apparent injury. In dry storage all the salts produced very much modified conditions as outlined. Flowers of sulfur effected no change. Cane sugar resulted in a very slight necrosis around a few lenticels under damp storage but produced no abnormality under dry conditions. Tea, coffee, cocoa, potato starch, corn meal, and bran do not produce necrosis but by their hygroscopicity induce an enlargement of lenticels and also provide media for development of rot-producing organisms which are afforded readier penetration through the lenticels.

Deep-eyed as opposed to shallow-eyed varieties seem predisposed to greater ravages by chemicals, and varieties with thin skin were found extremely susceptible to the rapid infiltrating and diffusing action of chemicals. The deleterious effects exhibited seem to demand that all sacks used to contain potatoes should be thoroughly washed before using, to insure complete removal of injurious substances.

Potato growing in Colorado, E. P. SANDSTEN (*Colorado Sta. Bul. 314 (1927), pp. 30, figs. 5*).—The status of potato production in the State is outlined, and accounts are given of soil and fertility needs, handling seed, varieties for different sections of Colorado, cultural and field methods, and harvesting and

storage practices. Important diseases and control methods are described briefly.

A method of crossing sorghums, H. N. VINALL (*Jour. Heredity*, 17 (1926), No. 8, pp. 296-299, figs. 3).—This method involves the use of a glass plate (about 6 by 8 in.) to collect pollen from the male parent. Several advantages are indicated.

Report on the sugar beet experiments [in Ireland], 1925 (*Dublin: Dept. Lands and Agr.*, 1926, pp. 54).—Experimental results with sugar beets in 1925 considered with previous (1911-1913) results demonstrated that with proper care and management crops comparing favorably in yield and sugar content with continental crops can be grown in Ireland. While German and Dutch varieties appeared somewhat superior to the Danish and French varieties in sugar content, no marked difference in yields was noted. Any soil producing satisfactory root crops seemed suitable for sugar beets. The position of sugar beets in the rotation did not influence yield or sugar content materially. Top-dressing with sodium nitrate at the rate of 1 cwt. per acre after singling increased the average yield without lowering sugar content, and seemed to stimulate the growth of crops backward because of mangel fly attack or unfavorable soil or weather conditions. Relatively narrow drills and thorough and frequent after-cultivation were indicated for maximum yields.

The effect of increased applications of sodium nitrate on the quality of sugar beets [trans. title], J. SOUČEK (*Ztschr. Zuckerindus. Českoslovak. Repub.*, 50 (1926), Nos. 47-48, pp. 419-422; 49, pp. 499-503; 50, pp. 507-514).—In 65 comparative fertilizer experiments with sugar beets in 1924 in Czechoslovakia, similar to and in continuation of previous (1923) work (E. S. R., 52, p. 834), sodium nitrate applications were equivalent to 0, 100, 200, 300, and 450 kg. per hectare (0, 89, 178, 267, and 400.5 lbs. per acre). As general averages the respective yields of beets amounted to 32,900, 35,400, 37,000, 38,400, and 39,800 kg. per hectare; leaves 16,900, 18,600, 20,200, 21,600, and 23,400 kg.; sugar content 19.18, 19.31, 19.33, 19.35, and 19.18 per cent; purity of juice 89.8, 90.2, 90.1, 90.2, and 90; and nitrogen content of root 0.141, 0.14, 0.144, 0.148, and 0.156 per cent.

Contrary to results in 1923, sodium nitrate produced enhanced yields of roots and leaves under the influence of favorable weather conditions and caused reduction in neither sugar content nor purity of juice, the latter being rather larger in the treated beets. The beets of 1924 were more mature than those of 1923; they had relatively fewer leaves. The nitrogen content of the root was augmented slightly by progressive additions of sodium nitrate, and more beets per unit area were found on treated plats. In the 44 tests where the soil was analyzed, the influence of sodium nitrate apparently varied according to the nitrogen and calcium carbonate contents of the soil, its mechanical condition, and time of harvest. Sodium nitrate affected the yield and quality of the beets more favorably when the soil contained less nitrogen, when the beets were riper, and where the soil had a high moisture capacity (heavy clay). When the soil had a small calcium content, the effects of the 100 and 200 kg. applications of sodium nitrate were most intensive, probably due to neutralization of soil acidity.

The composition of biennial white sweet clover as related to soil enrichment, A. L. WHITING and T. E. RICHMOND (*Soil Sci.*, 22 (1926), No. 2, pp. 83-95).—The composition of tops and roots of biennial white sweet clover was determined at various growth stages at the Illinois Experiment Station to get information on handling the crop in cropping systems.

Sweet clover tops appeared to decrease in nitrogen, phosphorus, and sulfur with maturity the first season, while the roots increased in nitrogen and apparently in other elements while increasing in dry matter. In the second season the roots increased slightly at first and then decreased, paralleling somewhat the concurrent decrease in the tops. These changes seemed partly due to translocation.

Nitrogen was the outstanding element in both tops and roots at most sampling periods, much being found in a soluble form in the roots. Mineral elements are present in quantity generally in the order potassium, calcium, magnesium, sulfur, and phosphorus. Potassium and calcium appeared to be needed in relatively large amounts. More calcium is present in seed and leaves than other elements except nitrogen. The magnesium present in the seed equals about one-third of the phosphorus content, whereas two or three times as much magnesium as phosphorus is present in the leaves. Sulfur occurs in relatively large amounts and exceeds phosphorus in most cases. It is high even in the seed and very high in the leaves. More phosphorus was found in the fall roots than in other samples. Analyses of root samples taken in the fall at 0 to 7 in. and 7 to 40 in. showed that the roots at considerable depth maintain the same percentage composition as near the surface. Data cited indicated that the composition of sweet clover may be influenced considerably by applications of limestone, phosphorus, and potassium.

[**Tobacco investigations in Canada in 1925**], C. M. SLAGG, J. E. MONTEUIL, H. A. FREEMAN, and T. G. MAJOR (*Canada Expt. Farms, Tobacco Div. Rpt. 1925, pp. 40, figs. 6*).—Tobacco investigations (E. S. R., 55, p. 738) in Canada during 1925 embraced varietal studies at Ottawa and elsewhere in the Dominion, fertilizer, seed bed, and rotation experiments, and notes on the nicotine content of varieties variously treated. A report by Freeman on the status of Canadian tobacco in the British Isles, a discussion by Major of progress in disease studies, and the usual statistics on acreage and yield in Ontario and Quebec are also included.

Glass-covered semihotbeds excelled in production of early, vigorous seedlings at both Harrow, Ont., and Farnham, Que., and treatment of seeds with various organic and inorganic mercury compounds showed little or no advantages. Beds made and steamed in the fall were fully as satisfactory as those made and steamed in the spring.

At Harrow it has been found possible to control the root-rot disease when tobacco is grown in 4-year rotations of corn, grain, hay, tobacco, and corn, tobacco, grain, hay. The best results in fertilizer tests were obtained on flue-cured tobacco with formulas supplying ammonium sulfate, acid phosphate, and potassium sulfate equivalent to 1,000 lbs. of 2.8-9-10 of mixed fertilizers per acre, with Burley equivalent to 1,000 lbs. of 9-8-8, and with the Green River type to 1,000 lbs. of a 5-6-7.5 mixture. Drilling again proved superior to broadcasting fertilizer, and the most satisfactory rate for manure used with commercial fertilizer was 14 tons per acre. From the viewpoint of yield, manures at the acre rate of 12 tons ranked in the order poultry, sheep, horse, cow, and hog. Little difference was noted in the quality of cured leaf.

The use of commercial fertilizers improved both yield and quality of cigar binder tobacco grown at Farnham, whereas lime lowered both yield and quality. Using commercial fertilizer with manure gave an average yield of 200 lbs. more per acre and a net profit of about \$20 per acre over manure applied alone.

A disease survey showed that damping-off in the seed bed, *Thielavia* root rot in the bed and field, and mosaic continue to be the most serious troubles

affecting tobacco in Canada. Steaming seed bed soil for 30 minutes at 50 lbs. pressure satisfactorily controlled Thielavia root rot. In tests of certain commercial preparations as soil disinfectants the dust treatments injured the germination and stand and reduced the size of plants. Formaldehyde preparations did not seem as injurious to the host plants as the organic mercury compounds. Soaking seed with water before sowing appeared to stimulate growth somewhat. Air-dried samples of sandy loam soils were found slightly more acid than fresh samples.

On the biology of tobacco fermentation [trans. title], J. J. SCHMIDT (*Tropenpflanzer*, 28 (1925), No. 2, pp. 64-68).—Investigations by the author revealed striking differences in the bacterial flora of tobacco from different sources and differing in quality. Development of microorganisms present on the green leaves was found to occur during the fermentation process. Species differed in their development according to the optimum temperatures for their groups. The flora of tobaccos differing in source and quality varied in respect to numbers and types of species of microorganisms. No differences in the number of species were observed between similarly fermented German and foreign tobaccos. The imported and domestic tobaccos differed regarding the species of microorganisms found thereon, although the bacteria pertained to the same groups. Differences in number and kind of species were observed on tobacco fermented by different methods, e. g., German and North American. The bacteria isolated from domestic and foreign tobaccos could be grouped according to their physiological characteristics and temperature optimums as cocci, short rods, and fluorescent types, spore producers of the size and type of *Bacillus mycoides* and *B. megatherium*, mesentericus forms, and Plectridia and Clostridia (only from poor quality tobacco). The bacteria from different tobacco varieties were observed to behave differently in their relation to protein and carbohydrates. Mesentericus forms decomposed different proteins quickly, whereas cocci and short rods decomposed protein slowly. Species related to *B. mycoides* and *B. megatherium* decompose protein and carbohydrates quite rapidly.

Spring wheat production in Illinois, R. W. STARK (*Illinois Sta. Bul.* 287 (1927), pp. 337-351, fig. 1).—Although spring wheat is grown to a limited extent in all parts of the State, it is of importance only in northern and central Illinois. It has been found less profitable than corn and winter wheat but more gainful than oats. Tests at De Kalb and the station recommended the use of the Marquis variety, a 2-bu. acre rate, seeding in 4-in. rather than 8-in. drills, and planting March 1 or soon thereafter. While spring wheat may advantageously substitute for winter wheat when fall weather conditions prevent seeding the latter, it usually replaces oats and follows corn. If cornstalks have not been plowed under carefully spring wheat should be sown elsewhere to avoid wheat scab. Preparation and seeding practices are outlined, and the characteristics and behavior of varieties tested are summarized.

The influence of certain soil amendments upon the quality of soft red winter wheat in Ohio, L. E. THATCHER (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 8, pp. 629-648, figs. 3).—When sodium nitrate was applied to Dawson Golden Chaff wheat at monthly intervals from March 15 to June 15 at the Ohio Experiment Station, the straw yield and number of tillers per plat and the total nitrogen removal per plat in the crop were greater as the applications were made earlier in the season. The grain to straw ratio decreased with the later applications. Very little effect was noted on protein content of grain.

In a 5-year rotation fertility test, the 10-year average test weight per bushel was lowest on untreated plats and on plats receiving sodium nitrate alone.

Phosphorus alone and potassium alone gave consistently heavier wheat than nitrogen alone. The test weight was lowered when nitrogen was added to either phosphorus or potassium and raised when nitrogen was added to phosphorus with potassium. The effect of liming the land upon test weight and straw to grain ratio seemed to be correlated with seasonal conditions. Milling and baking records, together with protein and ash determinations, on wheat from the 1925 crop on these plats are tabulated and discussed.

[The Swedish State Seed Testing Station], H. WITTE (*Meddel. Statens Cent. Frökontrollanst. [Sweden], No. 1, (1926), pp. 1-38, figs. 7; Eng. abs., pp. 37, 38.*)—An account is given of the history and organization of this station, its equipment, and its activities during the fiscal year 1924-25.

Recent Indiana weeds, 1925, A. A. HANSEN (*Ind. Acad. Sci. Proc., 41 (1925), pp. 199, 200.*)—Plants reported as recently occurring in Indiana since the previous report (E. S. R., 55, p. 740) include fitsroot (*Astragalus glycyphyllos*), Japanese bindweed (*Convolvulus japonicus*), Canada thistle, wild marigold (*Matricaria matricarioides*), stinking goosefoot (*Chenopodium vulvaria*), and wood sage (*Teucrium canadense*). Infestations of prairie mimosa (*Acuan illinoensis*), Bermuda grass, and perennial sow thistle are also noted.

Weed control, H. GROH (*Canada Expt. Farms, Div. Bot. Rpt. 1925, pp. 19, 20.*)—Further experiments (E. S. R., 54, p. 834) indicated that moderately deep plowing followed by disking may be recommended for mouse-ear hawkweed as for other hawkweeds. Eradication without breaking up was tried by using dry salt with scattered patches, but recovery from the roots was prevented only with considerable injury to the grass. Common mouse-ear chickweed may be controlled in lawns by raking out the weed and then seeding in fresh grass.

The distribution of weed rye (*Secale cereale*) in the mountains of central Asia [trans. title], G. A. BALABAEV (BALABAJEV) (*Trudy Prikl. Bot. i Selekt. (Bul. Appl. Bot. and Plant-Breeding), 16 (1926), No. 4, pp. 101-134, figs. 2; Eng. abs., pp. 132-134.*)—Intensive studies in the mountainous districts of Samarkand established a definite regularity in the distribution of weeds, especially rye, according to the mountain zones. A tough-spiked winter rye, met with only in cereal fields, was noted chiefly in irrigated winter wheat, less frequently in winter barley, and rarely among spring grains on nonirrigated land or among other field crops. The spread of rye increases according to altitude, and in the mountain zones (1,330 to 2,440 meters) wheat is entirely supplanted.

HORTICULTURE

Methods of interpreting results of horticultural experiments, R. D. ANTHONY (*Amer. Soc. Hort. Sci. Proc., 21 (1924), pp. 256-258.*)—A brief contribution pointing out the importance of determining the influence of individual variation where the number of individuals is small, and discussing also the application of the Mitchell and Grindley and Bessel formulas and the Student method for analyzing the results of horticultural investigations.

Effect of various lengths of day on development and chemical composition of some horticultural plants, E. C. AUCHTER and C. P. HARLEY (*Amer. Soc. Hort. Sci. Proc., 21 (1924), pp. 199-214.*)—In studies at the University of Maryland of the effect of modifying the length of light exposure upon soy beans, peppers, lettuce, and radishes grown under high and low nitrate conditions, the soy beans blossomed much earlier and the peppers considerably earlier under a shortened day. On the other hand, lettuce and radishes blossomed sooner under a lengthened day. In the case of soy beans, very little difference was noted in the response to light changes of the high and

low nitrogen series, a fact due probably to the leguminous nature of the soy bean. On the other hand, a lack of nitrates delayed blooming in peppers, lettuce, and radishes irrespective of the length of day.

Analyses of soy beans showed short-day plants at the time of blooming to have a higher percentage content of total carbohydrates than plants of other treatments. At the same time the percentage of total nitrogen was lower. The normal-day plants reached a similar composition at blossoming time (86 days). Plants subjected to intermittent light failed to respond in the same way as plants receiving an equal amount of light in a continuous application. In the case of soy beans, intermittent-light plants at the time of blooming were low in sugars, starches, and soluble nitrogen and high in insoluble nitrogen. Soy beans lighted at night with electricity did not bloom in 160 days, the duration of the study. Since the percentages of soluble carbohydrates were somewhat lower in the continuous-light series, the authors deem it likely that the carbohydrates were used in growth extension rather than in fruiting.

[Breeding work at the South Dakota Station], N. E. HANSEN (*South Dakota Sta. Rpt. 1926, pp. 28-31*).—This comprises brief notes upon various breeding activities and the resulting seedlings, including pears, grapes, crab apples, walnuts, and roses. In general, homozygous parents have been found more valuable than heterozygous in the development of valuable seedling fruits.

Fertilizer experiments with greenhouse lettuce and tomatoes, J. W. LLOYD (*Illinois Sta. Bul. 286 (1927), pp. 309-336, figs. 3*).—A report upon greenhouse experiments with soils and fertilizers for lettuce and tomatoes.

A soil mixture made up of 4 parts brown silt loam, 2 parts rotted manure, and 1 part sand when supplemented with nitrate of soda at the rate of 0.86 lb. per 100 sq. ft. or dried blood at the rate of 3.96 lbs. per 100 sq. ft. produced better average yields of lettuce and equally as good crops of tomatoes as a soil mixture made up of 4 parts of soil, 4 parts of rotted manure, and 1 part sand, thus indicating that part of the manure might be effectively replaced by commercial fertilizers. The addition of acid phosphate to the nitrate of soda reduced the yields of lettuce and increased those of tomatoes. This detrimental effect upon lettuce was overcome by liming. Potassium sulfate proved of no value to lettuce and only slightly beneficial to the tomatoes when used in connection with other materials. Excessive quantities of commercial fertilizers had a tendency to reduce the yields of both the lettuce and the tomatoes.

Steam sterilization increased the yields of lettuce and decreased the yields of tomatoes growing in the 4-4-1 soil mixture. Sterilization apparently rendered the soil nutrients more quickly available, thus resulting in an exhaustion of the soil earlier in the season. In respect to the use of acid phosphate, the author suggests that none be used upon the lettuce but that small quantities be applied as a top-dressing to the tomatoes after the last crop of lettuce has been harvested.

A case of arsenical injury to tomato plants, F. A. FENTON (*Iowa Acad. Sci. Proc., 31 (1924), pp. 135-137, figs. 4*).—Bran mash poisoned with Paris green and used as a bait for cutworms is believed to have caused the death of tomato plants about whose bases it was placed. The death apparently resulted from girdling lesions caused by water-soluble arsenic.

Trials with commercial varieties of canning peas, A. N. HUME (*South Dakota Sta. Bul. 221 (1927), pp. 15, figs. 2*).—Herein are presented the results of a test of 10 commercial strains of 8 varieties of canning peas, supplemented

with general information upon culture, inoculation, canning factory operations, etc. Data upon the comparative yields of inoculated and uninoculated seed gave conflicting results, distinct increases being obtained from inoculation in only 5 of 11 trials. However, averaging all strains, inoculation increased the yield 5.96 per cent and the weight of green vines 23.7 per cent.

Watermelon culture, M. F. WHARTON (*Arizona Sta. Timely Hints for Farmers, No. 156 (1926), pp. 7, figs. 4*).—This comprises general cultural information.

Essentials to successful fruit culture in Arizona, F. J. CRIDER (*Arizona Sta. Bul. 117 (1926), pp. 337-395, pl. 1, figs. 20*).—General information is presented upon fruits and varieties of fruits suited to different elevations and suggestions are given upon the soil requirements, planning and planting of the orchard, the use of filler trees, care of the orchard, dry land operations, general outlook of the fruit industry in Arizona, etc.

Fruit bud formation and growth, H. D. HOOKER (*Amer. Soc. Hort. Sci. Proc., 22 (1925), pp. 123-126*).—Emphasizing the close association of carbohydrate accumulation with the rest period and fruit-bud differentiation in pome fruits, the author suggests that shoot growth is determined by a series of consecutive, reversible chemical reactions, in which an accumulation of end products such as carbohydrates retards and eventually stops the reaction. On the other hand, carbohydrate accumulation is not an end product of root activity and hence does not retard development. It is deemed likely that the accumulation of carbohydrates in the vicinity of the buds at time of differentiation may affect the morphological development of the growing point in such a way as to suppress the development of photosynthetic machinery and so favor the formation of floral parts.

Comparative rates of imbibition in apple wood tissue, C. F. ROGERS (*Iowa Acad. Sci. Proc., 31 (1924), p. 134*).—Observations upon finely ground, air-dry wood of 12 apple varieties placed in a saturated atmosphere at a constant temperature showed the maximum rate and the greatest total imbibition in those varieties which have proved to be least hardy in Iowa.

The chemical composition of developing flowers and young fruits from weak and vigorous spurs of the apple, F. S. HOWLETT (*Amer. Soc. Hort. Sci. Proc., 21 (1924), pp. 194-199*).—Analyses, at the Ohio Experiment Station, of flowers collected from weak and vigorous Fall Pippin apple spurs at the time the central flowers were about to open showed, despite the fact of the reduced weight of the weak-spur blooms, no significant differences in the percentage composition of the two groups whether computed on the basis of green or dry weight. However, the average total amounts of nitrogen, free reducing substances, total sugars, and acid hydrolyzable polysaccharides were greater in flowers from vigorous spurs. The same relations held in flowers gathered just after the petals had fallen. Analyses of flowers collected from the same trees at the time abscission had begun showed higher nitrogen and lower free reducing substances and total sugars in the flowers which remained upon the tree, thus bearing out very closely previously noted results with Roxbury Russet flowers (*E. S. R., 50, p. 835*).

A comparison of the composition of flowers about to abscise with that of flowers from which the petals had just fallen showed no significant increases in total nitrogen and carbohydrates. Assuming equal pollination for blooms on strong and weak spurs, the author believes that many of the latter are incapable of fertilization from the beginning, due to some unknown cause such as egg cell degeneration or inadequate nutrition.

Some observations on the effect of inbreeding on the vigor of apple seedlings, H. L. LANTZ (*Amer. Soc. Hort. Sci. Proc., 22 (1925), pp. 115-123*).—

Apple breeding studies at the Iowa Experiment Station have shown that in-breeding is not only difficult but usually results in seeds of fair to poor viability and trees low in vitality. Sib and back crosses, though accomplished quite easily, also yielded seedlings showing in the main lower vigor than those of out crosses. Two combinations, viz, Salome × Jonathan and McIntosh × Longfield, have been especially productive of valuable progeny. Results of sib and back crosses in these two lines are discussed in some detail.

Apple stock variation and its relation to scion growth, J. T. BREGGER (*Amer. Soc. Hort. Sci. Proc.*, 21 (1924), pp. 313-318).—Measurements taken at Cornell University of the initial growth of McIntosh and Rhode Island scions grafted upon equal sized root pieces taken from pairs of 6-year-old McIntosh trees which had received identical soil treatment but differed significantly in size showed a greater growth in progeny of large sized trees in 11 out of 14 pairs. The differences proved statistically significant, the odds in one case being equivalent to five times the probable error.

In a second experiment in which Delicious scions were grafted upon large and small sized apple seedlings, measurements taken of the first summer's growth revealed no significant differences which could be correlated with the sizes of the original seedlings. This fact is believed to indicate that factors which affect the initial growth of the scion do not influence its further development. Furthermore differences in seedling size may be due in part to differences in the time of seed germination.

The relation of temperature to pollen tube growth in vitro, H. E. KNOWLTON and H. P. SEVY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 110-115, figs. 3).—Studies at the West Virginia Experiment Station with the pollen of a number of varieties of apples placed upon agar medium containing 10 per cent cane sugar and held at various temperatures from 32 to 97° F. showed the greatest growth rate for all varieties except Yellow Transparent to be between 65 and 70°. Except at the lower ranges, temperature had no effect on the percentage of germination. The rate of growth of Rhode Island pollen was conspicuously slower than that of other varieties. In the case of Stayman Winesap and Arkansas pollen germination was so poor that no typical growth curves could be determined. Pollen held at low temperatures with little or no growth behaved normally when removed to a satisfactory temperature, but cultures taken from above the optimum temperature and placed at the optimum failed to recover. Practical deductions are set forth.

The causes and results of partial pollen sterility in apples and pears [trans. title], F. KOBEL (*Landw. Jahrb. Schweiz*, 40 (1926), No. 3, pp. 441-462, fig. 1).—A further report (*E. S. R.*, 52, p. 739) upon pollination studies at the horticultural experimental station at Wädenswil, Switzerland.

Continuation of pollen viability tests showed slight fluctuations from previous results, leading the author to suggest that viability of pollen is apparently influenced to a limited degree by internal and external nutritive conditions. Pollination tests with high and low viability varieties again demonstrated that varieties with low pollen viability are not good pollinizers. Cytological studies showed varieties with normal, odd number, triploid, and tetraploid chromosomes. The viability of the pollen was closely related to chromosome constitution; the greater the abnormalities, the lower the viability of the pollen grains. The haploid number was 16. Berner-Rosenapfel with a pollen germination of 97 per cent had 16 chromosome pairs, which behaved normally in the various divisions of the pollen mother cell. On the other hand, Gravenstein with a 7 per cent viability had 48 instead of 32 chromosomes in the somatic cells. William Christbirne (Bartlett) with 46 per cent viability had 16 pairs and 2 odd chromosomes.

Varieties with poorly germinating pollen bore fruits with many sterile seeds, a condition traceable to the abnormal chromosome constitution. Varieties with above the normal number of chromosomes inclined to parthenocarp. A statistical analysis shows that under otherwise normal conditions the average fruit weight increased with an increasing seed number. In ripe fruits of two pear varieties an increase in the number of seeds per fruit was found to be accompanied by an increase in sugars and total acids. This phenomenon did not occur in apples, but there was noted a distinct rise in sugar content as the weight of the fruit increased.

Pectic constituents of peaches and their relation to softening of the fruit, C. O. APPELMAN and C. M. CONRAD (*Maryland Sta. Bul.* 283 (1926), pp. 8, figs. 3).—Analyses of the fresh pulp of Crawford peaches harvested at various stages of maturity failed to reveal any pectic acid or pectates. Determinations of protopectin and soluble pectin in fruits picked hard ripe and allowed to soften in a room averaging 65° F. showed a close inverse relationship between the contents of the two substances. As soluble pectin increased the amount of protopectin showed a corresponding decrease. The maximum soluble pectin content was found in fully ripe fruits. The sum of the pectin and the protopectin apparently increased slightly as the fruits softened. The pectic changes in fruits stored at 37.5° was much slower than that of higher temperatures.

Fruits removed from the tree in the hard ripe stage and stored at 37.6° and those allowed to remain on the tree showed no increase in soluble pectin at the end of 3 days, whereas a comparable lot stored at 72° showed decided changes. The fruits at 72° became very soft, indicating a close parallel between softening and pectic changes. Similar results were obtained in a comparable experiment with greener peaches. Storage at low temperatures was found detrimental to quality, and it is deemed advisable to leave hard ripe peaches on the tree for a few days if marketing conditions are unfavorable.

The influence of potash upon the yield and quality of grapes [trans. title], C. DUSSERRE and C. GODET (*Ann. Agr. Suisse*, 26 (1925), No. 5, pp. 639–643).—Data obtained in a Chasselas vineyard located on the gravelly calcareous soil at the viticultural station at Auvernier show that potash fertilizers significantly increased yields, the average yield per vine for three years being 574, 654, and 699 gm. for the control, potassium sulfate, and potassium muriate plats, respectively. At the same time the sugar produced per acre was considerably greater on the potash plats, especially the muriate of potash plat.

Correlation of chemical composition with hardness in brambles, R. V. LOTT (*Missouri Sta. Research Bul.* 95 (1926), pp. 22, figs. 4).—A close correlation was found between the amount of actual winter injury in blackberries growing at Turner Station on a rather poor loess soil and the percentage of freezable water in the bark of lateral shoots, as determined by the dilatometer. Comparing the effect of four cultural treatments, namely, cover crop with and without nitrate of soda and ordinary culture with and without nitrate of soda, the least injury was found upon the cover crop and nitrate plat. This increase in hardness is believed due to the stimulation of the nitrogen upon the cover crop which in turn was better able to use more of the soil moisture otherwise available to the blackberries. Determinations showed the highest percentages of bound water in the cover crop-nitrate plants. In the case of raspberries grown in the same vicinity, cover crops without added fertility increased hardness.

The study of bark samples taken from raspberries growing at Columbia, part of which had the young shoots removed twice in early spring, showed the highest percentage of bound water and the least amount of killing in the

treated plants. The largest percentage of bound water, of pectin, and of protein nitrogen found in any bush fruits was in 2-year-old currants grown under ordinary culture. An evident correlation was noted between hardness as measured by the percentage of bound water and the percentages of pectin and protein nitrogen. The correlation coefficients were 0.67 ± 0.06 and 0.6 ± 0.07 , respectively. No relation was observed between hardness and total sugars or total pentosans and only a slight correlation between hardness and the percentage of dry weight.

Unlike the raspberry, the blackberry samples showed no seasonal development in pectin and bound water, suggesting that the blackberry probably attains its maximum hardness earlier than does the raspberry. In the raspberry the seasonal increases in the percentages of bound water and pectin were particularly marked in those plants which had the first two crops of shoots removed.

The avocado stock problem, H. J. WEBBER (*Calif. Avocado Assoc. Ann. Rpt. 1925-1926*, pp. 37-41).—Citing the present day use of untested Mexican avocado seedlings as stocks for improved varieties, the author points out the advantages of using known seedlings of proved value both in respect to soil adaptability and effect upon the scion.

Results of pollination and other experiments on avocados at the orchards of the Point Loma Homestead, O. I. and A. B. CLARK (*Calif. Avocado Assoc. Ann. Rpt. 1925-1926*, pp. 85-94).—Avocado trees responded quickly to nitrogen applications either in the form of nitrate of soda or of ammonium sulfate provided they had not reached a critical stage of undernourishment when treated. Attempts to increase the set of fruit with nitrogen yielded negative results. A combination of animal and chemical fertilizers gave very good results.

In reporting further (E. S. R., 52, p. 343) upon pollination tests, the authors found no loss in fruit setting in the Fuerte variety when half the tree was inclosed in a tent which excluded practically all insects. The inclosure of portions of Fuerte and Spinks trees in a single tent with bees resulted in practically no set of fruit. Comparing cross- and self-pollination on the Dickinson variety, cross-pollination was invariably much more successful in producing fruits.

The citrus industry in South Africa, H. J. WEBBER (*Citrus Leaves*, 6 (1926), No. 9, pp. 4-8, figs. 4).—This contribution from the Citrus Experiment Station, Riverside, Calif., is a general discussion pointing out the present extent and distribution of the citrus industry in South Africa, together with comments upon its condition and future outlook.

Orange cincturing and root pruning tests, C. G. SAVAGE (*So. Aust. Min. Agr. Rpt. 1925*, p. 36).—Based on records taken at the State Experiment Orchard, Berri, South Australia, orange trees girdled in 1923 when in full bloom yielded 259 lbs. of fruit per tree, as compared with 185 lbs. for trees girdled when the new growth had just started and an average of 30 lbs. for untreated trees. Root pruning, on the other hand, had but slight effect upon yields, and the trees treated in this manner were for some time following sickly in appearance. Data taken the succeeding season upon the same trees without further treatment showed 129 lbs. of fruit for trees originally girdled when in full bloom as compared with 76 lbs. for those treated at the time new growth was starting. Root-pruned trees, on the contrary, yielded much larger crops the year following the treatment.

Studies in the Kao Pan Siamese seedless pomelo [trans. title], T. TANAKA (*Nôgaku Kwaihô (Jour. Sci. Agr. Soc. [Japan])*, No. 275 (1925), pp. 288-299,

pls. 3, figs. 2; Eng. abs., pp. 12, 13).—Brief descriptive notes are presented upon the fruits of the Kao Pan seedless pomelo, imported directly from Siam, the native habitat of the tree. The adaptability of this highly esteemed variety to various citrus-growing regions of Japan is also briefly considered.

Pollination of feijoas, O. I. CLARK (*Calif. Avocado Assoc. Ann. Rpt. 1925-1926, pp. 94, 95*).—Covered and uncovered feijoa blossoms produced 9 and 40 per cent of fruits, respectively. No insect save the honey bee was seen to visit the blooms. Hand pollination tests showed the Coolidge variety to be 100 per cent self-fertile, and of many tested this was the most productive and bore the largest and best quality fruits.

The effective use of flowering plants, A. ERNST (*Die Zweckmässige Verwendung der Blütenstauden. Möhringen-Stuttgart: [Author], 1926, pp. [4]+108 pls. 20, figs. 16*).—Practical information is offered upon the planning and planting of flower gardens, with notes on the adaptability of various plants for special locations.

Improving small home grounds in Illinois (*Illinois [Sta.] Circ. 314 (1927), pp. 40, figs. 15*).—This includes information of a general nature concerning the planning and planting of home grounds, with notes upon garden fencing and furnishings, upon the preparation and care of the lawn, and upon trees, shrubs, and other smaller perennials.

FORESTRY

The new book of trees, M. WOODWARD (*London: A. M. Philpot [1926], pp. 310 figs. 91*).—This book contains popular descriptions and indicates the principal characteristic features of native and exotic trees of Great Britain.

Acacia seedlings, Part XI, R. H. CABBAGE (*Roy. Soc. N. S. Wales, Jour. and Proc., 59 (1925), pp. 230-248, pls. 5*).—Technical descriptions are given of the seedlings of several Acacia species, with notes on the nocturnal movement of early leaves and the closing of cotyledons at night.

Forestry legislative survey (*Washington, D. C.: Amer. Tree Assoc., 1927, pp. 67*).—A résumé of forestry organizations and activities in the various States.

Some aspects of forestry in South Australia, D. MAWSON (*[Adelaide]: Univ. Adelaide, 1925, pp. [1]+30*).—A general statement upon the forestry situation in South Australia.

The line-plot system: Its use and application, W. M. ROBERTSON (*Jour. Forestry, 25 (1927), No. 2, pp. 157-163*).—On the assumption that a large number of small plats evenly distributed throughout the area will yield more accurate information for the whole forest than will a few large sample plats, a line plat system was devised wherein records were taken upon small permanent sample plats spaced regularly along blazed perpendiculars run off at regular intervals from a permanent base line. Such a system offers the added advantage that it lends itself readily to statistical analysis, formulas for which are given in the text.

Accuracy of methods in estimating timber, R. H. CANDY (*Jour. Forestry, 25 (1927), No. 2, pp. 164-169*).—Studies at the Petawawa Reserve and at the Lake Edward Forest Experiment Station, Quebec, of the line plat survey as a method for estimating timber showed that this method may be relied upon to give a sufficiently accurate estimate. Furthermore, this system had the great advantage of being susceptible to ready analysis concerning accuracy. Comparison between the strip and line plat methods showed much lower percentage of error in favor of the latter.

A new growth per cent formula, S. R. GEVORKLIANTZ (*Jour. Forestry, 25 (1927), No. 1, pp. 44-49*).—Following a critical analysis of methods commonly

used in determining growth percentage, the author presents a new method devised by himself for deriving a growth percentage formula which he deems to be simpler than older formulas and to yield more accurate results.

The air seasoning of lumber in the Douglas fir region, H. H. JOHNSON and W. H. GIBBONS (*Timberman*, 27 (1926), No. 12, pp. 38-41, figs. 14; 28 (1926), Nos. 1, pp. 38-41, figs. 14; 2, pp. 40-44, fig. 1; 28 (1927), No. 3, pp. 38-41, figs. 8).—Herein are presented the results of an extended study of various practices in piling lumber in commercial establishments. With a view to outlining the most efficient and successful procedure, tables are included showing the amount and character of depreciation, and charts are given showing the rate of drying in different types of piling. Data are given upon the estimated time required to air season Douglas fir timber of various moisture contents.

Waste kauri wood as a source of paper pulp and resin (*Bul. Imp. Inst.* [London], 24 (1926), No. 4, pp. 654-664).—Tests conducted by the Imperial Institute, London, England, upon the properties of Kauri wood indicated that this could be converted into paper pulp of considerable value, whether in the original condition or following the removal of the resin. A large resin content reduced the yield of pulp so considerably that it is suggested that this substance might profitably be removed prior to pulping, especially when its content is more than 10 per cent. Preliminary studies upon resin extraction indicated that this material might be extracted from waste kauri wood at a reasonable profit.

DISEASES OF PLANTS

The relation of environment to disease in plants, L. R. JONES (*Amer. Jour. Bot.*, 11 (1924), No. 10, pp. 601-609, figs. 3).—Holding that relatively less emphasis, in the stage attainable, should now be placed on the parasite as an independent organism and relatively more on the disease, the author urges as a first step increased attention to the relation between environment and disease inception and development.

Bibliography of the literature of plant protection, H. MORSTAT (*Biol. Reichsanst. Land u. Forstw. Berlin-Dahlem, Bibliog. Pflanzenschutzlit.*, 1925, pp. IV+228).—The present issue covers the plant protection literature of 1925, retaining, in the main, the plan and features of the 1920 issue, previously noted (*E. S. R.*, 50, p. 142).

Indiana plant diseases, 1923, M. W. GARDNER (*Ind. Acad. Sci. Proc.*, 40 (1924), pp. 297-313, figs. 3).—This report is the fifth of this series (*E. S. R.*, 55, p. 242). An account of departures from normal temperatures and precipitations is followed by an account of economic diseases of plant hosts which are arranged alphabetically.

"The most destructive diseases noted this season were apple scab, blotch, fire blight, and bitter pit, cherry leaf spot, peach bacterial spot, plum brown rot, black raspberry anthracnose and leaf curl, and tomato leaf spot. Fire blight attracted the most attention.

"The diseases or parasites not previously recorded for the State were as follows: Apple, *Volutella fructi*, *Alternaria core* mold, and lenticel spot; Lima and seva bean, *Bacterium vignae*; blackberry, mosaic; buckwheat, *Ramularia anomala*; Canadian bluegrass, *Ustilago striaeformis*; slippery elm, *Phyllosticta ulmicola*; hickory, *Mirostroma juglandis*; June grass, *Helminthosporium vagans*; mulberry, *B. mori*; peach, Rhizopus rot; petunia, mosaic;

Lombardy poplar, *Dothichiza populea*; raspberry, mosaic, leaf curl, eastern bluestem; rose, *Cylindrocladium scoparium*; snapdragon, *P. antirrhini*; sweet pea, *B. pisi*; soy bean, *Diaporthe sojae*; tobacco, *Cercospora nicotianae*, *B. tabacum*; tomato, Rhizoctonia soil rot. In an experimental plat, mosaic was noted on velvet bean, broad bean (*Vicia faba*), scarlet runner bean (*Phaseolus coccineus*), asparagus bean (*Vigna sesquipedalis*), and *V. catjang*."

Observations concerning the disease susceptibility of cereals and wild grasses, E. B. MAINS (*Ind. Acad. Sci. Proc.*, 40 (1924), pp. 289-295, figs. 3).—Several hosts and diseases are included in this report of observations.

Conditions for heat canker and sun scald in plants, R. B. HARVEY (*Jour. Forestry*, 23 (1925), No. 4, pp. 392-394).—Heat cankers or sun scald injuries are due to excessive heat from the sun, conditions favoring scald being still, warm, cloudless days and dry soil. The injury may be decreased by shading, by increasing the soil moisture, and by keeping fruits as far above the soil as is practicable.

Mosaic and related diseases, L. O. KUNKEL (*Amer. Jour. Bot.*, 12 (1925), No. 8, pp. 517-521).—Beginning with the claim of Beijerinck published in 1899 (*E. S. R.*, 11, pp. 167, 359) to have discovered in tobacco a contagious principle or agent causing the condition now widely known as mosaic, the author gives consideration to a few of the hypotheses regarding the character and causation of this condition.

Observations on the spore characters and histology of some physiological species of *Puccinia graminis*, K. C. MEHTA (*Indian Sci. Cong. Proc. [Calcutta]*, 11 (1924), p. 138).—An account is outlined of the infection histology of *P. graminis tritici* and *P. graminis secalis* as cultivated on wheat, barley, and rye.

Studies in the life history and physiology of certain smuts, G. B. SARTORIUS (*Amer. Jour. Bot.*, 11 (1924), No. 10, pp. 617-647, pls. 3).—*Tilletia tritici*, *T. foetens*, *Ustilago tritici*, *U. hordei*, *U. zaeae*, and *U. heufleri* were studied.

What is considered by the author as the outstanding result of his work is the evidence presented that *U. hordei*, *U. tritici*, and *U. heufleri* can complete their morphological life history saprophytically in artificial culture media. Among the findings or confirmations as summarized, it is stated that infection of wheat by *T. tritici* occurs from the time of germination until a few days after the germination of the wheat, as reported by others. The germ tube from the fused sporidia enters between the cells of the sheath leaf. It is very seldom that the germ tube is intracellular. The mycelium and secondary spores of *T. tritici* are not able to infect the host, at least at the time and place where infection occurs from the usual infection tube. The mycelium and resting spores of *U. zaeae*, formed in culture, are not able to infect the host.

The toxicity of the spores of *Tilletia tritici* to animals, N. DOBSON (*Brit. Mycol. Soc. Trans.*, 11 (1926), pt. 1-2, pp. 82-91).—"From the point of view of the practical stock feeder, it may be safely accepted that grain infected with bunt [*T. tritici*] may be fed without injury to animals."

The relation of stinking smut virulence to soil character [trans. title], G. GASSNER (*Angew. Bot.*, 7 (1925), No. 2, pp. 80-87).—The alleged influence of soil character on the controllability of cereal stinking smut by seed steeping treatment, as appearing here in tabular and discussional detail, is typified by the fact that such plants succeeded better in sand than in garden soil.

Values in pickling media [trans. title], G. GASSNER (*Angew. Bot.*, 6 (1924), No. 1, pp. 1-16).—An attempt is made to adjust and judge seed treatments with regard to efficiency and safety.

Biological testing of seed treatments [trans. title], G. FRIEDRICH (Angew. Bot., 7 (1925), No. 1, pp. 1-9, figs. 2).—Seed treatment data are given for Kalimat, Germisan, and Uspulun.

Dust fungicides in Hungary, 1921-1924 [trans. title], H. KERN (Angew. Bot., 7 (1925), No. 1, pp. 19-24).—Advantages or disadvantages of different dusts are briefly indicated.

Preliminary studies on Pleosphaerulina briosiana, J. H. MILLER (Amer. Jour. Bot., 12 (1925), No. 4, pp. 224-237, pl. 1, figs. 7).—Having noted characteristic spots, not accounted for by known parasites, on alfalfa and related plants in 1922, and having later identified a causal organism as *P. briosiana*, first noticed in Europe by Pollacci (E. S. R., 14, p. 159) as causing a leaf spot on alfalfa in Italy, the author gives an account of this fungus in this connection, stating that the fungus collected here is identical with that described by Pollacci except as to the color of the ascospores.

It is stated that *P. briosiana* is not parasitic on alfalfa, the spots being made by an insect which is followed saprophytically by the fungus, and that the fungus confines itself to the spot unless the resistance of the leaflet is broken down by many insect attacks. The fungus spreads to young plants after a cutting by ejection of the ascospores from perithecia on leaves lying on the ground. The method of spread to new fields is not known.

Cabbage diseases in Indiana, C. T. GREGORY (Ind. Acad. Sci. Proc., 40 (1924), pp. 283, 284).—This deals with cabbage yellows, blackleg, and a seed stalk rot.

Corn ear rot, A. N. HUME (South Dakota Sta. Rpt. 1926, p. 9).—The author reports having produced from selections of the previous year about 100 separate strains of corn, and that they have been found to possess several heritable characters peculiar to strains of such corn. These characters include chlorophyll deficiency, rolled top, leaning tops, striped leaves, etc. Two molds (*Aspergillus niger* and *Fusarium moniliforme*) were isolated from strains of corn included in this study. An attempt was made to associate disease organisms with the development of supposedly heritable characters, and it is said that there is no reason to doubt that the organisms associated with corn diseases reduce the percentage of germination, usually interfere with growth, and seem to be associated with peculiarities of growth which may also be heritable.

The transmission of streak disease of maize by the leafhopper *Balclutha mbila* Naude, H. H. STOREY (Ann. Appl. Biol., 12 (1925), No. 4, pp. 422-439, pls. 3).—A streak disease of sugar cane, maize, and related grasses is said to have been originally indicated by Fuller (E. S. R., 13, p. 1062). This has been variously noted and has been described by the present author (E. S. R., 54, pp. 246, 250, 251), and the suggestion has been offered that this is a specific transmissible disease to be associated with others known to be of the mosaic type. Complete confirmation of the views of the present author had not then been obtained.

The present paper records experimentation in which the transmission of the disease was effected through the agency of a jassid leafhopper, *B. mbila*, the controls remaining healthy. In experiments in which individuals of *B. mbila* collected upon streak diseased maize were allowed to feed on single leaves of the experimental plants the disease resulted in 45 out of 48 plants. One jassid lived for 5 months and carried the disease to 8 separate plants. No loss of infective power occurred in any jassid tested, even in periods of starvation in some cases or of feeding on apparently immune plants in others. Certain individuals, collected upon streaked maize, were incapable of causing any infection under similar conditions. Jassids reared upon healthy maize

could not infect plants with streak disease, but after feeding upon diseased leaves for a week 26 per cent of the males and 86 per cent of the females, out of a total of 62 individuals, became infective. Negative results were obtained with *Aphis maidis*, *Peregrinus maidis*, and a number of undetermined jassids and fulgorids. Field observations showed that *B. mbila* was to be found whenever a field of maize recently infected with streak disease was thoroughly searched. It is therefore held to be the agent of spread of this disease in the field.

The testing of new varieties of hops, R. G. HATTON and J. AMOS (*East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 169-175*).—In a portion of this account of the testing of new varieties of hops, reference is made to hop downy mildew and incidence of mosaic in the hop garden.

Physiologic races of oat smuts, G. M. REED (*Amer. Jour. Bot., 11 (1924), No. 7, pp. 483-492, figs. 3*).—A summary of information to 1918 (E. S. R., 41, p. 152) and of later more or less related investigations by the author (E. S. R., 44, p. 747; 54, p. 250) has been followed up with an account of experimentation started in the greenhouse under controlled conditions in 1924. The data as tabulated or detailed and discussed show differences, which are not necessarily more distinct when widely separated geographically (Wales and Missouri) than when taken from the same locality or field.

The conditions of infection in potato wart, F. WEISS (*Amer. Jour. Bot., 12 (1925), No. 7, pp. 413-443, pls. 4, figs. 3*).—*Synchytrium endobioticum* is an obligate parasite, the only part or phase of its life cycle which is independent of a living host being that during the germination of the resting and soral sporangia and ensuing swarm period of the zoospores, which lasts only an hour or two. Studies here indicated show that the infection by *S. endobioticum* is dependent on the presence of particular varieties of its host and on environmental conditions in general favorable to vigorous growth of the potato plant. Germination of both resting and soral sporangia occurs in water, and there is an indispensable minimum of water for the distribution of the motile cells. Other conditions are indicated.

Although the potato wart fungus and the potato plant have similar requirements as to environmental factors, the disease can not spread widely under an effective quarantine on the movement of infected seed. Its controllability through the use of immune varieties tends to reduce it, in the United States, to a problem the solution of which is at hand.

The Helminthosporium disease of rice occurring in the southern United States and in the Philippines, G. O. OCFEMIA (*Amer. Jour. Bot., 11 (1924), No. 6, pp. 385-408, pls. 6*).—In an account previously noted (E. S. R., 50, p. 654), the author called this disease sesame spot of rice. The name is in the present article, as previously (E. S. R., 53, p. 853), expressly changed to Helminthosporium disease of rice, to make it distinctly a disease of rice and to avoid possible confusion with the Helminthosporium disease of *Sesamum indicum* caused by *H. sesameum*, which is said to be widely distributed in the Philippines.

The Helminthosporium disease of rice occurs in Java, Sumatra, Japan, China, India, Straits and Federated Malay States, Italy, the Philippine Islands, and Louisiana. It is primarily a seed bed disease arising from the planting of infected grains. Its severity varies in different places, probably on account of climatic conditions, losses among seedlings in the Philippines ranging from 10 to 58 per cent. In Louisiana no actual count was made. It appears to attack all cultivated rice varieties. The effects are described. The cause is *H. oryzae*, different strains existing as shown by morphological

and physiological differences. The fungus overwinters as dormant mycelium, the hyphae being responsible for the greater part of the primary infection in the field. *H. oryzae* is not known to produce the perfect stage. Conidia are wind borne, causing secondary infection. The fungus is pathogenic on other grasses. Infection from the overwintered fungus may be reduced or prevented by submerging the soil in water at from 24 to 28° C. (75.2 to 82.4° F.) to a depth of about 10 cm. (4 in.) Lowland rice varieties emerged through water 10 to 20 cm. deep, and the conidia mixed with the soil at planting or suspended in the water did not produce infection.

The relation of soil temperature to germination of certain Philippine upland and lowland varieties of rice and infection by the Helminthosporium disease, G. O. OCFEMIA (*Amer. Jour. Bot.*, 11 (1924), No. 7, pp. 437-460, pls. 4).—Rice Helminthosporium disease (*H. oryzae*) (see above) is said to be of considerable economic importance, unfavorable weather conditions promoting a serious seedling blight of rice on seed beds and in fields. Seedling infection is due mainly to seed-borne mycelium, though conidia or mycelium overwintered in soil or crop residues may cause some infection.

The present work included experiments to determine the effects of soil temperatures, moistures, and sterilization. Temperatures favorable to growth and sporulation of *H. oryzae* are about the same as those for the development of the Philippine varieties of rice. Severe infection occurs at temperatures of from 16 to 24° C. (60.8 to 75.2° F.), which may blight the seedlings before they emerge, whereas at 36° only occasional blighting occurs. Planting in soil or beds at from 32 to 36° materially reduces infection. Coleoptile, mesocotyl, and seedling-root infections and resulting lesions, though more abundant and rapid in developing at higher soil temperatures, are less harmful and are outgrown. At lower soil temperatures, even coleoptile, mesocotyl, and seedling-root infections are conducive to blighting after the seedlings have emerged through the soil.

A note on the sterilization of rice-grains, S. R. BOSE (*Indian Sci. Cong. Proc.* [Calcutta], 11 (1924), p. 143).—*Bacillus subtilis* in its sporing forms is common on rice grains, other seeds, and fruits. These forms are very resistant, but can be rendered harmless by dipping in 0.1 per cent mercuric chloride solution for from 4 to 6 minutes. The poison apparently does not penetrate the seed.

Puccinia coronifera on winter rye [trans. title], L. F. RUSSAKOW (*Angew. Bot.*, 7 (1925), No. 4, pp. 262-266).—In the autumn of 1924 an outbreak of *P. coronifera* on winter rye occurred in the neighborhood of Kamennaja Steppe, Voronezh Province, Russia, exceeding in severity the attacks by *P. dispersa* and *P. graminis*. The teleutospore stage of *P. coronifera* was unusually abundant, constituting about 85 per cent of all cases of infection. This is thought to be connected with the unusual dryness of the autumn weather.

Solanaceae as hosts for Synchytrium endobioticum [trans. title], F. ESMARCH (*Angew. Bot.*, 7 (1925), No. 2, pp. 108-120, figs. 6).—A study is reported, with short bibliography, of the potato wart organism, *S. endobioticum*, on various members of the nightshade family.

Influence of enviroinal factors on the infection of sorghums and oats by smuts, I, II, G. M. REED and J. A. FARIS (*Amer. Jour. Bot.*, 11 (1924), Nos. 8, pp. 518-534, figs. 7; 9, pp. 579-599, figs. 3).—The experiments described in part 1 were undertaken to determine the relation of soil factors, such as temperature, moisture, and reaction, to infection of sorghums by *Sphacelotheca sorghi* and *S. cruenta* and of oats by *Ustilago levis*. Results with the two sorghum smuts, which are the chief matters dealt with in this section, show that they respond

in quite similar fashion to temperature, moisture, and reaction as regards infection of susceptible varieties by *S. sorghi* and *S. cruenta*. Slightly acid soils favor high infection percentages. A wide temperature range as regards infection was established. The same was true of moistures, though the lower moistures greatly favored infection.

In part 2 the authors report a similar series of experiments on the infection of oats by *Ustilago levis*.

Of the two oat varieties used, *Avena nuda inermis* and *A. sativa victor*, the former became infected at all temperatures tested (6) from 5 to 30° C. with *U. levis*, the highest infection occurring at 25° (77° F.) *A. sativa victor* was also infected at all temperatures, but this consistently gave lower results than did *A. nuda inermis*, except at the highest temperature, 30°.

"Soil moisture, soil temperature, and soil reaction are interdependent factors. Their interaction determines whether infection will take place and also the severity of the attack. Any one of these factors may be a limiting one in the prevention of infection. The term 'optimum temperature for infection,' for example, is without significance unless due regard is paid to other possible influencing factors."

Cytological studies of the mosaic disease of tobacco, T. E. RAWLINS and J. JOHNSON (*Amer. Jour. Bot.*, 12 (1925), No. 1, pp. 19-32, pl. 1).—After careful study of about 345 slides showing the various stages of mosaic, the authors offer their interpretation of the evidence as to the cycle of development of the peculiar intracellular bodies found in mosaic tobacco leaves.

"The striate material, bodies of the small type, and the crescent-shaped bodies seem to be the first visible abnormalities to develop. All these bodies seem to appear at about the same stage in the development of the disease.

"The fact that the striate material is usually in contact with the nucleus during its early stages indicate that it may bear some rather close relation to the nucleus." Other facts cited are discussed. "With the exception of the striate material, all these types of abnormal intracellular bodies have shown a striking similarity in their staining reactions. While such similarity can not be considered proof of likeness in chemical nature, it is evidence of some value in that connection." With the exception of a type of abnormality indicated, "bodies of all the types described have been found in leaf cells containing mitotic figures. This fact is interesting in that it indicates that the presence of these bodies does not prevent what appears to be normal nuclear and cell division."

Acidity and varietal resistance of wheat to *Tilletia tritici*, A. M. HURD-KARRER (*Amer. Jour. Bot.*, 12 (1925), No. 7, pp. 359-371).—In former papers (*E. S. R.*, 49, p. 245; 51, p. 651), the author claimed that varietal resistance of wheat to stem rust (*Puccinia graminis tritici*) was not correlated with either the titratable acid or the H-ion concentration of the expressed juice. In view of the reports of Von Kirchner (*E. S. R.*, 35, p. 749; 42, p. 47) that susceptible wheat seedlings are less acid than are resistant plants, suggesting that high titratable-acid concentration is responsible for resistance, the author carried out a more exhaustive study of both the H-ion concentration and the titratable acidity of wheat varieties whose reactions to the smut organism ranged from extreme susceptibility to immunity, and the data obtained are recorded in this article.

The wheat varieties in the grouping characterized by low titratable acidity were Jones Fife, Hybrid 128, Jenkin, Martin, and (probably) White Winter. The high-acidity wheats were Hussar, White Odessa, Ridit, Florence, Little Club, and (probably) Banner Berkeley and Turkey (Washington 326).

The relatively low values for the immune Martin and the high values for the very susceptible Little Club are inconsistent with Von Kirchner's suggestion that high titratable acidity of the juice of wheat is responsible for resistance to *T. tritici*. Hybrid 128, Jenkin, and usually Jones Fife were characterized by relatively high H-ion concentrations, as was probably one other susceptible variety, White Winter, thus precluding the existence of a causal relation between a high concentration of hydrogen ions in the juice and resistance to *T. tritici*.

Breeding measures for control of loose and stinking smut of wheat [trans. title], G. SESSOUS (*Landw. Jahrb. Bayern, 15 (1925), No. 7-8, pp. 276-291*).—A comparative study of varietal resistance to wheat loose and stinking smut, as outlined, is discussed as to its bearings on the problem of protection against these two diseases.

The loose and stinking smuts in Indiana, C. T. GREGORY (*Ind. Acad. Sci. Proc., 40 (1924), pp. 285-288, fig. 1*).—The season of 1924 was exceptional in the general prevalence throughout Indiana of wheat loose smut, which caused losses twice as great as in the preceding year, the conditions lending unusual importance to the behavior of wheat from hot-water treated seed. Details and comparisons are given.

Field observations on the crown-gall of nursery stocks, H. WORMALD and N. H. GRUBB (*East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 122-125*).—Observations are outlined as made on galls found on layered apple stocks. Similar outgrowths have been seen by the authors on crab stocks, layered pear stocks and young pear trees, layered hawthorn stocks, plum and cherry trees, raspberry, loganberry, mangel, beetroot, melon, hop, and hollyhock. While it is admitted to be generally recognized that crown gall is caused by *Bacterium tumefaciens*, it is not held that all galls in which no parasite is detected are due to this organism.

Of the apple stocks produced at East Malling, not one has proved to be wholly immune to crown gall. The size of the galls, however, may be somewhat influenced by the variety of the stock. Certain trees kept under observation for 5 years show that those bearing galls are not noticeably inferior to those having no galls. Experiments carried out on stocks raised from layers and stools, as summarized, indicate that cutting the shoots from the layers or stools with a knife is preferable to tearing them off, as the clean-cut surface is less favorable to gall development than a rough tear. Covering the cut surface at the lower end of the stocks with grafting wax or Stockholm tar reduces both number and size of the basal galls. Galls on the stem above the base and root galls may be largely prevented by careful handling and planting, so as to minimize injuries.

Field observations on the incidence of leaf scorch upon the apple, R. G. HATTON and N. H. GRUBB (*Jour. Pomol. and Hort. Sci., 4 (1925), No. 2, pp. 65-77; also in East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 41-53*).—Observations covering 6 years have shown that the variety of rootstock influences strongly the development of leaf scorch. Among the layered stocks, three varieties, all classed as semidwarfing, have shown a notable tendency to increase the scorch. Among the seedling crab or free stocks, great variability is shown, but less tendency to scorch than is shown by semidwarfing varieties. These manifestations of varying susceptibility have been noted on the unworked stocks themselves and on very different types of soil. Different varieties show consistently different degrees of susceptibility. The order of susceptibility of the four varieties available for comparison proved to be identical on layered and seedling roots. Leader tipping tends to reduce scorch. A direct relationship

appears between blossoming and fruiting and leaf scorch, which may account for the effect as noted of leader tipping. Leaf scorch reduces directly the size of the fruit. In young trees, lack of organic manures accentuated scorch, though generous feeding of older trees with organic (predominantly nitrogenous) manures did not check the trouble.

An unusual form of pear canker, R. V. HARRIS (*East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 135, 136, pl. 1*).—In 1924 the author observed an unusual form of canker on a trained pear tree at West Malling. This is described in connection with the fungus, *Nectria galligena*, the cause of apple and pear canker, and its *Fusarium* stage. It is not known whether previous infection by the scab fungus is necessary for the canker fungus to gain entrance in this particular form of infection.

The mulberry "blight" in Britain, H. WORMALD (*Ann. Appl. Biol., 11 (1924), No. 2, pp. 169-174, pl. 1*).—In Sussex and Kent a mulberry bacterial blight has been found on stools and on both young and well-established mulberry trees. The black lesions on the leaves proved to be due to the white organism identified as *Bacterium mori*, an associated yellow organism failing to reproduce any of the disease symptoms. A die-back of some of the material studied was associated with *Fusarium lateritium*.

Mulberry bacterial blight, H. WORMALD (*East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 120, 121*).—This brief account, referring to the more detailed one above noted, mentions the additional fact that another disease of mulberry leaves, which may easily be confused with that caused by *Bacterium mori*, is due to the fungus *Gibberella moricola*.

The blue stripe wilt of the raspberry, R. V. HARRIS (*East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 126-134, pls. 3*).—A disease of cultivated raspberry, *Rubus idaeus*, is described as causing wilt of the canes, progressing upward, and eventuating in their death. The nature and extent of the damage to the crop is also discussed. Cultural work isolated a *Verticillium*, with marked constancy, from affected stools of many susceptible varieties. A controlled inoculation experiment, using plate cultures of the *Verticillium* from diseased canes, induced the disease with its characteristic field symptoms. It is proposed, for reasons stated, to designate this disease as the blue stripe wilt of raspberry.

Erysiphaceae croatiae, V. ŠKORIĆ (*Glasnik Šumske Pokuse (Ann. Expt. Forest.) [R. Univ. Zagreb Inst. Expt. Forest.], 1 (1926), pp. 52-118, pls. 32; Eng. abs., pp. 108-111*).—This is a phytopathologic-systematic monograph on the powdery mildews of Croatia, with 110 references to the literature of the subject.

The cause of spike disease in sandal (*Santalum album* L.), P. S. JIVANNA RAO (*Indian Sci. Cong. Proc. [Calcutta], 11 (1924), p. 149*).—A sandal tree about 10 years old was so trenched as to injure the roots of this tree and of its hosts. This resulted in the shortening of the leaves and in their accumulation of starch, apparently because of the limitation of the water supply. Want of good hosts (for example, shortness of their lives) is a limiting factor as regards the best growth of sandal. The welfare of the hosts thus appears to be of greater importance than the bestowal of care upon the parasite (*S. album*) itself.

The biology and pathology of some of the hardwood heart-rotting fungi, I, II, D. V. BAXTER (*Amer. Jour. Bot., 12 (1925), Nos. 8, pp. 522-552, pls. 3; 9, pp. 553-576, pl. 1*).—These two sections deal continuously with studies of wood-inhabiting fungi and their hosts, including *Polyporus hispidus* on *Fraxinus*

nigra; *Fomes fraxinophilus* on *Fraxinus americana*; *F. fraxinophilus ellisianus* on *Shepherdia argentea*; *F. applanatus* on *Morus rubra*; *F. connatus* on *Nyssa sylvatica* and *Acer rubrum*; *F. everhartii* on *Quercus velutina*, *Q. rubra*, and *Q. alba*; *F. igniarius* on *Fagus grandifolia*; *F. pomaceus crataegi* on *Prunus americana* and *Crataegus* sp.; also with studies in less detail of *F. conchatus* on *Fraxinus nigra* and *Crataegus* sp., and *Hydnum septentrionale* on *A. rubrum*.

The results of this study on the above heart-rotting fungi are said to show that visible changes in tree trunks or in wood generally referred to as decayed or as in an incipient stage of decay can not be used as a criterion of the extent to which the fungus has progressed in the apparently sound wood, that mycelium occurs in a radial or linear direction in advance of such visible decay to a considerable distance, and that mycelium grown on wood in the laboratory does not necessarily produce discolorations or other visible indications of rot in initial stages of decay. An improved method was used for the pure culture of wood-rotting fungi, the advantages of which are indicated. Six species were developed on artificial media or on wood blocks in flasks, namely, *Polyporus hispidus*, *Fomes igniarius*, *F. everhartii*, *F. fraxinophilus*, *F. fraxinophilus ellisianus*, and *F. pomaceus*, the latter three being studied in pure culture, it is said, for the first time. Each fungus on agar produced a luxuriant and distinctive vegetative growth. Decay rate of a given fungus depends upon the character of the wood. Field and culture study of *F. ellisianus* and *F. fraxinophilus* indicated that they should be considered as a single species. *F. ellisianus* is considered as a form of *F. fraxinophilus*.

Studies in wood decay.—III, The toxicity of western yellow pine crude oil to *Lenzites sepiaria* Fries, H. SCHMITZ (*Jour. Indus. and Engin. Chem.*, 14 (1922), No. 7, pp. 617, 618).—Previous papers of this series have been noted (*E. S. R.*, 48, pp. 352, 353). From this work it appears that western yellow pine oil has only very limited toxic properties and little value as a wood preservative against *L. sepiaria*, and also that its high rate of evaporation is a disadvantage. The toxic point (that at which growth of the fungus is completely inhibited) varied slightly with the kind of wood used (sawdust of lowland white fir, Douglas fir, and sugar maple).

Studies in wood decay, IV, V, H. SCHMITZ (*Amer. Jour. Bot.*, 11 (1924), No. 2, pp. 108–121, figs. 5; 12 (1925), No. 3, pp. 163–177, pls. 3).—Part 4 of this series, entitled The Effect of Sodium Carbonate, Bicarbonate, Sulphate, and Chlorid on the Rate of Decay of Douglas Fir Sawdust Induced by *Lenzites sepiaria* Fr. with Special Reference to the Effect of Alkaline Soils on the Rate of Decay of Wood in Contact with Them, considers only the indirect effect upon wood of the salts making up the "alkali" of alkaline soils; that is, the effect of these salts on the rate of decay induced by wood-destroying fungi.

It is thought that small amounts of sodium carbonate or of sodium bicarbonate increase the rate of decay in Douglas fir sawdust as induced by *L. sepiaria*, and that this stimulation is augmented by certain proportions of sodium sulfate, the question of such influence due to sodium chloride being regarded as unsettled. It is also said that results, not here recorded, from a preliminary series of studies were comparable in every way to those indicated in this report.

In part 5, Physiological Specialization in *Fomes pinicola* Fr., the four strains studied were obtained by the tissue method from sporophores. The dead but still erect trees from which these strains were taken were Douglas fir (*Pseudotsuga taxifolia*), white fir (*Abies grandis*), western hemlock (*Tsuga heterophylla*), and western white pine (*Pinus monticola*), and the wood-destroying proclivities of these different strains were tested on *Pinus ponderosa* (heart-

wood and sapwood), *P. monticola* (heartwood), *Larix occidentalis* (heartwood), *Pseudotsuga taxifolia* (heartwood), *Abies grandis*, *T. heterophylla*, and *Picea engelmanni*. The percentages of weight loss are tabulated.

The results, while not conclusive, are regarded as sufficiently so to indicate that there may be considerable physiological variation within the species *F. pinicola*, though it is uncertain whether or not this may result from host influence. The data also indicate the desirability if not the necessity of considering the source of wood-destroying fungus cultures in experiments dealing with the decay of wood under laboratory conditions.

ECONOMIC ZOOLOGY—ENTOMOLOGY

A biological survey of North Dakota, I, II, V. BAILEY (*U. S. Dept. Agr., Bur. Biol. Survey, North Amer. Fauna No. 49 (1926), pp. VI+226, pls. 21 figs. 8*).—In part 1 of this report (pp. 1-16) the author considers the physiography and life zones of North Dakota, listing characteristic mammals, breeding birds, and plants, and crop adaptations of the Upper Austral, Transition, and Canadian zones. Part 2 (pp. 17-217) deals with the mammals of North Dakota, including an introductory part upon their present and former abundance, useful and harmful species, Indian names, and measurements and weights. Then follow accounts of the mammalian fauna, the type locality, general characters, early abundance, distribution, food and other habits, economic status, etc., so far as known. The bibliography which follows includes 70 titles.

Some habits of mountain lions in Arizona. M. E. MUSGRAVE (*Jour. Mammal., 7 (1926), No. 4, pp. 282-285*).—This is a brief account by an agent of the U. S. D. A. Bureau of Biological Survey of the habits of mountain lions, particularly as related to the securing of food—the capture of cattle, horses, deer, etc.

Anatomy of the wood rat. A. B. HOWELL (*Baltimore: Williams & Wilkins Co., 1926, pp. X+225, pls. 3, figs. 37*).—Following an introduction, the several chapters of this work deal with the systematic position of *Neotoma* and its subgenera (pp. 6, 7), habits of the three subgenera studied (pp. 8-10), external features (pp. 11-21), myology (pp. 22-89), alimentary tract and adjacent glands (pp. 90-99), urogenital system (pp. 100-109), osteology (pp. 110-172), and a discussion of muscle action and limb motion and of subgeneric variation (pp. 173-216). A bibliography of 39 titles is included.

A disease in wild rats caused by *Pasteurella muricida* n. sp., K. F. MEYER and A. P. BATCHELDER (*Jour. Infect. Diseases, 39 (1926), No. 5, pp. 386-412, fig. 1*).—A detailed pathologic, anatomic, and bacteriologic study of 88 wild rats caught in the course of plague-control work in Oakland and Alameda, Calif., has proved the existence of four rodent diseases, namely, hemorrhagic septicemia (*pasteurella*), plagus, rat typhoid (due to *Bacillus enteritidis* and *B. paratyphosus* B), and pseudotuberculosis (due to *B. pseudotuberculosis rodentium* Pfeif.). The comparative anatomic findings and the significance of the diagnostic guinea pig inoculations and cultures are discussed.

“The causative organism of the hemorrhagic septicemia, for which the name *P. muricida* n. sp. is proposed, resembles morphologically, culturally, biochemically, and serologically the well-known representatives of the *pasteurella* group. It is highly pathogenic for guinea pigs, rabbits, mice, and white and gray rats. Barnyard birds and cats are refractory. A spontaneous epidemic among laboratory rats introduced by an animal experimentally infected by the nasal route is reported.”

The storing habit of the Columbian ground squirrel, W. T. SHAW (*Amer. Nat.*, 60 (1926), No. 669, pp. 367-373).—This contribution from the Washington Experiment Station is in continuation of investigations of this rodent (*Citellus columbianus columbianus*) previously noted (*E. S. R.*, 56, p. 56).

Records of birds bred in captivity, E. HOPKINSON (*London: H. F. & G. Witherby*, 1926, pp. IX+330).—This is a compilation of records of the different species of birds that have been bred in captivity. Part 1 (pp. 1-174) deals with species which have bred in confinement, part 2 (pp. 175-264) with hybrids, and part 3 (pp. 265-314) consists of a summary of the records.

The distribution of bird-life in Ecuador: A contribution to a study of the origin of Andean bird-life, F. M. CHAPMAN (*Bul. Amer. Mus. Nat. Hist.*, 55 (1926), pp. XIII+784, pls. 30, figs. 21).—This is a continuation of the biological survey of South America (*E. S. R.*, 38, p. 761). In part 1 (pp. 3-133) the author gives a review of the history of Ecuadorean ornithology, and deals with the American Museum's expeditions, the general physiography of Ecuador, distribution of forests, general climatic conditions, life zones of Ecuador and their bird life, discontinuous ranges and their significance, and the zonal distribution by families. Part 2 consists chiefly of a distributional list of species and subspecies (pp. 145-702), preceded by brief remarks on the classification and nomenclature, the treatment of genera and of subspecies, the number of species included, lists of 86 Ecuadorean birds described as new, and of families with the number of species and subspecies by which each is represented in Ecuador, remarks upon and a list of North American migrants found in Ecuador, and a note upon the scope of data presented, and is followed by a gazetteer, bibliography of 13 pages, addenda, and an index.

Protozoology, C. M. WENYON (*London: Baillière, Tindall & Cox*, 1926, vols. 1, pp. XVI+778, pls. 5, figs. 336; 2, pp. IX+779-1563, pls. 15, figs. 229).—The several parts of this work are as follows: Part 1, a general description of the Protozoa (pp. 1-152); part 2 (in both volumes), a systematic description of the Protozoa, with special reference to parasitic and coprozoic forms (pp. 153-1229); part 3, the Spirochaetes (pp. 1231-1288); part 4, methods of investigation and rules of nomenclature (pp. 1289-1349); part 5, blood parasites of vertebrates and Trypanosomidae of invertebrates (pp. 1351-1414); and part 6, references to the literature—Protozoa (pp. 1417-1505) and Spirochaetes (pp. 1505-1514).

Marine borers on the Atlantic coast of Canada, R. H. M'GONIGLE (*Canada Council Sci. and Indus. Research Rpt. 15* (1925), pp. 67, figs. 18).—Following a brief introduction, the author deals with the literature and reports upon a survey, local conditions, general conditions, and the influence of separate factors. A summary and a bibliography of four pages are included.

Studies on insect metamorphosis, III, H. SINGH-PRUTHI (*Brit. Jour. Expt. Biol.*, 3 (1925), No. 1, pp. 1-8).—The influence of starvation is dealt with.

A new method for comparing the efficiency of stomach insecticides [trans. title], R. JANISCH (*Nachrichtenbl. Deut. Pflanzenschutzdienst*, 6 (1926), No. 3, pp. 18-20; *abs. in Rev. Appl. Ent.*, 14 (1926), Ser. A, No. 4, p. 192).—Larvae of *Pieris brassicae* that had all undergone their last molt on the same day were placed in Petri dishes and fed for 1 to 2 days on unpoisoned leaves. They were then given cabbage leaves poisoned by being shaken up in a bottle containing the insecticide in dust form. The leaves were weighed before and after dusting, and their outlines were traced on squared paper before and after feeding. It was thus possible to ascertain the quantity of poison ingested up to death. A table is given showing the amounts for 21 metallic compounds, sulfur, and phosphorus, and a second table shows the number of days of feeding on the poisoned leaves. The experimental data are said to agree with

the results that have been obtained empirically with stomach poisons. Diortholead arsenate was found superior to all other relatively insoluble arsenical compounds.

Fish oil, an efficient adhesive in arsenate-of-lead sprays, C. E. HOOD (*U. S. Dept. Agr. Bul. 1439 (1926), pp. 22, figs. 16*).—Experimental work conducted from 1921 to 1924 has shown that linseed oil, fish oil, and corn oil, three drying oils, stand out preeminently as adhesives. Of these, corn oil is not so good an adhesive as either linseed oil or fish oil, but is much more efficient than any of the other adhesives tested, which rank in the following order: Proprietary miscible oil, proprietary casein product, lead oleate, flour, and soap. Since fish oil adheres to the leaves only slightly less than linseed oil and is much less expensive, it is the one to be recommended for use. The best results are obtained by adding the fish oil after the arsenate of lead has been well mixed with the water and while the mixture is being agitated. The mixture should be agitated at all times while it is being applied. In high-power spraying the agitation of the material is usually excellent, but with the smaller outfits, such as the barrel pump, the agitation is sometimes poor, and satisfactory results can not be obtained either in the even distribution of the poison or in the adhesive qualities of the mixture.

Tar-distillate washes: Their comparative effectiveness under different conditions, on various pests, and at increasing concentrations, W. GOODWIN, A. M. MASSEE, and R. H. LE PELLEY (*Jour. Pomol. and Hort. Sci., 5 (1926), No. 4, pp. 275-286, fig. 1*).—In preliminary trials in the field against the hop aphid, tar-distillate washes of known composition did not prove superior to a proprietary article, but none of the washes proved sufficiently toxic under the conditions described. At 7.5 per cent strength, a tar-distillate wash gave encouraging results against winter moth eggs in the field. Between 5 and 10 per cent is probably the optimum strength, although higher concentrations may slightly increase the actual efficiency. The experiments indicate the possibilities of evolving a fairly accurate technique for measuring the efficiency of egg-killing washes in the field.

Injury to glasshouse plants from hydrocyanic acid gas following the application of copper fungicides, E. F. GUBA (*Phytopathology, 16 (1926), No. 9, pp. 633, 634*).—In this contribution from the Massachusetts Experiment Station attention is called to the fact that fumigation of citrus trees with hydrocyanic acid gas following the application of Bordeaux mixture is accompanied by serious injury to the trees, the injury being manifested in the form of browning of the leaves and defoliation, often accompanied by severe pitting of the fruit. In some cases injury has resulted as late as 11 months after the copper spray was applied, although ordinarily little if any injury occurs 6 months after spraying. To avoid this injury where brown rot and other diseases are to be controlled, some growers have adopted the practice of spraying 2 or 3 days after fumigation, while others have discontinued the use of Bordeaux entirely in favor of other fungicidal preparations free of copper (*E. S. R., 49, p. 849*). It is pointed out that no data have been obtained to indicate how long after the application of copper greenhouses may be fumigated without danger of injuring the plants, although the author has record of an instance of no injury from fumigation with calcium cyanide 46 days after the copper treatment. Where fungus diseases are important in the greenhouse, the cyanide fumigant should always precede the application of the copper fungicide by 1 or 2 days, or the use of cyanide should be abandoned in favor of tobacco fumigants.

[Report of the South Dakota Station] department of entomology-zoology, H. C. SEVERIN (*South Dakota Sta. Rpt. 1926, pp. 19-22*).—This is a brief report on the progress of work with the common field cricket (E. S. R., 55, p. 355) and the lesser peach borer. The latter is a serious pest of plums in South Dakota and has been found in the eastern half of the State attacking cultivated cherry and chokecherry. The studies indicate the pest to be single brooded. Its natural enemies include a Microbracon parasite of the caterpillars. Experimental control work is under way.

Insect and other invertebrate pests of 1925, R. S. MACDOUGALL (*Highland and Agr. Soc. Scot. Trans., 5. ser., 38 (1926), pp. 151-194, figs. 27*).—In this annual report (E. S. R., 54, p. 257) the author deals with liver rot of sheep, gapes in poultry, hairworms in domestic water supply, the apple fruit moth or apple miner (*Argyresthia conjugella* Zell.), a more extended account of which has been noted (E. S. R., 55, p. 557), other insect enemies of apple fruits, arsenic and apples, the vapourer moth (*Orgyia antiqua*), the magpie moth (*Abraxas grossulariata*), the gooseberry sawfly (*Nematus ribesii*), *Enarmonia diniana* Gn. (*pinicolana* L.), the pea moth (*Cydia nigricana*), the cinnabar moth (*Hipocrita jacobaeae* L.), the gold spot (*Plusia festucae*) and the silver-Y (*P. gamma*) moths, hawk moths, *Diastrophus rubi*, the yellow dung fly (*Scatophaga stercoraria*), the green spruce aphid (*Myzaphis abietina* Wlk.), the lesser grain borer (*Rhizopertha dominica* Fab.), the greenhouse grasshopper (*Tachycines asynamorus*), and wood lice or slaters.

The principal enemies of alfalfa in Argentina [trans. title] (*Min. Agr. [Argentina], Secc. Propaganda e Informes [Circ.] 645 (1926), pp. 20, pls. 3*).—A brief account is given of the more important insect and related enemies of alfalfa.

[The animal enemies of rice], H. WINKLER (*Tropenpflanzer, 28 (1925), No. 4, pp. 174-189*).—An account is given of the more important insect and related enemies of rice, with references to the literature.

Notes on some unusual insect pests on fruit, F. V. THEOBALD (*Jour. Pomol. and Hort. Sci., 5 (1926), No. 4, pp. 241-247, figs. 6*).—These notes relate to *Mania maura*; *Forficula auricularia*; and an attack of thrips on American blackberries, two of the commonest of which were *Thrips tabaci* (Lind) and *T. flavus* Schr., while numbers of *T. adusta* (Uzel) occurred here and there and a few *Limothrips cerealium* Hal.

Citrus insects and their control, J. R. WATSON (*Florida Sta. Bul. 183 (1926), pp. 289-423, figs. 87*).—This is a revised edition of Bulletin 148, previously noted (E. S. R., 39, p. 557).

Insects affecting coffee in Trinidad and Tobago, F. W. URICH (*Agr. Soc. Trinidad and Tobago, Proc., 26 (1926), No. 8, pp. 384-388*).—A brief account of the more important coffee pests.

Experiments in fumigating olives with calcium cyanide for Phloeothrips oleae Costa [trans. title], M. BENLLOCH (*Bol. Estac. Patol. Veg. [Inst. Agr. Alfonso XII, Madrid], 1 (1926), No. 2, pp. 55-64, figs. 4*).—This is a brief account of fumigation work in olive groves at Mora, Toledo, Spain.

Heteroptera or true bugs of eastern North America, with especial reference to the faunas of Indiana and Florida, W. S. BLATCHLEY (*Indianapolis: Nature Pub. Co., 1926, pp. 1116, pls. 12, figs. 215; rev. in Science, 64 (1926), No. 1667, p. 578*).—This is the fourth and last of the author's manuals or treatises on certain groups of the insects of eastern North America, the preceding works having been noted (E. S. R., 24, p. 259; 36, p. 157; 43, p. 851).

In the introduction (pp. 3-30) the author discusses the classification, relation of the Heteroptera to other insects and animals, the external structure

of a true bug, habits, collection and preservation, etc. A descriptive catalogue of the order Heteroptera of eastern North America, which follows (pp. 31-1087), includes keys for the separation of the families, subfamilies, genera, and species. Descriptions are given of the genera and of 1,253 forms recognized by the author as occurring in eastern North America, together with their distribution, a few, chiefly from Florida, being described as new. A table showing the local distribution of eastern Heteroptera (p. 1087), a bibliography (pp. 1088-1110), and a general index are included. The review is by N. Banks.

Experiments on the control of the apple capsid bug (*Plesiocoris rugicollis* Fieb.), L. N. STANILAND (*Jour. Pomol. and Hort. Sci.*, 5 (1926), No. 4, pp. 267-274).—An account is given of the distribution of *P. rugicollis* and its importance as a pest in the Bristol Province, England. Experiments in control show that considerable ovicidal action was exercised by certain tar-distillate washes when used at 8 and 10 per cent strengths. The season's work suggests that winter washing with a suitable tar-distillate wash, followed by a spring application of a suitable oil spray or a nicotine wash, will prove an efficient method of controlling this capsid bug.

The genus *Erythroneura* north of Mexico (Homoptera, Cicadellidae), W. ROBINSON (*Kans. Univ. Sci. Bul.*, 16 (1926), No. 3, pp. 101-155, pls. 8).—A synopsis of this important genus, which includes the grape leafhoppers.

The plant-lice or Aphididae of Great Britain, F. V. THEOBALD (*London: Headley Bros.*, 1926, vol. 1, pp. IX+372, figs. 196; rev. in *Rev. Appl. Ent.*, 14 (1926), Ser. A, No. 7, p. 342; *Ent. Mo. Mag.*, 3 ser., 12 (1926), No. 139, p. 171).—This is the first volume of a work described by the author as a collective monograph of the British aphids exclusive of the Phylloxeridae (Phylloxera and Chermes in the broad sense), which are considered as separate from the true Aphididae. It deals with all the forms so far found or received by the author in Britain and includes such of Walker's species as are recognizable. Keys are given for the subfamilies, tribes, subtribes, genera, and species, and the classification is based upon that given by Baker (*E. S. R.*, 43, p. 758) for the North American representatives of the family. Descriptions are given of the species, and figures of structural details of most are appended.

Notes on the Aphididae of Egypt, W. J. HALL (*Egypt Min. Agr., Tech. and Sci. Serv. Bul.* 68 (1926), pp. VIII+62, pls. 3).—Following an introduction and list of the Aphididae of Egypt, the author presents notes on the Aphididae of Egypt (pp. 1-48), a list of the more important works consulted (pp. 49, 50), a host plant index (pp. 51-55), and a subject index (pp. 57-62).

The reaction to flea bites, A. E. BOYCOTT (*Nature [London]*, 18 (1926), No. 2973, p. 591).—The author points out that the irritating wheals which may follow the bites of various insects are anaphylactic in origin, and that it is only after a person has become sensitized to the proteid in the liquid which fleas inject in the process of biting that the familiar local irritable swelling develops. Some persons who are extensively flea bitten seem to become immune, and others are naturally immune.

The codling moth, F. W. PETTEY (*Union So. Africa Dept. Agr. Bul.* 9 (1926), pp. 15, pls. 7).—This is a general account dealing particularly with control measures.

The currant borer, P. H. THOMAS (*Tasmanian Fruitgrower and Farmer*, 12 (1926), No. 135 p. 11).—This is a brief account of one of the most serious pests of small fruits in Tasmania.

Levuana moth of the coconut, A. DESPEISSIS (*Fiji Dept. Agr. Ann. Rpt.* 1924, pp. 2, 3).—This is a brief account of *L. iridescens* and efforts being made for its control, particularly through the introduction of parasites, in Fiji.

Pieris brassicae and its parasite, *Apanteles glomeratus*, H. MACE (*Entomologist*, 59 (1926), No. 761, pp. 278, 279).—This is a brief account of observations made at Harlow, Essex, England, in which the author points out that the larva alone is attacked by this parasite.

Brief notes on the biology of the pink boll worm [trans. title], P. IBARRA GARCÍA (*Bol. Dir. Estud. Biol. [Mexico]*, 3 (1925), No. 1, pp. 1-11; *abs. in Rev. Appl. Ent.*, 14 (1926), Ser. A, No. 2, p. 83).—This paper contains data collected by the author, who was appointed by the Mexican Government in 1920 to study the biology of the pest in Mexico.

The "spruce budworm" biocoenose, I, II, I. W. BAILEY (*Bot. Gaz.*, 80 (1925), Nos. 1, pp. 93-101, pls. 3; 3, pp. 300-210, pls. 3, figs. 3).—The first part of this paper deals with frost rings as indicators of the chronology of specific biological events and the second part with structural abnormalities in *Abies balsamea*.

American two-winged flies of the genus *Microphthalma* Macquart, with notes on related forms, J. M. ALDRICH (*U. S. Natl. Mus. Proc.*, 69 (1926), Art. 13, pp. 8).—An account is given of seven species of *Microphthalma*, two of which are described as new to science. Members of this genus have been frequently reared as parasites of the larvae of May beetles of the genus *Phyllophaga*.

The pear midge: Further observations and control with calcium cyanide, D. MILLER (*New Zeal. Jour. Agr.*, 30 (1925), No. 4, pp. 220-224, fig. 1).—In this paper (*E. S. R.*, 46, p. 460) the results of control experiments are discussed. The results of these experiments, as gauged from the tents, showed that the dosage of 1½ lb. to 200 sq. ft. was the weakest effective strength that could be used for 100 per cent control.

Parasites of the pear-midge (*Perrisia pyri*): First attempt at their establishment in New Zealand, D. MILLER (*New Zeal. Jour. Agr.*, 32 (1926), No. 6, pp. 379-393, figs. 9).—This account records the parasitism during the summer of 1925 of the pear leaf-rolling midge (*P. pyri* Bch.) in the vicinity of Bordeaux by *Platygaster* sp., and later as high as 58 per cent in the vicinity of Paris. *Inostemma* sp. and several chalcids of one or more species were also found near Paris. Consignments of pears and leaves containing parasitized *P. pyri* were sent from France to New Zealand in August and October. It was found that both the *Inostemma* and *Platygaster* parasitize the eggs of the midge, and that their larvae are internal parasites of the midge larvae, while the larvae of the chalcidoids are external parasites of the latter.

British bark-beetles, J. W. MUNRO ([*Gt. Brit.*] *Forestry Comn. Bul.* 8 (1926), pp. 77, pls. 10, figs. 32).—The subject is dealt with under the headings of general biology, importance in forestry, and structure and classification, with brief accounts of genera and species. A list of British bark beetles arranged according to host plants and a bibliography of four pages are appended.

The Buprestidae of North America exclusive of Mexico, W. J. CHAMBERLIN (*Corvallis, Oreg.: Author*, 1926, pp. 291).—This catalogue includes the synonymy, a bibliography, the distribution, type locality, and hosts of each species of Buprestidae, of which 416 are recognized. A list of authors and titles is appended (pp. 245-289).

On the males and an intersex-like specimen of the parthenogenetic saw-fly *Pristiphora pallipes* Lep., A. D. PEACOCK (*Brit. Jour. Expt. Biol.*, 1 (1924), No. 3, pp. 391-412, figs. 17).—While conducting biological experiments on parthenogenesis in sawflies during 1923 the author obtained two males and an intersex-like specimen of the species *Pristiphora pallipes* Lep., which he here describes and discusses. It is stated that this species appears almost completely

thelytokous, the males being exceedingly rare, and that sexual abnormalities in it have never been observed before.

Studies in the parthenogenesis and sexuality of saw-flies (Tenthredinidae), II, A. D. PEACOCK (*Brit. Jour. Expt. Biol.*, 3 (1925), No. 1, pp. 61-84, figs. 10).—This second paper on the subject, the first of which is noted above, deals with a gynandromorph of *Pteronidea (Nematus) ribesii* Scop., with observations on gynandromorphism and saw-fly sexuality.

Descriptions of new reared parasitic Hymenoptera and some notes on synonymy, C. F. W. MUESEBECK (*U. S. Natl. Mus. Proc.*, 69 (1926), Art. 7, pp. 18).—This paper gives descriptions of 14 new species of Braconidae and synonymical notes involving certain of Provancher's species of the braconid subfamily Microgasterinae.

The work-day of the bee, J. M. HOVER and F. E. LORD (*Gleanings Bee Cult.*, 54 (1926), No. 11, pp. 710-712, figs. 3).—The authors describe an apparatus by which a colony records the fluctuating weight of the hive of bees day by day.

The first successful attempt to control the mating of queen bees, G. H. CALE (*Amer. Bee Jour.*, 66 (1926), No. 11, pp. 533, 534, fig. 1).—This is a report of work conducted by L. R. Watson, of Alfred, N. Y., who successfully accomplished the mating of queen bees artificially.

Beekeeping up to date, A. B. FLOWER (*London and New York: Cassell & Co.*, 1925, pp. X+110, pls. 8, figs. 7).—A practical account.

Seventh International Congress of Beekeepers, Quebec, September 1 to 4, 1924 (7. Congrès International d'Apiculture, Quebec, 1924. Quebec: Imp. Charrier & Dugal, 1925, Fr. Sect., pp. 1-277, figs. 68; Eng. Sect., pp. 278-500, figs. 58).—This is a report of the proceedings of this congress.

Infestation of flax seed by mites, A. G. DAVIN (*Linen Indus. Research Assoc., Research Inst. Mem.* 31 (1926), pp. 45-52, pls. 4).—An account of infestation by mites, particularly *Tyroglyphus longior*, *T. siro*, *Glyciphagus cadaverum*, and *Aleurobius farinae*, and methods of combat.

Etiology of Oroya fever.—V, The experimental transmission of Bartonella bacilliformis by ticks (Dermacentor andersoni), H. NOGUCHI (*Jour. Expt. Med.*, 44 (1926), No. 5, pp. 729-734, figs. 3).—In experiments here reported *B. bacilliformis* was transmitted from infected to normal rhesus monkeys by the bite of *D. andersoni* (*D. venustus* Banks). A long period of feeding, both on the infected and on the normal animal subjected to infection, was required in order to secure positive results. The infection transmitted by the ticks was mild, but definite, as shown by the recovery of *B. bacilliformis* from the lymph nodes and blood.

ANIMAL PRODUCTION

Natural history of the races of domestic mammals, M. HILZHEIMER (*Natürliche Rassengeschichte der Haussäugetiere*. Berlin: Walter de Gruyter & Co., 1926, pp. 235, figs. 124).—The various types of the different species of domestic mammals are described, with special reference to their development and zoological relations.

Materials for the physiology of the morphogenesis.—I, Cryptorch rams [trans. title], M. M. ZAVADOVSKIÏ (*Zavadowsky*) (*Trudy Lab. Éksper. Biol. Moskov. Zooparka* (Trans. Lab. Expt. Biol. Zoopark Moscow), 1 (1926), No. 1, pp. 67-80, figs. 7; Eng. trans., pp. 76-80).—An account is given of two cryptorchid Wallachian rams, which in contrast to normal males were hornless and showed a feeble development of the skull bones. The author discusses the fact that normally the horns start growing before the sex instinct develops,

while in these cryptorchids horn development had not started although the sex instinct was present in one individual.

The influence of castration on the development of horns in Merino sheep [trans. title], M. M. ZAVADOVSKIĪ (*Zavadowsky*) (*Trudy Lab. Èksper. Biol. Moskov. Zooparka* (*Trans. Lab. Expt. Biol. Zoopark Moscow*), 1 (1926), No. 1, pp. 49-66, figs. 13; *Fr. abs.*, pp. 64-66).—Studies of horn development in Merino sheep showed that the average size of the horns of ewes at one year was 1.6 cm., of castrated males 7.3 cm., and of normal males 58.9 cm. The size of the horns thus appears to be influenced by the presence of the sexual hormones.

Bilateral and unilateral castration in *Cervus dama* and *C. elaphus* [trans. title], M. M. ZAVADOVSKIĪ (*Zavadowsky*) (*Trudy Lab. Èksper. Biol. Moskov. Zooparka* (*Trans. Lab. Expt. Biol. Zoopark Moscow*), 1 (1926), No. 1, pp. 18-48, figs. 14; *Eng. abs.*, pp. 44-48).—This paper deals mainly with the effects of the sexual hormones on horn development in deer. The stages of horn growth were classified, and it was found that the development of knobs from which the horns form, the branching of the horns, and the hardening and drying of the growing horn were the stages dependent upon the sex hormone.

Bilateral castration was found to have an influence depending upon the age of the deer at the time of castration. Unilateral castration experiments showed no specific relation between the presence or absence of one testicle and the presence or absence of one horn. A female in which testicular tissue was transplanted showed male instincts on the ninth, tenth, and eleventh days after the operation.

Investigations of experimental hermaphroditism with variations in the amount of testicular and ovarian tissue [trans. title], W. KRAUSE (*Biol. Gen.*, 2 (1926), No. 3, pp. 262-300, pls. 7).—The characteristics of 36 male guinea pigs in which $\frac{1}{2}$, 1, or 2 ovaries were transplanted at from 4 to 8 weeks of age, with or without semicastration, are described, with special reference to the development of female secondary sex characters. The animals were under observation for from 1 to 7 months at the Physiological Institute of the University of Dorpat-Tartu, Esthonia.

In 4 of 16 cases in which 2 ovaries were transplanted into entire males, a noticeable development of the mammary glands and teats was apparent. All of 6 semicastrated individuals in which 2 ovaries were ingrafted showed similar characteristics. The time required for the action of the ingrafted ovary to become evident was variable, being the shortest when 1 testicle was removed. The mammary glands of the positive reacting animals were better developed both macroscopically and microscopically than the mammary glands of virgin females or females after lactation.

Observations on the oestrous cycle of the albino mouse, A. S. PARKES (*Roy. Soc. [London], Proc., Ser. B*, 100 (1926), No. B 701, pp. 151-170).—In studies of the oestrous cycle and various related factors in the albino mouse the duration of the cycle was found as follows: For unmated females 5.7 days, and for normal females mated with vasectomised bucks 11 days. The increase in the length of the cycle in the latter case was considered as due to the formation of a decidua, resulting from the stimulation of the vaginal plug. In 80 per cent of the matings of normal males with normal females in which a vaginal plug was formed pregnancy followed, the average gestation period being 19 days. Blood, however, appeared in the vaginal smear on about the tenth to twelfth day of gestation.

Continued lactation brought about by placing foster litters on the dam inhibited oestrus for about 3 weeks except for the post-partum period. The

number of young suckled in such cases was important, as in small litters oestrus occurred in less time than with large litters. Unilateral ovariectomy did not affect the cycle.

On the properties of the gonads as controllers of somatic and psychical characteristics.—IX, Testis graft reactions in different environments (rat), C. R. MOORE (*Amer. Jour. Anat.*, 37 (1926), No. 2, pp. 351-416, figs. 15).—In studies of the physiological properties of the gonads at the University of Chicago, whole rat testes have been successfully transplanted into normal and castrated males and females. Such transplantations have persisted for from 1 to 6.5 months in many of the animals.

Grafts showing various degrees of activity were found irrespective of the sex of the animal, but only those transplanted to the scrotum produced normal spermatozoa. This is assumed to be due to the temperature regulating properties of the scrotum (*E. S. R.*, 53, p. 428.)

The phosphorus metabolism and the influence of the testes upon it [trans. title], L. IÁ. BLÍÁKHER (L. J. BLACHER) (*Trudy Lab. Éksper. Biol. Moskov. Zooparka* (*Trans. Lab. Expt. Biol. Zoopark Moscow*), 1 (1926), No. 1, pp. 231-234; *Eng. abs.*, p. 234).—The determinations of phosphorus metabolism of four guinea pigs before and after castration indicated that the removal of both testicles resulted in a reduction in the amount of phosphorus excreted. The phosphorus balances were negative before castration but positive following the operation.

Histological changes in the testis of the guinea-pig during scurvy and inanition, B. LINDSAY and G. MEDES (*Amer. Jour. Anat.*, 37 (1926), No. 2, pp. 213-235, figs. 7).—In studies of the effect of scurvy and inanition on the histological structure of the testis of guinea pigs, it was found that inadequate amounts of feed or rations deficient in vitamin C caused a degeneration of the seminal epithelium of the testes. The characteristics of this degeneration included a reduction in the normal number of the late stages of spermatogenesis, desquamation of the germinal epithelium into the lumina of the tubules, and distintegration of the cytoplasm with the production of a reticular appearance. The Sertoli cells were not affected, and they persisted even in tubules showing the advanced stages of degeneration. Almost complete regeneration of the germinal tissue occurred within 17 days after removal from a scorbutic diet.

Preliminary analyses of the tissues and of the metabolism of animals suffering from dietary sterility, E. M. ANDERSON (*Anat. Rec.*, 32 (1926), No. 3, p. 227).—Studies at the University of California of the composition of the blood of animals fed on natural foods and on vitamin E deficient rations have indicated very similar results for animals on the two types of rations, and no definite change in the blood resulted from addition of vitamin E in the form of wheat germ oil to the ration. The young born in the first litters of female rats on vitamin E deficient rations were also analyzed at birth for crude protein, total lipoids, and ash. The crude protein, total lipoids, and ash account for only 73.4 per cent of the total solids in normal young, but the same constituents made up 91.5 per cent of the total solids in the young from pure-food mothers. This, however, suggests no relation to sterility. No differences in the nitrogen and fat metabolism on pure-food diets, with and without wheat germ oil, have been revealed which would account for the fertility of the mothers receiving vitamin E.

Vitamin E and reproduction on synthetic and milk diets, H. A. MATTILL and M. M. CLAYTON (*Jour. Biol. Chem.*, 68 (1926), No. 3, pp. 665-685, fig. 1).—Continuing the studies of vitamin E for reproduction (*E. S. R.*, 52, p. 864),

approximately 150 rats were reared from weaning on synthetic rations consisting of 18 per cent of casein, 4 per cent of salt mixture, 2 per cent of cod-liver oil, and 5 per cent of yeast, with 8 or 23 per cent of lard, the balance being composed of starch. In certain rations 5 per cent of wheat germ oil, cottonseed oil, or olive oil replaced an equal amount of lard, or 0.5 per cent of unsaponifiable constituents of cottonseed oil or 0.2 per cent of unsaponifiable constituents of olive oil replaced an equal amount of lard. In one lot 1 per cent of vitamin B Harris replaced the yeast, and the animals or feeds of another lot were irradiated.

Good growth was obtained on all rations except the one containing vitamin B Harris and the animals appeared in good condition, but normal reproduction occurred only on the ration containing the wheat germ oil. A few young were born on the other rations, and several resorptions occurred, but only for a short time when reproduction ceased entirely. The gonads of the males showed more or less complete degeneration on these rations. Two types of yeast were used but they did not appear to differ as sources of vitamin E.

In curative tests male animals from the above lots were given supplements of wheat germ oil or wheat germ, or were placed on the colony ration. Some regained fertility, while many remained sterile. Such variation in the prolificacy of individuals was evidently due to the length of time that the vitamin E deficient ration was fed before making the change in the ration, the stage of gonad degeneration, and the age of the experimental rats when the feeding commenced. Degeneration of the testicles was measured by comparative weights in these tests.

Fertility was restored in the females when the rations were supplemented with 1 per cent of wheat germ oil, but the number of young per litter did not approach normal. When larger amounts of wheat germ oil were given, litters of normal size were produced, though lactation was subnormal even with 5 per cent of wheat germ oil.

Increased food consumption in pseudopregnancy, H. Goss (*Anat. Rec.*, 32 (1926), No. 3, p. 232).—Records of the food consumption of pseudopregnant females indicated that during 2 weeks following mating with vasectomized males, when the oestrous cycle ceased, the food consumption increased from 25 to 50 per cent above normal, with a corresponding increase in body weight.

The feeding value of different grades of barley as they are separated in a modern seed-cleaning machine (Schule system) [trans. title], F. HONCAMP and W. SCHRAMM (*Landw. Vers. Sta.*, 104 (1926), No. 5-6, pp. 285-296).—In feeding experiments with 2 wethers, using the various grades of barley separated by the seed-cleaning device, it was found that the normal grain which was separated because of light weight contained 10.29 per cent of digestible protein and had a starch value of 85.9 kg. per 100 kg. of grain. The corresponding values for abortive grain were 9.93 per cent and 85.6 kg., and for the heavy sound grain 9.05 per cent and 82.6 kg., respectively. The nutritive values of other grades and of the grain direct from the threshing machine were also determined.

Investigations on the composition and digestibility of barley and its milled products [trans. title], F. HONCAMP and W. SCHRAMM (*Landw. Vers. Sta.*, 104 (1926), No. 5-6, pp. 297-312).—The amounts of digestible protein and the starch value as determined per 100 kg. of the barley products with wethers were for ground barley 10.93 and 83.2 kg., barley feed meal 9.31 and 72.9, the first separation of the bran 3.65 and 48.7, the second separation 3.83 and 40.7, and the third separation of the bran 12.41 and 75.1 kg., respectively.

Silage experiments at Nagpur, H. E. ANNETT and A. R. PADMANABHA AIYER (*India Dept. Agr. Mem., Chem. Ser., 8 (1926), No. 10, pp. 189-209*).—Changes in the composition of juar (*Sorghum vulgare*) ensiled in four pit silos and one tower silo are reported in various tables, and the data are discussed. When the silos were opened the top layer of all was moldy, and in the tower silo there was a considerable shrinkage from the sides, which likewise molded. The sample bags placed in different portions of the silos showed small changes in their dry-matter content. A part of the crude fiber appeared to have broken down during ensiling, which resulted in the formation of nitrogen-free extract, but the latter was at least partially changed into organic acids.

No significant differences were found between the tower or pit silos made in black cotton soil or in trap rock in respect to the changes in the composition of the silage. There appeared to be no advantage derived from sprinkling the crop with water after it was put in the silo or allowing the plants to wilt before ensiling.

Swedish fish meal, its composition and feeding value [trans. title], N. HANSSON (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden], No. 302 (1926), pp. 16; Ger. abs., p. 16*).—Tests with dairy cows and swine on the feeding value of a fish meal containing approximately 65 per cent of crude protein, 2 to 2.5 per cent of fat, and 16 to 17 per cent of inorganic matter have indicated that this feed may be advantageously included as a protein supplement in the rations of these animals. One kg. of fish meal was found to be the equivalent of one fodder unit. Amounts as large as 1 to 1.5 kg. of the fish meal daily had no influence on the flavor of the milk produced by dairy cows, and this feed appeared to increase the butterfat content. The large percentage of minerals present was considerably in its favor, in addition to its high protein content.

Does the addition of sodium chloride increase the value of a corn ration for growing animals? H. H. MITCHELL and G. G. CARMAN (*Jour. Biol. Chem., 68 (1926), No. 1, pp. 165-181, figs. 3*).—In studying the sodium and chlorine requirements of animals at the Illinois Experiment Station, eight pairs of 5-week-old rats and four pairs of chicks were selected for growth and balance studies during 12 weeks. The basal ration fed to one animal of each pair consisted of 87 parts of ground corn, 10 parts of casein, 2 parts of cod-liver oil, and 1 part of calcium carbonate. One part of the corn was replaced by one part of sodium chloride in the ration fed to the other individual of each pair. The basal ration thus contained 0.047 per cent of sodium, 0.041 per cent of chlorine, and 2.58 per cent of nitrogen, while the latter ration contained 0.481 per cent of sodium, 0.724 per cent of chlorine, and 2.57 per cent of nitrogen.

The data on growth showed that the animals receiving the sodium chloride supplement made more rapid gains and required less feed per unit of gain than those on the basal ration only. In four pairs of rats which received similar amounts of feed the rate of growth of those on the basal ration tended to overtake the growth of the other individuals of the pairs toward the end of the period, due to the restriction in food consumption of the larger animals. The other pairs, for which the amount of feed was allotted in proportion to the two-thirds power of the body weight, did not exhibit this tendency. The individuals receiving sodium chloride exceeded their litter mates in growth by 43 per cent in the 4 former pairs and 89 per cent in the 4 latter pairs of rats. The results with the chicks were very similar.

The balance trials with both the rats and the chickens showed distinctly more favorable balances of both sodium and chlorine when the ration was

supplemented with sodium chloride. The rats showed a considerable negative sodium balance on the basal ration which it is stated could not have continued through the entire 82 days, and therefore can not be typical of the entire experimental period. The nitrogen balances were also larger on the supplemental ration, but the digestibility of the nitrogen and the metabolizable energy of the two rations were similar.

It is concluded that the concentration of sodium and chlorine in corn is not sufficient to promote normal growth in rats and chickens, and that this deficiency limits the utilization of its energy and protein for growth.

The value of green corn stacked as a feed for cattle, J. W. WILSON (*South Dakota Sta. Rpt. 1926, p. 5*).—Five lots of five 2-year-old cattle were used for comparing stacked green corn, corn silage, corn fodder, alfalfa hay and corn silage, and all the alfalfa hay the steers would eat. Stacked green corn proved to be the poorest feed ever used at the station, as the steers not only lost weight during the 54-day period but were inferior to the cattle in the other lots.

A comparison of white and yellow corn for growing and fattening swine and for brood sows, J. B. RICE, H. H. MITCHELL, and R. J. LAIBLE (*Illinois Sta. Bul. 281 (1926), pp. 177-204*).—Eight sows were divided into two equal groups. One lot received yellow corn, yellow corn bran, and tankage and the other lot white corn, white corn bran, and tankage. The sows were kept on the experiment through 2 gestation periods; 2 sows were fed white corn through a third and 1 of these through a fourth and fifth gestation period. Pigs farrowed by these sows were divided and fed the same rations as their dams. To further test the rations, two groups of 8 pigs each from sows on normal rations were fed as above. In still another growth experiment, 4 lots of 20 pigs each averaging a little over 60 lbs. were fed the following rations: (1) Silver Mine (white) corn and tankage, (2) yellow corn and tankage, (3) Silver Mine corn, tankage, and alfalfa meal, and (4) White Democrat corn and tankage. In a final experiment 2 lots of 10 pigs, each averaging 50 lbs., were self-fed white corn and tankage. One lot received cod-liver oil in amounts equivalent to 1 per cent of the ration.

Little or no difference was noted in the sows or pigs during the suckling period of the first two gestations, and the authors believe that sows developed on adequate diets can store enough vitamin A to carry them through two gestation and lactation periods. In the third gestation period, 1 sow died soon after farrowing. The other sow farrowed dead pigs for this and the subsequent period. The pigs farrowed had little hair, but were otherwise apparently normal. During the fifth period, 1 per cent of cod-liver oil was added to this sow's ration and at farrowing time she produced normal living pigs.

Normal weanling pigs farrowed by sows carried through gestation on white corn rations failed to thrive and ultimately developed pathological symptoms and died when carried further on the same ration. Pigs from sows receiving a normal diet and raised to 60 or 70 lbs. on these rations made normal gains for a time when fed on white corn, but at weights of 175 to 200 lbs. developed the characteristic symptoms of white corn feeding. Small amounts of alfalfa meal were effective in correcting white corn deficiencies in pigs weighing from 60 to 227 lbs. The addition of 1 per cent of cod-liver oil to the white corn ration indicated that the pathological symptoms were due to a lack of vitamin A since pigs so fed made normal growth. The varieties of white corn tested were decidedly deficient in their vitamin A content.

[Feeding experiments with swine at the South Dakota Station], J. W. WILSON (*South Dakota Sta. Rpt. 1926, pp. 5, 6*).—The results of the following experiments are briefly reported:

Factors in summer feeding of market pigs.—The results obtained in tests of various methods of feeding stocker pigs on limited rations of farm grains with alfalfa pasture were similar to those previously noted (E. S. R., 56, p. 565). Limited rations of corn and tankage, ground barley and tankage, corn without tankage, and whole oats and tankage were found to rank in the order given in relative desirability.

Tankage requirements of market pigs fed barley and pasture.—The results of this experiment indicated that the protein supplied in a ration of ground barley, tankage, and alfalfa or rape pasture formed such an efficient combination that a smaller quantity of digestible crude protein is required than is called for by present day feeding standards.

Winter feeding fall pigs.—In tests of the comparative value of rations for fall pigs a remarkably high value for alfalfa hay was observed. Choice oats as a substitute for corn in limited rations including linseed meal, tankage, and alfalfa hay gave excellent results during the stocker period, but were not as good as corn during the finishing period. Full feeding from weaning to market age proved more economical than a combination of limited and full feeding.

Winter rations for brood sows.—Rations containing oats gave poor results when fed to gilts but the best results when fed to older sows.

The hog: Its use as a domestic animal and its importance to agriculture [trans. title], F. P. STEGMANN VON PRITZWALD (In *Forschungsarbeiten aus der Landwirtschaftswissenschaft. Festschrift zum 70. Geburtstage von Wilhelm Edler. Berlin: Paul Parey, 1925, pp. 154-176*).—This is essentially a brief history of the development of the hog as an animal of economic importance, with descriptions of the German breeds.

Fertility in sheep, J. E. NICHOLS (*Jour. Min. Agr. [Gr. Brit.], 33 (1926), No. 3, pp. 218-225*).—Data related to the fertility of different breeds of sheep obtained by a second questionnaire have yielded information which agrees closely with that previously derived from the first questionnaire (E. S. R., 53, p. 667).

Conformation and appointments of the horse, R. S. TIMMIS (*London: Forster Groom & Co., 1926, pp. 138, pls. 18*).—Includes popular directions for the selection, management, and handling of horses.

Fragment of skull of a horse from the interglacial deposits near Puławy (Poland) [trans. title], B. KĄCZKOWSKI and R. PRAWOCHEŃSKI (*Pam. Państw. Inst. Nauk. Gosp. Wiejsk. Puławach (Mém. Inst. Natl. Polon. Écon. Rurale Puławy, 6 (1925), A, pp. 196-212, pls. 2, fig. 1; Eng. abs., pp. 211, 212*).—Measurements of a horse's skull found in the interglacial deposits near Puławy have been compared with similar measurements of skulls of wild ancestral types of horses, furnishing new information on the probable origin of the various species.

Report of the committee on research in poultry husbandry, M. A. JULL ET AL. (*Poultry Sci., 5 (1926), Spec. No., June, pp. 1-30*).—The report of the committee on research in poultry husbandry of the American Association of Instructors and Investigators in Poultry Husbandry consists mainly of the reports of the subcommittees on nutrition, by C. W. Carrick; on breeding, by W. A. Lippincott; and on diseases, by C. H. Weaver.

The subcommittee reports are based on the returns from questionnaires sent to the various agricultural experiment stations in the United States and Canada, requesting information on the projects under investigation, opinions on cooperation, and suggestions as to the fields of most important research. Certain faults in the method of attacking problems are pointed out as applying particularly to the different lines of research undertaken.

Biometrical measurements of laboratory animals.—II, Domestic fowl [trans. title], K. SALLER (*Ztschr. Wiss. Biol., Abt. D., Arch. Entwickl. Mech. Organ.*, 107 (1926), No. 4, pp. 625-650, figs. 12).—Various measurements and relations between different parts of the bird are suggested for making biometrical studies of the size of fowls (E. S. R., 55, p. 26).

Further studies on the growth of the skeleton of the White Leghorn chicken, H. B. LATIMER (*Anat. Rec.*, 32 (1926), No. 3, p. 236).—In further studies of the rate of growth of the various parts of White Leghorn chickens at the University of Nebraska (E. S. R., 52, p. 172) the relation of the weights of the long bones to the entire skeletal weight was determined and studied statistically. The coefficients of variability for such determinations of the different bones were as follows: Humerus 13.8 per cent, radius 13.2, ulna 16.1, femur 7.9, tibia 8.4, and the tarsometatarsus 12 per cent. The weights per millimeter of length for the same 6 bones when plotted against body weight formed a curve which rose from hatching to maturity, flattening between 1,200 and 1,600 gm. In males the humerus and tarsometatarsus were heavier than in females. Ratios between the lengths of the various bones are pointed out.

Standard breeds and varieties of chickens.—II, Continental European, Oriental, game, ornamental, and miscellaneous classes, M. A. JULI (*U. S. Dept. Agr., Farmers' Bul.* 1507 (1926), pp. II+30, figs. 43).—This is a revision of and supersedes Farmers' Bulletins 1221 (E. S. R., 46, p. 172) and 1251 (E. S. R., 46, p. 769).

The Sussex fowl, L. F. OUTRAM (*London: Poultry Press, Ltd.* [1926], pp. 68, pls. 11).—A popular account of Sussex fowls, with particular reference to the different varieties.

Poultry in Arizona, H. EMBLETON (*Arizona Sta. Timely Hints for Farmers*, No. 155 (1926), pp. 20, figs. 7).—Poultry conditions in Arizona are presented in a popular manner, and the problems of housing, feeding, and breeding of poultry are discussed. The marketing of poultry and poultry products and the methods of killing and dressing poultry are also considered.

[**Experiments with poultry at the South Dakota Station**], G. L. STEVENSON (*South Dakota Sta. Rpt.* 1926, pp. 32, 33).—The results of experiments with poultry are briefly reported, several of which are continuations of experiments previously noted (E. S. R., 56, p. 567).

Grains high in fiber when fed alone again gave poor production and threw the hens out of condition.

Studies of the best usage of alfalfa for poultry feeding have shown that alfalfa fed green gave as good results as sprouted oats but could be used through a much more limited season. Alfalfa hay and soaked alfalfa chaff were used with no marked advantage, but ground alfalfa proved to be a desirable ingredient of the poultry mash.

In another experiment in which various sources of protein were compared, the best results were obtained from milk powder, tankage, and meat scrap, while the results with soy bean meal, ground soy beans, and cottonseed meal were much inferior. A mixture of 10 per cent tankage and 10 per cent milk powder proved to be the most economical egg producer and the birds gained in live weight.

In another experiment chicks were successfully raised on a board floor under an electric brooder without access to the soil until they had reached an average of nearly 1.5 lbs. in live weight.

Tests of the variation in temperature in different incubators showed that in glass front machines the low temperatures were near the front, while the temperature ran relatively high under heating pipes where no shield was used.

From these tests the necessity of shifting the position of the eggs in the tray during hatching is indicated.

Poultry feeding experiments, L. HOH and Y. T. KAM (*Lingnaam Agr. Rev.*, 3 (1926), No. 2, pp. 99-108).—Three experiments dealing with the comparative value of local feeds for the crate fattening of poultry are reported from the Canton Christian College. Four rations were compared in each experiment as follows: Rice bran only; 3 parts of rice bran and 1 part of wheat bran; 2 parts of rice bran and 1 part of cooked polished rice; and 4 parts of rice bran, 2 parts of cooked polished rice, and 1 part of peanut cake. There were 12 pullets in each lot and the feeding period lasted 21 days, but lot weights were tabulated as taken on alternate days.

The results of the 3 tests showed that the maximum weights of the different lots were attained at from 14 to 18 days and a loss in weight occurred during the remainder of the feeding period. Unfavorable results were obtained in all experiments on the rations of rice bran only and of rice bran and wheat bran, but fairly satisfactory gains were made on the other two rations. Rice bran and cooked polished rice proved the most satisfactory in the first and second experiments, while the ration of rice bran, polished rice, and peanut cake was superior in the third test.

The effect of cod liver oil upon flavor in poultry meat, C. W. CARBICK and S. M. HAUGE (*Poultry Sci.*, 5 (1926), No. 5, pp. 213-215).—In studying the effect of cod-liver oil feeding on the flavor of poultry meat at the Indiana Experiment Station, 30 White Leghorn chickens, which had been reared in confinement to 5 or 6 months of age on a ration containing 2 per cent of cod-liver oil, were divided into 3 lots, which received the following respective amounts of cod-liver oil: None, 2, and 4 per cent. The birds were killed at intervals and cooked by different methods. The flavor was judged by 15 persons.

The results showed that when the 4 per cent diet was fed for 2 or more weeks, even after discontinuing the cod-liver oil for 10 days, an unusual taste was present in the chicken meat, and when 4 per cent of cod-liver oil was fed up to the time of killing, the flavor was very pronounced. The method of cooking and the temperature at which the meat was served were found to have a distinct effect on the amount of abnormal flavor reported. The flavor was least noticeable in fried chicken and most noticeable when the meat became cold.

It is apparent from the results that chickens should be fed on rations free from cod-liver oil for at least 2 weeks before slaughtering.

Application of "protozyme" (*Aspergillus oryzae*) to poultry feeding, F. H. CLICKNER and E. H. FOLLEWELL (*Poultry Sci.*, 5 (1926), No. 5, pp. 241-247).—A test dealing with the growth-promoting properties of protozyme, a group of vegetable enzymes produced by cultures of *A. oryzae*, is reported. Protozyme was included in the mash fed to 5 lots of 200 chicks each as follows: None, 1, 2, 3, and 5 per cent. Data on 100 pullets in each lot up to 20 weeks of age are given. At 20 weeks the average weights of the birds in the different lots receiving 0, 1, 2, 3, and 5 per cent of protozyme were, respectively, 2.65, 2.80, 2.89, 3.03, and 3.24 lbs. The total egg production in the pens at this time was, respectively, 24, 11, 2, 4, and 16.

In another experiment 4 lots of pullets, receiving supplements of 0, 1, 3, and 5 per cent of the protozyme in their mash, laid an average of 84, 88, 93, and 93 eggs per bird for the 7-months period, December to June.

Brooding and pullet development, P. MOORE and M. R. LEWIS (*Idaho Agr. Col. Ext. Bul.* 63 (1926), pp. 24, figs. 9).—This gives a popular discussion of

the methods of caring for young chicks during the brooding period, including the feeding and separation of the pullets, with suggestions on the control of diseases, and descriptions of different types of houses for poultry.

Hatching and raising chicks, J. R. SMYTH (*Ky. Agr. Col. Ext. Circ. 110*, 3. ed., rev. (1926), pp. 11, figs. 3).—Popular directions for the hatching, rearing, and feeding of chicks.

Hatching quality of eggs with relation to management, H. D. GOODALE (*Poultry Sci.*, 5 (1926), No. 5, pp. 216-218).—Brief results are given of the hatching qualities of eggs produced by hens and pullets having access to direct or filtered sunlight, and receiving rations with or without supplements of cod-liver oil or pig's liver. There was a general decline in the hatching percentage of the eggs of all lots from March 25 to April 22, followed by a sharp improvement, except for one pen receiving filtered sunlight and pig's liver which showed a continuous decline in hatching quality and the rate of egg production. Another lot receiving cod-liver oil and filtered sunlight also showed a low hatching percentage. The birds receiving unfiltered sunlight without supplements did better, but the best hatching was obtained with unfiltered sunlight, cod-liver oil, and pig's liver.

Report of the committee on egg-laying contest standardization, R. E. JONES (*Poultry Sci.*, 5 (1926), Spec. No., June, pp. 44-46).—A compilation of recommendations of representatives or managers of fourteen different egg-laying contests.

The Missouri plan of certified breeding, B. WINTON (*Poultry Sci.*, 5 (1926), No. 5, pp. 219-224).—A description of the method of certifying poultry breeders in Missouri.

DAIRY FARMING—DAIRYING

Manual of dairy science, A. H. R. AMESS and H. C. JOHNSON (*Auckland and London: Whitcombe & Tombs*, [1926], pp. 207, figs. 71).—A brief presentation of the principles of milk production and testing, and the manufacture of butter and cheese.

[**Experiments with dairy cattle at the South Dakota Station**], T. M. OLSON (*South Dakota Sta. Rpt. 1926*, pp. 15, 17, 18).—The results of two feeding experiments are briefly reported.

Self feeders for calves.—A continuation of this experiment (E. S. R., 54, p. 167) during 3 years has shown that the crooked legs and apparent stiffness were corrected when the calves were allowed access to sunlight.

Effect of ground soy beans and cottonseed meal on butter.—In a test to determine the amount of ground soy beans necessary to produce soft butter (E. S. R., 54, p. 66), the ration of 4 cows was modified at 10-day intervals by the replacement of 25, 50, 75, and 100 per cent of the grain with soy beans or cottonseed meal, but no marked differences were observed in the churning of the cream or the consistency of the butter. When 50 per cent or more of the ration consisted of soy beans the butter had an oily taste resembling castor oil.

Silage versus swedes for milk production, A. C. M'CANDLISH and A. M'VICAR (*Scot. Jour. Agr.*, 9 (1926), No. 2, pp. 194-201).—Eight cows were selected for studying the comparative value of Picton swedes and oat, pea, bean, and vetch silage for milk production at the West of Scotland Agricultural College. Each cow received 7 lbs. of mixed hay and 12 lbs. of oat straw daily, with a grain mixture according to production. The rations also included an average of 22 lbs. of silage during the first and third 20-day

periods, and 40 lbs. of swedes during the second 20-day period. Some silage was refused, especially toward the end of the feeding period.

The average results showed that while roots were fed 7 per cent more milk and 3 per cent more fat were produced. This difference was considered as significant, since every cow produced more milk with roots than with silage. Differences in the feed consumption, the composition of the silage and roots, and the equivalent values of the two succulent feeds are pointed out and discussed.

Nutrients required for milk production with Indian food-stuffs, F. J. WARTH, L. SINGH, and S. M. HUSAIN (*India Dept. Agr. Mem., Chem. Ser., 8 (1926), No. 9, pp. 153-187, figs. 4*).—In two digestion experiments of 14 and 10 days, respectively, with 8 cows in each experiment receiving a ration of fresh alfalfa, silage, hay, brewers' grains, peanut cake, wheat bran, cottonseed meal, and grams husk, the average digestibility of the protein was found to be decidedly less and the organic matter slightly less, but the digestibility of fiber and fat was distinctly greater than that computed according to Henry and Morrison's table. The ration used contained considerably more protein than is ordinarily recommended by American standards. The computed protein requirement per pound of milk was 0.092 lb., which is considerably higher than that allowed by American standards. This difference is explained as due to the lower digestible protein content of the roughages used and a lower digestibility of the protein by the cows in this experiment.

Raising dairy calves, A. R. MERRILL (*Conn. Agr. Col. Ext. Bul. 99 (1926), pp. 16, figs. 7*).—Brief directions for raising dairy calves, with discussions of milk substitutes or calf meals and other related information.

The effect of fat in the ration upon the percentage fat content of the milk, W. B. NEVENS, M. B. ALLEMAN, and L. T. PECK (*Jour. Dairy Sci., 9 (1926), No. 4, pp. 307-345, figs. 12*).—Four series of experiments with feeding periods varying in length from 2 days to 5 weeks were conducted at the Illinois Experiment Station to study the effect of rations high in oil content on the composition of the milk, and to establish the factor responsible for the changes in the butterfat content of the milk noted in the second series of experiments.

Throughout the experimental work the cows were fed sufficient roughage to satisfy maintenance requirements. The roughage consisted of corn silage and alfalfa hay in the first and second series of experiments, while dried beet pulp soaked replaced part of the silage and hay in the third and fourth series.

Rations containing a large percentage of oil were prepared by the addition of such substances as sunflower seed, soy bean seed, high oil corn, flaxseed, and peanuts. These rations were compared with mixtures low in oil or with the regular herd ration which was moderately high in its fat content. Particular attention was given in the third and fourth series of experiments to the estimated protein and digestible nutrient requirements of the animals on the rations compared.

In the first series mixtures of soy bean seed, sunflower seed, and high oil corn when fed to 2 cows did not appear to stimulate milk production, and any effects on the butterfat test were not apparent in weekly composite samples.

In the second series of experiments 4 cows were fed in 5 alternate periods with the herd ration and the mixtures of sunflower seed, high oil corn, and soy bean seed. The latter ration increased the butterfat test of the milk from 8 to 18 per cent, with slight changes in the percentage of total solids in the same direction.

In the 3 portions of the third experiment 6, 9, and 4 cows, respectively, were fed rations including soy bean oil meal, linseed oil meal, and peanut oil meal during the first and third periods, while these feeds were replaced, respectively, by soy bean meal, flaxseed meal, and peanut meal during the second period. The soy bean feeding did not appear to produce any significant increase in the butterfat test of the milk, but flaxseed produced an increase as great as 20 per cent in the fat test, and an average increase of over 10 per cent as compared with linseed oil meal. Peanuts produced an increase as high as 18 per cent and an average of 9 per cent over the fat test of the milk when peanut oil meal was supplied.

In the fourth experiment 4 to 6 cows were fed in 5 periods with either flaxseed, peanut, or soy bean oil meal in the first, third, and fifth periods, with flaxseed, peanut, or soy bean meal in the second period, and with the oil meal plus oil from the same seed in the fourth period. Four cows were used in the experiments with flaxseed and 5 each with peanuts and soy beans. As in the third series of trials, there was little difference between the soy beans and soy bean oil meal, but flaxseed meal and peanut meal or linseed oil or peanut oil added to the respective oil meals produced distinct increases in the fat tests.

From the results of these experiments the authors conclude that the percentage of fat in the milk has been materially increased by the feeding of rations high in oil. The oil may be supplied as the ground whole seed or as oil extracted from the seeds.

The four series of experiments indicate that it is the oil itself and not the stimulation due to a large excess of energy in the ration, nor to a so-called specific effect of feeds which may be closely associated with the oil, that is responsible for the increase in the fat test. Some latent effect of the high oil rations was apparent for from 12 to 36 hours after changes were made in the ration, and a similar time was required for the appearance of the effect of low oil rations. The greatest effect of high oil rations appeared to occur within the first 2 or 3 days. A decline tended to follow.

Common difficulties in farm dairying, their causes and remedies, C. N. SHEPARDSON (*Colo. Agr. Col. Ext. [Bul.] 246A (1926), pp. 12.*)—A popular discussion of the causes of variations in the fat test of milk and cream, defects in flavor and physical condition, and difficulties in churning butter.

How to run a milk business, H. W. PAINE and A. S. BONNEY (*Milwaukee, Wis.: Olsen Pub. Co., 1926, pp. 91.*)—Brief suggestions for the milk dealer.

Milk clarifiers and milk filters, T. M. OLSON (*South Dakota Sta. Rpt. 1926, pp. 16, 17.*)—Numerous tests with a clarifier and filter indicated that there is very little, if any, difference in the keeping quality of milk that has been clarified and pasteurized, and milk that has been pasteurized and filtered. Acidity tests likewise showed little difference. The time of pasteurization exerted a much more noticeable effect. Bacterial counts, methylene blue reductase tests, and Cooledge hydrogen-ion determinations substantiated these results. The clarifier, however, reduced the cell counts by more than 50 per cent, while the filter exerted no appreciable effect on the number of cellular elements in the milk.

Sediment tests were in favor of the clarified samples. Cream line, however, seemed least affected by the filter, as clarification at 80° F. caused a slight decrease in the cream line. The time required in assembling, dismantling, washing, and sterilizing the filter was considerably less than the time required for the same operation with the clarifier.

Canadian creamery buttermaking, W. F. JONES (*Canada Dept. Agr. Bul. 70, n. ser. (1926), pp. 30.*)—Recommended methods of churning, washing, working,

and salting, and packing and printing butter are discussed, with special reference to defects likely to result from faulty methods or improperly cleaned equipment.

Shrinkage of print butter, E. S. GUTHRIE (*Jour. Dairy Sci.*, 9 (1926), No. 4, pp. 346-350).—Tests of the effect of the amount of working of butter on the shrinkage of the prints in storage are reported from the New York Cornell Experiment Station.

In one test butter held in storage for 155 days at 45 to 50° F., which had been worked for 50 revolutions in a Victor churn with one set of rolls, lost an average of $\frac{2}{3}\frac{5}{2}$ oz. per print, while similar lots worked 68 revolutions lost $\frac{4}{3}\frac{2}{2}$ oz. per print. In a second test, using a Victor churn with two sets of rolls, butter worked sufficiently to give a uniform color and stored for about 8 months at 0 to +5° F. lost an average of $\frac{19}{3}\frac{7}{2}$ oz., while other samples worked 10 additional revolutions in a similar type of churn lost only $\frac{2}{3}\frac{3}{2}$ oz.

The author believes that "this limited study indicates that the shrinkage of butter by evaporation and leakage can be largely controlled by thoroughly incorporating the moisture in the fat in the working process."

The relation of bacteria to the quality of graded butter, W. SADLER, R. L. VOLLUM, and W. C. CAMERON (*Canada Natl. Research Council Rpt. 16* (1926), pp. 23).—The bacterial content of 31 samples of butter from 7 creameries submitted to the 1919 Grading Competition of the British Columbia Dairymen's Association was determined, and 140 of the most prevalent types of bacteria were isolated. A study of the results indicated that the flora of the butter from the respective creameries was distinctive, but there was no relation between the bacterial content and the award made by the judges. Since a large number of the organisms were killed by pasteurization, it is supposed that approximately 80 per cent of the organisms found gained access to the cream and butter subsequent to pasteurization.

Studies of the conditions at 2 creameries producing off-flavored butter indicated that the conditions were due to contamination after pasteurizing the cream. In one case the source appeared to be in the water supply, while at the other creamery the wash water was stored in a tank which had not been thoroughly cleaned.

Appendixes are given on The Suggested Control of Creamery Operations by the *coli* Determinations, by W. Sadler, and a Report on Experimental Butter, by W. Sadler and W. C. Cameron.

Cottage cheese manufacture in dairy plants, E. L. REICHART and H. P. DAVIS (*Nebraska Sta. Bul. 217* (1927), pp. 16, figs. 7).—A method of manufacturing cottage cheese which has proved very successful at the University of Nebraska is described. The necessary equipment, the making of starters, and the correct methods of handling, packing, and selling of cottage cheese are discussed. Defects in flavor, body, and texture and suggested remedies are described.

A defect of pimento cheese, D. H. WARREN (*Jour. Dairy Sci.*, 9 (1926), No. 4, pp. 351-358).—In studies at the Bureau of Dairying, U. S. D. A., of the cause of the development of a sharply acid and bitter flavor in pimento cheese on standing, preliminary investigations pointed toward an anaerobic spore-forming, Gram-positive, motile bacillus similar to *Clostridium butyricum*.

To test this hypothesis cheese was made from milk sterilized in the autoclave and divided into 3 lots, each of which was inoculated with 0.5 per cent of a 24-hour-old culture of *Streptococcus lactis*. Two of the lots were further inoculated with spores of the anaerobe, which in one case had been heated (shocked) for the promotion of more rapid growth. The flavor of

the cheese remained clean and mildly acid throughout the 6 days of the experiment in those samples inoculated with *S. lactis* only, but by the fourth day a noticeably bitter taste appeared in the lots inoculated with spore-forming organism. The defect appeared more rapidly and was more pronounced in the lot inoculated with the shocked spores.

Analyses of the cheese showed that there was an increase in volatile acids of 16 and 8.8 per cent in those lots inoculated with shocked and unshocked spores, respectively, and 4.7 per cent in the cheese inoculated with *S. lactis* only.

The cultural characteristics of the spore-forming organism are briefly noted.

VETERINARY MEDICINE

A textbook of pathology, J. M. BEATTIE and W. E. C. DICKSON (*London: William Heinemann, 1926, 3 ed., pp. XXV+1103, pls. 17, figs. 499*).—This is a largely rewritten edition of a work, based upon the teaching of the Edinburgh school, which first appeared in 1908. Part 1 (pp. 1-496) deals with general pathology, and part 2 (pp. 497-1067) with special pathology. Recommendations made by the Chemical and Physiological Societies of Great Britain as to the nomenclature of albuminous substances and Adami's classification of tumors⁵ are given in appendixes.

Histological technique for normal tissues, morbid changes, and the identification of parasites, H. M. CARLETON (*London and New York: Humphrey Milford, Oxford Univ. Press, 1926, pp. XV+398, figs. 17*).—This work presents in compact form the chief methods employed in the microscopic examination of mammalian organs. Part 1 of this work (pp. 3-23) gives the structure and composition of the cell in relation to histological technique; part 2 (pp. 27-150) type methods of normal histology; part 3 (pp. 153-195) accessory methods of examination; part 4 (pp. 199-300) methods for special organs, tissues, and cell components; and part 5 (pp. 303-366) technique of morbid histology, including methods for the identification of microorganisms and other parasites.

An attempt to increase the virulence of a micro-organism by method of culture, K. R. K. IYENGAR (*Indian Jour. Med. Research, 13 (1926), No. 3, pp. 555-557*).—The author concludes that the virulence of *Bacillus avisepticus* can not be increased without animal subpassage, and that the same conclusion applies to other organisms as well.

Human protozoology, R. W. HEGNER and W. H. TALIAFERRO (*New York: Macmillan Co., 1925, pp. XIX+597, pls. 2, figs. 197*).—The several chapters of this work deal with the subject as follows: Introduction to the organization of the Protozoa (pp. 1-18), a general consideration of the Sarcodina (pp. 19-46), the ectozoic and entozoic Sarcodina (pp. 47-90), a general consideration of the Mastigophora (pp. 91-125), the haemoflagellates and allied forms (pp. 126-200), the intestinal flagellates (pp. 201-265), a general consideration of the Sporozoa (pp. 266-269), the gregarines and coccidia (pp. 270-292), the order Haemosporidia exclusive of the malarial parasites (pp. 293-312), the malarial parasites (pp. 313-360), the Neosporidia (pp. 361-377), a general consideration of the Infusoria (pp. 378-408), ectozoic and entozoic Infusoria (pp. 409-447), genetics and physiology of reproduction in the Protozoa (pp. 448-480), and the diagnosis of the intestinal Protozoa (pp. 481-513). A classified bibliography is included (pp. 515-566).

⁵ On the Classification of Tumours, J. G. Adami. Jour. Path. and Bact., 8 (1902), pp. 243-259.

The ultra-microscopic viruses, I, II, G. M. FINDLAY and R. J. LUDFORD (*Brit. Jour. Expt. Path.*, 7 (1926), No. 5, pp. 223-264, figs. 66).—In the first part of this account (pp. 223-255) the authors deal with cell inclusions associated with certain ultra-microscopic diseases, in which a pictographic review is included. The references to the literature are presented under the headings of 23 different diseases.

In part 2 (pp. 256-264), the cytology of fowl-pox is dealt with.

Symposium on "filterable viruses" (*Jour. Bact.*, 13 (1927), No. 1, pp. 16-25).—The first part of the symposium on filterable viruses held at the annual meeting of the Society of American Bacteriologists at Philadelphia in 1926 was contributed to by the following members: Filterable Viruses—A Critical Review, by T. M. Rivers (pp. 16-20); The Nature and Significance of Cellular Inclusion Bodies in Diseases Due to Filterable Viruses, by E. V. Cowdry (pp. 20, 21); Recent Research on Foot-and-Mouth Disease, with Special Reference to the Work of the American Commission, by H. W. Schoening (pp. 21-23); Some Characteristics of Virus Diseases of Plants, by L. O. Kunkel (pp. 23, 24); and Studies on Vaccinia Virus, by E. H. Oppenheimer (pp. 24, 25).

Agglutinin absorption, C. KRUMWIEDE, G. COOPER, and D. J. PROVOST (*Jour. Immunol.*, 10 (1925), No. 1, pp. 55-239, figs. 2).—In summarizing this report of investigations and review of the literature, the authors point out that there is no means of measuring the specific agglutinin content of a serum except by using the bacterial type which is known to have stimulated the production of the agglutinins in a serum, even though this means may not always be adequate. "There is no basic validity, therefore, in a procedure which assumes the reliability of determining the infecting bacterium or bacteria by testing the absorptive capacity of several cultures on the agglutinins present in the patient's serum for each of such cultures. Such a procedure does not take into account all the possible alternatives. The observation of the character of the clumping and the use of the specific component for test purposes may give strongly suggestive results. The probable alternatives in such methods are discussed."

Relation of anaphylaxis to immunity.—I, Passive desensitization in dogs, W. H. MANWARING, P. W. SHUMAKER, P. W. WRIGHT, D. L. REEVES, and H. B. MOY (*Jour. Immunol.*, 13 (1927), No. 1, pp. 59-62).—In work at Stanford University the authors find that the blood of an actively immunized dog contains no antibody that serves as a demonstrable circulating defense to hypersensitize fixed tissues. "The immune blood, however, does contain a desensitizing substance, capable of causing complete desensitization of hypersensitive fixed tissues. This desensitization is effected only after a latent period of about 48 hours. All phenomena of passive desensitization or passive immunization thus far studied in dogs may be accounted for as a result of the action of this desensitizing antibody. As pointed out in previous papers, there is conclusive evidence that in dogs the sensitizing antibody and desensitizing antibody are of different chemical composition, and that neither of these substances is identical with the specific precipitin of our test tube reactions."

The nature of bacteriophage, E. B. MCKINLEY and M. HOLDEN (*Jour. Infect. Diseases*, 39 (1926), No. 6, pp. 451-456, pls. 2).—The authors concur with d'Herelle in the view that bacteriophage is a particulate substance. "Being particulate does not in and of itself imply its living nature, though its power of multiplication and adaptation are strong arguments for it. We question the theory of its being an ultramicroscopic virus in that adequate proof is lacking for this conception. However, it is possible to conceive of an ultramicroscopic particulate substance, diastatic in its action, granular in

form and inanimate, which may be derived from the bacterial cell during a stage in its life cycle as a result of the influence tissue cells of the host have had upon it. Bordet has called this 'hereditary vitiation,' and it may well be. The susceptibility of the bacteriophage to the action of ultra-violet rays is suggestive of its living nature, though it is well known that enzymes are also destroyed by them and such a criterion would not serve in proving this point."

Studies on the metabolism of *Bact. abortus-melitensis-bronchisepticum-alcaligines* group.—I, Nitrogen metabolism, J. G. McALPINE and C. A. SLANETZ (*Jour. Bact.*, 13 (1927), No. 1, pp. 11-13).—This is a contribution from the Connecticut Storrs Experiment Station in which 8 strains of *Bacterium abortus*, 5 of bovine and 3 of porcine origin, 5 strains of *B. melitensis* from various sources, 2 strains of *B. bronchisepticum*, and 2 strains of *B. alcaligines* were studied. The preliminary experiments indicate a decided difference in the metabolic activities of *B. melitensis* and *B. abortus* of bovine origin, at least in the strains used in the present study. Cultures of *B. abortus* from porcine sources resembled more closely *B. melitensis* than the bovine strains of *B. abortus*.

Distribution of the spores of *Bacillus botulinus* and *Bacillus tetani* in the soil.—I, In Maryland, S. R. DAMON and L. B. PAYABAL (*Jour. Infect. Diseases*, 39 (1926), No. 6, pp. 491-501, figs. 2).—Out of 62 soil samples obtained from the various localities throughout Maryland, 4 contained toxin-producing organisms that could not be identified by antitoxin protection tests. *B. tetani* was present alone in 6 samples, *B. botulinus*, type A, was present alone in 8, *B. botulinus*, type B, was present alone in 25, and *B. botulinus*, type C, was present alone in 5 samples. *B. botulinus*, types A and C, were present together in 4, and types B and C were present together in 5 samples. The three types of *B. botulinus* were not found together, and neither were *B. botulinus* and *B. tetani* found together in any single sample. The sources of the soil samples and a comparison of the results with those of similar surveys by workers in California and Illinois are shown in illustrations.

Meningitis due to *B. enteritidis* Gaertner, G. STUART and K. S. KRICKORIAN (*Jour. Hyg. [London]*, 25 (1926), No. 2, pp. 160-164, fig. 1).—In this contribution from the Central Laboratories, Department of Health, Government of Palestine, the authors report upon a case of meningitis in an 11-year-old boy. Agglutination tests of the causative organism showed it to be of the *B. enteritidis* Gaertner type, with fully developed labile antigen. The absorption tests showed that this organism and typical *B. enteritidis* Gaertner possess identical labile and stable receptor apparatus.

Undulant fever as a public health problem, T. G. HULL and L. A. BLACK (*Jour. Amer. Med. Assoc.*, 88 (1927), No. 7, pp. 463, 464).—Following a brief reference to the literature on the subject, the authors report upon agglutination tests with *Brucella abortus* antigen made on blood serums sent in for Widal tests at the laboratories at Springfield, Ill. Among 69 specimens of blood from fever patients who consistently gave negative Widal reactions, agglutination reactions with *B. abortus* antigen were positive in 5 in dilutions of 1:200 or greater. The histories of 4 of the 5 cases are reported, 3 of which gave a positive agglutination reaction at dilutions of 1:500. In the macroscopic test, used in dilutions ranging from 1:25 to 1:500, 5 others agglutinated in 1:25 only and a sixth agglutinated in 1:50. The authors point out that undulant fever seems to be much more common than is ordinarily suspected.

The tuberculosis of domestic Carnivora, G. LESBOUYRIES (*La Tuberculose des Carnivores Domestiques*. Paris: Vigot Bros., 1926, pp. 140, pls. 2, figs. 13).—Following a brief introduction, the subject is dealt with in five parts, namely,

frequency of tuberculosis (pp. 3-5), etiology and pathogenesis (pp. 6-17), lesions and symptoms (pp. 18-81), diagnosis (pp. 82-111), and treatment (pp. 113-125). A classified bibliography of nine pages is included.

Coccidiosis in feeder cattle, E. R. FRANK (*Jour. Amer. Vet. Med. Assoc.*, 69 (1926), No. 6, pp. 729-733).—This is a contribution from the Kansas Experiment Station which deals briefly with life cycle, infection, diagnosis, and case reports. Reference is made to cases among beef cattle recorded at the veterinary hospital in 1924, 1925, and 1926, from which it is concluded that the degree of transmissibility of the disease is very low.

Parasites and parasitic diseases of goats, M. C. HALL (*Goat World*, 10 (1925), Nos. 6, pp. 1-3; 7, pp. 8-11, figs. 4; 8, pp. 5-8, figs. 3; 9, pp. 10-13; 10, pp. 3-6; 11, pp. 4-7).—This is a practical summary of information on the parasites and parasitic diseases of goats, both external and internal.

Annual report of camel specialist for the year 1923-24, K. SINGH ([*Punjab*] *Camel Specialist Ann. Rpt. 1923-24*, pp. 3+3+9).—This includes reports on the treatment of surra by the Cross method, experiments on treatment of surra in ponies and donkeys, etc.

Tick paralysis in pigs (*Queensland Agr. Jour.*, 26 (1926), No. 6, pp. 550, 551).—A brief account is given of paralysis in pigs caused by *Ixodes holocyclus*, which is comparatively common along the coastal districts of New South Wales and Queensland.

Nematodes belonging to the genus Setaria parasitic in the eyes of horses, B. SCHWARTZ (*North Amer. Vet.*, 8 (1927), No. 2, pp. 24-27, figs 2).—The author reports upon cases of Setaria (Filaria) from the eyes of horses which he has observed, differentiation of species of Setaria from the eyes of horses, the injuries produced by Setaria in the eye of the horse, and the life history of Setaria.

Notes upon the action of mercurochrome on horses, W. L. WILLIAMS (*North Amer. Vet.*, 8 (1927), No. 1, pp. 51-59).—The author's observations indicate that the intravenous administration of mercurochrome in 1 per cent aqueous solution in doses of 4 to 5 mg. per kilogram of body weight is readily tolerated by the horse and produces no symptoms of notable distress. There appear to be marked variations in the effect of mercurochrome according to the temperament of the animal, those of nervous temperament, including thoroughbreds and trotters, being definitely more susceptible than draft types. The horse quickly acquires tolerance to the drug, and successive doses may be increased.

Animal feeding experiments with Bacterium pullorum: The toxicity of infected eggs, L. F. RETTGER, C. A. SLANETZ, and J. G. McALPINE (*Connecticut Storrs Sta. Bul.* 140 (1926), pp. 97-110, figs. 3).—This is a report of investigations conducted in continuation of those by Rettger, Hull, and Sturges, previously noted (*E. S. R.*, 35, p. 683). In the present investigation 12 kittens and 24 young rabbits were employed in feeding experiments, the details of which are given. The results obtained are considered to be quite in accord with the earlier observations and to show that large numbers of *B. pullorum*, when administered by mouth to young kittens and rabbits, cause disturbances in them which resemble in some measure at least those that are commonly associated with bacterial food poisoning. All of the kittens recovered from the effects of the *B. pullorum* feeding, but 18 of the 21 infected rabbits died, and from the blood of each of those which succumbed *B. pullorum* was recovered without difficulty. All of the three control rabbits lived and were in apparently normal condition throughout the investigation. Charts showing the influence of *B. pullorum* feeding on the temperature of rabbits and tables showing the influence of *B. pullorum* feeding on their weight and temperature are included.

Coccidiosis and bacillary white diarrhea in chicks, E. L. BRUNETT and R. C. BRADLEY (*N. Y. Agr. Col. (Cornell) Ext. Bul. 148 (1926), pp. 13, figs. 5*).—This is a practical summary of information.

Investigation on a diarrhea in young chicks in Japan, N. NAKAMURA (*Jour. Japan. Soc. Vet. Sci., 1 (1922), No. 2, pp. 93-100, pl. 1*).—Investigations of the disease among chicks in Japan known as "Babatara" have led to the conclusion that it is not identical with the white diarrhea of chicks in other countries, and that the anaerobic bacillus isolated from the intestinal contents of the affected chicks was the causative organism.

Vaccination of poultry against diphtheria and fowl pox (contagious epithelioma) with antidiptherine [trans. title], T. VAN HEELSBERGEN (*Schweiz. Arch. Tierheilk., 67 (1925), No. 13, pp. 333-338, fig. 1; abs. in Vet. Rec., 7 (1927), No. 5, p. 114*).—It is pointed out that in the vaccination of poultry with the antidiptherine of de Blicke and van Heelsbergen, as previously noted (*E. S. R., 53, p. 785*), during the winter of 1924-25, 200,000 fowls were vaccinated without a single accident. Good results were also obtained from the treatment of fowls actually suffering from the disease. Observations made at several poultry experiment stations and on large farms are said to have shown that the immunity acquired was still active after two or three years. It was observed that the number of eggs from fowls vaccinated during the laying season was not diminished.

Iodine on the poultry farm, W. L. CHANDLER (*Poultry Sci., 6 (1926), No. 1, pp. 31-35*).—The author points out that iodine has two important uses on poultry farms, the first being that of dosing the birds for worms, and the other the treatment of poultry houses and runways for the destruction of worm eggs and larvae and the cysts of coccidia.

Diseases and treatment of the rabbit, M. W. MEEK (*Arcadia, Calif.: Natl. Assoc. Rabbit Indus., 1926, pp. 77, figs. 20*).—This is a practical summary of information on the diseases of the rabbit.

AGRICULTURAL ENGINEERING

Agricultural engineering and its place in Canadian agriculture, L. G. HEIMPEL (*Sci. Agr., 6 (1925), No. 2, pp. 41-46, fig. 1*).—In a contribution from Macdonald College, Quebec, an analysis is presented of the field of agricultural engineering in Canadian agriculture. Special attention is drawn to the relation of this work to practically all of the recognized branches of agriculture, and to the factors limiting the development of the work in Canada.

Drainage by means of pumping from wells in Salt River Valley, Arizona, J. C. MARR (*U. S. Dept. Agr. Bul. 1456 (1926), pp. 22, pls. 3, figs. 15*).—The practice is described, and an analytical study of some of the results obtained in conjunction with the existing conditions is presented.

Test borings in the Salt River Valley project showed that about half of the project is underlaid by a coarse water-bearing formation from which water may be pumped. The use of electrically driven pumps in wells located in damaged areas was successful in reclaiming water-logged land and in checking the rise of ground water in sections not yet damaged. The pumped water has also been used very largely to augment the supply available for irrigation. The cost of the completed drainage system for 203,000 acres of cultivated land was approximately \$5.20 per acre.

Plants as indicators of ground water, O. E. MEINZER (*Jour. Wash. Acad. Sci., 16 (1926), No. 21, pp. 553-564*).—In a contribution from the U. S. Geological Survey a study is presented of the desert phreatophytes, and data are pre-

sented on the general limits of the depth to the water table indicated by the principal phreatophytes in the areas investigated.

These indicate that the species investigated, with the possible exception of pickleweed, may grow where the upper layer of ground water contains only small amounts of mineral matter and is of good quality. Thus of 13 samples of ground water obtained in Big Smoky and Ralston Valleys, Nevada, at points where salt grass was growing, 11 samples contained less than 1,000 parts per million of total solids, 8 contained less than 500 parts, and 5 less than 300 parts. More than half contained less than 35 parts per million of chloride. On the other hand, the data show that all these species may be found growing where the ground water is highly mineralized, even mesquite not being an exception.

The soil dynamics problem, E. G. MCKIBBEN (*Agr. Engin.*, 7 (1926), No. 12, pp. 412, 413).—In a contribution from the California Experiment Station an analysis is presented of those factors, both past and present, which make the soil what it is, and of the resultant properties which affect its utilization in agriculture. On the basis of this analysis the soil dynamics situation is divided into three major problems which include (1) the determination of those dynamic properties of soils affecting their drainage, irrigation, tillage, traction, and use as a foundation and building material, and the effect of changing chemical, physical, and biological conditions upon these dynamic properties, (2) the determination of what should be done to the soil and when it should be done, and (3) the determination of the best methods and machines for accomplishing the desired results.

Earth pressures on culvert pipes, G. M. BRAUNE (*U. S. Dept. Agr., Public Roads*, 7 (1927), No. 11, pp. 222-229, figs. 18).—The progress results of a series of tests being conducted at the University of North Carolina to determine earth pressures on culvert pipes, using conditions conforming to practice as closely as possible, are reported.

Tests of four sections of 30-in. cast iron pipe, 2.5 ft. long and 1 in. thick, so placed as to permit a 50 per cent projection, showed that the earth pressure on the test pipe was 84 per cent of the weight of the earth prism immediately over the pipe. This ratio remained practically constant for the entire height of the fill except for the first 4 ft., where the earth pressures were greater than the weight of the earth prism.

In a test using a 50 per cent projection and a clay fill, the pressures were found upon completion of the embankment to be less than for the projection condition, the ratio of the pressure to the weight of the prism over the pipe decreasing as the fill was raised. The pressures decreased from March to the middle of August, and sudden variations in the weather had but little effect upon the pressure.

Combined concrete and timber in flexure, G. D. BURR (*Wash. [State] Univ., Engin. Expt. Sta. Bul.* 37 (1926), pp. 22, figs. 15).—The results of studies of concrete and timber in flexure are reported, the results of which indicate that timber may be made to take the tension and concrete the compression in a structural member, thus using both materials to their greatest advantage. It was found that concrete and timber combined as a single member will produce a beam several times stronger than the same quantity of materials not so combined. Increased stiffness is secured, thus reducing deflections and vibration. It was found that adding the concrete to the timber produced a beam nine times more rigid than the original timber.

Rough timber may be used, resulting in a twofold saving. The strength is greater and the cost may be reduced somewhat by avoiding the surfacing operation. It was found that the irregular dimensions of the unsurfaced ma-

terial are not objectionable, since the plasticity of the fresh concrete allows for the irregularities.

Form cost is small by reason of the small amount of form work required, the simplicity of the forms, and their adaptability to re-use. This is brought about by the fact that the timber provides the strength to carry the dead load while the concrete is setting.

The conclusion is drawn, however, that this study can not be regarded as completed. There are some factors which can be determined only by the actual use of this type of construction for long periods of time or else by exhaustive experiments.

The use of explosives on the farm, A. J. SCHWANTES (*Minn. Univ. Agr. Ext. Spec. Bul. 110 (1926), pp. 20, figs. 18*).—Practical information on the subject is presented, with particular reference to the use of explosives for stone and stump removal under Minnesota conditions.

Public Roads, [January, 1927] (*U. S. Dept. Agr., Public Roads, 7 (1927), No. 11, pp. 209-232+[2], figs. 20*).—This number of this periodical contains the apportionment of Federal-aid funds for the fiscal year ending June 30, 1928, and the status of Federal-aid highway construction as of December 31, 1926, together with the following articles: The Collection and Disposition of Motor Vehicle Revenues, by H. R. Trumbower; Earth Pressures on Culvert Pipes, by G. M. Braune (see p. 680); The Downward Kick of the Rear Wheels of Vehicles in Starting from Rest to Motion, by T. K. A. Hendrick, and Motor Truck Impact Tests Now in Progress.

Ultra-violet spectroscopy of flames of motor fuels—preliminary experimental survey, G. L. CLARK and W. C. THEE (*Indus. and Engin. Chem., 18 (1926), No. 5, pp. 528-531, figs. 2*).—Preliminary studies conducted at the Massachusetts Institute of Technology are reported in which the ultra-violet spectra were photographed of the detonation, explosion, and combustion flames in an engine of several commercial brands of gasoline, of gasoline containing butyl nitrite, a detonation inducer, tetraethyl lead, a detonation suppressor, and of benzene and alcohol.

The spectra of detonation, explosion, and combustion were found to be different, the first being characterized by a strongly banded structure. Both tetraethyl lead and butyl nitrite were found to affect the spectra. The former suppressed the strong bands and shortened the ultra-violet, while the latter even accentuates the intensity in the far ultra-violet, thus throwing some light on the radiation theory of detonation control.

The strong lead lines and the absence of lead compound bands showed that the metallic lead atoms or the process of decomposition of the tetraethyl lead molecule is the effective agent in the reaction propagation, and that combination with the bromine introduced as ethyl bromide takes place subsequently to the oxidation reaction. The copper lines from the plug spark appeared as emission lines in the presence of lead in the vapor, but as absorption lines in its absence.

The results in general are considered to be sufficiently important and clear to warrant thoroughly quantitative investigation with the spectroscope data correlated with known composition of fuels, pressures, reaction rates, and amounts of detonation.

The gas engine on the farm.—III, Running troubles and their remedy, F. G. BEHREND and F. L. FAIRBANKS (*N. Y. Agr. Col. (Cornell) Ext. Bul. 147 (1926), pp. 48, figs. 26*).—Practical information on the subject is presented.

Report of investigational work on the use of electricity in agriculture by the farm mechanics department of University of Illinois, E. W. LEH-

MANN (*Springfield, Ill.: R. V. Prather, 1926, pp. 16, figs. 2*).—A brief description is given of the work on the subject being done by the Illinois Experiment Station, and some of the progress results are briefly presented.

Hydro-electric power in Washington.—Part II, A bibliography of technical papers, 1878–1925, C. E. MAGNUSSON (*Wash. [State] Univ., Engin. Expt. Sta. Bul. 36 (1926), pp. 143, figs. 2*).—A bibliography of technical papers on the subject is presented (E. S. R., 52, p. 182).

Testing draft horses, E. V. COLLINS and A. B. CAINE (*Iowa Sta. Bul. 240 (1926), pp. 193–223, figs. 27*).—The development of methods and apparatus for testing the pulling power of horses is outlined, and the results of actual draft tests are presented and discussed in the first part of the publication. A second part presents the results of a study of the horse as a motor (E. S. R., 55, p. 579).

The experiments as outlined required a steady, constant pull, and the load did not vary either going up or down small hills. Two years' studies demonstrated clearly that it is possible for horses weighing from 1,500 to 1,900 lbs. or more to continuously exert 1 h. p. or more for periods longer than 1 day. It is also possible for a well-trained horse to exert an overload of over 1,000 per cent for a short time.

Daily observations of horses working during all kinds of summer weather indicated that humid days are much harder on them than dry, hot days. The correct fitting of collars and the proper care of shoulders are also essential if maximum work is to be obtained. If it is necessary to work horses hard during rainy weather, housings should be provided to keep the collars and shoulders as dry as possible.

Three years of experimental work also demonstrated that it is possible for horses to exert a tractive effort of from one-tenth to one-eighth of their own weight, and to travel a total of 20 miles per day without undue fatigue.

Characteristics of full and partial journal bearings, H. A. S. HOWARTH (*Indus. and Engin. Chem., 18 (1926), No. 5, pp. 453–460, figs. 18*).—An analysis is presented of bearings bored with running clearance and bearings fitted carefully to the journal. The first type includes full or complete bearings, central partial bearings in which the line of action of the resultant load bisects the bearing angle, and offset partial bearings in which the line of action of the resultant load intersects the bearing surface usually more than half way from the leading edge.

Graphical studies of these types are reported, the purpose being to provide a complete set of fundamental laws which must govern the actual lubrication of all plain journal bearings. The bearing characteristics as given represent ideal conditions in that they show the maximum film thickness which may be realized for a given load. These laws may serve as a guide in the study of actual bearings in which such factors as end leakage and surface roughness play a modifying part and prevent the carrying power from being as great as in the ideal case.

The question as to the advantages of employing two or more pivoted segments instead of a single partial bearing to support a journal is cited as an example of the use of these laws. It is shown that the film is thinner in the case of the bearing of two segments, the total arc of each bearing and other conditions being equal. In a similar manner a 3-segmented bearing is inferior to one of two segments.

The kinematics and dynamics of the wheel type farm tractor, E. G. MCKIBBEN (*Agr. Engin., 8 (1927), No. 1, pp. 15, 16, fig. 1*).—This is the first of a series of articles on the subject, which are based on a study conducted at the

California Experiment Station. This number of the series presents the results of a study of the possible motions of a tractor. An analysis is given of rectilinear and curvilinear motion and of instantaneous axis of rotation.

Root cutting as an aid in harvesting grain sorghums with a "combine," J. P. CONRAD (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 9, pp. 729-742, figs. 3.)—Studies conducted at the California Experiment Station are reported from which the conclusion was drawn that the difficulty of harvest is one of the important reasons why grain sorghums are not more widely planted. Root cutting preparatory to harvesting with a combine was found to have many theoretical advantages over systems of harvesting now used. Root cutting of grain sorghum plants was accomplished with heavy horizontal blades attached to a heavy orchard cultivator and running beneath the crowns of the plants. Where all of the roots were cut at 9 in. or less from the surface the plants dried out rapidly except when irrigated immediately afterward. No plant whose roots were cut at least 5 in. from the surface went down due to the overturning of the sod. Only a very few plants remained standing when cut at 2.5 in. or less from the surface. Between 90 and 95 per cent of the heads were secured by harvesting with a combine after root cutting.

Farm building plans, H. B. WHITE and M. G. JACOBSON (*Minn. Univ. Agr. Ext. Spec. Bul.* 111 (1926), pp. 8, figs. 3).—A list of farm building plans available from the Minnesota Experiment Station is presented.

The Gothic barn roof with sprung rafters, F. E. FOGLE (*Agr. Engin.*, 8 (1927) No. 1, pp. 13, 14, figs. 5).—In a contribution from the Michigan Experiment Station an analysis is presented of the Gothic barn roof with sprung rafters. It is stated that when built on Shawver truss frames the sprung rafter Gothic roof is very rigid, and since the rafters are supported near their middle there is much less liability of the roof becoming uneven as compared with the self-supporting frame. It is noted that a sprung roof invariably shows some unevenness of its surface due to the practical impossibility of maintaining such a high degree of uniformity in workmanship and material as to prevent minor variations in curvature, but it is considered apparent that such irregularities do not of necessity indicate structural weakness. With reference to curvature, it is considered good practice to use two-thirds or three-fourths of the width of the barn as the radius of rafter curvature and to locate the center of the arc about 3 ft. below the top of the plate.

Automatic control of natural draft ventilation of stables, J. L. STRAHAN (*Agr. Engin.*, 8 (1927), No. 1, pp. 9, 10, figs. 2).—This is an abstract of a paper presented at the twentieth annual meeting of the American Society of Agricultural Engineers at Lake Tahoe, Calif., in June, 1926.

The conclusion is drawn that dampers should be omitted entirely from out-take flues, and that the latter should be made smooth on the inside. This transfers the entire burden of control to the intakes. A device is illustrated and described which adds to a back-draft control device the function of regulating the volume of air flow in the normal or proper direction, which function was previously left entirely to hand dampers. The purpose of this device is to keep the volume of air flow automatically within a specified maximum, regardless of a wide variation in draft-producing conditions.

Aside from the galvanized-iron housing, with its removable cover, the essential parts of the device are the aluminum vane or damper supported by a suitable transverse shaft and bearings, the counter weight, and the control weight. The damper has two closing positions, one being the position to prevent back drafting and the other the fully closed position for preventing excessive flow in a normal direction.

The question is raised as to whether thermostatic control will in practice be as effective a means of minimizing inside temperature variations as a device such as the one described, which operates as a function of air flow velocity in the ducts.

Hog houses and equipment, H. P. TWITCHELL (*Ohio Agr. Col. Ext. Bul. 57* [1927], pp. 24, figs. 18).—Practical information, working drawings, and bills of material for hog houses and equipment adapted to Ohio conditions are presented.

Artificial lighting for poultry houses, R. E. CRAY (*Ohio Agr. Col. Ext. Bul. 56* [1926], pp. 16, figs. 6).—The results of experiments on the artificial lighting of poultry houses to increase egg production are reported, and information is presented on the proper equipment for this purpose.

It has been found that electric light is the most efficient, easiest to operate, and best all-round kind of light for poultry houses. One 40-watt bulb should be used for each 200 sq. ft. of floor space, and the lights should not be placed more than 10 ft. apart.

The best results have been secured by using reflectors as they intensify the light on the floor. The reflector should be 16 in. in diameter and cone shaped, with the cone 4 in. high at the center. For best distribution of light when reflectors are used, the lights should be suspended 6 ft. from the floor, 10 ft. apart, and half way from the front of the dropping board to the front of the house.

It is stated that the available data, while quite limited, indicate that on farm lighting plants the cost of operation is about 5 cts. per bird for the winter period.

Properties of refrigerants, H. D. EDWARDS (*Amer. Soc. Refrig. Engin. Circ. 2* (1926), pp. 24, figs. 20).—A compilation of data is presented on the properties of different refrigerants, dealing especially with physical properties, effect on various lubricants, toxicity, inflammability, explosive qualities, method of testing purity, and precautions essential in handling.

RURAL ECONOMICS AND SOCIOLOGY

Agricultural problems in their international aspect (*Rome: Internat. Inst. Agr., 1926, pp. 392*).—Statements relating to agriculture prepared for the use of the preparatory committee of the International Economic Conference, with an introductory article on the essential elements in the increase of agricultural production and their international aspects, are included. Statistics are given of the production, trade, consumption, and prices in different countries of wheat, rye, barley, oats, maize, rice, potatoes, tea, coffee, sugar, linseed, cottonseed, rubber, cotton, flax, hemp, wool, butter, cheese, and livestock, and material relating to certain aspects of agricultural economics, as follows:

The economic conditions of production.—This article includes (1) index numbers for the United States obtained by comparing pre-war and postwar prices of agricultural products and items of farm expenses; (2) index numbers for Switzerland of farm products for 1920–1923 (1906–1913 price equals 100) and of increased cost of seasonal labor, interest on capital, cost of buildings, improvements, implements and machinery, cattle and horses, hire of implements and machinery, working expenses, and net returns for the different pre-war and post-war periods; (3) the weighted index numbers for Germany obtained by comparing prices for 1924–25 and 1925 with 1913 for agricultural products and commodities used on the farm; (4) index numbers for England and Wales for 1920–1923 (1911–1913 equals 100) for agricultural products, forage, and ferti-

lizers; and (5) average prices among the farmers in Czechoslovakia of agricultural products and farm implements, materials, labor, etc., before and since the war.

The marketing of agricultural products and its effect on increasing costs.—A short review is given of studies made in Great Britain and the United States of the differences between pre-war and postwar prices paid producers and paid by consumers for agricultural products and products manufactured from such products. Tables are included of prices paid farmers, wholesale prices, and retail prices for dairy products, fruits and vegetables, meats, poultry, eggs, cereals, flour, and bread at different periods from 1911 to 1923 in Great Britain. For the United States comparisons are shown (1) of prices received by producers and costs of marketing grains, fruits and vegetables, livestock, and eggs at different times from 1912 to 1921; (2) of the cost of raw materials, cost of manufacturing and distribution, margin, and profit at different times of manufacturing rolled oats, canned milk, bread, and wheat cereals, and of dressing beef; and (3) of the costs of wholesale and retail distribution of different commodities at different times. A special inquiry into the milk industry of Queensland is briefly summarized. A bibliography is included.

What the farmers have accomplished by means of cooperation.—A brief review is given of the development and status of cooperative credit societies and organizations for the cooperative purchase of agricultural requisites, cooperative sale of agricultural produce, and direct trading relations between cooperative organizations of producers and consumers in various countries. A list of the more important publications of the Institute on cooperation in the different countries is included.

International agricultural credit.—Reconstruction of agricultural holdings, replenishing of livestock, etc., labor shortage, distribution of rural property as result of agrarian reforms, over-population of some States requiring more intensive cultivation and the industrialization of agriculture have brought about an increased demand for agricultural credit in nearly all countries and the need of an international banking organization. The International Committee of Agricultural Credit of the International Scientific Council recommends the issuance of a questionnaire and the convening of an international conference for further study. Such a questionnaire has been issued by the International Institute of Agriculture.

[Investigations in agricultural economics at the South Dakota Station, 1926], M. R. BENEDICT (*South Dakota Sta. Rpt. 1926, pp. 24-28*).—Results are given for the year ended June 30, 1926, for the following projects:

Farm organization in Brown County.—A preliminary report for the year 1925 shows that the costs of production of wheat varied from 74 cts. to \$1.65 per bushel, oats from 18 to 31 cts. per bushel, barley from 26 to 56 cts. per bushel, corn from 51 cts. to \$2.20 per bushel, butterfat from 33 to 66 cts. per pound, and pork from \$6.06 to \$28.33 per 100 lbs. Operators' earnings varied from \$723 to \$5,039 per farm, and labor and management wages from —\$1,038 to +\$3,298.

Taxation problems of agriculture.—Detailed analyses of net earnings and taxes paid for the years 1919 and 1924 in Brookings, Hamlin, Pennington, and Beadle Counties show that the taxes equaled $17\frac{1}{2}$ per cent of the average net rent from farms in 1919 and $33\frac{1}{8}$ per cent in 1924.

The trend toward a more effective use of the land as shown by the yield per acre of certain crops, B. O. WERTZ (*U. S. Dept. Agr. Bul. 1458 (1926), pp. 32, figs. 10*).—A study is made of the trend in yields of corn, wheat, oats, and potatoes in the United States since 1885 to ascertain what part of the

increased supply has been due to increased yields and what part to increased acreage. From 1885-1889 to 1920-1924, the harvested acreage of corn increased 39 per cent, wheat 67, oats 66, and potatoes 58 per cent, and notwithstanding that much of the new acreage, especially in the case of wheat, was on soils that produced yields below the average, the average yield of corn increased 4.3 bu. per acre, wheat 2, oats 3.9, and potatoes 30 bu. The combined acreage of the four crops increased 52 per cent, the combined production 77 per cent, and the composite yield, weighted by acreage, 17 per cent per acre. The trend in the combined acreage, total production, and composite yield per acre of the four crops were 90, 131, and 145 per cent, respectively, for the Middle Atlantic States; 120, 150, and 125 per cent for the east North Central States; and 87, 155, and 177 per cent for the northern section of the South Atlantic States.

It is stated that wheat yields in northwestern Europe have gradually risen from between 6 and 10 bu. per acre to 20 bu. per acre in France and to over 32 bu. per acre in England and Germany.

Land settlement in England and Wales ([*Gt. Brit.*] *Min. Agr. and Fisheries, Rpt. Proc. Small Hold. and Allot. Acts [etc.]*, 1919-1924, pp. 150, pls. 2).—This report deals with the workings of the Land Settlement (Facilities) Act, 1919, from its passage and the proceedings under the Small Holdings and Allotment Act, 1908, from 1915 to March 31, 1925.

From 1915 to 1924 the total net increase in lands acquired by purchase and lease was 249,118 acres and in the number of small holders settled 17,309. The county councils now have a rent roll of statutory small holdings of approximately £1,000,000 per year. Of the 22,000 men settled on small holdings since the Armistice, 10 to 12 per cent have left for financial reasons and may be considered failures. Only in exceptional cases have men with little or no agricultural experience succeeded. Of approximately 500 disabled men given a short course in some branch of agriculture and cottage holdings, about 25 per cent are successful and about 50 per cent have already failed and left their holdings. The capital cost of the scheme has been heavy, owing to the cost of providing cottages, buildings, roads, etc., and it was estimated that by March 31, 1926, £16,000,000 capital would have been spent, of which probably one-half will have to be written off. The average interest on capital loans has been over 6 per cent, while such estates at present can not provide a net return of more than 2 or 3 per cent on capital outlay.

Notes on some successful ex-service small holders and county and county borough reports on provisions of small holdings for ex-service men are included.

Crop insurance in relation to farm credits, S. M. THOMSON (*Manfrs. Rec.*, 90 (1926), No. 1, pp. 57-59).—The advantages, possibilities, problems, etc., of crop insurance as a protection to sources of agricultural credit are discussed. The article is based upon the study, experiments, and experience of the Hartford Fire Insurance Co. in connection with crop insurance in its southern department.

An index number of farm taxes in New York, and its relation to various other economic factors, M. S. KENDRICK (*New York Cornell Sta. Bul.* 457 (1926), pp. 47, figs. 18).—The index number of farm taxes used in this study is a simple arithmetical index based on farm taxes in 34 townships in 34 counties, the average for the period 1910-1914 being taken to equal 100.

In preparing the index number townships containing cities, incorporated villages, unincorporated villages of any size, State-owned forests, much poor or nonagricultural land, and steam or electric railroads were excluded. The taxes on public utilities following highways were deducted from the aggregate levies in the selected townships.

The accuracy of the index numbers was checked in several ways, including comparisons of indexes of school taxes in the selected townships with the cost of maintaining schools throughout the State, of computed and actual taxes in the townships for a number of years, of the index numbers computed on township and acreage basis for various years, of the soil of the selected townships with the average of the counties in which located and of the State, of the indexes and actual taxes for a period of years on farms keeping cost accounts, and of the trends and fluctuations of the index numbers for the selected townships and for all general property taxes in the State.

The general index number of farm taxes in the 34 townships increased from 55 in 1887 to 62 in 1903 (secular trend 1887-1903 +0.034), to 123 in 1916 (secular trend 1904-1916 +6.76), and to 220 in 1924 (secular trend 1916-1924 +12.38). From 1887 to 1900, 23.5 to 29.8 per cent of the general property taxes levied in the 34 townships went for county purposes, 24.4 to 31.4 for township purposes, 21.8 to 27.2 for school purposes, and 16.4 to 26.1 per cent for State purposes. From 1905 to 1924, 18.3 to 25.8 went for county purposes, 40.1 to 51.6 for township purposes, 25.3 to 34.3 for school purposes, and 0 to 9.3 per cent for State purposes.

The following table gives the index numbers of farm taxes and assessed valuations in the 34 selected townships and of wages, school teachers' salaries in New York townships, and prices:

Index numbers (1910-1914=100) of farm taxes and assessed valuations in 34 selected townships, wages, school-teachers' salaries, and prices in 1890, 1900, 1910, and 1924

	1890	1900	1910	1924
Taxes in 34 townships:				
All farms.....	64	59	82	220
County.....	85	68	93	225
Township.....	38	38	78	202
School.....	51	58	89	219
State ¹	579	425	-----	530
Assessed valuations of real and personal property in 34 townships.....	121	101	97	132
Assessed valuations of personal property in 34 townships.....	482	423	128	18
Union wages in the United States.....	71	75	96	233
Salaries of school-teachers in New York townships.....	61	69	94	² 254
Prices:				
Wholesale.....	83	83	103	153
Building materials.....	84	84	100	180
Wholesale, nonagricultural commodities.....	-----	-----	102	162
Paid to farmers in New York.....	-----	-----	101	128
Wholesale, farm products in the United States.....	70	70	103	143

¹ Wide fluctuations, with gaps in years with no State tax levied.

² 1923.

The assessed valuation of personal property as shown above not only decreased rapidly, but the number of townships assessing personal taxes decreased from 30 or more from 1887 to 1912 to 10 in 1922-1924. The receipts in the 34 townships from other sources than general property taxes increased from less than 20 per cent of such taxes in 1911 to over 49 per cent in 1924. The index numbers (1911-1914=100) of school taxes and State aid to schools in the 34 selected townships increased from 42 and 69, respectively, in 1887 to 213 and 288, respectively, in 1924.

A comparison of tax data for the 34 selected townships and those of 21 to 27 cities grouped according to size is shown in the following table:

Comparison of tax data for the 34 selected townships and those for 21 to 27 cities

	Percentage increase	
	34 townships	21 to 27 cities
Assessed value of real and personal property, 1915-1924.....	25	50-102
Estimated value of real and personal property, 1915-1924.....	34	61-130
Aggregate general property tax, 1911-1924.....	126	80-236
General property tax per capita, 1911-1920.....	136	8-132
School tax, 1911-1924.....	145	131-383
School tax per capita, 1911-1920.....	167	22-155
Receipts from State for public schools, 1911-1924.....	197	401-1,176
Receipts from State for public schools per capita, 1911-1924.....	94	65-200
Receipts from taxes on mortgages, 1911-1924.....	108	75-281

Rural taxation in the Province of New Brunswick, W. C. KEIRSTEAD (*Jour. Polit. Econ.*, 34 (1926), No. 6, pp. 669-690).—A description of the existing tax system of the Province. The weaknesses and inequalities of the present system are discussed and recommendations made for their correction.

Forecasting the price of wheat, C. C. BOSLAND (*Jour. Amer. Statis. Assoc.*, 21 (1926), No. 154, pp. 149-161, figs. 3).—World production plus carry-over was found to be the most significant factor affecting the price of wheat. A formula based on conditions prevailing from 1897 to 1914 is presented for estimating wheat prices. Using this formula the standard error of estimate for the period was 11.4 per cent, being 6.3 per cent for the 5 postwar years and 12.5 per cent for the pre-war years.

Year-to-year and seasonal fluctuations in hog prices, R. M. GREEN and H. HOWE (*Kansas Sta. Circ. 132* (1926), pp. 14, figs. 6).—A study of the fluctuations of the average monthly receipts and average monthly prices of hogs during the period 1901-1923. Between June, 1862, and the summer of 1924, the price cycle for hogs was repeated no less than 11 times, the length of the cycle varying from about 3 to about 9½ years and averaging 67 months, of which the average upward movement lasted 36 months and the average downward movement 31 months. The normal yearly trend of average monthly receipts from 1900 to 1925 at four markets divides itself into two periods, with a maximum high point in December and January and a secondary high point in May and June, with an extreme low point in September and a secondary low point in April. The average monthly prices show a distinct upward tendency from June to the maximum in August or September, a sharp decline to the minimum in December, a rise to March or April, followed by a frequent downward tendency to June. In years of big corn crops and lower corn prices there is a distinct tendency for receipts to slow up from August to January and to increase from February to August following, as compared with years of small corn crops. In the 23 years, 1901 to 1923, the monthly receipts moved contrary to the average trend 41 times and the Chicago prices 85 times.

United States standard tobacco sizes, F. B. WILKINSON (*U. S. Dept. Agr., Misc. Circ. 83* (1926), pp. II+24, figs. 12).—A simple system for sizing tobacco is outlined. The system was devised for use under the United States Warehouse Act, but is not mandatory.

Washington agriculture, Parts 4, 5 (*Wash. State Col. Ext. Bul. 134* (1926), pts. 4 pp. 35, figs. 33; 5, pp. 6).—These bulletins continue the series previously noted (*E. S. R.*, 55, p. 585) and give the data on cereal crops submitted to and the recommendations and resolutions passed by the Economic Conference held

at Spokane on June 14 and 15, 1926. Part 4 of this bulletin, by E. G. Schafer and L. Hegnauer, deals with cereal crops, and part 5 with recommendations and resolutions.

Some economic phases of the fruit industry in Rhode Island, R. B. CORBETT (*Rhode Island Sta. Bul.* 207 (1927), pp. 72, figs. 6).—This study, which is part of a general study of the New England apple industry, was undertaken to obtain data as to the varieties and ages of trees, relative importance of commercial varieties and of orchards of different sizes, the probable future production of important varieties, whether the varieties now grown are best suited to market needs, the practices in grading and packing preferred by the trade, and the consumers' knowledge of fruit and his preferences. Information was secured by personal visits in 1925 to 133 farms having orchards of 100 or more bearing trees, from retailers in Providence, and from 251 questionnaires returned by consumers in Providence. Tables are given and analyzed showing (1) the size of orchards, the number of trees by variety and age, rate of total planting, probable future production, and grades of apples grown; (2) the varieties, grades, and sizes preferred and handled by retailers, type of container preferred and quantity of apples purchased by retailers, and the sources of supply; and (3) for consumers, the sources of supply, purposes for which apples were used, varieties that could be identified, varieties of apples and peaches preferred for eating raw and for cooking, factors influencing purchases, use and consumption of apples, and storage facilities. The argument pro and con for planting McIntosh, Delicious, and Rhode Island Greening is given.

The survey shows that the production of apples in Rhode Island by 1940 can be expected to increase 22 per cent, that the production of McIntosh apples may increase 135 per cent, the Delicious apples 490, the Gravenstein 68, and the Baldwin 6.5 per cent, while the production of Wealthy apples may be expected to decrease 9 per cent and that of Rhode Island Greenings 30 per cent.

Some data are included in regard to retailers' preferences and the quantities of single purchases and sales of peaches.

The market outlet for Massachusetts apples, L. P. JEFFERSON (*Massachusetts Sta. Bul.* 231 (1927), pp. 40, figs. 7).—This study, which is part of a general cooperative study of the economic aspects of the New England apple industry, was undertaken to discover (1) the present market for New England apples, and (2) the sections where consumption could be easily increased. It is based on personal interviews with wholesalers, both exporters and domestic, and retailers, and from questionnaires sent to consumers. Tables are given showing by years the production from 1916 to 1925 of the commercial apple crops of New England, Massachusetts, New York, and Washington; the carload shipments in 1925 from different sections to 17 selected markets throughout the United States; monthly carload arrivals on the Boston market from 1920–21 to 1924–25 from the principal sources; carload arrivals in Boston from 1921 to 1925 of apples and the chief competing fruits; sources of supplies of Massachusetts retailers; types of container handled by Massachusetts retailers; grades and sizes preferred by different types of retail trade; and the production, exports, and imports of different foreign countries. A study was made of the yearly and seasonal fluctuations in prices of apples and in the prices of the Baldwin and McIntosh varieties, variety preferences, quantities, sizes, and grades preferred by customers.

Information is given as to tariffs, transportation, packing, costs, market preferences, etc., for exported apples.

The California poultry industry: A statistical study, E. C. VOORHIES (*California Sta. Bul.* 413 (1926), pp. 172, figs. 52).—Tables and charts are given and analyzed for California and the United States covering the size, distribution,

and development of the poultry industry; the production, consumption, cold-storage holdings, prices and purchasing power, exports and imports, etc., of poultry and eggs; the egg-feed price ratio; the price relationships between grades of eggs; commercial hatcheries in California; egg shipments from California; and other items. Poultry statistics are included for Canada, Mexico, China, Japan, Australia, New Zealand, and South American, European, and African countries.

Results of a study by M. W. Buster and L. W. Fluharty of the cost of producing eggs on 38 poultry farms in Sonoma County during the year ended October 31, 1925, are included.

Co-operation in the United States (*Toledo: Grain Dealers Natl. Assoc., 1925, pp. 126*).—The history, advantages and disadvantages of, and the legislation regarding cooperative organizations, especially cooperative marketing organizations, are set forth. A large part of the information is quoted from Federal and State bulletins and publications, studies and work on cooperation, and reports, etc., of cooperative organizations.

The sociology of rural life, H. B. HAWTHORN (*New York and London: Century Co., 1926, pp. [XI]+517, figs. 48*).—Socialization is held to be a fundamental problem of rural society, and the rural socialization process is considered the dynamic field of sociological study in the rural community. The interpretation, meaning, and philosophy of socialization are discussed. The social contact—the exposure or contact of a person for one hour to an event or situation having definite socializing value—is used as the standard for measuring the efficiency and economy of socialization in different communities and with different types of organization. The physiological, psychological, geographical, economic, sociological, and other factors in socialization are analyzed and the method and systems of community organization discussed.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Elements of statistics, A. L. BOWLEY (*London: P. S. King & Son; New York: Charles Scribner's Sons, 1926, 5. ed., pp. XI+463, pls. 12, figs. 25*).—The fifth edition of a work previously noted (E. S. R., 45, p. 299).

Foods and cookery, M. L. MATTHEWS (*Boston: Little, Brown & Co., 1926, rev. ed., pp. XII+297, figs. 86*).—This is a revision of a textbook previously noted (E. S. R., 45, p. 697).

The house and its care, M. L. MATTHEWS (*Boston: Little, Brown & Co., 1926, pp. XI+413, pl. 1, figs. 126*).—A textbook for senior high schools and junior colleges, including material on house planning, decoration, and furnishing, and the management of the home.

Elementary home economics, M. L. MATTHEWS (*Boston: Little, Brown & Co., 1926, rev. ed., pp. XIV+472, pl. 1, figs. 167*).—The two preceding books bound together.

A girl's problems in home economics, M. B. TRILLING and F. WILLIAMS (*Philadelphia and London: J. B. Lippincott Co., 1926, pp. [3]+314, figs. [163]*).—A textbook for use in junior high schools or beginning high-school grades. The subject matter selected is based upon the particular interests of girls in junior high schools and lower high-school grades, and covers healthful clothing, dress design, clothing construction, interior decoration, household textiles, and the care of the home.

The home project: Its use in home-making education, G. FISHER (*Fed. Bd. Vocat. Ed. Bul. 71, rev. ed. (1926), pp. VII+95*).—A revision of a bulletin previously noted (E. S. R., 46, p. 296).

Boys, and girls, 4-H club work under the Smith-Lever Act, 1914–1924, G. E. FARRELL (*U. S. Dept. Agr., Misc. Circ. 85 (1926), pp. II+55, figs. 17*).—The early history of the club movement and the growth of the movement and of demonstrations from 1914 to 1924 are described and statistics given on enrollment, projects, demonstrations, results, etc. In 1924, 510,355 different boys and girls were enrolled in 38,120 clubs, and 283,283 completed the work. Since the passage of the Smith-Lever Act, 5,000,000 boys and girls have received definite instruction and practice in 4-H clubs.

FOODS—HUMAN NUTRITION

What is what in groceries, A. TODOROFF (*Chicago: Grocery Trade Pub. House, 1926, pp. 208, pls. 16, figs. 15*).—By means of questions and answers useful information is given on a wide variety of food products entering into the grocery trade, including their production and preparation for market, definitions and trade names, and standard grades and sizes of canned goods.

The household preservation of eggs, F. T. SHUTT (*Canada Expt. Farms Circ. 31 (1926), pp. 2*).—While admitting that “nothing has been discovered that will serve to retain without a suspicion of taint the fine flavor of the strictly newlaid egg,” the author is of the opinion that limewater is a reliable home preservative of eggs and is superior in some respects to water glass. The limewater should be prepared by slaking freshly burned quicklime, thinning with water to the consistency of cream, and further diluting, with constant stirring, to the desired volume (1 lb. of quicklime to 5 gal. of water). The solution may be used without settling, or allowed to stand for an hour or more and the clear liquid decanted from the excess lime. The eggs in any suitable clean receptacle should be covered with limewater and stored in a cool place. Salt should not be added to the limewater.

Salads all the year, D. A. LOUDON (*N. Dak. Agr. Col. Ext. Circ. 72 (1926), pp. 30*).—This circular contains a serviceable collection of recipes for salad dressings and salads, the latter being selected with particular reference to securing combinations high in vitamin content and utilizing foods, particularly vegetables, common to North Dakota.

Studies of basal metabolism in New Orleans, R. HAFKESBRING and P. BORGSTROM (*Amer. Jour. Physiol., 79 (1926), No. 1, pp. 221–228, fig. 1*).—In this and the following three papers are reported various phases of a general study of metabolism in New Orleans as representative of semitropical climate. A series of 89 basal metabolism determinations was made on 9 subjects (7 men and 2 women) at approximately 1½-hour intervals from 13.5 to 19 or 20 hours after the preceding meals, which varied in kind and quantity.

The results, calculated in calories per square meter of body surface (Du Bois formula), showed in nearly every case a definite drop to a minimum, followed by a rather sharp rise to values in some cases above the values first obtained. The minimum values tended to be approximately the same for each subject, but the time at which they occurred was dependent upon the kind and quantity of the food eaten. The minimum values for all of the subjects were lower than the Du Bois, Harris-Benedict, and Dreyer standards, the average deviations from these standards being –18, –16, and –14 per cent, respectively.

These results are considered of significance in suggesting a lowered basal metabolism in semitropical climates. “It has been shown that the protein intake in New Orleans is approximately 60 per cent of that of the northern standards, and whether this is one of the factors for a lowered metabolism remains to be studied. The whole subject of metabolism in tropical and semi-

tropical climates is one that is much in need of investigation, and the validity of applying standards which have been determined in temperate climates is open to question."

Study of the protein intake as indicated by urinary nitrogen, P. BORGSTROM and R. W. BOST (*Amer. Jour. Physiol.*, 79 (1926), No. 1, pp. 229-236, figs. 2).—Two of the male subjects of the preceding study served as subjects in the present study in which daily determinations of urinary nitrogen were made for a year. During this period one of the subjects was in North Carolina during June, July, and August and the rest of the time in New Orleans. The other subject was in New Orleans the entire time.

The range in daily urinary excretion was from 8.8 to 13.59 gm. per kilogram of body weight for the first subject and from 8.33 to 11.44 gm. for the second. Some daily variations were shown which were thought to be due to variations in the amount of exercise. There was also some seasonal variation in the second subject while living at home but questionable variation when eating at the boarding house. Climatic conditions are thought to be the probable cause for the lowered protein intake.

Dietary studies in New Orleans in 1925, P. BORGSTROM, R. W. BOST, and R. HAFKESBRING (*Amer. Jour. Physiol.*, 79 (1926), No. 1, pp. 237-241).—In this attempt to determine the number of calories eaten by a normal individual in a warm climate, three of the subjects of the foregoing studies lived for several days on weighed diets of apples, bananas, bread, butter, cheese, eggs, milk, oatmeal, potatoes, sugar, and ripe tomatoes. The amounts eaten by each were such as to satisfy the appetite, adjustment being made where necessary. It is noted, however, that at the end of the experiment the subjects felt that they had been eating more than a normal amount. The diets were calculated daily for fat, carbohydrate, protein, and calories and the amounts averaged after five days. Two five-day periods in August and September were reported for two of the subjects and one for the third. Urinary nitrogen determinations were included.

In the September period the total calories per 70 kg. of body weight for the three subjects were 3,410, 2,580, and 4,050, respectively. The distribution of calories was fat 40.8, 28.1, and 32.6 per cent and protein 12.4, 11.6, and 12 per cent, respectively. In all cases the urinary nitrogen was higher than accepted normal values. Assuming that this represented a food intake above normal, a recalculation of the energy values was made. The corrected or assumed normal values were 2,530, 2,380, and 2,730 calories, respectively. The basal metabolism figures for the three subjects were 1,325, 1,400, and 1,395 calories, respectively. It is pointed out that the average of the normal calculated values was about twice the average of the basal requirement.

The data are thought to indicate that the calorific intake in the south does not vary much from that of the north, but that the protein intake is lower.

Effect of increased diet on basal metabolism in New Orleans, P. BORGSTROM, R. HAFKESBRING, and R. W. BOST (*Amer. Jour. Physiol.*, 79 (1926), No. 1, pp. 245-253, figs. 2).—Basal metabolism experiments were conducted on five subjects, four men and one woman, of the preceding metabolism study of Hafkesbring and Borgstrom and on one additional woman subject at about the same time after meals varying widely in caloric value as determined for the most part by fluctuating urinary nitrogen.

With increased food intake there was a large fluctuation in basal metabolism, the first change occurring being a marked decrease in oxygen consumption, with fairly constant values of carbon dioxide. When the increased food intake was maintained at a fairly constant level the values of oxygen consumption

gradually returned to normal, but with another change in diet the same phenomenon occurred.

Several possible causes for these fluctuations are discussed, and the question is raised as to whether the phenomenon is general or is characteristic of warmer climates with lowered basal metabolism.

The straight and narrow path to normal weight, H. H. MITCHELL (*Sci. Amer.*, 136 (1927), No. 2, pp. 110, 111, fig. 1).—A popular discussion of the most advisable methods of reducing weight by diet restrictions.

Growth and reproduction on synthetic diets, Part I, G. A. HARTWELL (*Biochem. Jour.*, 20 (1926), No. 6, pp. 1273-1278, fig. 1).—In an effort to obtain more satisfactory synthetic diets for nutrition experiments with rats, six diets composed of practically the same constituents in various combinations and all prepared by the cooked method (*E. S. R.*, 55, p. 411) were tested on young rats, starting at 23 days of age and continuing for over a year.

Good but not maximal growth was obtained with all of the diets. One gave almost as good growth as a mixed diet but was inadequate for reproduction, while another gave less satisfactory growth but good reproduction. The diet giving a growth curve corresponding most closely to the mixed food curve consisted of caseinogen (purified from vitamins A and B) 20 gm., pure potato starch 64 gm., cod-liver oil 4 and cottonseed oil 10 cc. (both of which were replaced after 4 weeks by butter 12 gm.), Hartwell's salt mixture 4 gm., marmite 5 gm., and water 300 cc.

Growth in children with diabetes mellitus, W. S. LADD (*Amer. Jour. Diseases Children*, 32 (1926), No. 6, pp. 812-838, figs. 13).—The histories of 34 cases of diabetes mellitus and 1 case of possible renal diabetes in children varying in age from less than a year to 20 years are discussed with reference to well-known standards of growth and food intake.

At the onset of the disease all but 4 of the patients were either overweight or overheight for age or both. During the progress of the disease, except under insulin treatment, growth in height diminished or ceased entirely. The impulse for growth in height persisted longer and was slower in starting again than the impulse for changes in weight. Under insulin treatment growth followed. The optimum weight for the diabetic child is considered to be the average weight for height as expressed in the Bardeen growth curve of normal children, and the optimum food intake to be about two-thirds of the total calories of the Holt and Fales standards (*E. S. R.*, 48, p. 654). The average proportions of carbohydrate, protein, and fat in the diets employed were 35, 15, and 50 per cent, respectively, of the total calories. It is pointed out, however, that this is not necessarily the best proportion, and that in some cases proportions nearer the normal according to the Holt and Fales standards may yield excellent results.

A comparison of the effects of supplementary feeding of fruits and milk on the growth of children, A. F. MORGAN, G. D. HATFIELD, and M. A. TANNER (*Amer. Jour. Diseases Children*, 32 (1926), No. 6, pp. 839-849).—In this comparison of the value of milk, orange, and figs as supplementary lunches, 47 children from the California State School for the Deaf and Blind were divided into two groups of 13 each, one of 10, and a control group of 11. All received the usual diet, supplemented in one group by $\frac{1}{2}$ pint of milk, another by 1 medium orange, and another by 4 pulled figs. During the 18 weeks of the experiment the children were repeatedly examined by the Baldwin-Wood, Pirquet, and Dreyer methods.

At the end of 14 weeks the milk, orange, and fig groups had shown almost the same amount of improvement, and the control group only about one-fourth

as much as judged by the Baldwin-Wood standard. As judged by the Pirquet sitting height-body weight standard, the orange group showed the greatest gain, followed by the fig and control groups with about one-half as much, while the milk group had fallen off a little. By the Dreyer chest circumference-sitting height standard the orange group led, followed by the control and milk groups, with the fig group least. The average gains by all three standards were highest for the orange group, followed in decreasing order by the fig, milk, and control groups. The gross average gain in weight was largest for the milk group, and the average percentage gain in weight above the expected gain according to the Holt standards was highest for the orange and milk groups.

At the end of this period 7 of the children were changed from the milk to the orange lunch and 7 from the orange to the milk and the feeding continued for 4 weeks longer. During this time the rate of gain in weight was decreased in those changed from orange to milk but very little affected in the other group. "The percentage of the original groups showing increases after 14 weeks in standing and sitting heights was greatest in the milk group, in chest circumference, chest expansion, and vital capacity in the fig group, and in hand-grip strength in the orange group. Of these six measurements, real differences in proportion of increase are thought to be shown only in sitting height in which the milk group excelled, and in chest circumference, chest expansion, and vital capacity in all of which the fig group excelled. The average of all measurements showed the number of increases in the fig group to be the largest."

The effect of fat on the tryptic digestion of protein in vitro, M. MAUGHAN (*Biochem. Jour.*, 20 (1926), No. 5, pp. 1046-1051, figs. 3).—In this study a solution of egg albumin, pH 1.7, previously digested with pepsin for 24 hours at 37° C. was subjected to trypsin digestion in M/10 buffer solution of sodium phosphates, starting at pH 8, in the presence of a gum acacia emulsion of olive oil. A control experiment was run with the oil omitted, and the rate of trypsin digestion in both was determined by the Sørensen formol titration method. In the adjustment of the H-ion concentration, two methods were used, in the first of which the control mixture was brought to pH 8 by the addition of the sodium hydroxide solution and an equal volume of sodium hydroxide solution was added to the emulsion mixture. In the second both the control mixture and the emulsion mixture were brought to pH 8.

In the first method the variations which occurred were almost all within the limits of experimental error, although a slight accelerating effect of the fat emulsion was evident in every case. This acceleration increased as digestion proceeded but never exceeded 10 per cent. In the other method no definite effect of the olive oil was observed, but a higher pH was recorded in the concentrations of oil in which variations in pH could be detected.

Various factors are suggested as affecting the rate of digestion of such mixtures. "At the present stage it is impossible to say how far each of these factors is concerned, but the gross results of the foregoing experiments show that olive oil, unhydrolyzed and in the form of an emulsion, does not retard the action of trypsin in vitro on albumin previously digested with pepsin. The explanation of the retarding action of fat on the digestion of protein in vivo may be found either in the action of the products of the hydrolysis of fat or in some specific action of fat in the alimentary canal."

The physiological rôle of vitamin B, I, II (*Biochem. Jour.*, 20 (1926), No. 6, pp. 1229-1263, figs. 13).—Two papers are presented.

I. *The relation of vitamin B to tissue oxidations*, J. C. Drummond and G. F. Marrian (pp. 1229-1255).—The extensive and conflicting literature on the possible relationship of vitamin B to the oxidative activity of animal tissues and

on the general problem of the physiological rôle of vitamin B has been reviewed critically, with a repetition of much of the experimental work under carefully controlled conditions.

Evidence is first presented that absence of vitamin B brings about no reduction in the oxidative activity of excised muscle and liver tissue of rats and pigeons, as determined either by the rate of reduction of methylene blue or direct measurement of the oxygen consumption. Determinations of the oxygen consumption of rats during progressive vitamin B deprivation indicated that the consumption remains at a normal level until the final phase of the disturbance, which is characterized by a sharp fall of body weight, rectal temperature, and oxygen consumption. Parallel experiments conducted on rats receiving from 0.5 to 1 gm. of yeast extract as their sole food gave identical results, from which the conclusion is drawn that the fall of body temperature and oxygen consumption are the result of an exhaustion of reserve food materials and not of failure of the oxidative mechanism of the tissue. Further evidence of the similarity of the symptoms of extreme vitamin B deprivation and simple inanition was furnished by the fact that in both cases temporary recovery followed an artificial increase in body temperature brought about by warming the animal. Moreover, the concentration of reducing substances in the blood of rats suffering from inanition and vitamin B deficiency followed the same course—hyperglycemia (associated with hypertrophy of the adrenal glands), followed by a sharp fall to values below the normal level at the time of decreased body temperature and oxygen consumption.

In the authors' opinion the explanation of the physiological effects of vitamin B is to be sought in the relation of vitamin B to appetite as pointed out by Osborne and Mendel (*E. S. R.*, 38, p. 568) and confirmed by Karr (*E. S. R.*, 44, p. 860) and by Cowgill and his coworkers (*E. S. R.*, 54, p. 194), and the resulting quantitative relationship between the amount of vitamin B and the total food intake.

II. *Relation between vitamin B and protein in the diet of growing rats*, V. Reader and J. C. Drummond (pp. 1256-1263).—In the experimental work reported in this paper, young rats of approximately 50 gm. weight were fed in one series diets the composition of which was so adjusted as to give similar ratios between the amount of protein and yeast (as a source of vitamin B) but of different caloric value, and in another series diets composed of the same materials so adjusted as to give the same proportion of protein, with varying amounts of vitamin B. The object of these variations was to determine whether there is a quantitative relationship between vitamin B and total calories or between vitamin B and protein as shown by growth records.

The growth curves and food consumption records over a period of several weeks showed in the first series no correlation between the total calories or carbohydrate content of the diet and the vitamin B. In the second series, with the protein fixed at 70 per cent of caseinogen and the vitamin B varying from 4 to 20 per cent of yeast extract, a normal rate of growth was attained only with at least 16 per cent of yeast extract. Varying fat content was without effect.

In all the groups the ratio between the weight of thyroid and total body weight was within the normal limits given by Donaldson. On the low vitamin B-high protein diets the kidneys were hypertrophied, but there was no destruction of kidney tissue.

The quantitative relation between protein and vitamin B thus demonstrated confirms the views of Hartwell (*E. S. R.*, 55, p. 694), and appears to offer an explanation of the inadequacy for growth of the high protein diets previously employed by the authors (*E. S. R.*, 53, p. 863).

Gaseous metabolism in the final state of B avitaminosis in birds [trans. title], B. A. LAWROW and S. N. MATZKO (*Biochem. Ztschr.*, 179 (1926), No. 4-6, pp. 332-347, figs. 3).—This paper also summarizes the conflicting literature on the effect of lack of vitamin B on the oxidation processes in the body, and reports a series of gaseous metabolism experiments conducted on two fowls before and during polyneuritis. The data reported indicate no alteration in the oxygen consumption per kilogram of body weight with the onset of polyneuritis, but a slight increase in carbon dioxide production resulting in a higher respiration coefficient.

The authors reached the same conclusion as Drummond and Marrian that the final lowering of gaseous metabolism in polyneuritis is the result not of a lowering of the oxidative power of the organism but of starvation.

Yeast extract as a supplement to gelatin, G. A. HARTWELL (*Biochem. Jour.*, 20 (1926), No. 6, pp. 1279-1281, fig. 1).—Growth experiments with rats are reported which indicate that yeast extract, marmite, has a supplementing effect for gelatin unrelated to its content of vitamin B.

Vitamin content of canned spinach, E. PIERSON (*South Dakota Sta. Rpt.* 1926, p. 23).—Ten gm. of spinach canned by blanching for 15 minutes in steam and processing for 90 minutes in the pressure cooker at 15 lbs. pressure failed to delay the onset of scurvy or prolong the lives of guinea pigs on the basal scorbutic ration of Sherman, La Mer, and Campbell. Animals receiving the same amount of spinach steamed for 15 minutes developed scurvy at an early date, but lived somewhat longer than those receiving the pressure-cooked spinach. This is thought to indicate that the greater part of the vitamin C in the spinach is destroyed in the blanching process.

The vitamin C of lemon rind, S. G. WILLIMOTT and F. WOKES (*Biochem. Jour.*, 20 (1926), No. 5, pp. 1013-1015).—In continuation of the studies on citrus fruits (E. S. R., 55, p. 593), data are given on the vitamin C content of lemon rind as determined on guinea pigs by the preventive method.

The extract prepared as described in the previous study, but concentrated to such an extent that 1 cc. represented 1 gm. of the rind, was fed to three groups of 4 guinea pigs each in amounts of 0.5, 0.75, and 1 cc. daily as supplement to a basal diet of bran and oats, 2:1, supplemented by 50 cc. daily of fresh milk autoclaved at 15 lbs. pressure for one hour. None of these amounts furnished sufficient vitamin C to prevent the development of scurvy.

It is concluded that the protective dose of fresh lemon flavedo must be much larger than that reported for fresh orange peel by Hess and Unger (E. S. R., 39, p. 771).

A reliable specific ration for experimental scurvy [trans. title], N. BEZSSONOFF (*Compt. Rend. Acad. Sci. [Paris]*, 183 (1926), No. 20, pp. 921-923).—In the opinion of the author the inclusion of autoclaved milk in a basal scorbutic ration, as proposed by Chick and Hume and used by many workers, is open to criticism on account of the variable but appreciable amounts of vitamin C which may be present in the milk. In his experience 22 per cent of the guinea pigs placed on this ration survived to the fortieth and 7 per cent to the fiftieth day. As a substitute for the milk fresh egg yolk is suggested. On a basal diet composed of 900 gm. of oats mixed by hand with 100 gm. of bran, 40 gm. of fresh yeast, and 75 gm. of egg yolk emulsified with 125 cc. of water, guinea pigs are said to succumb without exception before the thirty-third day. Using this ration, the minimum antiscorbutic dose of fresh lemon juice for a 400-gm. guinea pig was found to be 3 cc., as compared with 1.5 cc. reported by Chick and Rhodes and by Davey (E. S. R., 45, p. 869) with the use of the other ration.

Distribution of endemic goiter in the United States as shown by thyroid surveys, R. OLESEN (*Pub. Health Rpts. [U. S.]*, 41 (1926), No. 48, pp. 2691-2703).—This summary of the distribution of endemic goiter in the United States, as shown by thyroid surveys in 40 States, indicates foci of endemic goiter in localities not previously regarded as being located in goitrous territory. In the opinion of the author, however, the incidence of goiter is not so universal as to require wholesale prophylaxis in all States.

TEXTILES AND CLOTHING

Textiles and the new generation, E. W. CAMP ET AL. (*Lubbock, Tex.: Tex. Technol. Col.*, 1927, pp. 47, figs. 48).—This pamphlet is descriptive of the textile activities, aims, and equipment of the Texas Technological College and points out opportunities in the textile field.

South American wools, H. KENNINGHAM (*Jour. Textile Inst.*, 18 (1927), No. 2, pp. T81-T98, pls. 4, figs. 8).—The status of wool production in the South American countries is summarized, and typical wools are described and illustrated.

Effect of alkalis on wool.—II, Experiments comparing effects of sodium compounds, potassium compounds, and temperature, H. C. CHAPIN (*Amer. Dyestuffs Rptr.*, 16 (1927), No. 2, pp. 90-94).—In further studies (E. S. R., 54, p. 596) at the Lowell Textile School the strength of wool was measured before and after treatment with water, alkali carbonate solutions, and soap solutions at about 50° C. (122° F.).

Conclusions applicable only to action within the bath were that the effects of small changes in treatment were so apparent as to justify use of weakening effect as a measure of surface harshening effect, provided only that some direct connection exists between the two. In solutions of equal molecular concentration sodium carbonate and potassium carbonate had equal weakening effect. Sodium soap was small in effect compared with that of the hot water in which it is dissolved and much smaller than that of 0.1 N sodium carbonate or potassium carbonate solution. A soap which weakens wool in water alone may in solution with alkali carbonate reduce the weakening effect of the carbonate. A rise of 1° in scouring temperature had about the same weakening effect on wool as an increase of 25 per cent in carbonate concentration when the temperature is near 50° and carbonate concentration near 0.2 N. For control of scouring bath alkalinity with delicacy equivalent to that of observation of effects on wool pH should be carefully measured to within a few hundredths of a unit, although rougher measurements might serve to indicate wide departure from desired conditions.

The structure and development of the cell wall in plants.—I, Bast fibers of Boehmeria and Linum, V. C. ALDABA (*Amer. Jour. Bot.*, 14 (1927), No. 1, pp. 16-24, pls. 3).—According to studies reported on from the Bussey Institution of Harvard University, the bast fibers of *B. nivea* may attain a length of more than 550 mm. The processes of cell enlargement and of cell wall differentiation occur simultaneously in the bast fibers of *B. nivea* and *L. usitatissimum*. The elongating apical portion of an actively growing fiber is invested solely by a tenuous, hyaline membrane which is in direct continuity with the outermost lamella of the thick wall jacketing the basal portion of the fiber. The development of the cell wall and fiber is outlined.

The distribution of nitrogen in the flax plant and its elimination from flax in the processes of manufacture, J. W. PORTER (*Jour. Soc. Chem. Indus.*, 45 (1926), No. 39, pp. 335T-337T).—The nitrogen content of flax seed ranged

from 2.5 to 3 per cent in the samples examined. The chaff contained 0.538 per cent, which would add to the value of the seed for feeding. There was a gradual increase in the nitrogen content of the stem from the root up, i. e., root ends 0.256, middles 0.342, and tops 0.455 per cent, with a mean of 0.348 per cent. The branched portion of the stem had a rather high nitrogen content, 0.832 per cent. The bulk of the nitrogen appeared to be associated with the cortex, and the nitrogen in the other portions of the flax plant seems due to adhering cortex.

Tracing Irish flax straw through various stages of manufacture from retting to bleaching gave considerable information on changes occurring, especially in the bleaching process. The difficulty of bleaching linen lies in the resistant nature of the cortex. Its potassium and phosphorus contents give the cortex a certain value for fertilizer.

Chemistry of pulping flax straw, M. W. BRAY and C. E. PETERSON (*Indus. and Engin. Chem.*, 19 (1927), No. 3, pp. 371, 372, fig. 1).—The action of sodium sulfite solution upon flax straw grown for seed purposes at two concentrations of chemical and at two ratios of chemical to oven-dry material under cooking conditions otherwise constant has been studied at the U. S. Forest Products Laboratory at Madison, Wis. A change of concentration of the sodium sulfite solution from 40 to 80 gm. per liter seemed to have little effect on time of cooking or upon the relation of chemical properties of the fibrous residue to yield, whereas a change in the ratio of chemical to straw from 20 to 40 per cent by weight greatly accelerated the rate of cooking. The progress and results of the reaction are outlined.

The specific volume of cotton cellulose, G. F. DAVIDSON (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 6 (1927), No. 3, pp. 41-52, figs. 2).—The specific volumes at 20° C., as determined in helium, were for American upland 85R soda boiled 0.638 and mercerized 0.645, Sea Island 0.642 and 0.647, and Sakel 0.64 and 0.645, respectively, viscose rayon 0.646, cuprammonium rayon 0.653, and nitro rayon 0.648. In every case the helium value was about 1 per cent lower and the water value from 3 to 5 per cent lower than the toluene value. The methods are outlined briefly.

MISCELLANEOUS

Research and experiment-station activities [of the New York State College of Agriculture at Cornell University, 1926], R. W. THATCHER (*N. Y. Agr. Col. (Cornell) Ann. Rpt.*, 39 (1926), pp. 15-31, 69).—An account of the research activities of the year, including the operations of the Cornell Experiment Station and its receipts and expenditures from the Federal funds, is presented for the fiscal year ended June 30, 1926.

Annual Report of [South Dakota Station], 1926, J. W. WILSON ET AL. (*South Dakota Sta. Rpt. 1926*, pp. 39).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1926, and department reports on the work of the station during the year. The experimental work reported is for the most part abstracted elsewhere in this issue.

Abstracts of Bulletins 328-346 and Circulars 32-42, A. D. JACKSON (*Texas Sta. Circ. 44 (1927)*, pp. 18).—The publications abstracted have been previously noted.

Publications for free distribution to farmers (*Vermont Sta. Circ. 12 (1924)*, pp. 2).—The available bulletins serviceable to farmers are listed.

NOTES

California University and Station.—The budget of the university for the ensuing biennium, as just passed by the legislature, carries an appropriation of \$300,000 for the construction and equipment of an animal science building for the branch of the College of Agriculture at Davis.

According to a note in *Science*, Dean and Director E. D. Merrill has been appointed director of the California Botanic Garden at Los Angeles, beginning June 1, on a partial leave of absence from the university. This enterprise is under the direction of the Garden Foundation, Incorporated, a nonprofit, nonstock corporation organized for scientific, educational, and charitable purposes. A tract of about 3,200 acres of land located in and around Mandeville Canyon is available, of which about 2,400 acres will be sold for residential purposes and the profits accruing utilized as the endowment fund of the institution and in the development of the remaining 800 acres as a botanical garden.

Georgia Station.—A manufacturer of peanut products has become interested in the breeding of a better type of peanut, and is contributing the salary and operating expenses of one member of the station staff to devote his entire time to research in peanut breeding.

Purdue University and Station.—During the next two years the station will receive in addition to its general maintenance funds a State appropriation of \$70,000 for a research unit of the agricultural engineering building and \$25,000 for an addition to the poultry building. In an act for combating the European corn borer \$75,000 was included for the station for research and demonstration work with the borer and the codling moth. George A. Ficht, who for two seasons has been in charge of the Dominion Corn Borer Laboratory in Ontario, has been appointed assistant entomologist for research on the borer, while Loren F. Steiner has been appointed assistant entomologist to carry on codling moth studies in an extensive way in southern Indiana orchards.

A corn borer exhibit train was operated in northern Indiana by the university in cooperation with the U. S. Department of Agriculture and the Pennsylvania Railroad from March 28 to April 8. Two cars were used, one for exhibits and one for lectures and moving pictures. At 26 stops, 6,614 people visited the train, which formed a part of the educational campaign which is being waged by the university and the Department to acquaint farmers with the seriousness of the corn borer situation.

A farm electric car equipped with electrical appliances suitable for farm and home use and operated by the university in cooperation with the principal traction companies of the State recently completed a tour of 48 counties over electric lines, covering a distance of 2,526 miles. The car was on the road 51 days, made 182 stops, and was visited by 27,034 people.

Laurenz Greene, head of the department of horticulture, has been granted sabbatical leave for one year to be spent at the University of California and in a study of the fruit and vegetable marketing problems of the Pacific coast.

Iowa College and Station.—Four new buildings are soon to be erected for the use of the college and station from a State appropriation just granted by the legislature. A new dairy manufacturing building will be erected and equipped at a cost of \$500,000, and \$150,000 will be used for erecting a new

feed storage barn, a horticultural crop storage building, and a storage building for the agronomy section.

Dr. H. E. Bemis, head of the college veterinary surgery department and vice dean of the veterinary division, has resigned to become head of the veterinary surgery work at the University of Pennsylvania. Dr. Charles S. Reddy, associate pathologist in the U. S. D. A. Bureau of Plant Industry, has accepted a position as assistant professor in the division of botany and plant pathology.

Massachusetts College.—President Edward M. Lewis has accepted the presidency of the University of New Hampshire and will enter upon his new duties September 1.

Montana College and Station.—President A. Atkinson has been granted leave of absence for study during the next college year. Dean and Director F. B. Linfield has been appointed acting president in his absence. Dr. Arnold H. Johnson, assistant chemist in the station, has also been granted leave of absence for one year to accept a fellowship for study in Europe given by the International Education Board.

C. N. Arnett, head of the department of animal husbandry and vice dean of agriculture, has resigned, effective September 1, to devote himself to his livestock interests.

New York State Station.—The 1927 legislature appropriated \$18,000 for special investigations on nursery stock production in New York in anticipation of the Federal quarantine on imported nursery stock to go into effect in 1930. H. B. Tukey, associate in research (horticulture) in charge of the Hudson River Valley fruit investigations of the station, has been appointed acting chief in research (horticulture) and given charge of the nursery investigations with headquarters at Geneva, part of the appropriation having been made immediately available. L. C. Anderson, county agent for Rockland County, has been appointed associate in research (horticulture) to succeed Mr. Tukey at Hudson, beginning May 1.

Frank J. Kokoski, analyst with the Massachusetts Station, has been appointed assistant in research (chemistry) to fill the vacancy caused by the resignation of R. B. Dayton, previously noted.

Under the auspices of several representatives of the electric light industry a series of investigations are to be begun this spring on the attracting of orchard pests by light. The work will involve both field and laboratory observations. An effort is to be made to get at some of the fundamental principles involved in light attraction of insects, and the cooperation of physicists from Cornell University has been secured to aid the entomologist of this station in the interpretation of their results. Lights of different intensities and colors are to be used, the observations continuing until harvest in the station orchards. The studies this season are regarded as largely preliminary, and continuation of the work will depend on the possibilities for practical results that may be obtained.

Wisconsin University.—Walter A. Duffy, who has been in the county agent service of the institution since 1920, became State commissioner of agriculture on April 1. It is thought that his appointment will insure a continuation of the close cooperation which has always been maintained between the college and the State Department of Agriculture in all movements for agricultural betterment in the State.

EDITORIAL DEPARTMENTS

Agricultural and Biological Chemistry—H. C. WATERMAN.
Meteorology—W. H. BEAL.
Soils and Fertilizers—H. C. WATERMAN.
Agricultural Botany and Diseases of Plants—W. H. EVANS, Ph. D., W. E. BOYD.
Genetics—H. M. STEECE, J. W. WELLINGTON, G. HAINES.
Field Crops—H. M. STEECE.
Horticulture and Forestry—J. W. WELLINGTON.
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.
Animal Husbandry, Dairying, and Dairy Farming—H. W. MARSTON.
Veterinary Medicine—W. A. HOOKER.
Agricultural Engineering—R. W. TRULLINGER.
Rural Economics and Sociology, Agricultural and Home Economics Education—
F. G. HARDEN.
Foods and Human Nutrition—SYBIL L. SMITH.
Textiles and Clothing—H. M. STEECE, SYBIL L. SMITH.
Home Management and Equipment—R. W. TRULLINGER, F. G. HARDEN.
Indexes—MARTHA C. GUNDLACH.
Bibliographies—ANNA HOWARD.

CONTENTS OF VOL. 56, NO. 8

Editorial notes:	Page
The first twenty years under the Adams Act.....	701
Recent work in agricultural science.....	708
Notes	798

SUBJECT LIST OF ABSTRACTS

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The proteins of green forage plants, I-IV, Davies.....	708
On the phosphorus nucleus of casein, Posternak.....	709
A study of the effect of heat upon wheat and flour, Kent-Jones.....	710
The chemical composition of Tunisian olive oil, Jamieson et al.....	710
Method for determining the phosphoric acid requirements of soils, Némec.....	710
Determination of arginine in proteins and tissues, Bonot and Cahn.....	710
The preservative action in catsup of salt, sugar, benzoate, and acid, Pederson and Breed.....	711
How to make and preserve cider, Fabian.....	711
Determination of the isoelectric point of wool and silk, Meunier and Rey.....	712
Waste sulphite liquor as an agricultural spray, Fleming and Reedy.....	712

METEOROLOGY

The Brückner cycle in the United States, Henry.....	712
Effect of local influences on general atmospheric conditions, Smith.....	712
Monthly Weather Review, [November-December, 1926].....	713

	Page
Climatological data for the United States, [November-December, 1926]--	713
The weather of 1926-----	713
Weather and hay in New York State, Mattice-----	714

SOILS—FERTILIZERS

Soil conditions and plant growth, Russell-----	714
[Soil and fertilizer work at the Wisconsin Station, 1924-1926]-----	714
Soil survey of Reeves County, Texas, Beck and Strike-----	716
Agricultural characteristics of the soils of the Saratov region, Kuz'min--	716
Black and white alkali soils of Asiatic Siberia and Turkestan, Glinka---	716
The contraction and expansion of soils when wetted, Bouyoucos-----	717
The moisture equivalent of heavy soils, II, Joseph-----	717
Effects of some electrolytes on kaolin and relation to the soil, Skeen---	717
Differences in the heat of reaction between artificial and soil gels of silica, alumina, and iron, with hydroxide, Bouyoucos-----	718
Fertility as related to forms of iron and manganese, Brewer and Carr---	718
Testing soils for acidity by the modified Comber method, Miller-----	718
The organic matter in heavy alkaline soils, Joseph and Whitfeild-----	718
The bacterial flora of serpentine soils, Lipman-----	719
Humus in Assam soils: Its depletion and recuperation, Mitra and Phukan--	719
[Soil fertility studies at the Arizona Station], Catlin and Vinson-----	719
Experiments in manuring, Harold-----	719
Note on the action of hydrogen peroxide on farmyard manure, Jones-----	719
Fertilizers, Voorhees, rev. by Haskell-----	720
Fertilizers: Their sources, manufacture, and uses, Cave-----	720
World conditions as to raw materials for the fertilizer industry-----	720
Factors influencing the efficiency of nitrogen, I, Smith-----	720
Potassium content of plants as an indicator of soil, Ames and Gerdel---	720
Losses of added phosphate by leaching from soils, Robinson and Jones---	721
Organic matter changes in two soil zones, as influenced by calcic and magnesian materials, MacIntire et al-----	721
Outgo of calcium, magnesium, nitrates, and sulfates from high-calcic and high-magnesian limes incorporated in two soil zones, MacIntire---	721
Composition of commercial fertilizers in New York in 1926, Van Slyke---	722

AGRICULTURAL BOTANY

Dictionary of botany, Gatin-----	722
Plant physiology in relation to agronomy, Harrison-----	722
A plant photometer, Johnston-----	723
A method of growing bacteriologically sterile potato plants, MacMillan---	723
The extraction of plant tissue fluids and their utility, Newton et al-----	723
Some protein properties of plant protoplasm, Pearsall and Ewing-----	723
The significance of soil colloids in relation to plant feeding, Truog-----	723
Nutrition of plants in relation to soil solution, I, II, Hoagland-----	723
Adjustment of iron supply to requirements of soy bean, Marsh and Shive--	723
The tolerance of plants for NaCl, Lipman et al-----	724
The absorption of water by the leaves in the genus <i>Atriplex</i> , Wood-----	724
Chlorophyll defect in barley, Honecker-----	724
Plant nutrition research-----	724
The development of sugar beets during the second year, Stehlik-----	725
Influence of time of threshing on germinability of grain, Morettini-----	725
Catalase activity and the germination of rice, Morinaga-----	725
The hydrostatic system of trees, MacDougal-----	725
Symbiosis in a deciduous forest, II, McDougall-----	726
The nutrition of mycorrhiza plants: <i>Calluna vulgaris</i> , Rayner-----	726
Some observations on the growth of yeast, Fulmer-----	726
Violent spore-discharge in <i>Tilletia tritici</i> , Buller and Vanterpool-----	726
Heterothallism in the genus <i>Penicillium</i> .—A preliminary note, Derx-----	727

GENETICS

The problem of the origin of species as it appeared to Darwin in 1859 and as it appears to us to-day, Osborn-----	727
Cell division from the physiological point of view, Gurwitsch-----	727

Page

Chromosome and gene mutations in <i>Datura</i> following exposure to radium rays, Gager and Blakeslee.....	727
The chromosomal constitution of Nubbin, Blakeslee.....	727
Chromosome behavior in <i>Oenothera lamarckiana</i> , Håkansson.....	727
The chromosomes of rodents, Painter.....	727
Symbols for mutations in mice, Gates.....	728
The proportion of exceptions in the offspring of exceptional females from X-ray treatment of <i>Drosophila</i> , Anderson.....	728
Crop and stock improvement, Bruce and Hunter.....	728
The genetics of wild populations.—Part I, Grasses, Gregor and Sansome.....	728
Variation with age of simple Mendelian ratio in cowpea, Harland et al.....	728
The question of spring and winter types in wheat, Nilsson-Leissner.....	728
Colour heredity in horses, Stirling.....	728
Inheritance of black in swine, Warwick.....	729
Inbreeding versus "accumulation of blood," Muller.....	729
Age and quality of offspring: The effect of age of parents, Chaudhuri.....	729
Influence of age of parents on offspring, Prawocheński and Kączkowski.....	729
Increased efficacy of subcutaneous when compared with intraperitoneal administration of the ovarian hormone, Evans and Burr.....	729
The determination of sex, Hance.....	730

FIELD CROPS

Crop yields and precipitation in the Great Plains area, Chilcott.....	730
Effect of climatic conditions on oats and barley, Christie and Gran.....	730
Plant breeding, Bryan and Pressley.....	730
[Agronomic work in Arizona, 1923], Thompson et al.....	731
[Experiments at South Mississippi Substation], Ferris and Anderson.....	731
[Field crops work at the Holly Springs, Miss., Substation], Ames.....	731
[Field crops experiments at Raymond, Miss., Substation, 1926], Wallace.....	731
[Field crops investigations in Wisconsin, 1924-1926].....	732
[Inoculation of legumes in Wisconsin].....	734
A study of the root-nodule bacteria of Wood's clover, Whiting et al.....	734
Alfalfa investigations, Kiesselbach and Anderson.....	734
Resistance to low temperatures shown by clover varieties, Steinbauer.....	735
The immediate effect of gametic relationship and of parental type upon the kernel weight of corn, Kiesselbach.....	736
Cotton fertilizers and varieties, O'Kelly, Anders, and Hull.....	736
Studies on <i>Festuca ovina</i> , I, Turesson.....	736
[Peanut production in Gambia], Brooks.....	736
Studies of self-fertilization in rye, Brewbaker.....	736
The behavior of the P. O. J. 234 cane in Tucuman and elsewhere, Cross.....	737
Story of Sugar in Hawaii.....	737
Tobacco: Its cultivation and preparation, Corbett.....	737
Wheat experiments at Northern Montana Branch Station, Morgan and Bell.....	737
Results of seed tests for 1926, Eastman.....	738
[Report of Canadian Seed Growers' Association, 1924-25].....	738

HORTICULTURE

[Horticultural investigations at Arizona Station], Crider and Albert.....	738
Work at South Mississippi Substation, 1926, Ferris and Anderson.....	739
[Horticultural investigations at the Wisconsin Station].....	739
[Vegetable studies at the Raymond, Miss., Substation], Wallace.....	740
Sunshine sweet corn, Yeager.....	740
The home fruit garden on the northern Great Plains, Baird.....	740
The propagation of fruit tree stocks by stem cuttings, I. Knight.....	740
Propagation of apple trees on their own roots, Lagassé.....	741
Normal variation in the chemical composition of fruit spurs, Harley.....	741
The fruiting habit of the York Imperial apple, Dorsey.....	741
Relation of growth to fruitfulness in apple, Dorsey and Knowlton.....	741
Temperature and respiratory enzymes of apples, Drain.....	742
Responses of the sour cherry to fertilizers and to pruning, Tukey.....	742
Raspberry breeding experiments, Darrow.....	742

	Page
Banana culture in Hawaii, Pope.....	743
The Regal lily, Griffiths.....	743
American bulbs under glass, Griffiths.....	743
House plants, Laurie.....	743

FORESTRY

A study of the vegetation of northeastern Arizona, Hanson.....	744
Root studies with the Scotch and Austrian pines, Hesselink.....	744
Inter-relationship of yield and vegetative characters in Hevea, Taylor.....	744

DISEASES OF PLANTS

Plant pathology, Brown and Gibson.....	745
[Plant disease investigations at the Wisconsin Station].....	745
Some factors in the incidence of plant diseases, Shaw.....	747
Epidemic plant diseases, Brooks.....	747
Economic mycology, Barker.....	747
Notes on plant diseases in 1924, Wormald.....	747
[Plant diseases, Philippine Islands, 1924], Youngberg.....	748
Botany and plant pathology, Evans.....	748
The germination of conidia of <i>Botrytis cinerea</i> , Staritzky.....	748
A new species of <i>Monochaetia</i> , Wilson and Ford-Robertson.....	748
Fruit-rotting Sclerotinias.—III, Longevity of brown-rot mummies, Ezekiel.....	748
Methods of disinfection of seed and soil in cereal culture, Morón.....	749
Dry treatment of wheat seed for smut, Marchionatto.....	749
The effect of formalin on the vitality of seed wheat, Baker.....	749
Disease of wheat caused by <i>Pseudomonas tritici</i> , Fahmy and Mikhail.....	749
Diseases of cabbage and related plants, Walker.....	749
Life history of <i>Polythrincium trifolii</i> , Bayliss-Elliott and Stansfield.....	749
A study of clover failure in Kentucky, Fergus and Valteau.....	750
Parasitism of certain fungi causing boll rots of cotton, Laycock.....	750
Strains of <i>Rhizoctonia solani</i> Kühn, Briton-Jones.....	750
Two new cotton plant bacteria in Armenia, Kalantarian.....	750
Rosette disease of peanuts.....	751
Indexing of potatoes for mosaic.....	751
Apple tufts, Carpenter.....	751
Citrus diseases and their control, Fawcett and Lee.....	751
Effects of spraying citrus trees on the fruit, Juritz.....	751
The operations against bud rot of palms in south India, McRae.....	751
A mildewless rose-garden, Knowlton.....	751
The conquest of mildew, Hazlewood.....	752
A cautionary word about fungicides, Massey.....	752
The transmissibility of violet smut by violet seed, Pape.....	752
Fungi parasitic on cultivated trees in Argentina, Marchionatto.....	752
South Indian Loranthaceae and their host plants, Jivanna Rao.....	752
A <i>Rhizoctonia</i> causing root disease in Uganda, Small.....	752
Notes on <i>Rhytisma acerinum</i> and <i>Rhytisma pseudoplatani</i> , Bracher.....	753
Observations on the "slime-fluxes" of trees, Ogilvie.....	753
Observations on <i>Camarosporium abietis</i> n. sp., Wilson and Anderson.....	753
Tree mycorrhiza, Paulson.....	753
Observations on <i>Fistulina hepatica</i> and hollow, stag-headed oaks, Braid.....	753

ECONOMIC ZOOLOGY—ENTOMOLOGY

The migrations of birds, Wetmore.....	754
Birds of western Canada, Taverner.....	754
Birds of the Netherlands, II, Van Oort.....	754
Unique method of pollination by the ruby-throat, Pickens.....	754
Wild plants and seeds for birds, Morse.....	754
Synopsis for identification of amphibians and reptiles of Indiana, Myers.....	754
Value of sodium hydroxide, copper sulphate, and fermentation in disinfecting excreta containing eggs of hookworms and <i>Ascaris</i> , Stiles.....	754
A synopsis of the families and genera of Nematoda, Baylis and Daubney.....	754
Dr. Ransom's bibliography, compiled by Hassall.....	755

	Page
Entomology, Vorhies.....	755
Insects of Indiana for 1925, Davis.....	755
[Work with economic insects in Wisconsin].....	755
[Reports of entomologists of Gold Coast], Patterson and Cotterell.....	756
Annual report of the Government entomologist, Hargreaves.....	756
Annual report of the assistant entomologist, Hancock.....	756
Insect enemies of cotton in French West Africa, Vayssière and Mimeur.....	756
A list of the insects affecting sugar cane in Cuba, Van Dine.....	756
Insect pests of our garden plants and their control, Weigel.....	756
Pollination in orchards.—VII, Insect visitors, Wilson.....	756
Insects caught in light traps, Theobald.....	757
An important Queensland insect pest, Veitch.....	757
Irritation due to insect secretion, Hoffman.....	757
Life-history and habits of <i>Sahlbergella singularis</i> and <i>S. theobroma</i> , with suggested control measures, Cotterell.....	757
Chemical changes during life cycle of tent caterpillar, I, II, Rudolfs.....	757
Results of some experiments for the control of codlin moth, Fowler.....	758
An infectious disease fatal to the larvae of the wax moth, Chorine.....	758
<i>Lyonetia clerckella</i> L. in Sweden, its biology and control, Kemner.....	758
The bronzed cutworm (<i>Nephelodes emmedonia</i> Cramer), Crumb.....	758
Some hints on the preparation and study of genitalia, Tams.....	758
Poisoning the cane borer with sodium fluosilicate, Holloway et al.....	758
The gall midges of vegetables and market garden crops, Barnes.....	758
Results of field trials on ox-warble control, Imes.....	758
Occurrence of <i>Cuterebra</i> in western Canada, Cameron.....	759
Life history of <i>Oedemagena tarandi</i> and <i>Cephenomyia trompe</i> , Hadwen.....	759
A destructive potato beetle.....	759
Some Coccinellidae of the tribe Telsimiini, Chapin.....	759
Natural history of ants, De Réaumur, trans. and annotated by Wheeler.....	759
The origin of mixed broods in polyembryonic Hymenoptera, Leiby.....	759
Rearing colonies of bumblebees in artificial nests, Frison.....	759
Intensive apiculture and the rearing of queen bees, Perret-Maisonneuve.....	760
Present position regarding adult bee disease in Great Britain, Sturges.....	760
Four new species of parasites from aphidophagous Syrphidae, Kamal.....	760
A new case of phoresie: Trichogrammidæ on Orthoptera, Ferrière.....	760
Description of a new braconid parasite of <i>Artona catæxantha</i> , Rohwer.....	760
Observations on scorpions, Smith.....	760
Life history and biology of tree-toad chigger, <i>Trombicula hylae</i> , Ewing.....	760
Redescription of <i>Taenia krabbei</i> Moniez, Cram.....	760

ANIMAL PRODUCTION

The breeding and improvement of farm animals, Rice.....	760
Twin and multiple births in our domestic mammals, Richter.....	761
Feeding and handling livestock to prevent shrinkage and loss, Gerlaugh.....	761
Origin and quality of livestock marketed in Canada in 1925, Arkell.....	761
Diet and body fat, Mendel and Anderson.....	761
The composition of swedes, Lauder.....	761
Silage investigations.....	761
Eliminating the toxicity of cottonseed meal, Gallup.....	762
[Feeding experiments with beef cattle at the Wisconsin Station].....	762
Rhodes grass hay versus alfalfa hay as feed for cattle, Williams et al.....	762
The cattle of the world, Sanders.....	763
Morphological investigation of German Shorthorn cattle, Von Rümker.....	763
The Bhagnari breed of cattle in Sind and Baluchistan, Baluch.....	763
Rutabagas vs. corn silage for breeding ewes.....	763
Various methods of docking lambs, Williams et al.....	763
Sheep raising in central Alberta, Reed and Chapman.....	763
Development of coarse-wooled sheep in Russia, Chirvinsky and Elagin.....	764
Development of coarse-wooled sheep in Russia, [Chirvinsky and Elagin].....	764
Skeletal development in sheep, Chirvinsky.....	764
The goat: Breeds, breeding, and exploitation, Huart du Plessis.....	764
Hog-feeding investigations, Williams et al.....	764
[Swine feeding experiments at the Wisconsin Station].....	765
[Experiments with swine at the Central Experimental Farm], Rothwell.....	765

	Page
The value of fish meal in swine feeding, De Ruyter de Wildt.....	766
Modern swine husbandry, Bledisloe.....	766
Pig breeders' annual for 1926.....	766
Chopping timothy hay for work horses.....	766
The evolution of the horse, Loomis.....	766
The ass: Horses used for mule breeding and the mule of Poitou, Sausseau.....	767
[Poultry experiments at the Wisconsin Station].....	767
Nutrient requirements of growing chicks, Mussehl.....	767
Corn as a nutrient for growing chicks, Mussehl et al.....	767
"Artificial" enzymes and poultry feeding, Holst.....	768
The nutritional requirement of the chicken, VI, Hart et al.....	768
Relation between the amount of ultra-violet light received by hens and the amount of antirachitic vitamin in the eggs, Hughes et al.....	768
The 1927 New Jersey chick ration and method of chick feeding, Clickner.....	768
Egg production, costs, and receipts on New Jersey farms, Allen.....	768
Broiler production, Thompson and Penquite.....	768
Capon production, Botsford.....	769
Influence of vertical position of eggs on development of embryos, Umanski.....	769
On the influence of sexual hormones upon the number of erythrocytes and percentage quantity of hemoglobine by fowl, Blacher.....	769
The cat: Races, breeding, and diseases, Larioux and Jumaud.....	769
Theory and practice of fox ranching, Allen and McLure.....	769

DAIRY FARMING—DAIRYING

History of the dairy industry, Pirtle.....	769
Proceedings of the Congress for the Feeding of Cattle and Dairy Control.....	770
The effect on milk production of feeding more than the Haecker, Eckles, and Savage requirements, Converse.....	770
Mineral supplements in rations for dairy cattle and green feed versus dry feed for dairy cattle, Cunningham and Davis.....	771
Fat-soluble vitamin, XXVI, Steenbock et al.....	771
[Feeding experiments with dairy cattle at the Wisconsin Station].....	771
[Experiments with dairy cattle at the Central Farm], Rothwell.....	772
Care and management of the milk goat, Voorhies.....	772
The secretion of butterfat, Porcher.....	772
Testing dairy products, Newlander.....	772
A comparison of the Babcock, Gerber, and Roese-Gottlieb methods for determining the percentage of fat in milk and cream, Dahlberg et al.....	773
[Experiments with dairy products at the Wisconsin Station].....	773
Process cheese and Joint Resolution No. 54, S., Emery and Klueter.....	773

VETERINARY MEDICINE

[Work in animal pathology in Wisconsin].....	773
Report of the veterinary director general for 1926, Hilton et al.....	774
Handbook of the Diseases of Animals Acts and orders thereunder.....	774
Reports of the Bombay Veterinary College and Civil Veterinary De- partment for 1925-26, Hewlett et al.....	774
Textbook of comparative physiology, Rogers.....	774
The operative technique of animal experiments, Haberland.....	775
The relation of animal diseases to public health, Hull.....	775
Local immunization: Specific dressings, Besredka.....	775
Pharmacopoea germanica.....	775
Method for repeatedly sampling blood of portal vein, Blankenhorn.....	775
Microbic dissociation: The instability of bacterial species, Hadley.....	775
The filtrable viruses, Lucksch.....	775
Animal parasites of man.—I, Natural history, Braun.....	775
Animal parasites of man.—II, Clinic and therapy, Seifert.....	775
Sensitising powers of proteins of parasites, Turner.....	776
Dogs and cats concerned in creeping eruption, White and Dove.....	776
A biochemical method of differentiating <i>Brucella abortus</i> from <i>Brucella</i> <i>melitensis-paramelitensis</i> , I, Huddleson and Abell.....	776
Investigations with acid-fast bacteria.....	777
The histological expression of the natural resistance of rabbits to infec- tion with human and bovine type tubercle bacilli, Lewis and Sanderson.....	777

	Page
Anaphylaxis and the tuberculin reaction, Dorset.....	777
The use of vaccines in the treatment of mastitis in cattle, Moore.....	777
Vibrios from calves and their relation to vibrio fetus, Smith and Orcutt.....	777
Cutaneous tuberculosis (?) in buffaloes, Kok and Roesli.....	777
A spirillum as the cause of infectious abortion in sheep, Grimm.....	777
Immunizing young pigs against cholera, III, Benner.....	777
Autogenous vaccines in treatment of chronic nasal catarrh, Davenport.....	777
Bacillary white diarrhea in Maine, Hitchner and Russell.....	778
The metazoan parasites of poultry in Australia, Ross.....	778

AGRICULTURAL ENGINEERING

[Agricultural engineering studies at the Wisconsin Station].....	778
Surface water supply of New Mexico, 1888-1925, Neel.....	778
Irrigation and drainage problems in the Gallatin Valley, Murdock.....	778
[Irrigation studies at the Arizona Station], Smith et al.....	779
Irrigation by overhead sprinkling, Wadsworth.....	779
Irrigation with treated sewage in western Texas, Roberts and Jones.....	779
Water supply and sewage disposal systems, Wood.....	779
The farm water supply.—Part II, The hydraulic ram, Behrends.....	779
Stone removal as a phase of land clearing, Schwantes.....	779
Terracing farm lands in Texas.....	780
A. S. T. M. standards, 1926.....	780
Statically indeterminate stresses, Parcel and Maney.....	780
Requirements for working stresses in building materials, Woolson et al.....	780
Concrete designers' manual, Hool and Whitney.....	780
Elements of heat-power engineering, Part I, Barnard et al.....	780
Detonation characteristics of petroleum motor-fuels, Marley et al.....	780
Detonation specifications for automotive fuels, Edgar.....	781
Studies in rural electrification.....	781
Effective haying equipment and practices, Reynoldson and Kinsman.....	781
Dust respirators: Their construction and efficiency, Katz et al.....	782
Plans for concrete houses.....	782
Sunlight movable hog houses for Kentucky, Wilford and Kelley.....	782
House the hen efficiently and economically, Halpin et al.....	783
The Dutch oven or cement brooder stove, Carroll and Hillier.....	783
Principles of refrigeration, Motz.....	783

RURAL ECONOMICS AND SOCIOLOGY

[Investigations at the Wisconsin Station, 1924-1926].....	783
The principle of comparative advantage applied to farm management studies of regional competition between farmers, Tapp.....	784
Cost of production in Choctaw County, Miss., 1925, Long and Reynolds.....	784
Cost of producing winter wheat and incomes from wheat farming in Sherman County, Oreg., Washburn and Scudder.....	784
Cost of using horses, tractors, and combines on wheat farms in Sherman County, Oreg., Washburn and Scudder.....	785
Incomes from farming in the Shenandoah Valley, Va., Swinson.....	785
Increasing farm profits with more early potatoes in Indiana, Overton.....	785
Washington agriculture.—Part 6, Poultry. Part 7, Recommendations.....	786
Adjusting agricultural production and distribution in the Clarksburg area to meet home market demands, Armentrout.....	786
Agricultural progress in a typical Maryland community, Metzger.....	786
An outline of the New York State system of taxation, Kendrick.....	786
Michigan farmers' tax guide, Newton.....	787
The McNary-Haugen plan as applied to wheat, Taylor et al.....	787
Kentucky livestock auction sales organizations, Johnson.....	788
Cooperative marketing and price control, Jesness.....	789
The balance of trade in farm products, Jefferson.....	789
Food costs and city consumers, Artman.....	789
Crops and Markets, [January-February, 1927].....	789
The agricultural map of U. S. S. R., Makarov, edited by Vavilov.....	790
Agricultural colonisation in Palestine, Ruppin, trans. by Feiwel.....	790
International yearbook of agricultural statistics for 1925-26.....	790

AGRICULTURAL AND HOME ECONOMICS EDUCATION

	Page
Workers in subjects pertaining to agriculture in State agricultural colleges and experiment stations, 1926-1927, Agnew.....	790
Agricultural evening school classes in dairying, Luker.....	790
What a poultry project should contain, Shrader.....	790
Fruit tree and orchard judging, Duruz.....	790
Clothing and textiles, Matthews.....	790
How to make and use an operating statement, Powell.....	790
Merits of circles and bars for representing component parts, Eells.....	791
Further studies in the graphic use of circles and bars.....	791
Use of motion pictures in agricultural extension work, Perkins et al.....	791
Motion pictures of the United States Department of Agriculture.....	791

FOODS—HUMAN NUTRITION

Food and health, Plimmer.....	791
Food and health manual for classes in nutrition, George.....	791
Nutrition laboratory, Benedict.....	791
Relation of cooking to the quality and palatability of meat, Howe.....	791
The art of cooking and serving, Splint.....	792
A calendar of dinners with 615 recipes, Neil.....	792
Dental caries resulting from experimental diets, Marshall.....	792
The basal metabolism and the specific dynamic action of foods in children in various conditions of nutrition, Morgan and Hatfield.....	792
Chinese diet in the light of modern knowledge of nutrition, Wu.....	793
Further evidence that small quantities of copper, manganese, and zinc are factors in the metabolism of animals, McHargue.....	793
The nutritional value of oysters and other sea food, Jones.....	793
Antirachitic content of canned oysters.....	794
Biological food tests.—IX, Vitamin A in cheese, Morgan.....	794
Losses of vitamin B in vegetables in cookery.....	794
Vitamin B in fresh and dried yeast, Scheunert and Schieblich.....	794
Studies in the physiology of vitamins, IV, Cowgill et al.....	795
Fasting and rice disease in pigeons, Barlow.....	795
Vitamin studies, II, Wierzchowski.....	795
Effects of diet during pregnancy on rickets in offspring, Greenebaum et al.....	796
Studies on experimental rickets, XXVIII, McCollum et al.....	796
Imparting antirachitic properties to foods.....	797
The anti-rachitic action of irradiated sawdust, Rosenheim and Webster.....	797
Deriving the formula for a diabetic diet, Collens and Shelling.....	797

MISCELLANEOUS

Thirty-fourth Annual Report [of Arizona Station, 1923], Thornber et al.....	797
Report [of] South Mississippi Substation, 1926, Ferris and Anderson.....	797
Report [of] Raymond Branch Experiment Station, 1926, Wallace.....	797
Report of the director, [Wisconsin Station, 1925-1926], Russell et al.....	797

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

Stations in the United States

	Page
Arizona Station:	
Thirty-fourth Ann. Rpt. 1923	719,
730, 731, 738, 745, 755, 762, 763, 764, 768, 771, 779, 797	790
California Station:	
Circ. 309	790
Delaware Station:	
Bul. 147	741
Hawaii Station:	
Bul. 55	743
Indiana Station:	
Bul. 305	785
Kentucky Station:	
Bul. 269	750
Bul. 270	788
Bul. 271	789
Maryland Station:	
Bul. 284	748
Bul. 285	786
Michigan Station:

EXPERIMENT STATION RECORD

VOL. 56

JUNE, 1927

No. 8

Announcement is made that the forthcoming report of the Office of Experiment Stations for the fiscal year ended June 30, 1926, is to contain a discussion of the first 20 years under the Adams Act. This legislation, approved March 16, 1906, became effective on June 29 of that year, so that the fiscal year 1926 terminated investigations under its provisions extending over a score of years. Reports as to the operations thereunder have been made year by year, but there has not as yet been attempted any comprehensive summary of the period as a whole.

In many ways the passage of the Adams Act was one of the notable events in the history of agricultural research. The Hatch Act of 1887 had initiated the policy of Federal aid to agricultural experimentation through a system of stations associated with the colleges of agriculture, but this action was itself in the nature of an experiment, and the new legislation was first of all a vote of confidence in the wisdom of the undertaking after nearly 20 years of trial. Its practical effect of doubling within a few years the Federal contributions to these institutions was also an important benefit, though more vital in the case of some of the States than others.

Looking backward over the years, however, the outstanding significance of the Adams Act is seen to be its restriction to the "conducting of original researches or experiments bearing directly on the agricultural industry of the United States." As was predicted in these columns at the time of its passage, "if held strictly to the purposes specified in the act it will have a great opportunity for placing the American stations on a high level as research agencies, and give them a leadership in developing the science of agriculture. It is the greatest opportunity for continued systematic research along agricultural lines which has ever been presented in any country, and this opportunity and the realization of the ultimate importance of investigation should be the inspiration of every station man and every friend of agricultural advancement. It should be a strong incentive to the careful choice of problems to be investigated, thor-

ough and exhaustive work in their solution, and the securing of permanent and far-reaching results."

The Adams Act came into operation at a time when the stations were beginning to feel acutely the need for funds which could be devoted to the more fundamental aspects of original research. Experience had taught that while some of the simpler problems could be solved quite readily, there were many others so intricate that long-continued and intensive investigations would be essential if material progress was to be made. The act, therefore, was a response to the feeling that there should be larger opportunity for quiet, undisturbed research than was possible in any considerable degree with the resources available and the popular demand for immediately available findings. This condition was prevalent in nearly every State, since even in many where the stations were most generously supplied with State or local funds these were restricted closely to specific inquiries and often designed to meet emergency situations.

The new legislation started with an appropriation of \$5,000 to each State, increasing by \$2,000 a year until it reached maturity in 1911, and authorizing an appropriation of \$15,000 for that year which has since been continued annually. This provision for gradual enlargement of the appropriation was a wise one, for not all of the stations were prepared at that time to use to advantage an appropriation of the ultimate amount provided. The gradual increase gave them opportunity to adjust themselves and their forces to the new provision. As it was, a shortage of competent investigators developed in some lines and proved in numerous instances a limiting factor to rapid progress. Fortunately, however, the standards set were from the first such as to attract new recruits who saw in this field a larger opportunity for a true research career, and served as an incentive and encouragement to others to prepare themselves by thorough training. The fund, therefore, has served the double purpose of establishing and maintaining definite lines of original inquiry and of stimulating more extensive development in this field throughout the stations.

One helpful factor in organizing the new work on a high plane was the constructive attitude of the Association of American Agricultural Colleges and Experiment Stations. The feeling of this body was early expressed by its committee on experiment station organization and policy, which laid down the following broad proposition: "It is evidently the intention of the Adams Act to provide the means for carrying on investigations of a relatively high order, with a view to the discovery of principles and the solution of the more difficult and fundamental problems of agriculture. To this end it is very desirable that careful attention shall be given to the

choice of definite problems to be studied and the methods by which the solution of these problems is to be sought. Investigations in connection with which there is good reason to expect the establishment of principles of broad application should be preferred to those which have only local or temporary importance, or from which only superficial results are to be obtained." In the years which followed, this view was consistently adhered to.

In the administration of the Adams Act, the distinct innovation was instituted of placing the work done under its provisions on a basis of concrete projects, for the support of which, after approval by the Office of Experiment Stations, definite allotments of funds were made by the respective stations. This was the real beginning of any general employment of the project system by the stations. It has now become an established procedure at most of these institutions for both Federal and State funds, and has added greatly to the definiteness and methodical prosecution of the station work as a whole.

At the close of the 20-year period a total of 443 projects were being supported as a whole or in part from the Adams fund. The number had become substantially stabilized, 58 projects being concluded or transferred to other funds during the fiscal year and 63 new projects inaugurated. The number of projects per station ranged from 2 to 17, but these extremes were exceptional, and in most instances the number was not far from the average of a little over 9. This means an average support from the Adams fund of about \$1,625 per project, but the amount varies widely with the nature of the individual project, the number of Adams projects at a station, and the extent of its other resources. While no estimate is available of the State contributions to the Adams projects, in many cases they fully equal the Federal funds allotted.

One point on which an interesting light is now revealed is that of the relative permanence of the Adams projects. Of the 443 projects active in 1926, over half had been under way for over 5 years and over one-fourth for 10 years or more. Nearly 10 per cent had been in progress for over 15 years, and no fewer than 22 projects had been continued from the beginning of the 20-year period. This illustrates at once the intricate nature of many problems and the fact that time is a primary requisite for their solution. Such subjects as the cumulative effect of various treatments on soils, the nutritive requirements of apple trees at the different stages of their growth, the interrelation of stock and scion, or the nature and transmission of an obscure disease or physiological trouble naturally require protracted research which should not be interrupted until definite conclusions have been reached. It is fortunate that the way is open for such protracted studies when occasion arises.

Many of the older projects have been restated from time to time to conform with the progress of the investigations. Some projects inevitably develop and expand as the work goes on. One step leads to another, and it is in accordance with the nature of research that the procedure should be adapted to the new situation. The primary object in the administration of the Adams fund has been to conserve it for lines which make progress and hold promise and to keep the project statements reasonably up to date as an expression of the status of the investigation as well as of its nature and purpose. This effort has met with cordial response, which has resulted in the high type of work maintained under the act.

Such a condition, however, is not to be confused with vacillation and shifting of purpose. The point of view and the means employed may change, but purposeful inquiry adheres to its objective as long as there is adequate encouragement to do so. It will not allow itself to be diverted merely because something else has arisen which looks attractive. Nor is it a justification of an occasional tendency to prolong a project by digressing into unrelated side lines or of a disposition to allow projects to become stereotyped and to drift along without conviction that the work is advancing or even that the method is adequate. Such tendencies overemphasize the feature of continuity and fail to stress constructive effort with concentration on a definite objective. The experience of the 20 years has brought about a general realization of the need of this concentration.

As would be expected, the projects have from the beginning covered a wide range of subject matter. By far the largest group is that of plant diseases and related troubles, on which 94 of the 443 projects, or over one-fifth of the total number, are centered. The next largest are the soils and fertilizers projects, numbering 60, and the breeding and genetic studies with 54. There are 44 projects dealing with economic insects, 43 with animal diseases and pests (including poisonous plants of the western ranges), 41 on various botanical, breeding, agronomic, and other aspects of field crops, and 38 in horticulture and forestry. Fundamental studies of nutrition and animal production are represented by 36 projects, dairying has 11, agricultural engineering 4, and the remaining 18 relate to chemical studies of various kinds, the technology of cane sugar making, and miscellaneous subjects.

Within these various groups the projects range quite widely. The subject of soils and fertilizers includes investigations on the nutritive requirements of plant growth and factors affecting them, the availability and utilization of plant nutrients in soils under different methods of treatment, the toxicity of soils due to various

causes, and the nature and formation of humus. Other projects deal with the physical-chemical aspects of soil acidity; the influence of rotations on maintenance of soil fertility; problems of alkali soils and their treatment; the importance and action of sulfur, manganese, and magnesium compounds in the soil; fundamental soil moisture constants; and a variety of studies on the bacterial activity of soils, factors influencing it, and relationship to fertility.

The water requirements of crops as related to plant characters and environmental factors, the influence of soil types and of fertilizers on the composition of crops, relation of light to plant response, the duty of water on crops as affected by various conditions, and factors influencing the growth and development of special plant parts, such as cotton buds and bolls, constitute another group. Conditions which affect the milling strength and baking qualities of wheat flour form the subjects of several projects, while others are devoted to biochemical changes due to various causes, such as frosting of wheat, and their effects on bread-making quality and market value. There are physiological studies relating to changes in the ripening of crops and in their storage and transportation, the latter notably with sweet and Irish potatoes. Of interest to range agriculture are numerous projects on the toxic properties of poisonous plants and the stage of growth at which they are particularly dangerous, and studies of the injury to grazing tracts by rodents and the means of their control.

The work in genetics, which from the first has been a favorite field, includes both plants and animals. Under the former come studies of general principles, the laws and modes of inheritance, the value of mutations, linkage relations and variability, and the application of breeding principles in the systematic improvement of a great variety of field crops and fruits. With animals, the breeding work includes such subjects as inbreeding, inheritance of milk production and associated characters in cattle, analysis of hereditary factors determining milk and meat production, principles involved in fixing certain desirable characters in sheep, inheritance of fleece characters in purebred and crossbred sheep, fecundity of swine and conditions affecting it, cause and control of sterility in mares, and inheritance and physiology of various qualities in poultry.

The subject of plant diseases and similar troubles has always been one of very active attack, as already indicated. A wide range of diseases affecting a large variety of plants are under study as to their pathological, biological, and physiological relationships, as well as means of control. Mosaic diseases of crops, the degeneration troubles in potatoes, the means of transmission of disease in obscure instances, and the basis or nature of resistance and susceptibility occupy a prominent place. Notable among the latter are studies of the relation of nutritional deficiencies to prevalence of corn rots, the influence of

temperature and moisture conditions on plant infection, and the physiological aspects of parasitology as a key to the occurrence of these troubles. The biologic or physiologic forms and races of disease organisms and conditions producing them are the subject of another important series of investigations.

The study of economic insects, the factors influencing outbreaks, parasitic enemies, and other means of control have always constituted a prominent feature of the Adams fund program. The present list of such studies is a long one. In addition to the detailed investigation of individual insects and groups, a dozen or more projects relate to the chemical and physical properties of insecticides and fungicides, the manner in which they operate, and their effect on foliage; while others deal with insect attractants and repellents in relation to their chemical nature and arsenical residues on fruits—the means of removal and effect on storage.

It is gratifying to note that after a somewhat belated start, horticulture comes in for a goodly number of thoroughgoing investigations. Many of these relate to the physiological manifestations in the group of plants it represents, such as the nutrition of apple trees, the influence of fertilizer applications on the physiological functions of the tree, fertility and sterility of varieties, fruit bud formation, pruning in relation to growth and as a factor in blooming and the setting of fruit, value of bud selection in the apple, factors determining hardiness, and the nature, cause, and prevention of winter injury.

The subject of vitamins, which has been so richly contributed to by the stations, continues to receive much attention, including not only studies of their relation to proper nutrition but factors which affect them, such as conditions of growth and curing of crops, effect of commercial processes in condensing milk, relation to breed of cows, and capacity of storage in the animal body. Other nutrition studies pertain to the nature and value of proteins from various sources, the requirements of protein and energy for different purposes, the importance of ash ingredients, mineral metabolism and mineral requirements, basal metabolism studies, protein storage in protoplasmic tissue, and a long list of other fundamental investigations in nutrition, many of which have applications to man. There are numerous studies on the physiology of milk secretion, the chemistry of milk and its constituents, dairy and creamery sanitation, factors causing sandiness and swell in ice cream, and tolerance and nutritive value for children of milk of varying composition.

With poultry there are projects relating to feeding and management as affecting the vigor of germ in hen's eggs, effects of deficiencies of feed of hens on the vitality of chicks, conditions of incuba-

tion, and the nature and cause of watery whites in eggs. Most prominent among the studies of animal diseases are abortion, hog cholera, tuberculosis, and white diarrhea of chicks, but in addition a considerable list of other diseases affecting various kinds of livestock are under active investigation.

The above survey is in no sense exhaustive, but affords an idea of the range of the research and the fundamental subjects with which it is dealing. Its significance is not confined to agriculture itself, but in large measure the studies are of very vital importance for the welfare of the human race in its proper feeding and the maintenance of health, as well as the means of meeting the prospective demands of an increasing population.

A measure of the influence which the Adams Act is exerting on agricultural research might be sought by attempting to visualize the station programs with these various projects omitted or confined to their more popular phases. This does not mean, of course, that all the more advanced activities in these lines are confined to Adams projects, for many of the stations are spending on such research many times their Adams allotment of \$15,000 per year. It would be difficult and withal not particularly profitable to attempt to segregate the precise returns from the Adams dollars from those derived from other sources, so intimately have they become intermingled in the warp and the woof of the fabric which the stations have been weaving in the past generation.

Probably the outstanding result of the Adams legislation has been its stimulating influence on the remainder of the station work, an influence far in excess of its contribution to the station treasury. This it has done by setting up and maintaining relatively high standards and demonstrating by its concrete achievements that ultimately the returns are larger from this slower but more substantial and conclusive type of investigation. Thus the first 20 years have resulted in raising appreciably the level of all agricultural experimentation. So far from pauperizing or even diminishing the responsibilities of the several States, as is sometimes feared may result from a Federal subsidy, this legislation has furnished an excellent example of a Federal appropriation which has brought about a stimulation and an increased development which is of general advantage to all.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The proteins of green forage plants, I-IV, W. L. DAVIES (*Jour. Agr. Sci. [England]*, 16 (1926), No. 2, pp. 280-301; 17 (1927), No. 1, pp. 33-43).—The results are presented of four studies on the proteins of fresh vegetable tissues, in which it was sought (1) to characterize the purified protein, comparing this when possible with the seed protein of the same or a related species; (2) to determine the nature of the nonprotein nitrogen; and (3) to secure information upon other components of the extracts, such as soluble ash, sugars, pectinous substances, and mucilages. The literature is briefly reviewed in the introductory paper.

I. *The proteins of some leguminous plants* (pp. 280-292).—Alfalfa, sainfoin, vetch (*Vicia sativa*), red clover, and crimson clover (*T. incarnatum*) were studied. The general method was to bring about a cytolysis of the finely ground tissue by treatment with ether-saturated water, as proposed by Chibnall and Schryver (*E. S. R.*, 47, p. 109), and to precipitate the protein from the aqueous solution of liberated cell contents either by adding successively increased percentages of alcohol or by heat coagulation. The pulp was reextracted with water until no further removal of protein was indicated, after which the residual protein was in some cases extracted with hot or cold alcoholic alkali. The preparations were purified by solution in dilute aqueous alkalies, carbonate or hydroxide, and reprecipitation with acid. It proved advantageous to freeze some of the tissues before extracting them.

The dried protein preparations were greenish, dusty powders having the characteristic properties of vegetable protein preparations. They yielded an ash containing principally calcium, magnesium, sulfate, and phosphate. The nitrogen distributions of the preparations were determined by the Hausmann and the Van Slyke methods. The lysine, as determined by the latter method, varied from 3.5 (red clover) to 9.4 per cent (one of the vetch protein preparations). Cystine varied from 0.9 (one of the vetch protein preparations) to 1.8 per cent (an alfalfa protein preparation), arginine ranged from 6.0 (a sainfoin and one of the vetch protein preparations) to 9.3 per cent (an alfalfa protein preparation), and the histidine percentages were from 2.1 in one of the vetch protein preparations to 8.5 in a preparation from red clover. Amide nitrogen in the protein-free extracts was constant, but ammonia nitrogen was variable.

II. *The proteins of the mangold root; comparison with the proteins of mangold seed* (pp. 293-301).—Methods similar to those above noted in connection with leguminous plant tissues were used, with the exception that it was found necessary to hold the mangolds in storage for eight weeks since otherwise little coagulum was obtained from the extracts. Preparations containing about 11 to 12 per cent of nitrogen were obtained. They were dusty, slate gray powders, and responded to all the protein tests. They also contained carbohydrate, as indicated by the Molisch test. The ash contained calcium, sulfates,

and phosphates, with traces of iron, magnesium, and chlorides. The average diamino acid contents of two preparations were: Arginine 7.9, histidine 3.2 lysine 5.7, and cystine 1.8 per cent. The percentages of diamino acids found in two globulins (A and B) from the mangold seed were: Arginine 10.73 and 13.65; histidine 6.53 and 2.28; lysine 1.32 and 2.17, and cystine 2.63 and 2.69, respectively. A trace of albumin was found to be present in the 10 per cent sodium chloride extracts of ground mangold seeds. The elementary analyses of the two seed globulins showed them to differ principally in the sulfur content, globulin A containing 1.01 per cent of sulfur and globulin B 0.41 per cent.

III. *The proteins of forage plants of the natural order Cruciferae (Genus Brassica); comparison with colzalin, a globulin from rapeseed* (pp. 33-40).—Protein preparations were obtained by coagulation from the filtered press juice of the minced leaves of cabbage, kohlrabi, narrow stem kale (leaves and stems), and turnips (leaves and roots). Preparations were also obtained from the press cake of the cabbage and turnip leaves by extracting with 0.2 per cent alcoholic sodium hydroxide at 70° C., the protein being precipitated by acidification. The nitrogen distribution and the basic amino acid content of the preparations as determined by Van Slyke's method are compared with those of colzalin, a globulin from rapeseed (*B. rapa*). "It is apparent that the quantities of diamino acids do not suffer a change" when the protein is stored in the seed, and that "an analysis of a seed protein would give a fair indication of the diamino acid content of the protoplasmic protein of the same species."

IV. *The proteins of some plants of the natural order Umbelliferae* (pp. 41-43).—Carrots and parsnips were studied. The protein was extracted by methods similar to those used for other fleshy vegetable tissue. Certain marked differences between the proteins of the two roots were found. The carrot protein contained the larger percentage of monoamino nitrogen, the parsnip protein having the larger percentage of proline and oxyproline, and the carrot protein more arginine and less histidine than the parsnip protein. The sums of these basic amino acids, however, were roughly the same in the two proteins, so that no difference in nutritive value can be attributed to this difference, arginine and histidine being biologically interchangeable.

On the phosphorus nucleus of casein [trans. title], S. POSTERNAK (*Compt. Rend. Acad. Sci. [Paris], 184 (1927), No. 5, pp. 306, 307*).—In the tryptic digestion of casein a polypeptide containing 4 atoms of phosphorus and 18 atoms of nitrogen was obtained. This compound contained the greater part of the phosphorus of the casein and was very resistant to trypsin. With a very active pancreas preparation, however, it was possible to isolate compounds containing 16 and 15 atoms of nitrogen to 4 of phosphorus. The simplest of these products crystallized from dilute alcohol and furnished material for a study of the phosphorus nucleus of casein. The three compounds obtained were designated α -, β -, and γ -lactotyrynes, were soluble in water, were strongly acid to methyl orange, formed water-soluble salts with the alkaline earth metals as well as with the alkalis, were strongly levorotatory, and gave a rose color in the biuret reaction, but no colorations with the Millon, Molisch, and xanthoproteic reactions. Caustic alkalis and baryta very slowly separated almost all the phosphorus from these compounds as phosphoric acid at room temperature. This reaction became rapid on boiling. α -Lactotyryne was hydrolyzed with difficulty and only with some deamination, yielding, beside ammonia and pyruvic acid, 3 molecules of glutamic acid, 0.6 of aspartic acid, a little more than 3 of isoleucine, about 3 molecules of serine, and 4 molecules

of phosphoric acid, together with small quantities of dipeptides and larger quantities of tri- and tetra-peptides. In accordance with the structure assigned to α -lactotyryne, it should show 12 acid equivalents on titration. With phenolphthalein as indicator, 11.6 acid equivalents were found. The apparent structure of α -lactotyryne indicates that the phosphorus nucleus of casein consists of serine-phosphoric acid residues.

A study of the effect of heat upon wheat and flour, especially in relation to strength, D. W. KENT-JONES (Dover, Eng.: Dover Ptg. and Pub. Co., 1926, pp. 116, pls. 9, figs. 2).—Flour can be subjected to considerable heating without altering the baking strength, but too high a temperature or too prolonged a treatment will ruin the baking qualities entirely. Between these extremes there is a region within which the heat treatment of a flour greatly enhances the baking strength. These facts are illustrated in a chart of temperature plotted against period of heating, the curves delimiting the regions of negative, beneficial, and deleterious effects. Suitable heating increases imbibitional power, reduces the protein soluble in 5 per cent aqueous potassium sulfate, reduces the Lintner value, and markedly reduces proteolytic activity. It has little or no effect upon the "a" and "b" quality factors of Sharp and Gortner (E. S. R., 50, p. 502), upon gas production or maltose content, upon the isoelectric point of the gluten, or upon the racemization of the glutenin. Heating apparently increases the baking strength by increasing the swelling power of the proteins. Selection and cultivation of wheat for high protein content, together with heat treatment of the weaker grades, is recommended as a means for the production of a strong English flour. Various chemical methods for the determination of flour characteristics were tested and compared, and the relative value of these methods is discussed.

An introduction reviews the literature and discusses the terminology of the subject, and a considerable bibliography is appended.

The chemical composition of Tunisian olive oil, G. S. JAMIESON, R. M. HANN, and W. F. BAUGHMAN (Oil and Fat Indus., 4 (1927), No. 2, pp. 63-65).—The chemical and physical characteristics of the Tunisian oil are tabulated in comparison with those of the Italian and California oils previously examined (E. S. R., 54, p. 610). A determination of the glycerides of oleic, linolic, myristic, palmitic, stearic, and arachidic acids showed that the Tunisian oil contained 14 per cent less oleic glyceride, about three times as much linolic glyceride, and about twice as much palmitic glyceride as either the Italian or California oils.

A chemical method for determining the phosphoric acid requirements of agricultural soils [trans. title], A. NĚMEC (Compt. Rend. Acad. Sci. [Paris], 183 (1926), No. 4, pp. 314-316).—The water soluble phosphoric acid, colorimetrically determined by reducing phosphomolybdic acid with hydroquinone and subsequently developing a blue color with sodium sulfite in alkaline solution, has been correlated with the soil requirement of phosphatic fertilizers for certain crops. Soils containing 35 mg. or more per kilogram of water-soluble P_2O_5 in the air-dried samples satisfied the phosphate requirements of sugar beets. Barley did not respond to phosphatic fertilizers when the soil contained 22 mg. per kilogram of water-soluble P_2O_5 . Potatoes required but 19 mg. per kilogram, and 15 mg. per kilogram supplied the needs of oats.

The determination of arginine in pure proteins and in the tissues by a modification of Jansen's method [trans. title], A. BONOT and T. CAHN (Compt. Rend. Acad. Sci. [Paris], 184 (1927), No. 4, pp. 246, 247).—Three gm. of dried tissue free from extractives and fat or 3 gm. of pure protein are hydrolyzed 48 hours with 60 cc. of 20 per cent hydrochloric acid. The solution is evaporated

to dryness on a water bath under reduced pressure to remove the acid. The residue, taken up in hot water, is transferred to a porcelain dish. This is heated to boiling with 0.5 gm. of a very pure and active animal charcoal, which removes the humin nitrogen and decolorizes, without absorbing, the arginine. The solution is filtered, and evaporated to dryness on the water bath to remove traces of hydrochloric acid. It is taken up again in water and made up to a volume of 250 cc., the reaction being made as exactly pH 9.9 as possible, using 2.5 N sodium hydroxide.

Arginase is allowed to react on the clear solution. The enzyme is prepared by precipitation with acetone from the juice pressed from dog liver. Its activity is determined on a solution of pure arginine. It is always desirable to use an excess of arginase.

The reaction is allowed to continue for 72 hours at 37° C. The large quantity of amino acids contained in the mixture acts as a buffer, so that the pH value does not change during the action of the ferment. In a mixture which contains no monoamino acids, it is necessary to use a suitable buffer solution, for instance, 1.5 gm. of glycine, in its determination. The mixture is neutralized with dilute acetic acid, is filtered, and evaporated on a water bath under reduced pressure below 70° to avoid hydrolysis of the urea. The residue is taken up in 70 per cent acetic acid and treated with a few drops of clarifying agent to remove remaining traces of protein coming from the arginase solution. The solution is then centrifuged.

The clear liquid is transferred to a beaker, and precipitation is secured by adding an excess of a 10 per cent solution of xanthydrol in methyl alcohol. The condensation and the precipitation of the dixanthydrol urea are complete in 10 hours. The precipitate is filtered off by suction and is washed with a little methyl alcohol saturated with xanthydrol urea. It is dried at 100° and weighed. Multiplying the figure for the urea by 0.414 gives the weight of the arginine.

Two trials of this method, in which were used in each case 0.150 gm. of arginine, gave the figures 0.147 and 0.148 for the arginine recovered. Arginine added to albumins was recovered with the same accuracy after hydrolysis. In general the error is less than 2 per cent.

The preservative action in catsup of salt, sugar, benzoate, and acid, C. S. PEDERSON and R. S. BREED (*New York State Sta. Bul.* 538 (1926), pp. 15).—Sixteen brands of catsup showing decided variations in acid, sugar, and salt content were inoculated with 32 cultures of 5 quite distinct types of bacteria, all of them nonspore-forming, Gram-positive rods isolated from spoiled tomato products, and with 2 yeast cultures from the same source. Four of the 5 bacterial types produced acid and gas, causing swells in tomato products. The fifth formed slime and acid without gas in tomato products. With the exception of *Lactobacillus lycopersici* Mickle, none were identified with previously described organisms, although some may be closely related to, or identical with, *Bacillus pleofructi* Savage and Hunwicke (*E. S. R.*, 51, p. 261). One per cent of acetic acid, 5 per cent of salt, or 0.2 per cent of sodium benzoate were required to stop the growth of all of the bacteria tested, but certain types were less resistant. Sugar has little effect, 35 per cent inhibiting the growth in certain types only. Sugar and salt combined were very effective; 15 per cent of sugar and 3.5 per cent of salt inhibited all save one yeast. Neither sugar nor salt, however, appreciably lowered the inhibitory concentration of acid.

How to make and preserve cider, F. W. FABIAN (*Michigan Sta. Circ.* 98 (1926), pp. 20).—The various apples commonly used for cider making are classified into five groups: (1) Acid to subacid, (2) subacid to mild, (3) aromatic,

(4) astringent, and (5) neutral. Percentages of these groups which may be combined to produce finely flavored ciders are suggested. The usual practices and apparatus used in the preparation of high-grade ciders are described, a flow sheet is given, and Federal regulations governing the manufacture and sale of cider and similar products are quoted.

The determination of the isoelectric point of wool and silk.—Applications [trans. title], L. MEUNIER and G. REX (*Compt. Rend. Acad. Sci. [Paris]*, 184 (1927), No. 5, pp. 285–287, fig. 1).—Two-gm. samples of wool or of scoured silk were immersed at the laboratory temperature in buffer solutions of pH values from 1 to 10 and left until equilibrium was established, usually in about 40 hours. The equilibrium pH of the solutions was then determined. The water mechanically held in the samples was removed by centrifugalization and the weight of the swelled fiber obtained. The difference between this weight and that of the absolutely dry fiber was taken as a measure of the swelling.

A curve, in which the equilibrium pH values are plotted as abscissas against the corresponding percentages of swelling as ordinates, is given. The minimum swelling in the case of wool was found to take place between the pH values 3.6 and 3.8. The values obtained with silk fiber were less definite, but indicated a minimum swelling in the neighborhood of pH 4.2. The shrinking of wool and silk fibers and the felting tendency of wool were least in liquids of a pH value corresponding to the isoelectric points of the fibers.

Waste sulphite liquor as an agricultural spray, C. S. FLEMING and J. H. REEDY (*Chem. and Metall. Engin.*, 34 (1927), No. 3, p. 159).—Calcium bisulfite is reduced by hydrogen sulfide with the formation of a sulfur-calcium sulfide mixture closely resembling lime-sulfur spray in composition, and the 7 to 9 per cent of organic matter, mostly a sugar-like substance, peptizes the sulfur rather well. The addition of 0.5 per cent of gelatin or of corn sugar enormously improves peptization so that the suspensions last for days and may be almost perfectly restored at any time by agitation. Small scale spraying experiments have been successful. The organic matter increases adhesiveness both directly and by the peptizing tendency. To cut shipping costs the sulfur can be precipitated by hydrochloric acid or other strong electrolyte and filter-pressed to a gummy solid which is easily wetted and resuspended. The filtrate from this operation contains fermentable sugars and can be utilized for the manufacture of alcohol.

METEOROLOGY

The Brückner cycle in the United States, A. J. HENRY (*Bul. Amer. Met. Soc.*, 8 (1927), No. 1, pp. 17–19; *U. S. Mo. Weather Rev.*, 54 (1926), No. 12, p. 507).—This is an abstract of a paper in which it is stated that an examination of data for rainfall and temperature during the nineteenth century did not tend to confirm Brückner's conclusion that groups of cold and wet and of warm and dry years succeed each other in a cycle having an average length of 35 years. On the other hand, it indicated that "both temperature and precipitation oscillate up and down in an irregular manner, but on the average in intervals of 7 to 10 years counting from maximum to maximum or minimum to minimum. In extreme cases the interval may be as long as 22 years and longer if one considers only the changes of great amplitude; there is, moreover, a lack of uniformity in the distribution of warm and cold, wet and dry years which increases as the area under consideration increases. Dry years are much more frequent in the United States and doubtless other countries than wet ones."

Effect of local influences in modifying the general atmospheric conditions, A. SMITH (*U. S. Mo. Weather Rev.*, 54 (1926), No. 11, p. 463).—A statis-

tical study of rainfall and temperature to ascertain whether the sandy nature of the soils in central Wisconsin exerts any marked influence on these two climatic factors showed that the influence, if any, is too small to be detected by the methods used.

Monthly Weather Review, [November–December, 1926] (*U. S. Mo. Weather Rev.*, 54 (1926), Nos. 11, pp. 453–484, pls. 13, fig. 1; 12, pp. 485–529, pls. 20, figs. 14).—In addition to detailed summaries of meteorological and climatological data and weather conditions for November and December, 1926, and bibliographical information, notes, abstracts, and reviews, these numbers contain the following contributions:

No. 11.—A. Ångström on “The Albedo of Various Surfaces of Ground,” by H. H. Kimball; Graphical Thermodynamics of the Free Air (illus.), by E. W. Woolard, L. T. Samuels, and W. R. Stevens; Waves and Vortices on a Quasi Stationary Boundary Surface over Europe, review by H. Willett; Results of Aerological Observations Made at Various Stations in the Netherlands during 1924, review by L. T. Samuels; The Direction of Wind and Cloud over Teneriffe, trans. by B. M. Varney; Weather and Hay in New York State (illus.), by W. A. Mattice (see p. 714); The Tornado in Southern Maryland, November 9, 1926, by T. R. Brooks; and Effect of Local Influences in Modifying the General Atmospheric Conditions, by A. Smith (see p. 712).

No. 12.—Application of the Polar-Front Theory to a Series of American Weather Maps (illus.), by C. G. Rossby and R. H. Weightman; “The Glacial Anticyclones:” A Review, by C. F. Brooks; Notes on Formulas for Use in Forecasting Minimum Temperature (illus.), by E. S. Nichols; The Tornado, by W. J. Humphreys; Thunderstorms at Lander, Wyoming, by McL. S. Collom; and The Weather of 1926 (illus.) (see below).

Climatological data for the United States by sections, [November–December, 1926] (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 13 (1926), Nos. 11, pp. [190], pls. 4, fig. 1; 12, pp. [194], pls. 4, fig. 1).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for November and December, 1926.

The weather of 1926 (*U. S. Dept. Agr., Weather Bur., Weekly Weather and Crop Bul.* 2 (1927), pp. 1–4, figs. 4; also in *U. S. Mo. Weather Rev.*, 54 (1926), No. 12, pp. 504–506, pls. 2).—Monthly and annual departures of temperature and precipitation from the normal during the year in different sections of the country are shown graphically and in tables.

It is stated that “for the country as a whole no marked unusual features as affecting agricultural interests were experienced. Conditions were rather unfavorable for development of some of the major crops, but were unusually favorable for others, with the general results as to yields satisfactory. More than half the country had for the year less than normal precipitation, more than normal warmth, and a longer than normal growing season. . . .

“Wheat came through the mild winter with no material harm, which, together with the subsequent favorable weather, resulted in an unusually good crop of the winter variety; likewise the general absence of damaging frost was responsible for one of the largest fruit yields in the history of the country, and the widespread favorable weather in the South gave an unprecedentedly large crop of cotton. Conditions were somewhat less favorable for corn, though the per-acre yield was only slightly below the preceding 10-year average, while heat and drought materially reduced the yield of spring wheat. . . . The composite yield of all crops was below the 10-year average from the central Great Plains and lower and middle Mississippi Valley northward, slightly below in two South Atlantic States and Nevada, and generally above normal elsewhere.

Of the 48 States, 34, comprising approximately two-thirds of the area of the country, had a composite yield of crops above the 10-year average. . . . A feature of the weather in northern districts, which also penetrated southward to include the middle Mississippi Valley, was the more than usual cloudiness."

Weather and hay in New York State, W. A. MATTICE (*U. S. Mo. Weather Rev.*, 54 (1926), No. 11, p. 461, fig. 1).—Correlating the rainfall and temperature of the growing season with yields of hay for the period 1894–1923, the author found that the most important factor in determining yield is the rainfall from April to June, inclusive, and the second in importance is the May and June mean temperature. The estimate of yield as computed from weather factors averaged 47 per cent closer than the deviation of yield from the average.

SOILS—FERTILIZERS

Soil conditions and plant growth, E. J. RUSSELL (*London and New York: Longmans, Green & Co., 1927, 5. ed., pp. VIII+516, pls. 6, figs. 42*).—In the preparation of this fifth edition (E. S. R., 46, p. 809) all except the historical portions of the book have been rewritten. The most striking advances in soil study since 1921 appear to have been in the chemistry of soils. The developments in the pure chemistry and physics of colloids have opened possibilities, immediately made use of, for further advance in soil chemistry. Investigations in bacteriology and physics have also advanced the application of these sciences to the study of the soil.

The book contains chapters on soil conditions affecting plant growth, the composition of the soil, chemical relationships, the carbon and nitrogen cycle, soil population, biotic conditions, methods of examination, etc. Methods of analysis and a selected bibliography of about 320 references are given in appendixes.

[**Soil and fertilizer work at the Wisconsin Station, 1924–1926**] (*Wisconsin Sta. Bul.* 388 (1926), pp. 50–59, figs. 3).—The following work is reported:

Fertilizer value of activated sludge.—In greenhouse plat experiments activated sewage sludge proved a better source of nitrogen for corn grown in quartz sand than did digested leather, and was about equal to tankage, cottonseed meal, and dried blood. In field experiments sludge compared favorably with tankage and with ammonium sulfate as the sole source of nitrogen for sweet corn, cucumbers, and pumpkins, and with tankage for cabbages. The sludge was also effective for potatoes, though slightly less so than tankage or ammonium sulfate. The largest increases were usually obtained with mixtures having both organic and inorganic nitrogen, under which conditions the sludge was quite as effective as tankage. Sludge proved a good source of nitrogen for golf courses and lawns, satisfactorily replacing manure in the usually used top-dressing mixtures. It is weed-free, requires neither composting nor screening, contains more phosphoric acid and nitrogen than manure, and possesses, in common with the other organic nitrogen carriers, the colloidal nature and absorptive capacity which favorably affect the mechanical condition of soils and improve the conditions for bacterial activity, and its nitrogen is not subject to rapid leaching. Commercial greenhouse trials of sludge in the past year have produced increases of from 10 to 30 per cent in the number of blooms on carnations, and an increase of 686 blooms per 1,000 sq. ft. on roses. O. J. Noer was in charge of the field and laboratory work.

Fertilizer trials on peat at Coddington.—In experiments prior to 1926 potatoes were fertilized at Coddington with mixtures containing either 200 or 150 lbs. of potash. By applying 400 lbs. of muriate, Early Ohio potato yields were increased from 150 bu. for the preceding three years to 312 bu., the potash

being half broadcast and half in rows. By a 400-lb. broadcast alone, 250 bu. per acre were obtained. The yields for 1926 of oats, peas, and carrots are also noted.

Fertilizer tests at Marshfield.—Experiments to determine if the supplementing of manure with commercial fertilizers would give corn an earlier start on the Colby silt loam showed that when hill dropped at the rate of 200 lbs. per acre in conjunction with 8-ton manure applications all resulted in an earlier spring start, maturity from 10 days to 2 weeks earlier, and an increase in yield from 58.65 bu. with manure alone to nearly 75 bu. The most economical manure supplement was 16 per cent acid phosphate.

Potato trials at Ashland.—Supplementation of 8-ton manure applications with 400 lbs. of 16 per cent acid phosphate increased the yield of potatoes grown on a belt of red clay with tracts of sandy loam overlying the clay from 212.5 bu. produced with the manure alone to 299.4 bu. Potash fertilizers appeared to be also especially good for potatoes on this soil.

Alfalfa continues to succeed at Hancock.—Additional lime had no effect upon stand or yield at the Hancock Substation, the liming of 1917 still remaining adequate. Acid phosphate alone or with manure gave no increase, but phosphate supplemental to 300 lbs. of muriate of potash showed increases in proportion to the phosphate. Potash gave important increases alone, with manure, or with phosphate. The duration of the effect of the potash remains to be determined, but 200 to 300 lbs. appears sufficient for one or two crops of alfalfa.

Studies of soil solutions.—A study by E. Truog of the effect of moisture conditions upon the mineral element concentration of soil solutions showed an initial marked decrease on the addition of water, followed by a slight increase prior to the establishment of apparent equilibrium. The manner of moistening does not appear to affect the final concentration, but stored soils give a much higher concentration than do those fresh from the field, the effect of storage being independent of the moisture content over a considerable range. In an uncropped field soil the total quantity of salts in solution was constant over long periods. The concentration of total salts of calcium and, to a less degree, of magnesium varied inversely with the moisture content. The potash and phosphoric acid concentrations showed no variation with the moisture content.

Determining the H-ion concentration of soils.—The electrometric method was found by Truog and W. H. Pierre unsuited to ordinary soil extracts and solutions but could be used with soil suspensions. The colorimetric method was found suitable and convenient for perfectly clear extracts and solutions, such as may be obtained by filtering through washed filtering paper with special suction apparatus. Centrifuging does not clarify all soil extracts, and stoppered containers must be used in centrifuging to avoid a decrease in acidity by exposure to the air. As the reaction of extracts and solutions changes on standing, determinations must be made without delay, and well-weathered glassware should be used. Neutral indicators are necessary, and, if grinding is required, agate mortars and pestles must be used, since glass and porcelain contaminate the indicators with alkaline substances.

The effect of carbonic acid on the H-ion concentration of soils.—Adding carbon dioxide at the bottom of a soil suspension increased the H-ion concentration, but in displaced soil solutions from either acid or alkaline soils bearing growing plants the H-ion concentration was the same as in these soils when uncropped. The pH of an actual soil solution does not appear to be affected significantly by carbon dioxide from plant roots or from decomposing organic matter.

The effect of the soil-water ratio on the H-ion concentration of soils and the nature of soil acidity.—The pH of some soils is not affected by changing

the soil-water ratio from 1:2 to 1:50, and soils whose pH is affected show no such effect after the soluble salts and the more soluble acids are washed out. These experiments support the theory that soil acidity is due principally to such relatively insoluble mineral acids as silicic and alumino-silicic. At equilibrium the soil solution is saturated with these relatively insoluble acids, and as long as some remain undissolved the pH is the same for different soil-water ratios.

Potato experiments at Spooner.—Manure at the rate of 9 tons per acre was found by F. L. Musbach to give excellent results with potatoes grown in sandy soil. Supplementing with commercial fertilizers slightly increased the yield, and may be economical when potato prices are good.

Soil survey of Reeves County, Texas, M. W. BECK and W. W. STRIKE (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1922, pp. III+1257-1294, pls. 2, fig. 1, map 1).—In this survey, made in cooperation with the Texas Experiment Station, the soils of an area of 1,661,440 acres in southwestern Texas near the New Mexico line are classified and mapped. The area slopes in general toward the east and southeast. It has a fairly well-established drainage and lies from 2,400 to 5,000 ft. above sea level. The average annual precipitation is about 11 in., of which more than one-half usually falls within the period July to October, inclusive.

Three distinct soil groups were found: (1) Upland soils of the outwash-plain region, (2) residual soils from the igneous and limestone rocks, and (3) first-bottom soils, representing recent alluvium. Excessive alkali was found in many of the soils, most of which, however, can probably be reclaimed by ditching and flooding. The soils have been classified and mapped in 8 series of 10 types, the Reeves silty clay loam, the Reeves gravelly loam, and the Verhalen clay occupying, respectively, 33.2, 27.0, and 12.1 per cent of the area, with rough stony land, unclassified, amounting to 4.5 per cent.

The agricultural characteristics of the south chernozem, dark chestnut, and alkali soils of the Saratov experiment region [trans. title], M. S. KUZ'MIN [KOUSMIN] (Zhur. Opytn. Agron. Iugo-Vostoka (Jour. Expt. Landw. Südost. Eur.-Russlands), 3 (1926), No. 1, pp. 16-31; Eng. abs., p. 31).—Statistical methods and an investigation of soil dynamics were utilized in a study of the values of three principal soil types at the soil laboratory of the Saratov Experiment Station. All three were comparatively rich, their differences arising principally from the physical nature of their origins. In the alkali soil, in spite of the supposedly poor aeration of its compact horizon, the mobilization of the nutrient supply is adequate, but unfavorable moisture conditions appear to limit the development of its potential productiveness. The limiting factor in the case of the dark chestnut soil seems to be the compact horizon. Its conditions with respect to aeration, moisture, and nutrients are unfavorable to the lower horizons. Some correlation was found in comparing the character of the exchangeable base with the physical properties in the south chernozem, dark chestnut, and alkali soils.

Black and white alkali soils of Asiatic Siberia and Turkestan, K. D. GLINKA (Solontsy i Solonchaki Aziatskoï Chasti SSSR (Sibir i Turkestan). Moscow: "Novaia Derevnâ," 1926, pp. 74).—A detailed account of the various types of alkali soils of Siberia and Turkestan is given. These soils are classified into zones as follows: Podsol, chernozem, chestnut, brown, and gray. The profile, structure, horizon, mode of formation, vegetation, and geographic distribution of each zone are described. The formation of black alkali is traced in each case. In certain cases, where precipitation prevents the accumulation of soluble salts, black alkali is formed from white alkali, but black alkali is not

necessarily derived from white alkali. The podsol zone contains sulfate soils, the chernozem zone carbonate soils with a considerable sulfate, the chestnut and brown zones sulfate and chloride soils, and the gray zone primarily sulfate soils.

The phenomena of contraction and expansion of soils when wetted with water. G. J. BOUYOUKOS (*Soil Sci.*, 23 (1927), No. 2, pp. 119-126, fig. 1).—In a series of experiments at the Michigan Experiment Station, three distinct modifications of the dilatometer method were tested, and a specially constructed dilatometer was used. A contraction on wetting varying with the character of the soil was observed, the organic constituents showing the greatest contraction. The volume contraction showed a close relationship to both organic matter content and the heat of wetting. The relationship to the colloid content was not so close and consistent. The contraction is attributed principally to surface condensation of some of the water upon the soil particles or colloids, but a small part may be caused by hydration.

The moisture equivalent of heavy soils, II. A. F. JOSEPH (*Jour. Agr. Sci. [England]*, 17 (1927), No. 1, pp. 12-20).—Experiments are described, in continuation of a previously noted study (E. S. R., 50, p. 421), on the extent to which the moisture equivalent is an additive property, dependent on the nature of the fractions under the modifying influence of electrolytes and possibly humus. The moisture equivalent of pure clay varies with (1) the chemical composition, (2) the method of separation, if the material be centrifuged, and (3) the replaceable bases. The imbibitional water content also shows a close connection with the same variables. Good additive relationships can only be obtained from series of soils of the same nature and sometimes only if these be taken at the same depth. This is at least partly due to differences in composition and properties between the clays of soils and subsoils. Pure silt fractions from different soils differed markedly in chemical composition and moisture content.

Effects of some electrolytes on kaolin and the probable relation to the soil. J. R. SKEEN (*Soil Sci.*, 23 (1927), No. 3, pp. 225-242, figs. 4).—A preliminary physicochemical study, at the University of Pennsylvania, on the behavior of kaolin in solutions of certain electrolytes, with the object of explaining the formation of the hardpan in acid clay soils, is discussed. Data are presented for their comparative value only on the turbidity of supernatant solutions, on the final volume of kaolin sedimented from various solutions, on the conductivity of solutions, and on the sign and intensity of the particular charge. Various concentrations of hydrochloric acid, sodium hydroxide, sodium chloride, sodium sulfate, sodium citrate, barium, calcium, and aluminum chlorides, sucrose, and urea were used.

The aluminum ion clears the supernatant liquid in dilute solutions immediately after shaking, whereas the citrate and sulfate ions stabilize the suspension. There is some correlation between turbidity and the final volume of sediment. The final sediment volume is generally much less in the most turbid solutions, but nearly all the aluminum solutions greatly increase the final sediment volume. Sucrose and urea do not affect kaolin. Only the aluminum and sodium ions flocculate kaolin, and the degree of flocculation appears to be independent of the particular charge. Hydrochloric acid is largely adsorbed at all dilutions, but none of the other electrolytes used was adsorbed from dilute solutions. Adsorption apparently is not a function of pH in clays. The aluminum concentration in the soil solution seems to depend both upon the phosphate content and upon the pH of the soil. A great decrease in either controlling factor may but slightly increase the dissolved aluminum; but a

slight decrease in both phosphate content and pH will greatly increase dissolved aluminum and iron. The formation of hardpan is tentatively attributed to an acid (about pH 5) solution of aluminum and iron at the surface. These elements, not being adsorbed by the clay, are carried down in quantities ultimately sufficient to flocculate the clay at some depth, dependent on the pH. The aggregated clay particles cause the formation of a tight layer about the aggregates of which, after drying, aluminum and iron are deposited as oxides mechanically binding an impermeable mass. Analytical evidence in support of this view is presented.

Differences in the heat of reaction between artificial and soil gels of silica, alumina, and iron, with hydroxides, G. J. BOUYOUKOS (*Soil Sci.*, 23 (1927), No. 3, pp. 243-247).—Experiments are reported from the Michigan Experiment Station, in which it was found that the heat of reaction, as distinct from the heat of wetting, of soil colloids when treated with sodium and potassium hydroxides is very small in comparison with that of artificial gels of ferric hydroxide, alumina, and silica. Apparently the soil colloid gels of iron, alumina, and silica are either of a constitution, or in a state, quite different from that of the corresponding artificially prepared gels. This difference has not been brought out in determinations of the heat of wetting of soil and artificial colloids.

Fertility of a soil as related to the forms of its iron and manganese, P. H. BREWER and R. H. CARR (*Soil Sci.*, 23 (1927), No. 3, pp. 165-173, figs. 2).—A study of the soil of the Scottsburg experiment field of Purdue University indicated the presence of a toxic substance, and showed most of the iron present to be in the ferric condition, not available to plants at a pH of about 6.0. This condition is largely counteracted by the reducing action of manures, but is not improved by commercial fertilizers. Manuring did not greatly alter the percentages of iron and manganese present, but the lower state of oxidation of these elements appeared the more favorable for plant growth, as indicated by annual increases of about one-third in corn and wheat yields and by an approximate doubling of the clover yield.

Testing soils for acidity by the modified Comber method, M. F. MILLER (*Missouri Agr. Col. Ext. Circ.* 184 (1926), pp. 4, figs. 2).—Practical directions are given, together with a color chart and liming indications for several crops. Attention is drawn to the fact that no test for the lime requirements of soils is absolutely accurate. The modified Comber test is deemed as accurate as any and more satisfactory than most.

The organic matter in heavy alkaline soils, A. F. JOSEPH and B. W. WHITFIELD (*Jour. Agr. Sci. [England]*, 17 (1927), No. 1, pp. 1-11).—The composition of three soils from the Blue Nile, Khartum, and the Gezira, and the Upper White Nile, 100 and 800 miles south of Khartum, was studied. A modification of Beam's method for humus determination was used.

Sudan soils were found to be low in organic matter, the total organic carbon being usually below 1 per cent. Humus could not be obtained ash free. Specimens from widely different sources contain nearly the same percentage of carbon. Humus solutions in very dilute alkali keep fairly well in the dark, and in the light when air is excluded. Colorimetric standards may be used if not kept too long.

Field studies showed a greater humus content in good than in poor soils. There is a marked inverse connection between salt and humus content. This conclusion does not apply to the depth distribution, however. The total nitrogen of the soils studied was low. About one-fifth of the total was humus nitrogen. The carbon-nitrogen ratio was about 12:1.

The bacterial flora of serpentine soils, C. B. LIPMAN (*Jour. Bact.*, 12 (1926), No. 5, pp. 315-318).—Experiments at the University of California, forming a part of a study of the infertility of dominantly magnesian soils, are reported. These experiments included bacterial counts and a study of the nitrifying and nitrogen-fixing bacteria of three serpentine soils from the Mount Diablo region of California. The infertility of these soils was found to be due to a high pH and a deficiency in especially the nitrate and phosphate ions.

The bacterial population consisted principally of nonchromogenic forms, with very few fungi and Actinomyces. No active nitrifying flora were found, though a few *Azotobacter* cells appeared in one soil. The poverty in microorganisms is attributed to (1) ammonia deficiency, due in turn to deficiency in easily decomposed protein and like substances; (2) paucity in ammonia-forming organisms; (3) deficiency in available phosphoric acid; and (4) deficiency in carbon compounds.

Humus in Assam soils: Its depletion and means of recuperation, S. K. MITRA and L. N. PHUKAN (*Assam Dept. Agr. Bul.* 1 (1926), pp. 6).—Seventeen Assam soils were examined for humus content. A table shows percentages of humus in the plains districts ranging from 0.66 (sandy soils) to 2.75 (clay soils). In alluvial plains subject to flood the natural silt is quite suitable for crop production. The burning of weeds and stubble instead of plowing them under, the washing of the soil during the monsoon rains, and the practice of the continuous one-crop system are assigned as principal causes of humus depletion in the Assam region. The application of farmyard manure, green manuring, liming of excessively acid soils, and rotation are recommended. Important leguminous crops which can be grown in rotation with sugar cane are listed.

[**Soil fertility studies at the Arizona Station**], C. N. CATLIN and A. E. VINSON (*Arizona Sta. Rpt.* 1923, pp. 447-450).—Treatment of two black alkali soils with various acid materials, including aluminum compounds, showed the sulfide and sulfate to be the only aluminum salts having a neutralizing effect on the black alkali.

The application of 100 tons of sulfuric acid on eight tracts in the Casa Grande Valley proved promising, but marked crop increases were obtained in only a few cases. Laboratory studies showed increased percolation, especially near the surface. The calcium sulfate formed on treating lime soil with sulfuric acid is in a finer and consequently more soluble condition than the gypsum ordinarily applied to alkaline lands. Calcium bicarbonate increased the percolation rate in "tight" soils.

Experiments in manuring, F. C. HAROLD (*Jour. Min. Agr. [Gt. Brit.]*, 33 (1926), No. 9, pp. 811-814).—Experiments to determine the maximum economic outlay in phosphatic, nitrogenous, and potassic fertilizers on loam soil over freestone are briefly reported. The results appear to be primarily of local significance.

Note on the action of hydrogen peroxide on farmyard manure in different stages of decomposition, G. H. G. JONES (*Jour. Agr. Sci. [England]*, 17 (1927), No. 1, pp. 104-108).—Six per cent hydrogen peroxide was used in experiments for the fractionation of soil organic matter into the humified and nonhumified portions. There appears to be a good correlation between the degree of decomposition of farmyard manure as indicated by its appearance and known history and the extent of humification as indicated by the peroxide treatment. "Degree of humification" might be used as a criterion of the condition of farmyard manures.

Fertilizers, E. B. VOORHEES, rev. by S. B. HASKELL (*New York: Macmillan Co., 1926, 2. ed., rev., pp. XIX+310, pls. 16, figs. 4*).—In this second revised edition (E. S. R., 36, p. 119) it has been the purpose to use the many additions to the knowledge of fertilizer manufacture and application, "but in doing so to leave the book itself true to its original concept, and, in so far as may be possible, to have it still the product of one who was himself a pioneer in the field of fertilizer use." Some new matter has been added, and the older matter has been brought up to date.

Fertilizers: Their sources, manufacture, and uses, H. CAVE (*London and New York: Isaac Pitman & Sons [1926], pp. XI+116, pl. 1, figs. 17*).—A general nontechnical account of the sources, manufacture, and uses of fertilizers is presented. The subject is viewed principally from the commercial standpoint. The book contains a general introduction and chapters on mineral phosphates, superphosphate and basic slag, nitrogenous fertilizers, atmospheric nitrogen compounds, potash fertilizers, organic and other products, utilization of fertilizers in agriculture, and commercial information.

World conditions as to mineral raw materials for the fertilizer industry (*Washington, D. C.: Natl. Fert. Assoc., 1926, pp. 180, figs. 7*).—This book contains a series of addresses by specialists from U. S. Government Departments, from the universities, and from the industries on potash, phosphates, sulfur, and nitrogen.

A study of the factors influencing the efficiency of different forms of nitrogen as related to soil type and cropping system in the Atlantic Coastal Plain region, Part I, A. M. SMITH (*Soil Sci., 23 (1927), No. 2, pp. 137-164, fig. 1*).—Two series of fertilizer experiments on surface soil from Snow Hill, Md., are reported from the Maryland Experiment Station, the first constituting a study of the influence of soil moisture on the nitrification rate, the second dealing with the influence of soil temperature on the rate of nitrification. The optimum moisture condition for various nitrogenous materials applied in a 7-6-5 fertilizer to Norfolk sandy loam soil was from 50 to 60 per cent of the water-holding capacity. At 70 per cent of capacity there was more nitrate accumulation from urea than from ammonium sulfate, dried ground fish, or tankage. After the initial rapid nitrification, fluctuations in nitrate nitrogen in this soil appeared to be due to microorganism activity rather than to differences in moisture, temperature, or reaction. Up to 20 to 30° C., nitrate production increased directly with the temperature. At all temperatures urea gave the highest rate, and, at all except the lowest temperature level, ammonium sulfate gave the highest final accumulation of nitrate nitrogen. Considered with respect to both production and accumulation rates, the materials ranked as follows: Sodium nitrate, urea, ammonium sulfate, dried ground fish, tankage, and activated sewage sludge. Leaching varied with the proportion of the applied nitrogen supplied by sodium nitrate. There was little difference in the nitrate leaching rates from the various materials, save that at first more nitrate was leached from the cylinder receiving urea.

Potassium content of plants as an indicator of available supply in soil, J. W. AMES and R. W. GERDEL (*Soil Sci., 23 (1927), No. 3, pp. 199-216, pls. 4*).—A modification of the seedling method of soil analysis was applied in experiments reported from the Ohio Experiment Station to a study of potassium abstraction in its relation to available supplies of potassium and of other nutrients. Optimum experimental conditions appeared to be obtained with 100 wheat seedlings grown in 200 gm. of soil diluted with 1,000 gm. of sand. Corn and buckwheat seedlings were also used in some experiments.

The potassium removal was found closely related to increased growth produced by adding nutrients. Applications of available potassium stimulated the growth of wheat seedlings. The addition of potassium in fertilizers and manures furnished a potassium residual readily available to wheat seedlings. Potassium abstraction by wheat seedlings from a limed soil fertilized only with acid phosphate for over 30 years did not indicate such a depletion of available potassium as did dilute acid extraction and recently decreasing corn yields. Corn plants grown beyond the seedling stage in undiluted soil varied in potassium content consistently with the available supply.

Losses of added phosphate by leaching from N. Welsh soils, G. W. ROBINSON and J. O. JONES (*Jour. Agr. Sci. [England]*, 17 (1927), No. 1, pp. 94-103).—Experiments are reported which show that under the extremely humid conditions of North Wales and in soils of very low base content phosphate applied to permanent grassland in the form of high-grade basic slag is of fugitive effect. Profile analyses show that after from 6 to 10 years added phosphoric acid has been removed from the surface layers, which have reverted to their original poverty in available phosphorus. It is suggested that the phosphate content of soils may be differentiated into (1) native, stable phosphate and (2) added phosphate which is unstable under North Welsh conditions, being subject to removal by leaching.

Organic matter changes in two soil zones, as influenced by difference in form, fineness, and amount of calcic and magnesian materials, W. H. MACINTIRE, W. M. SHAW, and E. M. CRAWFORD (*Soil Sci.*, 23 (1927), No. 2, pp. 107-117, fig. 1).—Lysimeter experiments at the Tennessee Experiment Station on the effect of various liming materials applied in varying degrees of fineness to both surface and subsurface zones are reported. Organic carbon dioxide was used as a measure of oxidation. The experiments covered the 4-year period from May, 1921, to May, 1925, during which time the soil was not cropped or stirred. The surface zone only of the soil of one series of tanks was treated and the lower zone only of the soil in the other series.

In general the accelerative effects of the liming materials were comparable in the two zones. The final organic carbon dioxide content of the surface zone of the untreated soil was somewhat greater after exposure than that of the original soil, whereas in the subsurface zone the content was decidedly less. This is attributed to surface deposition of soot and to the unavoidable growth of algae and the like on surface soil, together with a possible gravitational readjustment of the soil particles. Loss in the lower zone is attributed to increased bacterial activity, caused by greater moisture and exclusion of sunlight.

Out of 16 treated surface zones, 14 showed less organic matter than the untreated surface zone controls. Out of 16 treated subsurface zones, 15 showed less organic matter than the corresponding subsurface zone controls. No positive differences in organic carbon dioxide residues could be traced to variation in fineness of limestone. Some variation between the coarsest and finest dolomites was observed. The zone influence was apparently greater than that of liming materials with respect to oxidation of organic matter in the soil studied when under fallow conditions, unstirred, and with exposure to natural rain water only.

Outgo of calcium, magnesium, nitrates, and sulfates from high-calcic and high-magnesian limes incorporated in two soil zones, W. H. MACINTIRE (*Soil Sci.*, 23 (1927), No. 3, pp. 175-197, figs. 4).—The results of a 4-year lysimeter study, conducted at the Tennessee Experiment Station, on the losses from a loam soil of calcium, magnesium, calcium-magnesium, nitrate, and

sulfate from additions of calcium hydroxide, burned dolomite, and a lime-magnesia mixture to the surface and subsurface zones at a constant rate of 3,570 lbs. of calcium carbonate per 2,000,000 lbs. of soil are reported.

The loss of calcium from each liming material was in all cases greatest during the first year, decreasing progressively. The magnesium loss from surface-zone treatments with the lime-magnesia mixture was augmented during the first year, but was practically the same as from the controls during the following three years. In the subsurface treatments this loss was increased in all four annual leachings, though greater in the first than in subsequent years. The aggregate leachings of calcium-magnesium from the treated surface zones were comparable for each year and for the 4-year period.

The total calcium-magnesium losses from the subsurface zone were similarly comparable with first year maxima for each of the three liming materials. The annual leachings from the lower zones were about five times as great as those from the upper zone. A slight interchange of calcium for magnesium was found when the excess of calcium salts from the treated surface passed to the untreated lower zone, but "reciprocal repression" took place in the direct leachings from the absorbed calcium excess in the lower zone.

Comparable increases in nitrate and sulfate losses from treatments with calcium oxide and with the lime-magnesia mixture were noted during the first year; but, as there was no marked variation thereafter, the increases for the 4 years were about the same as the corresponding ones for the first year. No marked difference in nitrate losses from the two zones was noted. Even as increased by the treatment, the sulfate losses did not equal the rain water increment. Upper zone leachings carried about twice as much calcium as magnesium, whereas the lower zone treatments gave about twice as much magnesium as calcium. A number of differences in the leachings were noted as between calcium hydroxide and calcium oxide plus magnesium oxide treatments. The progressively decreasing calcium and calcium-magnesium outgo is apparently due rather to diminishing solubility than to diminishing concentration of residuals. Repetition of liming may be needed, not to offset losses, but to supply more freshly absorbed and more soluble lime residues.

Composition and prices of commercial fertilizers in New York in 1926, L. L. VAN SLYKE (*New York State Sta. Bul. 539 (1926), pp. 21*).—The author concludes that in 1926 the complete fertilizers contained a larger average percentage of plant food than at any previous time recorded. There was a marked increase in the number of fertilizers of high grade as based on total content of plant food, with a relative decrease in the lower grades, and a larger percentage of fertilizers than in previous years was found above the guaranteed analysis, especially as available phosphoric acid and potash. Data with regard to the composition and cost of plant food in such unmixed fertilizer materials as acid phosphate, sodium nitrate, ammonium sulfate, potash salts, bone, tankage, dried blood, dried animal manures, and lime compounds are given.

AGRICULTURAL BOTANY

Dictionary of botany, C. L. GATIN (*Dictionnaire de Botanique. Paris: Paul Lechevalier, 1924, pp. XIX+847, figs. 700*).—In one alphabet are contained botanical terms, from several languages, which are translated into French.

Plant physiology in relation to agronomy, T. J. HARRISON (*Sci. Agr., 6 (1926), No. 11, pp. 380-382*).—Illustrations given and claimed to show the value of plant physiology in the explanation of field data point to the necessity of understanding the physiology of the plant in order to interpret correctly the results of field crop experimentation.

A plant photometer, E. S. JOHNSTON (*Plant Physiol.*, 1 (1926), No. 1, pp. 89, 90).—Light may influence plant growth by its intensity, its duration, and its quality (wave length), but a study of one of these factors is complicated by the presence of the other two. The present paper describes briefly a method of studying the quality or wave length of light as it affects plant growth in phototropic bending. The apparatus, its use, and its possibilities are very briefly discussed.

A method of growing bacteriologically sterile potato plants, H. G. MACMILLAN (*U. S. Dept. Agr. Bul.* 1465 (1927), pp. 22, pls. 6, figs. 6).—A description is given of a method by which bacteriologically sterile potato plants grown from vegetative cuttings or tubers may be developed under sterile conditions.

The extraction of plant tissue fluids and their utility in physiological studies, R. NEWTON, W. R. BROWN, and W. M. MARTIN (*Plant Physiol.*, 1 (1926), No. 1, pp. 57-65, fig. 1).—Plant tissues finely ground and gently pressed at temperatures near 0° C. yield a fluid which is believed to have substantially the same composition as the original tissue fluids. Experimental data show the need for careful standardization of the extraction procedure, particularly the pressures employed.

By supplementing ordinary tissue analyses with analyses of the expressed fluids, the distribution of any constituent between the physiologically active and inert portions of the plant may be conveniently determined. The important influence of the physical state of the tissue fluids on their freezing point and the difficulty of proving the identity of the press juice with the actual fluids in the plant are illustrated experimentally.

Some protein properties of plant protoplasm, W. H. PEARSALL and J. EWING (*Brit. Jour. Expt. Biol.*, 2 (1925), No. 3, pp. 347-356).—The protein properties or behaviors of plant protoplasm here dealt with include precipitation, chemical combination, changes in volume and in viscosity, heat coagulation, and pH relation. "The result of the comparison would seem to justify the working hypothesis that the properties of the protoplasm can be foretold, to a certain extent, if those of the more important protein constituents are known."

The significance of soil colloids in relation to plant feeding and conservation of essential elements, E. TRUOG (*Jour. Amer. Soc. Agron.*, 17 (1925), No. 5, pp. 280-285).—It appears that colloids influence or control practically all the physical properties of soils, and collectively they must be regarded as a most important soil constituent.

Some phases of the inorganic nutrition of plants in relation to the soil solution, I, II, D. R. HOAGLAND (*Sci. Agr.*, 6 (1926), Nos. 5, pp. 141-151, figs. 4; 6, pp. 177-189, figs. 4).—The first part of this account deals with the growth of plants in artificial culture media and the second with soil solutions as media for plant growth. Details and tabulations are given, and the attempt has been made to outline the results and methods by which scientific understanding of the relation of plant growth to the soil moisture might be obtained.

"Scientific research on soils and plants must place great reliance on the results of experiments conducted in the laboratory or greenhouse." The literature cited comprises 28 titles.

Adjustment of iron supply to requirements of soy bean in solution culture, R. P. MARSH and J. W. SHIVE (*Bot. Gaz.*, 79 (1925), No. 1, pp. 1-27, figs. 2).—In tests of the effects of four soluble iron compounds, used singly, upon the growth and appearance of soy bean plants grown in culture solutions of three types, continuously renewed and constantly aerated, large, healthy, vigorous plants were produced when the iron supply was adjusted from day

to day to meet the requirements, regardless of the type of culture solution or the iron compound employed.

When the available iron supply is slightly excessive the plants may become chlorotic or they may show symptoms of iron toxicity. Healthy green plants show lower dry-weight percentages of iron than do chlorotic plants or plants suffering from iron toxicity. In healthy green plants the iron content appears to be uniformly distributed in the stems and leaves. In the chlorotic plants the iron content is high in stems and low in leaves. In plants suffering from iron toxicity the iron percentage is high in all parts. In order to maintain the plants in the healthy green condition the iron solution must be kept as low as is possible without inducing chlorosis from lack of available iron. A concentration of soluble iron slightly above the optimum may result in iron toxicity throughout the plant, or chlorosis may result from lodgment of iron in the roots and stems. "Small additions of available iron to the culture solution as the plant appears to require it tend to produce equal distribution throughout and to keep it in a healthy green condition. The general appearance of the plant must serve as an index of the iron supply in each case. Definite applications of iron to the culture media at fixed intervals during any given physiological stage of development are not practicable, since the ever-changing plant environment has pronounced influence upon the iron requirement. It appears that a delicate balance exists within the plant which requires that the available iron in the culture medium be limited to a very narrow range of concentrations to produce optimum growth."

The tolerance of plants for NaCl, C. B. LIPMAN, A. R. DAVIS, and E. S. WEST (*Soil Sci.*, 22 (1926), No. 4, pp. 303-322, figs. 3).—Studies conducted at the University of California on the effects of a wide range of concentrations of sodium chloride on the growth of wheat, barley, and peas in solution cultures are reported.

All of the plants tested showed a very high resistance to sodium chloride, and under some environmental conditions it was highly stimulating to wheat even at concentrations of 4,000 parts per million or more. It was found that small concentrations of from 500 to 1,000 parts per million may depress growth, particularly in the early stages, but the concentration at which the most marked depression occurred was about 8,000 parts per million. The results are taken to indicate that environmental conditions are a very important determinant of the kind of results which can be obtained.

The selective absorption of chlorine ions, and the absorption of water by the leaves in the genus *Atriplex*, J. G. WOOD (*Aust. Jour. Expt. Biol. and Med. Sci.*, 2 (1925), No. 1, pp. 45-56, fig. 1; *abs. in Nature [London]*, 116 (1925), No. 2905, p. 27).—The more rapid absorption of water in the case of characteristically desert plants (*Atriplex* spp.) is thought to be due measurably to the high osmotic pressure in the tissues of these plants. "Extensive absorption of water does not occur at all times through the roots, and the success of the plant in these regions must be attributed to its ability to absorb water rapidly through its leaves."

Chlorophyll defect in barley [trans. title], L. HONECKER (*Ztschr. Pflanzenzücht*, 10 (1925), No. 2, pp. 172, 173).—A paling or chlorosis of barley, which began to show (in part of the progeny of a crossing indicated) about May 3 and to prove fatal about May 12, affected the plantlets in the ratio of approximately one chlorotic to three normal individuals.

Plant nutrition research (*Wisconsin Sta. Bul.* 388 (1926), pp. 123, 124).—In a previous publication (E. S. R., 55, p. 520) W. E. Tottingham et al. showed the response of sugar beets to light and temperature. Continued

investigations indicate that sugar beets in strong light stored the largest amount of sugar and protein at a relatively low temperature, or in the cool, fair weather of autumn, but this was not true of corn. It appears that the amount of soluble protein in the leaf is one of the factors determining the response of the leaf to light and temperature. Observations which have continued for two years on the chemical composition of crops grown at the main station and the Ashland Substation are said to indicate that the clovers grown at Madison have a higher protein content than those grown at Ashland. Some differences have also been noted between corn, oats, and barley grown at the two stations.

The development of sugar beets during the second year, with reference to the distribution of sugar, dry matter, ash, and marc [trans. title], V. STEHLÍK (*Listy Cukrovar.*, 44 (1925-26), pp. 17- ; trans. in *Ztschr. Zuckerindus. Českoslovak. Repub.*, 50 (1926), Nos. 35, pp. 295-300, figs. 4; 36, pp. 301-308, figs. 4; 37, pp. 309-315, fig. 1).—Continuing a previous account (E. S. R., 53, p. 24), which dealt principally with the first year of growth of the sugar beet, work is here recorded as done in four parts, dealing, respectively, with development in quartered beets under glass in poor soil with reference to the distribution of materials, development of entire beets in poor soil under glass, development of entire beets in the field and distribution of materials during the whole development, and development in beet sets.

Both composition and distribution of materials depend upon the growth of the plants individually. Particulars are given in comparison with developments during the first year. The distribution of marc (pulp) corresponds to the anatomical structure, depending more strictly in this respect upon the vascular bundle material. Raw-fiber content corresponds on the one hand to the degree of development and on the other to anatomical structure in a given part. The distribution of dry-substance content depends upon the distribution of other materials. In the first year of growth this dependence is more important to the sugar refiners and in the second year to beet breeders and seed raisers.

The influence of the time of threshing upon the germinability of grain [trans. title], A. MORETTINI (*Staz. Sper. Agr. Ital.*, 58 (1925), No. 1-6, pp. 161-182).—Threshing injury to grains did not seriously impair germinability for seeding purposes.

Catalase activity and the aerobic and anaerobic germination of rice, T. MORINAGA (*Bot. Gaz.*, 79 (1925), No. 1, pp. 73-84).—The work here reported was undertaken to throw light on the relation of catalase to the dynamic cell processes.

The amount of catalase in dry rice seeds is only about one-tenth as great as in wheat, barley, oats, or rye. Rice germinating aerobically contains about seven-tenths as much as does germinating wheat, barley, or oats. In anaerobic germination catalase does not increase, but in a medium having a reduced amount of oxygen catalase increases slowly. Catalase activity increase appears to be a function of the free oxygen present in the medium. Free oxygen affects directly or indirectly the development of plumule and radicle and also that of the chlorophyll. The catalase once increased by aerobic conditions decreases during anaerobiosis, while growth of the plant continues. Aerobically grown seedlings with high catalase use much more oxygen than do anaerobically grown seedlings with low catalase activity. The anaerobic seedlings, however, give off a comparatively large amount of carbon dioxide during respiration, whether under normal aerobic or under anaerobic conditions.

The hydrostatic system of trees, D. T. MACDOUGAL (*Carnegie Inst. Wash. Pub.* 373 (1926), pp. III+125, pl. 1, figs. 20).—Recognizing that knowledge of

major sap movements in large trees must rest upon a good grasp of hydrostatic conditions, the author has, in the present monograph, included results upon which certain phases of sap pressure are explained, without, however, accounting for all root pressures. A unified conception of the large leafy plant as a hydrostatic system has been attempted in a paper previously noted (E. S. R., 56, p. 218).

Some important modifications based upon results set forth in the present paper are proposed. "The principal advances concern the body of gas in the older wood; the capillary extension of the water column in this wood; the strictness of conduction of solutions in the outer layers; or, more briefly stated, the localization of mechanical factors and of the physiological action affecting movements of solutions." The data and conclusions from the numerous phases of the present study are summarized in some detail.

Symbiosis in a deciduous forest, II, W. B. McDOUGALL (*Bot. Gaz.*, 79 (1925), No. 1, pp. 95-102, fig. 1).—It is the purpose of the present installment of this series (E. S. R., 49, p. 523) to discuss a few recently studied examples of nutritive disjunctive symbiosis and their effects on the vegetation in the woods previously indicated, which were formerly much grazed by cattle with the result of suppressing certain species and of favoring others. The parts played by some other animals were also studied and are indicated.

The nutrition of mycorrhiza plants: *Calluna vulgaris*, M. C. RAYNER (*Brit. Jour. Expt. Biol.*, 2 (1925), No. 2, pp. 265-292, pls. 3, figs. 5).—In an observation of the formation and seasonal development of mycorrhiza in *C. vulgaris*, digestion of the intracellular complex of mycelium was noted, and this is reported, supposedly for the first time. The cytology of the process is described. Knowledge of the distribution of the endophyte has been extended, and this has been confirmed by recovery and identification of the endophyte.

It is claimed that *Calluna* is associated with infection and seedling development and not with mycorrhiza formation and growth. The view is expressed that plants would probably grow quite well without mycorrhiza if seedlings could be raised without infection. The evidence for exchange of nutritive material is stated and examined, and the view has been reached that such exchange exists, with a balance of profit on the side of the vascular plant.

Some observations on the growth of yeast, E. I. FULMER (*Plant Physiol.*, 1 (1926), No. 1, pp. 67-76, figs. 4).—The author attempts to formulate and illustrate certain general principles and their several corollaries with reference to the study of the growth of organisms, as instanced by the behavior of yeast, reproduction being a criterion here employed.

The relative potencies of two materials as they affect the growth of a microorganism can not be ascertained by the comparison of the effect of equal weights or concentrations of materials. Such relation of potencies may not hold equally at different temperatures, so that such terms as optimum temperature, thermal death point, and temperature coefficient of growth have no general meaning but are, in fact, functions not only of the components of the medium but also of their concentrations.

Two materials can not be compared as a source of a protoplasmic constituent on the basis of their effect as regards growth rate of a microorganism unless secondary effects are compensated in a series. Comparisons of two materials as affecting the growth of microorganisms at one growth phase may not apply in case of any other growth phase. Results obtained by means of one criterion of toxicity are not necessarily applicable to any other criterion.

Violent spore-discharge in *Tilletia tritici*, A. H. R. BULLER and T. C. VANTERPOOL (*Nature*. [London], 116 (1925), No. 2930, pp. 934, 935, fig. 1).—Studies

briefly recounted are considered as confirmatory of the view that the Tilletiaceae belong to the Basidiomycetes, also as showing that the so-called secondary conidia of *T. tritici* and *Tilletia* spp. are in reality the true basidiospores, and that the sporidia or primary conidia of O. Brefeld and others are morphologically equivalent to sterigmata. It is thought that further research will show that the authors' new conception of the basidium in the genus *Tilletia* may be successfully applied to the basidia of the other genera of the Tilletiaceae.

Heterothallism in the genus *Penicillium*—A preliminary note, H. G. DERY (*Brit. Mycol. Soc. Trans.*, 11 (1926), pt. 1-2, pp. 108-112).—" *P. luteum* . . . furnishes the first example of heterothallism in this common genus."

GENETICS

The problem of the origin of species as it appeared to Darwin in 1859 and as it appears to us to-day, H. F. OSBORN (*Science*, 64 (1926), No. 1658, pp. 337-341).—The author points out that considerable knowledge of the mode of the development of species has been acquired, but that little is known of the causes of the variations responsible for the origin of new species.

The problem of cell division from the physiological point of view, A. and L. GURWITSCH (*Das Problem der Zellteilung Physiologisch Betrachtet. Berlin: Julius Springer, 1926*, pp. VII+221, figs. 74).—Cell division is technically discussed under three main headings, the beginning of cell division, cell division as a factor in evolution, and the course of mitosis.

Chromosome and gene mutations in *Datura* following exposure to radium rays, C. S. GAGER and A. F. BLAKESLEE (*Natl. Acad. Sci. Proc.*, 13 (1927), No. 2, pp. 75-79).—The effect of treatment of buds of *D. stramonium* with radium emanation was studied at the Brooklyn Botanic Garden as an outgrowth of early studies (E. S. R., 20, p. 929). In the offspring of a single capsule were obtained 17.7 per cent chromosomal mutants (chiefly nondisjunctional forms), a much higher percentage than ever obtained from untreated capsules, the average for over 15,000 offspring being 0.47 per cent; a new compound chromosomal type, Nubbin; and two new gene mutants out of 18 individuals tested. The authors believe that the radium treatment may be held largely responsible for most, if not for all, of these three types of results.

The chromosomal constitution of Nubbin, a compound ($2n+1$) type in *Datura*, A. F. BLAKESLEE (*Natl. Acad. Sci. Proc.*, 13 (1927), No. 2, pp. 79-85, figs. 4).—This contribution from the Carnegie Institution is concerned with "Nubbin," a new compound chromosomal type, whose origin is indicated above.

Chromosome behavior in the heterotypic division in *Oenothera lamarckiana* and some of its mutants and hybrids [trans. title], A. HÅKANSSON (*Hereditas*, 8 (1927), No. 3, pp. 255-304, pl. 1, figs. 5; *Eng. abs.* pp. 300-302).—This is a contribution from the Botanical Institute at Lund, Sweden.

The chromosomes of rodents, T. S. PAINTER (*Science*, 64 (1926), No. 1657, p. 336, figs. 5).—The author briefly presents the results of studies by graduate students at the University of Texas of the chromosomes of the house mouse, the albino rat, and the guinea pig.

E. Cox found in numerous counts that the diploid number for the male mouse was 40, with 20 as the haploid number. The sex chromosomes were of the X-Y type, and in the first maturation division the X and Y appeared at first to be joined but later segregated to opposite poles. I. Kehoe found the spermatogonia of albino rats to contain 42 chromosomes. This number was further confirmed in studies of the amnion of a number of male and female embryos. B. League found the diploid chromosome number of guinea pigs to be between 60

and 64, while the haploid number was 30. No sex chromosomes were identified. It is of special interest that the chromosome number is lower in pro-phases of spermatogonia than in the equatorial plate stages. The chromosome number of the rabbit has been found in earlier studies to be 44.

Symbols for mutations in mice, W. H. GATES (*Science*, 64 (1926), No. 1657, p. 328).—Symbols are given as recommended by the Mouse Club for the mutations in mice.

The proportion of exceptions in the offspring of exceptional females from X-ray treatment of *Drosophila*, E. G. ANDERSON (*Mich. Acad. Sci., Arts, and Letters, Papers*, 5 (1925), pp. 355-365).—The progeny of 46 nondisjunctive noncross-over and 19 nondisjunctive cross-over flies were classified as to the regular and exceptional young produced. All but 2, which were cross-over flies, gave the expected percentage of exceptions, approximately 4 per cent. The 2 showed high percentages of exceptional offspring, being 27 per cent for one and 14.1 per cent for the other.

Crop and stock improvement, A. B. BRUCE and H. HUNTER (*London: Ernest Benn*, 1926, pp. 119).—This manual endeavors to explain in simple language and to illustrate the principles of crop plant and animal improvement.

Experiments on the genetics of wild populations—Part I, Grasses, J. W. GREGOR and F. W. SANSOME (*Jour. Genetics*, 17 (1927), No. 3, pp. 349-364, figs. 10).—Experiments with *Lolium perenne*, *Dactylis glomerata*, and *Phleum* spp. at Corstorphine, Edinburgh, by the Scottish Society for Research in Plant Breeding suggested that definite hereditary habitat types exist within the grass species. The habitat type appears to represent the genotypical response of the species population to a definite habitat. Habitat types did not necessarily arise through chance isolation of variations or by a gradual change from one type to another without selection of individuals. The phenotypic uniformity and incomplete genotypic similarity in the coastal population of perennial ryegrass indicated that phenotype selection and genotype selection have been in progress. The reaction of the plants to environment and the occurrence of prostrate forms in the several species is commented on.

On a progressive variation with age of a simple Mendelian ratio in the cowpea, S. C. HARLAND, J. C. HAIGH, and J. L. LOCHRIE (*Genetica [The Hague]*, 8 (1926), No. 5, pp. 507-512, fig. 1).—To see whether the segregation ratio varied with age of plant, studies were made on F₂ families derived from two plants, in constitution *XX* and *xx*, respectively. The factor *X* in the cowpea manifests itself by production of anthocyanin pigmentation in the leaf axil and at the junction of the pinnae with the petiole. The plant body is colorless in absence of this factor.

The results showed that in F₂ cultures from successive days of flowering an orderly variation occurs in the simple Mendelian 3:1 ratio, an excess of recessives in the first nine days being compensated for by an excess of dominants as the plants grow older. There is some indication also that as the plants are completing their first flowering period an excess of recessives again occurs.

The question of spring and winter types in wheat [trans. title], G. NILSSON-LEISSNER (*Hereditas*, 8 (1927), No. 3, pp. 339-350).—Further observations are recorded on the material described earlier (*E. S. R.*, 55, p. 127), special reference being made to segregation for spring and winter habit.

Colour heredity in horses, H. B. STIRLING (*Scot. Jour. Agr.*, 8 (1925), No. 1, pp. 32-39, pls. 2).—An account is given of the inheritance of color in the horses of a privately owned stud, all of which descended from a single gray mare purchased in 1878. The mares were repeatedly mated to brown and black

Clydesdale stallions. It is shown that the colors segregated out in succeeding generations, but in no cases were grays produced except from a gray parent. There appeared to be no connection between gray and roan, as each seemed to be a distinct color.

Inheritance of black in swine, B. L. WARWICK (*Jour. Heredity*, 17 (1926), No. 7, pp. 251-255, figs. 2).—The 125 F_1 progeny of matings between a Duroc-Jersey boar and Poland-China sows at the Wisconsin Experiment Station were all black spotted with the body color varying from almost white through sandy to red. Of the 138 F_2 offspring produced, 107 had one or more black spots, while black was absent in 31. Further tests of F_1 and F_2 sows by back crossing them with the Duroc-Jersey boar also indicated that the presence or absence of black was due to the action of a single pair of factors. The amount of black appeared to be governed by multiple factors.

Inbreeding versus "accumulation of blood": Defense of the genetical concept of inbreeding attacked by Baashuus-Jessen, H. J. MULLER (*Jour. Heredity*, 17 (1926), No. 7, pp. 240-242).—A critical review of the article by Baashuus-Jessen previously noted (E. S. R., 55, p. 525), in which it is stated that the means suggested for measuring inbreeding is based merely on the accumulation of blood of a single parent.

Age and quality of offspring: The effect of age of parents on the quality of offspring in cattle, A. C. CHAUDHURI (*Jour. Heredity*, 17 (1926), No. 10, pp. 368-370).—In studies at the animal breeding research department of the University of Edinburgh, the first five winners in the classes of over 20 of the Highland and Agricultural Society's shows were classified as to the age of the parents on a point basis, and compared on the basis of the number of cows calving at each age as selected from volumes 58 to 70 of Coates' Herd Book. The author concludes from the study that though the number of points per cow shows a possible slight but irregular increase with the age of the dam, this can not be considered as significant, since cows are more likely to be kept to an advanced age in the herd when they have produced offspring above the average. The greatest number of prize winners were produced by sires which were 2 years old when the winners were born, probably due to the practice of a majority of breeders of using young bulls.

A contribution toward the analysis of the influence of the age of parents upon their offspring: The age of ewes and the rate of growth of their lambs [trans. title], R. PRAWOCHEŃSKI and B. KĄCZKOWSKI (*Pam. Państ. Inst. Nauk. Gosp. Wiejsk. Puławcach (Mém. Inst. Natl. Polon, Écon. Rurale Puławy)*, 7 (1926), A, pp. 139-157 figs. 2; *Eng. abs.*, pp. 156, 157).—Studies of the birth weights and growth of lambs produced by young ewes and old ewes, both of which were mated to the same ram, indicated that the birth weight of the offspring of young ewes was much less than that of older ones, and that the rate of growth of the lambs during suckling was also greater for the lambs produced by the older group. As soon as the lambs began to consume pasture those produced by the younger ewes grew more rapidly and soon overtook the lambs produced by the older ewes. Several breeds of lambs were used in the study, including Southdown, Świnarka czarna, Świnarka biała, Podhalański, and crossbreeds.

Increased efficacy of subcutaneous when compared with intraperitoneal administration of the ovarian hormone, H. M. EVANS and G. O. BURR (*Amer. Jour. Physiol.*, 77 (1926), No. 3, pp. 518-521).—Tests made at the University of California have shown that the minimum dose of the ovarian hormone, necessary to cause the presence of cornified epithelial cells of the vaginal smear of spayed rats, was considerably less when the doses were divided into four parts and

administered on four successive days than when the complete dose was given at one administration. Considerably less of the hormone was required to cause oestrus when administered subcutaneously than when administered intraperitoneally.

The determination of sex, R. T. HANCE (*Sci. Mo.*, 24 (1927), No. 1, pp. 25-30, fig. 1).—The physiological and physical hypotheses of sex determination are reviewed. The followers of the latter hypothesis believe that the chromosome complex is the cause and the physiological changes the effect, while the followers of the former hypothesis hold the opposite view. The chromosome theory is considered by the author as better established than the physiological theory.

FIELD CROPS

The relations between crop yields and precipitation in the Great Plains area, E. C. CHILCOTT (*U. S. Dept. Agr., Misc. Circ. 81* (1927), pp. 94, figs. 67).—In an endeavor to determine their relations, crop yields and precipitation (also evaporation) data obtained during 20 years on 23 field stations in the Great Plains area under natural field conditions over a broad range of soils, climate, tillage, methods, and crop sequences and equivalent to 303 years of practical farming are made available, portrayed graphically, and discussed in detailed and summary form. The hazards, advantages, and prospects of agriculture in the region are briefly described.

Although annual precipitation is a vital factor in determining crop yield, it appears to be seldom if ever the dominant factor. Not only the seasonal and monthly but also the daily distribution of the precipitation may be much more important than its annual magnitude. The limitation of crop yield is often due to the operation of one or more inhibiting factors other than shortage of rainfall.

Yields equivalent to 10 bu. or less per acre of wheat have occurred in 75 of 218 crop years during which these investigations were made at 16 stations on the northern Great Plains. During 23 of the 75 years the annual precipitation was less than 12 in. During 52 of the 75 crop years the low yields were due to inhibiting factors other than inadequate annual precipitation. Nevertheless, the composite crop yields averaged throughout the 218 crop years the equivalent of 16.1 bu. of wheat per acre.

The mean annual precipitation of the Great Plains as represented by the 23 dry-land field stations is sufficient to produce crops equivalent to those obtained at the 16 stations if the inhibiting factors are no more potent than they have been during the period covered by these investigations. "With respect to climatic conditions, no extensive portion of the Great Plains as represented by these field stations is markedly superior or inferior to any other portion."

The effect of different climatic conditions on pure lines of oats and barley [trans. title], W. CHRISTIE and H. H. GRAN (*Hereditas*, 8 (1926), No. 1-2, pp. 207-228, figs. 5).—The study reported on is concerned with the reactions of two lines of barley and seven of oats to culture under the varied environmental conditions of six localities in Norway, as shown by germination, production, length and diameter of culms, tillering, and ripening.

Plant breeding, W. E. BRYAN and E. H. PRESSLEY (*Arizona Sta. Rpt. 1923*, pp. 493-497, figs. 2).—High uniformity was observed among first and second seed generation progenies from hairy Peruvian alfalfa (*E. S. R.*, 53, p. 734). Considerable difference existed between progenies in regard to hay value, some being fine stemmed and leafy and others having coarse stems with scant

foliage. There seemed to be a tendency to light seed production in the leafy progenies and to heavy seed production in the nonleafy progenies.

Blooming and shedding studies revealed averages of 67 per cent of shedding in Acala cotton, 71 in Lone Star, and 80 per cent in Hartsville. Acala exhibited the widest range in shedding percentage.

Milling and baking tests with several pedigreed wheats showed some of the Arizona flours to compare very favorably with Kansas patent flour in absorption, loaf volume, bread color, and texture.

[**Agronomic work in Arizona, 1923**], G. E. THOMPSON, R. S. HAWKINS, and S. P. CLARK (*Arizona Sta. Rpt. 1923*, pp. 451-463, 485-487, figs. 2).—Continued experiments (E. S. R., 53, p. 733) reported on included variety tests with cotton, corn, wheat, barley, oats, grain sorghums, sorgo, sweet potatoes, and miscellaneous legumes and forage crops; fertilizer trials with cotton and wheat; a source of seed test with potatoes; and pruning and spacing tests with sweet potatoes. Outstanding results on the Prescott, Sulphur Spring Valley, Yuma, and Salt River farms are summarized.

[**Field crops experiments at the South Mississippi Substation**], E. B. FERRIS and W. S. ANDERSON (*Mississippi Sta. Bul. 238 (1926)*, pp. 3-6, 8-10, 11, 12, 16, 17).—Continued investigations (E. S. R., 55, p. 228) reported on embraced variety tests with corn; fertilizer tests with corn, oats, sweet potatoes, and tobacco; trials of winter cover crops, lespedeza, and certified seed potatoes; and breeding work with sweet potatoes. Acre yields of seed cotton obtained after peas averaged 1,205 lbs., soy beans 1,125, velvet beans 1,170, corn 1,015, corn and peas 1,190, corn and soy beans 1,185, and corn and velvet beans 1,195 lbs. Indiscriminate winter grazing of velvet beans seemed a probable cause of injury to land rather than velvet bean culture itself.

[**Field crops work at the Holly Springs, Miss., Substation**], C. T. AMES (*Mississippi Sta. Bul. 239 (1926)*, pp. 28, figs. 9).—Continued experiments (E. S. R., 53, p. 131) reported on embraced variety trials with cotton on hill and valley land, corn, and soy beans; fertilizer tests with cotton and corn; spacing trials with cotton and sweet potatoes; and an interplanting trial of corn with velvet beans and soy beans. Methods for growing these crops, sorgo for silage, vetch, and lespedeza are outlined, and the advantages of dairying in the region are cited briefly.

From 1921 to 1926, inclusive, Lone Star 65 and Delfos 6102 and 631 have been outstanding on both hill and valley land, although other sorts also had merit. Spacing trials suggested from 2 to 3 stalks per foot in 3.5-ft. rows on valley land and 3 to 4 stalks per foot in 3-ft. rows on hill land. Fertilizer experiments have shown deficiency in phosphorus and nitrogen and perhaps to some extent potassium. From 400 to 600 lbs. per acre of an 8-4-4 fertilizer or of a mixture of acid phosphate 200 lbs., sodium nitrate 100 lbs., and potassium sulfate or chloride 25 lbs. or kainit 100 lbs. is advised for cotton.

[**Field crops experiments at the Raymond, Miss., Substation, 1926**], H. F. WALLACE (*Mississippi Sta. Bul. 240 (1926)*, pp. 3-11).—Tests during several years (E. S. R., 55, p. 228) indicate Trice (Mississippi Station), Willis, Miller, D. & P. L. No. 4, Cleveland 54, and Acala cotton for hill land and Delfos 631 and 6102, Lone Star 65, Trice, and D. & P. L. No. 6 for valley land. From 500 to 600 lbs. per acre of 8-6-4 fertilizer is indicated, with modifications for certain conditions. Several nitrogen sources gave substantial increases over no nitrogen. Spacing recommendations are 2 to 3 stalks per foot in 3.5-ft. rows on valley land and 3 to 5 stalks per foot in bunches in 3-ft. rows on hill land.

Laguna, selections of Cocke and Whatley Prolific, and Mexican June led the corn varieties over a period. Fertilizer trials suggested an acre application of a mixture including acid phosphate 100 lbs., sodium nitrate 150 lbs., and kainit 50 lbs. Sodium nitrate and calcium nitrate led the nitrogen sources in increases. A variety test with soy beans is reported briefly.

[Field crops investigations in Wisconsin, 1924-1926] (*Wisconsin Sta. Bul.* 388 (1926), pp. 26-39, 41, 47-50, 126, 127, figs. 6).—The continuation of earlier experiments (*E. S. R.*, 53, p. 432) is reported on.

L. F. Graber observed that lack of snow and presence of ice sheets have been the most general causes of recent winterkilling of alfalfa. A thin straw mulch applied for winter protection has been found valuable for alfalfa cut late in the fall or seeded late in summer. Alfalfa appeared to be in no danger of smothering itself due to heavy fall growth. Blue grass and timothy in alfalfa cut twice a year, similarly to the alfalfa, made much better growth than when in alfalfa cut three times annually, although the percentage of grass was higher in the hay from the latter plats. Timothy and alfalfa yields were higher in all plats cut in the full bloom stage and only twice a year. Early and frequent cutting evidently reduced the vigor of alfalfa and of pasture and hay grasses as well. Recent trials showed that such cutting delays recovery of alfalfa, whereas even one late and mature cutting aids it greatly.

Alfalfa has been seeded successfully just prior to the last cultivation of corn in southern Wisconsin. Alfalfa or sweet clover gave excellent results when seeded with oats and the oats pastured off by cows. Late summer seedings could not withstand unfavorable winters unless covered with straw. Timothy and bluegrass grew better with alfalfa than when seeded alone. Sweet clover seeded on bluegrass sod burned before the frost left the ground made a much better stand than on unburned sod. Its use to rejuvenate old bluegrass pasture is suggested.

In tests with supplementary pastures and hay crops G. B. Mortimer found that Sudan grass seeded in May and June would give considerable grazing for dairy cows in the summer. Peas, 2.5 bu., and oats, 1.5 bu., gave the highest cured hay yields of their combinations, and Sudan grass and soy beans produced their best results at respective rates of 10 lbs. and 1.5 bu. Soy beans sown alone for hay on weedy land required heavy seeding.

The date of seeding influenced both root and top development of wheat and consequently had a bearing upon winterkilling, according to results of a study by G. Janssen. The most resistant plants were developed by seeding in the last half of September. It appeared that those plants which actively stored plant food well into the fall and lost reserve substances rather slowly during the rest of the period survived the winter best and resumed growth earlier in the spring. Late fall plantings suffered most from root fracturing and consequent drying out. Less winterkilling resulted on soil with a low moisture content. High osmotic pressure in plants was correlated with hardness in the 1922-23 crop but had little or no relation the next year. Very little fluctuation was apparent in the total nitrogen in the wheat plant during the fall and winter dormant season. The soluble and protein nitrogen seemed to increase with a lowering of temperature. However, the protein nitrogen dropped rapidly after the freezing point of the plant. Hexose and hexosan (sugar) compounds did not appear to be the direct factors causing hardness. The optimum seeding rates for oats and winter wheats are indicated.

In a 4-year test by H. W. Albertz little seemed to be gained by planting soy beans in corn when soil and climatic conditions are optimum for corn. If conditions favor soy beans but not corn the combination outyields corn alone.

When conditions favored corn the soy beans made an early rapid growth, but as soon as the corn shaded them they tended to become slender and to lose their lower leaves in dry seasons. On fertile soil in warm summers with plentiful rainfall throughout the growing season the combination produces more silage but less ears. A. L. Stone reported that growing Wisconsin strains of corn such as Wisconsin Nos. 7, 8, 12, and 25 in States with a somewhat milder climate tends to distinctly prolong the maturing period such that the use of such corn for seed is not advised where ripe grain is desired.

Brief accounts of the status of hemp and flax production in the State are presented by A. H. Wright. His tests showed that for the best combination of quality and yield in hemp, cutting can safely begin when the pollen is readily observable. Experiments on five marsh soil areas indicated that, regardless of the fertilizer application, hemp can not be satisfactorily grown on marshes until the excess of available nitrogen has been reduced. Marshes poor in available nitrogen have grown satisfactory hemp with commercial fertilizers, yields of 1,600 to 1,800 lbs. per acre being obtained by the use of 400 lbs. of 0-8-24 (N-P-K) fertilizer. It is believed, however, that most marsh soils will not produce a suitable quality of hemp fiber. Complete fertilizer, such as 5-8-7 or 4-8-6, has been most satisfactory on the mineral soils growing hemp. Barnyard manure has given good results and can be supplemented by commercial fertilizers under certain conditions.

Extensive studies (E. S. R., 55, p. 829) demonstrated that while flax can be grown with any small grain, wheat is most satisfactory and oats reasonably so, while barley usually matures too early for the flax. About equal quantities by weight of flax and wheat or oats give best results, whereas the flax-barley seed mixture should be about one- and two-thirds, respectively, by weight. On weed-free soil flax alone did better than a flax-cereal mixture, but with weedy land flax-wheat mixtures seemed to excel. Difficulty in separating the flax and grain after the grain is threshed is an important factor with oats and barley. Flax and small grains grown together yielded about the same as when the different crops were grown alone. Flax-oats and flax-barley mixtures were not satisfactory from the viewpoint of feeding.

Mixtures of small grains, such as wheat and oats, barley and oats, or wheat, oats, and barley, again indicated distinct advantages over growing the grains separately. The crops mixed gave higher yields than when grown alone in five years' work, indicating that an increased relative yield of 15 to 20 per cent may be expected from the combinations.

Neither a liquid herbicide nor a similar solution of sodium arsenite destroyed weeds satisfactorily in tests by Stone.

A new root rot-resistant strain of tobacco, Havana 142, developed in cooperation with the U. S. Department of Agriculture, is indicated for old tobacco soils where root rot is generally present; the strain grows upright and has many leaves per plant. Fertilizer trials by J. Johnson suggest from 500 to 1,000 lbs. of a 2-12-4 formula with the potassium as sulfate. When applied in the row by a fertilizer attachment at planting, about 250 lbs. per acre should be used. The best system for tobacco in Wisconsin seems to be to grow tobacco continuously on the same land after a satisfactory field has been found.

Studies by F. V. Owen indicate that mottling in soy beans often may be caused by environmental conditions. Seed free from mottling is ordinarily obtained when the plants are grown in thick stands in fertile soil. Different strains exhibited marked differences in their tendency toward mottling. "The investigation shows that yellow and green beans have a factor for the production of pigment and that it is only because of a restriction factor that we can ever

have pure yellow or green soy beans, and while the presence of this restriction factor can sometimes be explained on a simple Mendelian basis, in other cases it is clearly evident that other genetic factors are also involved."

[Inoculation of legumes in Wisconsin] (*Wisconsin Sta. Bul.* 388 (1926), pp. 85-90, figs. 2).—Much work along this line has been summarized (E. S. R., 56, p. 526).

In inoculation experiments by A. L. Whiting with canning beans appreciable increases resulted in the number of pods and in the nitrogen content of the soil. Nodules were abundant on all roots in sand, whereas practically none were found in silt during the growing season. The spread of bean diseases through wetting and mixing the seeds, as required by inoculation, occurred only with some lots of seed of only one variety. Nodule production on the beans showed a relationship to the nitrate content but apparently none to variety, soil acidity, or soil type. Moisture conditions seemed to have greatly influenced the root development of beans as well as their growth.

Red and alsike clovers made a decided response to inoculation in stands and growth. Growth differences were also shown by *Dalea alopecuroides*. Bacteria with free access to air grew much better than those in stoppered bottles. Field observations revealed very serious injury to the seed and a reduction of nodule production on soy beans caused by the application of 200 and 400 lbs. of ammonium sulfate, potassium chloride, monocalcium phosphate, and calcium chloride, whereas calcium carbonate and tricalcium phosphate resulted in increased growth and abundant nodule production.

A study of the root-nodule bacteria of Wood's clover (*Dalea alopecuroides*), A. L. WHITING, E. B. FRED, and G. E. HELZ (*Soil Sci.*, 22 (1926), No. 6, pp. 467-475, figs. 3).—Experiments at the Wisconsin Experiment Station showed that Wood clover (*D. alopecuroides*) does not possess root nodule bacteria in common with any other legume group. As a consequence it is grouped alone for inoculation purposes. The nitrogen content of this annual legume was found very high and to compare favorably with other legumes. The root nodule organism of Wood clover produces in milk a serum zone characteristic of the bacilli group. The organism is motile, and its flagella are peritrichous.

Alfalfa investigation, T. A. KIESSELBACH and A. ANDERSON (*Nebraska Sta. Research Bul.* 36 (1926), pp. 125, figs. 27).—The investigations reported were made to determine the relation of variety, source of seed, and cultural practice to the yield and quality of alfalfa hay produced. Extensive reviews deal with other work on varieties and regional strains, maturity stages, and curing practices, a total of 137 titles being cited.

The merits of varieties and strains have been noted (E. S. R., 54, p. 32). Variation in flower color of the variegated sorts was the most obvious physical difference between varieties. Root and crown measurements of several sorts did not show differences enough for varietal classification.

Variations between cuttings were more striking than varietal or strain differences. The average yields of seven varieties declined from the first to fourth cuttings, and the leaf percentage and protein content increased from the first to third and stem diameter and plant height decreased. Tillage of established stands of alfalfa with different types of harrows did not increase yields, and the most intensive treatment caused some reduction. During 5 years there was a 30 per cent reduction in the stand on untilled plats and 43 per cent on plats disked and spring-tooth harrowed. No relation was apparent between tillage and plant development as measured by root diameter.

During 4 years alfalfa harvested at the prebloom, initial bloom, one-tenth bloom, half-bloom, full-bloom, seed, and new growth stages yielded 3, 3.03,

3.35, 3.42, 3.19, 2.82, and 3.51 tons per acre, respectively, and the proportion of leaves at harvest was 57.3, 56.6, 55.8, 53.2, 49.4, 33.3, and 52.8 per cent. Measurable seed production from seed plats occurred in only one year. Harvesting alfalfa in relatively immature stages tended to thin the stand and retard root development. The protein and ash content of the hay gradually decreased from the prebloom stage to the full-bloom stage, and crude fiber increased. The slight variation in N-free extract and fat does not appear associated with maturity. The stems of alfalfa hay harvested at six (omitting the seed stage) stages contained 75, 43, 249, 91, and 46 per cent as much ash, protein, crude fiber, N-free extract, and fat, respectively, as the leaves. The stem: leaf ratio in protein content remained practically constant regardless of maturity. Of the total protein in the hay, that in the leaves ranged from 75 per cent in the least mature to 70 in the ripest stages. The first, second, and third cuttings of the six maturity stages consisted of 48.7, 56.4, and 58.1 per cent of leaves and of 18.96, 19.83, and 20.03 per cent of protein. Considering acre yield of hay and feed constituents, hay quality, and permanency of stand, harvesting alfalfa at about the new growth stage should probably prove most desirable. With normal blooming conditions, this usually falls between the tenth and half-bloom stages.

Gypsum, sulfur, lime and sulfur, or lime applied as top-dressing to established alfalfa failed to increase the yield, while manure applied every 4 years produced 13 per cent increase. Alfalfa and timothy seeded in combination did not materially outyield alfalfa alone. Seeding experiments indicated that seeding practices should be adapted to local conditions. Inoculation appeared seldom necessary in Nebraska, but it is recommended where repeated failures to obtain stands have been experienced. The maintenance of alfalfa stands and the behavior and subsequent effects of the crop in rotations are discussed briefly.

Curing studies demonstrated that windrowing and cocking relatively green alfalfa hay materially extended the curing period as compared with swath curing. Prolonged swath curing resulted in undue loss of leaves and bleaching. Judicious partial swath curing to hasten the rate of drying followed by windrowing before the leaves shatter appeared to be the best farm practice for the region. The normal transpiratory function of the leaves of cut alfalfa was found to be a negligible factor in the curing process. Normal hay with leaves dried somewhat faster than the bare stems, but when the curing of the stems and leaves were averaged the rates were similar. A close relation was observed between weather conditions and curing rate. Drying of external moisture has a similar relation to weather conditions and method of curing as that of internal moisture but usually takes place more rapidly.

Differences in resistance to low temperatures shown by clover varieties, G. STEINBAUER (*Plant Physiol.*, 1 (1926), No. 3, pp. 281-286, figs. 2).—Investigation at the Minnesota Experiment Station demonstrated that the viability of red clover seeds with a moisture content of less than 15 per cent of the dry weight is not affected by temperatures as low as -48° C. (-54.4° F.) for short periods, whereas in seeds with high moisture content germination is greatly impaired by low temperatures, declining very rapidly in seeds containing above 25 to 30 per cent of moisture. Plants of the same clover variety varied with age in respect to killing temperatures, susceptibility to injury being most pronounced when about 3 weeks old or at the time of the formation of the first pair of permanent leaves. Considerable difference among varieties was observed in ability to withstand low temperature. European or southern varieties generally proved less resistant than those grown in northern areas

of the United States, this variation existing both in seedlings and mature plants.

The immediate effect of gametic relationship and of parental type upon the kernel weight of corn, T. A. KIESSELBACH (*Nebraska Sta. Research Bul. 33 (1926), pp. 69, figs. 5*).—Elaborate investigations to determine the relation of the kernel weight of corn to the source of pollen with which it was fertilized involved in various aspects commercial varieties, strains inbred to different degrees or selected for certain purposes, and seasonal, kernel, and endosperm types. The relative moisture contents of pure and hybrid kernels, sources of experimental error in tests, the effect of crossing upon the endosperm character, and the color of various corn types were also dealt with. See earlier work along the same line (E. S. R., 52, p. 336).

Consideration of the extensive data suggested that in general practical advantages are not to be expected from annually mixing seed of commercial varieties of corn. The effect of cross-pollination occurring in comparative yield tests of commercial varieties similar in endosperm type does not seem to be of sufficient magnitude to be a serious disturbing element in arriving at correct conclusions.

The kernel weight increases of sweet varieties when fertilized by starchy types and of inbred strains and F_1 hybrids between two pure lines when fertilized by foreign pollen are large enough to suggest that the acre yields may be affected thereby. In this event such yields may not accurately represent their productivity in comparison with other corn. Serious yield effects due to source of pollen under field conditions seem unlikely with double crosses and synthetic varieties because of their more complex constitution.

Cotton fertilizers and varieties, J. F. O'KELLY, C. B. ANDERS, and W. W. HULL (*Mississippi Sta. Bul. 241 (1926), pp. 12, fig. 1*).—Additional fertilizer investigations with cotton led to conclusions in harmony with those noted earlier (E. S. R., 55, p. 33). Cook, Cleveland strains, and Half-and-Half made highest average yields, and Delfos, Cleveland 54, Trice, and Miller were foremost in acre value during the period 1922–1926. D. & P. L. No. 6, Deltatype Webber, Delfos selections, and Trice were high as to acre value among the standard varieties compared in 1926. Watson, Super Seven, Lightning Express, and Dixie Triumph led in acre value in the wilt-resistance test.

Studies on *Festuca ovina*.—I, Normal, sexual, and partially and wholly viviparous types of northern origin [trans. title], G. TURESSON (*Hereditas, 8 (1926), No. 1–2, pp. 161–206, figs. 14; Eng. abs., pp. 200–205*).—The extensive studies reported on were concerned with sexual and partial and wholly viviparous types of *F. ovina eu-ovina vulgaris*, collected in their natural habitats in Scandinavia, the Faroes, and Scotland, and grown in comparative cultures to determine the nature of different characteristics (whether modificatory or genetic) and to ascertain how climatic and edaphic factors control the composition of the population in various natural habitats.

[Peanut production in Gambia], A. J. BROOKS (*Gambia Dept. Agr. Ann. Rpt. 1925, pp. 13–21, 22–25, 29–33, 47–52, pl. 1*).—Fertilizer and variety trials with peanuts and analyses of varieties are reported, and the status of the industry in the colony is reviewed, with an account of marketing practices.

Studies of self-fertilization in rye, H. E. BREWBAKER (*Minnesota Sta. Tech. Bul. 40 (1926), pp. 40, figs. 10*).—Continuous selection of single plants of Minnesota No. 2 rye with distance isolation of the progeny lines for 10 years resulted in several lines highly pure for grain color and relatively so for certain other characters. The presence of many seedling and plant abnormalities characterized certain of these strains. Inheritance studies of yellow-green stripe,

golden-green blend, and virescent white, abnormal types recognizable in seedling or plant stages, as well as a brittle plant character (E. S. R., 51, p. 848) indicate each to be a simple recessive to the normal condition. A number of individuals in the selfed strains as well as in the Minnesota No. 2 variety appeared highly resistant to *Puccinia graminis secalis*.

No consistent difference was apparent in degree of seed setting as a result of fertilization within a single floret or between two florets on the same head. The characters, high and low self-fertility, appeared to be heritable. Ability to set seed under controlled conditions was evidently influenced considerably by seasonal conditions. The approach toward homozygosity in the selfed strains was generally accompanied by marked reduction in vigor, considerable shriveling, and lack of plumpness in the grain, and some reduction in plant height. While in general there was a reduction in vigor and yield, certain strains appeared to be promising in comparison with Minnesota No. 2 rye.

The behavior of the P. O. J. 234 cane in Tucuman and elsewhere, W. E. CROSS (*Planter and Sugar Manfr.*, 77 (1926), No. 18, pp. 350, 351).—P. O. J. 234 has surpassed native sugar canes in Tucumán under mosaic conditions, although apparently it did not equal P. O. J. 36 and 213. In Spain P. O. J. 234 is considered superior to native cane and the two other Java canes. The author feels that P. O. J. 234 in Louisiana might give results similar to those in Tucumán.

Story of sugar in Hawaii (*Honolulu: Hawaiian Sugar Planters' Assoc.*, 1926, pp. 96, pls. 3).—This book gives information on the history and development of the sugar industry in Hawaii, outlines the principal factors involved in the production of cane sugar in the Territory, and indicates the commercial status of Hawaiian and other American sugar.

Tobacco: Its cultivation and preparation, G. CORBETT (*Mauritius Dept. Agr., Gen. Ser. Bul. 33* (1926), *Eng. ed.*, pp. 30, pls. 9).—Information concerning the production of dark and bright cured leaf is presented for Mauritius, based extensively on practice in southern Africa. Insect pests are described by W. H. Edwards and diseases by E. F. S. Shepherd.

Wheat experiments at the Northern Montana Branch Station, G. W. MORGAN and M. A. BELL (*Montana Sta. Bul. 197* (1926), pp. 48, figs. 14).—Experiments with spring and winter wheat during the period 1917–1925, inclusive, dealt with the effects of methods of preparing the seed bed and of the preceding crops on the yield and variety trials, all on dry land. The quality of wheat in Montana and soil and climatic conditions in the locality are discussed in some detail. Information on experimental methods, tillage operations, milling and baking trials, the yields of wheat in rotations, and wheat varieties are appended.

Climatic conditions in northern Montana are described as semiarid, with the heaviest precipitation in summer. The total amount and distribution of rainfall in June and July have an important relation to the wheat yield, as also have temperature and wind. Six seasons during 9 years of experimental work were considered unfavorable and three as average or above.

Spring wheat made its highest average yield, 13.4 bu., on fallow (E. S. R., 52, p. 527), exceeding those on disked corn ground, spring plowing, and fall plowing in 5 of 9 years. The yield after continuous cropping was 7.1 bu. and on disked ground 10.7 bu. Yields on disked corn ground in manured rotations slightly exceeded those in similar but unmanured rotations. Spring plowing for spring wheat (average 10.5 bu.) surpassed fall plowing (average 9 bu.) in 6 of 9 years.

Spring wheat immediately after sunflowers yielded much less than after corn, whereas yields the second year after these crops were about the same. Cereals

and pea-grain mixtures grown for hay were not desirable substitutes for fallow, wheat yields on disking after such crops resembling those obtained by continuous cropping. Russian thistles, the worst weed pests in spring wheat, were usually thicker on early than on later seeding. However, delaying seeding for a week or 10 days after preparing the seed bed and immediately preceding the drill with a light, thorough cultivation controlled Russian thistle growth and increased yields.

Marquis and Supreme, outstanding among the hard red spring varieties, are recommended for general production. Peliss led the durums and Baart the white wheats.

Winter wheat gave unsatisfactory results chiefly because of severe winter-killing followed by excessive weediness. Winter wheat on fallow plowed in May yielded much higher than that on fallow plowed in July. Manure applied before plowing for fallow slightly decreased the yields. Yields on fallow plowed 8 in. deep surpassed those on shallower or deeper plowing. Compared with ordinary fallow a decrease in the winter wheat yields followed crops of rye, peas, and sweet clover turned under for green manure.

Results of seed tests for 1926, M. G. EASTMAN (*New Hampshire Sta. Bul.* 226 (1926), pp. 18).—The percentage germination and purity are tabulated for 369 official samples of agricultural seed collected in New Hampshire and tested during the year ended June 30, 1926.

[Report of Canadian Seed Growers' Association, 1924-25] (*Canad. Seed Growers' Assoc. Ann. Rpt. 1924-25*, pp. 82, pl. 1, figs. 7).—The annual meeting held at Edmonton, Alta., in June, 1925, is reported, and the activities of the association and its branches during the period of March, 1924, to March, 1925, are reviewed.

HORTICULTURE

[Horticultural investigations at the Arizona Station], F. J. CRIDER and D. W. ALBERT (*Arizona Sta. Rpt. 1923* pp. 477-485, figs. 4).—The usual annual report (E. S. R., 53, p. 740).

Work in date propagation recently noted in bulletin form (E. S. R., 56, p. 239) is again discussed. Among promising date varieties are Saily, Iteema, Hayanay, Tadala, and Maktum. Saily is believed especially well suited to the foothill and mesa districts of southern Arizona, where the ripening season is long and humidity low. The Tadala was found one of the few early varieties not injured by humid weather.

Notes made in a young citrus orchard established at Yuma in 1920 showed some fruiting in Marsh Seedless grapefruit and Washington navel orange. Ammonium sulfate applied at the rate of 4 lbs. per tree per year in four divisional doses resulted in darker foliage and more vigorous growth. Legume cover crops used at Yuma required seed inoculation to succeed.

A study of the distribution of the roots of citrus trees growing in a sandy soil at Yuma showed in the case of 3-, 6-, and 25-year-old trees 41.42, 44.55, and 3.02 per cent of roots in the upper foot and 14.68, 39.27, and 24.17 per cent, respectively, in the second foot. In the case of the 25-year-old tree 0.05 per cent of the roots occurred in the ninth foot. Similar observations upon a 25-year tree growing in a sandy loam overlaid with tenacious subsoil in the Salt River Valley gave 17.09, 47.89, 24.8, 10, and 0.24 per cent of the roots in the first to fifth feet, respectively, and none at greater depths. Soil moisture determinations made in cooperation with the agricultural chemistry section showed following irrigation a decided loss in the first 3 ft. of soil. The wilting point was reached in about 12 days in the upper foot, suggesting the advisability of fre-

quent irrigations. The ball of earth about the roots of newly set trees dried more rapidly than did the surrounding soil.

Athel trees planted as windbreaks about citrus orchards at Yuma continued to send roots into the citrus orchard despite a 5-ft. open trench. Bud selection studies in the Salt River Valley revealed several promising strains of Washington navel orange. Studies pursued for 3 years with the olive showed no effect of pruning upon fruit size. Among vinifera grapes tested the Malaga and Sultanina appeared especially adapted to southern Arizona. Other promising varieties included Black Muscat and Almeria.

A comparison of long, short, and intermediate types of pruning upon deciduous fruit trees showed the intermediate to be most satisfactory, giving size and quantity.

Pecan trees failed to thrive on shallow soils underlaid with hardpan or on those strong in alkali. Difficulty in transplanting pecans was overcome by severe top pruning at the time of planting and shading during the first season. Success, Schley, and Delmas appeared to be promising varieties. At Prescott Dry Farm apples, pears, peaches, plums, cherries, grapes, and currants produced fair crops despite a very low rainfall, averaging 15.42 in. per year. Small fruits in the Greaterville district thrived once the plants were established, even though the rainfall amounted to only 16 in.

At Yuma acid phosphate was found to have a remarkable effect in hastening the maturity and increasing the compactness and size of lettuce. Potash and sulfur and various forms of nitrogen used singly had no appreciable effect, but a combination of blood meal and acid phosphate gave excellent results.

Report of horticultural work at the South Mississippi Experiment Station for 1926, E. B. FERRIS and W. S. ANDERSON (*Mississippi Sta. Bul.* 238 (1926), pp. 11, 12-16, 17, 18).—A test of some 500 selections of wild blueberries collected in Florida showed a few types sufficiently promising to warrant propagation. In a fertilizer test with tomatoes the largest yield increase and the greatest net profit per acre were obtained with a mixture of 450 lbs. of nitrate of soda, 675 lbs. of acid phosphate, and 150 lbs. of sulfate of potash, a formula practically the same as the most successful of the preceding year (E. S. R., 55, p. 235). Data are presented upon the results of variety tests with peaches, plums, almonds, apples, pecans, persimmons, figs, grapes, strawberries, and other fruits. A comparison of dust and spray for the control of insect and fungus pests of the peach gave inconclusive results, both materials yielding clean, attractive fruit. On grapes spray gave somewhat better control of leaf diseases. Vinifera grapes on native roots proved a decided failure, and attempts to propagate *Pyrus calleryana* stocks met with completely negative results.

[**Horticultural investigations at the Wisconsin Station**] (*Wisconsin Sta. Bul.* 388 (1926), pp. 42-45, 45-47, 75).—In the same manner as the preceding (E. S. R., 53, p. 438), this report discusses progress in various horticultural lines.

Breeding work with canning peas conducted by E. J. Delwiche and E. Renard recently presented in bulletin form (E. S. R., 56, p. 236) is again discussed. At the Marshfield Substation it was found that on soils of the prevailing type at least 3 to 5 years should elapse between pea crops. At the Spooner Substation the Scotch and Golden Vine varieties yielded 28 bu. of seed per acre. Impurities in pea stocks arose from natural crossing and less frequently from mutations. Persistent removal of these odd plants is deemed essential to the maintenance of satisfactory seed stocks.

Pollination studies conducted by R. H. Roberts at Sturgeon Bay upon certain cherry trees which had failed to yield despite abundant blooming showed these to be self-sterile and also intersterile with several varieties. However, when pollinated with Early Morello, Governor Wood, Elton, and an unknown sort, excellent sets of fruit were obtained. Studies of the effect of pruning and of shortening the period of daylight upon blossom bud formation in nitrated and nonnitrated apple trees failed to show any specific influence of either treatment upon the composition or performance of the trees. Pruned trees without nitrogen fertilizer tended to be fruitful, while those with an excess of nitrogen tended to be unfruitful. Trees given a short period of daylight tended to be fruitful without nitrogen and unfruitful with nitrogen. In the case of normal daylight trees nitrogen promoted fruitfulness. Thinning the fruits of Wealthy and Duchess resulted in improved grades and larger yields.

Roberts, reporting upon grafting studies, states that the top bud usually makes the best growth, that the callus union takes place along the matched tongues of the graft, and that the rapid rise of sap is in a vertical line.

Three new yellows-resistant types of cabbage developed by J. C. Walker are described. These are named All Head Select, Marion Market, and Globe.

[Vegetable studies at the Raymond, Miss., Substation], H. F. WALLACE (*Mississippi Sta. Bul. 240 (1926), pp. 11-14*).—As usual (*E. S. R., 55, p. 236*) the tomato because of its commercial importance received the greatest consideration. The Gulf States Market was the highest yielding variety of eight tested, but the fruits were rather small. The wilt-resistant varieties, Norton, Marvel, and Marglobe, proved valuable on infected soil. Of several fertilizer treatments compared for tomatoes, the greatest net profit per acre was obtained from a 2,000-lb. application of 3-8-3 (N-P-K) mixture. No significant differences in yield or earliness were obtained with mixed fertilizers, the nitrogen of which was derived from different sources. Potash added in varying amounts to mixed fertilizers gave no definite results but on account of the effect upon the plant is deemed an essential ingredient. Work with garden peas and beans suggested the desirability of a 3-10-3 (N-P-K) mixture with the nitrogen derived from ammonium sulfate.

Sunshine sweet corn, A. F. YEAGER (*North Dakota Sta. Bul. 205 (1927), pp. 8, figs. 4*).—A brief discussion of the parentage, methods employed in the development, and the important characteristics of the Sunshine variety of sweet corn produced by the station.

The home fruit garden on the northern Great Plains, W. P. BAIRD (*U. S. Dept. Agr., Farmers' Bul. 1522 (1927), pp. II+49, figs. 30*).—Emphasizing the fact that cold and drought greatly handicap fruit production on the northern Great Plains, the author presents helpful information discussing such points as climate, selection of site, protection from wind, planting, culture, spraying, pruning, and planning the home fruit garden. Particular attention is paid to the species and varieties which have proved suitable to the region.

The propagation of fruit tree stocks by stem cuttings.—I, Observations on the factors governing the rooting of hard-wood cuttings, R. C. KNIGHT (*Jour. Pomol. and Hort. Sci., 5 (1926), No. 4, pp. 248-266*).—In trials with various hardwood cuttings no direct association was found between callus formation and root production. Callusing was apparently favored by high water content of the soil and rooting by a medium water content which favored adequate aeration. The formation of callus and of roots are considered distinct processes, having no consequential relation to each other, and callusing is deemed no assurance of rooting. The immersion of cuttings prior to planting in solutions of potassium permanganate, boric acid, and phenol gave no con-

sistent results. Potassium nitrate, on the other hand, definitely reduced rooting in the Brompton plum. Sugar solutions in favorable concentration benefited rooting in certain varieties.

Propagation of apple trees on their own roots, F. S. LAGASSÉ (*Delaware Sta. Bul.* 147 (1926), p. 28).—The third sentence in the final paragraph of a previous abstract (E. S. R., 56, p. 341) reading "3-in. scions were slightly better than those 2 in. in length" should read "Stayman scion wood 3 ft. in. length gave a slight increase in stand over 2-ft. lengths."

Normal variation in the chemical composition of fruit spurs and the relation of composition to fruit bud formation, C. P. HARLEY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 134-146, fig. 1).—Analyses at the University of Maryland of Stayman Winesap spurs showed a much higher variability in the chemical content in samples of variable lengths and age than in uniform samples. Old growths were more variable than new growths, indicating the desirability of restricting the samples to the new growth. At the time of flower-bud differentiation nonbearing spurs averaged 31.1 sq. in. of leaf area as compared with 16.13 for bearing spurs. At the same time the bearing spurs averaged more leaves, due to many small leaflets on the cluster base. The optimum spur length for Stayman Winesap in respect to number of blossom buds was 25 mm. (1 in.). Seasonal changes in spur composition were not as clearly defined in old as in new growth. High sugar and starch content in new spur growth at differentiation time suggests the importance of these substances at this stage. A correlation was noted between leaf area, starch content, and flower-bud formation. A decrease in December of polysaccharides and an increase in free reducing substances and total sugars indicated a hydrolysis of acid hydrolyzable materials related possibly to low temperatures. A high percentage of nitrogen was present in new growths of bearing spurs following fruit setting. Dry matter content of spurs increased uniformly as the season advanced. At the time of fruit-bud differentiation nonbearing spurs were relatively high and bearing spurs relatively low in starch as compared to nitrogen.

Some studies on the fruiting habit of the York Imperial apple, M. J. DORSEY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 172-189).—Studies by the West Virginia Experiment Station upon York Imperial trees in three commercial orchards in different conditions of vigor and productivity indicate that in old, unpruned trees, or those making slow growth, there is a marked tendency to develop too many growing points, which gradually become fruiting spurs and ultimately result in the production of many small fruits. Complete alternation of bearing was associated with an overabundance of short spur growths. Nitrate of soda without pruning stimulated growth, bloom, and set in the shorter growths. It is believed that a well-distributed pruning, accompanied or not by an application of nitrate of soda, will induce an improvement in the size of fruit which can not be obtained by nitrates alone. Detailed pruning alone resulted in a growth response on unproductive 20-year-old trees equivalent to a 3-lb. nitrate treatment. In certain trees large limbs were observed to act independently, becoming in a measure separate entities. Little evidence was obtained to indicate that alternate fruiting habit in York Imperial can be overcome.

The relation of growth to fruitfulness in some varieties of apple, M. J. DORSEY and H. E. KNOWLTON (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 161-172, figs. 5).—Records taken by the West Virginia Experiment Station upon the growth of Grimes, Rome Beauty, Ben Davis, and York Imperial apple trees included in fertilizer experiments show that Ben Davis and Rome Beauty,

because of their terminal bearing habit reach their maximum fruitfulness on much longer twigs than do Grimes and York Imperial. Nitrate of soda applications to Rome Beauty trees increased the percentage of blossoms on shorter length classes, but not on classes over 6 in. A study of the relation of the length of the preceding season's growth to the set of fruit showed in Rome Beauty and Ben Davis higher percentages of set associated with longer growth, and, though less clearly defined, the same tendency was observed in York Imperial and Grimes. Nitrate applications modified the length distribution of Rome Beauty spurs, reducing by one-half those in the $\frac{1}{2}$ in. class. Percentages of spurs in the longer growth classes which both bloomed and set were markedly increased by nitrate applications. The percentages of set followed in a general way those of bloom.

Temperature and respiratory enzymes of apples, B. D. DRAIN (*Bot. Gaz.*, 82 (1926), No. 2, pp. 183-194, pl. 1).—Determinations made at the University of Chicago of the respiration rate at 0 and 25° C. (32 and 77° F.) for Maiden Blush, Oldenburg, and Winesap apples showed that varieties vary greatly in respiration rate and response to temperature. The rate for Oldenburg varied but little with temperature changes, while that for Maiden Blush was greatly slowed down at 0°. Catalase activity, as indicated by the hydrogen peroxide test, was considerably lower in Oldenburg than in Winesap. Catalase was particularly active in the periphery of the fruits. Oxidase determinations showed a decreased activity when the fruit was hard ripe. In the fruit of many varieties oxidase activity tended to be localized near the core, while in others the zone of greatest activity was in the periphery. That the localization of oxidase activity may be due to gaseous exchange was indicated in a long-continued negative activity in the core region with fruits in which the calyx tube was sealed at the hard ripe stage. Determinations of iron in Winesap apples showed the greatest concentration in the periphery, i. e., in the same general region as that of catalase activity.

Responses of the sour cherry to fertilizers and to pruning in the Hudson River Valley, H. B. TUKEY (*New York State Sta. Bul.* 541 (1927), pp. 26, pls. 5, figs. 2).—Pointing out the growth and fruiting characteristics in the Early Richmond, Montmorency, and English Morello cherries and the high correlation between vigorous annual growth and productivity, the author discusses the results of fertilizer and pruning studies with these cherries.

Of various fertilizer combinations applied, only those containing nitrogen had any material effect upon the growth of new wood. None of the materials had any effect on yield the first season. Duplications of the applications in the spring of the second season resulted in material yield increases on the nitrogen plats, increases which were even greater the third season. Apparently the first season applications increased shoot growth, some of the longer ones fruiting in the second season and some bearing spurs which in the third year contributed to production. Measurements of trunk diameter from year to year showed a distinct correlation between yield and girth increase, which was most pronounced on the nitrogen trees. The leaves of the nitrogen trees were conspicuously larger, but the maturity of fruit was delayed as much as 10 days.

A comparison of no treatment, pruning, and pruning plus nitrogen showed that severe pruning checks growth significantly, but when supplemented with nitrogen the pruned trees recovered quickly, soon surpassing the control trees in yield. Apparently all three varieties responded in much the same manner to pruning and nitrogen fertilization.

Raspberry breeding experiments: Hybrids and back crosses between red and black varieties, G. M. DARROW (*Jour. Heredity*, 17 (1926), No. 9, pp. 338-

348, figs. 6).—Pointing out that practically all the newer varieties of raspberries are being produced by systematic breeding rather than chance selection, the author discusses the work at the U. S. D. A. Horticultural Field Station, Glen Dale, Md.

In crossing red and black raspberries no hybrids were obtained when the red was used as ovule parent. Hybrids between Winfield (black) and Golden Queen yielded purple fruit practically indistinguishable from that produced by the progeny of Winfield \times Cuthbert. Marked differences were noted in the fertility of the progeny of different crosses. Progeny of Winfield crossed with Golden Queen, Cuthbert, and Marlboro were mostly sterile, while Winfield \times Newman and Farmer \times Latham gave a high proportion of fertile seedlings. Crosses of purples with reds yielded promising seedlings, some of which bore firmer fruits than that of either parent or of any known raspberry. Furthermore, these back-cross progeny covered a greater range in ripening season than their parents, some maturing later than any known variety.

Banana culture in Hawaii, W. T. POPE (*Hawaii Sta. Bul.* 55 (1926), pp. 48, pls. 17).—This paper, devoted principally to the description of varieties, discusses the history and distribution, botanical characters of the plant, flowers, and fruit, composition and food value, methods of propagation, cultural requirements, harvesting and shipping, and the control of pests.

The Regal lily, D. GRIFFITHS (*U. S. Dept. Agr. Bul.* 1459 (1926), pp. 19, pls. 4).—The Regal lily, a comparatively recent introduction from north-central China, has been found to lend itself readily to propagation from seed, which may be sown either in the greenhouse or outdoors. Except for a susceptibility of new growth to late spring frosts, this lily has proved perfectly hardy and holds great promise as an outdoor as well as a forcing plant. Stem bulblet formation may be induced by subjecting the bulb to unfavorable cultural conditions, which apparently arrest normal development. The various practices involved in the propagation, culture, handling, and forcing of bulbs are discussed in detail, together with notes on habits of growth, resistance to pests, etc.

American bulbs under glass, D. GRIFFITHS (*U. S. Dept. Agr. Bul.* 1462 (1926), pp. 23, pls. 11, fig. 1).—Observations upon the behavior in a forcing house of a large variety of American-grown bulbs, tulip, narcissus, lily, etc., indicated that very satisfactory results may be obtained with such stocks if properly grown and handled. Uniformity and constancy in behavior such as characterizes imported stocks can not be expected in the general run of home-grown material but may be secured if the stock is grown in a single location with exacting care. The cutting of the flowers apparently reduced the forcing value of tulips. The size of the bulb was found to be an important consideration, and large size may be secured by allowing sufficient space per bulb and in retention of large sized bulbs among those saved as parent stock.

It was found that bulbs are very easily injured in storage and in transit by overheating and rough handling, and that such treatment is the source of much of the disease manifested in native material. Suggestions are given as to the better practices in culture and in storage. Broken-flowered mutants frequently occurring in tulips are believed due to a virus disease, and if these offtypes are grown at all it is advised that they should be isolated from normal stock.

House plants, A. LAURIE (*Michigan Sta. Circ.* 99 (1926), pp. 18, figs. 16).—General information is presented upon the light, moisture, air, and soil requirements of various house plants, together with instructions for controlling pests. Suggestions are given upon the preparation and arrangement of window boxes and hanging baskets, with lists of plants adapted for these special uses.

FORESTRY

A study of the vegetation of northeastern Arizona, H. C. HANSON ([*Nebr.*] *Univ. Studies*, 24 (1924), No. 3-4, pp. 94, pl. 1, figs. 33).—Studies of the forest and ground cover in the vicinity of the San Francisco Mountain in northeastern Arizona showed six rather distinct plant formations, namely, Alpine meadow, subalpine, montane, woodland, grassland, and sagebrush. The plant species occurring in four of these vegetational types are carefully enumerated, and the underlying causal differences such as elevation, temperature, soil, rainfall, and wind exposure are discussed.

Root studies with the Scotch and Austrian pines [trans. title], E. HESSELINK (*Meded. Rijksbosbouwproefsta. [Wageningen]*, 2 (1926), No. 3, pp. [3]+187-278, pls. 27; *Ger. abs. pp. 241-249*).—Following up a suggestion that the quotient obtained by dividing the total length of roots by the number of growing root tips might be constant for forest species, records were taken at the Wageningen Forest Experiment Station, Holland, upon young trees of the Scotch and Austrian pines. It was found that in seedlings grown in the same soil the root quotient was quite constant at any one time, even though the root lengths of individuals in a species varied sharply. On the other hand, considerable variability was recorded in the root quotient of the same plants measured at different times in the growing period. A temporary rise found in the root quotient in late summer suggests that at this season the tendency arises for the greater extension of the roots rather than for the formation of new roots. Observations upon the comparative root development in drift sand and in good soil showed that the root quotient is also affected by environmental factors. The death of roots in unfavorable soils resulted in a high root quotient. Studies of the effect of root pruning upon the quotient showed no lasting influence; in Scotch pine the balance was restored the following season and in Austrian pine the same season, providing pruning was carried on very early in the spring.

Observations upon older trees showed that the root quotient is greatly disturbed by the various relations under which the roots are growing. Length development was large in poor soils except where drought had injured the roots, and often very poor soil limited normal extension. The root quotient of the Scotch pine was different from that of the Austrian pine and in fact varied between the strains of a single species.

The inter-relationship of yield and the various vegetative characters in *Hevea brasiliensis*, R. A. TAYLOR (*Ceylon Dept. Agr. Bul.* 77 (1926), pp. 67, pls. 13, fig. 1).—This is a further report (E. S. R., 51, p. 444) upon the behavior of a population of *Hevea* trees descended through the medium of open-pollinated seed from a single productive parent. Yield records taken in the 1923-24 and 1924-25 seasons showed a tendency for the low-yielding trees to improve and for the high yielders to lose some of their original lead. Although the inter-relationship between yield and cortex thickness remained practically constant during four years, that between yield and girth became less marked and that between yield and the number of latex vessel rows increased. An increase in yield, on the other hand, showed no marked relation to any other character, leading the author to suggest that yield is probably an inherent quality independent of the factors which control growth. Girth was, as expected, closely correlated with cortex thickness and less so with the number of latex rows. There was a marked correlation between the number of latex vessel rows in untapped cortex and that in renewing cortex, indicating that the number of rows is characteristic of the tree.

DISEASES OF PLANTS

Plant pathology, J. G. BROWN and F. GIBSON (*Arizona Sta. Rpt. 1923, pp 498-506, figs. 5*).—Notes are given of a number of diseases of economic plants, the data having been secured through surveys of various localities.

In continuation of a previous report (E. S. R., 53, p. 745) further experiments have shown the value of the use of concentrated sulfuric acid for sterilizing cotton seed. In addition to destroying disease organisms, the delinted seed was more readily planted, and germination was hastened by from one to five days.

Experiments on the effect of alkali on the prevalence of angular leaf spot of cotton made on plants grown in screened pots and in field tests seem to indicate that the amount of angular leaf spot was greater in the alkali-free plots. Primary infection was found to take place through the cotyledons. Later infections resulted from the movement of the bacteria through the petioles of the cotyledons, as well as from infected cotyledons coming in contact with plants.

A disease of mesquite trees, in which a number of trees were defoliated, was found to be due to *Scleropycnium aureum*.

A scalding of citrus nursery stock is briefly reported upon. Rhizoctonia and Pythium were found present, but it is believed that high temperatures and liberal irrigation may have contributed to the occurrence of the disease.

Treating lettuce seed with corrosive sublimate did not reduce the occurrence of bacterial slime in the variety New York Special. It is considered probable that the bacteria causing the disease were present in the soil, and that they gained entrance to the leaves after frost injury. The disease has been repeatedly produced in healthy plants in the laboratory through inoculation experiments.

[**Plant disease investigations at the Wisconsin Station**] (*Wisconsin Sta. Bul. 388 (1926), pp. 76-85, figs. 3*).—Investigations by J. G. Dickson on resistance of corn to seedling blight are said to have shown that resistance to the cortical rots is not a simple factor or group of factors but is closely associated with the plant metabolism and growth. The resistant corn strains are considered to be resistant principally because the cell walls of the protective sheath tissues are cellulose, impregnated with suberin, which prevents fungus penetration, and because the carbohydrate and protein materials available in the cell walls and cell protoplasm are not the most suitable for the rapid growth of the fungus. The penetration of the parasite and subsequent growth and blighting is checked or greatly retarded due to these conditions within the host plant. A similar set of reactions was found to be set up within the susceptible strains when they are grown at high temperatures, or under conditions most favorable for the corn seedling. It is considered that resistance to the cortical rots in corn is directly associated with the nutrition and growth of the corn seedling, and that so-called resistant strains have a greater capacity to produce a well-balanced, vigorous growth even under unfavorable environmental conditions.

In a previous publication J. C. Walker showed that resistance of onions to smudge depended on the presence of a toxic substance in the outer scales of the bulbs of colored varieties (E. S. R., 49, p. 843). Investigations on disease resistance in onions were continued to include studies of neck rot, *Fusarium* bulb rot, and black mold. Onions are found to be resistant to neck rot for the same reason as they are to smudge, the causal organism attacking the bulbs through the scales and coming in contact with the toxin. The *Fusarium* of

bulb rot attacks the root, and consequently is not destroyed as the toxin is only in the colored scales. The parasite of black mold was found not to be sensitive to the toxic principle.

Continued experiments on the control of barley stripe are said to have shown consistent control by Germisan and good results with Uspulun and Semesan. Barley smuts were likewise fairly well controlled by this treatment and seeding in a moderately cool soil.

Investigations of grain rusts reported upon consisted of studies on the overwintering of stem rust (*Puccinia graminis*) in the red rust stage and the nature of resistance of wheat to leaf rust (*P. triticina*). Several hundred tests made in March and April confirmed earlier findings that spores of the red rust stage do not live through the winter season under conditions of alternate freezing and thawing, such as occur in Wisconsin. The studies made on the resistance to leaf rust showed that the parasite enters the stomatal cavity in both resistant and susceptible wheat strains, but the subsequent development is different as the fungus mycelium within the stomatal cavity of the resistant wheat strain does not develop rapidly and frequently not much beyond the infection vesicle. In other instances the haustorium enters the cell, which results in the death of the host cell and subsequent death of the rust parasite.

Investigations by G. W. Keitt and E. E. Wilson on the control of apple scab and cherry leaf spot are reported, and it was found that there was a marked relationship between the time of leaf fall and the time of maturity of the spores of the apple scab fungus. Ascospores developed to maturity in leaves which fell in early fall much earlier than in those which remained on the tree until late fall or early winter. A discussion is given of the temperature relations of the fungus. For the control of cherry leaf spot plats of trees which had been sprayed with Bordeaux mixture and lime sulfur in 1924 received reversed treatments in 1925, with the result that in both seasons the weight of the fruit sprayed with lime sulfur was approximately 15 per cent greater than that of the fruit sprayed with Bordeaux mixture.

Field and laboratory work by Keitt and A. N. Brooks on fire blight and its control showed that the overwintering of the fire blight organism occurred not only in connection with cankers on the larger branches but also in blighted twigs as small as $\frac{1}{8}$ in. in diameter. Twig infection appeared in advance of blossom blight during the past year, and early in the season fully 90 per cent of it could be traced to rain-borne inoculum from suitably located hold-over cankers or twigs. Twig infection occurred at intervals until late July. Rain was found to be an important agency for the local dissemination of fire blight. The development of fire blight is said to be favored by temperatures of from 65 to 85° F., relatively high humidities, cloudy weather, frequent showers, infestations of aphids and leafhoppers, heavy blossoming of trees, the abundant activity of bees and other pollinating insects, the presence of large plantings of the more susceptible varieties, and a high stage of vegetative vigor of the host plant.

Studies by R. E. Vaughan and J. Brann are said to show that by the use of hot formaldehyde solution, 1 lb. of formaldehyde to 15 gal. of water, the control of potato scab is less expensive and less time is required than by some of the methods previously tested. It is recommended that potatoes should be treated in this solution for 2.5 minutes at from 122 to 125° instead of 1.5 hours as is practiced with corrosive sublimate. This treatment is also effective in controlling black scurf and blackleg as well as scab.

In continuation of studies of crown gall of apple trees, A. J. Riker and Keitt have shown that enlargements or growths on the apple trees of the type which

did not yield the crown gall bacteria are mostly the result of factors other than the crown gall organism. For the most part they appear to be overgrowths at points where the downward passage of food in the tree was interfered with, and in most cases this was due to the failure of some part of the scion to unite with the stock. An examination of several thousand apple grafts showed ample misfits to account for a large percentage of the root knot found. Root knots were readily produced by making ill-fitted grafts or wounding young trees.

Field studies by M. B. Linford and F. R. Jones on pea blight are said to have shown that root rot caused by *Aphanomyces euteiches* was much less destructive in 1925 than in 1924. There were, however, some districts where root rot was exceptionally severe, and these were chiefly in the Colby silt loam region where soaking rains kept the soil wet during a period of warm weather. The long persistence of the pea root rot organism in the soil is considered to be due in part at least to the fungus attacking other plants than peas. Preliminary tests with different varieties are said to have indicated that those which had been regarded as somewhat resistant to root rot may prove highly resistant to pea wilt.

A survey by Vaughan, L. R. Jones, and W. J. Zaumeyer of diseases of canning beans showed the presence of a bacterial disease, which causes the blighting of leaves and pods, and mosaic to be of common occurrence under Wisconsin conditions. One of the standard green canning varieties of beans, which is relatively resistant to the bacterial blight, is found to be seriously susceptible to mosaic.

Some factors in the incidence of plant diseases, F. J. F. SHAW (*Indian Sci. Cong. Proc. [Calcutta], 10 (1923), p. 192*).—Since the incidence of disease may be closely connected with the chemical and physical properties of the soil and with conditions of humidity and temperature, it is thought that mycological research should be on a physiological basis in order that the factors which contribute to the success of the parasite may be correctly estimated.

Epidemic plant diseases, F. T. BROOKS (*Brit. Mycol. Soc. Trans., 9 (1924), pt. 4, pp. 229-239*).—Contrasting the favoring conditions characteristic, respectively, of animal and of plant diseases, the author considers it safe to say that weather conditions are frequently or usually all important in determining whether or not a plant disease shall appear in epidemic form. These and other conditions are discussed in their respective bearings.

Economic mycology, B. T. P. BARKER (*Jour. Bath and West and South, Counties Soc., 5. ser., 19 (1924-25), pp. 137-140*).—Record is made of reports of field bean chocolate spot, lettuce ring spot (*Marssonina panattoniana*), apple and pear black scab (*Venturia inaequalis* and *V. pyrina*), potato blight (*Phytophthora infestans*), currant leaf spot (*Pseudopeziza ribis*), plum silver leaf, die-back (*Diaporthe perniciosa*), and leaf shot hole, and a pear fruit rot. Diseases of 19 economic plants are listed, the plants being affected with some 34 diseases associated with a nearly equal number of causal organisms.

Notes on plant diseases in 1924, H. WORMALD (*East Malling [Kent] Research Sta. Ann. Rpt. 1924, pp. 110-119*).—These notes deal with potato blight (*Phytophthora infestans*); certain apple, hop, onion, quince, and plum diseases (associated with *Botrytis* spp.); so-called brown rot diseases, including sweet cherry blossom wilt (*Sclerotinia cinerea*); apple blossom wilt (*S. cinerea mali*); plum withertip (*S. cinerea pruni*); apple and quince fruit rot (*S. fructigena*); plum and cherry die-back (*Diaporthe perniciosa*, *Cytospora leucostoma*, and bacteria); cherry leaf scorch (*Gnomonia erythrostoma*) and small leaf (soil conditions?); apple and pear scab (*Venturia inaequalis* and *V. pyrina*); pear canker (*Nectria galligena*); apple nursery stock canker; apple tree root rot

(*Armillaria mellea*); pear root rot (*Roesleria hypogea*); apple fruit rot (*S. fructigena* or *Gloeosporium* sp.); quince leaf and fruit blotch (*Fabraea maculata* (*Entomosporium maculatum*) and *Phoma* spp.), and fruit rots (*S. fructigena* and *B. cinerea*); raspberry mildew (*Sphaerotheca humuli*), rust (*Phragmidium rubi-idaei*), and wilt (*Verticillium* sp.); currant and gooseberry defoliation (*Pseudopeziza* (*Gloeosporium*) *ribis*), rust (*Cronartium ribicola*), die-back (*Diplodia* sp.), mildew (*Microsphaera grossulariae*), leaf spot (*Phyllosticta grossulariae* and *Ascochyta* sp.); walnut fruit blotch (bacterial?) and leaf spot (*Marssonina juglandis?* (*Gnomonia leptostyla*)); hop powdery mildew (*S. humuli*), downy mildew (*Pseudoperonospora humuli*), wilt (*Verticillium* sp.), and leaf spot (*B. parasitica*); lettuce rust (*M. panattoniana*), soft rot (*Botrytis* sp.), downy mildew (*Bremia lactucae*), and a disease not named (*Marssonina* sp.); and lavender scab (*Phoma lavandulae* and *Septoria lavandulae*).

[Plant diseases, Philippine Islands, 1924], S. YOUNGBERG (*Philippine Bur. Agr. Ann. Rpt.*, 24 (1924), pp. 167-196, pls. 7).—This portion of the acting director's report, covering the plant disease section and cooperative plant disease observations at the different stations, deals in some detail with the organization, identification, and recording of disease specimens (rice, sugar cane, abaca, coconut, and other miscellaneous crops), observations at Lamao, Tanauan, and La Carlota, eradication of coconut bud rot, eradication of abaca disease, system of survey and eradication, and a survey of abaca-growing provinces.

Botany and plant pathology, I. B. P. EVANS (*Union So. Africa Dept. Agr. Jour.*, 11 (1925), No. 6, pp. 571-576).—A botanical survey of portions of South Africa is briefly reported. Diseases of the virus group, as here briefly noted, include a streak disease of maize and sugar cane, mosaic of sugar cane and other grasses, and peanut rosette. Citrus plant diseases include canker (*Bacterium citri*), brown rot (*Pythiacystis citrophthora*), and lemon leaf spot and orange center rot (*Alternaria* sp.). Diseases of other plants include tobacco wildfire (*B. tabacum*), potato wart, pineapple brown spot, and quince black rot. Storage studies include preliminary investigations on the physiology of stored fruit.

The germination of conidia of *Botrytis cinerea* in solutions of various substances [trans. title], K. STARITZKY (*Centbl. Bakt. [etc.]*, 2. Abt., 65 (1925), No. 14-21, pp. 291-297).—A tabulation is presented of the germination results obtained from spores of *B. cinerea* in solutions differing in concentrations of 52 substances.

A new species of *Monochaetia*, M. WILSON and F. C. FORD-ROBERTSON (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 4, pp. 189-192, pl. 1).—The fungus which is herein described as the new species *M. cryptomeriae* was found in November, 1921, on dead leaves of *Cryptomeria japonica* which were still attached to the cast shoots. Although at the time of subsequent examination the material had been kept dry in the laboratory for 14 months, the spores when released after soaking were in condition to germinate, and on agar they readily produced abundant mycelium.

Fruit-rotting Sclerotinias.—III, Longevity of buried brown-rot mummies, W. N. EZEKIEL (*Maryland Sta. Bul.* 284 (1926), pp. 9-22, figs. 3).—In continuation of investigations on the fruit-rotting Sclerotinias (*E. S. R.*, 53, p. 448), studies were made of the duration of viability in peach brown-rot mummies under varying conditions. Preliminary experiments showed that burying mummies more than 1 in. below the surface of the soil prevented the growth of apothecia, but that no permanent effect was produced on the mummies unless they actually disintegrated before being again brought to the surface.

Extensive experiments, in which peach mummies were distributed in duplicate series at four different depths in both wet clay and dry sand soils, showed that in both soils the buried mummies disintegrated rapidly, while mummies on the surface were well preserved and produced apothecia. It is recommended that peach brown-rot mummies lying on the ground should be plowed under after rotten fruits are picked from the trees in the fall or before the early pink-bud stage of the blossoms in the spring.

Methods of disinfection of seed and soil in cereal culture [trans. title], M. M. MORÓN (*Rev. Facult. Agron. La Plata, 3. ser., 16 (1925), No. 1-2, pp. 157-163*).—Seed or soil disinfection methods here briefly outlined involve the employment of heat, electrification, formalin, copper sulfate, uspulun, caffaro (dust), hydrocyanic acid, and potassium cyanide.

Dry treatment of wheat seed for smut [trans. title], J. B. MARCHIONATTO (*Rev. Facult. Agron. La Plata, 3. ser., 16 (1925), No. 1-2, pp. 88-92, figs. 2*).—The best protective results against *Tilletia tritici* were obtained with the dust treatment "polvo X," with no loss of germinability.

The effect of formalin on the vitality of seed wheat, E. BAKER (*Union So. Africa Dept. Agr. Jour., 9 (1924), No. 5, pp. 454-457, fig. 1*).—It has appeared probable that 1 pt. formalin to 50 gal., possibly 1 pt. to 60 gal., of water is effective to control bunt of wheat, covered smut of oats or barley, or loose smut of oats. A tabulation of varietal percentages of germination after 1 to 52 weeks following treatments, as given, shows that the formalin-treated seed kept better than did the untreated seed, though a modifying (storage) factor is discussed. Apparently, seed wheat dipped in formalin and stored in the usual way does not suffer any great loss as to germinability.

The bacterial disease of wheat caused by *Pseudomonas tritici* (Hutchinson), TEWEIK EFF. FAHMY and TEWEIK EFF. MIKHAIL (*Agr. Jour. Egypt, n. ser., 1 (1923), No. 1, pp. 64-72, pls. 6*).—A disease of wheat which destroys the inflorescence, thus preventing seed formation, is distributed in patches throughout the infected fields. The disease may become evident at any stage of growth. The gummy substance formed by diseased plants contains vast numbers of bacteria, but so far as observed the bacterium *P. tritici* is not capable of producing the disease without the assistance of a nematode which is associated therewith, *Tylenchus tritici*. Apparently, the life histories of the nematode and of the bacterium are such that the nematode acts as carrier to the wounded parts of the plant. The disease is presumably spread by the use of seed carrying bacterial infective dust and nematode galls, also by sowing wheat in infected soil. Contemplated control measures are suggested.

Diseases of cabbage and related plants, J. C. WALKER (*U. S. Dept. Agr., Farmers' Bul. 1439 (1927), pp. II+30, figs. 14*).—As a revision of Farmers' Bulletin 1351 (E. S. R., 50, p. 45), popular descriptions are given of a number of diseases of cabbage and other cruciferous plants, and suggestions are given for their control.

The life history of *Polythrincium trifolii* Kunze, J. S. BAYLISS-ELLIOTT and O. P. STANSFIELD (*Brit. Mycol. Soc. Trans., 9 (1924), pt. 4, pp. 218-228, pl. 1, fig. 1*).—" *P. trifolii* develops a rather loose stroma on the under surface of leaves of *Trifolium repens* and produces during the course of its life history more compact and deeply seated stromata, which bear pycnidia containing pycnospores (*Sphaeria trifolii* Pers.) capable of infecting fresh clover plants. These stromata, on the decay of the leaf, fall to the ground and function as sclerotia. On further growth perithecial cavities are produced, containing the asci and ascospores characteristic of a *Dothidella* and not of *Phyllachora*, as has been assumed by various authors."

A study of clover failure in Kentucky, E. N. FERGUS and W. D. VALLEAU (*Kentucky Sta. Bul.* 269 (1926), pp. 139-210, figs. 21).—Laboratory, plat, and field studies were made of red and alsike clovers to determine the causes of failures, the critical time in the growth of the plants, and when the failures of established stands occurred.

It is concluded that clover failure results indirectly from unfavorable nutritional environment and probably directly as the result of the attack of pathogenic organisms upon the roots, the direct causes being able to operate in direct proportion to the condition of the plant resulting from the indirect causes. Among the indirect causes enumerated are low or unbalanced fertility, unfavorable H-ion concentration, and poor aeration. The general conclusion is reached that clover failures, such as are experienced in Kentucky and probably in eastern United States, result from unfavorable nutrition, in which soil infertility, unfavorable temperature, and droughty soil conditions are contributing causes. Such conditions are said to develop plants that are seriously injured by pathogenic root organisms. The application of lime, manures, and fertilizers to soils on which clover fails regularly has been found to decrease the mortality rate of the plant. Such applications, however, do not materially increase root development in unfavorable subsoils.

Preliminary investigations of the parasitism of certain fungi causing boll rots of cotton, T. LAYCOCK (*Nigeria Agr. Dept. Ann. Bul.*, 4 (1925), pp. 32-49).—Cotton internal boll disease at Ibaden is caused by a fungus, at present undetermined, but probably allied to *Nematospora*. Other fungi may contribute to the injury. The cotton stainer (*Dysdercus supersticiosus*) may carry and introduce the disease.

Anthracnose boll rot, caused by the supposedly facultative parasite *Glomerella* (*Colletotrichum*) *gossypii*, is one of the primary causes of the mummification and distortion of bolls, the damage being much more pronounced than in those caused by a *Fusarium* and as regards appearance distinguished with difficulty from the *Glomerella* rot.

Fusarium sp., occurring on both vegetative and reproductive parts of cotton, is a saprophyte and a less virulent boll-rotting factor than is the anthracnose organism. It is favored by damp conditions and is not concerned in the wilting of cotton in Nigeria.

Strains of *Rhizoctonia solani* Kühn (*Corticium vagum* Berk. and Curt.), H. R. BRITON-JONES (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 4, pp. 200-210, pls. 2).—During work in Egypt on cotton-seedling sore-shin disease (*R. solani*), the fungus was induced under experimental conditions to produce its fertile stage, *C. vagum*. Comparisons of the *R. solani* from cotton in Egypt with isolations of the same species from other countries showed considerable difference in the cultures. In order to ascertain whether these differences were permanent, the strains were grown under conditions permitting fair comparisons.

Some of the isolations proved to be easily distinguishable macroscopically, others with difficulty or not at all. The microscopic differences are considered as morphologically nonspecific. The name *C. vagum* (*R. solani*) is retained for the isolations compared as reported in this paper. At the same time it is recognized that the group contained several biological species or strains.

Two new cotton plant bacteria in Armenia [trans. title], P. KALANTARIAN (*Centbl. Bakt. [etc.]*, 2 Abt., 65 (1925), No. 14-21, pp. 297-301).—A cotton plantlet bacteriosis is ascribed to a bacterium to which the name *Bacterium erivanense* is applied. A bacteriosis of the older plant is described as due to the new species named *B. löhnisi*.

Rosette disease of peanuts (*Union So. Africa Dept. Agr. Jour.*, 11 (1925), No. 1, pp. 10, 11).—Recent studies said to have been carried out at Potgietersrust, Pretoria, and Durban by H. H. Storey and A. M. Bottomley with the assistance of J. S. MacKay have shown, it is claimed, that *Aphis leguminosae* is able to transfer the infective agent from diseased to healthy plants. Trials with other suctorial insects, occurring commonly in the fields, have given negative results. Peanut rosette appears to belong to the group of so-called virus diseases.

Indexing of potatoes for mosaic (*Wisconsin Sta. Bul.* 388 (1926), pp. 44, 45, fig. 1).—In a previous publication (E. S. R., 53, p. 443) it was shown that potato tubers bearing the mosaic diseases can readily be detected in the greenhouse by the so-called indexing method. Through greenhouse operations about 2,500 bu. of seed potatoes are said to be available for planting in 1927. The results of the work are said to have indicated that on most of the indexed plats inspected the amount of mosaic found did not exceed 3 per cent, and in special cases where control conditions and handling operations were entirely satisfactory the mosaic count ranged less than 1 per cent. In the parent seed stocks grown on the same farms from which the indexed stocks were secured the mosaic counts ranged from 15 to 40 per cent. It is believed that continued reindexing of the improved stock will result in further reduction of the mosaic.

Apple tufts, C. C. CARPENTER (*Bot. Gaz.*, 78 (1924), No. 4, pp. 414-423, figs. 6).—Tufts in apples (white growths on the carpel walls of some varieties) are not fungi, but are tissue proliferations developed in carpel fissures. They are found in high percentages in some of the best keepers, though admittedly they may take part in decay. Tufts are not correlated with open core, open calyx, or abortive seeds. Slight differences appear in tufts produced in different apple varieties.

Citrus diseases and their control, H. S. FAWCETT and H. A. LEE (*New York and London: McGraw-Hill Book Co.*, 1926, pp. XII+582, pls. 15, figs. 190).—The authors brought together information relating to citrus diseases occurring in all parts of the world. After the general consideration of citrus disease investigations, types of diseases, their distribution, conditions affecting severity, principles of prevention and treatment, and specific diseases are considered in detail, the diseases being grouped under the headings root and trunk diseases; diseases of branches, twigs, and leaves; and fruit diseases. Where a disease attacks more than one group of plant organs it is described in the group where it appears to be the most destructive. Keys are given for the identification of diseases in the different groups.

An extensive list of publications referred to by the authors is given as a partial bibliography of the subject.

Effects of spraying citrus trees on the composition and flavour of the fruit, C. F. JURITZ (*Union So. Africa Dept. Agr. Jour.*, 11 (1925), No. 3, pp. 240-243).—Arsenical spraying of orange trees was found to lower acidity and impair the flavor of the fruit without corresponding external alteration.

The operations against bud rot of palms in south India, W. McRAE (*Indian Sci. Cong. Proc. [Calcutta]*, 10 (1923), p. 188).—*Phytophthora palmivora* attacks the palmyra palm, *Borassus flabellifer*, and the coconut palm, *Cocos nucifera*, causing a rot of the bud or crown. Operations are referred to as having reduced annual deaths due to this rot from 100,000 in 1908 to 8,700 in 1921.

A mildewless rose-garden, W. DEP. KNOWLTON (In *The American Rose Annual. Harrisburg, Pa.: Amer. Rose Soc.*, 1925, pp. 86-88).—Freedom from

close heat and from sudden temperature changes is credited as being perhaps the principal factor among those here described in connection with complete freedom from rose mildew in case of very susceptible rose varieties.

The conquest of mildew, H. H. HAZLEWOOD (In *The American Rose Annual. Harrisburg, Pa.: Amer. Rose Soc., 1925, pp. 81-85*).—Evidence obtained in New South Wales, Australia, is submitted as pointing to the conclusion that a total potash content of 3.79 per cent, available potash content 1.02-1.09 per cent, was the influential factor in preventing rose mildew attack in case of rose varieties known to be very susceptible to this disease. "It is not intended to convey the idea that this amount is necessary for mildew immunity." Testimony is cited regarding the protective influence of potash in such connection.

A cautionary word about fungicides, L. M. MASSEY (In *The American Rose Annual. Harrisburg, Pa.: Amer. Rose Soc., 1925, pp. 89-92*).—Outlining the exacting requirements of a protective fungicidal treatment for roses, more particularly as against mildew and black spot, and emphasizing the protective values of such fungicides as sulfur dust, Bordeaux mixture, and liquid lime sulfur for the control of these diseases, the author expresses a preference for sulfur-lead dust as causing less foliage discoloration.

The question of the transmissibility of violet smut (*Urocystis violae*) by violet seed [trans. title], H. PAPE (*Centbl. Bakt. [etc.], 2. Abt., 65 (1925), No. 14-21, pp. 301-307, figs. 5*).—The (somewhat rare) occurrence is demonstrated of resting stages of *U. violae* in seed coats and appendages of *Viola odorata*.

Fungi parasitic on cultivated trees in Argentina [trans. title], J. B. MARCHIONATTO (*Rev. facult. Agron. La Plata, 3 ser., 16 (1925) No. 1-2, pp. 15-40*).—Parasitic fungi affecting cultivated trees over a wide range are systematically discussed.

A note on south Indian Loranthaceae and their host plants, P. S. JIVANNA RAO (*Indian Sci. Cong. Proc. [Calcutta], 10 (1923), p. 191*).—Loranthus, 12 species, and Viscum, 8 species, attacking 68 hosts have been listed. The hosts exert a definite influence on the form of the parasite and also on the size and color of the leaves, and cases of polymorphism occurring in the Loranthaceae are believed to be identical in some respects to spike in the case of sandal (*Santalum album*).

The Loranthaceae attack several hosts which are parasitized by sandal, and the susceptibility of these hosts for the attack of either family suggests physiological affinity among the parasites and hosts on the one hand and between the Loranthaceae and Santalaceae on the other. Cases of double parasitism and phylloidy have been reported.

A Rhizoctonia causing root disease in Uganda, W. SMALL (*Brit. Mycol. Soc. Trans., 9 (1924), pt. 3, pp. 152-166, pls. 2*).—In Uganda, the silky oak (*Grevillea robusta*), planted extensively as an ornamental, shade tree, and wind-break, is subject to root attack by white ants (*Termes bellicosus*), which may demolish the underground parts and cause a break at the ground level while the foliage still appears normal. This work of the termites is, however, claimed to be secondary to a weakening root attack by a Rhizoctonia, which occurs in trees up to five or more years of age. A study of the disease results in a technical description of the causal fungus, which is considered to be a new species and is named *R. lamellifera*. A fungus apparently identical with this has been found on tea, arnatto (*Bixa orellana*), *Coffea robusta*, and *Casuarina equisetifolia*. *Coffea arabica* has not yet been shown to be susceptible to this fungus.

Notes on *Rhytisma acerinum* and *Rhytisma pseudoplatani*, R. BRACHER (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 3, pp. 183-186, pl. 1).—The present preliminary account records observations made, during a cytological study of *Rhytisma*, on the general life history of that genus, the material having been collected in England, where it grows on *Acer pseudoplatanus*, and in America, where it grows on *A. saccharinum*. Life histories of the two forms are closely similar. The few minor differences are here recorded.

Observations on the "slime-fluxes" of trees, L. OGILVIE (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 3, pp. 167-182, fig. 1).—Investigations, beginning in 1921 on exudations from trunks and branches of trees, particularly elm, horsechestnut, apple, and willow, are outlined. The reddish flux of Huntingdon elm contained a *Fusarium* forming copious pink spore masses, an *Oospora* (*Oidium*), bacteria, and other organisms. The brown flux of elm and horsechestnut invariably contained a species of *Oospora*. An *Oospora* (*Oidium*), a sporing yeast, and a *Fusarium* were commonly but not constantly found. The flux also contained fluorescent bacteria, algae, and insect larvae. The apple tree flux, in and near Cambridge, always contained three nonsporing yeasts. The willow white flux contained an *Oospora* (*Oidium*), probably *O. ludwigii*, a sporing yeast and bacteria.

The first three kinds of flux persisted throughout the year. Calcium carbonate was abundant in the red and the brown flux. This is derived from the vessels of the wood, and it renders the reaction of the exudation favorable to the growth of organisms. The white fluxes originate in the bark, being always associated with wounds or unhealthy condition. They are more acid than the brown fluxes and persist only for a short time in the summer.

Observations on *Camarosporium abietis* n. sp., M. WILSON and R. B. ANDERSON (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 3, pp. 144-151, pls. 2).—A fungus is described as a new species, *C. abietis*, this form having been collected March 3, 1923, on *Abies lowiana* at Arniston, Midlothian. Lateral branches, destitute of leaves, bore black fructifications, though no signs of infection appeared on or near the main trunk. Though confirmatory experiments are still in progress, the fungus has appeared to be saprophytic only.

Tree mycorrhiza, R. PAULSON (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 4, pp. 213-218, pls. 2).—A close association of a fungus with a rootlet of a higher plant, constituting the phenomenon of mycorrhiza or fungus-root, occurs abundantly, almost without exception, in the case of *Quercus robur*, *Fagus sylvatica*, *Carpinus betulus*, *Betula alba*, *Castanea sativa*, *Pinus sylvestris*, and *Taxus baccata* in woodlands in southeastern counties at least, especially in those located on light soil. The object of the present notes, based for the most part on field observations, is to suggest that investigation following the lines indicated may assist in the elucidation of the hitherto unsolved question of the true relation that exists between the fungus and the root in the case of ectotrophic mycorrhiza. Field studies afford considerable evidence in favor of the view that the relation is something more than that of parasitism, and that it is mutual or symbiotic. The observations, inferences, and conclusions are detailed.

Some observations on *Fistulina hepatica* and hollow, stag-headed oaks, K. W. BRAID (*Brit. Mycol. Soc. Trans.*, 9 (1924), pt. 4, pp. 210-213).—Observations on hollowness and stag-headedness associated with the abundance of *F. hepatica* in oaks during 1921 and 1923 in Richmond Park inclined the author to the opinion that the insufficiency of wood vessels, rather than the lack or unavailability of water, is the primary factor in the production locally of

stag-headedness in oaks. "Fistulina apparently plays a large part in the hollowing of oaks in Richmond Park and is possibly also one of the main factors in causing stag-headedness." Certain observations are detailed.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The migrations of birds, A. WETMORE (*Cambridge: Harvard Univ. Press, 1926, pp. VIII+217, pls. 7*).—This account of observations on the migrations of birds was delivered in the form of six lectures before the Lowell Institute at Boston in the fall of 1925.

Birds of western Canada, P. A. TAVERNER (*Canada Dept. Mines, Victoria Mem. Mus., Mus. Bul. 41 (1926), pp. 380, pls. 84, figs. 315*).—In the introductory part of this work the author includes a discussion of classification, nomenclature, geographical distribution, migration, protection, means of attracting birds, bird study, permit principles, and ornithological literature, including books dealing with special groups of birds, books of special geographical interest, etc. This is followed by an illustrated key to the birds of western Canada. The main part of the work, presented under the heading of descriptive ornithology (pp. 35-352), is systematically arranged and gives descriptions of the known birds of western Canada, together with their nesting, distribution, habits, and economic status. A glossary and a complete subject index are included.

Birds of the Netherlands, II, E. D. VAN OORT (*De Vogels van Nederland. The Hague: Martinus Nijhoff, 1926, pt. 2. pp. VIII+265, pls. 83*).—This second volume of the work previously noted (*E. S. R.*, 50, p. 355) deals with the orders Falconiformes (pp. 1-96), Galliformes (pp. 97-124), Gruiformes (pp. 125-166), and Charadriiformes (pp. 167-253). Seventy-two forms are described, illustrated by numerous colored plates.

Unique method of pollination by the ruby-throat, A. L. PICKENS (*Auk, 44 (1927), No. 1, pp. 24-27, figs. 5*).—The author reports upon the cross-pollination of *Macranthera lecontei*, found growing along the Gulf Plain from Georgia to Mississippi and blooming in the summer and fall, by the rubythroat (*Archilochus colubris*), which carries the pollen on the back of its head.

Wild plants and seeds for birds, R. MORSE (*London: Cage Birds, 1926, pp. 110, figs. 22*).—This is a small illustrated dictionary of the best foods for use in the aviary.

A synopsis for the identification of the amphibians and reptiles of Indiana, G. S. MYERS (*Ind. Acad. Sci. Proc., 41 (1925), pp. 277-294, fig. 1*).—Keys are given for the separation of the amphibians and reptiles of Indiana.

Comparative value of sodium hydroxide, copper sulphate, and fermentation in disinfecting human excreta containing eggs of hookworms (*Necator americanus*) and of *Ascaris* (*Ascaris lumbricoides*), C. W. STILES (*Jour. Parasitol., 13 (1926), No. 1, pp. 47-55*).—The author's investigations show that copper sulfate and sodium hydroxide are good disinfectants for use against hookworm eggs. Fermentation was found to be a satisfactory method of killing eggs of *Ancylostoma*, *Necator*, and *Ascaris*, provided the process was continued long enough.

A synopsis of the families and genera of Nematoda, H. A. BAYLIS and R. DAUBNEY (*London: Brit. Mus. (Nat. Hist.), 1926, pp. XXXVI+277*).—In this compilation the authors have made some important proposals in regard to classification and have themselves examined material representing a large proportion of the parasitic genera.

Dr. Ransom's bibliography, compiled by A. HASSALL (*Jour. Parasitol.*, 13 (1926), No. 1, pp. 10-15).—This is a complete list of the writings of B. H. Ransom, extending from 1900 to 1924.

Entomology, C. T. VORHIES (*Arizona Sta. Rpt. 1923*, pp. 475, 476).—In referring to bee culture mention is made of honey from Hubam sweet clover, which is said to be darker and inferior in flavor to mesquite and cat's claw honey. The Putnam scale is recorded for the first time in Arizona, having been collected on apricot trees in Salt River Valley, and also reported to occur on peach and plum trees.

Insects of Indiana for 1925, J. J. DAVIS (*Ind. Acad. Sci. Proc.*, 41 (1925), pp. 303-319, figs. 7).—This is a discussion of the status of economic insects in Indiana in 1925 arranged according to the crops and products attacked.

[**Work with economic insects in Wisconsin**] (*Wisconsin Sta. Bul.* 388 (1926), pp. 60-75, figs. 10).—Reference is first made to successful poison bait control work by A. A. Granovsky and J. Johnson of grasshoppers attacking tobacco. It is pointed out that seed bed injury by flea beetles, etc., can be controlled by dusting with calcium fluosilicate or sodium silicofluoride without injury to the plants. In work with potatoes at Waupaca, C. L. Fluke and J. E. Dudley found that for insect and disease control Bordeaux spray gave higher yields of potatoes than did the use of dust preparations. Because of the ease and speed with which dust applications can be made, their use is said to be rapidly increasing.

The black cherry aphid, which has been observed in the Sturgeon Bay region for a long time, is primarily a pest of the sweet cherry although it occurs on certain sour varieties and is particularly destructive to the Early Richmond and to a lesser degree the Montmorency varieties. It was observed by Granovsky that the aphid feeds particularly upon the buds and tender foliage, usually on the lower side of the leaves of the terminal shoots, and in the process of feeding discolors the foliage and often causes curling of the leaves. Control experiments have shown dusting to be fairly efficient when the dust consists of 2 pints of Blackleaf 40 to 50 lbs. of hydrated lime. In experimental work in the spring of 1926, the petal spray appeared to be the best for control of the pest and the new insecticide Derrisol seemed to be particularly effective. Studies made of the life history of this aphid are briefly reported upon. The wild pepper grass, *Lepidium* sp., was found, late in 1926, to be the secondary host of the species.

An outbreak in 1926 of the hemlock spanworm (*Ellopiia fiscellaris* Gn.), which occurred in the Peninsular State Park in Door County, was combated under the direction of S. B. Fracker and Granovsky by the application of calcium arsenate dust by airplane, 15,000 lbs. of calcium arsenate being distributed over about 1,000 acres of infested forest. Quite effective results were obtained, the mortality being estimated at 90 per cent in hemlock forests and over 80 per cent in the mixed forest areas. Referring to the life history of the spanworm, it is pointed out that eggs deposited on the needles and bark of hemlock trees in the fall, usually in late September, hatch about the middle of the following June and the worms reach maturity in August. About 90 per cent of the trees attacked by this pest die and those that recover are in a very weak condition.

Control work with grasshoppers in Door County by Granovsky is reported upon, an account of which, from another source, has been noted (*E. S. R.*, 55, p. 355). In this work a mixture of sawdust, salt, and poison was found to be wholly satisfactory and quite materially reduced the expense.

It was found that under Peninsular region conditions early seeding of winter wheat tends to reduce injury from the Hessian fly as well as that from winter-killing.

Observations by Fluke upon parasitic control of the pea aphids by parasites and predators are referred to. Preliminary tests at Waupaca indicate that calcium fluosilicate gives considerable promise in the control of chewing insects, being fairly effective against the Colorado potato beetle. Reference is made to the thistle butterfly (*Vanessa cardui* L.), which is commonly met with in the State. Studies made of the transmission of mosaic disease by leafhoppers by Granovsky are referred to. In transmission work needle inoculation with crushed leafhoppers produced symptoms of disease on the apple leaf. Observations of Granovsky and F. R. Jones indicate that alfalfa yellows is caused by leafhopper injury, *Empoasca fabae* Harris being the species responsible.

[Annual reports of the Government entomologists of the Gold Coast for the year 1925-26], W. H. PATTERSON and G. S. COTTERELL (*Gold Coast Agr. Dept. Rpt. 1925-26, pp. 36-39*).—These brief reports deal with the more important insect enemies of the year, particular attention being given to the termites attacking cacao and buildings and means for their control. Reference is made to injury caused to ripe bananas by fruit-piercing moths, *Achres* spp. and *Ophideris fullonica*. Injury was caused on one plantation by the coconut scale (*Aspidiotus destructor*), the combat of which through the application of a spray was suspended due to the appearance of the ladybeetle *Chilocorus schiodtii* Muls. in large numbers. The ladybeetle was also the chief means of control of the coconut scale in another district. The leafhopper *Erythroneura* (*Typhocyba*) sp. was found to cause damage similar to that of the scale insect, but was held fairly well under control by natural enemies.

Annual report of the Government entomologist, H. HARGREAVES (*Uganda Dept Agr. Ann. Rpt. 1924, pp. 21-28*).—This is a report of the more important insects of the year 1924.

Annual report of the assistant entomologist, G. L. R. HANCOCK (*Uganda Dept. Agr. Ann. Rpt. 1925, pp. 25-28*).—The more important insects of 1925 are dealt with.

Insect enemies of cotton in French West Africa, P. VAYSSIÈRE and J. MIMÉUR (*Les Insectes Nuisibles au Cotonnier en Afrique Occidentale Française. Paris: Émile Larose, 1926, pp. IX+176, pls. 22, figs. 11*).—This is an account of the more important enemies of cotton in French West Africa, together with their important insect parasites and predators. Accounts (1) of the pink boll worm and its destruction in the seed and (2) of insect pests in French West Africa of crops other than cotton are appended. A bibliography of eight pages is included.

A list of the insects affecting sugar cane in Cuba, D. L. VAN DINE (*Trop. Plant Research Found. [Wash., D. C.] Bul. 3 (1926), pp. 16*).—The author presents a preliminary annotated list of 48 insects affecting sugar cane in Cuba. A list of 33 references to the literature is included.

Insect pests of our garden plants and their control, C. A. WEIGEL (*Amer. Hort. Soc. Bul. 3 (1926), pp. 12*).—This is a practical account.

Pollination in orchards.—VII, Insect visitors to fruit blossoms, G. F. WILSON (*Jour. Roy. Hort. Soc., 51 (1926), No. 2, pp. 225-251, pls. 6*).—This portion of the series previously noted (*E. S. R., 46, p. 840*) is an extended account of observations of insect pollination of blossoms, including a tabulated census of the chief pollinating agents of fruit trees at Wisley, Surrey, from 1920 to 1924, inclusive. The observations reported show that the insect pollination is by no means confined to the honey bee.

Insects caught in light traps, F. V. THEOBALD (*Jour. Roy. Hort. Soc.*, 51 (1926), No. 2, pp. 314-323, pls. 2).—This is a report of collections made by light traps, details of which are given, including the number of insects caught, the percentage of males and females, a list of the species of economic importance, and a list of the chief insects of noneconomic importance.

The results of two years' work show that much is accomplished by light traps in the destruction of tortricids, and that for this purpose they may be safely recommended for use in plantations infested with such pests. However, they supplement and should not displace the protection afforded by spraying. It is pointed out that when loganberries become infested with the shoot moth the traps might well be employed, since spraying does not control the pest and the moths are much attracted by light.

An important Queensland insect pest, R. VEITCH (*Queensland Agr. Jour.*, 26 (1926), No. 5, pp. 385, 386, fig. 1).—A small bug belonging to the genus *Nysius*, family Lygaeidae, is responsible for serious losses in Queensland. It is said to occur in enormous numbers in many fields and orchards, and the combined effect of its feeding is exercising a serious adverse influence on the plants attacked. When field crops are infested the leaves wilt and frequently die, and the yield of the crop is seriously reduced. When the outbreak is in an orchard many of the young attacked fruits fall to the ground, and of those that remain on the trees many are blemished. The bug has been found attacking many plants, among them potatoes, tomatoes, peaches, cherries, mangoes, grapes, and cotton.

Irritation due to insect secretion, W. A. HOFFMAN (*Jour. Amer. Med. Assoc.*, 88 (1927), No. 3, pp. 145, 146, figs. 2).—Following a brief discussion of the subject, the author reports upon a case of irritation personally experienced at Port au Prince, Haiti, caused by the pentatomid bug *Lora flavicollis*. Experiments made with other individuals of this bug are also briefly reported upon.

A preliminary study of the life-history and habits of *Sahlbergella singularis* Hagl. and *Sahlbergella theobroma* Dist., attacking cocoa on the Gold Coast, with suggested control measures, G. S. COTTERELL (*Gold Coast Dept. Agr. Bul.* 3 (1926), pp. 26, pls. 8).—This paper deals with the life history and habits of the two most destructive pests of cacao on the Gold Coast, with suggested control measures. The importance of the cocoa industry is discussed, attention being called to the fact that the Gold Coast is the leading exporting country.

Studies on chemical changes during the life cycle of the tent caterpillar (*Malacosoma americana* Fab.), I, II, W. RUDOLFS (*Jour. N. Y. Ent. Soc.*, 34 (1926), Nos. 3, pp. 249-256, figs. 2; 4, pp. 319-330, figs. 2).—Two parts are given.

I. Moisture and fat.—Chemical analyses made at the New Jersey Experiment Stations on the tent caterpillar during its life cycle indicated that the moisture content decreased gradually in the egg masses, increased rapidly in the young growing caterpillar (first two instars), remained constant until they were full grown, and decreased again rapidly from the time they were ready for pupation until the adults emerged. Moisture was lowest at the time of hatching (39.4 per cent) and highest during third to fifth instars, namely 83-85 per cent. Ether soluble material (fats) decreased fairly rapidly in the eggs after deposition, decreased slowly until the larvae hatched, increased gradually during the first two instars, increased rapidly during the next three instars, and increased at an accelerated rate during the first part of metamorphoses, while it decreased during the second part. Fat calculated on a dry basis was lowest upon hatching (0.66 per cent) and highest when larvae had just pupated (28.8 per cent). The relation between moisture and fatty substances during the life cycle is graphically shown.

II. *Nitrogen and its relation to moisture and fat.*—Analyses of egg masses, larvae, pupae, and adults of the tent caterpillar showed that the total nitrogen content of the egg masses from the time they were deposited to the hatching of the young larvae averaged 13 per cent. "There was an initial increase, followed by a decrease and again followed by an increase. The average nitrogen content of the growing larvae was about 10.2 per cent, decreasing from the time of hatching to the last instar. Nitrogen decreased considerably from the time the larvae were full grown until the larvae had 'just pupated' (prepupal stage), while it increased during the chrysalis stage. Adults again contained less nitrogen than the pupa in the last stage. The relation between nitrogen and moisture and nitrogen and fatty substances is shown."

Results of some experiments carried out at the Blackwood Experimental Orchard for the control of codlin moth, R. FOWLER (*Jour. Dept. Agr. So. Aust.*, 30 (1926), No. 3, pp. 240-251, fig. 1).—This is an account of experiments conducted in 1925-26 at the State Experimental Orchard at Blackwood with a view to discovering more effective methods of control. Much of the data is presented in tabular and graph form.

An infectious disease fatal to the larvae of the wax moth [trans. title], V. CHORINE (*Compt. Rend. Soc. Biol. [Paris]*, 95 (1926), No. 22, pp. 199-201; *abs. in Rev. Appl. Ent.*, 14 (1926), Ser. B, No. 10, p. 169).—The author has isolated two organisms from diseased wax moth larvae. The first, which is virulent to the larvae, he has named *Bacterium galleriae*, and the other, which is somewhat pathogenic to the larvae, *Streptococcus galleriae*.

Lyonetia clerckella L. in Sweden, its biology and control [trans. title], N. A. KEMNER (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden]*, No. 301 (1926), pp. 59, figs. 14; *Eng. abs.*, pp. 55-57).—This is an account of an apple leaf miner that sometimes occurs in Sweden in such numbers as to cause injury to, and even to entirely destroy, the leaves.

The bronzed cutworm (Nephelodes emmedonia Cramer) (Lepidoptera), S. E. CRUMB (*Ent. Soc. Wash. Proc.*, 28 (1926), No. 9, pp. 201-207, figs. 7).—In this paper the author describes the mature larva of the bronzed cutworm rather fully as a contribution toward a classification of noctuid larvae. Notes on distribution and seasonal history are included.

Some hints on the preparation and study of genitalia, W. H. T. TAMS (*Ent. Rec. and Jour. Variation*, 38 (1926), No. 11, pp. 145-149, pl. 1).—Directions are given for the study of the anatomy of genitalia of the Lepidoptera.

Experiments in poisoning the cane borer with sodium fluosilicate, T. E. HOLLOWAY, W. E. HALEY, and J. W. INGRAM (*Planter and Sugar Manfr.*, 77 (1926), No. 22, p. 431).—The work at the Louisiana Experiment Station previously noted (*E. S. R.*, 55, p. 455) led to tests by the U. S. D. A. Bureau of Entomology, a summary of which is given in this brief statement. Sodium fluosilicate was dusted with hand dust guns on sugar cane plants in Louisiana with negative results.

The gall midges of vegetables and market garden crops, H. F. BARNES (*Jour. Roy. Hort. Soc.*, 51 (1926), No. 2, pp. 331-336, pls. 4).—This account deals with the gall midges attacking crucifers, peas, mushrooms, vegetable marrows, and parsnips.

Summary of results of field trials by the U. S. Bureau of Animal Industry on ox-warble control, M. IMES (*Jour. Parasitol.*, 13 (1926), No. 1, pp. 42-46).—The author has found that the arsenical dip is not a satisfactory remedy to control or eradicate ox-warble flies, and that repeated dipping in any of the known cattle dips limits or reduces infestation but does not eradicate the fly. Treatment of cattle during the fly season in wading vats charged

with a 2 per cent solution of coal tar-cresote dip or processed crude petroleum or similar oils prevents gross infestation but does not effect complete eradication. The wading-vat method of applying fly repellents or insecticides to the legs of cattle is practical and economical for use on farms, and it can successfully be adapted to range use when watering places can be fenced. Processed crude petroleum or similar oils and a 2 per cent solution of coal tar-cresote dip are the most effective of the medicaments used in the field trials.

The occurrence of *Cuterebra* (Diptera, Oestridae) in western Canada, A. E. CAMERON (*Parasitology*, 18 (1926), No. 4, pp. 430-435, fig. 1).—This is a brief account of the occurrence of oestrids of the genus *Cuterebra* in western Canada, together with a description of larvae taken in several localities.

Notes on the life history of *Oedemagena tarandi* L. and *Cephenomyia trompe* Modeer, S. HADWEN (*Jour. Parasitol.*, 13 (1926), No. 1, pp. 56-65, figs. 2).—The author finds that the fly is on the wing from June to September, but that reindeer are not so heavily parasitized with *C. trompe* as they are with *O. tarandi*. *C. trompe* can make long flights, and when depositing its larvae causes more fear than *O. tarandi*, but few animals in a herd are attacked at one time owing to the lesser number of flies.

A destructive potato beetle (*Farming in So. Africa*, 1 (1926), No. 7, p. 250).—This is an account of a native ladybird beetle, *Epilachna dregei*.

On some Coccinellidae of the tribe Telsimiini, with descriptions of new species, E. A. CHAPIN (*Biol. Soc. Wash. Proc.*, 39 (1926), pp. 129-133).—One of the two species here described as new is *Telsimia nitida* from the island of Guam, where it feeds extensively on the coconut scale (*Aspidiotus destructor*). The other species, described as *T. emarginata*, originally from Foochow, China, has been introduced into California as an enemy of diaspine scales infesting citrus fruits.

The natural history of ants, R. A. F. DE RÉAUMUR, trans. and annotated by W. M. WHEELER (*New York and London: Alfred A. Knopf*, 1926, pp. XVII+280, pls. 4).—In this volume Wheeler reproduces Réaumur's unpublished manuscript on ants, written about the year 1742. Following an introduction (pp. XI-XVII), the life and work of Réaumur are considered (pp. 3-40), followed by the original text of the *Histoire des Fourmis* (pp. 43-128), a translation (pp. 131-217), annotations (pp. 221-262), a list of Réaumur's works (pp. 263-274), and an index (pp. 275-280). This unpublished manuscript, found by Wheeler in the archives of the Academy of Sciences of Paris in the spring of 1925, is considered by him to be even in its unfinished form the most important myrmecological document of the eighteenth century.

The origin of mixed broods in polyembryonic Hymenoptera, R. W. LEIBY (*Ann. Ent. Soc. Amer.*, 19 (1926), No. 3, pp. 290-299).—From the author's studies he now considers it safe to conclude that insemination or lack of it by fertilized females is controlled in the polyembryonic Hymenoptera thus far studied. Since only males are produced from unfertilized eggs, and since the species can obviously be continued only by the production of females, the control of insemination would be, and is, of advantage to the adult parasites of a brood.

Experiments in rearing colonies of bumblebees (Bremidae) in artificial nests, T. H. FRISON (*Biol. Bul. Mar. Biol. Lab., Woods Hole*, 52 (1927), No. 1, pp. 51-67, figs. 4).—In the studies conducted the author found it possible to induce the queens of certain species of North American bumblebees to start colonies in confinement when either one or two queens were used. In 1919 and 1920, an average success of over 70 per cent was attained in starting colonies under controlled conditions. It is pointed out that normal colonies of

bumblebees were obtained for the first time by confining in an artificial nest a single queen unaided by introduced workers. Attention is called to an account of experiments by Plath (E. S. R., 50, p. 259), who achieved similar results in 1922 by the confinement of a single queen assisted by from one to three workers. A bibliography of 14 titles is included.

Intensive apiculture and the rearing of queen bees, A. PERRET-MAISON-NEUVE (*L'Apiculture Intensive et l'Élevage des Reines*. Paris: Maurice-Mendel, 1926, 3. ed., pp. XXIV+550, pl. 1, figs. 88).—This is a third edition of the work previously noted (E. S. R., 50, p. 158).

The present position regarding adult bee disease in Great Britain, A. M. STURGES (*Bee World*, 8 (1926), No. 6, pp. 82-86).—This is a paper presented at the convention of the Apis Club held in July, 1926.

Four new species of parasites from aphidophagous Syrphidae (Hymenoptera), M. KAMAL (*Canad. Ent.*, 58 (1926), No. 11, pp. 283-286).—The parasites here described as new, all from California, include an encyrtid, a chalcidid, and two ceraphromids.

A new case of phoresie: Trichogrammidæ on Orthoptera [trans. title], C. FERRIÈRE (*Treubia [Batavia]*, 8 (1926), No. 3-4, pp. 274-278, pl. 1, figs. 2).—The author reports receipt of a number of grasshoppers collected by E. Jacobson at Samarang and Batavia in Java, which carried small hymenopterous parasites on their lower wings. These chalcidid parasites belong to the family Trichogrammidæ, or egg parasites, which it is thought probable were being transported by the grasshoppers awaiting the deposition of eggs by their host. It is pointed out that this is the first case of phoresie known involving the Trichogrammidæ and also the first trichogrammid parasite of Orthoptera to be recorded. The species is described as new under the name *Oligosita xiphidii*.

Description of a new braconid parasite of *Artona catoxantha* (Hymenoptera), S. A. ROHWER (*Ent. Soc. Wash. Proc.*, 28 (1926), No. 8, pp. 188, 189).—Under the name *Apanteles artonae* n. sp., the author describes a parasite of the early stages of the coconut pest *Artona catoxantha* Hamp., at Kuala Lumpur, Federated Malay States.

Observations on scorpions, F. R. SMITH (*Science*, 65 (1927), No. 1673, p. 64).—The author refers briefly to observations made of *Centruroides vittatus* Say in Arkansas. Each young scorpion was observed to be born in a very thin and transparent envelope, from which it freed itself in about 15 minutes. Molting took place in from 3 to 6 days and the young remained on the mother's back for from 5 to 15 days. It was thought that this scorpion probably attains maturity in 3 or 4 years.

The life history and biology of the tree-toad chigger, *Trombicula hylae* Ewing, H. E. EWING (*Ann. Ent. Soc. Amer.*, 19 (1926), No. 3, pp. 261-267, figs. 4).—The author records *T. hylae* from the tree toad, *Hyla arenicolor*, in California. This is believed to be the first time that nymphs and adults have been reared from a parasitic mite larva obtained from an amphibian host.

Redescription of *Taenia krabbei* Moniez, E. B. CRAM (*Jour. Parasitol.*, 13 (1926), No. 1, pp. 34-41, figs. 8).—A complete description is given of this parasite from Iceland and Alaska, the primary host of which is the domestic cat, the secondary host the reindeer.

ANIMAL PRODUCTION

The breeding and improvement of farm animals, V. A. RICE (*New York and London: McGraw-Hill Book Co.*, 1926, pp. XIV+362, figs. 113).—The principles of animal breeding are presented with reference to the underlying laws

of genetics. There are taken up in different portions of the book the fundamentals of reproduction, Mendelism, the physical basis of heredity, sex determination, methods of breeding, biometry, breed analyses, and the inheritance of characters in farm animals.

Twin and multiple births in our domestic mammals [trans. title], J. RICHTER (*Arb. Deut. Gesell. Züchtungsk.*, No. 29 (1926), pp. 119, figs. 2).—Based on records of various breeds of horses, cattle, sheep, goats, and swine, the author has studied the relative occurrence of multiple births and related conditions. The rate of breeding and the number of young per birth showed much variability in the different types of animals and in the different breeds of each type. The larger numbers of young at birth and the more regular breeding of goats and swine are considered as due to the long-continued selection of breeding animals for fertility.

Feeding and handling livestock to prevent shrinkage and loss, P. GERLAUGH (*Ohio Agr. Col. Ext. Bul.*, 21 (1925-26), No. 7, pp. 8, figs. 5).—Brief suggestions are given for the prevention of losses in shipping livestock, with special reference to hogs, which suffer particularly from overfeeding in warm weather.

The origin and quality of commercial livestock marketed in Canada in 1925, H. S. ARKELL (*Canada Dept. Agr., Livestock Branch Rpt. 6* (1926), pp. 58, figs. 3).—This publication deals with the origin and quality of livestock marketed in Canada during 1925, and is similar to the previous report (*E. S. R.*, 54, p. 466.)

Diet and body fat, L. B. MENDEL and W. E. ANDERSON (*Science*, 64 (1926), No. 1659, pp. 384-386, figs. 2).—In continuing the studies of the deposition of soft vegetable fats in rats (*E. S. R.*, 52, p. 109), a ration composed of dried skim milk and soy bean oil or peanut oil has been fed until average body weights of 250 and 175 gm. were attained on the rations with soy bean oil and peanut oil, respectively. Following the feeding of these rations the individuals were starved until the losses in weight varied from 23 to 27 per cent of the body weight. The fat was then hardened on a ration of starch until weights of approximately 275 and 225 gm., respectively, were attained on the two rations.

The results showed that the process of starvation largely removed the soft oily fats produced on the diets containing soy bean or peanut oils, and that the starch feeding produced a hardened fat. Individuals not subjected to the starvation period would have required a much longer feeding period on the carbohydrate feed to produce a fat of equal hardness than those which were first starved. It is also pointed out that the feed required for recovery after the starvation period was very low in proportion to the gains made, and that in the peanut oil lot the food intake of the starch diet was less than with the non-starved group.

The composition of swedes, A. LAUDER (*Scot. Jour. Agr.*, 9 (1926), No. 2, pp. 160-167, figs. 3).—The dry matter content as well as the percentage of soluble and insoluble solids of ten different varieties of swedes grown at Aberdeen, Edinburgh, and Glasgow have shown distinct differences, which are attributed to the locality and climate, and to the variety grown.

Silage investigations (*Wisconsin Sta. Bul.* 388 (1926), p. 92).—A new type of silage rot was found at the station, which upon examination showed no mold growth. The silage was hot, dark in color, offensive in odor, and moist and slimy to the touch. The rot is due to a bacterium which destroys the acid and is not checked by the by-products formed by the silage. Growth occurs rather rapidly even during the winter. No remedial measures have yet been

found, but cleaning and painting the walls of the silo with hot tar are recommended.

Eliminating the toxicity of cottonseed meal. W. D. GALLUP (*Jour. Dairy Sci.*, 9 (1926), No. 4, pp. 359-372).—In continuing the studies of Dowell and Menaul at the Oklahoma Experiment Station (E. S. R., 50, p. 468), cottonseed meal autoclaved or steamed for 1 hour and untreated meal in combination with other grains were fed to different lots of 3 pigs each at the rate of 1.3 lbs. of the cottonseed meal per 100 lbs. of body weight during a 75-day test. A check lot of inferior animals received tankage. The pigs receiving the steamed and autoclaved meal were in the best of condition throughout the test and always ate their feed with a relish, while the untreated meal was eaten only sparingly. The total gains per pig in the different lots were with steamed meal 26 lbs., autoclaved meal 22 lbs., and untreated meal 13 lbs.

In further studies of the effect of treatment on the toxicity of cottonseed, 2 feeding experiments were conducted with rats. The 4 lots of 4 individuals each used in the first experiment received rations containing 50 per cent of wheat and 35 per cent of untreated cottonseeds, 35 per cent of cottonseeds soaked for 4 hours and autoclaved for 1 or 2 hours, or 25 per cent of cottonseeds extracted with ethyl ether plus 10 per cent of commercial cottonseed oil. All rats receiving the ration containing untreated seeds were in poor condition during the latter part of the 9 weeks' experimental period, but the other lots made normal gains and produced normal young.

To further study the effect of cooking, lots of 4 rats received a ration composed mainly of 58 per cent of wheat plus 35 per cent of cottonseed meal steamed for 1 hour, or 35 per cent of untreated cottonseed meal. A third lot received 25 per cent of untreated meal in the ration. Slow growth and poor condition accompanied the feeding of the ration containing 35 per cent of untreated cottonseed meal, but 25 per cent did not show toxic effects in the 7 weeks' experiment. Steamed meal, however, produced much better gains.

The author concludes from these experiments that untreated cottonseed meal is quite toxic when fed in too large amounts or to young animals, but that the toxicity is overcome by autoclaving for 1 hour at 20 lbs. pressure or by cooking with steam for 1 hour.

[Feeding experiments with beef cattle at the Wisconsin Station] (*Wisconsin Sta. Bul.* 388 (1926), pp. 129, 130, 132).—Results of experiments are noted.

Chopping alfalfa hay for beef cows.—In work by J. G. Fuller and E. Arneson feeding beef cows with nursing calves by the reversal method for two periods of 63 days each showed a slight increase in favor of chopped hay. Cows on uncut hay gained 0.17 lb. per head daily and those on cut hay 0.38 lb. daily. There was no difference in the gains of the calves. In this experiment there was a saving of 10 per cent of the concentrates when cut hay was fed.

Cottonseed and linseed meal for fattening steers.—The results of one experiment by F. B. Morrison and B. H. Roche showed that calves receiving a protein supplement of half cottonseed meal and half linseed meal made practically identical gains with calves receiving linseed meal alone. It was calculated that the mixture was worth more than the linseed meal alone.

Rhodes grass hay versus alfalfa hay as feed for cattle. R. H. WILLIAMS, R. H. BURNS, and C. A. SMITH (*Arizona Sta. Rpt.* 1923, pp. 466, 467).—Two 2-year-old Hereford heifers fed Rhodes grass hay consumed 13 lbs. daily and gained 0.39 lb., while a similar lot fed alfalfa hay consumed 15 lbs. per day and gained 1.67 lbs. In a second test in which two lots of two Hereford cows and their 8-months-old calves were fed hay and a limited amount of silage,

40 lbs. to the lot, those fed alfalfa consumed 27 lbs. of hay per day as against 19 lbs. for those fed Rhodes grass hay. In the first lot the cows gained an average of 2.33 lbs. daily and the calves 1.99 lbs., while in the second lot the cows lost slightly in weight and the calves gained 1.21 lbs. daily.

The cattle of the world, A. H. SANDERS (*Washington, D. C.: Natl. Geogr. Soc., 1926, pp. [4]+142, illus. 114*).—A reprint of the article previously noted (*E. S. R., 55, p. 58*), with a supplement on the propagation of domestic cattle.

Morphological investigation of German bred Shorthorn cattle [trans. title], J. VON RÜMCKER (*Landw. Jahrb., 64 (1926), No. 1, pp. 1-39, fig. 1*).—This consists of a statistical study of various body measurements of several groups of Shorthorn cattle bred in Germany.

The Bhagnari breed of cattle in Sind and Baluchistan, H. G. BALUCH (*Bombay Dept. Agr. Bul. 126 (1925), pp. 16, pls. 6*).—A description of this little known breed of cattle.

Rutabagas vs. corn silage for breeding ewes (*Wisconsin Sta. Bul. 388 (1926), p. 133*).—In work by F. B. MORRISON and F. KLEINHEINZ, 20 Shropshire ewes were divided into two lots. One lot was fed 2 lbs. of silage and 3 lbs. of hay daily. The other lot received 3.2 lbs. of rutabagas and 3.3 lbs. of hay. The larger allowance of feed in the second lot was made to keep both lots in about the same condition. For about a month before lambing both lots were fed 0.5 lb. of a grain mixture per day. The ewes fed rutabagas made slightly less gain and produced lambs that were less thrifty at birth than those fed silage.

Various methods of docking lambs, R. H. WILLIAMS, R. H. BURNS, and C. A. SMITH (*Arizona Sta. Rpt. 1923, pp. 470, 471*).—The results of an experiment to determine the most satisfactory method of docking lambs are briefly reported, but no conclusions are drawn.

Sheep raising in central Alberta and a comparison of six breeds, F. H. REED and L. T. CHAPMAN (*Canada Dept. Agr. Bul. 68, n. ser. (1926), pp. 15, figs. 6*).—This publication contains an account of the comparative improvement through grading up a flock of 400 common range ewes of western Canada by the use of purebred Shropshire, Hampshire, Oxford, Cheviot, Corriedale, and Leicester rams from 1917 to 1925. The results showed that ewes could be rapidly improved by several successive generations of matings with purebred rams of any of the breeds.

The breeds were rated differently as to their ability to fix breed characteristics, live weight, quality and weight of the fleeces, lambing percentages, and mortality, weights, and dressing percentages of the lambs, but for general utility purposes they were rated in the order as given above. The Cheviots were criticized for nervousness, Leicesters for open fleeces, and Corriedales for being slow in their ability to obtain feed.

In feeding experiments lowland hay proved decidedly superior to oat green feed for fattening ewes. The results of a comparison of eight roughages when fed with oats to shearling wethers showed that the largest average daily gain per head, 0.35 lb., was made with cut oat green feed, followed closely by 0.34 lb. with upland hay. The smallest amount of roughage, 878 lbs., was required per 100 lbs. of gain by the lot receiving the upland hay. The smallest average daily gain per head, 0.10 lb., occurred in the lot receiving lowland hay, but one lot receiving cut oat green feed without the supplementary feeding of oat grain made an average daily gain of only 0.08 lb.

In another experiment with 6 lots of lambs there were produced with whole oats an average daily gain of 0.32 lb.; whole barley, 0.29 lb.; barley and oats, 0.28 lb.; screenings and oat chop, 0.24 lb.; oil cake meal, 0.23 lb.; and screenings

and bran, 0.21 lb. These were fed as the grain portion of a ration including alfalfa, oat green feed, and lowland hay.

Development of breeds of coarse-wooled sheep in Russia, N. P. CHIRVINSKY and V. B. ELAGIN (*Razvodimiyâ v Rossii Porody Grubosherstnykh Ovets. Kief: Kievsk. Politekhnich. Inst. Imp. Aleksandra II, 1916, pp. XV+133+96*).—Detailed descriptions are given of the character, adaptation, distribution, and general economic value of the coarse-wooled sheep in Russia. The breeds are grouped as coarse woolled, long woolled, Kurdian, and fat-tailed sheep and are discussed with reference to their development and to their importance in the different localities, regions, and governments.

Development of breeds of coarse-wooled sheep in Russia [N. P. CHIRVINSKY and V. B. ELAGIN (*Prilozhenie k Knigîe: Razvodimiyâ v Rossii Porody Grubosherstnykh Ovets. Kief: [Kievsk. Politekhnich. Inst. Imp. Aleksandra II], 1916, pls. 17; insert (legends), pp. 8*).—A collection of 111 figures illustrating breed characteristics, wool texture and quality, and pelt value, published as a supplement to the work noted above.

Skeletal development in sheep, N. P. CHIRVINSKY (*Razvitie Kostiâka u Ovets. Kief: Kievsk. Politekhnich. Inst. Imp. Aleksandra II, 1909, pp. VII+304, pls. 13*).—This book, an anatomical treatise on the development of the skeleton in sheep, devotes chapters to the conformation and development of the skull, spinal column, ribs, sternum, scapula, long bones, and other parts of the skeleton, and discusses the relation of sex, age, feeding or the plane of nutrition, castration, environment, and other factors to the growth and structure of these parts. Special attention is given to the effects of normal and insufficient nourishment at different ages. The comparative size and conformation of different parts of the skeleton are illustrated in 103 figures.

The goat: Breeds, breeding, and exploitation, [E.] HUART DU PLESSIS (*La Chèvre: Races, Élevage, Exploitation. Paris: Libr. Agr. Maison Rustique, 1926, pp. 156, figs. 45*).—This reference book deals with the breeds, management, housing, and breeding of goats, and includes chapters on the milk, cheese, and meat of the goat.

Hog-feeding investigations, R. H. WILLIAMS, R. H. BURNS, and C. A. SMITH (*Arizona Sta. Rpt. 1923, pp. 467-470*).—The results of the following experiments are briefly noted:

Vitamins for pigs.—This is a continuation of work previously reported (E. S. R., 53, p. 773) of 2 gilts on a restricted diet of ground hegari and tankage. One gilt was removed at the end of about 290 days. The other gilt was maintained on the same ration for about 500 days, at which time she weighed 469 lbs., had failed to conceive, had become blind, and showed evidence of nutritional deficiency. After being on alfalfa pasture for a short time she became healthy and thrifty and later conceived.

Ground yellow corn v. a mixture of ground yellow corn and 10 per cent tankage.—One lot of 8 pigs self-fed ground yellow corn weighed less than 150 lbs. after 17 weeks of feeding. A similar lot of 7 pigs self-fed ground yellow corn 90 per cent and tankage 10 per cent averaged 208 lbs. in the same length of time. It was doubtful whether any of the pigs fed corn alone would have ever reached market weight.

Fattening hogs on garbage.—A lot of 7 pigs, averaging 133 lbs., fed all the garbage they would consume, ate 17.92 lbs. per day and gained an average of 2.12 lbs. daily. It required 844 lbs. of garbage to produce 100 lbs. of gain, and the calculated value of the garbage was \$22.51 per ton. Another lot of six 40-lb. pigs ate 14.39 lbs. of garbage per day and averaged 1.54 lbs. daily gain. These pigs required 936 lbs. of garbage to produce 100 lbs. of gain, and the

garbage was calculated to be worth \$19.23 per ton. The average dressing percentages were 74.61 and 80 in lots 1 and 2, respectively.

Ground hegari v. ground yellow corn.—Two lots of 7 pigs each averaging 56 lbs. were selected to compare the feeding value of ground hegari and ground yellow corn when fed with tankage. The lot receiving corn and tankage gained an average of 1.28 lbs. per day for a period of 17 weeks, and required 403 lbs. of feed to produce 100 lbs. gain. The lot receiving hegari and tankage gained 1.9 lbs. per day over a period of 20 weeks, but required 458 lbs. of feed to produce 100 lbs. gain. All of the pigs in the first lot were in marketable condition at the end of 17 weeks, while only 3 in lot 2 had reached a desirable finish at the end of 20 weeks. At least 2 of the pigs fed hegari were totally deaf and blind and several had nervous spasms, apparently due to a vitamin deficiency. All of the pigs fed on corn were healthy and vigorous.

Sex as a factor in fattening pigs.—On a ration of cracked hegari self-fed, alfalfa pasture, and about 7 per cent skim milk, boars made an average daily gain of 1.64 lbs., and a mixed lot of barrows and gilts 1.6 lbs. The barrows in this last lot gained 37 per cent more than did the gilts. The boar pigs required 24 per cent more hegari and 2 per cent more skim milk to make the same gain than did the mixed lot of barrows and gilts. The mixed lot returned 23 per cent more profit than did the boars.

Two methods of growing gilts and maintaining brood sows.—A study was begun in 1919 of the effect of abundant and limited feeding upon the development of five gilts. Three gilts that were full fed became barren and were sold. Of the 2 gilts that had had a limited feed one also proved barren, while the other gilt has twice farrowed normal litters and raised an average number of pigs.

[Swine feeding experiments at the Wisconsin Station] (*Wisconsin Sta. Bul. 388 (1926), pp. 113, 114, 134, 135, figs. 2.*)—Results of feeding experiments are noted.

Is ordinary limestone a suitable supplement for swine?—Sows fed floats became stiff and bore dead offspring even when cod-liver oil was added to the ration, perhaps because of an excess of fluorine in the floats. When sows were fed limestone and cod-liver oil reproduction was normal, but the animals developed rickets in the absence of cod-liver oil.

Yeast for pigs.—Several trials by F. B. Morrison, J. M. Fargo, and Thomas with yeast as a part of the ration for swine failed to show any beneficial results, and in several cases pigs without yeast made faster gains. The cost of producing gains was materially greater in the lots that were fed yeast.

Semisolid buttermilk.—The results of three trials by Morrison et al. in which semisolid buttermilk (30 parts of water to 1 part of semisolid buttermilk) was fed showed no improvement in the health of the pigs nor increase in the rate of gain. The cost of 100 lbs. of gain was increased by the use of semisolid buttermilk.

Value of cheese parings.—In work by Morrison et al., pigs fed cheese parings made a gain of 1.04 lbs. per head daily on an average ration of 3.7 lbs. of corn and 1 lb. of cheese parings. The calculated value of cheese parings was \$60 per ton. This product should be used within a short time, as mold is apt to set in, which may either prove injurious or decrease the feeding value.

[Experiments with swine at the Central Experimental Farm], G. B. ROTHWELL (*Canada Expt. Farms, Anim. Husb. Div. Rpt. 1925, pp. 32-55, figs. 3.*)—Brief accounts are given of the results of experiments with swine dealing with various substitutes for skim milk in the feeding of weaned pigs, the use of potassium iodide, cod-liver oil, and yeast in the ration of market hogs, the value

of oat clippings, the influence of feeds and methods of feeding on various types of market pigs, the value of alfalfa meal for market hogs, and comparisons of various strains and breeds of swine (E. S. R., 54, p. 861).

The value of fish meal in swine feeding [trans. title], J. C. DE RUYTER DE WILDT (DE RUIJTER DE WILDT) (*Ver. Exploit. Proefzuivelboerderij Hoorn. Verslag 1925*, pp. 27-149, figs. 5; *Ger. abs.*, pp. 133-143; *Eng. abs.*, pp. 144-149; also in *Dept. Binnenland. Zaken en Landb. [Netherlands], Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta.*, 31 (1926), pp. 31-153, figs. 5; *Ger. abs.*, pp. 137-147; *Eng. abs.*, pp. 148-153).—The results of 6 experiments dealing with the value of fish meal as the protein supplement to rations of corn, barley, and whey or skim milk for fattening hogs are reported. All of the pigs received some fresh grass in summer or mangels in winter, and those not including fish meal were supplemented with 10 gm. of calcium phosphate per head daily. The flavor and odor of the boiled and baked meat and the hardness of the fat were determined for individual animals after slaughter.

In the first experiment, which lasted 140 days, the substitution during the second, third, and part of the fourth months of 250 gm. of fish meal daily for an equal amount of barley in a corn, barley, and whey ration was found not to affect the rate of gain, but the slaughter records showed that the pigs receiving fish meal were more fleshy and better proportioned and the meat was of a better quality. The flavor and odor after cooking were normal in both lots and no difference in the hardness of the fat was apparent.

In three further experiments in which corn, barley, and whey were fed for 3 to 4 weeks, followed by 3 to 4 months in which this ration was supplemented with 250 gm. of fish meal daily and finally by 4 weeks or more for finishing without fish meal, it was found that sufficient additional gains were produced by the fish meal to be practically equivalent to the amount of fish meal fed. The quality of the slaughtered carcasses produced with fish meal was equal to or slightly superior to the carcasses of those not receiving the supplement.

In two other experiments the fish meal was continued up to the time of slaughter without evidence of an appreciable effect of such feeding on the flavor or odor of the raw or cooked meat, though it was reported for one experiment that those receiving fish meal were somewhat fatter.

Modern swine husbandry, LORD BLEDISLOE (*Jour. Farmers' Club [London]*, 1926, pt. 6. pp. 88-98, figs. 4).—A description of English methods of swine production.

Pig breeders' annual for 1926 (*London: Natl. Pig Breeders' Assoc. [1926]*, pp. 17-99, pls. 19).—This contains several articles of primary interest to the swine producer.

Chopping timothy hay for work horses (*Wisconsin Sta. Bul.* 388 (1926), pp. 130, 131).—In experiments by J. G. Fuller and E. Arneson one horse in each of eight teams was fed chopped hay and the other horse uncut hay. Both lots were fed the same weight of hay, but the concentrate ration was reduced 10 per cent in the chopped hay lot. After eight weeks of such feeding the rations were reversed and continued for another period of eight weeks. During the first period the horses on chopped hay lost 70.2 lbs. per head and those on uncut hay 40 lbs. each. In the second period the horses on chopped hay lost 19.2 lbs. each and those on uncut hay gained 40.4 lbs. per head.

The evolution of the horse, F. B. LOOMIS (*Boston: Marshall Jones Co.*, 1926, pp. XVI+233, pls. 26, figs. 41).—In this volume the author attempts to describe in simple terms the story of the evolution of the horse. Chapters are devoted to the Eocene, Oligocene, Miocene, Pliocene, and Pleistocene horses, and the wild horses of to-day.

The ass: Horses used for mule breeding and the mule of Poitou, L. SAUSSEAU (*L'Ane: Les Chevaux Mulassiers et la Mule du Poitou. Paris: Libr. Des Sciences Agricoles, 1925, pp. 342, figs. 32*).—This book deals with the general importance of the ass and mule industry in Poitou and describes the types of asses and horses used and mules produced.

[Poultry experiments at the Wisconsin Station] (*Wisconsin Sta. Bul. 388 (1926), pp. 109–111, 115*).—The results of experiments are briefly noted.

Winter sunshine and egg production.—In work conducted by J. G. Halpin, pullets fed the regular Wisconsin ration and exposed to as much sunlight as possible during the winter of 1924–25 produced as well as those receiving cod-liver oil. During the winter of 1925–26 the best results were obtained by keeping the windows closed and irradiating the birds with ultra-violet light. Cod-liver oil and irradiated corn oil when fed at the rate of 5 per cent of the ration gave satisfactory results. Eggs from groups in which windows were kept closed and no additional treatment provided soon became practically unhatchable. The same was true when irradiated corn oil was fed. It was also evident that the birds could store enough of the sun's rays to protect themselves through part of the winter.

Minerals influence rate of growth of chicks.—Chicks fed the Wisconsin ration of 80 parts of yellow corn, 20 parts of middlings, 5 parts of chick-sized bone meal, 5 parts of chick-sized limestone, 1 part of salt, and free access to skim milk, grew to a weight of 509 gm. in 10 weeks. A similar lot in which the bone meal was left out averaged 486 gm., and a third lot in which limestone was omitted weighed 353 gm. At 19 weeks of age the chicks in the lots averaged 1,107, 903, and 460 gm., respectively.

Sunlight more important in bone building than amount of lime.—In work by E. B. Hart and Halpin to determine the necessity of lime supplements for chicks raised in the sunlight, groups fed a ration of yellow corn, skim milk, and salt were given 1, 2, and 4 per cent of calcium carbonate, respectively, and other groups received similar amounts of bone meal, respectively. Check groups were maintained indoors away from light.

At the end of 5 weeks bones from representatives of each group were analyzed for ash. For those confined indoors the lime content varied from 30 to 34 per cent, while chicks in the open had bones containing from 45 to 46 per cent lime. At the end of 16 weeks the bones of the chicks in the groups in the sunlight contained about 55 per cent ash. None of the chicks kept away from sunlight lived to 15 weeks of age.

Nutrient requirements of growing chicks, F. E. MUSSEHL (*Nebraska Sta. Research Bul. 38 (1926), pp. 19, figs. 11*).—The work herein reported is a summary of data noted previously (E. S. R., 53, p. 273; 54, p. 866) and above.

Corn as a nutrient for growing chicks, F. E. MUSSEHL, R. HILL, and J. A. ROSENBAUM (*Poultry Sci., 5 (1926), No. 6, pp. 281–284, fig. 1*).—In studying the deficiency of corn as a feed for growing chicks at the Nebraska Experiment Station 5 lots of 25 7-day-old Single Comb White Leghorn chicks each were selected for an 8-week test. The basal ration consisted of yellow corn for all lots. One lot received a supplement of quartz grit only, while distilled water was supplied for drinking. The other lots received tap water, and for each 97 parts of feed supplied 3 parts of a mineral mixture composed of bone ash, calcium carbonate, and sodium chloride (60:20:20) were included. The ration of yellow corn and minerals of 3 of these lots was supplemented with 5 per cent of egg albumin, one lot receiving also 5 per cent of yeast, while another was given green alfalfa twice daily. All birds received direct exposure to sunlight on clear days.

The results of the experiment indicated that yellow corn is deficient in minerals, proteins, and vitamin B, since the best growth was obtained in the lot receiving the yellow corn and mineral ration supplemented with egg albumin and yeast. Practically no growth was obtained in the lots in which the yellow corn was supplemented only with quartz grit or with the mineral mixture.

"Artificial" enzymes and poultry feeding, W. F. HOLST (*Poultry Sci.*, 5 (1926), No. 6, pp. 261-265).—A review of the literature dealing with the physiological action of enzymes on digestion, with particular reference to poultry.

The nutritional requirement of the chicken.—VI, Does the chicken require vitamin C? E. B. HART, H. STEENBOCK, S. LEPKOVSKY, and J. G. HALPIN (*Jour. Biol. Chem.*, 66 (1925), No. 2, pp. 813-818, fig. 1).—In continuing this series (E. S. R., 55, p. 867), the vitamin C content of the livers of chickens which had been fed from November 29 to February 11 on a ration of yellow corn, wheat middlings, raw bone, pearl grit, salt, and autoclaved skim milk plus ultra-violet light was determined by feeding 1 and 3 gm. daily of the livers to scorbutic guinea pigs. The guinea pigs receiving 1 gm. daily of such chicken liver showed some improvement but not complete recovery, though 3 gm. daily effected complete recovery.

Because of the possibility of the chickens accumulating vitamin C in their livers from small amounts present in the grain, the experiment was repeated, using a purified diet of dextrin, casein, yeast, salt, agar, and cod-liver oil. After 84 days of feeding this ration, on which poor growth was made, 1- and 3-gm. amounts of the livers were fed to scorbutic guinea pigs. Three gm. of the liver again cured scurvy, but 1 gm. daily did not supply sufficient amounts of vitamin C though some improvement followed its administration. Evidently the chicken does not require the presence of vitamin C in its diet.

The relation between the amount of ultra-violet light received by hens and the amount of antirachitic vitamin in the eggs produced, J. S. HUGHES, L. F. PAYNE, R. W. TITUS, and J. M. MOORE (*Jour. Biol. Chem.*, 66 (1925), No. 2, pp. 595-600).—A more complete account of experiments the results of which were previously noted (E. S. R., 55, p. 266).

The 1927 New Jersey chick ration and method of chick feeding, F. H. T. CLICKNER (*New Jersey Stas. Hints to Poultrymen*, 15 (1927), No. 5, pp. 4, fig. 1).—A chick ration is recommended for New Jersey poultrymen. The purpose of the ingredients of the ration, methods of brooding, and general management are included in the discussion.

Egg production, monthly costs, and receipts on New Jersey poultry farms, November, 1925-October, 1926, W. H. ALLEN (*New Jersey Stas. Hints to Poultrymen*, 15 (1927), No. 4, pp. 4, fig. 1).—This is a report for the period extending from November, 1925, to October, 1926. The data are a compilation from records of 28 poultry farms representing every poultry section of New Jersey.

Broiler production, R. B. THOMPSON and R. PENQUITE (*Arizona Sta. Rpt.* 1923, pp. 508-510).—In two experiments in the feeding of broilers the basis of the ration fed was ground milo 2 lbs., shorts 1 lb., and water 8 lbs. To this basic ration was added in lot 1 1 lb. of ground oats, lot 3 1 lb. of alfalfa meal, and lot 5 1 lb. of cottonseed meal. In lots 2, 4, and 6, 1 lb. of semisolid buttermilk mixed with 7 lbs. of water was substituted for the 8 lbs. of water. Otherwise the rations were the same as in lots 1, 3, and 5, respectively.

The cockerels given semisolid buttermilk made, with one exception, better gains than those not given buttermilk. All lots ate well except lots 5 and 6. These lots had a tendency to slow up on their eating toward the end of the experiment.

Capon production, H. E. BOTSFORD (*N. Y. Agr. Col. (Cornell) Ext. Bul. 143 (1926)*, pp. 16, figs. 13).—Directions for caponizing and related information.

The influence of the vertical position of eggs on the development of embryos in *Gallus domesticus* [trans. title], E. UMANSKI (*Zool. Anz.*, 68 (1926), No. 3-4, pp. 81-87, figs. 3).—In each of two experiments 28 eggs were incubated for 8 days in the vertical position, but in one experiment the small end of the egg was up and in the other the large end was up. After 8 days' incubation with the small end up there were 11 living and 11 dead embryos, while 6 had not developed. When the other end was up there were 15 living and 7 dead embryos, while 6 were undeveloped. Of the living embryos 5 in the former and 4 in the latter experiment were abnormal. Of 28 eggs incubated as controls in the normal position there were 20 living and 3 dead embryos.

The abnormalities observed in the eggs incubated in the vertical position were associated with irregularities in the development of the amniotic and allantois membranes. These abnormalities were explained in the eggs incubated vertically as due to the twisting and tension on the yolk membrane and chalaza resulting from the tendency of the germinal disc to remain on top.

On the influence of sexual hormones upon the number of erythrocytes and percentage quantity of hemoglobine by fowl, L. J. BLACHER (*Biol. Gen.*, 2 (1926), No. 4-5, pp. 435-441).—Studies of the number of red blood corpuscles and the percentage of hemoglobin in the blood of 26 cocks and 33 hens of different breeds showed that both the red cell count and the amount of hemoglobin were considerably higher in the males than in the females. This amounted to 23.8 per cent in the number of red cells and 26.1 per cent in the percentage of hemoglobin. In man the respective differences between the two sexes were 9 and 12.5 per cent.

After castration the number of erythrocytes and percentage of hemoglobin diminished significantly in males, but no significant differences were observed in females. When the sexual glands were transplanted into new hosts the number of erythrocytes was comparable with the number in the sex from which the gland was taken.

The cat: Races, breeding, and diseases, E. LARIEUX and P. JUMAUD (*Le Chat: Races, Élevage, Maladies. Paris: Vigot Bros., 1926*, pp. 272, figs. 29).—The origin of the different types of domestic cats, standards for the different varieties, and the anatomy and physiology of cats are taken up in turn, with a large portion of the book devoted to diseases.

Theory and practice of fox ranching, J. A. ALLEN and W. C. S. McLURE (*Charlottetown, P. E. I.: Irwin Ptg. Co., 1926*, pp. XV+248, pls. 23, fig. 1).—A popular presentation of the principles of fox farming, dealing with the selection and laying out of ranches, fox breeding, feeding, and management. A considerable portion of the book deals with fox parasites, diseases, and surgery.

DAIRY FARMING—DAIRYING

History of the dairy industry, T. R. PIRTLE (*Chicago: Mojonner Bros. Co., 1926*, pp. XXII+645, figs. 223).—The development of dairying in the different countries of the world is reviewed by first giving an idea of the natural conditions, types and breeds of cattle and their development or importation, and a historical account of the cream, butter, cheese, condensed and evaporated milk and ice cream industries, with related information on cooperative enterprises, consumption, educational institutions, cattle diseases, and the like. The account of each country ends with a list of important events in chronological order.

Proceedings of the Congress for the Feeding of Cattle and Dairy Control (*L'Alimentation du Bétail Bovin et le Contrôle Laitier. Travaux du Congrès. Paris, 1925. Paris: [Soc. Natl. Encour. Agr.], 1926, pp. [4]+786, figs. 23*).— This includes the papers presented before the two sections of this congress, which met in Paris on October 28 and 29, 1925.

The following papers were given before the cattle feeding section: History of Publications on the Feeding of Cattle in France, by A. M. Leroy (pp. 1–27); New Theories of Feeding, by H. Simonnet (pp. 29–63); The Feeding of Breeding Cattle, by A. Lecomte (pp. 65–94); The Feeding of Dairy Cattle, by G. Jannin (pp. 95–126); Grated Potatoes in the Feeding of Livestock, by C. Bacon (pp. 127–131); The Production of White Veal Cattle, by Perrault (pp. 133, 134); The Feeding of Beef Animals of the Bovine Species, by E. Letard (pp. 135–145); The Feeding Value of Silage, by L. Brétignière (pp. 147–181); Feeding Standards for Livestock, by R. Gouin (pp. 183–192); New Studies of the Practical Value of Feeding Standards and Those Which Concern the Feeding of Dairy Cattle, by A. M. Leroy (pp. 193–208); The Principles of Unifying the Methods of Estimating the Feeding Value of Feeds, and Organized Method of Feed Control under Practical Agricultural Conditions, by J. E. Lucas (pp. 209–227). Ten papers were also given on the feeding of livestock, especially dairy cattle, in various regions of France.

The following papers were presented before the section on the control of dairies: The Development of Dairy Control in France: The Necessity of Cooperation Between the Associations for Control of Milk and Butter, by A. M. Leroy (pp. 325–381); Foreign Milk Control: General Considerations, by C. Porcher (pp. 383–400); Chemical Methods of Evaluating the Fat and Solids in Milk: Application of the Working of Societies of Milk Control, by C. Brioux (pp. 401–419); Modern Organization of a Milk Control Syndicate, by Prévot (pp. 421–456); Relations Between Dairy Control Groups and Herd Books, by Hédiard (pp. 459–469); The Organization of Meetings of Milk and Butter Producers, by J. Lefèvre (pp. 471–497), as well as 22 papers dealing with the control of dairy products in different sections.

The effect on milk production of feeding more than the Haecker, Eckles, and Savage requirements, H. T. CONVERSE (*Jour. Dairy Sci.*, 9 (1926), No. 4, pp. 388–406, figs. 3).—The effect on milk production of supplying more digestible protein and more total digestible nutrients than necessary to maintain body weight was studied in 3 experiments conducted at the U. S. D. A. Experiment Farm at Beltsville, Md.

In the first and second experiments groups of 6 and 5 cows, respectively, were furnished with rations supplying the amounts of digestible protein and total digestible nutrients called for by the Savage standard to maintain body weight and milk production during the first and third 30-day periods. During the second period of the first trial the cows received 30 per cent more digestible protein and 15 per cent more digestible nutrients than were necessary to satisfy the requirements of this standard. The cows used were in advanced stages of lactation, having been milked from 6 to 18 months since freshening.

In the second period of the second trial the digestible protein and total digestible nutrients were 20 and 10 per cent, respectively, in excess of the requirement. In this experiment 10 days were allowed between periods for transition. The cows varied from 7 to 13 months in the period of lactation.

The results of these two experiments showed that milk production was 4.9 per cent in the first and 1.9 per cent in the second trial greater than the average for the first and third periods in the respective experiments. Calculations

lated on the basis of the decline observed in the standard periods, when the cows declined approximately 20 per cent in rate of production, the surplus feed caused an increased production of about 16 per cent in the second experiment.

In a third experiment 6 cows, which had previously completed 365-day records on rations supplying 17 per cent more nutrients than the Savage standard, produced 2 per cent less milk in a succeeding lactation period on a ration calculated to satisfy the Savage standard. Correcting these data for the effect of age on milk production according to Graves and Fohrman (E. S. R., 54, p. 68), and for differences in the length of time that the animals were pregnant according to Ragsdale, Turner, and Brody (E. S. R., 52, p. 478), it was estimated that the 17 per cent increase in nutrients caused an increased milk production of 14 to 16 per cent.

Mineral supplements in rations for dairy cattle and green feed versus dry feed for dairy cattle, W. S. CUNNINGHAM and R. N. DAVIS (*Arizona Sta. Rpt. 1923, p. 473*).—Sixteen cows were divided into 4 groups with 2 Jerseys and 2 Holsteins in each group. Group 1 was fed sodium phosphate, group 2 bone ash, group 3 air-slaked lime, and group 4 no mineral supplement. One-half of the cows in each group were fed green feed whenever available.

No advantage in yield of milk and butterfat from feeding minerals was shown. As much difficulty was experienced in getting cows bred when feeding minerals as when no minerals were used. The experiment was discontinued after one year.

Fat-soluble vitamin.—XXVI, The antirachitic property of milk and its increase by direct irradiation and by irradiation of the animal, H. STEENBOCK, E. B. HART, C. A. HOPPERT, and A. BLACK (*Jour. Biol. Chem., 66 (1925), No. 2, pp. 441-449*).—In continuing this series (E. S. R., 54, p. 491) the antirachitic potency of different samples of milk was tested with reference to the previous irradiation of the animal or the milk itself by supplementing the diet of rats fed for 29 days on a rachitic ration with from 0.5 to 12 cc. of milk daily during a 10-day period. The rats were then killed and examined for rickets. The results showed that 12 cc. of milk, produced by stall-fed cows allowed some exposure to sunlight, were required to produce definite evidence of calcium deposition in the rats, but that 1 cc. of milk which had been exposed in a thin film to ultra-violet light for 30 minutes had a similar effect. A test of the effect of different lengths of exposure of the milk indicated that 30 minutes gives optimum results.

In further studies, with a milking goat, of the effect of irradiation of the animal, it was found that 12 cc. of normal milk were required to bring about incipient calcium deposition, but that after irradiation of the animal for 30 minutes daily only 2 cc. were required and after irradiation of the milk itself 0.5 cc. were sufficient to have the same effect. The irradiation of this goat appeared to stimulate her appetite and general physiological condition.

Experiments with another milking goat, irradiated 1 hour daily, showed that the potency of the milk was somewhat increased on the second day of irradiation as compared with the first. In this animal, which had just freshened, the antirachitic properties of the milk were not as high as for the goat used in the preceding experiment.

[Feeding experiments with dairy cattle at the Wisconsin Station] (*Wisconsin Sta. Bul. 388 (1926), pp. 111, 112, 114, 115, 127-131*).—The results of some experiments by E. B. Hart et al. are briefly noted.

Mineral supplements to poor roughage are important.—Three cows fed timothy hay, corn silage, and a grain mixture were poor producers of milk. In

addition, they were slow to breed and when bred tended to dry up from 6 weeks to 2 months earlier than 3 cows fed alfalfa hay.

Do cows need mineral supplements in sunlight?—Cows milking from 50 to 60 lbs. per day kept without direct exposure to sunlight on an otherwise adequate ration failed to maintain a calcium balance. With the same cows on the same ration but exposed to 6 hours' sunlight per day the loss of calcium from the body was reduced 25 per cent.

Rock phosphate not a substitute for bone meal.—Cattle and swine fed rock phosphate instead of bone meal as a mineral supplement became exceedingly stiff, rough in coat, and generally poor in condition. It is suggested that this injurious effect is due to fluorine associated with the rock phosphate.

Soy bean v. alfalfa hay for dairy cows.—Cows fed soy bean hay produced approximately the same amount of milk and butterfat as cows fed alfalfa hay. The cows on the soy bean ration gained only about one-half as much in body weight and wasted more of their hay. From the results of this experiment soy bean hay was calculated to be worth 73 per cent as much as alfalfa hay.

Rations for dairy calves.—At 6 months of age calves fed skim milk (not over 14 lbs. per head a day), clover hay, and a mixture of corn, oats, bran, and linseed meal gained 1.77 lbs. daily. Calves fed a minimum of whole milk (not over 400 lbs. from birth) and a grain mixture similar to the above gained 1.3 lbs. daily. The whole milk was discontinued when calves were from 7 to 9 weeks of age. Feeding semisolid buttermilk and dry skim milk increased the rate of gain over those receiving whole milk but also increased the cost of gain by a considerable margin.

Chopping alfalfa hay for dairy cows.—Preliminary work by I. W. Rupel and E. Arneson indicates that there was no advantage in chopping good alfalfa hay for dairy cows.

Chopping soy bean hay for dairy cows.—There was practically no difference in the production of cows fed chopped and unchopped soy bean hay. However, there was little waste in feeding the chopped hay. Chopping soy bean hay in this case increased its value 23 per cent.

[Experiments with dairy cattle at the Central Experimental Farm], G. B. ROTHWELL (*Canada Expt. Farms, Anim. Husb. Div. Rpt. 1925, pp. 7-23*).—The results of various feeding experiments with dairy cattle, dealing with the effect of pastures, comparisons of silage and roots, ground and whole roughage, corn distillers' grains, rye distillers' grains, and oat clippings, calf meals, and skim milk in the ration of dairy calves are briefly reported (E. S. R., 54, p. 472).

Care and management of the milk goat, E. C. VOORHIES (*Calif. Agr. Col. Ext. Circ. 6 (1926), pp. 24, figs. 8*).—A popular bulletin on milch goat production dealing with the breeding, management, feeding, and housing of milch goats, with descriptions of the different breeds and uses of goats' milk.

The secretion of butterfat, C. PORCHER (*Le Procès de la Matière Grasse du Lait. Lyon: Le Lait, 1925, pp. [2]+255, pl. 1, figs. 82*).—The physiology of fat secretion is described from the standpoint of the histological changes in the mammary gland and the origin of fat in milk. Most of the book deals with the variations in the fat content of milk as affected by the individual, different quarters of the udder, different times of milking, season, etc. One portion of the book deals with the detection of modifications of the fat content.

Testing dairy products, J. A. NEWLANDER (*Milwaukee, Wis.: Olsen Pub. Co., 1926, pp. 128, figs. 47*).—An outline for the testing of dairy products, consisting of directions for making tests for butterfat, specific gravity, acidity, and moisture.

A comparison of the Babcock, Gerber, and Roesse-Gottlieb methods for determining the percentage of fat in milk and cream, A. C. DAHLBERG, G. E. HOLM, and H. C. TROY (*New York State Sta. Tech. Bul. 122 (1926), pp. 32*).—A total of 925 tests of milk and cream were made by the Roesse-Gottlieb, Babcock, and Gerber methods in three different research laboratories and four dairy control laboratories. The results of the Roesse-Gottlieb method varied in the different laboratories. The Babcock and the Gerber methods of determining the fat in milk and cream were found equally and sufficiently accurate for practical purposes.

[Experiments with dairy products at the Wisconsin Station] (*Wisconsin Sta. Bul. 388 (1926), pp. 94-98, fig. 1*).—The results of some recent experiments at the station are briefly noted, with special reference to the practical application. Some of these have been previously noted (E. S. R., 53, p. 474).

Bacteria in relation to heat sterility of milk.—Early work with this problem showed that the citrate fermentation in milk influenced its stability. Recent experiments by G. Helz et al. have shown that the ordinary acid-forming bacteria of milk do not attack the citric acid. It is, however, fermented by the colon bacteria and some other types. Citrates do not diminish until the acidity has reached a point which makes it unfit for ordinary use.

Pasteurization of curd in making American cheese.—Preliminary work by J. L. Sammis indicates that curd may be pasteurized by treating with hot water (140° F.) to improve the flavor and texture of cheese. The best results were obtained when pasteurization was done when curd acidity was high, about 0.6 per cent.

Stinker cheese investigations.—Recent investigations have led to the belief that stinker spots are caused by moist lumps of curd, due to imperfect cutting or accidentally left in the process of manufacture. The lumps are absorbed leaving a hole which, when the right combination of bacteria is present, results in a stinker spot.

Ice cream investigations.—Citrate and phosphates have been found by H. H. Sommer to have a pronounced effect in increasing the whipping ability of ice cream mixes. When 0.4 per cent sodium citrate was added to a mix and aged for 24 hours, a 100 per cent overrun was obtained in 4 minutes. The same mix without the sodium citrate required from 10 to 15 minutes for the same overrun. On the other hand, when 0.1 per cent calcium lactate was added an overrun of 90 per cent was produced in 18 minutes, and the same mix without the calcium lactate produced 95 per cent overrun in 12 minutes.

Sommer and his associates suggest methods that will simplify the testing for fat and total solid content of ice cream. The first of these tests is based upon the fact that glacial acetic acid will prevent the charring of sugars by concentrated sulfuric acid. The second test is a method for removing moisture in a steam heated vacuum oven.

Process cheese and Joint Resolution No. 54, S., Legislature of 1925, J. Q. EMERY and H. KLUETER (*[Wis. Dairy and Food Comn.] Bul. 15 (1926), pp. 45*).—The results of the study of the manufacture in several plants of so-called processed cheese are presented by Emery, and a discussion of the necessary legislation relating to this project is given by Emery and Klueter.

VETERINARY MEDICINE

[Work in animal pathology in Wisconsin] (*Wisconsin Sta. Bul. 388 (1926), pp. 102-108, figs. 2*).—In connection with cooperative control work with contagious abortion in cattle, F. B. Hadley and Lothe have found that animals, several of which agglutinated only in a dilution of 1 to 50, on retests eventually gave reactions in higher dilutions and most of them subsequently aborted.

The control work, in a herd in which the animals reacting to the blood test were removed, resulted in a gradual elimination of the disease. The best results have been found to follow the use of an agglutination test fluid prepared by pooling several strains of *Bacterium abortus* of bovine origin. It is pointed out that retests may well be made between 60 and 90 days, and continued until no new reactors to the test appear. Reactors that gradually become nonreactors should never be returned to the clean herd. The importance of stable hygiene and sanitation is emphasized, and a brief reference is made to the value of vaccination. In abortion work by B. L. Warwick, E. M. Gildow, and Hadley, rabbits were found to offer advantages, a virulent strain of *B. abortus* producing abortion in them in most cases when inoculated from the fourteenth to twentieth day of pregnancy. In studies of an outbreak of abortion in a flock of some 300 breeding ewes, Warwick found *Vibrio foetus* to be the cause.

Reference is made to the inheritance of hernia in swine, a report of which by Warwick has been noted (E. S. R., 56, p. 129). The importance of diseases in fox farming, and particularly a fatal affection of fetal and newborn fox pups due to a very short rod belonging to the Salmonella group is referred to as studied by Hadley.

In work with bacillary white diarrhea, B. A. Beach, Gildow, and D. M. Warren found that the older hens are not an important source of *B. pullorum* infection for chicks. They conclude that *B. pullorum* is quite commonly present in the content of the intestinal tract of hens that appear normal. They have found coccidiosis to be spreading rapidly, and to be the most destructive disease in commercial flocks in the State at the present time. Beach and Warren have found kamala to be a satisfactory remedy for the tapeworm in poultry (E. S. R., 55, p. 399).

Report of the veterinary director general for the year ending March 31, 1926, G. HILTON ET AL. (*Canada Dept. Agr., Rpt. Vet. Dir. Gen., 1925-26, pp. 41*).—In the first part of this report, G. Hilton (pp. 3-13) deals with some of the more important diseases to be guarded against, outbreaks of which occurred during the year. The work of the pathological division is reported upon by E. A. Watson and his associates (pp. 14-23), particular attention having been given to tuberculosis research work. The report of the meat and canned foods division, by R. Barnes (pp. 24-29) follows.

Handbook of the Diseases of Animals Acts and orders of the Minister of Agriculture and Fisheries thereunder (*London: Min. Agr. and Fisheries, 1926, pp. XIV+1-92, 121-185, 211-466, 491-706, 731-749*).—Following the introduction, the several parts of this handbook deal with the Diseases of Animals Act (pp. 1-92); Miscellaneous Acts (pp. 121-185); Disease Orders (pp. 211-466); Exportation, Importation, and Transit Orders (pp. 491-706); and Miscellaneous Orders (pp. 731-749).

Annual administration reports of the Bombay Veterinary College, Bombay City and Harbour Veterinary Department, and Civil Veterinary Department in the Bombay Presidency (including Sind) for the year 1925-26, K. HEWLETT, E. S. FARBROTHER, J. D. BUXY, P. R. CADELL, and A. S. V. SCOTT (*Bombay Vet. Col., City and Harbor Vet. Dept., and Civ. Vet. Dept. Ann. Admin. Rpts. 1925-26, pp. 60*).—These are the annual reports and include data on the occurrence of infectious diseases of livestock, results of preventive inoculation, etc. (E. S. R., 54, p. 379).

Textbook of comparative physiology, C. G. ROGERS (*New York and London: McGraw-Hill Book Co., 1927, pp. XVI+635, [pl. 1], figs. [148]*).—This volume is said to be the outgrowth of a course in comparative physiology offered for a

number of years to students in Oberlin College. A bibliography of 30 pages is included.

The operative technique of animal experiments, H. F. O. HABERLAND (*Die Operative Technik des Tierexperimentes*. Berlin: Julius Springer, 1926, pp. X+336, figs. 300).—A detailed, illustrated account of the methods employed in operative procedure.

The relation of animal diseases to public health, T. G. HULL (*Ill. State Acad. Sci. Trans.*, 17 (1924), pp. 274-278).—This discussion is a contribution from the Illinois Department of Public Health.

Local immunization: Specific dressings, A. BESREDKA, edited and trans. by H. PLOTZ (*Baltimore: Williams & Wilkins Co.*, 1927, pp. XI+181).—In the discussion of this subject there are several chapters dealing, respectively, with anthrax (pp. 1-45), staphylococcus and streptococcus infections (pp. 46-84), dysentery (pp. 85-107), the typhoid fevers (pp. 108-143), and theory (pp. 144-178).

Pharmacopoea germanica (*Deutsches Arzneibuch*. Berlin: G. Schenck, 1926, 6. ed., pp. LV+854; rev. in *Jour. Amer. Med. Assoc.*, 88 (1927), No. 9, pp. 648, 649).—The sixth edition of the German Pharmacopoeia.

A method for repeatedly sampling the blood of the portal vein in healthy animals, M. A. BLANKENHORN (*Jour. Expt. Med.*, 45 (1927), No. 2, pp. 191-194, fig. 1).—The author describes a method used at the Rockefeller Institute for Medical Research for repeated sampling of the blood of the portal vein in healthy animals, it having been employed in 13 dogs with success in 8.

Microbic dissociation: The instability of bacterial species with special reference to active dissociation and transmissible autolysis, P. HADLEY (*Jour. Infect. Diseases*, 40 (1927), No. 1, pp. 312, pls. 6).—This is a contribution from the hygienic laboratory of the University of Michigan.

The filtrable viruses [trans. title], F. LUCKSCH (*Prager Arch. Tiermed.*, 5 (1925), A, No. 3-4, pp. 83-140, figs. 12).—Following a general discussion the author deals with the acute infectious diseases due to filtrable viruses, 12 in number; those localized in particular organs or tissues, 2 in number; those causing changes in the central nervous system, 5 in number; and those localized in the haematopoietic system, 2 in number, etc.

Animal parasites of man, the diseases which they transmit, and their treatment.—I, Natural history of animal parasites of man, M. BRAUN (*Die Tierischen Parasiten des Menschen, die von ihnen Hervorgerufenen Erkrankungen und ihre Heilung*.—I, *Naturgeschichte der Tierischen Parasiten des Menschen*. Leipzig: Curt Kabitzsch, 1925, 6. rev. and enl. ed., pp. X+608, figs. 416).—The first volume in this work (E. S. R., 36, p. 354) deals with Parasites and Parasitism (pp. 1-8); Protozoa (pp. 9-157); Platyhelminthes (pp. 157-311); Nematoda (pp. 311-404); Acanthocephala (pp. 404-406); Gordiidae (p. 407); Hirudinea (pp. 407-410); and Arthropoda (pp. 410-488). The volume includes a classified bibliography (pp. 489-593).

Animal parasites of man, the diseases which they transmit, and their treatment.—II, Clinic and therapy of animal parasites of man, O. SEIFERT (*Die Tierischen Parasiten des Menschen, die von ihnen Hervorgerufenen Erkrankungen und ihre Heilung*.—II, *Klinik und Therapie der Tierischen Parasiten des Menschen*. Leipzig: Curt Kabitzsch, 1926, 3. ed., pp. VI+574, figs. 21).—This is the third edition of the second volume of the work noted above. It deals with Amoebina (pp. 1-51); Flagellata (pp. 51-61); Trypanosomidae (pp. 61-95); Haemosporidia (pp. 95-159); Infusoria (pp. 159-167); Platyhelminthes (pp. 167-188); Cestodes (pp. 188-268); Echinococcus (pp. 268-334); Nematoda (pp. 334-412); Hirudinei (pp. 412-419); Arthropoda (pp. 419-447); Insecta (pp. 447-501); and Myiasis (pp. 501-538).

Sensitising powers of proteins of parasites as tested by the isolated sensitized uterus reaction, A. W. TURNER (*Roy. Soc. Victoria, Proc., n. ser.*, 38 (1926), pp. 24-54, figs. 2).—In the course of investigations at the Veterinary Research Institute of the University of Melbourne the sensitizing powers of the following parasites were determined: *Ascaris equi*, *A. suilla*, *Toxascaris limbata*, *Onchocerca gibsoni*, *Fasciola hepatica*, *Gastrophilus haemorrhoidalis*, *G. nasalis*, and *G. intestinalis*. In addition, it was found necessary to determine the action on the uterus of a few substances which were needed as preservatives, including toluol, chloroform, phenol, and glycerine. The details in the investigation are presented, the conclusions reached being as follows:

“Protein-containing extracts of parasites can sensitize the uterus of guinea pigs when injected subcutaneously. Such sensitization is strictly specific, though a peculiar simultaneous nonspecific sensitiveness may exist toward extracts of other related forms. Desensitization of the uterus towards the nonspecific extract still leaves the muscle sensitive to the extract used for sensitizing the guinea pig. Desensitization towards the specific extract abolishes sensitiveness toward the nonspecific extract. The above phenomenon is analogous with that of agglutinin or precipitin action. The sensitized uterus reaction suggests itself as a means whereby mutilated parasites might be identified, or whereby the supposed identity of any two parasitic forms might be tested.” A list of 33 references to the literature is included.

Dogs and cats concerned in the causation of creeping eruption, E. F. WHITE and W. E. DOVE (*U. S. Dept. Agr., Off. Rec.*, 5 (1926), No. 43, p. 6).—The authors report upon investigations conducted by the Bureau of Entomology.

This human skin disease occurs chiefly in the South Atlantic and Gulf States, but has been reported as far north as New Jersey and it is said that cases have also been encountered in the interior as far north as Oklahoma. Working in 1925 in cooperation with J. L. Kirby-Smith at Jacksonville, Fla., the authors demonstrated the cause of the eruption to be a nematode larva. In a further study of the disease the authors have recovered in cultures infective nematode larvae from the feces of the dog and the cat examined from a locality where and when there was a high incidence of creeping eruption. They have applied these larvae to their own skin and produced thereby symptoms and lesions characteristic of and now known clinically as those of creeping eruption. They have thus far found two species of these nematode larvae, recognized morphologically as *Ancylostoma braziliense* De Faria and *A. caninum*, in 26 out of 27 dogs taken from the streets of Jacksonville and in both of two cats. *A. braziliense* was encountered in much larger numbers than *A. caninum*.

A biochemical method of differentiating *Brucella abortus* from *Brucella melitensis-paramelitensis*, I. F. HUDDLESON and E. ABELL (*Jour. Bact.*, 13 (1927), No. 1, p. 13).—This is a contribution from the Michigan Experiment Station.

The authors have found that *B. abortus* in its growth activity on a suitable medium under aerobic incubation causes the liberation of hydrogen sulfide gas, while *B. melitensis* or *B. paramelitensis* does not. The gas may be detected by means of lead acetate paper.

In the course of the authors' study 92 strains of *B. abortus*, 30 strains of *B. melitensis*, and 10 strains of *B. paramelitensis* were employed. All of the strains were isolated either in Europe or in this country from bovine, porcine, human, caprine, and equine sources.

The hydrogen sulfide test so far has agreed with the agglutinin absorption test in placing the strains in the abortus or melitensis group. The hydrogen sulfide test is considered to offer a rapid procedure for the grouping of newly isolated strains.

Investigations with acid-fast bacteria (*Wisconsin Sta. Bul.* 388 (1926), pp. 90, 91).—Studies by E. G. Hastings and B. A. Beach are briefly noted, with results previously referred to (*E. S. R.*, 55, p. 497).

The histological expression of the natural resistance of rabbits to infection with human and bovine type tubercle bacilli, P. A. LEWIS and E. S. SANDERSON (*Jour. Expt. Med.*, 45 (1927), No. 2, pp. 291-304).—The authors consider the natural resistance of rabbits to infection with the tubercle bacillus of human type to be apparently referable to a failure of this type of bacillus to multiply in the body of this species to any considerable extent.

Anaphylaxis and the tuberculin reaction, M. DORSET (*Jour. Amer. Vet. Med. Assoc.*, 69 (1926), No. 6, pp. 711-716).—An address presented at the Eastern States Tuberculosis Conference, held at Burlington, Vt., in June, 1926.

A few observations on the use of vaccines in the treatment of mastitis in cattle, G. A. MOORE (*Vet. Rec.*, 7 (1927), No. 7, p. 155).—A brief discussion with notes on three cases in which treatment with vaccines was tried with apparently beneficial results.

Vibrios from calves and their serological relation to vibrio fetus, T. SMITH and M. L. ORCUTT (*Jour. Expt. Med.*, 45 (1927), No. 2, pp. 391-397).—The authors find the calf vibrios thus far studied to include one strain serologically distinct from the fetal strains, while the others are closely related to the fetal strains though not identical with them. The pathogenic characters of the calf vibrios, either as possible descendants of *Vibrio fetus* or as independent factors in the production of enteritis, have not been demonstrated.

Cutaneous tuberculosis (?) in buffaloes [trans. title], J. KOK and M. ROESLI (*Nederland. Indische Bl. Diergeneesk.*, 38 (1926), No. 6, pp. 465-472, pl. 1; *Eng. abs.*, p. 472).—The authors record the finding of nodules, at different places on the bodies of three animals, which ranged from the size of a hazelnut to that of the average potato. Groups of acid-fast microorganisms resembling those of tuberculosis were detected. Three stages, (1) small tumors of firm consistence, (2) larger ones showing radial cheesy degeneration, and (3) the largest ones as abscesses containing whitish matter mixed with calcified particles, were distinguished.

A spirillum as the cause of infectious abortion in a flock of sheep [trans. title], W. GRIMM (*Tierärztl. Rundschau*, 33 (1927), No. 3, pp. 39-43).—The author reports upon the occurrence of abortion in a flock of sheep in Silesia, in which *Spirillum abortus ovis* was found to be the cause. Of 212 pregnant dams in the flock, 27 aborted. Pregnant guinea pigs which were subcutaneously injected with the spirillum-containing material aborted. The control of this infection was brought about by hygienic measures and the injection of all the animals with a 15 per cent solution of atoxyl.

Immunizing young pigs against cholera, III, J. W. BENNER (*N. Y. State Vet. Col. Rpt.* 1924-25, pp. 225-230).—This contribution is in continuation of previous experiments (*E. S. R.*, 55, p. 371).

Of 12 animals that received the hyperimmunizing dose of virus of 5 cc. per pound live weight intravenously, 5 died. Of 34 that received the trial injection of 2 cc. of virus intramuscularly, 4 died, and 1 of these had rickets badly when given the trial injection. Results in this experiment indicate a grade of immunity sufficiently high to withstand 2 cc. of virus intramuscularly, which is easily sufficient to protect from natural exposure but not sufficiently high to protect from the enormous doses of virus used in the special process of hyperimmunization.

Autogenous vaccines in the treatment of chronic nasal catarrh in horses, C. DAVENPORT (*Vet. Jour.*, 83 (1927), No. 620, pp. 78-83).—In this discussion of autogenous vaccines the author deals with the supply of material, preparation

of the vaccine, organisms present, sterilization of the vaccine, standardization of bacterial suspensions, adjustment of dosage, administration of the vaccine, and results. The study of the organisms present indicates that those causing chronic nasal catarrh in horses are, mainly, staphylococci and streptococci.

Four years' progress in the control and eradication of bacillary white diarrhea in Maine, E. R. HITCHNER and F. L. RUSSELL (*Poultry Sci.*, 5 (1926), No. 3, pp. 117-120, figs. 2).—This is a summary of results obtained during the 4 years of testing in Maine.

The metazoan parasites of poultry in Australia, I. C. ROSS (*Jour. Aust. Vet. Assoc.*, 2 (1926), No. 4, pp. 129-139, figs. 3).—A brief summary of information on the subject.

AGRICULTURAL ENGINEERING

[Agricultural engineering studies at the Wisconsin Station] (*Wisconsin Sta. Bul.* 388 (1926), pp. 11-17, figs. 3).—In continuation of studies on silo filling (*E. S. R.*, 55, p. 882), it has been found by F. W. Duffee that flywheel silage cutters of 11 in. or smaller are not economical to operate. In order to get good capacities on such small machines it is usually necessary to operate them at more than the most economical speed, which increases the difficulty of feeding. It seems better to operate a medium sized machine at a slower speed. It has been found that flywheel machines larger than 16 in. or cylinder machines larger than 18 or 20 in. are too large to be practical for ordinary use. Reducing the speed of the cylinder or flywheel also reduces the speed of the blower fan.

In corn cultivating tests by Duffee and J. B. Woods, the 2-row motor cultivator was apparently very practical in fairly small fields and on quite hilly land. The 4-row machine apparently would not be satisfactory under such conditions. Equally good, if not better, work was done with both the 2-row and 4-row cultivators than is commonly done with horses.

The tests of harvesting and threshing with the combine indicated that wheat, rye, barley, and oats can be threshed as soon as cut and the grain safely stored if provision is made for blowing air through the grain. Seven hours of blowing during as many days quite satisfactorily dried the grain and prevented it from heating.

In hay drying tests by Duffee and K. C. MacLeish it was found that 200 lbs. of coal was required to dry out 1 ton of hay. The results so far obtained are said not to warrant definite recommendations, and the proposition seems rather questionable except possibly under very special conditions.

Drainage of forest lands was followed by an increase in the rate of diameter growth dating back to the time of drainage.

Surface water supply of New Mexico, 1888-1925, G. M. NEEL (*Santa Fe: State Engineer*, [1926], pp. 373).—The results of measurements of flow made on the principal streams of New Mexico are presented.

Irrigation and drainage problems in the Gallatin Valley, H. E. MURDOCK (*Montana Sta. Bul.* 195 (1926), pp. 36, figs. 24).—Some of the pressing problems in irrigation and drainage in the Gallatin Valley, Mont., are described, and suggestions are offered for their solution.

In general the soils of the valley are of a fine texture, consisting of heavy alluvial or silty loams which frequently carry extensive accumulations of cobblestones and gravel. There seems to be a plentiful supply of water for irrigating all of the land in the valley, but the difficulty is to get this water to the right place at the right time. The problems of irrigation and drainage are rather intimately associated, as the seepage conditions throughout the

valley are largely brought on by the irrigation. During low water in some seasons the seepage and evaporation losses are excessive in the river channels. At present it is necessary to endure these losses in order to get a supply of irrigation water to the older water-right ditches which are in the lower part of the valley. If these needs could be supplied by pumping water from the underground supply, the problems of both irrigation and drainage would be at least partly solved. The belief is expressed that this is a practical and economical method of relief. It is also believed that the equitable and successful solution of the problems would require the organization of the valley into one large irrigation and drainage district.

[**Irrigation studies at the Arizona Station**], G. E. P. SMITH, W. E. CODE, and H. C. SCHWALEN (*Arizona Sta. Rpt. 1923, pp. 488-492*).—The progress results of ground water studies, artesian well tests, stream flow measurements, and related subjects are briefly reported.

Irrigation by overhead sprinkling, H. A. WADSWORTH (*Calif. Agr. Col. Ext. Circ. 4 (1926), pp. 37, figs. 12*).—Working data on the planning and installation of overhead sprinkling irrigation systems for California agriculture are presented, based on studies conducted by the California Experiment Station.

It has been found that irrigation by overhead sprinkling is costly and is limited to the production of high-priced crops on land of high value. Intensive soil moisture sampling during the irrigation season of 1925 indicated that adequate soil moisture penetration can be secured by the sprinkling of decomposed granite and sandy loam soils if the sprinkling equipment is properly selected and intelligently operated. The evidence with heavy soils is not so conclusive.

Irrigation with treated sewage in western Texas, H. N. ROBERTS and D. L. JONES (*Engin. News-Rec., 97 (1926), No. 26, pp. 1026-1028, figs. 3*).—A description is given of a sewage farm of 100 acres which is operated under the direction of the Texas Experiment Station and which has been receiving the effluent from the sewage works of Lubbock, Tex., since February, 1926. Eight different crops have been irrigated, and the flow averages about 1.05 acre-ft. per day. It is stated that not the slightest odor or other bad feature is noticeable except the light green color of the clear sewage in the canals. The soil is a fine, loose, sandy loam underlain by a sandy clay. These formations seem able to assimilate very large quantities of water and are able to retain a small rainfall for a long time. February irrigation has been found to be very important, and it is said to be possible to detect to a row where February irrigation was used.

Water supply and sewage disposal systems, I. D. WOOD (*Nebr. Agr. Col. Ext. Circ. 723 (1926), pp. 24, figs. 10*).—Practical information on the planning and construction of water supply and sewage disposal systems for farms in Nebraska is presented, together with working drawings and bills of material.

The farm water supply.—Part II, The use of the hydraulic ram, F. G. BEHREND (N. Y. Agr. Col. (Cornell) *Ext. Bul. 145 (1926), pp. 28, figs. 16*).—Practical information on the installation, operation, and use of the hydraulic ram in farm water supply systems is presented, together with numerous diagrammatic illustrations.

Stone removal as a phase of land clearing, A. J. SCHWANTES (*Agr. Engin., 7 (1926), No. 12, pp. 403-405, figs. 6*).—This paper, which is a contribution from the Minnesota Experiment Station, was presented at the twentieth annual meeting of the American Society of Agricultural Engineers at Lake Tahoe, Calif., in June, 1926. It is pointed out that practically all of the field stone in Minnesota is of granitic type. The handling of field stone is discussed, first, as to the removal of large boulders by explosives or special mechanical devices,

and, second, the removal of those stones which are small enough to be handled readily by one or two men.

Terracing farm lands in Texas (*Tex. Agr. Col. Ext. Bul. B-51* [rev.] (1926), pp. 16, figs. 11).—Practical information on the terracing of farm lands in Texas is presented, including descriptions of machines used for the purpose (E. S. R., 42, p. 888).

A. S. T. M. Standards, 1926 (*Philadelphia: Amer. Soc. Testing Materials, 1926, pp. 102, figs. 15*).—This pamphlet comprises the second supplement to the 1924 book of standards of the American Society for Testing Materials and contains 16 standards for materials used in structures and for metals used in machinery.

An elementary treatise on statically indeterminate stresses, J. I. PARCEL and G. A. MANEY (*New York: John Wiley & Sons; London: Chapman & Hall, 1926, pp. XIII+368, pls. 3, figs. 178*).—This book contains chapters on deflections; general theory of statically indeterminate stresses; special methods of attack; continuous girders; the rigid frame; the elastic arch; secondary stresses; and general discussion of statically indeterminate construction, historical review, bibliography.

Recommended building code requirements for working stresses in building materials, I. H. WOOLSON ET AL. (*U. S. Dept. Com., Bur. Standards, Elimination of Waste Ser., BH9* (1926), pp. VI+53, figs. 4).—This report is the sixth of a series on the elimination of waste and is in three parts. Part 1 describes the organization and purposes of the Building Code Committee, part 2 presents requirements recommended for adoption in building codes, and part 3 explains briefly the basis of the recommendations of part 2 and discusses the conditions by which they are limited. Various references to good building practice are also given, together with other information helpful to building code committees. Some of this material, especially stress tables and formulas for timber, seems quite suitable for use by agricultural engineers.

Concrete designers' manual, G. A. HOOL and C. S. WHITNEY (*New York and London: McGraw-Hill Book Co., 1926, 2. ed., pp. XII+329, figs. 222*).—This is the second edition of this book (E. S. R., 46, p. 85). It contains tables and diagrams for the design of reinforced concrete structures, and sections on slabs, flat slabs, rectangular beams, doubly reinforced beams, T-beams, shear reinforcement, columns, bending and direct stress, footings, symmetrical arches, miscellaneous topics, and rulings pertaining to design and working stresses.

Elements of heat-power engineering.—Part I, Thermodynamics and prime movers, W. N. BARNARD, F. O. ELLENWOOD, and C. F. HIRSHFELD (*New York: John Wiley & Sons; London: Chapman & Hall, 1926, 3. ed., pp. XII+493, pls. 3, figs. 257*).—This is the third edition of part I of this book. It contains chapters on fundamentals regarding energy and its transformation; historical outline; illustrations of modern power plants, energy equations; equilibrium, reversibility, and availability; entropy; the properties of gases; thermodynamic processes of gases; the indicator diagram; compressed air; gas cycles; efficiencies and performances of engines; internal-combustion engines—types and mechanical features; internal-combustion engines—actual operation, power, and performance; properties of vapors; thermodynamic processes of vapors; the simple cycles of vapor engines and vapors; the reheating, regenerative, and binary cycles; the reciprocating steam engine; and steam turbines—general.

Detonation characteristics of petroleum motor-fuels, S. P. MARLEY, D. R. STEVENS, and W. A. GRUSE (*Jour. Soc. Automotive Engin., 20* (1927), No. 2, pp. 214-220, figs. 3).—Studies conducted at the Mellon Institute of Industrial Research are reported.

The results showed that no dependable method is available for determining the detonating tendency of motor fuels except that of direct engine tests. A ratio was found for the knock-reducing tendency of a naphthene, an olefin, and an aromatic hydrocarbon differing from that indicated by the work of Ricardo. Evidence is presented for the general belief that the detonating tendency of gasoline fractions increases with a rise in the boiling point.

The conclusion is drawn that while it is probable that cracking offers the readiest way for most petroleum refiners to produce motor fuels of improved antiknock value from petroleum, it does not necessarily follow that all cracked gasolines constitute satisfactory antiknock motor fuels. The results obtained by the use of different standard fuels indicate the desirability of an agreement as to detonation standards.

An examination for detonating qualities of 18 petroleum gasolines, using a single cylinder engine, showed an aromatic equivalence of paraffins, naphthenes, and unsaturated and aromatic hydrocarbons of 5:4:1.

Experiments were made in which a constant proportion of one hydrocarbon of each class was added to a gasoline and the detonating tendency of the resulting mixture determined by engine tests. The use of two gasolines as base fuels and a system of intercomparisons gave results indicating an equivalence shown by the ratio 2:2:1. It was found that the degree of correlation between results by engine tests and results by chemical analysis will vary with the quality of the standard fuel employed.

Detonation specifications for automotive fuels, G. EDGAR (*Jour. Soc. Automotive Engin.*, 20 (1927), No. 2, pp. 245, 246).—It is pointed out that to draw detonation specifications for fuels a reproducible primary standard fuel must be developed and methods of comparing fuels must be agreed upon. The composition of gasoline is so complex and the knocking characteristics of its different constituents are so varied that great difficulty has been encountered in finding one or more hydrocarbons the purity of which could be definitely established by test and which would thus be absolutely reproducible. Two hydrocarbons are cited that seem to be ideally suited for standard reference fuels, namely, pure normal heptane, $C_7 H_{16}$, and pure octane, $C_8 H_{18}$, which is prepared synthetically from tertiary butyl alcohol. By mixing these two hydrocarbons in different proportions it has been found possible to duplicate the knocking characteristics of any commercial fuel between the limits of 60 per cent of heptane and 40 per cent of octane and 40 per cent of heptane and 60 per cent of octane.

Studies in rural electrification (*Wisconsin Sta. Bul.* 388 (1926), pp. 6-11, figs. 4).—The progress results of a series of studies by F. W. Duffee and W. C. Krueger on the application of electricity to different farm practices in Wisconsin are briefly presented.

A study of rates for rural service has indicated that a just rate should consist of a monthly service charge to cover approximately the fixed charges and a low rate for the current.

In studies of practical equipment, it has been found practical and economical to use electric cooking where cheap fuel is not available on the farm and electric refrigeration for the household and the dairy. House heating, other than auxiliary small heaters, field work with electric motors, ultra-violet ray treatment for ordinary farm conditions, and heating water for the household have not been found practical or economical.

Effective haying equipment and practices for northern Great Plains and intermountain regions, L. A. REYNOLDS and C. D. KINSMAN (*U. S. Dept. Agr., Farmers' Bul.* 1525 (1927), pp. II+28, figs. 23).—A description is given of improved equipment used for handling hay by ranches in different sections, of

effective practices that are employed, and of the organization and handling of haying crews on different ranches.

Dust respirators: Their construction and filtering efficiency, S. H. KATZ, G. W. SMITH, and E. G. MEITER (*U. S. Dept. Com., Bur. Mines, Tech. Paper 394 (1926), pp. IV+52, pl. 1, figs. 28*).—This paper describes representative types of dust respirators, and presents the results of laboratory tests to determine their filtering efficiencies and resistances to air flow.

The efficiencies of the industrial dust respirators in restraining tobacco smoke ranged from 5 to 33 per cent when the air is passed at the rate of 32 liters per minute. A gas mask canister with two filters of absorbent cotton showed 63 per cent efficiency. A flat felt filter was most efficient, showing 97 per cent. The efficiencies against silica dust floated in air ranged from about 9 to 70 per cent for the dust respirators. Most of the silica particles were 1 μ in diameter.

Filters of various fabrics, including cheesecloth, canton flannel, unbleached muslin, closely woven bleached muslin, filter paper, and absorbent cotton, all so made as to expose exactly 100 sq. cm. of filter area, were tested against tobacco smoke and silica dust in air flowing at the rate of 10 liters per minute. Each material was tested in a single layer and in multiple layers. The results showed that each layer of fabric removes about the same proportion of smoke or dust that penetrates to it before the filters become clogged or altered by deposits of an arrested material. Consequently, when the efficiency of a single ply of a filter is known, the efficiency of any multiple ply filter of that material may be calculated.

It was found that silica dust clogged filters rapidly and increased the resistance to air flow, but some materials were more resistant to clogging than others. The dense filters of paper or closely woven muslin clogged most rapidly. Filters of loose texture, like cheesecloth or absorbent cotton, clogged the least. The efficiencies of the filters were increased by clogging with dust until eventually many filters gave an efficiency of 100 per cent. Woolen fabrics proved to be no better filters than cotton fabrics of similar texture.

The efficiency of the filters decreased somewhat with an increase in the rate of air flow. The resistance of the filters to air flow increased in proportion to the number of plies of fabrics after the first ply. The first filter layer showed a somewhat higher resistance than the additional ones. It was found that air filters of high efficiency can be made with a sufficient number of plies of material that has a low efficiency per single ply. Such filters have less resistance to air flow than equally efficient filters made of fewer plies of the higher efficiency materials. The thicker filters of loose textured material clogged less rapidly than equally efficient filters composed of fewer plies of tightly woven materials.

A new type of dust respirator was designed and constructed according to the principles brought out in the tests, and consists of a large filter of canton flannel. At an air flow of 85 liters per minute the efficiency of this respirator was 93 per cent against silica dust.

Plans for concrete houses (*Chicago: Portland Cement Assoc., 1925, 3. ed., pp. 79, figs. 117*).—Plans and general specifications for a large number of concrete houses are presented.

Sunlight movable hog houses for Kentucky, E. J. WILFORD and J. B. KELLEY (*Ky. Agr. Col. Ext. Circ. 198 (1926), pp. 22, figs. 14*).—Practical information on the planning and construction of sunlight movable hog houses for Kentucky conditions is presented, together with working drawings, bills of material, and a list of hog-house plans and equipment.

House the hen efficiently and economically, J. G. HALPIN, J. B. HAYES, and N. S. FISH (*Wis. Agr. Col. Ext. Circ. 184 (1925)*, pp. 19, figs. 18).—Practical information on the planning of poultry houses for Wisconsin conditions is given, together with working drawings and bills of material.

The Dutch oven or cement brooder stove, H. B. CARROLL, JR., and E. B. HILLIER (*Pullman: Wash. State Col. Ext. Serv., 1926*, pp. [6], figs. 6).—The Dutch oven or cement brooder stove is described and illustrated.

Principles of refrigeration, W. H. MOTZ (*Chicago: Nickerson & Collins Co., 1926*, pp. XI+657, pls. 10, figs. 153).—This is a comprehensive treatise on the fundamental principles of the operation of ice making and refrigerating machinery, on the properties and values of the principal media used in modern refrigerating apparatus, on the transmission of heat, on the functions and values of insulating materials, on the construction and operation of the various parts of refrigerating apparatus, and on the application of refrigeration to its varied uses.

RURAL ECONOMICS AND SOCIOLOGY

[Investigations in agricultural economics at the Wisconsin Station, 1924-1926] (*Wisconsin Sta. Bul. 388 (1926)*, pp. 17-26, 126, figs. 2).—Results of work in agricultural economics not previously noted (*E. S. R., 55*, pp. 81, 84, 485) are given.

Farm cost investigations.—Farm incomes averaged \$1,074 in 1924 as compared with \$1,205 in 1923, as shown by a study conducted by P. E. McNall. The results of a study of the cost of horse work on 60 Walworth County farms were as follows:

Horse work costs, 60 Walworth County farms, 1922-1924

Year	Cost of horse labor per hour		Crop acres per horse		Average per horse for year	
	Average	Range	Average	Range	Hours worked	Cost
	<i>Cts.</i>	<i>Cts.</i>				
1922.....	15.0	7.8-23.6	17.7	8-30	707	\$106
1923.....	14.6	9.5-40.0	16.4	8-27	635	93
1924.....	14.4	8.7-29.1	16.5	7-39	675	97

Feed represented approximately two-thirds of the cost of keeping horses. The highest per hour cost of horse work was on farms having tractors, showing that horse work costs are not reduced in proportion to the increased cost due to use of tractors. The increasing of the number of hours of work per horse from 419 to 1,071 decreased the cost per hour from 19.8 to 10.9 cts.

A study of farm taxes.—In this study conducted by B. H. Hibbard and B. Allin analysis was made of 13,000 city, 1,854 village, and 4,214 farm State income tax reports filed in Dane County. In 1924, farmers spent 19 per cent of their net income for taxes, the city group 6.5 per cent, and the village group 5.9 per cent. Of the above number 214 of the farm group, 1,353 of the city group, and 133 of the village group made reports in the years 1913, 1914, 1918, 1919, 1923, and 1924. These reports showed the following changes in net income and percentage of such income paid for taxes.

Average net income and percentage spent for taxes, 1913 and 1914, 1918 and 1919, and 1923 and 1924

	1913 and 1914		1918 and 1919		1923 and 1924	
	Net income	Percentage taxes	Net income	Percentage taxes	Net income	Percentage taxes
Farm.....	\$1,089	13.1	\$3,156	7.9	\$1,436	20.8
City.....	2,037	4.8	3,103	7.5	4,161	9.2
Village.....	1,462	4.9	2,451	4.7	2,266	8.1

Similar comparisons based on 1,818 in the farm group, 3,224 in the city group, and 362 in the village group for 1918-1919 and 1923-1924 showed the increase in the percentages spent for taxes to be from 6.2 to 18.9 in the farm group, from 5.6 to 7.8 in the city group, and from 3.8 to 6.6 in the village group.

Studies in farm living costs.—Records of nine families on dairy and poultry farms show that from 15.4 to 40.1 per cent of the total income is spent for food. This study is being directed by A. L. Marlatt and W. Hale.

The principle of comparative advantage applied to farm management studies of regional competition between farmers, J. W. TAPP (*Jour. Farm Econ.*, 8 (1926), No. 4, pp. 417-426).—A discussion of the merits of the principle of comparative advantage as used by writers on international trade compared with the use of direct comparisons between production costs in farm management studies of regional competition.

Progress report on cost of production route in Choctaw County, Mississippi, 1925, L. E. LONG and H. W. REYNOLDS (*Mississippi Sta. Bul.* 237 (1926), pp. 23).—A report for the calendar year 1925 of a study previously noted (E. S. R., 55, p. 181), based on records from 19 farms obtained in cooperation with the U. S. D. A. Bureau of Agricultural Economics.

The weighted average of total value of products per farm was \$1,747.72, of farm income \$824.98, and of value of operator's labor \$312.86. The return on investment (farm income minus value of operator's labor) varied from -2.1 per cent to 28.2 per cent, averaging 12.2 per cent. The cost of producing the chief crops, butterfat, poultry products, and pork, varied as follows: Cotton from 3.5 to 16.3 cts., averaging 10.2 cts. per pound; corn 32 cts. to \$1.52, averaging 75 cts. per bushel; oats 19 cts. to \$1.09, averaging 41 cts. per bushel; lespedeza hay \$1.61 to \$48.47, averaging \$4.61 per ton; butterfat 16 to 88 cts., averaging 41 cts. per pound; eggs 10.7 to 64.9 cts., averaging 19.7 cts. per dozen; chickens (meat) 14 cts. to \$1.51, averaging 61 cts.; and dressed pork \$2.95 to \$25.32, averaging \$10.65 per hundred pounds.

From 44.4 to 230.4 hours of man labor, averaging 104.5 hours, and from 22.1 to 91.9 hours, averaging 37 hours, of horse labor were used per acre of cotton; and 21.4 to 153.4 hours, averaging 41.6 hours of man labor, and 14.9 to 163 hours, averaging 33.8 hours, of horse labor per acre of corn. The cost per animal unit of maintaining work stock varied from 9.2 to 25.1 cts., averaging 13.9 cts., per hour of work.

Cost of producing winter wheat and incomes from wheat farming in Sherman County, Oreg., R. S. WASHBURN and H. D. SCUDDER (*U. S. Dept. Agr. Bul.* 1446 (1927), pp. 40, figs. 12).—This bulletin is based on data on the cost of the factors of production and farm earnings obtained by personal interviews, 450 records being obtained, divided nearly equally among the years 1920, 1921, and 1922. The area studied is dry-farmed, approximately 36 per cent of the average acreage per farm in 1922 being in winter wheat, 39 in summer-fallow, 4 in other crops, 19 in pasture, and 2 per cent in waste land. So far as pos-

sible the data were reported in terms of physical requirements. The quantity requirements of labor and materials were analyzed, and the effect of differences in methods and practices on costs and returns were measured.

Tenure; distribution of livestock; farm area and capitalization; receipts, expenses, and earnings; quantity and value of products used on the farm; the cost and utilization of man labor, horse work, farm machinery, and their relation to the size of farm; costs by tenure; cash and noncash costs of production; variation in cost per bushel; and the relation of yields to costs are discussed.

Itemized estimates are included on the cost of production for 1923 and 1924, and suggested plans for the organization and management are given for a 640-acre farm, a 1,280-acre farm operated with horses, and a 1,280-acre farm operated with tractors.

Cost of using horses, tractors, and combines on wheat farms in Sherman County, Oreg., R. S. WASHBURN and H. D. SCUDDER (*U. S. Dept. Agr. Bul. 1447 (1926), pp. 44, figs. 12*).—The purpose of this study is to show the probable costs of using combines, horses, and tractors, and to present the important points to be considered in the selection of combines and motive power. The bulletin is based on data obtained in the study noted above. The kinds, amounts, costs, economy, efficiency, seasonal distribution, advantages and disadvantages, etc., of horse and tractor work, and the types of, and the cost and the advantages and disadvantages of using combines are discussed. Comparative costs are given for harvesting and threshing with horse and tractor-drawn combines; for harvesting and marketing bulked and sacked wheat cut with tractor-drawn combines; and for harvesting, threshing, and marketing wheat where combines and where headers and stationary threshers were used.

Incomes from farming and cost of apple production in the Shenandoah Valley, Frederick County, Va., C. R. SWINSON (*U. S. Dept. Agr. Bul. 1455 (1927), pp. 31, figs. 9*).—The study is based upon records for the period 1916–1920 from 32 general farms, on which less than 25 per cent of the receipts were from apples; 45 mixed farms, with 25 to 75 per cent of the receipts from apples; and 48 orchard farms, with 75 per cent or over of the receipts from apples. The labor income and return on farm valuation were \$235 and 3.5 per cent, \$618 and 4.9 per cent, and \$2,443 and 9.4 per cent, respectively, for the 3 types of farms. The bulletin is devoted principally to presenting data on farm organization and the costs of production for the 48 orchard farms and to analyzing such data to determine the most effective form of organization from the standpoint of lowering costs and increasing net returns.

On the 48 orchard farms the labor income per farm and the return on farm valuation increased for each 1,000-bbl. production group from \$292 and 3.2 per cent for the below 1,000-bbl. group to \$9,627 and 15.3 per cent for the above 4,000-bbl. group. The average yield per acre also increased from 28 to 53 bbls., except for a small decrease in the 3,000 to 4,000 bbl. group. The fixed costs (interest, operator's labor, cost of keeping work stock, repairs, buildings, machinery, depreciation, taxes, insurance, etc.) and the variable costs (hired labor, fertilizer, spraying, and harvesting) decreased from \$2 and \$1.58 per barrel for farms having 50 acres or less of bearing trees and a production of 40 bbls. or less per acre to \$1.04 and \$1.50 for farms having over 50 acres of bearing trees and a production of over 40 bbls. per acre.

Increasing farm profits with more early potatoes in northern Indiana, M. H. OVERTON (*Indiana Sta. Bul. 305 (1926), pp. 28, figs. 13*).—The yields, costs of growing, returns from, quality of, markets for, marketing of, and the place of early potatoes on northern Indiana farms are discussed. It is estimated that 10,000 additional acres of early potatoes can be profitably grown, and that

after deducting the extra cash cost of from \$120 to \$130, 5 acres of early potatoes will probably return \$275 more for the extra 225 hours of man labor, 65 hours of horse labor, and 12.5 tons of manure required over an equal acreage of corn.

Washington agriculture.—Part 6, Poultry. Part 7, Recommendations and resolutions (*Wash. State Col. Ext. Bul. 134 (1926), pts. 6, pp. 42, figs. 38; 7, pp. 10*).—Data submitted to and recommendations and resolutions passed by the Economic Conference held at Tacoma, Wash., on August 30 and 31, 1926. Part 6 of this bulletin is by J. S. Carver and W. D. Buchanan. Part 7 is in mimeographed form.

Adjusting agricultural production and distribution in the Clarksburg area to meet home market demands, W. W. ARMENTROUT (*West Virginia Sta. Bul. 212 (1926), pp. 40, figs. 9*).—This bulletin is the second of the series previously noted (*E. S. R.*, 52, p. 493) and presents the results of a study of food consumption in Clarksburg and its trade area and of farm production in Harrison County, W. Va., made during the summer of 1925. The freight shipments of the commodities, incoming and outgoing from Clarksburg, were summarized from freight records of both car lot and less than car lot shipments for the period June 1, 1924, to May 31, 1925. The estimates of commodities sold from farms were based on a canvass of 241 farms comprising about 15 per cent of the farm land of Harrison County. Tables are given showing quantities shipped in of potatoes, cabbage, onions, tomatoes, strawberries, vegetables, apples, livestock, packing house products, poultry and eggs, dairy products, and concentrated feeds and hay, and the possibilities of increased local production are discussed.

Agricultural progress in a typical Maryland community, J. E. METZGER (*Maryland Sta. Bul. 285 (1926), pp. 23-60*).—This study is based upon the records of the Enterprise Farmers' Club of Sandy Spring, Md., an association of approximately sixteen members which has existed since 1865. The association was formed "for improvement in agriculture upon the sociable principle of a mutual interchange of visits." It meets monthly at members' homes in rotation "to inspect the crops, stock, farm implements, and conveniences, and inquire into the modes of culture and general system of arrangement pursued by the member at whose house we may be. A free interchange of ideas upon agricultural subjects will be expected on the part of all, and if any member is making experiments which are likely to be useful or interesting, we shall take special care to notice their progress and results."

The practices, experiments, results, etc., of the members in crops, rotations, maintenance of fertility, dairying, livestock production, etc., are traced through the life of the club. Tables are given showing the prices and wages of different periods since the organization of the club and the date of the first use of modern farm machines by the members.

An outline of the New York State system of taxation, M. S. KENDRICK (*N. Y. Agr. Col. (Cornell) Ext. Bul. 152 (1926), pp. 21, figs. 4*).—In conjunction with work previously noted (*E. S. R.*, 56, p. 686), a study is reported of sources and the apportionment of State and local taxes and the purposes for which each is expended. More than 76.3 per cent of the total levy in 1924 was on general property. The general property tax constitutes 22.44 per cent of the revenues of the State, 90.33 of the city, 98 of the county, 72.27 of the township, 99.85 of the village, and 100 per cent of school districts. The index numbers for general property levies have increased from 110 in 1915 to 230 in 1924 (1910-1914=100). Among the reasons for present-day high taxes are the great expansion of Government functions, high prices—the index number for wholesale prices in 1924 being 152 (1910-1914=100), and high wages—the index

number for union wages in 1924 being 233 (1910-1914=100). More State support of roads and schools, elimination of the State levy on real estate, increased return of taxes collected to local units, use of other taxes such as an increased income tax, gasoline tax, etc., and changes in the administration of the general property tax are suggested as methods of easing the tax burden.

Michigan farmers' tax guide, R. W. NEWTON (*Michigan Sta. Circ. 100* (1927), pp. 11).—This gives information as to assessing property, levying and collecting taxes, and the sale and redemption of delinquent real estate, and also a farm tax calendar.

The McNary-Haugen plan as applied to wheat, A. E. TAYLOR, J. S. DAVIS, and E. M. BRAND (*Wheat Studies, Food Research Inst. [Stanford Univ.], 3* (1927), Nos. 4, pp. 177-234; 5, pp. 235-264).—Leading proposals for farm relief in the United States have rested on the assumption that the unprosperous condition of American farmers is caused by the low prices of farm products, due to there being surpluses produced that must be sold abroad at prices which depress the prices of the entire crops. The favorite remedy proposed has been to segregate the exportable surpluses, sell them abroad for what they will bring, and maintain domestic prices, behind the tariff wall, on levels substantially higher than would prevail otherwise. The central features of what is designated the McNary-Haugen plan of farm relief, so far as they apply to wheat, "are the operations of a Federal board, seeking to maintain domestic prices at enhanced levels behind the tariff wall, to segregate the surplus over domestic requirements and sell it for what it will bring, and to distribute operating costs and losses among the growers by means of an equalization fee on each bushel sold."

The purpose of the two publications is to examine the way a measure based on the McNary-Haugen plan might be expected to work with respect to wheat. No discussion is made of the assumptions underlying the proposed measures, constitutionality, nor other controversial matters.

No. 4 discusses the operating problems and probable economic consequences that would have followed if either of the McNary or Haugen bills introduced at the Sixty-ninth Congress had become a law, the analysis being based upon the assumption that the American price would be maintained by means of a sufficiently high tariff at a price at least 50 cts. a bushel higher than the Canadian price. The purpose of the bills, the policies, problems, and results of the United States Grain Corporation during the war, the standard for the domestic price, price fixing, price differentials between different grades of wheat in different sections of the country, the sources and disposition of the operating funds, the fixing and collection of equalization fees, the continuation of trading in wheat futures, the problems of wheat and flour exports and of the carryover, the effect on prices of flour and feed, the effect on the cost of living, and the effects on acreage, world prices, and the American farmer are discussed.

The general conclusions reached by the authors are that administratively the measure is workable if (1) the board is composed of men who would command respect for experience, judgment, vision, and courage, and who would evince ability to work together, to draw upon needed technical skill in various lines, and to enlist and retain the support of the growers and the business interests involved; (2) there is reasonable assurance that the policy of Congress and the policies of the board would not be subject to arbitrary reversal or to vacillating execution; (3) adequate working capital is available for all emergencies; (4) the operations are conducted with a minimum of disturbance to current relationships and practices in the grain trade and milling industry, including operations on the grain exchanges; (5) effective working agreements are concluded with

elevators, mills, and exporters, as well as with cooperative marketing associations; and (6) a general disposition on the part of the board is to limit, rather than to magnify, its responsibilities.

The principal sources of danger of a breakdown are the possibilities that the board can not secure competent technical organization and managerial ability; that the board may be swamped with a large and relatively unsalable surplus in a year of coincidence of large domestic crop with large world crop and low wheat prices; that several years of successive large crops and low prices might so magnify the carryover and losses on exports and so increase the difficulty of collecting adequate equalization fees as to break the board under the burden of carrying charges and frozen purchases; and the dangers from vacillation in the board's policy, withdrawal of political support from Congress, and the collapse of the growers' confidence in the undertaking. The crucial point of the proposition is deemed to be that the adoption and success of the policy will result in the rapid expansion of wheat acreage, increase in exportable surplus, and a future net price little or no higher, and possibly even lower, under the operation of the scheme than if no such measures had been adopted.

The analysis in No. 5 is made on the basis that the present tariff on wheat, 42 cts. a bushel, will continue. The fundamental limitations upon price increases of wheat, due to the intrinsic milling superiority of Canadian hard spring wheat, the tariff, and the existing regional relationships within the American milling industry in connection with freight rates on wheats and flour and with the geographical distribution of wheat production, are discussed. Tables are given showing weekly from July 7, 1923, to June 26, 1926, the margins between Winnipeg prices, plus 42 cts., and Minneapolis prices on the following bases of comparison: (1) Futures prices; (2) top cash prices of No. 1 Manitoba Northern wheat at Winnipeg and No. 1 Dark Northern Spring wheat at Minneapolis; (3) low cash prices of No. 3 Manitoba Northern at Winnipeg and No. 1 Dark Northern Spring at Minneapolis; (4) high cash sales of the same grades; (5) cash closing prices of the same grades; and (6) high cash price of No. 3 Manitoba Northern and high quotations on the basis of the nearest future of No. 1 Dark Northern Spring wheat. The annual averages on bases 2 to 6 ranged from 7.8 to 15.1 cts., averaging 10.2 cts., in 1923-24; from 16.1 to 33.3 cts., averaging 21.7 cts., in 1924-25; and from 5.5 to 17.5 cts., averaging 12 cts., in 1925-26.

Conclusions are reached that (1) with the present tariff of 42 cts. a bushel the prices of American spring wheats at Buffalo, the natural import threshold for Canadian wheat, could not be raised, except in unusual years, by more than 10 or 12 cts. a bushel; (2) that at most other markets prices of spring and winter wheats could not be raised appreciably over increase in price of hard spring wheats at Buffalo without stimulating imports and disrupting regional competitive relations in the milling industry; and (3) that the slight advance in prices, partially offset by equalization fees, would hardly justify the experiment.

An addendum to No. 5 contains observations on the concessions made in the latest bills before the Sixty-ninth Congress to the opponents of the central features of the plan. The conclusion is reached that the proposed alternatives or supplements to the equalization fee—loans to cooperative marketing organizations and price insurance—would impose heavier responsibilities on the board and decrease its chances of success without promising larger price enhancement to growers.

Kentucky livestock auction sales organizations, E. C. JOHNSON (*Kentucky Sta. Bul.* 270 (1926), pp. 211-256, figs. 13).—The organization, method of operation, accounting methods, rates, yards and equipment, advantages and disadvantages, and the fundamentals for successful operation of livestock auction

sales organizations are described. The study is based on a survey of 10 of the 13 organizations in central Kentucky. From October 1, 1924, to October 1, 1925, 8 of these organizations held 367 sales, at which 244,025 sheep and lambs, 143,851 hogs, and 105,366 cattle and calves were sold, the gross sales amounting to \$7,736,191.61. The costs per head in 5 organizations for which cost records were kept varied from 18.2 to 34.3 cts., averaging 22.7 cts., of which labor and salaries constituted 65.7 per cent, yard costs 18.9, office expenses 6.1, losses on livestock 6.2, and other costs 3.1 per cent. The average profits ranged from 2.4 to 13.3 cts. per head, averaging 6.7 cts.

Cooperative marketing and price control, O. B. JESNESS (*Kentucky Sta. Bul.* 271 (1926), pp. 257-279).—A general statement of the possibilities and limitations of cooperation in improving marketing and obtaining better prices for farm products.

The balance of trade in farm products, L. P. JEFFERSON (*Jour. Farm Econ.*, 8 (1926), No. 4, pp. 451-461).—A report on one of a series of studies undertaken by the Massachusetts Agricultural College on the food supply of New England. Data are presented as to the food supplies consumed in the city of Fitchburg, Mass., the food demand, and the sources of supply. The study was made to ascertain the racial and national food preferences, the quantities of specific products required, and the quantities of various products supplied from local sources. Fitchburg had a population in 1920 of 41,029, of which, according to the State census of 1915, 35 per cent were foreign born and 43 per cent native born but of foreign parentage. The percentages of the dietary of various foods in 1919 were cereals 18.3, canned goods 2.05, dairy products other than milk and cream 0.53, eggs 2.3, fats 2.66, fish 0.96, fruits 9.85, meats 5.76, milk and cream 28.36, poultry 0.38, sugar 3.6, and vegetables 25.12. The percentages of different commodities received from local sources were eggs 36.4, fruits 20.5, meats 7.1, milk and cream 100, poultry 45.6, and vegetables 18.8.

Food costs and city consumers, C. E. ARTMAN (*Thesis, Columbia Univ., New York, 1926, pp. 171, figs. 13*).—A thesis submitted to Columbia University in partial fulfillment of the requirements for the degree of doctor of philosophy. It treats in detail investigations previously noted (*E. S. R.*, 56, p. 387).

Crops and Markets, [January-February, 1927] (*U. S. Dept. Agr., Crops and Markets, 4 (1927), Nos. 1, pp. 32, figs. 3; 2, pp. 33-80, figs. 3*).—The usual tabulations, summaries, charts, and notes are given regarding crops, dairy products, cold-storage holdings, fruit and vegetable shipments, livestock and livestock products, prices and price movements of agricultural products, seeds, exports of grain, and world agriculture, formerly published in the Monthly Supplement to Crops and Markets (*E. S. R.*, 56, p. 586). Special reports are included in No. 1 on the December 1 pig survey, and prices to jobbers and total shipments of 14 fruits and vegetables, 1926, while in No. 2 special tables and reports are given on the agricultural outlook for 1927; the numbers, value per head, and total value of livestock on farms, January 1, 1925, 1926, and 1927, with monthly prices, 1910-1927; cattle, sheep, and lambs on feed, January 1; monthly prices of dairy and poultry products, 1910-1927; number of persons employed per farm on farms of crop reporters, December 1, 1923-1926, and January 1, 1924-1927; monthly corn and hog ratios by States, 1924-1926; yearly farm wages and index numbers, 1910-1927, and the average wages by States for January, 1925-1927; stocks, production, uses, and grades of potatoes, January 1, 1927; statistical report of the livestock and meat situation, December and January to December, 1925 and 1926; and the tariff rates on representative agricultural products under the tariff acts of 1913, 1921, and 1922.

No. 2 also includes tables showing (1) prices of livestock and meats; (2) weights and prices of stockers and feeders, and receipts of dairy and poultry

products, and wheat, corn, and oats at stated markets; (3) prices of butter and cheese, prices to jobbers of fruits and vegetables, and carload prices of hay, straw, and feedstuffs at important markets; and (4) other data formerly published in the weekly issues of Crops and Markets (E. S. R., 56, p. 387).

The agricultural map of U. S. S. R. [trans. title], I. F. MAKAROV, edited by N. I. VAVILOV (*Trudy Prikl. Bot. i Selek. (Bul. Appl. Bot. and Plant Breeding)*, 1926, Sup. 28, pp. 90, pl. 1, figs. 18; Eng. abs., pp. 85-90).—A map with explanatory text showing the acreage and distribution of different crops in the Union of Socialistic Soviet Republics.

The agricultural colonisation of the Zionist Organization in Palestine, A. RUPPIN, trans. by R. J. FEIWEL (*London: Martin Hopkinson & Co., 1926, pp. VIII+209, fig. 1*).—A brief history is given of the Zionist colonization, and the agricultural colonization policy of the Zionist Organization and the present state of the settlement are described. The points of dispute in the policy—individual or group settlement, extensive or intensive cultivation, settlement of immigrants with private means, the future system of administration, etc., are discussed.

International yearbook of agricultural statistics for 1925-26 (*Inst. Internatl. Agr. [Rome], Ann. Internatl. Statis. Agr. (Internatl. Yearbook Agr. Statis.)*, 1925-26, pp. XCVIII+558).—This is one of a series previously noted E. S. R., 54, p. 289) and gives tables showing the territorial area, population, apportionment of areas, agricultural production, and numbers of livestock by countries; the area, production, and yield of each of the principal crops by countries and continents; the numbers of different species of livestock; the international trade in the chief agricultural products by countries and continents; the prices of various products; ocean freight rates on cereals and cotton; the production, exportation, and importation by countries of fertilizers and chemical products useful in agriculture; and the rates of exchange. Texts, notes, table headings, etc., are in English and French.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Workers in subjects pertaining to agriculture in State agricultural colleges and experiment stations, 1926-1927, M. A. AGNEW (*U. S. Dept. Agr., Misc. Circ. 87 (1927), pp. III+130*).—The usual annual list (E. S. R., 55, p. 288).

Agricultural evening school classes in dairying, C. LUKER (*Tex. State Bd. Vocat. Ed. Bul. 199 (1926), pp. 30*).—This bulletin is based on 2½ years' experience in organizing and conducting evening school classes dealing with different phases of the dairy industry that reached approximately 300 milk producers. The possibilities for such courses, the method of organizing, the methods and devices used in teaching, the supervision of practice, and the results are described.

What a poultry project should contain, H. L. SHRADER (*Poultry Sci.*, 5 (1926), No. 6, pp. 274-280).—A critical discussion of extension projects with poultry.

Fruit tree and orchard judging, W. P. DURUZ (*California Sta. Circ. 309 (1927), pp. 27, figs. 3*).—Score cards for judging fruit trees and orchards, and directions for using such cards and for organizing and conducting judging contests are given.

Clothing and textiles, M. L. MATTHEWS (*Boston: Little, Brown & Co., 1926, rev. ed., pp. XII+180, figs. 83*).—This is a revision of a textbook entitled Sewing and Textiles, previously noted (E. S. R., 45, p. 697).

How to make and use an operating statement, W. POWELL (*N. Y. Agr. Col. (Cornell) Ext. Bul. 156 (1927), pp. 31, fig. 1*).—The making, analysis, and use of

an operating statement for a business as a whole and for departments of a business are explained by means of typical examples.

The relative merits of circles and bars for representing component parts, W. C. EELLS (*Jour. Amer. Statis. Assoc.*, 21 (1926), No. 154, pp. 119-132, figs. 2).—The results are given of an experiment made with a class of 93 to 97 students in general psychology to ascertain the relative ease, rapidity, and accuracy in reading circle and bar diagrams. The results show (1) that there is a slight advantage in favor of circles in ease and rapidity of reading; (2) that circle diagrams are read more accurately, both as regards number and size of errors, and that the accuracy of judgment increased with the number of subdivisions in the case of circles and decreased in the case of bars; and (3) that in judging parts in circles 25 per cent of the students considered areas, 23 per cent central angles, 51 arcs, and only 1 per cent chords, but there was no significant difference in accuracy of judgment by the different methods.

Further studies in the graphic use of circles and bars (*Jour. Amer. Statis. Assoc.*, 22 (1927), No. 157, pp. 31-39, figs. 8).—This article consists of a discussion and criticism of the study noted above.

Part 1, A Discussion of the Eells' Experiment, by R. von Huhn, criticizes the methods used and reaches the conclusion that the circle may be preferable to the bar only where a single total with rather numerous component parts is to be shown and where the parts need to be presented not only singly but also in groups.

Part 2, Some Additional Data, by F. E. Croxton, presents the results of an experiment to test the accuracy of the judgment of observers with bar and circle charts showing 1:1½ and 1:4 ratios. These results show that of the 287 observers, 132 estimated correctly from the 1:1½ bar chart and 95 from the pie diagram, and 119 and 74, respectively, from the 1:4 bar chart and pie diagram.

Use of motion pictures in agricultural extension work, F. W. PERKINS, H. GREENE, and G. R. GOERGENS (*U. S. Dept. Agr., Misc. Circ. 78 (1926), pp. 22, figs. 10*).—Information is given for the use of agricultural extension agents and others regarding motion picture equipment, its operation, film programs, etc.

Motion pictures of the United States Department of Agriculture (*U. S. Dept. Agr., Misc. Circ. 86 (1926), pp. II+31*).—A list of films of this Department available for distribution and data on how to obtain them.

FOODS—HUMAN NUTRITION

Food and health, R. H. A. and V. G. PLIMMER (*London and New York: Longmans, Green & Co., 1925, pp. [5]+64, pl. 1, figs. 11*).—This popular presentation of the essential principles governing the selection of food includes the scheme for the graphic representation of complete and incomplete diets noted previously (*E. S. R.*, 56, p. 290).

Food and health manual for classes in nutrition, R. GEORGE (*Toronto: Canad. Red Cross Soc., pp. II+117, figs. 15*).—A manual on the essential principles of food and nutrition.

Nutrition laboratory, F. G. BENEDICT (*Carnegie Inst. Wash. Yearbook 25 (1925-26), pp. 139-150*).—This annual report contains, as previously (*E. S. R.*, 55, p. 188), a brief outline of investigations in progress and abstracts of publications of the laboratory during the year, several of which have been noted from their original sources.

The relation of cooking to the study of the quality and palatability of meat, P. E. HOWE (*Jour. Home Econ.*, 19 (1927), No. 1, pp. 8-15).—This paper,

of particular value to those engaged in the studies of the quality of meat, deals with the physical and chemical changes occurring in meat on cooking and the effect of various factors on these changes, the most satisfactory methods of cooking meat for the purpose of judging its quality, and the various factors constituting what is known as palatability, with methods for evaluating these factors. Several references to the literature on the subject are included.

The art of cooking and serving, S. F. SPLINT (*Cincinnati: Procter & Gamble Co., 1926, pp. [4]+252, pl. 1, figs. 73*).—This small volume and the one noted below are published by the manufacturers of Crisco. Directions for table service with and without servants, selected recipes, and typical menus for the different seasons of the year are included, with many photographic illustrations, some in color.

A calendar of dinners with 615 recipes, M. H. NEIL (*Cincinnati: Procter & Gamble Co., 1925, 26. ed., pp. 233, figs. 22*).—This is chiefly a collection of menus, with accompanying recipes, for every day in the year. As in the preceding book, Crisco is the shortening agent used in all of the recipes. A description of the processes involved in the manufacture of Crisco is included.

Dental caries and pulp sequelae resulting from experimental diets, J. A. MARSHALL (*Jour. Amer. Dental Assoc., 14 (1927), No. 1, pp. 3-37, figs. 45*).—The particular object of the experimental work reported was a comparison of the changes produced in rats on deficient diets with those reported in the literature for dogs. The diet used for most of the work reported was one deficient in vitamin A, but furnishing an adequate supply of vitamin D in the form of irradiated lard and of vitamin B in yeast. On this diet enamel and dentin hypoplasia commonly occurring in the teeth of puppies on similar deficient diets were not noted nor was there evidence of caries in the teeth of the young rats, but on maturity a form of caries developed which resembled more closely the type found in adults than in children. Pulp lesions were sometimes found in teeth which did not show caries. The feeding of vitamin A after the development of caries did not check the progress of the decay.

The basal metabolism and the specific dynamic action of foods in children in various conditions of nutrition, A. F. MORGAN and G. D. HATFIELD (*Amer. Jour. Diseases Children, 32 (1926), No. 4, pp. 516-523*).—In connection with a nutritional study of children at the California State Schools for Deaf and Blind, basal metabolism determinations were made on 9 girls and 7 boys from 7 to 14 years of age. Of these, 10 were tested two or three times at intervals of a month or more.

The 6 children classed as of normal weight by the Baldwin-Wood standards for height and age had metabolic rates falling within ± 10 per cent of the Benedict-Talbot standards of weight and surface area. Of the 4 children classed as underweight, 2 had nearly normal and the other 2 high metabolic rates. Of the 6 children classed as overweight, 3 had low, 2 normal, and 1 high metabolic rates. Three of the girls showed wider divergencies from the Benedict height standards (E. S. R., 53, p. 862) than from the older weight and surface area standards.

In an effort to determine whether leanness and fatness may not be connected with some peculiarity in response of the individual to the specific dynamic action of food, 4 boys aged 10 years, 2 of whom were distinctly overweight and 2 of normal weight, were tested for an increase in metabolism following meals predominating in carbohydrate and protein, respectively. Although the increase in metabolism after the protein meal was more than twice that following the carbohydrate meal, there were no distinctive differences between the increases of the overweight and the normal boys.

Chinese diet in the light of modern knowledge of nutrition, H. WU (*Chinese Social and Polit. Sci. Rev.*, 11 (1927), No. 1, pp. 56-81, fig. 1).—This discussion of the adequacy of the Chinese diet is based upon the dietary studies of middle-class families in north China reported by Adolph (E. S. R., 54, p. 591) and a similar study of the composition of Peking dietaries made by the author. The latter study included 35 families composed of 146 adults and 47 children. In estimating the adult units the children were reckoned as fractions of adults according to the energy requirement for their various ages.

The diets furnished an average of 2,960 calories and 85.9 gm. of protein per man per day, these figures being considerably higher than those reported in the north China study. The percentage distribution of the foods among the various types was as follows: Cereal products 44.6; legumes and beans 7.5; meat, fish, eggs, and milk 5.2; fruits and vegetables 36.1; oils, sugar, and starch 2.3; and other foods 4.4 per cent. The distribution among the different types of food of protein and calories was cereals 71.1 and 72 per cent, respectively, legumes 11.5 and 5, vegetables and fruits 3.6 and 3.7, starch 0 and 0.7, fats and oils 0 and 7.8, meat and fish 8.3 and 6, eggs 2.3 and 0.8, milk and cheese 0.06 and 0.06, and miscellaneous 3.1 and 4.1 per cent.

The author is of the opinion that the calorie value of the Chinese diet is ample according to American standards for body weight, but that, considering the low biological value of the chief sources of protein, the protein allowance represents the bare minimum. The diet is considered to be barely adequate in vitamins A and B and adequate in C. The supply of phosphorus and iron is thought to be adequate and that of calcium probably inadequate.

As the most practical means of improving the diet, the author recommends an increase in the use of eggs, bean products, green vegetables, and fruits, the use of slightly milled grains instead of highly refined products, and modifications in methods of cooking to conserve vitamins and minerals.

Further evidence that small quantities of copper, manganese, and zinc are factors in the metabolism of animals, J. S. MCHARGUE (*Amer. Jour. Physiol.*, 77 (1926), No. 2, pp. 245-255, figs. 2).—Rats confined to a synthetic diet and under conditions said to be the best that could be improvised at the time gave results which the author interprets as indicating that compounds of manganese more definitely and possibly copper and zinc also have important biological functions in animal metabolism. "It is assumed that the compounds of these elements as they occur in the natural state in green leaves and seeds of mature plants and the vital organs of animals have a much more active biological potency than could be expected from feeding equal proportions of a crystalline salt of these metals in a synthetic diet."

The nutritional value of oysters and other sea food, D. B. JONES (*Amer. Jour. Pub. Health*, 16 (1926), No. 12, pp. 1177-1182, fig. 1).—This is essentially a summary of studies conducted at the Bureau of Chemistry, U. S. D. A., on the vitamin content of oysters and the equality of the proteins of oysters, clams, and shrimps.

To overcome difficulties in weighing the oysters in the vitamin tests, the oysters were frozen and weighed before thawing. In the vitamin B studies both protective and curative tests were employed. In both 3.5 gm. of oysters proved to be nearly, but not quite, sufficient to provide the necessary amount of vitamin B. Calculated on the dry basis, this amount corresponds to 0.56 gm. daily. "On this basis, oysters compare favorably as a source of vitamin B with foods which are recognized as excellent sources of this dietary factor." The cure of xerophthalmia induced by vitamin A-free diets was used as the criterion for estimating vitamin A. On 3.5 gm. daily, the rats showed rapid improvement in the condition of the eyes and in the rate of growth. On 2 gm.

daily, recovery from xerophthalmia was equally rapid but resumption of growth was slow.

In the protein studies, the oysters and clams were heated to coagulate the protein and then dried and ground to a meal and the shrimp muscle was dried and ground without heating. The dried materials were used as the sole source of protein at a 9 per cent crude protein level and their growth-promoting properties determined by the gains in weight in a 100-day period and by the gains per gram of protein consumed. The gains made on the shrimp and clam diets were about the same and considerably higher than on the oysters. Expressed in grams per gram of protein consumed during a 6-week period, the average values were clam 2.05, shrimp 2.15, and oysters 1.27 gm. These results are thought to indicate that "the proteins of clams, shrimp, and oysters compare favorably with the proteins of other articles that are highly regarded for their nutritive value."

The distribution of some of the amino acids in shrimp muscle was found to be as follows: Cystine 1.78 per cent, arginine 10.24, histidine 3.78, lysine 7.60, tryptophane 1.21, tyrosine 4.88, aspartic acid 6.98, and glutamic acid 15 per cent.

Antirachitic content of canned oysters (*Wisconsin Sta. Bul. 388 (1926), pp. 124, 125*).—Preliminary studies by H. T. Parsons indicate that both raw and canned oysters contain vitamin D in appreciable amounts.

Biological food tests.—IX, Vitamin A in three varieties of cheese, A. F. MORGAN (*Amer. Jour. Physiol.*, 78 (1926), No. 1, pp. 11–16).—In continuation of the studies previously noted (*E. S. R.*, 53, p. 62), the author reports that California cream cheese (Cheddar type) and Limburger cheese "appear to retain in an unusually concentrated form the vitamin A of the milk from which they are made." Imported Swiss cheese did not appear to be as rich in vitamin A. The evidence upon which these conclusions are based consisted of curative experiments conducted on only 4 or 5 rats for each cheese. The first two cheeses were fed in amounts of 1 gm. daily for 2 weeks, followed by 0.5 gm. daily. The Swiss cheese was fed in amounts of 0.5 gm. daily for 3 or 4 weeks, during which time there was no improvement, and then in amounts of 1 gm. daily. On the larger amount normal growth was secured, but the eye trouble was not cured in 3 out of 4 cases.

Losses of vitamin B in vegetables in cookery (*Wisconsin Sta. Bul. 388 (1926), pp. 125, 126*).—To supplement the studies of Peterson and Hoppert on the comparative losses of mineral matter from vegetables with different methods of cooking (*E. S. R.*, 55, p. 87), the losses of vitamin B in string beans and cauliflower cooked by the same methods were determined by H. T. Parsons.

With string beans the greatest loss occurred when they were cooked in large amounts of water and the smallest losses when cooked in the pressure cooker. In the cauliflower studies the pressure cooker was not used on account of the strong flavor developed by this process. In the steam process the steam was allowed to escape for 5 minutes and then confined in the vessel for the next 10 minutes, under which conditions there was no discoloration and but little increase in flavor. As judged by curative tests, some losses of vitamin B took place with all the methods. When a large amount of water was used this loss amounted to about 30 per cent.

Comparison of the content of vitamin B in fresh yeast and in dried yeast prepared from it [trans. title], A. SCHEUNERT and M. SCHIEBLICH (*Chem. Zelle u. Gewebe*, 13 (1926), No. 1, pp. 79–86, figs. 5).—The vitamin content of a commercial dried yeast prepared from waste brewery yeast by a process to remove the bitterness, followed by thorough washing and drying, was compared with that of the fresh yeast by the usual feeding experiments on young rats and protective experiments with pigeons on a polished rice diet. No appreciable

difference could be noted between the effect of the dried yeast and a comparable amount of the fresh in either case.

Studies in the physiology of vitamins.—IV, Vitamin B in relation to gastric motility, G. R. COWGILL, H. J. DEUEL, JR., N. PLUMMER, and F. C. MESSER (*Amer. Jour. Physiol.*, 77 (1926), No. 2, pp. 389-401, fig. 1).—The experiments reported in this continuation of the series of studies previously noted (*E. S. R.*, 54, p. 194) were planned for the purpose of determining whether the progressive loss of appetite characteristic of vitamin B deficiency in dogs is accompanied by any changes in the hunger contractions of the empty stomach.

Four dogs having permanent gastric fistulas were fed basal diets free from or extremely low in vitamin B (*E. S. R.*, 46, p. 358) but adequate in other respects. From time to time the motility of the empty stomach was recorded by means of an inflated rubber balloon placed in the stomach and connected with a chloroform manometer and recording device. When the animals had lost their desire to eat, beef juice was administered but with no effect upon the appetite. Harris vitamin powder was then administered with prompt restoration of the appetite.

The tracings of the hunger contractions showed no remarkable changes in character in the early stages of the vitamin B deficiency but almost complete atony in later periods. The administration of vitamin B was followed by rapid improvement in the stomach musculature as shown by the regularity of muscle contractions.

In discussing the significance of these experiments, the authors conclude that to the list of conditions which have been demonstrated to produce gastric atony must now be added prolonged subsistence on a diet low in vitamin B. It is suggested that the lack of appetite during convalescence from certain diseases may be due to the same condition and should be taken into consideration by clinicians.

"It is difficult, when dealing with such a parallelism as has been described, to decide whether or not vitamin B maintains the desire to eat simply by aiding in the preservation of the normal gastric tone. The marked systemic manifestations characteristic of advanced cases of vitamin B deficiency suggest that the loss of the desire to eat in such cases is due as much to a generalized systemic disturbance as it is to an abnormal condition localized in the alimentary canal."

Fasting and rice disease in pigeons; the parallelism of loss of body weight, temperature, and respiration rate; the absence of B vitamins from the cortex of the beef suprarenal, O. W. BARLOW (*Amer. Jour. Physiol.*, 78 (1926), No. 2, pp. 322-324, fig. 1).—This study is of interest not only in demonstrating that extracts of suprarenal cortex do not contain appreciable amounts of antineuritic vitamin, but also that the decreases in body weight, temperature, and respiration of pigeons on an exclusively polished rice diet are similar to, although more gradual, than the corresponding changes in fasting pigeons.

Vitamin studies, II [trans. title], Z. WIERZCHOWSKI (*Pam. Państw. Inst. Nauk. Gosp. Wiejsk. Puławach (Mém. Inst. Natl. Polon. Écon. Rurale Puławy)*, 5 (1924), A, pp. 15-69, figs. 3; *Fr. abs.*, pp. 62-69).—In continuation of the investigation previously noted (*E. S. R.*, 49, p. 160), an extensive study is reported of the nitrogen metabolism of polyneuritic pigeons as compared with normal and starving pigeons. The conclusion is drawn that the pathological symptoms induced by a deficiency of vitamin B are due in part to the loss of the power of assimilating digested food and in part to the secondary effects produced in the organism by inanition. Vitamin B is considered an indispensable factor of

assimilation, particularly of protein material. When vitamin B is lacking, the organism is considered to lose its faculty of synthesizing the specific proteins from the amino acids furnished by the digestive organs and the metabolism to acquire more and more a character corresponding to inanition. The vitamin is considered, however, not to take part in the metabolism of the tissues during inanition.

Effects of diet during pregnancy on development of rickets in the offspring, J. V. GREENEBAUM, T. K. SELKIRK, F. A. OTIS, and A. G. MITCHELL (*Jour. Amer. Med. Assoc.*, 87 (1926), No. 24, pp. 1973-1976, figs. 2).—In this investigation the diets of 25 women who previously had had rachitic children were supplemented during the last three months of pregnancy by vegetables, cereals, fruit, eggs, and milk in amounts designed to bring the quality and quantity of the daily food intake up to the proper standards for pregnant women. The standards set were 1 gm. of calcium, 1.45 gm. of phosphorus, and 0.015 gm. of iron, with a total of 2,500 calories daily.

In but few cases were all of the standards reached, but striking improvements were made, as shown by the daily dietary records obtained from each subject by the visiting dietitian in the short period of preliminary observation and during the experimental period proper. It is thought that the standard of calcium was reached, but that the phosphorus intake was slightly below and the iron and caloric intake definitely below the standards set. After delivery the dietary supervision was discontinued and the women for the most part returned to their former dietary habits. None of the babies received cod-liver oil during the eight months of observation, which included clinical and X-ray examination, and in some cases calcium and phosphorus determinations of the blood.

Of the 22 babies under observation, 16 showed rickets on clinical examination and 19 on X-ray examination by the eighth month. One did not develop rickets at all and 1 not until after the eighth month. The diet of the mothers of these 2 babies had most closely approximated the standard set. The degree of rickets appeared to be more closely correlated with the caloric deficiencies of the diet of the mothers than with the mineral intake. The babies whose mothers received a low intake of calories had a higher percentage of the more severe grades of rickets than those whose mothers received a higher caloric intake. None of the babies whose mothers had a caloric intake higher than 1,700 developed more than mild rickets at any time.

In the few cases in which blood examinations were made, the inorganic phosphorus of the mothers' serum during pregnancy was normal while that of the babies' serum was below normal. The calcium content of the serum of both mothers and babies was normal. The calcium content of the breast milk was frequently low but the inorganic phosphorus uniformly normal.

"Our experiment would indicate that if the diet of the mother during the last three months of pregnancy can be made approximately correct in caloric and mineral intake, while it will not prevent rickets, it will have a controlling influence on the development of the disease in her offspring."

Studies on experimental rickets.—XXVIII, Does vitamin D pass into the milk? E. V. MCCOLLUM, N. SIMMONDS, J. E. BECKER, and P. G. SHIPLEY (*Amer. Jour. Diseases Children*, 33 (1927), No. 2, pp. 230-243).—To determine whether it is possible for nursing women to increase the vitamin D content of their milk by taking cod-liver oil and, if so, when the treatment should begin and how long it should be continued, a series of feeding experiments in continuation of the studies previously noted (*E. S. R.*, 56, p. 296) was conducted upon female rats, with the addition of suitable amounts of cod-liver oil to a basal diet supposedly adequate in all respects except for a deficiency in vitamins A and D. A parallel series of experiments was run with butterfat in place of cod-liver oil for the

purpose of determining whether a diet complete in every respect except vitamin D is capable of producing milk with protective value against rickets. The entire time covered in any one experiment extended from about a month before mating until the young were eating the mother's diet, but the individual periods were varied to cover one or all of the periods before mating and during pregnancy and during lactation before and after the young eat of the mother's food.

When the rats were fed cod-liver oil before mating, during pregnancy, and during the first two weeks of nursing, considerable protection against rickets in the young was afforded, but not as much as when the young were continued on the cod-liver oil ration. When the cod-liver oil was fed only during the first two weeks of the nursing period, there was very little protection against rickets. No protection was afforded by the butterfat diet.

These experiments are thought to demonstrate that the vitamin D of cod-liver oil does pass into the mother's milk, but that to insure a considerable amount of this vitamin the diet should be supplemented by cod-liver oil during pregnancy as well as lactation.

Imparting antirachitic properties to foods (*Wisconsin Sta. Bul.* 388 (1926), pp. 121, 122).—A summary of the studies of H. Steenbock and his coworkers on the antirachitic vitamin and its synthesis in food materials by exposure to ultra-violet light.

Note on the anti-rachitic action of irradiated sawdust, O. ROSENHEIM and T. A. WEBSTER (*Biochem. Jour.*, 20 (1926), No. 6, pp. 1340, 1341).—Further proof of the part played by sawdust bedding in promoting growth and calcification of bones in irradiation experiments, as noted by Hume and Smith (*E. S. R.*, 56, p. 295), is afforded by a demonstration that a resinous matter extracted from sawdust by chloroform acquires antirachitic properties on irradiation.

A simple method for deriving the formula for a diabetic diet, W. S. COLLENS and D. H. SHELLING (*Jour. Amer. Med. Assoc.*, 88 (1927), No. 6, p. 396).—The authors have devised a chart for the rapid calculation of diabetic diets from the caloric requirements of the patient and the percentage of total calories to be given in the form of protein. The diets are based on the Wood-yatt ketogenic-antiketogenic ratio of 1.5:1.

MISCELLANEOUS

Thirty-fourth Annual Report [of Arizona Station, 1923], J. J. THORNER ET AL. (*Arizona Sta. Rpt.* 1923, pp. 431-510, figs. 13).—This contains the organization list, an administrative report on the work and publications of the station, a financial statement for the fiscal year ended June 30, 1923, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Report [of] South Mississippi Branch Experiment Station, 1926, E. B. FERRIS and W. S. ANDERSON (*Mississippi Sta. Bul.* 238 (1926), pp. 18).—The experimental work reported is for the most part abstracted elsewhere in this issue.

Report [of] Raymond Branch Experiment Station, 1926, H. F. WALLACE (*Mississippi Sta. Bul.* 240 (1926), pp. 16).—The experimental work reported is for the most part abstracted elsewhere in this issue.

Gleanings from science: Annual report of the director, [Wisconsin Station, 1925-1926], H. L. RUSSELL, F. B. MORRISON, and W. H. EBLING (*Wisconsin Sta. Bul.* 388 (1926), pp. 147, figs. 40).—This contains an account of the activities of the station, a list of the station publications of the biennium, and a financial statement as to the Federal funds for the biennium ended June 30, 1926. The experimental features not previously reported are for the most part abstracted elsewhere in this issue.

NOTES

Arizona University.—A portion of the basement of the agricultural building has been remodeled to provide greater space for the soil physics laboratory.

Arkansas University and Station.—Under plans drawn by the department of agricultural engineering, the department of horticulture is erecting a building on the station farm for packing fruits, in which mechanical graders will be used and the various kinds of packs will be demonstrated. The building will also be available for packing schools.

Michigan College and Station.—The 1927 Junior Farmers' Week was held May 5 and 6. Over 1,600 students from the vocational agricultural high schools participated, an attendance exceeding that of the previous year. The main events of the program were the livestock and crops judging contests. An evening banquet was attended by 1,100 boys and girls, who were addressed by Governor Fred Green and President K. L. Butterfield.

C. H. Spurway, research associate in soils, has recently developed a water soluble test for phosphorus in the soil, somewhat similar to that used in the Soiltex soil reaction test devised by him about three years ago. The phosphorus test is being given further trial before being placed on a production basis.

New appointments in extension work include O. I. Gregg as specialist in landscape architecture, J. W. Sims to succeed O. B. Price as soils specialist, and R. V. Gunn and Arthur Howland as specialists in economics.

Minnesota University.—The corner stone of the new plant industry building was laid March 22.

Cornell University.—An act was passed by the last legislature authorizing the trustees to contract for the foundations for the new plant industry building at a cost of \$100,000. Funds for this portion of the building are available from earlier appropriations for the building program, so that it is expected to complete the foundations this summer. The total cost of the building is estimated at about \$1,250,000. Accommodations will be provided for the departments of botany, plant pathology, pomology, floriculture, and plant breeding.

Dr. R. A. Emerson, head of the department of plant breeding, was recently elected a member of the National Academy of Sciences.

Pennsylvania College and Station.—According to a note in *School and Society*, appropriations totaling for the biennium \$4,234,500, of which \$1,000,000 is for new buildings and plant repairs, were made by the last legislature. The funds provided included \$2,181,000 for general college maintenance, \$403,500 for agricultural research, and \$650,000 for agricultural and home economics extension.

Utah College and Station.—The last legislature authorized the establishment of two experimental farms, one in Carbon County and the other on the peat lands of Sanpete County. Le Moyne Wilson of the class of 1927 has been appointed superintendent of the latter farm.

R. J. Becraft, assistant professor in charge of range management in the college and station, has resumed his range management investigations after a year's botanical study at the University of Chicago. Tracy H. Abell, assistant professor of horticulture and assistant horticulturist, has resigned to take up advanced study.

Beginning July 1, Dr. Joseph A. Geddes, professor of sociology, is to undertake rural life studies, and Dr. F. B. Wann, associate professor of botany, is to conduct some investigations in plant physiology.

Wisconsin University and Station.—The Chicago Medical Milk Commission has indicated to the regents of the university its willingness to continue the industrial fellowship founded two years ago and to increase the allocation of funds to \$4,400 for the year. This fellowship was founded for the purpose of studying the sanitary significance of streptococci in milk and milk products.

Two years ago the Chicago City Board of Health threatened to exclude several certified dairies in Wisconsin from the Chicago market because of the presence of certain streptococci in these supplies. This ruling was based on the supposition that all hemolytic (blood dissolving) streptococci were potentially dangerous in that they were regarded as capable of producing septic sore throat (tonsillitis) in man. In view of the apparent improbability that herds subject to close veterinary inspection and seemingly free from disease could be the cause of this disease in man, the certified milk producers subscribed to a fund which would enable a closely controlled scientific study to be made.

Dr. J. Howard Brown of Johns Hopkins University, W. D. Frost, and Miss Myrtle Shaw, working on this subject under the auspices of this medical industrial fellowship, have succeeded in perfecting differential culture methods which have enabled a separation to be made between streptococci of bovine and human origin. In an examination of over 1,200 cows made during the last 18 months, only 4 cows were found in certified milk herds which carried the streptococcus capable of causing human sore throat. Four additional cows have been found in other than certified herds in which this germ of human significance was found in milk.

The more refined methods of differentiation thus developed have added materially to a more accurate understanding of the relation between these blood-dissolving streptococci in the udder capable of producing infectious garget and the germ capable of producing septic sore throat in man.

A New Jersey firm of manufacturing chemists specializing in medical supplies has just given to the College of Agriculture \$1,500 to establish an industrial fellowship. This fellowship will enable a study to be made on the relation of wheat germ oil to vitamin E and iron assimilation. Miss E. C. Van Donk has been appointed fellow under this foundation.

Dr. A. C. Merrick, assistant in veterinary science, resigned March 1 and was succeeded by Dr. H. J. Fiege.

Office of Experiment Stations.—Henry C. Waterman of the Bureau of Chemistry, U. S. Department of Agriculture, has been appointed associate chemist and will have charge of the abstracting for *Experiment Station Record* in the sections of agricultural and biological chemistry and soils and fertilizers.

Blandy Experimental Farm, University of Virginia.—In the development of this farm, which was bequeathed to the university by the late Graham F. Blandy, the appointment has been recently announced of Dr. Orland E. White, curator of plant breeding and economic plants at the Brooklyn Botanic Garden, as professor of agricultural biology and director of the farm. Five research fellowships have been established, two of \$1,000 each and three of \$500 each, to which graduates from standard colleges who have majored in biology or agriculture will be eligible. Appointees are expected to register in the graduate department of the university and take work leading toward a higher degree.

Shade Tree Investigations at Yale University.—According to a note in *Science*, facilities have recently been provided at Yale University for work on

shade tree diseases. R. P. Marshall of the Office of Forest Pathology, U. S. Department of Agriculture, has been placed in charge of these studies, which will be carried on by the botanical department of the university in cooperation with this department and with the financial support of a commercial tree expert company.

Guggenheim Memorial Fellowships.—Announcement has recently been made of the 1927 awards of 54 fellowships under the John Simon Guggenheim Memorial Foundation. Of these fellowships three have been granted to members of experiment station staffs. One of these is Dr. William H. Eyster of the Maine University and Station, who is to study the physiology of the chloroplastid pigments, using genetic strains of *Zea mays* which vary in the amounts and proportions of the different chloroplastid pigments from a complete absence of one or more pigments to a full complement of all, principally with Dr. Richard Willstaetter of Munich and Dr. Otto H. Warburg of the Kaiser Wilhelm Institute of Biology in Berlin. A second fellowship was granted to Dr. Rodney B. Harvey, associate professor of plant physiology and botany and associate plant physiologist in the Minnesota University and Station, for an investigation of the effects of low temperatures on plants, principally at the low temperature station for research in biochemistry and physics at Cambridge University, England, and for a survey of work on the winter hardiness of plants at the Swedish Plant Breeding Station at Svalöf and the Institute of Applied Botany and Plant Improvement at Leningrad. The third fellowship has been granted to Dr. Richard Bradfield, associate professor of soils in the Missouri University and Station, who will work with Dr. Herbert Freundlich at the Kaiser Wilhelm Institute in Berlin, giving special attention to the principles involved in the purification of colloids by electro dialysis.

Mexican Agricultural Schools.—According to a note in *School and Society*, three new central agricultural schools are to be established during 1927 by the Mexican Government under a program looking toward the maintenance of an agricultural educational center in each State of the Republic. Construction was to be begun in March on the schools located near Atlixco, State of Puebla, Jiménez, State of Chihuahua, and Tenancingo, State of Mexico.

New Journals.—*Protoplasma*, an international journal of the physical chemistry of protoplasm, is being issued from time to time under the editorship of Josef Spek of Heidelberg and Friedl Weber of Graz with the special collaboration of Robert Chambers of New York and William Seifriz of Philadelphia. Among the four original articles in the initial number is one by W. A. Beck entitled Cane Sugar and Potassium Nitrate as Plasmolysing Agents. Several abstracts and bibliographies are also given.

Chinese Economic Journal is being issued monthly in English by the Chinese Government Bureau of Economic Information, replacing the *Chinese Economic Monthly*. The initial number contains several articles of agricultural interest, including Shop Credit for Farmers, by P. C. Hsu; The Soybean as Human Food, by A. A. Horvath; Farms in Soochow; and Flour Mills in Peking.

The Social Service Review, edited by the faculty of the Graduate School of Social Service Administration of the University of Chicago, is being issued quarterly. The initial number contains several original articles, together with book reviews, abstracts of public documents, notes, etc. Among the original articles may be mentioned The Budget of the Unskilled Laborer, by L. Houghteling.

JUNE ABSTRACT NUMBER

No. 9

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Chemistry and home economics, R. A. GORTNER (*Jour. Home Econ.*, 18 (1926), No. 11 pp. 613-619).—This paper, presented at the 1926 meeting of the American Home Economics Association, emphasizes the close relationship of chemistry to the problems of home making, particularly in the study of foods and of textiles and the value of cooperative research in the solution of these problems. "The scientific study of home making is just beginning. It will undoubtedly develop its own problems and its own technique for their solution, but the tools which it must use will in a large measure be derived from those basic sciences which underlie all natural phenomena, mathematics, physics, and chemistry."

New aspects of the chemistry of the oils and fats, J. C. DRUMMOND (*Jour. Soc. Chem. Indus.*, 45 (1926), No. 53, pp. 994-999, figs. 2).—A general discussion of the significance of the nonsaponifiable fraction of fats and oils as the source of fat-soluble vitamins, the ovarian hormone, and the hydrocarbon squalene.

Oxidation and hydrolysis of light wood oil, P. O. POWERS, A. LOWY, and W. A. HAMOR (*Indus. and Engin. Chem.*, 19 (1927), No. 2, pp. 306-308, figs. 3).—The combined lightwood oils from the distillation of hardwoods, as obtained (1) in the steam distillation of the settled tar, (2) from the refined pyro-ligneous acid in the copper stills, and (3) from the weak methanol distillate of the lime lee stills, were fractionated, and the products obtained by oxidizing the fractions boiling below 195° C. and by hydrolyzing them with lime were studied. The higher boiling fractions have found some use, but most of the oil produced is used as fuel. The fractions examined were free from nitrogen, sulfur, and halogens, and gave qualitative tests for the presence of aldehydes, ketones, esters, acids, furfuraldehyde, phenols, and unsaturated compounds.

Various oxidizing agents were tried, including nitric acid in concentrations from 6 to 20 per cent. The best results were obtained with 6 per cent boiling nitric acid, which gave in 16 hours a yield of 38.6 per cent total organic acids, 26.6 per cent being volatile. Vanadium pentoxide effectively catalyzed the oxidation of the oils with 9 per cent nitric acid. Blowing air through the mixture did not improve the yield of acids, and it removed the lower boiling fractions. The higher concentrations of nitric acid produced side reactions. At 70° the acid hydrolyzed the esters in the oil, being itself very slowly destroyed; at 80° the nitric acid was destroyed with the oxidation of the oil.

When the oil was boiled with an equal volume of water and a slight excess of lime, the products were principally methanol and calcium acetate from the lower boiling fractions of oil. The calcium salts from the fraction of oil boiling

between 160 and 195° contained principally salts of higher acids, including propionate and butyrates. The methanol obtained in the lime treatment contained ketones but no higher alcohols.

Observations on the oxidizing systems of fruits, W. V. CRUESS and W. Y. FONG (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 6 (1926), No. 3, pp. 13-15).—Using the terminology of Overholser and Cruess (*E. S. R.*, 50, p. 409), complete oxidase was satisfactorily detected in fruit flesh and skins by means of a 0.5 per cent solution of benzidine in 50 per cent ethyl alcohol, the positive indication consisting of the formation of a blue to purple color. This is not readily confused with natural fruit tissue color changes. If the color develops only on adding hydrogen peroxide, peroxidase only is indicated. Active catalase is indicated by the evolution of molecular oxygen from hydrogen peroxide. The benzidine tests are negative with thoroughly boiled fruit juice or flesh, minimizing the risk of positive reactions from nonenzymic oxidation. Guaiac tincture was found erratic in behavior, its reaction being capable of confusion with natural fruit color changes. Organic peroxide was detected by means of an acetic acid-starch-potassium iodide reagent.

In tests of 17 California fruits and fruit products the darkening of juices and of cut fruit surfaces was found in general to be most rapid in those fruits and juices giving a strong peroxidase reaction and a strongly positive reaction for chromogens (tanninoid substances turning brown on oxidation) with ferric chloride; e. g., Bartlett pears, Royal Anne cherries, Newtown apples, and avocados. Oranges and apricots darkened slowly and gave only faint ferric chloride reactions. The pH of the juice markedly affected the inactivation temperatures, as indicated by experiments, among others, in which juices adjusted to about pH 3 and about pH 5, respectively, were heated at 76° C. for from 15 to 25 minutes. Juices heated at pH 3.1 and 3.5 showed no peroxidase or organic peroxide, while those heated at pH 5.0, 5.2, and 5.5 gave positive tests. Even unheated juices gave negative reactions after standing at pH 2 to pH 3. The critical point on the alkaline side was found to be about pH 10 to 11. In fresh or dried apricots the oxidizing system was destroyed by heating about 3 minutes in live steam, and oxidation was inhibited temporarily in apricot juice by 60 mg. per liter of free SO₂, and permanently by adding 1,600 mg. per liter of SO₂ and subsequently neutralizing with NaHCO₃. It is suggested that high SO₂ concentrations, subsequently reduced below the legal maximum, might be used to produce fruit which could be dried without either darkening or illegal SO₂ content.

A study of gelatin viscosity and related problems, M. BRIEFER and J. H. COHEN (*Indus. and Engin. Chem.*, 19 (1927), No. 2, pp. 252-257, figs. 10).—Theories regarding the structure of gelatin jellies are discussed, and experiments on the viscosity of gelatin solutions as affected by time and temperature of standing and by agitation are reported. The most satisfactory conditions for the viscosity determination in gelatin testing were found to be a temperature between 40 and 45° C., and a gelatin concentration of 10 per cent.

Water-resistant animal glue, F. L. BROWNE and C. E. HRUBESKY (*Indus. and Engin. Chem.*, 19 (1927), No. 2, pp. 215-219, figs. 4).—The experiments described were based on the theory that the constant temperature gelation rate of an animal glue containing formaldehyde is a function of the free formaldehyde concentration. To secure a thorough final tanning of the glue, and at the same time to retain a long working life, formaldehyde polymers, hydrolyzable formaldehyde compounds, and adsorption complexes of formaldehyde were added in varying amounts to preparations made by soaking 100 gm. of ground glue in 225 to 250 cc. of cold water and melting at about 60° C. after complete

imbibition of the water. The derivatives used included commercial paraformaldehyde, α -polyoxymethylene, β -polyoxymethylene, mixture β - and γ -polyoxymethylenes, hexamethylenetetramine, formaldehyde-aniline, formaldehyde-urea, formaldehyde-starch, CH_2O adsorbed by charcoal, and CH_2O adsorbed by silica gel.

Most of these combinations improved the water resistance of the glue quite markedly, as indicated by the standard test of the Forest Products Laboratory, applied to panels soaked two days and tested to destruction while still wet, and the working life was in most cases long enough to be practicable. The addition of acids was found in general to lengthen, and the addition of alkalies to shorten the working life. Too much acid decreased the water resistance of the hardened glue. A glue of practicable life and possessing a water resistance sufficient to meet the requirements of the Navy casein glue specifications may be made by adding to animal glue as ordinarily prepared 10 parts by weight of paraformaldehyde and 5.5 parts of oxalic acid for each 100 parts of dry glue. The oxalic acid of this formula, sufficient to produce the maximum working life (7 to 9 hours) attainable with this acid, does not weaken the water resistance of the product. The water resistance of joints made with paraformaldehyde-containing glues was found to develop slowly, a curve showing an increase in breaking load per square inch from about 20 lbs. after 2 days to about 160 lbs. after 17 days. Temperature effects and some other factors were also studied.

Effect of hydrogen ion concentration upon the rate of destruction of vitamin B upon heating, H. C. SHERMAN and G. W. BURTON (*Jour. Biol. Chem.*, 70 (1926), No. 3, pp. 639-645).—The rate of destruction of vitamin B on heating as related to H-ion concentration has been studied quantitatively under conditions making possible a comparison of the relative effects of temperature and increased alkalinity (increased pH). Tomato juice, the medium used in a previous study by Sherman and Grose of the destruction of vitamin B by heat (*E. S. R.*, 51, p. 461), was heated at 100° C. for 1 hour and 4 hours, respectively, at its natural reaction, pH 4.28, and also at pH 5.2, 7.9, 9.2, and 10.9, and the content of vitamin B measured by the usual feeding experiments on young rats, using the technique of Sherman and Spohn (*E. S. R.*, 51, p. 368).

The changes in reaction of the medium resulted in successive increases in the destruction of the vitamin. This destruction began before alkalinity was reached, thus showing that the factor responsible was an increase in the proportion of OH-ions to H-ions on either the acid or alkaline side of neutrality. A change in H-ion concentration from pH 4.28 to 5.2 increased the rate of destruction to about the same extent as noted in the study of Sherman and Grose with an increase of temperature from 100 to 110°, and a change from pH 4.28 to 7.9 to a greater degree than a change of temperature from 100 to 130°.

Of the total initial amount of vitamin B, the percentages destroyed by 1 hour of heating at 100° were as follows: About 10 per cent at pH 5.2, from 30 to 40 per cent at pH 7.9, from 60 to 70 per cent at pH 9.2, and from 90 to 100 per cent at pH 10.9. Heating for 4 hours at 100° resulted in a destruction of about 20 per cent at pH 4.28, 31 per cent at pH 5.2, and 70 per cent at pH 7.9.

“In these experiments, oxidation does not seem to have played any appreciable part in the observed destruction of vitamin B. It is more probable that the vitamin was destroyed either by an hydrolysis or by intramolecular rearrangement, and that in either case the destruction reaction was catalyzed by hydroxyl ions. Change in the ratio of hydrogen to hydroxyl ions influences the rate of destruction in the same manner whether the pH of the solution were on the acid or on the alkaline side of neutrality, i. e., the rate

of destruction increased both by reducing the acidity of an acid medium, and by increasing the alkalinity when the medium had already been made alkaline. In other words, on both sides of neutrality, the rate of destruction of the vitamin was a function of the pH of the medium in which it was dissolved."

Significance of the occurrence of manganese, copper, zinc, nickel, and cobalt in Kentucky blue grass, J. S. McHARGUE (*Indus. and Engin. Chem.*, 19 (1927), No. 2, pp. 274-276, fig. 1).—The bluegrass region soils are richer in copper, manganese, and other metals than other parts of the State, and the luxuriant growth of the bluegrass is attributed principally to this cause. Analyses of young bluegrass blades are adduced in support of this view. Sand culture experiments are also reported, in which were supplied (1) the 10 elements usually recognized as essential, (2) the 10 elements plus manganese, and (3) the same, plus both manganese and copper. Experiment 2 showed nearly twice the apparent growth of experiment 1, and experiment 3 showed distinctly better growth than experiment 2.

Volumetric analysis, I, J. M. KOLTHOFF (*Die Massanalyse. Berlin: Julius Springer, 1927, pt. 1, pp. XII+254, figs. 20*).—This is the first or theoretical section of a monograph on volumetric analysis, and deals in a comprehensive way with the modern chemical physicochemical theory of acid-base, oxidation-reduction, and precipitation reactions employed in volumetric analyses, together with the related subjects of indicators for all types of titration, including "adsorption indicators," titration errors, reaction velocities, adsorption phenomena in precipitation reactions, the volumetric methods of organic chemistry, the stability of reagent solutions, etc. Tables giving the values of K_{sp} at various temperatures, dissociation constants of important acids and bases, solubility products of certain salts and alkaloids, some oxidation-reduction potentials, and other data are included.

Centrifuging as a substitute for filtration and calcination in the determination of tin and lead in their alloys [trans. title], M. FOÀ (*Gior. Chim. Indus. ed. Appl.*, 9 (1927), No. 2, pp. 69, 70).—With an alloy of low tin content, heat a 5-gm. sample, either finely divided or, preferably, in thin laminae, with 30 cc. of nitric acid of specific gravity 1.4 in a beaker covered with a watch glass. After the reaction has begun, add 15 cc. of water drop by drop down the wall of the beaker, and permit the reaction to complete itself, about 15 minutes being required. Remove the liquid and precipitate to a weighed centrifuge bottle, transferring the precipitate quantitatively with about 50 cc. of boiling water. Shake the liquid in the bottle to dissolve the lead nitrate separated in the reaction. Centrifuge at about 3,000 r. p. m. for 3 minutes. It is of the greatest importance to stop the centrifuge smoothly and to avoid shaking in removing the bottles. Carefully decant the clear supernatant solution and pour about 70 cc. of boiling water into the bottle, shaking thoroughly to break up the deposit adhering to the glass. Repeat the centrifuging and decantation until a drop of the centrifuged liquid on potassium iodide paper gives no test for lead. Two or three washings should be sufficient. After decanting the last washing, dry the bottle to constant weight in an oven at 110° C.

The lead is precipitated from the united washings as sulfate and similarly determined by means of the centrifuge.

For alloys of high tin content, 0.5-gm. samples are taken, treated with nitric acid of specific gravity 1.2, and centrifuged as above after allowing 10 minutes for the completion of the reaction.

In an alloy containing 2.50 per cent of tin, 2.510, 2.507, and 2.505 per cent were found by the method described. With 50 per cent of tin in the alloy less satisfactory results were obtained: 50.89, 50.76, and 50.50 per cent. The method

is much quicker than either the electrolytic method or the ordinary gravimetric procedure. Volumetric methods were not found satisfactory.

The determination of very small quantities of iron, H. L. SMITH and J. H. COOKE (*Analyst*, 51 (1926), No. 607, pp. 503-510, fig. 1).—This is a modification of the colorimetric method of Stokes and Cain,¹ who concentrate the ferric thiocyanate formed in aqueous solution by extracting with 5:2 amyl alcohol-ether. In adapting this principle to the determination of 5 parts or less per million of iron, it was found necessary to purify the best nitric acid and potassium or ammonium thiocyanate available. With this precaution, and using color standards prepared from solutions of known iron content, 0.001 mg. of iron per gram could be determined in silica. Hydrofluoric acid redistilled in platinum was required, however, and in the presence of large amounts of bismuth, which prevented the normal coloration in nitric acid-aqueous solutions, hydrochloric acid had to be substituted for nitric acid. High concentrations of zinc also prevented full development of the color, but good results were obtained by extracting the iron as ferric chloride from the hydrochloric acid solution of zinc compounds and completing the determination on the ether-free extract in the usual nitric acid-aqueous solution, followed by ether-amyl alcohol extraction. A modified Soxhlet extractor for separating ferric from zinc chloride is illustrated.

Determination of total nitrogen, nitrate-nitrogen, and total nitrogen not including nitrate-nitrogen: Further observations on a modification of the Official salicylic-thiosulphate method, E. R. RANKER (*Ann. Missouri Bot. Gard.*, 13 (1926), No. 4, pp. 391-424, figs. 3).—The following procedure,² recommended to replace the Official thiosulfate salicylic acid method, was studied with reference to its accuracy as applied to the determination of total nitrogen, including nitrate nitrogen, in plant materials, soils, etc., the Official method having been found inaccurate:

"Place the sample in an 800-cc. Kjeldahl flask; adjust to neutrality or make slightly alkaline; if water is present evaporate just to dryness on a water bath under vacuum. Add 35 to 40 cc. of salicylic acid mixture (1.0 gm. of salicylic acid to 30 cc. of concentrated nitrogen-free sulfuric acid); mix thoroughly and allow to stand for at least an hour with occasional shaking (if organic matter is present, stopper tightly with a rubber cork and allow to stand over night). Add 5 gm. of sodium thiosulfate and heat for 5 minutes with a low flame, cool, add 7 to 10 gm. of anhydrous sodium sulfate and a pinch of copper sulfate. Digest for an hour at the boiling point after the solution clears; just before the solution solidifies dilute to an estimated volume of 400 cc.; cool completely. Add a small piece of paraffin, 100 cc. of a saturated solution of sodium hydroxide, and a piece of mossy zinc; connect immediately to the distillation apparatus and distill 150 to 200 cc. over into standard acid during a period of 1 hour. Titrate the standard acid to neutrality with standard alkali and calculate the amount of nitrogen present."

The accuracy of this modified Official method has been established, the application of the method having been extended to a wide variety of samples. The Kjeldahl-Gunning-Arnold method as applied for the determination of total nonnitrate nitrogen was found inaccurate in the presence of nitrate nitrogen, appreciable amounts of which were demonstrated in certain plant materials, high results arising from reduction of a part of the nitrate being obtained, notably in the presence of sugars. Losses of ammonia and of nitric acid at various points were checked by qualitative Nessler and diphenylamine tests.

¹ Jour. Amer. Chem. Soc., 29 (1907), No. 4, pp. 409-443.

² Ann. Missouri Bot. Gard., 12 (1925), No. 4, p. 367.

Loss due to exposure of rubber connections to the ammonia in distillation, together with the influence of certain effects of other manipulative details on the accuracy of the method, was demonstrated.

Determination of gelatin in ice cream, R. E. REMINGTON and L. H. McROBERTS (*Indus. and Engin. Chem.*, 19 (1927), No. 2, pp. 267-269).—The Ferris method (E. S. R., 49, p. 13) was found to be improved in accuracy and convenience by the following modifications: (1) A smaller sample, (2) dilution by weight instead of by volume, (3) approximately isoelectric precipitation of casein, using hematoxylin as indicator, (4) the use of alum in addition to alcohol to secure complete precipitation of the gelatin, and (5) correction of the gelatin nitrogen for nonprecipitable milk nitrogen. The average nitrogen contents and specific rotations of 28 commercial ice cream gelatins were found to be 14.84 per cent and 117, respectively, equivalent to 17.53 per cent and 139 on the moisture- and ash-free basis. The modified method is as follows:

“Into a tared 400-cc. beaker weigh 200 gm. of the melted and thoroughly mixed sample. Add 25 cc. of water and enough hematoxylin indicator to color the sample distinctly pink. Heat to 40° C. and titrate with 10 per cent acetic acid until the pink color has completely disappeared. Return the beaker to the balance and add water until the weight of the contents reaches 250 gm. Accuracy of 0.5 gm. is sufficient. Mix thoroughly and return to the 40° water bath until the curd has fully separated. Filter through a small bag of cotton or linen.

“Weigh out 100 gm. of the filtrate, add 3 cc. of a saturated solution of potassium alum, then 200 cc. of 95 per cent alcohol, with stirring. Cooling hastens the separation of the precipitate. Filter by suction on a 9-cm. filter, using a Büchner funnel. Tear up the paper and place in water in a small beaker. Soak until the gelatin has an opportunity to swell. Then place the beaker in warm water for half an hour, first adding water to approximately 50 cc. Bring rapidly to incipient boiling and filter at once into a 100-cc. volumetric flask, washing with hot water until the flask is nearly full. Allow the flask to cool to near room temperature, make to the mark, and mix.

“The polarization can be made at once, using a jacketed tube. Circulate water, which has been heated, through the jacket until a thermometer placed in the tubulature reads 40°. Then shut off the water, allow the tube to cool to 35°, and read. If the flasks are not read at once they should be heated in a water bath at 35 to 40° for half an hour or more before placing in the polariscope tube. The weight of the serum to be used as a basis in calculating is obtained by subtracting the weight of fat and casein in 200 gm. of the sample from 250 gm. Using a 200-mm. tube for polarizing, the percentage of gelatin is given by $0.00074 \times R \times W$. Determine nitrogen in 25 cc. of the solution, deducting 2 mg. for the blank, and expressing the result in milligrams of nitrogen in the 25 cc. The percentage of gelatin is then found by $0.135 \times N \times W$.”

Factors influencing char filtration, E. W. RICE and G. W. MURRAY, JR. (*Indus. and Engin. Chem.*, 19 (1927), No. 2, pp. 214, 215).—There appears to be exchange adsorption between the solute and the char and also among several substances adsorbed at one time. Successive portions of materials filtered through a char may vary widely in analysis from this cause, especially when a refiner's char containing many chemical substances is used. The complete purification of raw sugar by the use of bone char alone is practically impossible.

METEOROLOGY

The problem of technical control of weather, A. WENDLER (*Das Problem der Technischen Wetterbeeinflussung*. Hamburg: Henri Grand, 1927, pp. 107,

figs. 7).—This is a review, with numerous references to the literature of the subject, of past attempts to control the weather by artificial means. The various means which have been employed to control the weather or modify its effects, including lightning, frost, and hail protection, and rain making, as well as the influence of forests, seas, marshes, rivers, mountains, and large towns, are discussed. The physical and chemical bases and principles underlying weather changes and the theories and hypotheses which have been advanced on the subject, including the polar front theory, forms of precipitation, and relation of catalysis and colloid chemistry to meteorology, are explained, and the technique of meteorological free-air experiments is described.

A study of the possibility of economic values in statistical investigations of rainfall periodicities, D. ALTER (*Bul. Amer. Met. Soc.*, 8 (1927), No. 3, pp. 45, 46).—Examination of rainfall data of the British Isles to determine their probable prediction value is stated to have led to indecisive results. The author considers it probable that "in the long run predicted results will be better than chance, but whether enough better for economic use is uncertain. Test predictions of 6 months means are given for the British Isles for the next 10 years."

The dependence of yield of crops in Prussia on precipitation and temperature [trans. title], E. LESS (*Met. Ztschr. [Brunswick]*, 44 (1927), No. 2, pp. 61-65).—This is a summary of a detailed report on the subject previously noted (E. S. R., 56, p. 413).

The Nile flood and world weather, E. W. BLISS (*Mem. Roy. Met. Soc.*, 1 [1927], No. 5, pp. 79-85, fig. 1; *abs. in Sci. Abs., Sect. A—Phys.*, 30 (1927), No. 350, pp. 88, 89).—A study of the Nile flood from 1869 to 1925, as measured by the annual departures from the mean of the Aswan discharges from July to October, indicates that "the Nile behaves as a member of the first group of the southern oscillation, and is inversely related to equatorial temperatures and to the North Atlantic circulation in the following winter." The correlation appears to be higher with subsequent than with preceding weather. A formula for predicting the Nile flood on June 1, based on Dutch Harbor temperature and Port Darwin pressure in the preceding quarter and Samoa temperature two quarters previously, was found to give a joint correlation of +0.72.

The yearly course of temperature and periods of plant growth [trans. title], E. RUBINSTEIN (*Met. Ztschr. [Brunswick]*, 44 (1927), No. 1, pp. 13-18).—The methods and results of the author's study of the relation of temperature to the progress of plant growth are compared with those of Köppen as presented in a paper previously noted (E. S. R., 55, p. 807).

[Solar radiation], F. BOEUF and L. GORCZYŃSKI (*Ann. Serv. Bot. [Tunis]*, 3, (1925), No. 1, pp. 5-73, pl. 1, figs. 5).—The utility of the study of solar radiation from the viewpoint of plant growth is discussed by Boeuf, and pyr heliometric measurements of the intensity of solar radiation made in the spring of 1924 in North Africa, particularly in the Sahara Oasis of Touggourt, are reported by Gorczyński and discussed with reference to causes and extent of variation in intensity. The apparatus used is described, and the methods employed in deducing the solar constant is explained.

Climatological data for the tropical islands of the Pacific Ocean (Oceania), W. W. REED (*U. S. Mo. Weather Rev. Sup.* 28 (1927), pp. III+22, figs. 8).—This supplement presents data regarding temperature, precipitation, relative humidity, cloudiness, winds, and tropical storms, compiled in large part from publications which are listed.

SOILS—FERTILIZERS

Colloidal behavior of soils and soil fertility.—III, Cation replacement and saturation of soil with Ca, J. S. JOFFE and H. C. McLEAN (*Soil Sci.*, 23 (1927), No. 2, pp. 127-135).—In continuation of this series of experiments, conducted at the New Jersey Experiment Stations (E. S. R., 55, p. 811), several soils of the Chenango series were treated with normal ammonium chloride solution, and the ammonia absorbed and exchangeable with potassium on treatment with normal potassium chloride was determined. The Veitch method and the method of replacement of H-ions by a normal barium chloride were compared in the determination of the lime requirement of a number of soil samples. The extent of the replacement of H-ions after 1 hour, 1 day, and 10 days in soils from the fertility plats at the stations, and H-ions replaced in 1 hour, 1 day, and 10 days, together with the H-ion replacement by normal potassium chloride in 1 day and 9 days in Chenango soils are reported. The relations of the cations of the inorganic and organic soil complex capable of base exchange, and the functions from the standpoint of base exchange of calcium ions in the soil-plant system are discussed. Methods for determining base exchange capacity and degree of unsaturation are given. The relation between unsaturation and lime requirement is analyzed, the experimental results being compared with methods for determining the lime requirement.

The liming indicated by the replacement method is deemed sufficient for best results. The degree of saturation and unsaturation in the soil profile layers suggests subsoiling for the preservation of bases leached from the surface soils.

A study of the mechanism of ionic exchange in a clay-lime complex [trans. title], A. DEMOLON and G. BARBIER (*Compt. Rend. Acad. Sci. [Paris]*, 184 (1927), No. 9, pp. 537-539).—In experiments on the base exchange capacity of the clay-lime complex, it was found that the equilibrium concentrations of calcium oxide in the solution (x) and in the clay (y), when various weights of the clay (0.25 to 5.0 gm.) were treated with the same volume (200 cc.) of solutions of potassium chloride, sodium chloride, and ammonium chloride, having concentrations equivalent to 2 per cent of potassium chloride, varied in close accordance with definite equations, different for each salt, as follows: For sodium chloride, $y=3.09 \times x^{0.60}$; for potassium chloride, $y=1.70 \times x^{0.43}$; and for ammonium chloride $y=1.26 \times x^{0.64}$. Similar experiments with N/16 carbon dioxide are reported. It is concluded that, due to the clay colloids and to the establishment of equilibria, decalcification tends to diminish in rate in proportion to its progress.

In determining exchangeable calcium, hydrochloric acid (2 per cent by volume) was found to give practically the same results in one extraction as did ammonium chloride in several extractions provided the ratio of clay to extractant solution was not greater than 1:100.

Researches on the breakdown of cellulose in the soil [trans. title], S. WINOGRADSKY (*Compt. Rend. Acad. Sci. [Paris]*, 184 (1927), No. 9, pp. 493-497).—The technique of Hutchinson and Clayton (E. S. R., 41, p. 632), was applied in the isolation from the soil of 10 fibrolytic bacterial forms, which are provisionally classed in two groups. The first, or cytophaga, group (*Spirochaeta cytophaga* H. & C.), consists of straight or curved, but rarely spiral, forms which have a powerful fibrolytic action, transforming filter paper into a transparent glair, the color of which, as well as the form of the cells, characterizes the organisms. Various strains producing rose-colored, orange, and egg-yolk yellow glairs were isolated in pure culture. In the second group 5 cultures of small vibrio forms, some of them slightly spiral, were isolated.

They had a much less marked fibrolytic property than the cytophaga group, but spread over filter paper with remarkable rapidity, producing a pale yellow coloration. The yellowed filter paper was not disintegrated when the cultures were incubated for a month. Other vibrio forms producing abundant glair, with a yellow-brown coloration of the paper and disintegration of the fibers, were isolated, one of them reducing the whole paper to a brown gelatinous mass. Autolysis is characteristic of both groups, though especially of the first; shortly after the swelled fibers lose their structure the microorganisms, also swollen, dissolve in the glair without leaving visible spores or other resting stages.

The organisms studied differ from cellulose-destroying anaerobes in that they produce neither gas nor volatile fatty acids. The silica gel is rendered alkaline, and there is a vigorous nitrate absorption. The products formed by these organisms resembled soil humus in being colloidal and nitrogenous, resistant to further bacterial attack, and soluble in dilute alkalis.

The ionimetric determination of acidity by the inversion of sucrose.—Application to complex mixtures: Soils [trans. title], V. VINCENT (*Compt. Rend. Acad. Sci. [Paris], 184 (1927), No. 6, pp. 338-340*).—The inversion of sucrose solutions by soils is not a measure of the actual ionization of the complex mixture of acids, but it indicates the magnitude of the immediate ionization of the reserve acids on heating and furnishes a means of estimating the neutralizing value of natural liming materials.

Contribution to the study of soil protozoa [trans. title], M. KOFFMAN (*Acta Zool., 7 (1926), No. 2-3, pp. 277-328, figs. 93*).—A detailed investigation of the protozoa of garden soils about Stockholm is reported, the 93 forms identified and drawn including both forms peculiar to the soil and aquatic forms which appear in soils only under certain conditions.

The protozoa were found very sensitive to slight changes in such physiological conditions as pH, temperature, salt concentration, nutrients, etc., in the culture media. Protozoa peculiar to soils, commonly small flagellates, together with their cysts, were present in normal soils, but most of the cysts found originated from forms not peculiar to soils alone. Results obtained by soil inoculations of culture media hardly give a true picture of the actual protozoan soil fauna, on account of the presence of cysts of protozoa not specifically soil forms and because of the above-noted sensitiveness of the protista. This applies equally to the identification and to the counting of the protozoa. The effect of the distribution of the protozoa on soil fertility can hardly be determined without knowing the kind and numbers of the forms present. A method applicable to the direct identification and counting of the soil protozoa, at least in certain soils, is given.

Marion County soils, R. S. SMITH, E. A. NORTON, E. E. DETURK, F. C. BAUER, and L. H. SMITH (*Illinois Sta. Soil Rpt. 34 (1926), pp. (2)+66, figs. 6, maps 2*).—This survey deals with the soils of an area of 361,894 acres in south-central Illinois. The county has a maximum range in elevation of 150 ft., and lies between two well-defined drainage basins of the Little Wabash and Kaskaskia Rivers. Notes on the geological history and soil development of the area are included, together with an explanatory appendix and soil fertility data from several experiment fields, the crop yields from these fields for some years being tabulated.

The soils are classified in 5 groups of 11 types, among which upland prairie gray silt loam on tight clay and upland timber yellow gray silt loam occupy 44.55 and 35.32 per cent of the total area, respectively. Data on the plant nutrients, fertility requirements, and crop adaptabilities of the various soil types are also given.

Soil Survey of Clay County, Indiana, G. B. JONES ET AL. (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1922, pp. III+1379-1422, figs. 2, map 1).—This report, prepared in cooperation with the Indiana Experiment Station, is in two parts:

I. [*Soil survey*], G. B. Jones et al. (pp. 1379-1409).—Clay County comprises an area of 231,040 acres of upland and alluvial plain, in part smooth plain and in part moderately rolling to hilly country, situated in the southwest quarter of the State and lying at an average elevation of 625 ft., the maximum local relief being 160 ft. The soils are mapped and described in 10 series of 18 types, in addition to mine dumps, consisting of coal mine waste, which occupy 0.5 per cent. The Vigo and Gibson silt loams occupy 34.3 and 33.1 per cent, respectively, of the area examined. Much of the bottom lands and parts of the upland plain are inadequately drained, but the Gibson, Parke, and Princeton soils have good surface and internal drainage.

II. *The management of Clay County soils*, A. T. Wiancko and S. D. Conner (pp. 1411-1422).—Analyses of these soils are reported, and suggestions for their management are given in some detail.

Soil survey of Berrien County, Michigan, J. A. KERR ET AL. (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1922, pp. III+1343-1378, figs. 2, map 1).—Berrien County comprises an area of 364,160 acres in the extreme southwestern corner of the State and has five natural topographical divisions: (1) A broken belt of sand dunes on the lake front, $\frac{1}{4}$ to 1 or more miles in width; (2) a belt of undulating to level land, in part poorly drained, 4 to 8 miles wide; (3) a 6- to 9-mile belt of higher and gently rolling to hilly land; (4) high outwash plains; and (5) the St. Joseph and Pawpaw River terraces. The average elevation of the county is about 800 ft.

In a survey made in cooperation with the Michigan Experiment Station, the soils of this county were mapped as 29 types and 16 series, Nappanee silt loam and Plainfield sand occupying 11.7 and 11.0 per cent of the area, respectively, while 5.9 per cent is occupied by muck, unclassified.

Soil survey of Kearney County, Nebraska, M. H. LAYTON ET AL. (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1923, pp. III+441-484, fig. 1, map 1).—In this report, prepared in cooperation with the University of Nebraska, the soils of an area of 330,240 acres, flat to gently rolling, situated at an average elevation of about 2,150 ft., in south-central Nebraska, are mapped as 18 types of 10 series, including dunesand 6.3 per cent, unclassified. The Holdrege and Grundy silt loams are the most prominent types, occupying 35.5 and 15.5 per cent, respectively, of the total area. The county has an average annual precipitation of 29.04 in., about 42 per cent falling in the growing season; and it is well drained, except in the flatter uplands and locally in the bottom lands, by tributaries of the Platte, Republican, and Little Blue Rivers.

[**Soil fertility experiments at the Colorado Station**] (*Colorado Sta. Rpt. 1926, pp. 10, 15-17, 26, 27*).—Experiments in continuation of the studies on excessive nitrate production (E. S. R., 55, p. 219) indicate that the application of an organic manure rich in carbon but low in nitrogen, such as straw, may be a possible remedy. In an attempt to control excessive nitrate production by means of acidity developed from green manure and crop residues plowed into the soil, pH determinations upon moist soils showed only a slight and economically unimportant development of acidity following the plowing under of green barley.

Studies of the part played by carbon dioxide in crop rotation showed clean fallow soils to be giving off carbon dioxide continuously, but the quantity

given off when the soil is occupied by a crop is from 3 to 10 times as great as that from fallow soil.

[Soil and fertilizer studies at the Florida Station], W. E. STOKES, R. W. RUPRECHT, and G. E. TEDDER (*Florida Sta. Rpt. 1926*, pp. 14-17, 31, 32, 114, 115).—The results of three series of greenhouse experiments with *Crotalaria striata* as a green manure indicate a distinct correlation between the composition of the plant, as affected by the stage of its growth, and its decomposition in the soil.

Tung oil press cake (about 3.5 per cent ammonia), urea, and leunasalt peter, applied with acid phosphate and potassium sulfate at proportionate rates equivalent to 1,000 lbs. per acre of a 5-7-5 fertilizer, gave good results with beans.

In water-table experiments at the Everglades Substation, plants were found to become yellow almost as soon as up with the water at 6- and 12-in. levels. The cylinders in which the water stood at 24- to 36-in. levels produced much better plants.

[Soil studies at the Kansas Station] (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 29-35).—Among the studies reported are the following:

The residual effect of alfalfa on the soil.—Plats allowed to remain in alfalfa for varying numbers of years have been planted to wheat and comparison made with plats planted with wheat continuously. The plats which had been in alfalfa contained more nitrate nitrogen at wheat seeding time than plats planted to wheat continuously. Data are presented showing the yield and nitrogen content of wheat to be greater following a year in alfalfa than when wheat was grown two years continuously. Wheat following two years in alfalfa also showed greater increases in yield than three years continuous wheat, and the increase in protein content (4.3 per cent) was more marked than in the first experiment above noted.

Plant nutrition investigations.—The relation of the molecular proportion of calcium nitrate to potassium dihydrogen phosphate was studied in greenhouse salt nutrition experiments with wheat grown to maturity. A high molecular proportion of the nitrate to the phosphate gave the best wheat growth. Greenhouse experiments on some of the Agronomy Farm soil types showed nitrogen fertilizers to give the largest increases of any of the single treatments, all of the soils responding to nitrogen, but the greatest yields were obtained by combining nitrogen with acid phosphate. Nitrogen was better absorbed from sodium nitrate than from calcium nitrate. Calcium phosphate secured better response than sodium phosphate. Alfalfa and sweet clover in an acid soil gave maximum yields when acid phosphate was used in addition to lime at the proportionate rate of 4,000 lbs. of lime to 300 lbs. of acid phosphate per acre.

A study of the soil solution as governed by the H-ion concentration.—The soil adsorption of the basic ions calcium, iron, aluminum, magnesium, potassium, sodium, etc., as affected by such anions as chlorine, sulfate, phosphate, acetate, etc., has been studied, the preliminary work having consisted of the development of methods for rapid leaching without contamination of the leachings with colloids, and for the determination of minute quantities of leached bases. Small concentrations of the sulfate ion favored the release and leaching of iron and aluminum.

[Soil studies at the Iowa Station] (*Iowa Sta. Rpt. 1926*, pp. 14-18, 56, 57).—Data showing the profit or loss from fertilizer treatment of 15 Iowa soil types in 42 experiment fields planted to corn, oats, and clover are presented in tabular form. Manure benefited all the soils, the greatest gain being on Marion silt loam and the least on Webster silty clay loam.

The application of 150 lbs. per acre of different fertilizers to corn gave the best results when mixed with soil in the hill. With quantities larger than

150 lbs. per acre broadcasting gave as good results as mixing in the hill. Tables present profit or loss from treatment of corn, oats, and clover with manure alone, with manure combined with lime and rock and acid phosphates, and with complete commercial fertilizers.

In nitrogen utilization experiments with corn, most of the nitrogen added as ammonium sulfate in an application of a 2-12-2 fertilizer had been taken up at the end of eight weeks. The difference in nitrogen content between the fertilized and unfertilized plants was several times the quantity of nitrogen applied, indicating that longer root systems developed by the fertilized plants secured more nitrogen from the surrounding soil.

Corn was found to utilize about 75 per cent of the phosphorus applied in acid phosphate and in a 2-12-2 fertilizer. The utilization of added phosphoric acid varied with the composition of the soil, being greater when the supply of natural soil phosphoric acid was low.

Field experiments on soils and crops, G. ROBERTS, E. J. KINNEY, and J. F. FREEMAN (*Kentucky Sta. Bul.* 272 (1926), pp. 281-351).—The progress (E. S. R., 44, p. 510) of a large number of soil and crop experiments at Lexington and in variously located experiment fields is reported for the period 1920-1925. Among experiments which have already yielded definite conclusions were those with 200-lb. applications per acre of sodium nitrate on Burley tobacco in rotation with wheat, clover, and orchard grass, the nitrate giving increases equal to those from 20 tons of manure; 43 tests of 100 lbs. of sodium nitrate per acre on wheat following tobacco in three fields and during periods of from 4 to 11 years, showing the nitrate to give little increase when the rotation included clover; and hemp experiments, showing good yields and profitable increases from 300-lb. treatments of sodium nitrate on lands not in the highly fertile condition usually deemed essential.

AGRICULTURAL BOTANY

Methods of descriptive systematic botany, A. S. HITCHCOCK (*New York: John Wiley & Sons; London: Chapman & Hall, 1925, pp. VII+216*).—The author here presents the results of experience during 25 or more years in the art and science of taxonomic work. The first six chapters deal with the elements of descriptive taxonomy. The remainder of the work deals with the subject from the standpoint of advanced students or those beginning their professional careers as assistants in botanical institutions.

Monocotyledons: A morphological study, A. ARBER (*Cambridge, Eng.: Univ. Press, 1925, pp. XIV+258, pl. 1, figs. 160*).—This work, one of the Cambridge Botanical Handbooks edited by A. C. Seward, though undertaken at the behest of E. Sargent and dedicated to her memory, admittedly departs fundamentally from the views which she held and advocated.

The 10 chapters deal, respectively, with the principles of morphology, the root, the axis, the foliage leaf descriptively, the leaf interpretatively, the prophyll, the seedling and its significance, the reproductive phase, taxonomy and its interpretation, and parallelism in evolution. Both bibliography and index are extensive and analytical.

The relations between distribution, structure, and transpiration of arid South Australian plants, J. G. WOOD (*Roy. Soc. So. Aust. Trans. and Proc.*, 48 (1924), pp. 226-235, pl. 1, figs. 6).—The transpiration studies here presented in descriptive and tabular detail are believed to give, when taken in conjunction with the soil-water relations of the plant, a valuable insight into the determination of the distribution and of the habitats of desert plants, and to show

(as regards Australian habitats) the reasons for the dominance of individual species in particular localities.

Drought resistance of crop plants (*Kansas Sta. Bien. Rpt. 1925-26, pp. 36-38*).—According to this summary, Bordeaux mixture appeared to have no significant effect on the rate of transpiration of potato plants, but the rate of transpiration of sprayed tomato plants was approximately 6 per cent higher than that of the unsprayed plants. The temperature of potato leaves sprayed with Bordeaux mixture was consistently from 0.1 to 0.2° C. higher than that of the unsprayed leaves. The difference in tomato leaves could not be detected by the apparatus used.

The results of comparative transpiration experiments indicated that under like conditions there is a specific difference in the transpiration rate of corn, dwarf yellow milo, pumpkin, cowpea, and soy bean plants, and that this difference depends on the age of the plants as well as on other factors not determined.

The daily variation of the total nitrogen content of the leaves of corn, sorghums, soy beans, and cowpeas was determined. The preliminary results are said to indicate that there is a rise of the nitrogen content in the leaves of the legumes during the day and a fall at night, but that such a change does not take place in the leaves of corn and the sorghums.

The rate of growth of the corn plant during the growing season was obtained by determining the average dry weight of five representative plants selected at random in the field at 7-day intervals. The leaf area of the plants was determined as well as their transpiration rate. The average dry weight, leaf area, and amount of water transpired by a single plant during each 7-day period is shown, from which it appears that the leaf area and transpiration increased steadily for about 80 days, at which time the plants were in full leaf development and had reached their maximum of transpiration. Dry matter continued to increase to the end of the experiment, while transpiration fell off rather abruptly.

Microchemical and morphological studies of effect of light on plants, N. E. PREIFFER (*Bot. Gaz., 81 (1926), No. 2, pp. 173-195, pl. 1, figs. 4*).—It is found that in plants under short exposures to light there are usually low carbohydrate and low protein reserves with less total growth and less production of differentiated tissues than in plants grown during longer intervals. In plants under longer exposures there is an increase in carbohydrate reserves without proportionately increased use in elaboration of proteins and tissue production.

Nitrates were present in considerable amounts in all tomato plants except the control and gantry crane house specimens. The maximum development of the plant, considering height and differentiated tissue, occurred in the 12-hour tomato and the 17-hour buckwheat. Injury was evident in tomato exposed for 17 hours or more, resulting in marked decrease in photosynthetic ability. Continuous light tended to produce thinner leaves, with the palisade layer shorter or lacking. Thinner leaves usually showed an increase in the number of stomata except under light of continuous intensity. Root development in fibrous systems appeared roughly comparable with that of the aerial parts. In the storage roots of four-o'clock, maximum development occurred in the gantry crane houses and continuous light, while maximum height of stem occurred in the 17-hour plant.

The anthocyanin pigments of plants, M. W. ONSLOW (*Cambridge, Eng.: Univ. Press, 1925, 2. ed., pp. VIII+314; abs. in Nature [London], 116 (1925), No. 2923, p. 672*).—"Since the appearance of the first edition the publications

of greatest value on the subject of anthocyanin pigments have been in connection with the chemistry and biochemistry of these substances. This later work has now been included, and the present state of our knowledge of the significance of the pigments in relation to plant metabolism has, as far as possible, been indicated. . . . An attempt has been made to record the majority of these publications [on genetics], but it has been impossible, within the size and scope of this book, to give detailed accounts of the researches on the inheritance of soluble pigments. Such curtailment, however, should not be serious."

Coloring of citrus fruits, L. E. DUPONT (*Florida Sta. Rpt. 1926*, pp. 68, 69).—Tests of various chemicals having a tendency to increase respiration (benzene, toluene, acetic acid, ethyl acetate, etc.) showed that they act with remarkable rapidity, but the taste they impart to the fruit renders their use impossible. Unsaturated hydrocarbons are of little value in increasing ripening, with the exception of ethylene and acetylene in concentrations of 1:1,000, and these give promising results. Most aldehydes proved too caustic and injured the texture of the rind, but acrylic aldehyde at a concentration of 1 per cent acted favorably. Combining the desirable effect of both ethylene and acrylic aldehyde, it is claimed that a process has been devised whereby the time of coloring has been reduced from 4.5 to 3 days.

Release of cell division activity due to injection of tissue fluids and cell parts [trans. title], H. REICHE (*Ztschr. Bot.*, 16 (1924), No. 5, pp. 241-278, pl. 1).—Both rule and exceptions, as here noted, have a common explanation in the alleged fact that wall orientation is determined by the diffusion course of the wound-stimulus materials.

Plasma swelling and growth [trans. title], H. WALTER (*Ztschr. Bot.*, 16 (1924), No. 7, pp. 353-417, figs. 10).—The question whether absorption or osmotic forces are operative in plasma is difficult, if not impossible, to decide. Between absorption and osmosis no important difference can be shown. The transition from the one to the other phase of the phenomenon is as gradual and imperceptible as is that from colloid solution to molecular disperse phase. Every solution, as well as every absorptive body, possesses a certain so-called suction, which gives some conception as to its condition. The relation of these facts and conditions to growth are discussed. Numerous references to the literature are furnished.

H-ion concentration and permeability in calcifugous plants [trans. title], W. MEVIUS (*Ztschr. Bot.*, 16 (1924), No. 11, pp. 641-677, fig. 1).—It is stated as the most important outcome of this work that in Sphagnum as in *Pinus pinaster* simple neutralization effects can not cause calciphobosity. The high pH value of these limy soils prevents these plants from making their way normally. A direct relation holds between the pH value and the conditions in the protoplasm, some features of which are discussed.

Some conditions influencing the determination of catalase activity in plant tissue, J. E. KNOTT (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 398-407).—It is found that above 10° C. (50° F) catalase deteriorates, and bacterial growth soon affects catalytic activity. Toluene used at 1 to 100 parts prevents bacterial growth, but affects the velocity of catalysis. The best method to follow, when it is necessary to keep over preparations of spinach and celery, is to place the bottles on ice immediately after maceration and dilution. Tomato catalase will, however, lose its activity somewhat even when on ice for 24 hours. Catalase preparations after standing at cool temperatures will show a speeding up or increase in relative activity when small portions are exposed to air before making the catalase determination.

The rôle of chloroplasts in albumin formation in green plants [trans. title], H. ULLRICH (*Ztschr. Bot.*, 16 (1924), No. 9, pp. 513-562, figs. 5).—Studies

are outlined as carried out on leaves of *Phaseolus*, *Lactuca*, *Tropaeolum*, *Brassica*, *Cucurbita*, and *Zea*, mostly detached from plants grown without nitrogen supply. Such leaves, when afterwards furnished in light with nitrogen as NO_3 , showed throughout the formation of nitrogenous materials, which tests proved to have been accumulated in the chloroplasts and presumably formed there. Nitrogen starvation shows diminution in size of the chloroplasts.

Growth of seedling in relation to composition of seed, M. E. REID (*Bot. Gaz.*, 81 (1926), No. 2, pp. 196-203, pls. 3).—Both in darkness and in light, a high-protein, high-oil food supply appears to be the most efficient in producing growth. The results, though free from contradictions, are not regarded as conclusive and are to be repeated and elaborated.

The relation of temperature to pollen tube growth in vitro, H. E. KNOWLTON and H. P. SEVY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 110-115, figs. 3).—Methods and data are given. It is believed that pollen germination and initial tube elongation on an artificial medium are normal.

It is suggested that since temperature affects in a similar way the growth rate of pollen of the varieties studied, it would probably affect them similarly in the orchard whether they were growing in selfed or in crossed pistils. As pollen tubes are not injured by temperatures above freezing (35 to 40° F.) for limited periods (48 hours), it would seem that the only effect of short spells of cool weather at bloom would be that pollen-tube growth is slower with a consequent delay in fertilization. When temperatures are constantly below 50° at pollination time, the set of fruit may be considerably decreased because of slow pollen-tube growth, the embryo aborting before the pollen tube reaches it. Abnormally high temperatures at bloom (75 to 85°) may reduce the set by its permanently injurious effect on pollen tubes and pollen-tube growth.

On the determination of the percentage of abortive pollen in plants, N. FERGUSON (*Brit. Jour. Expt. Biol.*, 2 (1924), No. 1, pp. 65-73, fig. 1).—The percentage of the abortive grains in pollen of *Lathraea clandestina*, *Ranunculus bulbosus*, and *Rubus* sp. appears to be a positive function of the age of the flowers used.

Anomalies in maize and its relatives, II, III, P. WEATHERWAX (*Bul. Torrey Bot. Club*, 52 (1925), Nos. 3, pp. 87-92, figs. 4; 4, pp. 167-170, figs. 10).—In the second member of this series (*E. S. R.*, 47, p. 326), entitled Many-flowered Spikelets in Maize, the author notes a variation, recently observed, which appears to involve a structural change of a more fundamental nature than the variability observable in maize, in that the rachilla of the spikelet is often more complex, the number of flowers in a spikelet is more than two, and the order of the flowers is reversed. The occurrences are described, with discussion as to their history and significance.

In part 3, entitled Carpellody in Maize, two strains of corn are dealt with which have a type of defective grain, the morphology of which has, supposedly, not been described previously. The anomaly, giving a very slender grain of the shoe-peg type, originated independently in two inbred lines of ordinary field corn. It is inherited as a recessive plant character. The two generations grown from these seeds show evidences that the peculiarity is due to the metamorphosis of rudimentary stamens of the female flower into imperfectly formed pistils.

Experiments with various plants to produce change of sex in the individual, J. H. SCHAFFNER (*Bul. Torrey Bot. Club*, 52 (1925), No. 2, pp. 35-47).—Citing particular results of work done with *Thalictrum dioicum*, *Cannabis sativa*, *Morus alba*, *Arisaema triphyllum*, and *A. dracontium*, the author claims that "all of these experiments add decidedly to the weight of the accumulating evidence that sexuality is primarily a physiological condition, that it is prima-

rily not at all Mendelian in nature and not amenable to Mendelian analysis, that it can frequently be controlled and reversed at will even with our present crude methods, and that it is preeminently a subject for ecological and physiological experimentation.

"A final conclusion is that the time has arrived for an honest revision of the ordinary textbooks and treatises dealing with heredity and sex to conform them to the evidence established, and to discontinue the presentation of untenable hypotheses which in the first place had little more evidence in fact as a basis for their promulgation than the fertile imagination of their proponents."

Sterile culture of higher plants, G. KLEIN and J. KISSER (*Die Sterile Kultur der Höheren Pflanzen*. Jena: Gustav Fischer, 1924, pp. 64, figs. 20).—A critical and systematic treatment of sterile culture as applied to higher plants concludes with a bibliography of 114 titles.

GENETICS

A list of chromosome numbers in angiosperms, L. O. GAISER (*Genetica* [The Hague], 8 (1926), No. 5, pp. 401-484).—The list in this contribution from McMaster University chiefly includes data published between 1921 and 1925, inclusive. The bibliography embraces about 330 titles.

The chromosomes of the chick soma, R. T. HANCE (*Biol. Bul. Mar. Biol. Lab., Woods Hole*, 51 (1926), No. 6, pp. 443-448, pl. 1).—Considerable difficulties are involved in the determination of the number of chromosomes in the chick, due to the small size of the shortest chromosomes and the failure of the component granules to unite or clearly indicate their proper relations until the late metaphase stage, if at all. The average of 78 counts of the somatic cells in studies at the University of Pennsylvania was 33, but 35 or 36 is suggested as more probable. The larger chromosomes are all in the form of J's, while the shorter ones are rod shaped. The sex chromosomes are the largest pair in the male (homozygous) and the largest single one in the female. The similarity between the morphology and the behavior of the chromosomes in somatic and germinal tissue, in conjunction with the complete inability of the highly specialized somatic cells to regenerate other than like tissue leads to the somewhat tentative hypothesis that the somatic chromosomes, as far as their genetic function is concerned, have either become functionless or their cytoplasmic environment is incapable of reacting to their potentialities.

An effect of temperature and age on crossing-over in the first chromosome of *Drosophila melanogaster*, C. STERN (*Natl. Acad. Sci. Proc.*, 12 (1926), No. 8, pp. 530-532, fig. 1).—Data are presented from experiments conducted at Columbia University, in which the amount of crossing over was increased within the bar to bobbed region of the sex chromosome among the flies developing from eggs laid during the first seven to nine days of adult life, by raising the females at 30° C. (86° F.), as compared with controls raised at 25°. Eggs laid at more advanced ages showed a considerable decrease in the amount of crossing over. As ova require about seven days to develop from the oocyte stage to maturity, it is assumed that the effect of the temperature is in some way associated with the localization of the spindle fiber attachment.

Correlations in orchard grass (*Dactylis glomerata*) [trans. title], Z. MAZURKIEWICZ (*Rocz. Nauk Rolnicz. i Leśnych*, 13 (1925), No. 3, pp. 538-563; *Ger. abs.*, p. 563).—Among the correlations determined on orchard grass plants in the third vegetative year were those between total weight and number of culms $r = +0.524 \pm 0.039$, total weight and weight of culms $+0.899 \pm 0.011$, total weight and absolute leaf weight $+0.885 \pm 0.012$, and between absolute leaf weight and weight of culms $+0.647 \pm 0.032$.

Mendelian analysis of the pure breeds of livestock.—IV, The British Dairy Shorthorns, H. C. MCPHEE and S. WRIGHT (*Jour. Heredity*, 17 (1926), No. 11, pp. 396-401, fig. 1).—Using methods similar to those described in previous studies (E. S. R., 54, p. 430), the coefficients of inbreeding and relationship inter se to the entire breed, to Favourite, and to Champion of England have been calculated for 100 cows selected at random from volume 6 of the Register of the British Dairy Shorthorn Association, and compared with the coefficients for the 100 highest producing cows selected from the same volume. The average milk production of the two groups, corrected for age, was 11,701 and 7,113 lbs., but no significant differences were observed between the two groups in the degree of inbreeding or relationship or when compared with the Shorthorn breed as a whole. Dairy Shorthorns have thus developed by the selection of high milk-producing animals more or less at random from the entire Shorthorn breed rather than by inbreeding from a small number.

[Genetic studies with poultry at the Connecticut Storrs Station] (*Connecticut Storrs Sta. Bul.* 142 (1926), pp. 177-179).—The studies of inbreeding and the production of abnormal embryos have been continued (E. S. R., 55, p. 26).

Inbreeding.—The first generation crosses between inbred lines showed a distinct improvement in hatchability, growth of chicks, weight of adult birds, winter egg production, and especially in the rate of attaining maturity. One such crossbred family was inbred by brother and sister matings for one generation without showing decline in vigor.

Hatchability of eggs.—Studies of abnormal embryos of the "parrot" type, which resembles chondrodystrophia in mammals, indicate that this condition arises early in development and that its chief characteristics are disturbances in the cartilage originating in the first week of development, and premature bone formation in the central part of the leg bones, in the base of the skull, and other parts, resulting in thickened and bent legs and short, misshapen heads. The ductless glands do not appear to play a part. The creeper fowl, which presents a similar condition in external appearance, has been found to be due to a single dominant factor, which is lethal when homozygous.

Further studies of the inheritance of rumplessness have shown that this condition is not lethal when homozygous, one bird having been found which produced all rumpless chicks when mated with normal males. Factors evidently operate in modifying the rumpless condition.

[Inheritance studies with poultry at the Kansas Station] (*Kansas Sta. Bien. Rpt.* 1925-26, pp. 105-107).—The inheritance of breed characters and egg production have been studied.

Inheritance of standard characteristics of breeds of poultry.—Matings of Rhode Island Reds having pale or bay red eyes produced equal numbers of offspring having pale, medium, and red eyes in the different crosses, indicating that these eye colors were not inherited. Variations in the down color of Rhode Island Red chicks studied in a similar way proved to be heritable.

A study of the inheritance of the characteristics in which the Single Comb White Leghorns and the Jersey Black Giants differ.—In studies of the inheritance of color in this cross it was found that the F_1 birds were predominantly white because of the epistatic behavior, rather than the dominance, of white to black. The yellow shank color of the White Leghorn was sex linked and dominant to the slaty shank of the Black Giant. The ear lobe color appeared to be inherited in a complex manner, but the tendency in the F_1 is toward white and the location is in an autosome.

The inheritance of egg production in Single Comb White Leghorns.—The effect in this project has been mainly directed toward the establishment of a strain which breeds true for low egg production by selection and inbreeding from an exhibition flock. After four generations many evidences of low vitality are becoming apparent.

Colour inheritance in sheep.—II, **The piebald pattern of the Piebald breed**, J. A. F. ROBERTS (*Jour. Genetics*, 17 (1926), No. 1, pp. 77–83, pls. 2).—Further studies of the genetic composition of the piebald pattern in sheep (E. S. R., 56, p. 32) have shown that the Piebald breed differs from other breeds in that it possesses a factor for dominant black and a recessive factor for spotting which restricts the black to certain areas in the piebald animals. This is a continuation of the series previously noted (E. S. R., 53, p. 223).

Color breeding in pigeon plumage, J. METZELAAR (*Geneva, Ill.: Amer. Pigeon Keeper*, 1926, pp. 55, pls. 2, figs. 6).—A popular presentation of the knowledge of the inheritance of colors in pigeons.

Sex-linkage and other genetical phenomena in canaries, F. M. DUBHAM (*Jour. Genetics*, 17 (1926), No. 1, pp. 19–32, pl. 1).—An account is presented of the results of matings between black-eyed and pink-eyed (cinnamon plumage) canaries, the latter being a sex-linked recessive. Matings were concerned particularly with the occurrence, though rare, of pink-eyed males and black-eyed females from matings between black-eyed and pink-eyed birds. The results of crosses of cinnamon birds with lizard canaries and with the species *Chrysomitris cucullata* are also reported.

Studies in animal reproduction and inheritance (*Kansas Sta. Bien. Rpt. 1925–26*, pp. 113–115).—Experiments so far conducted with guinea pigs indicate that there is no linkage between pink eye (*p*), nonextension (*e*), nonyellow (*Cr*), nonagouti (*a*), chocolate (*b*), and smooth (*r*).

An analysis of the sex ratio of 19,000 guinea pigs produced from 1914 to 1925 showed that there were 105.8 males to 100 females. Dams were found to produce a preponderance of males in their offspring when 15 months of age.

In a study of size inheritance in rats, the F_2 generation was more variable than the F_1 , pointing toward Mendelian inheritance, but the larger strains have become sterile, probably due to not mating until after 200 days of age.

In Chinchilla rabbits it was found that blue eyes are recessive to brown. The blue-eye factor is also linked to *Cr*, the factor causing the absence of red in the Chinchilla coat. The light-brown eyed condition of Flemish Giants was found to be recessive to dark-brown eyes.

A study of the inheritance of eye defects in rabbits (*Kansas Sta. Bien. Rpt. 1925–26*, p. 117).—In an effort to duplicate the work of Guyer (E. S. R., 44, p. 566), fowl serum immunized against rabbit lens protein was injected intravenously into female rabbits on alternate days from the seventh to the fourteenth day of pregnancy, while the lens of other females was broken up or needled on about the ninth day of pregnancy. Of the 59 offspring from pregnant rabbits receiving the antilens protein serum and the 110 offspring from females having the lenses needled, only one possible abnormality appeared. One animal having a slight abnormality in one eye appeared among young from untreated females. The results so far may be considered as entirely negative.

The morphogenetical value of the weight of rabbits at birth, S. KOPEĆ (*Jour. Genetics*, 17 (1926), No. 2, pp. 187–193, figs. 4).—Data are presented from studies of 60 rabbits forming the F_2 generation from 2 Himalayan does sired by a Silver buck, at the Government Institute for Agricultural Research at Puławy, Poland, showing that the birth weights of the rabbits were dis-

tinctly related to the size of litter ($r = -0.443 \pm 0.099$). There was no such relationship between the rabbits at maturity when the number raised per litter was reduced to 4, having birth weights varying from 30 to 60 gm. When separated into two groups of approximately equal numbers according to weight at birth, and into the two sexes, those heavier at birth continued to have higher average weights up to 16 months. The correlations between the weights at the different months and the birth weights varied from 0.27 to 0.72 and were nearly all greater than 3 times the probable error. It is, therefore, concluded "that though both external and genetic agencies affect the weight of newborn rabbits, only the latter have a distinct influence upon the weight of growing and adult animals." Birth weights, therefore, give an indication of mature weight sufficiently satisfactory for studies of the inheritance of weight in rabbits.

Gynandromorphs and other irregular types in Habrobracon, P. W. and A. R. WHITING (*Biol. Bul. Mar. Biol. Lab., Woods Hole, 52 (1927), No. 2, pp. 89-120, pls. 2, figs. 8*).—This contribution is a continuation of articles previously noted (*E. S. R.*, 56, p. 223).

Influence of age of mother on appearance of an hereditary variation in Habrobracon, P. W. WHITING (*Biol. Bul. Mar. Biol. Lab., Woods Hole, 51 (1926), No. 6, pp. 371-384, pl. 1, fig. 1*).—Studies of the occurrence and inheritance of an hereditary deficiency of the external genitalia associated with a deficiency of the posterior part of the digestive tract, at the University of Maine, showed that the abnormality could be increased and maintained by selection, but the character appeared to be very complex genetically. Similar results were obtained in working with a deficiency of the genitalia associated with deficient antennae. The percentage of deficient offspring was, however, found to increase with the age of the dam up to 10 or 14 days of adult life, after which there was a decrease. No significant change in the type of deficiency associated with the age of the dam was apparent. Three explanations were suggested, of which an increased amount of crossing-over associated with the dam's age of 10 to 14 days, which coincided with the time of producing the largest percentages of abnormal offspring, appeared most probable.

The menstrual cycle in the monkey: Effect of double ovariectomy and injury to large follicles, E. ALLEN (*Soc. Expt. Biol. and Med. Proc., 23 (1926), No. 6, pp. 434-436*).—Continuing studies of the oestrous cycle in the monkey (*E. S. R.*, 56, p. 227), it was found that the removal of both ovaries on the first day of menstruation had no apparent effect on the period, but double ovariectomy or injury to the large follicles after the follicular phase of the cycle was followed in from 4 to 6 days by typical menstruation. These menses occurred from 5 to 13 days before expectation, from which it is concluded "that menstruation is probably due to an absence of follicular hormonal stimulus after it has been acting for a certain period of time." It is, however, noted that the presence of the follicular hormone in human corpora lutea has been demonstrated, and the corpus of the monkey may also continue to secrete the follicular hormone, thus postponing the onset of menstruation.

Studies of the thyroid apparatus.—XXXIII, The rôle of the thyroid apparatus in the growth of the reproductive system, F. S. HAMMETT (*Amer. Jour. Physiol., 77 (1926), No. 3, pp. 527-547, figs. 6*).—In continuing this series of studies (*E. S. R.*, 55, p. 859), data are presented showing the rate of growth of the testis, ovary, epididymis, and uterus of normal and thyroparathyroidectomized and parathyroidectomized male and female rats up to 100 days of age. It is concluded from the correlations made that the male reaches sexual maturity at an earlier age than the female, but environmental or dietary

conditions may hasten or retard sexual maturity. The ovary was found to develop more rapidly than the uterus. The growth of the reproductive system was not related to the activity of the thyroid or parathyroid glands except as the latter were related to body growth. The reproductive system of the male was less sensitive to thyroid and parathyroid deficiency than the reproductive system of the female.

The family resemblance of female rats with respect to (1) the ages of first oestrus, and (2) the bodyweights, C. P. STONE (*Amer. Jour. Physiol.*, 77 (1926), No. 3, pp. 625-637, fig. 1).—An analysis of the relation between oestrus phenomena and growth in litter mates of female rats in the University of California colony is reported. As the age of attaining first oestrus did not appear to be affected by the litter size, individuals from all sized litters were paired at random with a litter mate, using in one comparison each individual only once and in another comparison using all possible combinations within the litter for determining the correlation between litter mates for the age at which the first oestrus occurred and the weights at 30, 40, 50, 60, 70, and 80 days.

According to the various methods used, the correlation between the litter mates for the age of attaining first oestrus was approximately 0.2, from which it was concluded that there was only a slight advantage in selecting litter mates for studying factors affecting the age at first oestrus. The body weights of sisters were much more closely correlated, ranging from approximately 0.4 to nearly 0.7, being highest at 30 days. There is, therefore, a considerable advantage in selecting litter mates for comparative studies of body weight, especially at the younger ages.

The anomalous appearance of male sexual characters in female fowls, A. S. PARKES and F. W. R. BRAMBELL (*Jour. Genetics*, 17 (1926), No. 1, pp. 69-76, pls. 3).—Observations and descriptions of the reproductive organs of five female fowls which exhibited male secondary sexual characteristics are presented. The post-mortem examinations showed that one of the fowls was a functionally active female with complete male plumage. Another showed the presence of ovarian and testicular tissue, and was, therefore, a possible case of sex reversal. The other three were females with male head furnishings and female plumage, but showed no trace of testicular tissue.

FIELD CROPS

[Agronomic studies in Colorado, L. S. DURELL] (*Colorado Sta. Rpt.* 1926, pp. 19-21, 23, 24).—Deferred rotation seemed preferable to continuous grazing in low foothill pasture (cattle), the latter showing overgrazing and injury to vegetation. Inclosures protected from grazing in the national forests gave evidence that natural revegetation is fairly rapid, provided a natural stand of palatable plants has not become too thin. Intensive studies were made on mixtures of tame grasses variously clipped.

Heating alfalfa seed at 60° C (140° F.) for 1 hour was found to correct the condition known as hardness (E. S. R., 53, p. 135) and to raise the germination to 95 per cent or more. The epidermal layer of the seed coats was shown to be the factor influencing permeability, and the use of certain dyes indicated that heating so changes the chemical composition of the cells of this layer that they can absorb water. No loss of viability followed heating, as with scarification.

In tests of the field value of frosted seeds of oats and barley, often produced in the high altitudes, it was found that by using low temperatures such seeds will germinate nearly as well as normal seeds do by the usual methods. Field plantings in different parts of the State showed that frosted barley giving 95

per cent germination by the low temperature method produces about 90 per cent as good a stand as normal barley germinating 95 per cent, while frosted oats produces about 70 per cent as good a stand as normal oats.

Arsenical sprays were effective over a wide range of concentration on annual weeds and were injurious at all growth stages. However, penetration in quantities lethal to the subterranean organs was not evident with the poisons studied. The herbicidal value of Cyanogas, cyanamide, and carbon disulfide was also tested. Horizontal roots of poverty weeds grew from 4 to 10 ft. a year in natural conditions in soft soil. Morning glory roots did not spread much more but often grew deeper, and their food storage capacity seemed greater. The poverty weed roots live through three growing seasons. The size and gross morphology of roots of these weeds seem to depend on the physical characteristics of the soil. When root sections were planted at depths of from 15 cm. down to 90 cm. and single pieces below 90 cm. the morning glory showed no difference in regenerative activity due to depth as did the poverty weed. In all cases the regenerative capacity was a function of the size of the root. A definite relation was found between the rate of regeneration and season, those taken in the fall showing the highest rate. Roots of these weeds could withstand great desiccation in the soil.

Annual weeds, except those that came up from seed, were completely controlled by cutting even with the ground, and poverty weeds were materially injured. Annuals were killed by covering with soil 6 to 18 in. deep, whereas perennials penetrated the 18-in. layer. Morning glories, dug down to 6, 12, and 18 in. and all roots removed, came through 6 in. of soil but not from greater depths.

[Agronomic work at the Connecticut Storrs Station] (*Connecticut Storrs Sta. Bul. 142 (1926), pp. 174-176, figs. 2*).—Silage corn planted early generally excelled late plantings. Canadian-grown oats of a pure line were no better than home-grown seed of that line. Disease seemed a more important factor than climate in degeneracy in potatoes. Sources of seed of Green Mountain and Irish Cobbler potatoes in tests from 1921 to 1925, inclusive, ranked, respectively, Maine 100, 100; New York, 105, 111; Vermont, 105, 118; and Canada, 94, 108. Hubam sweet clover continued to surpass oats as a nurse crop for alfalfa. Attempts to get a stand of sweet clover in old pastures have been unsuccessful. The climate seemed too severe for kudzu. Fertilizer tests on pastures and rotations are noted briefly.

[Field crops investigations in Florida], W. E. STOKES, R. W. RUPRECHT, A. F. CAMP, O. F. BURGER, J. H. JEFFERIES, W. B. TISDALE, and G. E. TEDDER (*Florida Sta. Rpt. 1926, pp. 13, 14, 17-22, 32, 33-40, 81, 102-104, 109-111, 116-122, figs. 3*).—Experiments with field crops (E. S. R., 55, p. 824) at the station and substations embraced variety trials with corn, oats, sorghum, cotton, potatoes, tobacco, soy beans, peanuts, velvet beans, alfalfa, *Crotalaria* spp., and miscellaneous legumes and lawn and pasture grasses; fertilizer tests with corn, peanuts, tobacco, and pastures; breeding work with cotton and peanuts; trials of silage, cover, and green manure crops; planting tests with *Crotalaria* and soy beans; comparisons of delinted v. untreated cottonseed; studies of the growth, behavior, and productivity of pasture grasses; and observations on the root systems of sod-forming grasses. Analyses were made to determine the mineral content of grasses and forage crops.

[Farm crops investigations in Iowa] (*Iowa Sta. Rpt. 1926, pp. 10-14, 18, 37, 43, 55, 59*).—Field crops of particular merit included Canadian variegated alfalfa, Iobred wheat, Ames Amber sorgo, and Iogold oats. When common alfalfa from North Dakota winterkilled 30 per cent and that from Kansas

50 per cent, such sorts as Grimm, Baltic, and Cossack had practically no loss, whereas seed from Argentina, Africa, Italy, and Spain winterkilled about 100 per cent. No imported clover seed, except from Canada, was found safe for Iowa conditions. Wood clover seemed limited in its soil adaptation. The best ten F_1 corn hybrids yielded about 30 per cent more dry corn than the best standard varieties. Inheritance studies with dent sweet corn hybrids have been noted (E. S. R., 56, p. 519). Iogren oats has outyielded Iowa 103, Lowar, Green Russian, and home-grown varieties.

Farmers comparing methods of interplanting corn and soy beans reported that soy beans in corn reduces the corn yield about 10 per cent and about 15 per cent when an unsatisfactory distribution of beans is had. The reduction in the corn yield was notably greater when the beans had no nodules. In inoculation of soy beans with soil the degree of inoculation increased with the quantity of soil used from 0.5 pt. to 24 pt. per bushel of seed. Soil broadcast at the rate of 500 lbs. per acre resulted in the best inoculation. The number of soy bean organisms used in inoculation seemed of significance in obtaining desirable results. The total protein in inoculated soy beans was found to bear a definite relation to the number and size of the nodules. The percentage of protein increased with the degree of inoculation and was highest in plants best inoculated. On the test soil hydrated lime did not affect the weight of tops and roots of inoculated soy beans but increased the protein percentage very markedly in both tops and roots, whereas acid phosphate increased the weight of tops and roots but had no effect on the protein content. A method developed for sterilizing legume seeds provides for treatment of the seeds with a 20 per cent concentration of hydrogen peroxide for 30 minutes.

[Report of field crops work in Kansas, 1924-1926] (*Kansas Sta. Bien. Rpt. 1925-26, pp. 39-51, 133-138, 141-143, 144-147*).—Agronomic experiments (E. S. R., 52, p. 433) reported on from the station and substations for the period indicated comprised variety trials with winter and spring wheat, corn, oats, barley, rye, grain sorghum, sorgo, cotton, soy beans, cowpeas, alfalfa, and turf and lawn grasses; cultural and planting tests with oats, corn, wheat, and miscellaneous forage crops; a cutting test with alfalfa; fertilizer trials with wheat and alfalfa; and improvement work with wheat varieties and hybrids, oats, barley, corn, and sorghum. The resistance of certain oats strains to smut is indicated, and the behavior of false wild types and other aberrant forms in Kanota oats is again commented on.

Such sorghums as feterita, milo, Amber sorgo, and shallu were severely injured by chinch bug, while durra, kaoliang, Sumac, kafir, and the hybrids milo \times kafir, hegari \times milo, and Kansas Orange \times milo were distinctly resistant. Plants showing the most heterosis apparently withstood chinch bug attack most successfully. Smut resistance studies revealed that, excepting a few susceptible strains, feterita, Kansas Orange, Sumac, and hegari \times milo were generally resistant, whereas Dwarf Yellow milo, kafir, and some natural milo hybrids were generally susceptible.

Interplanting tests showed the yield of corn to be reduced in proportion to the quantity of soy beans produced. During 10 years April 20 to May 1 has been the optimum planting period for corn, and planting with a furrow opener on plowed land resulted in larger yields than listing and surface planting. From 16 to 20 in. in 42-in. rows has been optimum for corn of the Pride of Saline type. The main purpose of cultivation was shown to be weed control, and stirring the ground with a one-horse cultivator after corn is laid by seemed a waste of time and effort. Of hybrids between selfed lines of corn, the highest yielding combinations were crosses between lines of locally adapted sorts.

No consistent decrease in the number of bindweeds was observed to result from any of several chemical treatments compared with hoed fallow except on plats sprayed with sodium chlorate solution. Tests at the Fort Hays Substation suggested starting work with fallow in April and May, since spring-plowed fallow encourages more rapid growth of the weed. Sorghum smother crops succeeded best when sown about July 1 after an intensive fallow period. Effective eradication appeared to have resulted from 8 tons or more of salt without mulching or watering. With these treatments the salt was less effective. Under moister soil conditions all rates below 20 tons were ineffective.

In the tillage experiments at Fort Hays increased winter wheat yields were secured by early fall listing or early plowing as compared with late plowing. A study of the relation of crop yield to climate indicated that the character and distribution of rainfall is much more important than the total quantity. The distribution of rainfall appeared to be the prime factor governing the degree of tillering, time of heading, and seed production of grain sorghums grown in variously spaced rows. In 1924 and 1925 drought preceding the heading period and followed later by excessive rainfall was more favorable for seed production in wide-spaced rows than in single-spaced rows, while in years of normally distributed rainfall the reverse held true. Total yields in single spaced rows, however, have always exceeded those in rows spaced wider.

During 11 years for which data are available at Garden City winter wheat failed six times regardless of the cultural method. Wheat on fallow in rotation averaged 10.8 bu. per acre. The highest yielding continuously cropped plat, early fall listed, averaged 7.6 bu. per acre as compared to 6.1 bu. for early fall plowing and 4.8 bu. for late fall plowing. Ordinary rows have produced more milo grain than double width rows. The fertility experiments under irrigation during 5 years did not show material benefit from commercial fertilizers. The lowest and highest average yields of alfalfa were made on land receiving 24 and 64 in., respectively, of irrigation water annually, the optimum appearing to lie between 36 and 42 in. for average years. The average yields of the various feed, grain, and row crops in the irrigated rotations showed that considerable benefit resulted from the use of alfalfa in rotation with these crops.

[Field crops investigations in Kenya, 1923-24 and 1924-25], A. HOLM, G. L. J. BURTON, G. M. HAMILTON, E. HARRISON, W. L. WATT, and R. J. LATHBURY (*Kenya Colony Dept. Agr. Ann. Rpts. 1924, pp. 8-13, 15-17, 112-121, 128-135; 1925, pp. 10-14, 16-18, 22-24, 149-152, 160-163, 175-177, 192-201, pls. 3*).—These pages report the continuation of experiments with various field crops noted earlier (E. S. R., 53, p. 632).

[Field crops work in Uganda in 1924 and 1925], S. SIMPSON, L. HEWETT, ET AL. (*Uganda Dept. Agr. Ann. Rpts. 1924, pp. 4-6, 8, 14-17, 30, 31; 1925, pp. 4-6, 7, 8, 13, 14, 16-22, 34, 35*).—The continuation of previous investigations (E. S. R., 52, p. 34) is reported on.

The results of examinations by the Imperial Institute on silk (*Anaphe infracta*) from Uganda, describing degumming tests and yarns and fabrics made therefrom, are given in the 1924 report. Twenty-five species of native grasses being tested for their forage value are described in the 1925 report.

Varieties of general crops for muck land, P. M. HARMER, C. E. CORMANY, and E. E. DOWN (*Michigan Sta. Quart. Bul., 9 (1927), No. 3, pp. 83-89*).—The comparative yields on fertilized and unfertilized muck lands and recommendations are given for varieties of oats, barley, corn, potatoes, and sugar beets.

Fertilization and yield on different peat soil types [trans. title], A. BAUMAN (*Svenska Mosskulturför. Tidskr.*, 40 (1926), No. 4, pp. 300-310).—The yields secured in experiments conducted for a series of years in different localities with a variety of crops are reported and briefly discussed. The weight of the soil per cubic meter and the soil content of organic matter, lime, and nitrogen for the different localities are given, together with the crop rotation followed. The fertilizer applications per hectare on the larger number of plats, consisting of 200 kg. (178 lbs. per acre) of 40 per cent potash salt and 200 kg. of 20 per cent superphosphate, were compared with the use of no fertilizer and applications of 250 kg. of the potash salt and 200 kg. of the superphosphate, 30 tons of barnyard manure (12.14 tons per acre), 30 tons of the manure with 300 kg. each of the potash salt and the superphosphate, and 300 kg. of the potash salt with 400 kg. of Thomas slag.

In nearly all cases the fertilizer applications produced the largest crop increases on the soils more recently brought under cultivation. Meadows treated with light applications in the beginning of the test produced larger increases in yield than those secured where the initial applications were heavy. On sphagnum moor soil meadows, largely of clover, and on land growing leguminous crops, the yields of green forage were about the same under the potash and superphosphate treatment; but when the meadows were in grass a supplementary treatment of 100 to 150 kg. per hectare of nitrate of soda or Norwegian nitrate was required to make the yields uniform.

Liming lime-poor peaty soils produced marked yield increases, and the effect of liming was perceptible for 10 years. The application of 250 to 500 cubic meters per hectare (132 to 265 cu. yds. per acre) of sand, gravel, or clay on peat or moor soils proved efficient in increasing the yields and making them more uniform.

Characteristics of the roots of meadow and pasture plants [trans. title], D. SCHRÖDER (*Landw. Jahrb.*, 64 (1926), No. 1, pp. 41-64, figs. 24).—The distinctive characteristics of the roots of 24 grasses and other meadow and pasture plants are set forth in a determinative key, supplemented by illustrations of enlargements (200:1) of cross sections.

Work of the Swedish Moor Culture Association, 1886-1925 [trans. title], H. OSVALD (*Svenska Mosskulturför. Tidskr.*, 40 (1926), No. 4, pp. 239-287, figs. 9).—In this publication the history of the Association is outlined, the various activities are described, and the results of the work are summarized.

Permanent pastures, M. E. MCCOLLAM (*Washington Col. Sta. Bul.* 211 (1927), pp. 56, figs. 8).—The importance of pastures in western Washington, pasture land types and current practices, the characteristics of permanent pasture grasses and clovers, seeding mixtures, and recommended cultural and management practices are described, with a report of pasture experiments at the Western Washington Station.

In 4 years' tests, a mixed sod originally in good condition and subjected to grazing, was successfully maintained by alternate grazing, close grazing, and heavy stocking. Further treatment, including manure and superphosphate top-dressing, scarifying, and reseeding, produced marked improvement in the grass yield, this being the most promising improvement method tested. Scarifying with a spike-tooth harrow successfully controlled moss, while a lime top-dressing did not. Noteworthy behavior of the flora on the various plats included the equalization of the percentage of the several grasses under the manure and superphosphate treatment as well as an increase in white clover, a heavy increase of white clover under the superphosphate with and without lime, no diminution of velvet grass under close grazing, maintenance of Italian

ryegrass on the reseeded plats and disappearance on those not reseeded, and a remarkable increase in hop clover on the untreated pasture.

Effect of growing legumes upon succeeding crops, F. LÖHNIS (*Soil Sci.*, 22 (1926), No. 5, pp. 355-389, fig. 1).—Field, greenhouse, and laboratory experiments conducted by the Bureau of Plant Industry, U. S. D. A., dealt with the effects of legumes upon succeeding crops, involving a number of crop rotations.

The results are said to have shown conclusively that the beneficial after effect exerted by legumes harvested for hay is due to a considerable extent to favorable changes in the microflora of the soil. These changes are still marked and even increase a few weeks after the surface growth of the legumes has been removed, but several months later, and especially after the soil has dried out thoroughly, this beneficial effect upon the succeeding crop no longer seems to be noticeable. The increases in the succeeding crops caused by this after effect of harvested legumes often exceed those caused by legumes used as green manures, and the author holds it probable that in field tests the crop increases ascribed to green manuring are in fact more frequently due to the special after effect of the growing legumes.

Fallow for small grains, R. S. TOWLE (*Wyoming Sta. Bul.* 150 (1927), pp. 33-42, figs. 2).—In experiments at the Sheridan Field Station (E. S. R., 52, p. 527) in cooperation with the U. S. Department of Agriculture during the period 1918-1926, inclusive, winter wheat yielded nearly twice as much on fallow as after winter wheat, 46 per cent more than when seeded on oats stubble, and 37 per cent more than on disked corn ground. While higher yields of spring wheat and oats were made on fallow than on land cropped the year before, the gain by the fallow was smaller than with winter wheat. Fair yields were made on fallow in years when the crop after small grain or corn was poor or practically failed. Barley averaged nearly as much on corn ground as on fallow. The increase in winter wheat yield due to fallow appeared enough to pay for the fallow, except possibly where the crop may follow corn, whereas the increase with spring grain did not seem economical. Part of the small grain acreage should be grown on fallow to insure a crop in dry years and to aid in weed control.

Experiments with grain crops, R. SUMMERBY and E. A. LODS (*Quebec Dept. Agr. Bul.* 90 (1925), pp. 15, figs. 3).—The results of varietal trials with barley, oats, and wheat, and seeding trials with barley, oats, wheat, and field peas carried on at Macdonald College within the period 1906-1921 are summarized.

The after-ripening of cereals [trans. title], Z. PIETRUSZCZYŃSKI (*Rocz. Nauk Rolnicz. i Leśnych*, 15 (1926), No. 1, pp. 206-235; *Ger. abs.*, pp. 234, 235).—Extensive experiments by the author showed that the period required by cereal grains to attain full maturity and maximum germination energy varied with the species, variety, and race. The after-ripening period is longest in oats, shorter in barley and wheat, and shortest in rye, and shorter in winter cereals than in spring grains. The period differed among different varieties grown under like conditions, being shorter in the early rather than in late maturing varieties. Seasonal conditions in different years produced a variation in the period in the same variety. In dry years the seed attained its maximum germinability early, while the period was prolonged in damp years.

Breeding improved varieties of smooth-awned barleys, H. K. HAYES (*Jour. Heredity*, 17 (1926), No. 10, pp. 371-381, figs. 6).—Methods used at the Minnesota Experiment Station in breeding desirable economic smooth-awned barleys (E. S. R., 47, p. 228) are described, with comments on several smooth-awned varieties obtained thereby.

A first series of purified hybrids between smooth-awned sorts and standard barleys failed in Minnesota because they were more susceptible to the spot

blotch disease (*Helminthosporium sativum*) than standard varieties. In a second series of crosses, wherein the problem of resistance to *H. sativum* was attacked, two or three main pairs or groups of genetic factors were involved, and there was linkage between the factors for susceptibility v. resistance with the factors for black v. white grain color and smooth v. rough awn. The linkage, however, was not absolute, and crossovers made it possible to obtain smooth-awned, white-seeded varieties, also resistant to *H. sativum*, e. g., Velvet, Comfort, and Glabron. These barleys appear to equal Manchuria in yielding ability, strength of straw, and resistance to attacks of *H. sativum*. Glabron seems more desirable as to strength of straw than Manchuria (Minnesota 184), the currently recommended variety in Minnesota, being adapted therefore for rich lands where ordinary varieties of Manchuria lodge badly.

“The McNaughton system” of curing beans, H. R. PETTIGROVE (*Michigan Sta. Quart. Bul.*, 9 (1927), No. 3, pp. 113-116, figs. 2).—The McNaughton system, essentially consisting of stacking windrowed pulled beans on a straw pad around a steel fence post, is outlined. Experience at the station indicates that this method will eliminate most harvest hazards, facilitate curing, reduce losses, and permit earlier seeding of fall grains.

Hard seeds and broken seedlings in red clover (*Trifolium pratense*).—II, Storage problems, A. NELSON (*Bot. Soc. Edinb. Trans. and Proc.*, 29 (1925-26), pt. 3, pp. 282-290, figs. 5).—As in a previous report (E. S. R., 52, p. 831) abrasion resulted directly in the production of broken seedlings proportional to the intensity of abrasion. Immediately on storage the percentage of broken seedlings declined, with concurrent rise in the percentage of seeds which germinate normally. Further storage resulted in a rapid loss in value of the abraded lots, due to a rapid death rate proportional to the degree of abrasion.

Broken seedlings are attributed to testa weakness caused by abrasion and their subsequent disappearance and the following death rate to continued loss of embryonic vigor, resulting in a return to a balance of internal pressure to seed coat strength. All these fluctuations are proportional to the degree of abrasion. Moist storage kills off a class of seed distinct from the abraded seed, probably those with a weak or immature embryo.

“Hard seeds” in Leguminosae, A. NELSON (*Nature [London]*, 118 (1926), No. 2979, pp. 804, 805).—Working with sweet peas and other legumes, the author found good evidence for the belief that hardness does not lie in the seed coat itself but is the result of a varnish-like deposition on the seed surface produced within and by the pod. It is suggested that the watery fluid found bathing the seeds, when fully concentrated, deposits the varnish, which on drying becomes insoluble in water and forms an impermeable film. Treatment with dilute sulfuric acid, even for a short period, causes hard seeds to behave normally, whereas prolonged digestion with concentrated caustic potash has no effect. Hard seeds occur in practically every sample and are considerably affected by the weather previous to harvest. “Further, the best ripened seeds always contain most hard seeds.”

Moisture content of corn in relation to relative humidity and temperature of the atmosphere, H. W. ALBERTS (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 1029-1034, fig. 1).—The moisture content of shelled Reid Yellow Dent corn was observed at constant temperatures of about 0, 10, 20, and 30° C. at relative humidities ranging from 0 to 100 per cent at the University of Illinois.

The moisture in the corn was found to be practically independent of temperature and to vary only with relative humidity, except when the latter was extremely low or extremely high (below 10 per cent and above 90 per cent).

When the relative humidity was about 100 per cent, the moisture content of the corn was greatest at the highest temperature, and when the relative humidity approached 0 per cent the moisture content was greatest at the lowest temperature. Since a rise in temperature increases the moisture-absorbing capacity of the air, application of artificial heat, together with ventilation, is deemed advisable on cold winter days to maintain a low moisture content in corn in seed-corn storage houses.

Removal of plant food in thinning corn, J. DAVIDSON (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 962-966).—Analysis of Boone County White corn seedlings removed during thinnings to 3 per hill at 18 days after planting and to 2 a week later showed that the seedlings pulled out took away considerable quantities of nitrogen and potassium from the hills but left behind small quantities of the phosphorus originally contained in the seed. About twice as much potassium and nitrogen was absorbed between the first and second thinnings by the corn seedlings as between planting and the first thinning. The young corn seedlings contained appreciable quantities of nitrates and ammonium salts.

Application of sodium nitrate and ammonium sulfate consistently increased the absorption of nitrogen, potassium, and phosphorus by the seedlings during the period between planting and the first thinning, but this effect became less pronounced at the time of the second thinning. Prompt thinning, avoiding over-planting, and the use of good seed may conserve the nutrients immediately available to seedlings remaining after thinning.

Results of fertilizer experiments with cotton on Alabama soils, J. T. WILLIAMSON (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 1050, 1051).—The average of numerous experiments by the Alabama Experiment Station showed that a complete fertilizer gives best results on cotton on nearly all Alabama soils. Recent tests on rate and ratio of applying fertilizer to cotton made on Norfolk, Orangeburg, Dekalb, and Decatur soils showed that the proper rates for combining materials for cotton is sodium nitrate 100 lbs., acid phosphate 200 lbs., and potassium chloride 25 lbs. Combined in the above ratio the average profit from the use of 650 lbs. per acre surpassed that from rates of 325 and 975 lbs.

A botanical study of the flax plant.—V, The effects of artificial fertilizers on the external and internal characters of the flax plant, A. G. DAVIN (*Linen Indus. Research Assoc., Research Inst. Mem.* 27 [1925], pp. 15, fig. 1).—Observations on the effect of superphosphate, ammonium sulfate, and potassium chloride on flax (*E. S. R.*, 53, p. 522) grown in plats subjected to statistical analyses showed that potassium not used in excess may cause an increase in length and superphosphate an increase in the percentage of fiber. A combined dressing of 5 cwt. per acre of superphosphate and 2 cwt. of potassium chloride is indicated for tallness, high fiber percentage, and early maturity. The use of ammonium sulfate, except on soils known to be deficient in nitrogen, did not seem advantageous, as it produces thick succulent stems which are easily lodged while the quantity of fiber remains the same.

Investigations on the fruiting habits of the horse bean (*Vicia faba major*) [trans. title], J. GOLIŃSKA (*Rocz. Nauk. Rolnicz. i Leśnych*, 15 (1926), No. 3, pp. 528-553, figs. 4; *Eng. abs.*, pp. 551-553).—Studies on plants of Windsor and Mazagan horse beans, variously pruned to 1 and 2 pods per leaf axil, topped, or with the flowers stripped from the lower half of the stalks, demonstrated the existence of a close relation between the vegetative and reproductive stages. Removal of pods seemed to prolong the growing season, increase the leaf surface, and promote bushiness of the plant. The degree of bushiness did not appear to affect the size of the seed or the height of the plant. Quality of seed

does not depend on the place of fruit setting or on the percentage of pods gathered. The size of seed was smaller in topped plants and in plants with the lower half stripped than in normal plants. Correlations regarding 100-seed weight were generally low, whereas those between size of seed and height of plant and grain yield were relatively high. The plants with single pods on each leaf axil bore the largest pods and seeds.

Influence of spacing on the yield and individual variability of potatoes [trans. title], Z. RUEBENBAUER (*Rocz. Nauk Rolnicz. i Leśnych*, 15 (1926), No. 2, pp. 339-370; *Ger. abs.*, pp. 368-370).—The investigations reported on were concerned with effects of spacings of 30 by 30 cm., 42.5 by 42.5, and 60 by 60 cm. on the yields, number and weight of tubers, starch yields, and starch content of the Silesia and Jubel potato varieties. Several correlations are indicated.

[Descriptions of potato varieties cultivated in Poland] J. GOLIŃSKA (*Rocz. Nauk Rolnicz. i Leśnych*, 14 (1925), No. 1, pp. 57-111, figs. 17; *Fr. abs.*, pp. 77, 78).—Forty-five potato varieties cultivated in Poland are described, important flower, germ, stalk, and tuber characters being arranged in comparative tables.

Seed potato certification in Pennsylvania, W. A. McCUBBIN, R. E. HARTMAN, and K. W. LAUER (*Penn. Dept. Agr. Bul.* 420 (1926), pp. 45, figs. 16).—This bulletin briefly reviews the development and status of seed potato certification in the United States and Pennsylvania, outlines inspection and certification standards, and indicates important factors in the growing of seed potatoes. Prominent varieties are described and are classified on a flower color and tuber color basis. A detailed discussion of disease and insect control is supplemented by a key to the common potato diseases. Diseases affecting seed certification are described and illustrated, and control methods are outlined.

Sisal culture in German East Africa, R. HINDORF (*Der Sisalbau in Deutsch-Ostafrika*. Berlin: Dietrich Reimer, 1925, pp. VIII+171 figs. 33).—This book relates the development and status of sisal production in East Africa, particularly in the former German colonies, points out growth conditions and other factors in economical production, outlines cultural and field practices, harvesting, and methods of preparing the fiber, gives an account of breeding work with sisal, and indicates the prospects of the crop.

A preliminary note on the relation of photosynthetic carbohydrate to nodule formation on soybeans, L. T. LEONARD (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 1012-1116).—Preliminary experiments in the Bureau of Plant Industry, U. S. D. A., indicated that nodule formation on certain varieties of soy beans is intimately connected with a carbohydrate-forming function of the plant to such extent that nodule formation will be greatly inhibited when insufficiency of light, carbon dioxide, or chlorophyll excessively diminishes the plant's capacity to produce the proper carbohydrate.

A critical study of methods used in varietal tests with sugar beets [trans title], F. KOROWSKI (*Rocz. Nauk Rolnicz. i Leśnych*, 13 (1925), No. 3, pp. 509-537; *Eng. abs.*, p. 537).—Statistical studies on 38 strains of sugar beets showed the existence of systematic errors. The variation observed emphasized the Gaussian law in about three-fourths of the strains. The use of control plats restricted the limits of variation in each strain. Reducing the replications from 16 to as low as 8 did not alter the reliability of the results.

Fitting and fertilizing soil for sugar beets, J. D. ROMAINE (*Michigan Sta. Quart. Bul.*, 9 (1927), No. 3, pp. 103-105).—Soil preparation and fertilizer practices are outlined for sugar beets. Application of 300 to 400 lbs. of commercial fertilizer per acre has generally given the highest profits. With mod-

erate quantities, 300 lbs. or less, application in the row by the fertilizer attachment on the beet seeder has given satisfactory results, whereas broadcasting has been better for heavier applications.

Production test of commercial sugar beet seed, J. G. LILL (*Michigan Sta. Quart. Bul.*, 9 (1927), No. 3, pp. 110-113).—The stand, acre beet and sugar yields, sugar content and purity, and relative behavior of beets grown from each of 44 brands of commercial beet seeds in 1926 are tabulated.

Tucumán seedling canes [trans. title], W. E. CROSS (*Rev. Indus. y Agr. Tucumán*, 17 (1926), No. 1-2, pp. 5-31).—Agronomic studies and analyses on sugar cane seedlings (E. S. R., 51, p. 640) produced in Tucumán are reported on for the crop years 1923-24 and 1924-25.

Sugarcane varieties of Bombay Presidency, India, J. B. KNIGHT (*Bombay Dept. Agr. Bul.* 122 (1925), pp. 28, figs. 5).—Fifteen varieties of sugar cane are described and grouped in a determinative key.

Exotic sugarcane varieties in the Bombay Deccan, P. C. PATIL and V. G. PATWARDHAN (*Bombay Dept. Agr. Bul.* 125 (1925), pp. 45, pls. 7).—Promising introduced sugar cane varieties are described, with data on yields and analyses.

The blooming of the sunflower [trans. title], O. N. ARNOL'DOVA (ARNOL'DOVA) (*Zhur. Opytn. Agron. Iugo-Vostoka (Jour. Expt. Landw. Südost. Eur.-Russlands)*, 3 (1926), No. 1, pp. 131-143; *Eng. abs.*, p. 143).—Investigations on the blooming of sunflowers under field conditions at the Saratov, U. S. S. R., Experiment Station demonstrated that sunflower pollen is capable of functioning for extended periods. With pollen preserved for from 11 to 12 months at room temperature from 18 to 24 per cent of fertilization was obtained, with pollen from 4 to 33 days old 26.2 to 80.4 per cent, and with pollen from 1 to 3 days old 72 to 97 per cent. The stigmas were observed to maintain receptivity up to about 16 days. This functionality of the pollen and stigmas is claimed to permit the hybridization of forms differing widely in their blooming periods.

Seasonal changes in the composition of winter wheat plants in relation to frost resistance, R. NEWTON and W. R. BROWN (*Jour. Agr. Sci. [England]*, 16 (1926), No. 4, pp. 522-538, figs. 3).—Further studies (E. S. R., 52, p. 835) were made at the University of Alberta of the changes occurring during fall and winter in winter wheat plants of varieties widely different in winter hardiness.

The reduction in moisture content, which takes place to a greater degree in hardy varieties, seemed to be a most important change in the quantitative relations of the plant constituents. The resulting concentration of colloids and sugars in the cell fluids increases the resistance to freezing. Proteins were found to constitute the bulk of the cell colloids, about 90 per cent of the total protein of the plants being contained in the fluids. Pentosans are restricted almost wholly to the structural parts of the plant, although pentose sugars are present in small concentration in the fluids, and the ash occurs mainly in the fluids. Sugars accumulate in all varieties in the fall, but in general reach and maintain a higher concentration in hardy varieties. As the sugar protection of the proteins against frost denaturation increases with concentration, this apparently gives the hardy varieties an important advantage. Lipoids seem unimportant in the physiology of frost resistance in wheat. While amino nitrogen and noncoagulable nitrogen increase as the season progresses, no correlation has been found between the apparent degree of protein splitting and the relative hardiness of varieties.

A better method for winter wheat production, W. L. QUAYLE and A. L. NELSON (*Wyoming Sta. Bul.* 151 (1927), pp. 43-54, figs. 3).—In experiments on the Cheyenne Experiment Farm in cooperation with the U. S. Department of Agriculture winter wheat (1923-1926) seeded with the common drill averaged

8.8 bu. per acre on early plowed fallow and 13.5 bu. on late plowed fallow; that sown with the furrow drill averaged 18.4 and 18.7 bu., respectively. Winter wheat (1924-1926) on fallow cultivated with the duck foot cultivator averaged 25.9 bu., on plowed fallow 19.2, and on duck footed oats stubble 12.2 bu. The furrow drill helps avoid winterkilling, insures better germination, and leaves the land in better condition to retain rain and snow and to protect against winds, drying, and soil blowing. Use of the duck foot cultivator minimizes drying, excess run-off, and soil shifting, distributes better and saves man and horse labor, and is more effective in controlling weed growth.

Wheat-breeding investigations at the Plant Breeding Institute, Cambridge, R. H. BIFFEN and F. L. ENGLEADOW [*Gt. Brit.*] *Min. Agr. and Fisheries, Research Monog. 4* (1926), pp. 114, pls. 24, figs. 7).—With a view of explaining the bearing of research on practical agriculture, this monograph reviews the wheat-growing problem and discusses heredity and its complications, general breeding methods, and the means and results of breeding wheat for stiffness of straw, disease resistance, and for yield and quality of grain.

Correlations and yields in bread wheats, H. B. SPRAGUE (*Jour. Amer. Soc. Agron.*, 18 (1926), No. 11, pp. 971-996).—Intensive studies were made at the New Jersey Experiment Stations on important agronomic characters of Red Rock and Kanred wheats grown at New Brunswick, N. J., in 1924 and 1925, and also on Kanred from the 1925 crop at Lincoln and North Platte, Nebr., and on Nebraska No. 60 (Turkey) grown under various conditions at the Nebraska Experiment Station in 1921 and 1922. The crops were grown in drilled rows with normal seeding rates, and a unit of area comprising 1-ft. sections of drill row was used as a basis of comparison. Thirty-six units of area furnished the data for each variety at each station, except that 10 1-ft. units were taken from each of the several treatments accorded Nebraska No. 60. A physiological explanation of the various correlations is given, and their application to breeding and selection work is suggested.

Correlations between averages of the characters per culm or spike per unit of area gave approximately the same coefficients as those obtained by using individual culm or spike characters as the basis of comparison. Yields per acre and the means of the culm and spike characters varied widely with the climatic conditions and the variety.

The more favorable conditions for growth resulted in more tillers per unit of area or in an increase in the size of the individual tillers without greatly influencing the correlations existing between tiller characters. Correlations between the tiller characters measured, except those involving culm length or weight per kernel, were fairly stable, regardless of the variety or where it was grown. Correlations between culm length and other tiller characters, except straw yield per culm, fluctuated widely, but without definite relation to climatic data available for the crops used. Average weight per kernel was found highly correlated with straw yield per culm only when climatic conditions favored normal ripening.

[Factors influencing the quality of Kansas wheat] (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 51-57).—Analyses and milling and baking tests on wheat from fertility and rotation plats (*E. S. R.*, 52, p. 439; 56, p. 39) showed that in general applications of nitrogenous fertilizers, except in the form of barnyard manure or cowpeas plowed under for green manure, slightly increased the protein content of wheat. The most phosphorus was obtained from plats fertilized with acid phosphate. The phosphorus content of the flour bore no relation to that of the grain, since the bran which is removed in milling contains about eleven times more phosphorus than the endosperm. The ash in wheat

and the acidity of wheat and flour did not vary with the different fertilizer and rotation treatments.

Tests of the 1924 crop samples failed to show superiority for the new varieties. Poor results were had with Blackhull, Nebraska No. 28, and a Turkey selection, which all appeared to have weak gluten, while for other sorts a strong gluten was indicated. Varieties grown at Fort Hays averaged from 4 to 5 per cent more protein than those grown at the station, but this was not reflected in correspondingly better baking qualities. Comparable results on samples of Kanrad, Turkey, Blackhull, and Fulcaster revealed the protein contents to be higher in 1925 than in 1924, but not as high as in 1923. Marked varietal differences were not seen in 1924, while in 1925 Blackhull was distinctly the poorest, giving a smaller volume and poorer texture for all ranges of protein, suggesting that this variety has gluten of weaker quality than the others observed. The general averages as well as the range in protein content for 749 samples representing 20 varieties of Kansas-grown wheat were greater in 1924 than in 1925. The protein range in any one variety so exceeds the differences in protein between varieties that protein content did not seem to be a varietal characteristic.

Studies on farm-stored wheat indicated that there is little danger of heating and damage to combine wheat if fully ripened when cut and if not wet by rain. Excess moisture due to immaturity of grain appears to be a more serious and frequent cause of damage by heating than moisture from rain or dew. Unsatisfactory baking results were had when over 5 per cent of bin-burned wheat was mixed with sound wheat.

[Weed control in Iowa] (*Iowa Sta. Rpt. 1926, pp. 29, 30, 33*).—An investigation of the competition between weeds and bluegrass showed that bluegrass pastures lost 50 per cent of their forage value because of the presence of small ragweed, which is destructive during August and September. It is easily destroyed by iron sulfate at the rate of 100 lbs. to a barrel of water applied best during July. Sow thistle has been found in eight or ten different localities in the State. Chemical studies upon the underground portions of Canada thistle, made with a view toward eradication, demonstrated that the least quantities of stored food material occurred just before the flowers bloomed and the most in December. Roots absorbed mineral elements from the soil even when it was frozen solid.

Weeds of ponds, water-courses, and undrained lands, J. PERCIVAL and H. C. LONG (*Jour. Bath and West and South. Counties Soc., 5. ser., 20 (1925-26), pp. 31-53, pls. 4, figs. 15*).—Some of the more important weeds of undrained land, ditches, ponds, and streams are briefly described, with outlines of methods of control by means of weed cutters and other devices, swans, and chemicals.

HORTICULTURE

Report of the horticulturist, E. P. SANDSTEN (*Colorado Sta. Rpt. 1926, pp. 33, 34, 35-37*).—Like that of the preceding year (*E. S. R., 55, p. 235*), this report includes brief summaries of progress. The production of first generation hybrid tomato seed as a commercial proposition failed to meet with the expected success, the increases in yield being insufficient to offset the increases in the cost of production. Plant selection gave better results. In soil studies in an orchard at Austin the growing of cover crops greatly improved the quality of the fruit. Denia and Valencia onions yielded at the rates of over 1,000 and 1,200 bu. per acre, respectively. Fertilizer studies with lettuce and tomatoes showed the superior value of animal to chemical manures.

[**Horticultural investigations at the Florida Station**] (*Florida Sta. Rpt. 1926, pp. 30, 31, 51-56, 59-64, figs. 5*).—Tomato fertilizer studies, conducted by R. W. Ruprecht in Dade County, in cooperation with the U. S. D. A. Bureau of Plant Industry, emphasized the value of manganese, both in promoting growth and yields. The long-continued studies (E. S. R., 55, p. 832) at Lake Alfred of various sources of phosphoric acid for citrus fruits were concluded, due to the sale of the grove. Quantitative studies with potash at Lake Alfred failed to show any obvious external or internal difference in either oranges or grapefruit that could be attributed to potash. Chemical analysis indicated that fruits on high potash plats took up more potash but had a lower sugar content than those on the low potash plats. Qualitative tests with potash at Lake Alfred and at Vero Beach failed to show any marked differences due to the form used. Pecan fertility studies carried on in cooperation with the Bureau of Plant Industry showed that fertilizers, especially ammonia and potassium, have increased growth and productivity. Potassium apparently had greater influence on pecans in sandy soil than in heavier types.

Root stock studies conducted by H. Mowry suggested that the Rusk and Morton citranges and the citrangequat, all of which may be grown from seeds or cuttings, may have value in Satsuma orange propagation. In strawberry tests the Missionary proved the outstanding variety. Of various forms of *Rubus* observed, the Florida Marvel, McDonald, Dallas, and an unknown Californian variety proved most satisfactory. Notes are included on various other tests, including extensive grape variety plantings.

As reported by G. H. Blackmon, the greatest growth in pecan nuts of several important varieties occurred in the period from June 24 to August 4, inclusive. On account of an even rainfall the growth curves were smooth and regular.

[**Horticultural investigations at the Iowa Station**] (*Iowa Sta. Rpt. 1926, pp. 32, 33, 34, 37, 44-46, 47, 48*).—In continuation of work discussed in the preceding report (E. S. R., 55, p. 535) it was found that weather conditions during the growing season may affect the reliability of the dye absorption test as a means of determining hardness in apples. A dry summer followed by a rainy autumn stimulated a late growth. As a result, all varieties behaved practically in the same manner in respect to the absorption of dye. Studies upon the germination of apple seeds are briefly reviewed (E. S. R., 53, p. 535).

Studies of the economic possibilities of the common milkweed showed that a very good quality of paper may be made from the stem and leaf tissue, and that the seeds are relatively rich in oil and protein and may have value for stock feeding. Fiber suitable for upholstering was obtained, and rubber in small amounts was extracted from the latex.

Observations upon the chemical changes taking place during the ripening of apples showed but little correlation between chemical composition and keeping quality in cold storage. The ripening process, both on the tree and in storage, was associated with loss of moisture, acid, insoluble sugar, and starch and an increase in pectin and soluble sugars. A comparison of high calcium and high magnesium limes as ingredients for Bordeaux mixture showed that a satisfactory reaction results from using large quantities of high magnesium lime but that the amount of sediment is greatly increased. Certain of the standard apple stocks were killed back to the ground in October, 1925. Of those which survived and are being propagated, some were found to root freely from cuttings. Varieties which showed rough excrescences on the limbs and trunk were always easy to root. An anatomical study of these knots showed that the tissue strands traced back to a point of origin in the medullary rays of 1-year wood. Some of the more promising station seedlings are being propagated in large numbers.

Orchard management studies indicate that pruning accompanied by the application of quickly available nitrogen fertilizers is the best means of regulating growth and fruitfulness in the apple and in a partial way at least prevents biennial fruiting. Moderate pruning distributed over the head of the tree gave better results than severe pruning. Three to 5 lbs. of nitrate of soda applied 2 or 3 weeks prior to blossoming proved a satisfactory treatment for Wealthy trees.

Sweet corn studies have resulted in the development of home-grown strains superior in vigor and production to those purchased. Irrigation greatly increased the yield of vegetables during the dry summer of 1925. Many ornamental plants, including white pine, arbor vitae, *Salix babylonica*, *Rosa rugosa*, and weigela, suffered severe winter injury in 1925-26. Douglas fir was found to have value as a plant material for shelter belts. Many varieties of walnuts, pecans, and hickories were collected with a view to determining their value as food and timber.

[Horticultural investigations at the Kansas Station] (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 58-64, 65).—The usual report (E. S. R., 52, p. 440).

Both lime sulfur and Bordeaux mixture were effective in the control of leaf spot in the cherry. In the case of sour-cherry trees, some sprayed with lime sulfur and some with Bordeaux mixture, a larger number of fruits were recorded per pound on the Bordeaux-treated Early Richmond and Montmorency and a considerable less number on the Bordeaux-treated English Morello. Measurements of the length of new growth put forth by cherry branches following the removal of the terminal bud showed greater development both in the distal shoots and the laterals upon the pruned branches. Disbudding experiments with young apple trees showed no significant effect in the first season from the removal of various numbers of buds. Trees disbudded near the base made less diameter gain but the greatest total twig growth.

Soil management studies with the apple indicated that manure alone was more effective than manure plus phosphorus. Rather inconclusive results were obtained with straw mulch on Delicious trees. In one instance the control plat outyielded one of the straw plats. Measurements of growth showed about 40 days of rapid twig extension, while in contrast trunk circumference gain was fairly constant throughout the entire growing period, April to September.

Pruning frozen shoots of Niagara and Moore Early grapes had no beneficial effect as compared with no treatment. Of different systems of training studied, the Kniffin and Munson proved best, respectively, for Concord and Worden, with the fan system poorest in all cases. Of forest trees tested for adaptability to Kansas conditions, *Pinus ponderosa* proved superior to the Austrian and Scotch pines. Red cedar is considered valuable for upland sections. Pecans grown in a fertile soil near Coffeyville reached a productive age at 8 years.

Vegetable plants, VILMORIN-ANDRIEUX & Co. (*Les Plantes Potagères. Paris: Vilmorin-Andrieux & Co., 1925, 4. ed., pp. XX+812, figs. 933*).—This, the fourth French edition of a well-known work, contains descriptive and cultural material on practically all known varieties of vegetables.

Principles to be considered in planning experiments with fertilizers for asparagus, V. A. TIEDJENS (*Jour. Amer. Soc. Agron., 18 (1926), No. 6, pp. 521-525*).—Pointing out that the spring spears of asparagus are necessarily formed largely from reserves stored in the previous growing season, the author suggests the advisability of applying quickly available nitrogen fertilizers after cutting has ceased rather than in the early spring.

[Natural crossing in the tomato], S. V. ANAN'eva (ANANIEVA) (*Zhur. Opytn. Agron. Tugo-Vostoka (Jour. Expt. Landw. Südost. Eur.-Russlands, 3*

(1926), No. 1, pp. 93-96, figs. 8; *Eng. abs.*, p. 96).—Observations at the Saratov Agricultural Experiment Station upon the progeny of tomatoes which had been grown in close proximity to one another showed a considerable amount of segregation, indicating a large amount of natural crossing. An examination of the flowers of the tomatoes showed that the structure and habit of blossoming favored cross-pollination.

The importance of phosphorus in the production of seed and non-seed portions of a tomato fruit, J. H. MACGILLIVRAY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 374-379).—Determinations at the University of Wisconsin of the phosphorus content of the seed and surrounding pulp and of the pulp of the outer and intra carpel walls of tomato fruits gathered at various stages of development from plants grown in media differing sharply in phosphorus content showed more total phosphorus in the nonseed portion than in the seed portion, irrespective of the stage of maturity or of the phosphorus nutrient treatment. The percentage of phosphorus was, on the other hand, always greater in the seed portion and higher in young than in ripe fruits. The larger quantity of phosphorus in the nonseed portion of tomatoes is deemed by the author satisfactory evidence that phosphorus is as important in the production of the fleshy part of the fruit as of the seeds.

Tomato culture in Utah, A. L. WILSON (*Utah Sta. Circ.* 63 (1927), pp. 36, figs. 2).—This circular, presenting general information upon tomato growing in Utah, discusses in detail the growing of plants, culture, improvement by plant selection, control of pests, etc.

The fruit garden, A. J. MACSELF (*London: Thornton Butterworth*, 1926, pp. 222, pls. 12, figs. 20).—This text, illustrated in part in color, contains general information primarily of use to the English home fruit grower.

Orchard irrigation, S. FORTIER (*U. S. Dept. Agr., Farmers' Bul.* 1518 (1927), pp. [2]+27, figs. 31).—This publication, a revision of and superseding Farmers' Bulletin 882 (*E. S. R.*, 38, p. 242), contains information on the selection of locations, clearing and grading land, contour method of planting trees, cost and measurement of water, irrigation layouts for orchards, methods of irrigating, water requirements, and winter irrigation of orchards, etc.

Vegetative plant propagation with special reference to cuttings, P. W. ZIMMERMAN (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 223-228).—A report upon investigations conducted at the Boyce Thompson Institute upon certain environmental factors concerned in the rooting of hardwood cuttings. That aeration is not as important as generally accepted was indicated in good rooting along the entire length of *Lonicera* sp., *Philadelphus* sp., and *Salix* cuttings planted 2 ft. deep, with a tendency for the strongest roots to appear at the basal end. Of several gaseous atmospheres tested, the best growth was obtained in one composed of from 15 to 33½ per cent of oxygen and from 85 to 66⅔ per cent of nitrogen. No rooting occurred where from 90 to 100 per cent of oxygen was present. For *Ilex*, Delaware grapes, and some species of *Viburnum*, peat moss proved a better rooting medium than sand. In certain plants the age of the cutting wood determined success in rooting. For example, cuttings of *Prunus tomentosa* rooted well if taken in late May and poorly in the autumn. Certain conifers showed similar peculiarities. Under nonwilting conditions, the larger the leaf area on green wood cuttings the quicker the rooting. Cuttings possessing rooting ability apparently had an optimum rooting temperature. Callus formation was not indicative of rooting ability, as apple, cherry, and blue plum, very difficult rooting forms, callus abundantly. The regularity with which adventitious roots appear about nodes is deemed an indication of the importance of food storage or specialized cell structure at these points.

The propagation of own rooted apple stocks, T. J. MANEY (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 211-217).—In studies at the Iowa Experiment Station with several apple varieties, including McIntosh, Northern Spy, Fameuse, and Malinda, apple grafts with the stock in sand and the scion in heavier composted soil developed strong scion roots. Scion rooting was induced in Patten grafts by wrapping the union tightly with Bordeaux-treated string, which caused an accumulation of starch above the union. Copper wire had a similar effect in Virginia crab, Hiberna, Dudley, and other varieties of free rooting proclivity. Mound layering gave excellent results with Dudley, Virginia, Hiberna, and Northern Spy, fair results with Wolf River, McIntosh, and Whitney, and negative results with Malinda, Patten, Tolman, and Oldenburg. Bending over and burying 1-year grafts yielded rooted shoots in many varieties. Burr-knots were found to contain an abundant supply of stored starch. Attempts to transmit burr-knot to free trees by scarification of the bark gave negative results. The use of burr-knot wood as scion material was followed by ready scion rooting.

Polarity in the formation of scion roots, W. H. CHANDLER (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 218-222, figs. 2).—A study at the California Experiment Station of apple grafts made in the normal manner and with a point of union 2.5 and 5 in. above the lower end of the scion showed a tendency in certain varieties, such as Northern Spy, Jonathan, McIntosh, and Delicious, to develop roots on the section of the scion below the graft union. At the same time very little tendency was noted for root formation to take place above the union, suggesting that the stock in some way inhibits rooting above. Rooting was more successful on 2.5 than on 5-in. stubs, but in both cases was insufficient to be deemed a commercial success.

Fruit spur composition in relation to fruit bud formation, G. F. POTTER and H. R. KRAYBILL (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 146-150).—Three conditions, (1) localization of food materials within the spur, (2) differentiation in the nature of the nitrogen supply, and (3) dominance of the fruit over bud development, are set forth as possible causes for the sharply contrasting blossom-bud performance at the New Hampshire station of Baldwin fruit spurs having essentially the same chemical composition and which, according to the carbohydrate nitrogen-ratio concept of Kraus and Kraybill (*E. S. R.*, 40, p. 40), might be expected to be in a similar reproductive condition. No significant differences in carbohydrate composition were found which could be associated with the percentage of fruit-bud formation except in the content of relatively inert substances such as starch.

Is fruiting of the apple an exhaustive process? A. E. MURNEEK (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 196-200).—Following earlier studies (*E. S. R.*, 53, p. 142) which showed that a tomato fruit is able to utilize all the available nitrogen supply at the expense of the rest of the plant, the author determined the percentage and grams of total nitrogen in the various parts of the apple-spur system at different stages of development. An expected seasonal decrease in the percentage of total nitrogen was noted for all parts of the spur system, particularly the fruit. When measured in grams of total nitrogen, there was found a definite movement of nitrogen to the fruit. On July 15, when the fruit was half grown, over 80 per cent of the total nitrogen was concentrated in the fruits. The greatest nitrogen increase in the leaves occurred early in the season, at the time of their rapid growth. Defoliation or defruiting increased the total quantity of nitrogen in the older wood and in the leaves. Since defoliated spurs are able to set and develop fruits to a considerable size, it is concluded that part of the nutrients are obtained from general reserves

in the tree, or at least further back than the spur system. Fruiting is apparently an exhaustive process, especially in years of heavy production and in years of limited nitrogen supply.

The relation of leaf area to the growth and composition of apples, M. H. HALLER and J. R. MAGNESS (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 189-196).—Studies at Arlington Experiment Farm, Virginia, upon the growth of apples borne on twigs girdled to prevent translocation of carbohydrates indicate that the volume and weight of growth of the fruit is directly correlated with the leaf area upon which the fruits are able to draw carbohydrates. Data taken in the 1925 season indicated that approximately 40, 50, and 75 leaves should be available, respectively, for each Grimes, Ben Davis, and Delicious fruit. Apparently each fruit requires more synthesized food than can be manufactured by the foliage of its own spur. Apples grown with no leaves remained green and made but little gain in size. Those on unringed limbs made somewhat less growth than on ringed limbs, indicating a movement of carbohydrates away from the apples. Apples grown with abundant leaf area were higher in percentage of dry weight, sugars, and acids than those grown with less leaf area.

The first year's effect of different nitrogen fertilizers on bearing apple trees low in vigor, A. L. SCHRADER and E. C. AUCHTER (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 150-161).—Studies at the University of Maryland upon the comparative value of ammonium sulfate and nitrate of soda as sources of nitrogen for apples indicated that bearing trees suffering from a lack of nitrogen respond much more quickly to nitrate of soda, this material apparently becoming available much more rapidly than ammonium sulfate. Observations upon changes in foliage color showed a much more rapid response to nitrate of soda than to ammonium sulfate. Measurement of the terminal growth, trunk circumference increment, and spur growth for the first season following treatment gave definite evidence of the superior value of nitrates. For example, trunk gains for trees receiving 10 lbs. of sodium nitrate, 7.5 lbs. of ammonium sulfate, and nothing were 1.54, 1.14, and 0.81 in., respectively. Where fertilizers were applied in the fall the differences in spur growth were not so marked as with spring treatments. Analyses of total nitrogen in apple spurs showed consistently higher content in spurs of nitrated trees. Nitrate applications made three weeks before blooming actually increased the nitrogen content of the blossoms plus the new growth, while corresponding applications of ammonium sulfate showed no effect. A fairly close correlation was found between the soluble nitrogen content of blossoms plus new growth and spur growth of that year. A relatively high content on June 27 of total nitrogen and soluble nitrogen in the new growth spurs of spring sulfated trees indicates at least a partial availability of that material.

Cross fertilization of the Arkansas (Mammoth Black Twig) apple, E. C. AUCHTER and A. L. SCHRADER (*Amer. Soc. Hort. Sci. Proc.*, 22 (1925), pp. 96-105).—Failure of the Arkansas apple to set reasonable crops under normal environmental conditions was found in studies at the Maryland Experiment Station to be due largely to self- and intersterility. Applications of Grimes, Stayman Winesap, and Arkansas pollen to Arkansas pistils yielded no fruit, while Delicious, Jonathan, Hubbardston, Yellow Transparent, and some other pollens gave fair results.

Observations in various commercial Arkansas orchards showed that satisfactory fruiting occurs where Delicious and Jonathan are interplanted, but poor fruiting where only Stayman Winesap, Grimes, or York Imperial are present. Unfortunately, Grimes has been used as an interplant in many

Arkansas orchards. Since Grimes pollen germinates well in sugar solutions, poor sets on Arkansas are considered due to cross incompatibility. Inconsistencies in Arkansas fruiting from season to season indicate that nutrient conditions within and without the tree have a bearing on fruit setting in this variety.

Nursery stock identification: Plums, pears, peaches, cherries, W. H. UPSHALL (*Ontario Dept. Agr. Bul. 319 (1926), pp. 31, figs. 33*).—In this contribution from the Vineland, Ont., Horticultural Experimental Station the author discusses, along the lines suggested by Shaw (E. S. R., 47, p. 641), certain distinguishing foliage, shoot, and bud characters which have proved useful in the identification of young nonbearing trees. Numerous photographic reproductions of leaves are included.

Temperature and respiration of ripening bananas, A. J. OLNEY (*Bot. Gaz., 82 (1926), No. 4, pp. 415-426, fig. 1*).—Studies conducted at the University of Chicago upon the ripening of bananas arriving in the green condition from the West Indies indicated that refrigeration at 53.6° F. or lower not only retarded ripening but also permanently prevented the development of bright yellow color, high quality, and aroma, even though the fruits were later transferred to a more favorable temperature. On the other hand, at 63° bananas ripened in 6 days to an attractive condition.

Respiration measurements showed that the volume of carbon dioxide liberated and of oxygen absorbed were practically equal, indicating that oxidation consists solely of the combustion of carbohydrates. The rate of respiration increased rapidly at the beginning of the ripening process and fell off gradually. Respiration was much slower at low than at high temperatures. The amount of heat (0.3 calorie per kilogram per hour) given off by bananas ripening at 68° is deemed sufficient to cause heating, with a consequential too rapid ripening in transit, and emphasizes the urgent need of the ventilation of transportation chambers.

Carnations for every garden and greenhouse, M. C. ALLWOOD (*London: Country Life; New York: Charles Scribner's Sons, 1926, pp. XVI+139, [pls. 65]*).—A comprehensive and well-illustrated discussion upon outdoor and indoor culture of the carnation.

Rhododendrons for everyone, F. K. WARD (*London: Gard. Chron., Ltd., 1926, pp. 122, pls. 16*).—General information prepared by a famous plant explorer is offered upon rhododendron species and varieties and their care.

The flora of South Africa, R. MARLOTH (*Cape Town: Darter Bros. & Co.; London: Wheldon & Wesley, 1913, vol. 1, pp. XVIII+264, pls. 65, figs. 109; 1915, vol. 4, pp. X+208, pls. 60, figs. 62; 1925, vol. 2, sects. 1, pp. XII+1-120d, pls. 42, figs. 75; 2, pp. IV+121-272, pls. 38, figs. 88*).—This contains carefully prepared descriptive material and synoptical tables of the genera of the higher plants, and is illustrated in part in color.

FORESTRY

Soil temperature as influenced by forest cover, T. T. LI (*Yale Univ. School Forestry Bul. 18 (1926), pp. 92, pls. 9, figs. 7*).—Records taken at four contrasting stations, namely, (1) completely denuded area, (2) grassed, (3) young forest, and (4) old forest established in the Yale Demonstration and Research Forest near Keene, N. H., showed that the forest and ground covers are very important factors in influencing soil and air temperature, evaporation, humidity, etc.

The complete denudation of the forest and ground cover resulted in a rapid cooling or heating of the surface soil. In the denuded area the moisture

content in the first 9-in. layer of soil was higher than in any of the other locations. Evaporation, as measured by the Livingston atmometer, was also highest there.

Soil-temperature records taken at 6-, 12-, and 24-in. depths showed fluctuations corresponding to but lower in degree than those occurring at the surface. At 24 in. the soil temperature was less sensitive to surface conditions than at lesser depths. The forest and grass covers significantly lowered the maximum and raised the minimum surface soil temperatures during the hot summer months. The forest reduced the maximum, minimum, and mean soil temperatures at all depths throughout the entire period July 1 to October 31 except that the minimum at 6 in. was raised by the forest in October. The forest exerted a greater influence than did grass in lowering soil temperature, and both the young and the old forest had practically the same effect. As measured by the difference between evaporation of black and white atmometers, sunlight was only 14 per cent of the possible total in the old forest and but 6 per cent in the young forest.

Spruce and balsam fir in the Upper Peninsula, W. MARTIN (*Michigan Sta. Quart. Bul.*, 9 (1927), No. 3, pp. 99, 100).—Based on records gathered in a logged-over area in northern Michigan, diameter and height tables are presented for a 60-year growth of spruce and balsam. At 60 years spruce averaged 9.8 in. in diameter and 47.1 ft. in height and balsam 10.6 in. in diameter and 62.5 ft. in height.

The bitternut hickory, *Carya cordiformis*, in northern Minnesota, A. M. JOHNSON (*Amer. Jour. Bot.*, 14 (1927), No. 1, pp. 49–51, pls. 3, fig. 1).—A brief record of the discovery of fine mature trees of the bitternut hickory fully 200 miles farther north in Minnesota than had hitherto been reported.

The palms of British India and Ceylon, E. BLATTER (*London, New York, and Bombay: Humphrey Milford, Oxford Univ. Press, 1926, pp. [12]+XXVIII+600, figs. [163]*).—This comprehensive treatise on palms contains descriptive material, notes on habitat, and utilization of species native and introduced in India.

Notes upon Madagascarian woods [trans. title], M. LOUVEL (*Madagascar Bul. Écon.*, 23 (1926), I, No. 1, pp. 116–126, pls. 30).—Descriptions and notes are given upon various species of the genus *Eugenia* occurring commonly in the forests of Madagascar and recognized by the natives under the collective name *Rotra*.

The forests of Japan [trans. title], V. F. OVSIANNIKOV (OVSIANNIKOFF) (*Mem. Univ. État Extrême-Orient (Trudy Gosud. Dal'nevostoch. Univ.)*, 4. ser., No. 2 (1926), pp. 65, figs. 9; *Fr. abs.*, pp. 52, 53).—A survey of the forests of Japan showed them to occupy about 63.5 per cent of the entire area. Four distinct forest zones occur, namely, (1) subtropical with an average annual temperature of 21° C. (69.6° F.), (2) evergreen zone with a temperature of 12°, (3) broadleaf deciduous zone with a temperature ranging from 6 to 12°, and (4) a coniferous zone with the average temperature below 6°. The most important species are bamboo, evergreen oaks, camphor, beech, *Zelkova acuminata*, *Cryptomeria japonica*, *Chamaecyparis obtusa*, *Thujopsis dolabrata*, and various pines. Forest administration is under governmental control and cutting is mostly upon the continuous yield basis. There are 53 forest schools, but 4 of university rank. A list of the component species is added.

Forestry in Denmark, A. S. SABROE, trans. by J. SAXE (*Copenhagen: Danish Forest Soc.*, 1926, pp. 64, figs. 8).—A small handbook concerning the distribution of the forests, legislative matters, rates of growth of important species, silvicultural practices, statistics and finances, forest institutions, etc.

Statements of progress of forestry in the Empire (In *Imperial Conference, 1926. Appendices to the Summary of Proceedings. London: Govt., 1927, pp. 339-360*).—This contribution consists of brief summaries upon the forestry situation and forest service activities in the various units of the British Empire.

DISEASES OF PLANTS

[Investigations at the Colorado Station on some bacterial diseases of plants], W. C. SACKETT (*Colorado Sta. Rpt. 1926, pp. 17, 18*).—Corroborative evidence has been secured indicating that bacteria are a factor in the recently reported wilt and root rot of alfalfa, *Aplanobacter insidiosum* having been isolated from affected stems and roots of alfalfa.

A bacterial disease of green tomatoes, which manifests itself as a soft, black rot of the fruit, is said to have made its appearance in commercial greenhouses in Denver.

Steam under pressure discharged into soil through perforated pipes is said to have proved very satisfactory for the sterilization of soils in greenhouses and seed beds.

Field experiments were reported to have shown that planting 2-year-old seed greatly reduced the number of bean plants affected with bacteriosis.

[Plant disease investigations at the Colorado Station] (*Colorado Sta. Rpt. 1926, pp. 18, 19*).—Investigations carried on in cooperation with the station bacteriologist are said to have shown that alfalfa plants affected by root rot die through a lack of water induced by a plugging of the water ducts with a pentosan gum. This is said to reduce the water supply to one-fourth the normal requirement, resulting in a wilting and failure of starch production and storage. It is said that such plugging can be produced independent of the organism by the use of certain salt solutions.

Tests were reported on the control of stinking smut of wheat, in which 2,500 test plats were used in a comparison of the effect of copper carbonate with formalin, copper sulfate, and a number of commercial compounds. Temperature and growth records gave valuable data on conditions of infection of wheat. Tests were also made on treatments for sorghum smut, etc., in which copper carbonate was used successfully.

Spraying and dusting experiments for the control of cucumber mildew were successful in greenhouses near Denver, but field tests for the control of mildew on pumpkins showed that while control was effected the treatment was too expensive.

Report of plant pathologist, O. F. BURGER (*Florida Sta. Rpt. 1926, pp. 68, 70-80, 81-83*).—Laboratory work by K. W. Loucks showed that when citrus seed was planted in soil inoculated with *Bacterium citri* the resulting plants were not infected. However, young kumquat and grapefruit seedlings inoculated soon after sprouting were readily infected.

Field and laboratory investigations of scaly bark of citrus were made by E. West. It is claimed that this disease can be controlled by pruning in conjunction with good grove management. Attempts were made to isolate the causal organism, and of a considerable number of fungi obtained a Cladosporium was secured that resembled the species which is claimed to cause the disease. Inoculation experiments, however, gave negative results.

Continued studies by A. S. Rhoads of citrus blight have confirmed the opinion that this trouble is due to extremes of soil moisture conditions.

The temperature and moisture relations of pecan scab were investigated by R. E. Nolen. Spore germination was secured at from 6 to 32° C., with an

optimum temperature of from 20 to 22°. The incubation period in a greenhouse at Madison, Wis., was from 7 to 15 days, while in the field at Gainsville, Fla., it was from 4 to 21 days.

Studies of coconut diseases by J. L. Seal consisted mainly of isolations of the fungus connected with bud rot. Several strains of *Phytophthora faberi* were isolated and successfully inoculated into coconut trees. No correlation was found between temperature and outbreaks of coconut bud rot, but definite correlations were established between rainfall and disease occurrence.

Investigations of truck crop diseases and their control by G. F. Weber revealed an unusual freedom from serious infection during the year. Powdery mildew of cucumbers was rather destructive, and experiments on its control by spraying and dusting were undertaken but without definite results. Angular leaf spot of cucumbers was satisfactorily controlled by dusting or spraying. Experiments with various fungicides for the control of seed-borne diseases of tomatoes, eggplant, and pepper indicate the value of seed treatment with corrosive sublimate 1:1,000 for about 8 minutes. An extensive spraying and dusting experiment for the control of nailhead rust of tomatoes gave negative results, owing to the scarcity of the disease.

Potato disease experiments by L. O. Gratz included seed treatments, symptoms, and yields of Maine selected samples diseased with mosaic, spindle tuber, and Verticillium wilt. Corrosive sublimate was compared with various organic mercury compounds in tuber treatment experiments with little benefit from any of the treatments except Semesan. Spraying and dusting experiments are said to have indicated some superiority in favor of spraying. Tests of two lots of seed tubers, one infected with spindle tuber and the other with Verticillium wilt, when grown in comparison with healthy stock showed diminished yields, especially with the lot infected with spindle tuber. Experiments with copper-lime dust for the control of blight were disappointing, as the disease was not a factor during the season.

An investigation of strawberry diseases in Florida was begun by A. N. Brooks. A preliminary report is given of a yellowing and dying of the plants, which is believed to be connected with the application of lime to the soil.

Plant pathology (*Iowa Sta. Rpt. 1926, pp. 30-32*).—Test plats were studied to determine the effect on the succeeding crop by planting seed infected with the dry-rots *Diplodia zeae* and *Basisporium gallarum*. Corn infected with these fungi was planted with corn practically free from molds, and the results showed that seed practically free from dry-rots gave a better stand, more vigorous plants, fewer nubbins, fewer barren stalks, and a higher yield than did infected seed. Seed heavily infected with *Diplodia* dry-rot was improved when treated with any of several compounds, but the infected treated seed in no case yielded as much as seed practically free from dry-rot, selected by the modified rag-doll test.

Investigations of aster wilt are said to indicate that the *Fusarium* which causes aster wilt is different from the species causing cabbage yellows. Tests of varieties showed certain ones to have a higher degree of resistance than others.

The investigations on mosaic disease, conducted to determine the specific nature of the virus from certain species of plants, are said to indicate that three distinct mosaic viruses were studied. All were transmitted to tobacco and their differences observed. One of these is the commonly known mosaic of tobacco and the other Solanaceae, which is capable of withstanding desiccation for long periods and appears to be restricted to the Solanaceae and to zinnia. Another form is the virus causing mosaic of cucumbers and other

plants, which appeared to be capable of infecting a wide range of hosts belonging to numerous orders and families. The third virus, from sweet clover, was distinct as to symptoms produced on tobacco, and transmission to any species except tobacco was not successful.

Studying rust resistance of oat hybrids, 26 F₇ selections from a cross between Iowa 105 and Green Russian gave an increased yield of from 17 to 44 per cent compared with Iowa 105.

Isolations from crown gall and other overgrowths of apples showed that all such knots are not caused by microorganisms. Viable crown gall bacteria were obtained from less than 20 per cent of the overgrowths. The others were found to be caused by imperfect graft unions. Organisms were found in the overgrowths at the union of apple trees that closely resembled the crown gall bacteria, but they failed to produce typical galls when inoculated into healthy tomato plants. Further studies of other excrescences resembling crown gall, especially burrknots, have not shown the presence of crown gall bacteria.

Field tests in 1925 of the cabbage variety Iacope are said to have shown that it was very resistant to cabbage yellows and satisfactory as to type and time of maturity.

For the control of wheat bunt nine different fungicides were tested in various strengths, and the results are said to indicate that copper carbonate was very effective for the control of this disease. Some of the other fungicides used gave as good control, but additional data are considered necessary before recommending them for use.

Diseases of plants (*Kansas Sta. Bien. Rpt. 1925-26, pp. 65-71*).—Investigations of cereal and forage crop diseases have resulted in the production of a number of F₂ and F₃ plants of a Kanred×Fulcaster cross, some of which are said to be very promising for leaf rust resistance. The inheritance of resistance to leaf rust was studied, and it was found that while resistance was recessive in the seedling stage, it was apparently dominant in the heading stage. Plants that were immune in the seedling stage did not change later in their reaction to rust. It was found that true immunity was recessive and apparently due to a single main factor difference. The effect of leaf rust on yield was studied, using potted plants grown in the greenhouse, and, in general, there was found to be a reduction in yield, but the nature and cause of the reduction were not fully determined. Dusting wheat with sulfur both in the greenhouse and in the field was found to prevent leaf rust infection.

On stinking smut a study was made on the date of planting and the effect of recontaminating treated seed with smut by soil and seed inoculations. Early plantings in September while the soil is warm resulted in little or no smut, while plantings in October and up to the middle of November gave the highest infection. Various brands of copper carbonate were tested, and those containing from 50 to 55 per cent copper gave the best smut control, especially when seed wheat was badly infected. Seed wheat treated with copper carbonate and afterwards heavily recontaminated with smut spores was infected by smut, indicating that copper carbonate did not necessarily protect against recontamination.

Wheat foot-rot disease is said to have assumed a serious aspect. Investigations show that *Ophiobolus graminis* is present where wheat foot rot occurs, and other organisms, such as *Helminthosporium* spp. and *Wojnowicia graminis*, have been isolated from infected plants. Five seasons' observations are said to show that early deep plowing favors the spread of the disease, while late shallow plowing, disking, or merely removing the weeds suppresses it. No resistance to *O. graminis* has been found in any variety of wheat.

In experiments for the control of oat smut satisfactory control was secured with a number of organic mercury and phenol compounds, but they did not prove as reliable as the formaldehyde soaking treatment. Furfural gave no smut control in hulled oats, and copper stearate failed to control smut in either hulled or hull-less varieties. Dusting treatments with copper carbonate and various forms of sulfur are said to have given excellent smut control in hull-less oats, but both were ineffective when used with a hulled variety. Experiments on the effect of dehulling the oat kernels on smut infection showed that the glumes of oats are a great natural protection to susceptible varieties.

A kernel smut of dwarf yellow milo was found at the Colby Substation, and this is said to be the first time a kernel smut has been reported on milo. All varieties of sorghum, with the exception of feterita, are considered subject to attack by milo smut. Experiments for the control of the kernel smut of sorghum showed that copper carbonate in various forms and several brands of superfine sulfur gave nearly as good control as the formaldehyde treatments. Copper stearate and colloidal copper failed to give satisfactory smut control, but some of the organic mercury compounds proved promising.

In corn smut investigations a number of inbred lines were studied, and several have been secured that are considered quite resistant to smut, while others are extremely susceptible. Physiological studies on the corn smut organism *Ustilago zea* indicate the possible existence of physiologic forms. Copper carbonate and sulfur dusts are said to have exerted some effect on the control of smut on sweet corn.

Several root rot diseases of alfalfa have caused serious damage in Kansas, one of which, the bacterial disease known as wilt, is said to be widespread.

In the fruit and vegetable disease investigations 3 minutes in the hot formaldehyde solution in sacks was found as effective for the control of Rhizoctonia in seed potatoes as corrosive sublimate for 90 minutes. Sulfur did not materially reduce the amount of Rhizoctonia on the stems. Copper dusts as a group gave slight control, but all caused a stunting of the plants. One of the organic mercury dusts gave excellent control, but two others were valueless.

Experiments indicated that neither sulfur alone nor green manure crops alone can be relied upon to control potato scab economically. The symptoms of mosaic are said to be masked in Kansas by the high temperature during the growing season, nevertheless plants carrying the disease, although appearing healthy, are greatly reduced in yield. Spindle tuber of potato is considered of greater economic importance in Kansas than mosaic.

Tests are reported of varieties or strains of tomatoes resistant to wilt, a disease caused by *Fusarium lycopersici*. Rhizoctonia crown rot of carrots is said to have been locally severe and destructive near Kansas City. The fungus was found to be weakly parasitic, causing serious loss only under very humid conditions and at fairly high temperatures.

Under Kansas conditions varieties of cabbage which are resistant to cabbage yellows are not considered desirable from the standpoint of type and date of maturity. Experiments are in progress with commercial Copenhagen and Golden Acre, popular early varieties susceptible to yellows, to secure, if possible, an early wilt-resistant type of cabbage.

A disease of apple trees caused by *Stereum purpureum* has appeared in the northeast section of the State.

Plant disease investigations [in British Guiana], R. A. ALTSON (*Brit. Guiana Dept. Sci. and Agr. Rpt. 1924, pp. 45-53*).—This account deals with sugar cane root disease, top rot, chlorosis, ring spot, pineapple disease, and leaf sheath red spot; coconut bud rot and red ring; rice blast; plantain (moko) dis-

ease; cacao witch-broom disease; coffee wilt; Para rubber endemic leaf disease; and mango anthracnose.

The more injurious fungus parasites of plants cultivated in the Provinces of Turin, Cuneo, and Novara, 1922-23 [trans. title], P. VOGLINO (*Ann. R. Accad. Agr. Torino*, 67 (1924), pp. 93-99).—About 40 fungus parasites of plants of economic significance are listed, as are also the Schyzomycetes *Pseudomonas phaseoli* and *P. campestris* and the dodders *Cuscuta epithimum* and *C. pentagona*.

Studies in the physiology of parasitism.—X, The growth reactions of certain fungi to their staling products, C. BOYLE (*Ann. Bot. [London]*, 38 (1924), No. 149, pp. 113-135, figs. 5).—The present study is a continuation of the series previously noted (*E. S. R.*, 47, p. 349; 49, p. 240).

Fusarium sp. grown on Richards' solution, potato extract, or apple extract soon renders the medium unsuitable for further growth. This toxic action of *Fusarium* growth products is not specific, as is shown by the fact that *Botrytis cinerea* spores are more susceptible than are *Fusarium* spores to the metabolic products of *Fusarium* sp. Details are given. "Within wide limits the pH value of a staled solution does not appear to be a limiting factor in growth." Filtration through a 90 per cent collodion membrane removes some of the toxic properties from a staled medium. The toxic substances in such a medium are partly deactivated by precipitation with alcohol, the reconstructed medium appearing less stale than the original.

[Soil sterilization in greenhouses] (*Kansas Sta. Bien. Rpt. 1925-26*, p. 64).—The value of steam soil sterilization was investigated in experiments in which 20-, 40-, and 60-minute treatments were employed. The 60-minute treatments are considered the most practical, and under the conditions of the experiment such sterilization is found to cost about 10 cts. per square foot for the treatment.

Plant diseases due to smut fungi, P. C. BOLLE (*Die Durch Schwärzepilze (Phaeodictyae) Erzeugten Pflanzenkrankheiten. Proefschr., Rijks-Univ., Utrecht, 1924*, pp. 77, pls. 3, figs. 2).—This Utrecht University thesis on plant smut fungi (Phaeodictyae) consists of the phytopathological and the mycological part, each having four chapters.

Infection tests with Erysiphaceae [trans. title], S. BLUMER (*Centbl. Bakt. [etc.]*, 2. Abt., 65 (1925), No. 1-5, pp. 62-70).—This account deals with studies and their results as applying to *Erysiphe polygoni* on Ranunculaceae, Umbelliferae, and Papilionaceae, *Microsphaera bäumleri* on *Vicia silvatica*, and *M. astragali* on *Astragalus glycyphyllus*, with a general statement as to the specialization of *E. polygoni*.

Studies of the genus *Fusarium*.—I, General account, W. BROWN and A. S. HORNE (*Ann. Bot. [London]*, 38 (1924), No. 150, pp. 379-383).—Details are reported, and work in progress is indicated.

The physiology of *Fusarium coeruleum*, E. S. MOORE (*Ann. Bot. [London]*, 38 (1924), No. 149, pp. 137-161, pls. 2, figs. 10).—Examination of the growth rate of *F. coeruleum* at different temperatures has been effected by determination of dry weight of mycelium in liquid culture, diameter of colony on solid media, and length of germ tube of conidia in germination drops. The maximum is near 30°, the minimum slightly below 5° C. (41° F.). Conidia are killed by heating for 10 or 15 minutes in water at 45-46°, or for a longer period at a lower temperature. Treatment which is insufficient to kill the spores may still delay germination. The maximum acidity tolerated is around pH 3.0. Marked morphological change occurs in growths between pH 3.0 and 3.5, but growth is still possible at pH 10.5. The fungus utilized glycerol, salts of tartaric, citric,

and acetic acids, and carbohydrates, but not oxalates or formates. As nitrogen sources, asparagin and certain salts of some organic and inorganic acids are utilized. Concentrations, both absolute and relative, of the nitrogen and carbon supplying compounds influence both type and amount of growth. Phosphate concentration has relatively little influence. The fungus secretes diastase, invertase, and cytase. The existence of both varietal and seasonal differences in the susceptibility of tubers has been confirmed. These differences appear to be due neither to the varying sugar content nor to differences in acidity of the expressed juice. They are not attributed to any differences in the cell walls of susceptible as opposed to resistant tubers when acted upon by an extract of the fungus.

The grass rusts of South America, based on the Holway collections, J. C. ARTHUR (*Amer. Phil. Soc. Proc.*, 64 (1925), No. 2, pp. 131-223, figs. 10).—The present account, a contribution from the botanical department of the Indiana Experiment Station, is the result of study based on some of the extensive rust collections made in South America during 1919-1922 by E. W. D. Holway, with the assistance of his wife. Included in this presentation are a bibliography of South American grass rusts, a species key, and a rust index.

A new disease of the Gramineae, *Pleosphaeria semeniperda* nov. sp., C. C. BRITTLEBANK and D. B. ADAM (*Brit. Mycol. Soc. Trans.*, 10 (1924), pt. 1-2, pp. 123-127, pls. 2).—In 1919 an outbreak, at first designated as take-all, was reported as present on both wheat and oats at Hopetoun, Victoria. The associated fungus, as regards the ascomycetous form, is said to belong in *Pleosphaeria*, the conidial form agreeing closely with *Podosporiella verticillata*, perhaps identical with this.

The perfect stage, *Pleosphaeria semeniperda*, is said to have been first observed on *Avena fatua*. Further occurrences are noted as involving *Bromus sterilis* and *A. sativa*.

Physiologic specialization and parasitism of *Helminthosporium sativum*, J. J. CHRISTENSEN (*Minnesota Sta. Tech. Bul.* 37 (1926), pp. 101, pls. 12, figs. 2).—Results are given of an extensive study of the *Helminthosporium* disease of cereals, with special attention to that of wheat and barley, caused by *H. sativum*. This species is widespread and destructive. It is a common inhabitant of the cereal seeds, the amount varying with locality, year, and variety. More than 1,000 isolations were made from wheat plants affected with basal stem rot, and *H. sativum* was the most prevalent organism.

Numerous physiologic forms of *H. sativum* were recognized and 37 studied in detail. These forms are distinguished in cultural as well as pathogenic characters. Asexual mutation was found to occur in some forms, and reversions apparently occur, but when they do they are always in the form of sectors. The mutants differ from their parents not only in morphological characters but also in pathogenicity, some being decidedly more virulent than the parents. Light is not considered necessary for the formation of spores. The optimum temperature for sporulation for Form I was between 16 and 25° C., the maximum about 29° and the minimum about 10°. The conidia of *H. sativum* were found to remain viable for a long time under proper conditions, several forms remaining viable for three years. The longevity of the spores is said to depend somewhat on the physiological form concerned, although environmental conditions have a greater effect. Spores of Form I were found to withstand exposure to both low and high temperatures for considerable periods of time if the relative humidity was low. Aeration is important in determining the length of time conidia can remain viable. Spore germination is influenced by slight changes in environment. The virulence of Form I was not attenuated as a result of growing six years on artificial media.

The development of the *Helminthosporium* disease on cereals is said to depend on several factors: The physiologic forms present, the amount of inoculum produced, the effect of environmental factors in the development of the pathogene, varietal susceptibility, and factors predisposing the host. Many dust and liquid fungicides were used in an attempt to destroy the mycelium of *H. sativum* in the seeds of wheat and barley, but none were entirely effective. Treating the seed with fungicides did not affect the rate of growth of seedlings nor did it control root rot and basal stem rot or increase the yields when the seed was sown in soil in which the organism was present. All varieties of *Triticum* investigated became infected with root rot and basal stem rot, but there were great differences in susceptibility, the durum wheats, in general, being the most susceptible.

Breeding wheats resistant to flag smut, J. P. SHELTON (*Agr. Gaz. N. S. Wales, 35 (1924), No. 5, pp. 336-338*).—In 1921 several American winter wheat varieties were reported by Tisdale and Griffiths (*E. S. R., 45, p. 245*) to possess quite marked resistance to flag smut. Seed of a number of such varieties were secured and were planted April 15 and May 25, 1922, alternate rows being sown with inoculated seed with a very susceptible Cleveland wheat for the purpose of comparison. The test was repeated in 1923.

The results for the two years are tabulated, and indicate that while some of the varieties tried are rather more resistant to flag smut than the New South Wales varieties, Galgalos alone showed sufficient merit to warrant its use as a resistant parent in breeding experiments. In 1923 this variety was crossed with Canberra, Cleveland, Federation, and Yandilla King, and material for extensive breeding tests was obtained. In 1923, also, 14 additional varieties were forwarded from the United States as highly resistant to flag smut, and trials with these also were projected.

Wheat pickling, H. A. MULLETT (*Jour. Dept. Agr. Victoria, 23 (1925), No. 5, pp. 233-238*).—Pickling seed wheat in Victoria to prevent ball smut, while comparatively effective as regards prevention of infection, causes loss of about 25 per cent of the seed and retards germination considerably. The new dry process, as carefully tested out, depends for its effectiveness on the purity of the copper carbonate and on its covering capability. Dilution with lime or gypsum showed a proportionate loss of effectiveness. Very fine powders fly into the air better than do coarse powders, they get into the crease and brush better, and they are more effectively distributed over the grain so as to come near the smut spores. Details are given.

Treatment of wheat for smut, A. E. V. RICHARDSON (*Jour. Dept. Agr. Victoria, 22 (1924), No. 4, pp. 224-230*).—Comparative tests indicated are considered to show that finely pulverized fungicidal dusts (copper carbonate and copper sulfate) are superior to the standard fungicidal solutions as treatments of wheat seed for protection from smut. Copper carbonate effectively kills smut spores without the depressing effect on germination and vitality that is caused by the standard solutions of formalin and copper sulfate, especially where the sowing is delayed after treatment. It is usually sufficient when used at the rate of only 2 oz. per bushel where the infection with bunt spores is not very heavy. The cost of materials, though comparatively high, is more than offset by the advantages.

Finely pulverized copper sulfate is nearly as advantageous. It is more effective than is copper carbonate for killing smut spores, but it affects slightly the vitality of the seed, though not so much as does the standard solution.

Control of seedbed diseases of cruciferous crops on Long Island by the mercuric chloride treatment for cabbage maggot, E. E. CLAYTON (*New York*

State Sta. Bul. 537 (1926), pp. 29).—A report is given of experiments conducted during the years 1923, 1924, and 1925 to determine the disease-control value of the corrosive sublimate treatment for maggots when used in cabbage, cauliflower, and Brussels sprouts seed beds. Long Island farmers who treat their seed beds for maggot control are accustomed to making two applications and sometimes three. In the experiments reported the number of applications was generally two or three. Clubroot infection was reduced to a low minimum by applications of corrosive sublimate solution. Two applications were generally quite effective, but in one experiment a single treatment given just as the plants were showing first true leaf reduced the amount of clubroot from an average of 66.3 per cent in the untreated checks to 2.6 per cent in the treated plats. Corrosive sublimate appeared to be equally effective in dilutions of 1:2,000 or stronger. Organic mercury preparations proved as effective against clubroot and were less likely to injure the plants, but they were inferior to corrosive sublimate in controlling maggots.

Two to three seed-bed treatments gave marked control of blackleg in all but one of the experiments in which the blackleg infection was seed borne. Where the source of the blackleg infection was the soil and not the seed, the seed-bed treatments were ineffective. The results secured in the black rot experiments were similar to those secured with blackleg. Seed-bed treatments as used in these experiments failed to control damping-off, and it is believed that under the conditions treatments would have to begin with the appearance of the plants above ground to check this disease.

Considering the results as a whole, it may be said that the disease-control properties of the corrosive sublimate treatment as used for cabbage maggot are very considerable, in that danger from clubroot is greatly reduced and that blackleg and black rot infections carried with the seed are largely destroyed.

Corn disease studies (*Iowa Sta. Rpt. 1926, pp. 61, 62*).—The relation of the mildew disease caused by *Sclerospora graminicola* on foxtail grass to corn was studied. Oospores of *S. graminicola* produced infection on 15 varieties of field corn, 6 varieties of pop corn, and 5 varieties of sweet corn. By inoculating sterile soil with oospores and planting the grain, the infection was manifest in from 8 to 10 days after planting. Oospores have not been found on corn.

Ear rot of maize, H. TRYON (*Queensland Agr. Jour., 25 (1926), No. 3, pp. 237-258, figs. 22*).—This memoir indicates that the trouble which has hitherto been regarded by farmers in Queensland as a form of deterioration of the mature maize grain, and has been called locally moldy or mildewed corn, is a disease of the growing plant due to *Diplodia zaeae*. Supposedly, infection occurs at silking time and is favored by rainfall. No kind of maize is known to be immune. Alternation appears to be the most hopeful control measure.

Blackarm disease of cotton, with special reference to its epidemiology in the Sudan, R. G. ARCHIBALD (In *Report of a Meeting in the Sudan Gezira in Dec., 1925, for the Discussion of . . . Cotton Growing. Khartoum: Wellcome Trop. Research Labs., 1926, pp. 9-14*).—The cotton stem blight commonly referred to as blackarm, the leaf disease known as angular leaf spot, and the capsule spot known as boll rot are mentioned as localizations of one and the same infection, the causal organism being *Bacterium malvacearum*. This disease has, it is thought, existed in the Sudan for many years, escaping attention earlier owing to the comparative harmlessness which has characterized its presence until recent years.

The organism resists feebly sunlight, desiccation, or heat. The infection is carried within the seed coats, which renders seed treatment ineffective. The

organism has not been found in soil or water. It is probably not carried by insects. No hosts other than cotton have been found. Predisposing factors include unsuitable soil or climatic conditions and bad agricultural methods. Storage of cottonseed appears to lessen the liability of transmission.

[**Flax rust**], G. RUSCHMANN and W. BAVENDAMM (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 65 (1925), No. 1-5, pp. 43-58, figs. 2).—An account is given of flax rust associated with *Plectridium pectinovorum* (*Bacillus amylobacter*) and *B. felsineus*.

Studies on the nature of wilt resistance in flax, C. I. NELSON and M. DWORAK (*North Dakota Sta. Bul.* 202 (1926), pp. 30, figs. 25).—In a study on the nature of wilt resistance in flax the authors obtained globulins from the seed of two varieties, one of which was resistant to wilt and the other susceptible. The globulins were found to separate into two fractions, one dark in color and the other quite light. Precipitin tests made with sera produced against the various fractions, both singly and in groups, are said to indicate the high specificity of the homologous fraction and also the high specificity of the homologous group of fractions. The data do not indicate which fraction carries the greater amount of the specificity for the plant variety.

Resistance to wilt is considered to be a definite flax variety characteristic inasmuch as it is associated definitely with the globulin fractions. Whether the resistance is a result of the globulin structure or not is still to be determined.

The downy mildew of the hop, [I], II, E. S. SALMON and W. M. WARE (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1925), No. 12, pp. 1144-1151, pls. 3, figs. 2; 32 (1925), No. 1, pp. 30-36).—Hop downy mildew (*Pseudoperonospora humuli*), considered when first reported (E. S. R., 52, p. 747) as an introduction, is now viewed as a result of more recent disclosures as probably native to the hop in England. The present article describes the fungus and its effects on cultivated hops.

Investigations have shown that the downy mildew which is common on nettles is almost identical with that on hop, and it is thought that the causal fungus can pass from either plant to the other. Theories are advanced as to the recent behavior of the fungus in this locality.

Three diseases of cultivated mushrooms, F. E. V. SMITH (*Brit. Mycol. Soc. Trans.*, 10 (1924), pt. 1-2, pp. 81-97, pls. 2).—Mushrooms in England are subject to disease attributed to any of three parasitic fungi, *Mycogone perniciosa*, *Cephalosporium costantinii*, or *C. lamellaecola*, the last two having been described in the present article as new species by the author. Sclerodermoid mushrooms may be produced by either *C. costantinii* or *M. perniciosa*. The pathology of the latter fungus has been investigated in detail, and the fungus has been shown to be distributed by infected soil or spawn, each mushroom being infected directly from the soil when young. *M. perniciosa* may be controlled by fumigation or by spraying with formalin or lysol and by soil sterilization.

The control of onion smut, N. L. ALCOCK, A. E. S. M'INTOSH, and G. B. WALLACE (*Scot. Jour. Agr.*, 9 (1926), No. 1, pp. 65-70).—Onion smut (*Urocystis cepulae*), said to have been recognized in the United States since 1869 and in Great Britain for 12 or 15 years though probably present much longer in the north of England and south of Scotland, attacks both onion and leek in the Edinburgh districts.

Experiments with formalin solution, 2 oz. per gallon of water, applied in the furrow while seeding at 1 gal. per linear yard, carried out from April to September, 1925, showed that though a small amount of disease may escape

the treatment practical control of the disease may be obtained. The majority of the plants remained healthy and the crops more than doubled in weight.

Potato leaf-roll, G. H. PETHYBRIDGE (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1924), No. 9, pp. 863-869, pl. 1).—A brief historical account is given of potato running-out diseases in England and neighboring territory, with more particular reference to the recent losses by leaf roll. In affected plants, food manufacture and translocation are interfered with. Aphids carry the disease material, the precise nature and the causal agent of which are not known. Seed selection, roguing, aphid control, and early digging assist greatly in controlling the disease.

On a curious effect of mosaic disease upon the cells of the potato leaf, K. M. SMITH (*Ann. Bot. [London]*, 38 (1924), No. 150, pp. 385-388, figs. 4).—"During a critical search of the tissue of mosaic-infected potato leaves, the writer noticed the almost invariable presence, in the leaf cells, of a number of peculiar amoeba-like bodies. It is the purport of this note to give an accurate description of these bodies."

Diseases of sugar cane in Mauritius, E. F. S. SHEPHERD (*Mauritius Dept. Agr., Gen. Ser. Bul.* 32 (1926), pp. 18, pls. 10).—This publication presents a list of the principal sugar cane disease in Mauritius, a description of each disease, and appropriate control measures.

[**Report of tobacco disease investigations in Florida**], W. B. TISDALE (*Florida Sta. Rpt.* 1926, pp. 105-109).—In a series of fertilizer experiments with shade tobacco on account of soil infestation with the organism causing black shank, a strain of Big Cuba tobacco was planted which showed considerable resistance to the disease. Nematode infection was prevalent, and it is considered to be a factor in the invasion of the roots by the black shank organism.

Additional work was carried on in testing varieties and strains of tobacco for resistance to black shank. No commercial type of tobacco, except *Nicotiana rustica*, was found immune to the disease. Selections of Big Cuba and an F₄ selection of a cross between Big Cuba and Porto Rican are reported to be almost completely resistant, and the type appears to be fixed.

Investigations on the overwintering of wildfire are said to indicate that the causal organism (*Bacterium tabacum*) may possibly winter over in the soil of seed beds on low wet land. No evidence was found of the overwintering of wildfire in upland seed beds.

Brief notes are given of the occurrence of black fire, root knot, mosaic, and stem injury caused by fermenting poison mixture.

The blue mould (Peronospora) disease of tobacco, D. B. ADAM (*Jour. Dept. Agr. Victoria*, 23 (1925), No. 7, pp. 436-440).—An account of spraying and manurial tests and studies on resistance, the importance and rôle of the oospore, and meteorological data emphasize the importance of continuing attempts to produce resistant plants, of cleaning all seed before sowing, and of destroying early all remaining plants and early destruction of old plants and refuse in the tobacco field.

A Rhizoctonia disease of Vigna, C. H. GADD and L. S. BERTUS (*Ceylon Dept. Agr. Yearbook* 1926, pp. 31-33, pls. 2).—The extended cultivation of *Vigna oligosperma* as a cover crop has favored *R. solani*, which attacks this and various other economic plants here indicated. Studies were carried out to see whether this fungus might prove to be serious as a local disease.

The experiments show that it may be difficult to raise healthy plants from seed on soil infected with *R. solani* (*Corticium vagum*). No likelihood appears of the disease spreading to Hevea, tea, coconuts, cacao, or other woody plants, though it is said to be a serious disease on many herbaceous plants.

A method of inoculating the apple, K. GRANGER and A. S. HORNE (*Ann. Bot. [London]*, 38 (1924), No. 149, pp. 212-215, figs. 6).—The particulars, bearings, and limitations are indicated regarding a method of inoculation said to be applicable to apples but not to potatoes.

Blister canker (*Iowa Sta. Rpt. 1926*, p. 47).—Studies on the control of blister canker are said to indicate that it can be controlled quite efficiently by tree surgery methods. It is recommended that the diseased portions be chiseled out and the surface painted with a paint made from white lead mixed with raw linseed oil to which is added 0.5 oz. of powdered corrosive sublimate to each quart of mixed paint. Some paints with an asphaltum base were also found to be efficient as disinfectant coverings for the canker treated wounds.

Trials with controls for apple mildew, W. LE G. BREBETON and H. BROADFOOT (*Agr. Gaz. N. S. Wales*, 35 (1924), No. 3, pp. 209, 210).—Recommendations resulting from tests outlined as to control of apple mildew include winter destruction of mildewed twigs, spraying with atomic or atomized sulfur (12 lbs. to 100 gal. of water) or colloidal sulfur at the spur-bursting stage, and spraying with atomic or atomized sulfur (12 lbs. to 100 gal. of water) or colloidal sulfur combined with lead arsenate at the times when the latter is to be applied.

Polyporus adustus (Wilkl.) Fr. as a wound parasite of apple trees, F. T. BROOKS (*Brit. Mycol. Soc. Trans.*, 10 (1925), pt. 3, pp. 225, 226).—Preliminary study indicates that *P. adustus* (ordinarily a saprophyte on broad-leaved trees) is the cause of an apple tree disease, which is briefly noted. Stockholm tar and gas tar proved to be wholly ineffective as protective coverings.

Apple and pear scab, E. S. SALMON and W. M. WARE (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1924), No. 6, pp. 546-554, pls. 3).—Recent studies are said to have shown that in this as in other fruit-growing countries the apple scab fungus (*Venturia inaequalis*) and the pear scab (*V. pyrina*) develop a winter stage in the dead scabbed leaves on the ground. The resulting winter spores are expelled in the spring and infect the young leaves and fruit, reproducing the scab. This fact emphasizes the necessity for suitable and timely spraying.

Spraying experiments against apple scab, N. B. BAGENAL, W. GOODWIN, E. S. SALMON, and W. M. WARE (*Jour. Min. Agr. [Gt. Brit.]*, 32 (1925), No. 2, pp. 137-149, pls. 2).—Spraying experiments against scab, or black spot, carried out during 1923 and 1924 in a commercial plantation at Egerton, Kent, are described. These were applied to bush apple trees planted in 1915, principally of the variety Bismarck, this variety being extremely susceptible to scab as regards both leaves and fruit.

The sprayings, as outlined, employing either of the three fungicides, Bordeaux mixture, lime sulfur, and lime sulfur plus lead arsenate, controlled scab to a marked extent, without serious leaf injury or fruit russetting, though there was some dropping of young fruits in case of the last two preparations named.

Apple rot fungi in storage, M. N. KIDD and A. BEAUMONT (*Brit. Mycol. Soc. Trans.*, 10 (1924), pt. 1-2, pp. 98-118, pls. 2).—A systematic account is given of apple rot storage fungi based on examination of all rots developing during the seasons 1921-22 and 1922-23. Forms named, with technical descriptions, as new species include *Phoma fuliginea*, *P. bismarckii*, *Oospora mali*, *Cephalosporium malorum*, *Hyalopus albidus*, *Sporotrichum malorum*, *Tilachlidium cinabarinum*, and *Graphium malorum*. A few varieties claimed to be new are indicated.

Cold storage for Iowa apples (*Iowa Sta. Rpt. 1926*, pp. 46, 47).—In cooperation with the chemistry section of the station a comprehensive study was made on the acidity of apples under cold storage conditions to determine whether there was a correlation between the rate of loss of acidity and the development

of such storage troubles as scald, breakdown, and Jonathan spot. It was found that fruit stored at temperatures of from 30 to 32° F. are more apt to breakdown and soft scald than fruit stored at slightly higher temperatures. An investigation of the cold storage trouble known as Jonathan spot showed that the black spots are caused by a color change in the pigment around the lentils. H-ion determinations indicate that the spotted areas are less acid than the normal skin, which has a clear red color. By treating spotted apples with fumes of hydrochloric acid, the original color is restored. In experiments in which impregnated wraps were used the percentage of Jonathan spot was reduced from 44 to 7 per cent.

The dwarfing, shriveling, and dropping of cherries and prunes, W. O. GLOYER (*New York State Sta. Bul.* 540 (1926), pp. 18, pls. 4, fig. 1).—The author states that the fungus constantly associated with the lesions on the pedicels of the English Morello cherry did not prove to be the causal agent of the condition described as "small cherry." The fungus, which has been identified as *Coniothyrium olivaceum*, is present as a saprophyte on the pedicels, fruit, and epidermis of the 1- and 2-year-old twigs. Orchard practice; seasonal conditions; mechanical, insect, or spray injury; and fungal and bacterial infection may influence the size of the fruit, but it is considered that the data obtained definitely show that the pedicel injury, and the subsequent dropping and dwarfing of the fruit, should be attributed to acid lead arsenate. The injury was associated with lead arsenate when combined with Bordeaux mixture, lime sulfur, wettable sulfur, or sulfur dust, the least injury being noted where light applications of the last two fungicides were made.

Applications of lead arsenate also caused injury to various varieties of prunes similar to that produced on the English Morello cherry.

Silver-leaf disease of fruit trees, F. T. BROOKS (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1925), No. 10, pp. 954-957).—Victoria and Czar plums, two of the best varieties as regards quality and cropping capacity, are particularly susceptible to wilt. Such varieties as Early Rivers, Pershore, Greengage, Purple Egg, and Monarch are comparatively rarely attacked.

Progress report on red plant of strawberries, A. H. LEES and L. N. STANTLAND (*Jour. Bath and West and South. Counties Soc.*, 5. ser., 19 (1924-25), pp. 196-199).—Referring to the fact that Ballard and Peren in the report of the previous year (*E. S. R.*, 52, p. 748) had accepted the presence and activity of *Aphelenchus fragariae* as causal in strawberry red plant, the present authors give an account of studies testing that view. The results are considered as justifying retention of that hypothesis for the present at least, but also as indicating the necessity of studies of the place of infection (leaf base or growing point), amount of dose, and state of the plant.

Vine black spot and erinose, F. DE CASTELLA (*Jour. Dept. Agr. Victoria*, 23 (1925), No. 7, pp. 432-435).—Vine black spot and erinose are among the few vine diseases which are amenable to winter treatment. The first of these has recently threatened to become disastrously prevalent, and the second has increased to an alarming extent.

For black spot (anthracnose, due to *Manginia ampelina*), the modified wash (iron sulfate 20 lbs., sulfuric acid 8 lbs., and hot water 10 gal.) seems to be of ample strength, if supplemented where needful by copper sprays. The so-called erinose disease is due to an acarion (*Phytoptus vitis*), for which the winter treatment above indicated is effective, destroying the hibernating mites.

Spraying experiments for downy mildew, H. G. WHITE (*Agr. Gaz. N. S. Wales*, 35 (1924), No. 2, p. 94).—Experiments in spraying for control of downy mildew were carried out at the Narara Viticultural Nursery during the season of

1923, which was very dry, the outbreak occurring late and in mild form. The applications included Bordeaux mixture at 6-4-40, 6-4-50, and 10-5-50; also at 6-4-40 with casein as a spreader (1 oz. to 10 gal.), and at the same strength with fish oil as a spreader (1 pt. to 25 gal.). A proprietary Bordeaux mixture and a proprietary Burgundy mixture were also used. These applications were made December 29, January 31, February 21, March 7, and April 4. All checked equally well the downy mildew present. The spreaders were satisfactory.

A disease of fig [trans. title], C. GHIRLANDA (*Ann. R. Accad. Agr. Torino*, 67 (1924), pp. 71-76, figs. 2).—A fruit fall of figs in Turin was found to be associated with the fungus *Alternaria fici*, formerly described technically by Farneti (E. S. R., 16, p. 987) as causing a fig fruit disease.

Bunchy top—what it is, how to detect it, what to do (*Queensland Agr. Jour.*, 25 (1926), No. 3, pp. 259-268, figs. 9).—This article, written for the guidance of banana growers by the Bunchy Top Investigation Committee, outlines facts known regarding the bunchy top disease, its early detection, and approved protective measures. The disease is not caused, but is carried, by the banana aphid, becoming evident about a month after its transmission. Once transmitted it spreads to all plants or suckers in the stool affected. Specific directions are given.

The cause of citrus scab, E. M. DOIDGE and E. J. BUTLER (*Brit. Mycol. Soc. Trans.*, 10 (1924), pt. 1-2, pp. 119-121, fig. 1).—Citrus scab or verrucosis, formerly ascribed to the fungus *Cladosporium citri*, but in 1923 attributed by Winston (E. S. R., 48, p. 647) to another fungus not named, is dealt with briefly by the present authors, who technically describe the fungus as a new species, which is named *Sporotrichum citri*.

Black spot on dried orange peel from China, W. A. BIRMINGHAM (*Agr. Gaz. N. S. Wales*, 35 (1924), No. 5, p. 345).—Record is made of citrus fruit black spot caused by *Phoma citricarpa* in China.

Cool storage of Washington Navel oranges, J. E. HARRISON (*Jour. Dept. Agr. Victoria*, 23 (1925), No. 7, pp. 428-432).—The year's experimentation emphasizes the points that fruits from different districts differ as regards keeping quality, that sweating best minimizes mold outbreak in cool storage of Washington Navel oranges, that an average temperature of 32° F. causes danger of freezing, and that 34° is the most satisfactory storage temperature.

Coffee root disease [trans. title], A. STEINMANN (*Arch. Koffie Cult. Nederland. Indië*, 1 (1925), No. 1, pp. 79-81, pls. 2).—Brief discussion is given regarding a coffee root disease associated with what is considered as a new fungus, *Polyporus rubidus*.

A note on branch canker of tea, C. H. GADD (*Ceylon Dept. Agr. Yearbook 1926*, pp. 7, 8, pl. 1).—Tea branch canker in Ceylon is caused by *Corticium salmonicolor* and *Macrophoma theicola*. These are described, as are the protective measures found to be locally indispensable, which include a waterproof antiseptic covering, as tar, for all wounds. A Bordeaux spray may also be necessary.

A leaf disease of tea caused by *Macrophoma theicola* Petch, C. H. GADD and C. RAGUNATHAN (*Ceylon Dept. Agr. Yearbook 1926*, pp. 16-18, pl. 1).—In 1924, a tea branch disease in the Ragalla district was studied. This is ascribed to *M. theicola*, apparently here a wound parasite, at least so far as leaves are concerned. Its action on the tea stem varies with conditions, bark of young shoots up to 1 cm. in diameter being attacked. Natural causes may arrest the canker after elongated oval patches of the bark have been killed; or shedding of the bark may be followed by a branch canker and eventually by a dieback.

Cultures made from branches showing cankers in April, 1925, developed the same disease on wounded but not on unwounded tea leaves.

A die-back disease of dadap (*Erythrina lithosperma*), M. PARK (Ceylon Dept. Agr. Yearbook 1926, pp. 9-12, pls. 2).—In the Badulla district early in 1924 a disease of dadap (*E. lithosperma*) was noted, and later sporadic appearances were observed elsewhere. The symptoms are described. Experimentation showed that a *Fusarium* which has been isolated can cause the disease, though it probably enters by way of wounds, results suggesting that the infection more often enters through cut ends of branches of lopped trees and that damp atmospheric conditions are necessary to a serious outbreak. Apparently where growth conditions are particularly favorable to dadap, the disease tends to be mild. The disease is serious chiefly at those elevations at which it is difficult to establish the host. Pruning back to healthy tissue, tarring cut ends, and burning cut branches reduce the likelihood or amount of infection by air-borne spores.

[Pecan] disease control, G. H. BLACKMON (Florida Sta. Rpt. 1926, pp. 65, 66).—Spraying experiments with Bordeaux mixture and lime sulfur with various spreaders and stickers showed that while all the materials used gave fairly good results, the calcium caseinate caused the Bordeaux mixture to adhere to the foliage, nuts, and branches for a longer period than any of the other fungicides used, and no detrimental effects were experienced in using any of them. A portion of the trees sprayed had been top-worked to other varieties, and excellent results were obtained in controlling scab to permit the nuts to develop and mature to normal size, while on the unsprayed trees they scabbed so badly that practically all of them shed before maturity. Several dusts were used experimentally for the control of pecan scab, but no definite results are reported.

A disease of narcissus bulbs caused by a sclerotium-producing fungus N. L. ALCOCK (Brit. Mycol. Soc. Trans., 10 (1924), pt. 1-2, pp. 127, 128).—In 1922, narcissus bulbs examined showed white mycelium and black sclerotia, the fungus, as isolated and studied, recalling in some ways *Sclerotium oryzae*.

Hevea mildew, C. H. GADD (Ceylon Dept. Agr. Yearbook 1926, pp. 22, 23).—A study in 1925 of a Hevea leaf cast involving chiefly the young leaves, which are attacked just as they are expanding from the bud, showed the presence and presumed agency of an *Oidium*. This is said to attack also the flowers, and is also said here to be itself parasitized by a *Cicinnobolus*. The Hevea disease may be identical with Hevea mildew as known in Java, it is said, since 1918. Other plants, it is suspected, may harbor this *Oidium* locally in dry weather, which is not favorable to its development on Hevea.

A preliminary note on a *Phytophthora* associated with patch canker of Hevea brasiliensis in Malaya, A. THOMPSON (Malayan Agr. Jour., 13 (1925), No. 5, pp. 139-141).—Patch canker of *H. brasiliensis* has been attributed to *P. faberi*, as the disease has been claimed to follow inoculation with that fungus; but, it is here stated, no investigation has so far as ascertained originally isolated *P. faberi* from Hevea patch canker. In November, 1924, the author succeeded in isolating a fungus from diseased Hevea bark, the symptoms of which in this one instance resembled somewhat those of claret-colored canker. The fungus is considered to be a *Phytophthora* with a zoospore-liberating method closely similar to that in *Pythium*. Other differences are noted. Successful preliminary inoculations on Hevea have been made, and the fungus has been recovered from the inoculated trees. From these inoculations it appears that the fungus, which is not identical with *Phytophthora faberi*, is the cause of the Hevea patch canker in Malaya. It is considered probable

that, in mixed cacao and Hevea areas where cacao is attacked by *P. faberi*, this fungus would be responsible for the canker in Hevea. Further work is indicated as necessary to settlement of questions raised.

A collar disease of rubber seedlings, A. SHARPLES (*Malayan Agr. Jour.*, 13 (1925), No. 6, pp. 150-153).—The author calls attention to a disease of rubber basket seedlings in Malaya, also to observation on study by others of similar occurrences on rubber or other plants elsewhere. The prominent fungus in both cases observed by the author was the common *Diplodia* said to be responsible for a rubber branch die-back. The stems of seedlings 9 to 12 in. high were attacked at or near the ground level, finally causing collapse of the plantlet. Comparisons are outlined, showing differences.

Spraying with 5 per cent Izal killed all badly infected plants, but no healthy plants, the treatment thus being entirely successful. It is thought that 2.5 per cent Izal would be sufficient and preferable.

Visual determination of penetration of sodium fluoride in treated wood, G. T. PARKER and H. A. GEAUQUE (*Amer. Wood Preservers' Assoc. Proc.*, 20 (1924), pp. 20-26).—An effective method is described of determining visually the limits of the portions which have been reached with the effective fungicidal sodium fluoride treatment in woods of such widely divergent qualities as pine, oak, and fir. Sharp and permanent tests are obtained in timber of any type, this statement including expressly woods having high tannin content. The color contrast is sharp and permanent to the dividing lines. The test is easy to make and inexpensive.

The comparative resistance of 17 species of wood-destroying fungi to sodium fluoride, C. A. RICHARDS (*Amer. Wood Preservers' Assoc. Proc.*, 20 (1924), pp. 37-44, figs. 2).—*Lenzites trabea* is the most resistant and *Poria incrassata* the least resistant of the fungi tested to sodium fluoride. The relative resistance of the fungi which were intermediate as regards resistance is shown in tabular form. These included *Polystictus abietinus*, *Lentinus lepideus*, *P. versicolor*, *Stereum fasciatum*, *Fomes roseus*, *F. pinicola*, *Trametes carnea*, *Lenzites sepiaria*, *P. hirsutus*, *Polyporus schweinitzii*, *T. pini abietis*, *F. annosus*, *L. striata*, *Schizophyllum commune*, and *Pleurotus ostreatus*.

The comparative resistance of eighteen species of wood-destroying fungi to zinc chloride, C. A. RICHARDS (*Amer. Wood Preservers' Assoc. Proc.*, 21 (1925), pp. 18-22).—Tests with zinc chloride and the same fungi as in the work with sodium fluoride noted above are reported, and the results obtained by the two salts, to which most of the fungi react in ways quite different, are compared.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The wild animals of Australasia, A. S. LE SOUEF and H. BURRELL (*London and Sydney: George G. Harrap & Co.*, 1926, pp. 388, [pls. 61], figs. [81]).—In this work, following the introduction, an account is given by E. Le G. Troughton on The Bats of Australia and New Guinea (pp. 21-88). This is followed by accounts by the authors of wild dogs (pp. 89-93), seals (pp. 94-102), sea cows (pp. 103, 104), rats and mice (pp. 105-165), pouched animals or marsupials (pp. 166-369), and egg-laying mammals or monotremes (pp. 370-380). In all about 400 species of mammals belonging to these 7 distinct groups are known to occur in Australasia to-day.

The yellow ground squirrel of Turkestan, *Cynomys fulvus oxianus* Thomas, D. KASHKAROV and L. LEIN (*Ecology*, 8 (1927), No. 1, pp. 63-72, figs. 3).—This is a contribution from the state university at Tashkent, Turkestan.

Ecology of the red squirrel, A. B. KLUGH (*Jour. Mammal.*, 8 (1927), No. 1, pp. 1-32, pls. 5).—A report of studies of *Sciurus hudsonicus* and subspecies.

An evaporation cup useful for chemotropic studies of insects in the field, A. PETERSON (*Jour. Econ. Ent.*, 19 (1926), No. 6, pp. 863-866, fig. 1).—The author describes a small evaporation cup capable of holding aromatic chemicals which he has found to be useful in making studies of insect chemotropism under field conditions when liquid traps are employed.

A good type of cage for rearing parasites, S. KELER (*Jour. Econ. Ent.*, 19 (1926), No. 6, pp. 866, 867, pl. 1).—The author describes a cage which he found useful while working in Poland on the bionomics of *Pimpla nucun* Rtz.

The effect of moisture, temperature, and light on the decomposition of lead arsenate in sulfur-lime dry mix spray, J. M. GINSBURG (*Jour. Econ. Ent.*, 19 (1926), No. 6, pp. 841-853).—In this contribution from the New Jersey Experiment Stations it is reported that large amounts of water soluble arsenic are liberated when sulfur-lime dry mix spray containing acid lead arsenate is exposed to the atmosphere in thin layers on glass plates, being brought about by the calcium carbonate formed from the hydrated lime. Still greater percentages of soluble arsenic are formed when the $\text{Ca}(\text{OH})_2$ is entirely replaced by CaCO_3 . Apparently high humidity, intense sunlight, and a temperature of 110° F., singly or combined, do not play any significant rôle in decomposing the PbHAsO_4 but may cause arsenical injury to foliage indirectly by increasing the permeability of plant tissue to water soluble arsenic. A list of references to the literature is included.

Notes on some of the newer spray materials, W. C. DUTTON (*Michigan Sta. Quart. Bul.*, 9 (1927), No. 3, pp. 117-120).—The author here points out the advantages and disadvantages of some of the newer spray materials, indicating the conditions under which they may be safely used. The materials considered include dry lime sulfur, other sulfur sprays, dry-mix sulfur-lime spray and wettable sulfur, casein spreader dusts, miscible oils and oil emulsions, and calcium arsenate.

Trials of tar-distillate washes in the West Midlands, S. G. JARY (*Jour. Min. Agr. [Gt. Brit.]*, 33 (1926), No. 8, pp. 753-761).—Of the washes given 2-year tests those known as Mortege and Carbokrimp were found the most effective. The eggs of aphids, apple suckers, and, to some extent, winter moths and tortricids are killed by these washes at 4 and 8 per cent strengths, but a concentration of 10 per cent is considered most effective and is also far more deadly against capsid eggs. In no case did any damage occur to buds sprayed with a 10 per cent strength, providing they were dormant at the time of application.

The toxic values of certain fluorides, S. MARCOVITCH (*Jour. Econ. Ent.*, 19 (1926), No. 5, pp. 795, 796).—This is a contribution from the Tennessee Experiment Station, on which the author is led to conclude that for insecticidal purposes the fluosilicates (1) are more effective than relatively insoluble fluorides, (2) kill more rapidly than do the fluorides, (3) are readily obtained in commercial quantities whereas the relatively insoluble fluorides are not in a form suitable for dusting, and (4) are cheaper than the fluorides.

Report of the entomologist, C. P. GILLETTE (*Colorado Sta. Rpt. 1926*, pp. 30-32).—This is a brief statement of the occurrence of several of the more important insects of the year and control work conducted. The rose chafer became for the first time of economic importance in the State, particularly in the vicinity of Pueblo. The alfalfa weevil was discovered for the first time in portions of Routt, Rio Blanco, and Ouray Counties, this apparently having been an extension of the infested area in southwestern Wyoming and not a spread of the insect from the infested areas in western Colorado.

Investigations of the codling moth were continued by W. Yetter, Jr., in Mesa County and J. H. Newton in Delta County. While its control with sprays has been very successful with arsenate of lead in Delta County, an additional brood that occurs in Mesa County renders its control more difficult there, but the trapping of moths gives promise of being a valuable supplementary control measure.

Brief reference is made to grasshopper control work under the direction of G. Langford, outbreaks of which pest during the year were below the average.

Report of the entomologist, J. R. WATSON (*Florida Sta. Rpt. 1926, pp. 42-50*).—In reporting briefly upon the status of the citrus aphid (*Aphis spiraeicola* Patch), the author records the rearing and liberation in groves of the Chinese ladybeetle (*Leis* sp.) received from California and its recovery the following year. It was found that heavy, dashing rains are very destructive to the aphids. Finely ground tobacco (snuff) was found to be one of the most promising insecticides for controlling this pest. Extensive tests in the fumigation of citrus trees with calcium cyanide dust conducted from September to March and again in May and June indicate that this method can be used any time of the year when spraying with oil emulsions is practicable, in sunlight as well as at night and under any ordinary weather conditions except when the trees are wet.

Life history notes on the citrus aphid by A. N. Tissot, based on observations at Gainesville, are presented (pp. 46-48), the details being given in tabular form. A temperature of 25° F. was found to kill some of the aphids outright, and a great many more were destroyed indirectly by the freezing of the tender growth upon which they were feeding. The observations seem to indicate that the most favorable temperature conditions for the development of the aphid are average daily maximum temperatures of 80 to 85° and average daily minimum temperatures of 60° or above. When the maximum temperature is above 90° for a few days there seems to be a slowing up in the rate of growth of the aphid and also a decrease in the daily and total number of nymphs produced. Likewise, development seems to be retarded when the average minimum temperature is below 50° for a few days. The apple and cherry laurel are added to the previously recorded food plants of this aphid.

Fumigation with calcium cyanide dust resulted in the killing of about 95 per cent of white fly larvae and purple scale and 96 per cent of the Florida red scale. The experience of the year indicates that fumigation will control rust mites for two or three months.

Observations of the Florida flower thrips (*Frankliniella tritici bispinosa* Morg.) show it to be common on almost any tender succulent growth, the young and tender shoots of the cherry laurel being a favored breeding ground.

Reference is made to control work with the bean leafhopper (*Empoasca fabae*), in which a hood was devised and found effective by Beyer, as described in Bulletin 164, previously noted (E. S. R., 47, p. 758).

Reference is made to work with pecan insects by H. E. Bartley. Case-bearers proved to be by far the most destructive insects to the pecan, the nut case-bearer being the worst enemy followed closely by the leaf case-bearer.

Entomology (*Iowa Sta. Rpt. 1926, pp. 39-43*).—This is a brief account of the occurrence of and control work with some of the more important insects of the year.

Myzus houghtonensis Troop was found to be a source of injury to the gooseberry during the summer of 1925. The carrot weevil (*Listronotus rudipennis* Blatch.) was a source of injury in several localities, due to the tunneling of

the carrots by the larvae, often causing a loss of from 50 to 90 per cent of the crop.

Reference is made to honeyflow conditions during the year and activities of individual bees by means of a method devised for determining the character of the contents of the honey sac without injury to the bee. It was found that nectar carriers required on the average from one-half to three-quarters of an hour to make a round trip, while water carriers, obtaining their loads within 50 yds. of the apiary, completed their round trips within an average of five minutes. In a study of protection for bees it was found that in Iowa they need protection in the fall equally as much as during the winter, and that during the spring they need it more than in winter by 50 per cent.

Injurious insects and other pests (*Kansas Sta. Bien. Rpt. 1925-26, pp. 71-84*).—This is a brief report of some of the more important features of the entomological work of the two years. Reference is made to climate and injurious insect investigations, the Hessian fly and other wheat insects, corn ear worm and other insects injurious to corn, the control of fruit and vegetable insects, control of insects attacking the sorghums, insects attacking the roots of staple crops, insects injurious to alfalfa and allied plants, shade tree insects, and investigations in the control of injurious rodents.

[Contributions on economic insects] (*Ztschr. Angew. Ent., 11 (1925), No. 3, pp. 325-458, figs. 33; 12 (1926), No. 1, pp. 1-184, pl. 1, figs. 34*).—Papers here presented (E. S. R., 55, p. 854) include the following in No. 3: The Coffee Berry Beetle Borer in the Dutch East Indies, by K. Friederichs (pp. 325-385), which includes a bibliography of 108 titles; The Introduction of the Woolly Apple Aphid Parasite *Aphelinum mali* (Hald.) into Germany, by R. Schander and O. Kaufmann (pp. 386-394); A Contribution on the Action of Arsenical Compounds on Lepidoptera, by W. Speyer (pp. 395-399); A Survey of Insect Enemies of Agriculture in Brazil, by K. Guenther (pp. 400-414); A Survey of the Insects of Agricultural Importance in Rio Grande do Sul, Brazil, by J. Wille (pp. 415-426), 265 being listed; The Coccid Fauna of Baden, by H. Wünn (pp. 427-451); A New Method of Combating Migratory Grasshoppers in Bulgaria, by A. K. Drenowski (pp. 452-455); and On the Winter Quarters of Cerambycid Beetles of the genus *Rhagium*, by M. Dingler (pp. 455-458).

The papers presented in No. 1 are as follows: The Use of Arsenicals in Plant Protection in Germany; A Retrospect and Prospect with the Aid of the Experience in Other Countries, by F. Stellwaag (pp. 1-49); The Pine Geometrid (Spanworm) in Bavaria in 1925, with Particular Reference to the Problem of Parasites, by H. Eidmann (pp. 51-90), including a bibliography of 23 titles; On the Prediction of the Number of Generations in Insects.—III, The Significance of Climate for Agricultural Entomology, by F. S. Bodenheimer (pp. 91-122), including a bibliography of 58 titles; On the Periodicity of the May Beetle—A Preliminary Note, by F. Zweigelt (pp. 123-137); Biology of *Angitia fenestralis* Holmgr. (Hymenoptera, Ichneumonidae), a Parasite of *Plutella maculipennis* Curt, and Notes on Immunity in Insects, by N. F. Meyer (pp. 139-152), including a bibliography of 14 titles; Weevil Studies.—II, New Contributions on the Generations of *Hylobius abietis* L., by M. Dingler (pp. 153-161); and Contributions to the Knowledge of an Amebic Disease of the Honey Bee (due to the organism *Vahlkampfia (Malpighamoeba) mellificae* n. sp.), by H. Prell (pp. 163-168), which includes a bibliography of 9 titles. A German translation is given of an address³ by L. O. Howard on The Needs of the World as to Entomology (pp. 169-184).

³ Ann. Ent. Soc. Amer., 18 (1925), No. 1, pp. 1-21.

A preliminary list of food-plants of some Malayan insects, B. A. R. GATER and G. H. CORBETT (*Fed. Malay States Dept. Agr. Bul. 38 (1926), pp. XVII+95*).—Following a brief preface and introduction with economic notes, the authors present a classified list of insects with their food-plants (pp. 1-26), then a classified list of the food-plants and the insects attacking them (pp. 27-85) and a list of miscellaneous foods (pp. 86-88). A list of 32 references and an index to the subject matter are included.

Insects injurious to the household and annoying to man, G. W. HERRICK (*New York: Macmillan Co., 1926, rev. ed., pp. XVII+478, pls. 8, figs. 152*).—This is a revised edition of the work previously noted (*E. S. R., 32, p. 449*).

Fighting locusts with a contact insecticide, C. H. GABLE (*Jour. Econ. Ent., 19 (1926), No. 6, pp. 861-863*).—This is a contribution from the U. S. D. A. Bureau of Entomology in which the author reports observations made during an outbreak of one of the "bird grasshoppers," or larger obscure locust (*Schistocerca obscura* Fab.), at Pleasanton, 30 miles south of San Antonio, Tex.

It is pointed out that, unlike the common injurious grasshopper, individuals of this species seldom touch the ground after they develop wings, congregating in the tops of trees and brush along the edges of the field, and fly in to feed about 8 or 9 o'clock in the morning. The observation that 90 per cent of the grasshoppers left the field at night and roosted on a strip of trees and brush 50 ft. wide led to the use of a contact spray. A cattle dip composed of total water-soluble arsenic 15.14 per cent, actual arsenious oxide (As_2O_3) 20.02 per cent, water 44.40 per cent, and equal parts of soft soap and sodium cresolate 20.44 per cent, with the strength of 1 part to 80 parts water killed 85 per cent of the pest and saved the entire crop of cotton. The spray mixture was applied with a barrel sprayer with 25 ft. of hose equipped with a Bordeaux nozzle, reaching the tops of the highest trees in the entire strip of infested brush.

The Thysanoptera of Europe, H. PRIESNER (*Die Thysanopteren Europas. Vienna: Fritz Wagner, 1926, pts. 1, pp. 238, pls. 3, figs. 2; 2, pp. 239-342, pl. 1*).—Following a brief introduction and an account of technique, this first part deals with the general morphology and anatomy of the Thysanoptera (pp. 12-64), observations of the morphology of the immature stages and metamorphosis (pp. 64-72), phylogeny (pp. 72-78), and special morphology and classification (pp. 78-238), with tables for the separation of the families, followed by a consideration of the suborder Terebrantia, including the superfamilies Aeolothripodea (pp. 84-116) and Thripodea. Part 2 is a continuation of the Thripodea.

Cotton hopper control, H. G. GOOD (*Jour. Econ. Ent., 19 (1926), No. 6, pp. 869, 870*).—The author reports briefly on the results of dusting with S-dusting mixture in controlling the cotton hopper at the Alabama Experiment Station. This mixture is composed of 50 per cent sulfur and 50 per cent calcium cyanide, the cyanide content being between 17 and 25 per cent. It was found that this mixture was a good control medium for the cotton flea hopper, 8 to 10 lbs. per acre applied once a week being most satisfactory, and that no burning of foliage resulted from its application.

Determining the effectiveness of dormant treatments against the San Jose scale, W. S. ABBOTT (*Jour. Econ. Ent., 19 (1926), No. 6, pp. 858-860*).—The author concludes that a count of the first-generation young settling on new wood furnishes a reliable index of the effectiveness of dormant treatments against the San Jose scale. A comparison of these counts will show the relative efficiency of various treatments. A high negative correlation between this count and the percentage of hibernating scales found dead indicates the re-

liability of the latter count. The correlation coefficients indicate that in these experiments the records taken 30 days after treatment were accurate.

Life history studies of seven described species of the genus *Lachnus*, M. A. PALMER (*Ann. Ent. Soc. Amer.*, 19 (1926), No. 3, pp. 300-330, pls. 6).—Five of the seven species of *Lachnus* here described have been reared from the egg through successive generations to the summer forms. Sexual forms of all, except *L. pseudotsugae*, have been reared from summer forms captured in nature and cared for in the insectary.

Dry-season studies of cane Homoptera at Soledad, Cuba, with a list of the coccids of the district, J. G. MYERS (*Harvard Inst. Trop. Biol. and Med. Contrib.* 3 (1926), pp. 63-110, fig. 1).—Following a brief introduction, the author presents a summary of present knowledge of insect transmission of mosaic of cane, the mosaic situation at Soledad, the feeding habits of Hemiptera in general, and the cane Homoptera of Soledad, followed by a general summary and conclusions. A description of *Phaciocephalus cubanus* n. sp., taken from sugar cane at Soledad, is given in the first appendix, and a list of coccids of Soledad and their host plants in the second appendix. A bibliography of three pages is included.

A contribution to the study of the biology and classification of the Coccidae [trans. title], P. VAYSSIÈRE (*Min. Agr. [France], Ann. Épiphyties*, 12 (1926), No. 4-5, pp. 197-382, pls. 6, figs. 95).—The first part of this work (pp. 202-347), following a brief introduction, deals with the subfamily Monophlebinae, treating of its general characteristics (pp. 202-213), a biological study of a monophlebine, *Guerinia serratulae* Fab. (pp. 214-256), and the classification of the subfamily Monophlebinae, with descriptions of new species (pp. 256-347). The second part (pp. 348-376) deals with the coccids from the standpoint of biogeography, including hosts, distribution of coccids on their hosts, geographical distribution of coccids, and various methods of dispersion of coccids. A bibliography of five pages is included.

Report on sugar-cane borers at Soledad, Cuba, G. SALT (*Harvard Inst. Trop. Biol. and Med. Contrib.* 3 (1926), pp. 9-62, pls. 4, figs. 2).—This account is based upon 10 weeks' study of borers at Soledad, Cuba, particularly the sugar-cane borer, the silky cane weevil, and the shot-hole borer *Xyleborus* sp. A list of parasites and predators of *Diatraea* is presented in the first appendix and a list of ants inhabiting *Diatraea* borings in sugar cane in the second appendix. A bibliography of four pages is included.

The maize-stalk borer (*Busseola fusca*, Fuller), R. O. WAHL (*Farming in So. Africa*, 1 (1926), No. 8, pp. 279-281, 282, figs. 3).—This is an illustrated summary of information on an important enemy of the corn crop in South Africa and means for its control.

Apple leaf-rollers of the genera *Amorbia*, *Archips*, *Eulia*, *Pandemis*, and *Peronea*, S. W. FROST (*Jour. Econ. Ent.*, 19 (1926), No. 6, pp. 813-819, fig. 1).—This is said to be an introductory paper to a more complete and detailed study of economic leaf-rollers. The author summarizes numerous scattered life-history studies, comparing them as to range of food plants, number of broods, manner of hibernation, and other minor habits. Many original notes are included.

Codling moth in the Arkansas Valley, W. R. MARTIN (*Kans. State Hort. Soc. Bien. Rpt.*, 38 (1924-25), pp. 51-56).—The author reports that, beginning with 1922 and continuing up to the time of writing, the codling moth has increased very rapidly in the Arkansas Valley in Kansas, and that about 75 per cent of the crops of both 1923 and 1924 showed codling moth injury. In 1925 from 15 to 20 per cent of the fruit was wormy and from 50 to 70 per

cent of the remainder was stung. The investigations conducted in 1925 showed other factors than the proper timing of the sprays to be necessary for satisfactory control. These factors include materials used, population of moths, set of fruit, and injury of the fruit. A chart is presented which graphically illustrates the emergence of the codling moth and the application of sprays in 1924.

A test made of the efficiency of commercial spreaders in control of codling moth and apple blotch indicates that the oil spreaders were slightly more efficient, but that neither the oil nor the casein showed enough improvement over the check to warrant its general use. It is pointed out that the population of codling moth depends upon 4 factors, namely, winter mortality, packing sheds, natural enemies, and crop failures. The table presented shows the effect of light and heavy crops of apples on different trees in the same orchard in regard to codling moth control.

Oriental fruit moth invades Ohio, D. M. DELONG (*Agr. Student*, 33 (1927), No. 5, pp. 117-119, 137, 138, figs. 3).—A brief account of this pest, which was first found in Ohio at Columbus in the summer of 1925, when fruit on some trees under observation was found infested to the extent of 5 to 10 per cent.

The European corn borer *Pyrausta nubilalis* Hubn.—I, A discussion of its dormant period, K. W. BABCOCK (*Ecology*, 8 (1927), No. 1, pp. 45-59).—This account is based upon investigations, details of which are given in tabular form.

The author finds that after a certain period of development the intervention of a dormant or rest period is essential for the general welfare of the species. The inception of dormancy in the corn borer is not initiated by a fall in temperature, nor does heat alone at certain times during this period cause it to emerge from this state and resume development. The larva is very sensitive to changes in contact moisture during the dormant period. If desiccation occurs at this time, retardation of pupation results, and if the loss of moisture is not compensated for before active development begins, the number of one-generation individuals present in the descendants tends to increase.

The moth that destroys our fruit, C. P. VAN DER MERWE (*Farming in So. Africa*, 1 (1926), No. 2, p. 53).—An account of the *Achaea lienardi*, which attacks and injures fruit that is ripe or nearly ripe.

The relation of the red-backed cutworm to diversified agriculture in western Canada, K. M. KING and N. J. ATKINSON (*Sci. Agr.*, 7 (1926), No. 3, pp. 86-91, fig. 1).—In this discussion it is pointed out that the damage caused by *Euxoa ochrogaster* Gn. (E. S. R., 55, p. 855) depresses the growing of those crops which it is most desirable to introduce in the Prairie Provinces in an effort to promote diversified agriculture, and exerts a strong pressure tending toward a continuance of the straight grain farming now practiced. The principal crops which it is desired to introduce are sweet clover, alfalfa, flax, corn, and sunflowers. These suffer more severely than grain because they are preferred to cereals by the cutworm, if cut while young they have no powers of recovery, and the seedlings, at least of the first three mentioned, are very small.

The cheese skipper as a pest in cured meats, P. SIMMONS (*U. S. Dept. Agr. Bul.* 1453 (1927), pp. 56, pl. 1, figs. 10).—This is a summary of information on *Piophilha casei* (L.), based upon a review of the literature in connection with a bibliography of 83 titles and investigations conducted by the author. The subject is presented under the headings of systematic position and synonymy, common names, distribution, materials infested, the cheese skipper and disease, nature of injury to cured meat, the adult insect, the egg, the larva, metamorphosis, emergence of adult, life cycle, insects found associated with the cheese

skipper, and control measures, of which the principal are preventing the adults from entering storage rooms and infesting the meats.

Syllabus of insect biology.—Coleoptera, I, H. BLUNCK (*Syllabus der Insektenbiologie. Coleopteren. Lieferung 1. Berlin: Borntraeger Bros., 1925, [No. 4a], pp. 136; rev. in Ent. News, 38 (1927), No. 1, pp. 28, 29*).—This first part of the author's syllabus includes the Coleoptera through Histeridae. In the preparation of this work an attempt is being made to record all that has been published upon the life histories of insects, group by group and species by species. The review is by L. O. Howard.

The parasites of *Popillia japonica* in Japan and Chosen (Korea) and their introduction into the United States, C. P. CLAUSEN, J. L. KING, and C. TERANISHI (*U. S. Dept. Agr. Bul. 1429 (1927), pp. 56, pl. 1, figs. 35*).—This is a summary of information on investigations of parasites of the Japanese beetle initiated in Japan in the spring of 1920 at Yokohama and extended in 1922 to Chosen. The subject is dealt with under the special headings of the parasites and their biology (pp. 3–44), life history of *Popillia japonica* in Japan (pp. 44–47), food plants of *Popillia* in Japan (pp. 47, 48), climatic conditions in the main fields of investigation (pp. 48–51), agriculture and natural lands of Japan and Chosen in relation to *Popillia* (pp. 51–53), and the species of *Popillia* in Chosen, i. e., *P. atrocoerulea* Bates, *P. castanoptera* Hope, and *P. mutans* Newm. (pp. 53, 54).

The parasites and predator dealt with include the following: *Centeter cinerea* Aldrich, *Eutrixopsis javana* Towns., *Ochromceigenia ormioides* Towns., *Prosenia siberita* (Fab.), *Dexia ventralis* Aldrich, *Campsomeris annulata* (Fab.), *Tiphia popilliavora* Roh., *T. vernalis* Roh., and *T. koreana* Roh., and the carabid predator *Craspedonotus tibialis* Schaum, representing three species of Tachinidae, two species of Dexiidae, and four species of Scoliidae. Among the tachinids *C. cinerea* is the most promising species, since in its native habitat it is very abundant and exerts a marked control upon *P. japonica*. *O. ormioides* is more common in the warmer regions in Japan, though it ranges into Chosen and northern China, which would indicate that it is not limited to mild climatic conditions. Of the *Tiphia* species, *T. popilliavora* at Koiwai effects a parasitism of 20 per cent upon grubs of *J. japonica*. It was found that in the Orient *P. japonica* occurs only in Japan proper, and in that country it is of very minor importance as an enemy of economic crops.

Sodium fluosilicate as a control for blister beetles on soybeans in southwestern Louisiana, J. W. INGRAM (*Jour. Econ. Ent., 19 (1926), No. 6, pp. 853–858*).—This contribution from the U. S. D. A. Bureau of Entomology reports on experiments conducted in southwestern Louisiana for the control of blister beetles on soy beans. The details are given of the work conducted, a brief account of which has been previously noted (*E. S. R., 55, p. 662*).

The control of wireworms in glasshouses, H. W. MILES and F. R. PETHERBRIDGE (*Jour. Min. Agr. [Gt. Brit.], 33 (1926), No. 10, pp. 931–939*).—In the experiments reported calcium cyanide used at the rate of 1.5 to 3.5 lbs. per 180 cu. ft., in conjunction with a suitable method of baiting, gave a good control. The results indicate that the finer the soil the more effective the treatment, and the nearer the middle of the bait rows the calcium cyanide is deposited the higher the mortality among the wireworms.

Effect of highway slash on infestation by western pine beetle studied (*U. S. Dept. Agr., Public Roads, 7 (1927), No. 12, pp. 251, 252*).—This is a brief account of the results obtained in a 4-year investigation of the effect of slash from highway clearing on insect infestation of surrounding timber. The work was conducted by J. E. Patterson, of the U. S. D. A. Bureau of Entomology, on

a highway in the Cascade Mountains of southern Oregon. The study was commenced in 1920 with the clearing of a highway through a larger timber area consisting of yellow pine, sugar pine, Douglas fir, white fir, and true fir, the slash consisting of entire trunks and tops of trees dragged to either side of a clearing 60 ft. wide and 24 miles long.

The results obtained in this region, where the western pine beetle is the principal insect enemy of the mature western yellow pine, show that line slash is very attractive to it, practically all such slash being attacked by this bark beetle. Its attack on the slash was not so heavy, however, as on mature standing timber, about one-half as many beetles attacking a unit area of bark on the felled trees. Due to an abnormal mortality the increase of beetles developing in the slash studied was only 64 per cent of the number of beetles making the attack, whereas the corresponding increase in adjacent timber at the same time was 135 per cent. It was found that bark beetles from the surrounding standing timber were attracted to the slash at the time of attack, and a temporary concentration of infestation occurred in its immediate vicinity. However, normal distribution of the infestation was resumed within a year. This concentration and the breeding of beetles in line slash did not increase or greatly influence infestations in the surrounding forest, the cycle of infestation continuing regardless of the slash. The study indicates that the infestation of line slash by *Dendroctonus brevicomis* is not a serious menace to neighboring mature timber, and may be disregarded when the problem of slash disposal is under consideration.

The western pine beetle control problem, J. M. MILLER (*Jour. Forestry*, 24 (1926), No. 8, pp. 897-910).—The problem of controlling the western pine beetle is considered under the headings of character of damage, basis for control methods and strategy, results of early control projects, importance of natural control factors, maintenance control, control of an isolated infestation, a million acre project (the southern Oregon—northern California), improved methods needed, possibility of control through forest management, and the need for further investigations.

Boll weevil investigations (Florida Sta. Rpt. 1926, pp. 40, 41).—In a study made by E. F. Grossman of a large number of mixtures, it was found that one consisting of 1 lb. of calcium arsenate, 1 gal. of water, and 1 gal. of sirup was the most effective in its resistance to rain, drying, and surface caking, as well as being cheaper than the more concentrated mixtures commonly recommended. A mixture consisting of 1 lb. of calcium arsenate, 2 gal. of water, and 1 gal. of sirup was also found to be very effective. The fact that the supernatant liquid obtained when these mixtures settled did not contain sufficient arsenic to be toxic to the weevils emphasizes the need for stirring these mixtures while using. Laboratory tests with weevils upheld the contention that blackstrap is much inferior to higher grade sirups for making sirup mixtures. In the experiments the weevils would actually refuse blackstrap and, in most cases, feed immediately upon higher grade sirups if offered.

The life history and control of the cranberry weevil, *Anthonomus musculus* Say (Coleoptera: Curculionidae), D. S. LACROIX (*Jour. Econ. Ent.*, 19 (1926), No. 6, pp. 819-829).—This is a contribution from the Massachusetts Experiment Station dealing with a pest that occurs sporadically on Massachusetts bogs, often causing considerable loss to the cranberry crop before its presence is suspected. It is pointed out that the true cranberry weevil is *A. musculus* Say, not *A. suturalis* LeConte as it has been referred to in the past. It has a single generation a year in Massachusetts and both the larvae and the adults are of economic importance. Control measures carried out experimentally

resulted in the adoption of a mixture of Bordeaux, calcium arsenate, lime, and fish-oil soap. This insecticide has proved efficient when applied commercially. The Bordeaux and soap tend to spread the mixture evenly over the waxy cuticle of the cranberry leaf and fruit and to make it stick under severe conditions.

Bees, wasps, and ants, C. A. HALL (*London: A. & C. Black, 1925, pp. VIII+88, pls. 12, figs. 5*).—This is a popular account dealing with the social and solitary bees and wasps and the ants.

Bee investigations (*Kansas Sta. Bien. Rpt. 1925-26, pp. 117, 118*).—Particular mention is made of a study of the causes which affect the granulation of honey. The work indicates that (1) diffused light does not influence crystallization, (2) low temperatures combined with extreme variations in daily temperatures hasten the beginning of crystallization and also shorten the period of time (3) air incorporated into honey has a tendency to hasten the beginning of crystallization and shortens the period required, (4) crystallization of a blend of two or more honeys is influenced by the ratio of crystallization and shortens the period required, (5) crystallization of a blend of two or more honeys is influenced by the ratio of crystallization to noncrystallizable sugars which it contains, (6) a correlation exists between the percentage of dextrose in honey and the number of days from extraction until crystallization begins, and (7) a correlation exists between the percentage of dextrose in honey and the length of time required for the completion of the crystallization process.

The domestic bee, its care and product, L. ICHES (*L'Abeille Domestique, son Élevage et ses Produits. Paris: Garnier Bros., [1925], pp. XXI+351, figs. 134*).—This is a practical account.

Telenomus cosmopeplae Gahan, an egg parasite of *Cosmopepla bimaculata* Thomas, W. V. BALDUF (*Jour. Econ. Ent., 19 (1926), No. 6, pp. 829-841*).—It is pointed out that the pentatomid *C. bimaculata* Thomas is a potential pest of the snapdragon on which it is commonly found. It is held in check, however, by a new egg parasite, *T. cosmopeplae* Gahan. In the present paper the author reports upon the manner of oviposition, larval habits, life cycle, and economic value of the parasite. *Triphleps insidiosus* Say is suspected of reducing the effectiveness of the parasite by preying on the *Cosmopepla* eggs, both parasitized and unparasitized.

The anatomy of a British phytophagous chalcidoid of the genus Harmolita (Isosoma), H. C. JAMES (*Zool. Soc. London Proc., 1926, I, pp. 75-182, figs. 70*).—This is a report of an extended anatomical study of the eurytomid *H. graminicola* (Giraud).

Notes on some feeding habits of two chalcid parasites, G. H. GRISWOLD (*Ann. Ent. Soc. Amer., 19 (1926), No. 3, pp. 331-334, fig. 1*).—The author here adds *Aphidencyrtus inquisitor* Howard and *Aphelinus jucundus* Gahan, which were reared from the geranium aphid *Macrosiphum cornelli* Patch, to the increasing list of chalcids that have been observed feeding at puncture holes made by the ovipositor.

Insect control, G. H. BLACKMON (*Florida Sta. Rpt. 1926, pp. 66, 67*).—The pecan culturist reports that in cooperative work with the department of entomology excellent results were obtained in control of the leaf-case bearer by the use of 1 lb. of arsenate of lead and 3 lbs. of lime to 50 gal. water, or by adding it to Bordeaux in the same proportion. Two applications, made about July and August, have a somewhat better control than did one.

The cultivation of Herpetomonas muscarum (Leidy 1856) Kent 1881 from Lucilia sericata, J. J. DRBOHLAV (*Jour. Parasitol., 12 (1926), No. 4, pp. 183-190, pls. 2; abs. in Jour. Trop. Med. and Hyg. [London], 29 (1926), No. 24,*

p. 412).—This herpetomonas, requiring a medium of low hydrogen-ion concentration, namely, pH 5.6 to 6.4, was isolated in pure live culture from the green-bottle fly, *L. sericata*. It was found in 83.4 per cent of the specimens examined.

ANIMAL PRODUCTION

The interpretation of the feeding trial, E. W. CRAMPTON (*Sci. Agr.*, 7 (1926), No. 2, pp. 41-50).—This article explains the application of biometry to the data of feeding trials for fattening and dairy animals. It also shows how biometry is used in the interpretation of these data.

Preliminary investigations regarding the influence of the size of the ration on the productive value of feeding stuffs [trans. title], I. POIJÄRVI (*Statens Lantbruksförsöksverks. [Finland] Vetensk. Pub. 6* (1926), pp. 43, figs. 5; *Eng. abs.*, pp. 38-41).—This preliminary work indicates that as the bulk in the ration increases the digestibility decreases. Three reasons have been tentatively assigned for this reduction in digestibility; (1) increased bulk passes through the digestive tract quicker and hence has less time for digestion, (2) the bacterial action which aids in digesting crude fiber may be limited, and (3) there may be a limit to the capacity of the intestines to absorb digested nutrients.

Animal nutrition work [at the Iowa Station] (*Iowa Sta. Rpt. 1926*, pp. 34, 35).—The continuation of the study of the effect of mineral supplements (E. S. R., 55, p. 561) has dealt largely with the value of salts of fluorine. Successive generations of rats fed less than 0.025 per cent sodium fluoride apparently reproduced well but did not grow normally. Reproduction in this case is usually slow, the mortality high, and the weight of each successive generation is less. Calcium fluoride apparently has the same effect as sodium fluoride, but being less soluble rats can tolerate it in larger amounts. Rats tolerate both salts in larger amounts when fed with a mixed ration than when fed with a purified ration or a single grain ration.

Feeding beef cattle in California, H. R. GUILBERT (*Calif. Agr. Col. Ext. Circ. 3* (1926), pp. 19, figs. 4).—A popular discussion of the reasons, the methods, and the principles for feeding beef cattle in California.

Cattle feeding experiments (*Iowa Sta. Rpt. 1926*, pp. 18, 19).—Eight lots of 2-year-old steers were fed for 120 days to compare silage and hay, and dry roughage as the roughage portion of a ration and also the value of mineral supplements. Two commonly used Corn Belt rations were fed in this experiment: (1) Shelled corn, oil meal, alfalfa hay, and salt and (2) the same except that corn silage was added.

The results indicate that the above rations were of equal merit from the standpoint of gain and cost of gain. The addition of 1.25 oz. of a simple mineral mixture increased the rate of gain 5 per cent and raised the selling price from 15 to 25 cts. per hundredweight. Steers ate an average of 3.25 oz. of black loam per day. Black loam increased the daily gains, decreased the feed required for 100 lbs. of gain, and increased the selling price 50 cts. per 100 lbs. Corn fodder and alfalfa hay as the roughage portion of a ration was not successful either in rate or economy of gains.

Buying and feeding cattle, R. BERESFORD and C. W. McDONALD (*Iowa Agr. Col. Ext. Bul. 117* (1926), pp. 31, figs. 12).—A popular presentation of the problems of buying and feeding beef cattle.

Beef-cattle feeding investigations [at the Fort Hays Substation] (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 139, 140).—The results of experiments with kafir and cane in the form of dry roughage and in the form of silage have been previously noted (E. S. R., 55, p. 358). The calculated return per acre for

feeds consumed by lots receiving silage was \$18.13 and where no silage was fed \$5.18. Calves receiving 13.67 lbs. of alfalfa hay and 1 lb. of cottonseed cake per day gained 0.73 lb. daily, while calves fed the same ration except that Sudan hay was substituted for alfalfa gained 0.47 lb. daily. Cows fed on cut kafir or sorgo butts with alfalfa hay made somewhat larger gains than those fed whole kafir or sorgo butts. However, the difference was not great enough to pay for the cost of cutting.

Swine feeding experiments, J. M. SCOTT (*Florida Sta. Rpt. 1926, pp. 26-28*).—In three experiments of two lots each, in which 7, 10, and 7 hogs per lot, respectively, were fed to compare rations of (1) shelled corn 9 parts and fish meal 1 part and (2) shelled corn 9 parts, alfalfa meal 2 parts, and cottonseed meal 1 part, the pigs fed alfalfa meal and cottonseed meal made an average of 0.13 lb. per head greater daily gain than the lot fed fish meal. The feed requirement for 100 lbs. gain was less when fish meal was used.

[**Swine feeding and breeding experiments at the Iowa Station**] (*Iowa Sta. Rpt. 1926, pp. 20, 21, 22, 23*).—Results of two experiments not previously reported are briefly noted.

Hogging down corn to best advantage.—Seven lots of 15 120-lb. pigs were fed in different cornfields and compared with a check lot on rape pasture. Pigs receiving standing corn and minerals required 693 lbs. of feed to produce 100 lbs. of gain, while in a similar field in which soy beans were planted and tankage and minerals allowed the pigs required only 412 lbs. of feed to produce the same gain. The first lot made an average daily gain of 1 lb. per day, while those in the second lot made $1\frac{2}{3}$ lbs. per day. Standing corn supplemented with whole soy beans, or tankage, or beans in the pod, or tankage and beans in the pod, or rape and tankage, or rye and tankage, gave better results than standing corn and minerals. Beans planted in the hills of corn reduced the yield of corn, and hence reduced the hog gains per acre. Beans as the sole supplement to corn are not satisfactory. Hogging down corn when properly managed has been much more economical than feeding the husked corn to pigs on rape pasture.

Swine inbreeding v. outbreeding.—A record of 11 outbred and 8 inbred litters showed that the inbred sows produced 8.9 pigs per litter, while the outbred sows produced 6.8 pigs. However, 36 per cent of the inbred pigs died before the end of the suckling period, while only 18 per cent of the outbred pigs died. Seven outbred litters required 220 days to reach 225 lbs. in weight, while 4 inbred litters required 249 days to reach the same weight.

[**Investigations with swine at the Kansas Station**] (*Kansas Sta. Bien. Rpt. 1925-26, pp. 84-86, 88-91, 92*).—The results of experiments are briefly noted.

The nutritive requirements of swine.—This is a continuation of work previously noted (*E. S. R., 52, p. 469*). A chemical analysis of the blood, bone, and brain of pigs fed a ration of white corn, tankage, and bone ash to an advanced stage of avitaminosis A showed no significant difference when compared with normal hogs. Of 4 sows fed an optimum ration of white corn, tankage, bone ash, alfalfa meal, sprouted oats, butterfat, and cod-liver oil, 2 farrowed good litters and 2 poor. Individuality of the animals seemed to play an important part in the production of this lot.

Swine feeding investigations.—During the winter of 1924-25 5 lots of 10 pigs each were fattened in dry lot on corn and a protein supplement which consisted of (1) tankage, (2) 3 parts tankage to 1 part linseed oil meal, (3) 2 parts tankage and 2 parts linseed oil meal, (4) 1 part tankage and 3 parts linseed oil meal, and (5) linseed oil meal. Alfalfa hay was fed to all lots. In this experiment it was found that the greater the proportion of tankage

and the less linseed oil meal in the ration the greater the gains and finish and the cheaper the gains.

Three lots of 15 pigs each were fattened during the summer of 1925 on alfalfa pasture, corn, and a protein supplement consisting of (1) tankage, (2) tankage 50 per cent and linseed oil meal 50 per cent, and (3) linseed oil meal. There was little difference in the rate or economy of gains in the first and second lots. In the third lot the feed required per unit of gain was about the same as in the other lots, but the rate of gain was 14 per cent less.

During the winter of 1925-26, 6 lots of 8 pigs each were fattened in dry lot on corn and the following supplements: (1) Tankage and salt, (2) tankage and alfalfa hay, (3) tankage, alfalfa hay, and salt, (4) equal parts of tankage and linseed oil meal, (5) equal parts of tankage and oil meal and alfalfa hay, and (6) equal parts of tankage and oil meal, alfalfa hay, and salt. The rate and economy of gains were greater in lots fed tankage. The use of alfalfa hay resulted in more vigorous and healthy pigs. The addition of salt to a ration containing alfalfa hay reduced the rate of gain and increased the feed required per unit of gain.

Pigs fed corn and tankage on alfalfa pasture made an average daily gain of 1.47 lbs. over a period of 105 days. Pigs fed ground kafir and tankage on Sudan pasture gained 1.37 lbs. daily. It required 341.42 lbs. of corn and 3.8 lbs. of tankage on alfalfa pasture and 354.44 lbs. of ground kafir and 17.52 lbs. of tankage on Sudan grass pasture to produce 100 lbs. of gain.

A comparison of different methods of feeding spring pigs.—A study was made of different methods of feeding spring pigs: (1) Deferred full feeding v. immediate full feeding, (2) growing feeder pigs on alfalfa pasture, and (3) fattening feeder pigs on new corn. One group of pigs fed 1 lb. of corn and 0.2 lb. of tankage on alfalfa pasture from June 15 to September 28 made an average daily gain of 0.53 lb. It required approximately 2 bu. of corn and 20 lbs. of tankage besides the alfalfa pasture to grow these pigs from 60 to 115 lbs. From September 28 these same pigs were fed an average of 8.24 lbs. of corn and 0.25 lb. of tankage for 60 days. During this period they averaged approximately 2.05 lbs. per head daily gain. It required 9 bu. of corn and 15 lbs. of tankage to increase the live weight from 115 to 238 lbs. The other lot full fed from the start made an average daily gain of 1.51 lbs. for a period of 105 days. These pigs ate an average of 4.96 lbs. of corn and 0.2 lb. of tankage and required about 9.5 bu. of corn and 20 lbs. of tankage to increase from 60 to 218 lbs. in weight.

A study of pasture values and pasture methods for horses, cattle, sheep, and swine.—In a study of pastures sweet clover proved to be less valuable than alfalfa for swine but satisfactory for sheep and cattle. Little trouble was experienced with bloat. Sudan grass proved to be one of the most satisfactory summer pasture crops for all classes of livestock. Orchard grass was one of the most satisfactory permanent pasture grasses.

[Irrigated pastures at the Garden City, Kans., Substation] (*Kansas Sta. Bien. Rpt. 1925-26, pp. 143, 144*).—Two lots of 50- to 60-lb. spring pigs were fed on irrigated alfalfa pasture for 108 days. One lot received 2 lbs. of ground milo per 100 lbs. live weight, and the other lot was self-fed ground milo. Lot 1 gained an average of 0.55 lb. per head daily, and lot 2 gained 1.2 lbs. It was found that the pigs in lot 2 were ready for market at the end of the grazing season, while those in lot 1 needed a finishing period in dry lot. The calculated return per acre of alfalfa was \$75.37 less cost of milo in the case of lot 1, and \$109.18 in the case of lot 2.

Two half-acre plats were seeded to a mixture of 9 varieties of tame grasses. A third plat was seeded to sweet clover. One of the grass plats was treated with barnyard manure. During 1925 the mixed grass plats furnished 143 days' pasture at the rate of 2 dairy cows per acre, and the sweet clover plat furnished 140 days' pasture at the same rate. The net return from the untreated grass plat was approximately \$37.50, from the treated plat \$51.75, and from the sweet clover plat \$54.70.

Some experiments in mineral feeding, R. D. SINCLAIR and J. P. SACKVILLE (*Sci. Agr.*, 6 (1926), No. 11, pp. 373-379, figs. 5).—The results of two trials with the feeding of minerals to hogs on pasture are reported. The pigs in these experiments averaged from 45 to 55 lbs. in weight at the beginning of the trial. All lots were run on rape pasture, and the grain ration consisted of oats, barley, and shorts. Buttermilk was fed to all lots at the beginning of the test, but the amount was decreased until none was being fed at the end of 28 days. Where tankage was fed the amount given was 5 per cent of the grain ration.

In both trials the addition of a simple mineral mixture when tankage was not fed resulted in increased gains and lower feed requirements. Complex mineral mixtures were not as economical, either in rate of gain or feed required, as the simple mixtures.

Very good results were obtained in feeding salt as a supplement, indicating that sodium chloride is an essential ingredient to mineral mixtures. No ill effects from salt feeding were observed.

The addition of a simple mineral mixture to tankage did not indicate that tankage needed mineral supplements. In all tests the addition of the simple mineral mixtures to grain alone gave more rapid and more economical gains than when tankage was added.

The influence of different quantities of salt upon the palatability and keeping qualities of hams and bacon (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 92-94).—During 1924-25, 5 lots of hams and bacons were put in cures in which the amount of salt varied. The formula used in lot 1 was 12 lbs. of salt, 3 lbs. of brown sugar, and 3 oz. of saltpeter dissolved in 6 gal. of water for each 100 lbs. of meat. The bacons were left in the cure for 2 days per pound per piece and the hams 3 days per pound per piece and then smoked for 24 hours with hickory smoke. In lots 2, 3, 4, and 5 the cure was the same except that the salt was reduced to 11, 10, 9, and 8 lbs., respectively. From the standpoint of palatability, the use of 9 and 10 lbs. of salt (70 to 76° by the salinometer) gave the best results. A chemical analysis of these two lots showed the salt content of the bacons to be 3.05 and 2.82 per cent and for the hams 4.45 and 4.68 per cent, respectively. The amount of salt used had no effect upon the development of molds. The sugar content was about 50 per cent less than that present in commercial products, and the saltpeter was also less. This was thought to be due to the calcium content of the salt and water.

In 1925-26 the cure used in lot 1 was the same as described above except that the time in smoke was reduced 4 hours. In lot 2, 10 lbs. of Kansas salt was used; in lot 3, 10 lbs. of Michigan salt; and in lot 4, 8 lbs. of Kansas salt. In lots 5 and 6 smoked salt was used as directed by the manufacturers, lot 5 using the dry cure and lot 6 the brine cure. Eight lbs. of salt (65° by the salinometer) was found to be satisfactory. The amount of salt had no apparent effect upon shrinkage. In palatability and physical appearance the Kansas salt produced the same results as Michigan salt. Smoked salt was fairly satisfactory, the meat shrinking less than when cured by the regular method, but being inferior as to color, flavor, and cooking qualities. The brine cure proved most efficient when smoked salt was used.

The Chow Chow, E. L. DIETRICH and L. M. DAVIES (*Chicago: Judy Pub. Co., 1926, pp. 72, figs. 35*).—This book contains a brief history and suggestions on the management, feeding, and showing of the chow dog.

Operation of a four-unit poultry plant for commercial year 1925-1926, B. F. KAUPP (*North Carolina Sta. Bul. 251 (1927), pp. 28, figs. 7*).—Two years' results of a 10-year experiment are reported in this bulletin. It is a continuation and elaboration of work previously noted (*E. S. R., 55, p. 265*).

[**Poultry investigations at the Kansas Station**] (*Kansas Sta. Bien. Rpt. 1925-26, pp. 107-111, 123, 124, 125*).—The results of experiments are briefly noted.

Poultry flock management.—This is a continuation of work previously noted (*E. S. R., 52, p. 474*). High winter egg yields were gotten by placing March or April hatched pullets in the laying house October 1, confining them until April 15, and forcing for egg production during this period. Hens that have completed one or more years' production produce eggs of good fertility and hatchability when allowed free range all winter and spring.

Effect of feeding white and yellow corn and supplementary feeds on egg production and hatchability.—Ten Rhode Island Red pullets fed white corn and meat scrap produced an average of 50 eggs from November 1 to June 1 that were 82 per cent fertile, but only 38 per cent of these hatched. A similar lot fed yellow corn and meat scrap produced 89 eggs, 74 per cent of which were fertile, and 60 per cent of these hatched. With soy bean meal and 3 per cent mineral mixture added to the white corn ration, the number of eggs was larger by 8, but there was no effect upon fertility, and the hatchability was raised to 61 per cent. With white corn, meat scrap, and alfalfa meal the egg production was 77, the fertility 44 per cent, and the hatchability 56 per cent.

White Leghorn pullets fed a scratch ration of yellow corn and a mash of ground yellow corn, meat scrap, and dried buttermilk produced an average of 58 eggs from November 1 to May 1, of which 91 per cent were fertile, and 76 per cent of these hatched. A similar lot fed white corn instead of yellow produced 37 eggs, 85 per cent of which were fertile, and 65 per cent hatched. Replacing the meat scrap in the latter ration with soy bean meal and a mineral mixture in place of the dried buttermilk apparently reduced the egg production more than half and also decreased the fertility and hatchability. The addition of ground alfalfa leaves to the white corn ration gave the best results. Pullets in this lot produced 74 eggs, 90 per cent of which were fertile, and 86 per cent of these hatched.

The effect of an inadequate ration on the production and hatchability of eggs.—Continuing this project (*E. S. R., 52, p. 474*), it was found from a biological analysis that eggs from hens which received ultra-violet light either from direct sunshine or from a quartz mercury arc light contained more vitamin D than eggs from hens receiving sunlight through window glass.

A study was made of the relative antirachitic value of sources of ultra-violet light and various substances containing vitamin D as measured by the development of growing chicks fed an adequate diet. As indicated by the weights of chicks at 56 days of age, ultra-violet light from a glass tube for 9.5 hours daily gave best results. This was followed by 0.5 per cent cod-liver oil in the ration, direct sunlight, ultra-violet light through a quartz tube for 15 minutes, ultra-violet light through a glass tube for 8.25 hours, 2 per cent irradiated cottonseed oil, 2 per cent irradiated Wesson oil, and sunlight diffused through window glass.

Relation of adequacy of diet to disease.—Experiments indicated that there was little relationship between losses due to avitaminosis A in adult chickens and the mineral content of the feed or the presence or lack of vitamin D.

Feeding experiments with Leghorns, L. W. CASSEL (*Washington Col. Sta. Bul. 210 (1927), pp. 32, figs. 13*).—The results of three experiments are reported in this publication. Two of these have been previously noted (*E. S. R.*, 56, p. 567).

The third is a comparison of ground v. unground grain mixtures with sour skim milk for laying hens, with a standard laying ration. Seven pens of 20 Single Comb White Leghorn pullets hatched May 16 were fed from November 1, 1925, to October 31, 1926, in pens 15 by 6 ft., with a cinder yard 324 sq. ft. in area. Sour skim milk, grit, oyster shell, and charcoal were available at all times in all lots. The green feed for all lots consisted of dried alfalfa leaves in the fall and winter and green alfalfa in the spring and summer.

Lot 1 received the W. S. C. standard laying ration, consisting of scratch and laying mash. Lots 2, 3, and 4 received a scratch, no mash ration, consisting in lot 2 of 66 lbs. of wheat and 34 lbs. of oats, in lot 3, 50 lbs. of wheat, 25 lbs. of oats, and 25 lbs. of barley, and in lot 4, 35 lbs. of wheat, 35 lbs. of cracked yellow corn, and 30 lbs. of oats. In lots 5, 6, and 7 the birds received a whole grain mash, no scratch ration, consisting of the same feeds in the same proportions as in lots 2, 3, and 4, respectively, except that the grains were ground.

The results indicate that under the conditions of this experiment, the ground grain mixtures (no scratch) with sour skim milk were somewhat superior to unground grain (no mash) or the standard laying ration for feeding producing hens.

Feeding and housing for laying hens, W. L. QUAYLE and A. CHRISTENSEN (*Wyoming Sta. Bul. 149 (1927), pp. 31, figs. 3*).—The results of two years' experiments in feeding pullets show that with a ration containing 20 per cent of protein there were produced over 50 dozen more eggs per year from a flock of 100 birds than with a ration containing 10 per cent of protein. Pullets receiving the high protein ration returned a greater profit than the low protein flock.

Insulating a poultry house with straw showed an annual increase in egg production of over 62 doz. eggs per flock of 110 birds over a noninsulated house. A large portion of this increase was during the winter months when the price of eggs is high.

Pullets produced $1,909\frac{1}{2}$ doz. eggs per year as compared to $1,288\frac{1}{2}$ doz. eggs for yearling hens. The pullets also increased 48 per cent more in weight than did the hens.

A comparison of the growth of chicks behind window glass and a glass substitute, W. F. WOOD, JR. (*Poultry Sci.*, 6 (1926-27), No. 2, pp. 62-70, figs. 2).—Since ordinary window glass does not permit the radiation of ultra-violet rays, this experiment was undertaken to test the effect upon growth of a glass substitute.

Three groups of 25 chicks each were fed the ration of Hart et al. (*E. S. R.*, 47, p. 871) which produces leg weakness. Lot 1 was placed behind ordinary window glass, lot 2 behind Cel-O-Glass, and lot 3 was kept under the same conditions as lot 1 but fed 2 per cent of cod-liver oil in addition to the basal ration. Weights were taken individually each week.

Only the group receiving sunlight through window glass developed leg weaknesses, and a study of leg bones from chicks in this lot showed anatomical rickets. Lot 1 made a subnormal growth, lot 2 normal, and lot 3 about normal. The value of a glass substitute depends upon (1) its power to transmit the protective rays, (2) the season of the year, and (3) the amount of pure sunlight during the midday hours.

Early growth rates of chickens with special reference to ultra-violet light, H. D. GOODALE (*Amer. Jour. Physiol.*, 79 (1926), No. 1, pp. 44-60, figs. 5).—

The author found that early growth rate in chicks in excess of that reported as "normal" may be obtained. Chicks hatched in the early part of the season grew faster than those hatched in the latter part. Chicks from hens 2 years old and over were heavier at 30 days of age than those from hens 1 year of age.

Irradiation of chicks from 5 to 15 seconds daily with a mercury vapor lamp was ineffective in promoting growth. Thirty seconds was not completely adequate, but 1 minute gave as good results as exposures up to 3 hours. Radiation from 1 to 10 minutes twice weekly gave normal growth, while less frequent radiation appeared inadequate. There were some indications that prolonged radiation retarded growth. Winter sunlight appeared to be both growth promoting and a preventive of leg weakness.

Exposing the dry mash to a mercury lamp for 10 minutes appeared to favor growth but did not wholly prevent leg weakness, while exposure to sunlight for 30 minutes did not favor growth. Forced feeding nonirradiated chicks with the droppings of irradiated chicks was ineffective in promoting growth.

Rearing of pullets in confinement, F. R. BEAUDETTE, J. J. BLACK, and C. S. PLATT (*New Jersey Stat. Hints to Poultrymen*, 15 (1927), No. 6, pp. 4, fig. 1).—Directions are given for rearing pullets in confinement, especially in regard to prevention of infection from internal parasites. The construction of houses and yards, amount of feeding and floor space necessary, and the water and feed supply are discussed.

Influencing the development of the chick (*Connecticut Storrs Sta. Bul.* 142 (1926), pp. 179, 180, figs. 2).—During normal incubation a sudden increase in mortality beginning on the seventeenth day is noted, and about 65 per cent of the eggs hatch. When developing eggs were injected on the sixth day with 2 cc. of a physiological salt solution, after an initial mortality due to the injection, there is only a slight increase in mortality in the later stages and about 50 per cent of the eggs hatch. When a small amount of lithium chloride is added to the fluid injected the reaction is the same as above up to the nineteenth day, when a high mortality occurs bringing the hatch down to 30 per cent. These results led to the belief that the cause of the late peak mortality may be sought in the early stages of incubation.

Value of milk in the chick ration (*Iowa Sta. Rpt.* 1926, pp. 27, 28).—An experiment was conducted to compare the antirachitic properties of whole and skim milk. Weights were taken at the end of 8 weeks to determine the value of the various rations in promoting growth. Corn and milk did not produce normal growth. Adding 3 per cent of a mineral mixture increased the weight per chick. The addition of casein to the minerals did not improve the value of the ration. Whole milk contained more of the antirachitic vitamin than skim milk. Exposure to ultra-violet light prevented leg weakness, stimulated feed consumption, and increased the weight of the chicks.

Rickets in chicks, I, II, G. F. HEUSER and L. C. NORRIS (*Poultry Sci.*, 6 (1926-27), Nos. 1, pp. 9-17, figs. 2; 2, pp. 94-98, fig. 1).—In the first of these two articles, 3 tests with White Leghorn chicks to determine the variation in the antirachitic properties of different brands of cod-liver oil are reported. Seven brands were selected at random, two of American origin and five Norwegian refined oils. In the first two trials the rations were typical chick rations, but in the third trial the feed was given entirely in the form of mash. The cod-liver oil was so mixed in the feed as to constitute 0.5 per cent of the ration. Each trial was of 8 weeks' duration, and chicks were confined without exposure to direct sunlight throughout each trial. Only vigorous normal chicks were used, and they were weighed individually when transferred from the brooder

and weekly thereafter, except in trial 1, when they were weighed only at the end of the test.

The authors found that different brands of cod-liver oil vary significantly in their vitamin content when measured by means of chicks. With plenty of calcium and phosphorus in the ration the amount of cod-liver oil necessary to protect against rickets depends upon the antirachitic potency of the oil and the amount of this factor stored in the body of the chick at the time of hatching.

In the second article of the series 4 different grades of cod-liver oil were studied to test their antirachitic values for chicks. One was an American refined cod-liver oil tested biologically, another was an untested American refined oil, the third a Norwegian refined oil, and the fourth a brown cod-liver oil. These oils were incorporated at the rate of 0.2 per cent in both grain and mash. One lot was fed as a check.

Results indicate that only the tested and brown cod-liver oil provided complete protection against rickets. Three individuals from each lot were taken for bone analysis. There was no lameness nor beading on the ribs of any chick on either the tested, brown, or untested American refined oils, although the mineral content in the last lot was somewhat lower than in either other case. In the lot receiving the Norwegian refined oil the mineral contents of the bone were low, and lameness and beading on the ribs were evident.

Care and management of baby chicks, W. C. THOMPSON and F. H. T. CLICKNER (*New Jersey Stas. Circ. 199 (1927)*, pp. 32, figs. 31).—This is a revised edition of Circular 169 previously noted (E. S. R., 51, p. 777).

DAIRY FARMING—DAIRYING

The principles of dairy-farming, G. H. GARRAD (*London: Ernest Benn, 1926*, pp. 199).—This book is intended for the practical dairyman dealing with the management and feeding of dairy cattle. The problems of selecting and stocking a dairy farm, together with the handling and disposal of the milk, are discussed.

[**Dairy experiments at the Connecticut Storrs Station**] (*Connecticut Storrs Sta. Bul. 142 (1926)*, pp. 169–171, figs. 2).—The results of experiments are briefly noted, some of which have been previously mentioned.

Types of corn for silage for milk production [and effect upon consumption of hay].—This is a continuation (E. S. R., 52, p. 174) of work on types of corn for silage. When fed on a dry matter basis it was found that the feeding value of the early, medium, and late types of corn was equivalent pound for pound. Cows and heifers both consumed a greater amount of hay when fed silage made from late type corn.

Care of milking machines.—This is a preliminary report of studies in which it has been found that the chlorine disinfectants commonly used lose strength rapidly in warm weather. At this time the double strength solution should be used and new solutions made twice a week or 4 oz. of disinfectant added daily. Running water below 55° F. is effective in keeping down the bacteria count.

[**Feeding experiments with dairy cattle at the Kansas Station**] (*Kansas Sta. Bien. Rpt. 1925–26*, pp. 94–99, 101).—The results of several experiments with dairy cattle are noted.

Factors influencing the mineral metabolism of dairy cows.—This is a continuation of work previously noted (E. S. R., 52, p. 477). Four cows were kept in a barn away from direct sunlight and fed winter rations. The calcium,

phosphorus, sulfur, and magnesium balance was determined during two 1-week periods; then the cows were treated 15 minutes per day with ultra-violet light, during which time the balance was again determined. This was followed by two 1-week periods without light. No increase in mineral balance was found during exposure to light.

Sunlight in relation to the growth of calves.—Two lots of 4 Holstein calves each were fed the same ration, consisting of whole milk until 6 weeks of age and skim milk to 5 months of age, prairie hay, and a grain mixture of white corn, wheat bran, and linseed oil meal. One lot was housed in a darkened shed, while the other lot had access to direct sunlight. Blood samples were taken for calcium and phosphorus determinations at the beginning and at 60-day intervals. Two calves in the sunlight group refused to drink milk consistently and became stunted, and one calf in the darkened pen died of pneumonia. There was little difference in the physical appearance of the two lots and no evidence of rickets. The blood of both lots was normal. Neither lot made normal growth on the ration fed.

[Feeds for dairy cattle].—A lot of 9 cows was fed by the double reversal system through three 30-day periods, in which the first 10 days of each was considered preliminary, to compare ground soy beans and linseed oil meal. Alfalfa hay and topped cane silage formed the roughage part of the ration, and the concentrated part consisted of 4 parts corn chop and 1 part protein supplement. Linseed oil meal was fed through the first and third periods and ground soy beans of inferior quality through the second period. Slightly more milk was produced when linseed oil meal was fed, but the fat production was slightly higher while on ground soy beans.

Ground kafir, ground sorgo seed, and corn chop were fed with alfalfa hay to 3 lots of 4 heifers each for a 6-months period to compare their effect upon growth. The daily gains were somewhat greater for those fed corn chop. The heifers fed sorgo made greater increases in height than the other lots. The heifers in the corn lot ate less salt than in the other lots and showed less tendency toward a depraved appetite.

Dairy calf feeding investigations.—Calves fed ground kafir and ground sorgo seed made slower gains than those fed ground corn, but in growth they were slightly superior at 6 months of age. Dried buttermilk diluted with nine times its weight of water caused some digestive disturbances; also considerable difficulty was experienced in getting calves to drink the mixture.

Silage investigations.—The hour of the day that the sorgo was harvested had a noticeable effect upon its composition. A sample cut at 2 p. m. contained 50 per cent more sugar than a sample cut at 6 a. m. The starch content of the green sorgo remains unchanged in the silo. The sugars almost entirely disappear, being replaced by acids. There is little difference in the quantity of protein, ether extract, and crude fiber found in cured silage as compared with the green sorgo. The loss of material resulting from ensiling varies from 1.07 to 4.77 per cent. The moisture content of the cured silage is about 1 per cent higher than that found in green sorgo.

A study of the use of fly repellents for the control of flies on dairy cattle.—The results of 2 years' work with 5 fly repellents used on 32 cows showed that the number of flies on cows were reduced when sprayed. There was a slight increase in the amount of milk given during the time the cows were being sprayed.

The feeding of cows, A. C. M'CANDLISH (Scot. Jour. Agr., 8 (1925), No. 1, pp. 55-59).—The results of several experiments in feeding dairy cows are reported.

Steamed bone flour as a mineral supplement for milk cows.—Two lots of 4 cows each were fed for three periods of 25 days each by the double reversal method. The first 5 days of each period were considered preliminary. All animals were fed the same ration and amount of roughages, while the concentrates were fed according to production and condition. The mineral supplement was added to the grain ration of lot 1 during the first and third periods and to lot 2 during the second period. It was fed at the rate of 0.5 lb. per cow daily.

The steamed bone flour had no marked effect upon the milk or butterfat production. When the milk was subjected to a standard rennet test no significant variations were found in the acidity or rates of coagulation of the different samples.

Water for dairy cows.—Over a period of 90 days cows consumed on the average 9.18 gal. of water per head per day, or 5.5 gal. of water per gallon of milk. The cows varied in their individual requirements for water and in the consumption from day to day.

Salt for cows.—Four cows producing 17 lbs. of milk per day consumed 0.75 oz. of salt over a 90-day period while kept in a barn. When turned on pasture, 2 cows of the same group produced an average of 18 lbs. of milk and consumed 0.02 oz. of salt per day. In another herd 18 cows consumed an average of but 0.03 oz. of salt per day. It was evident that the salt requirements of a cow are controlled by her individuality and production and by the nature of her ration.

Grapefruit refuse as a dairy feed, J. M. SCOTT (Florida Sta. Rpt. 1926, pp. 25, 26).—Two lots of cows were fed by the reversal method for three periods. During the first period all cows were fed alike. During the second period grapefruit refuse, analyzing moisture 18 per cent, fat 5.25, protein 5.31, carbohydrates 61.69, and fiber 9.75 per cent, was added to the grain ration of one lot and during the third period the rations were reversed. The grapefruit refuse seemed to have a tendency to increase the milk flow.

The length of the interval between calvings, H. G. SANDERS (*Jour. Agr. Sci. [England], 17 (1927), No. 1, pp. 21-32, fig. 1*).—An attempt has been made to ascertain the best interval between calvings so that a cow's weekly yield of milk over a long period may be at a maximum. From the data tested indications are that a cow should calve at intervals of not less than a year and not more than 13 months.

The influence of the stage of lactation and the breed of the cow on the yield and quality of the milk, T. J. DRAKELEY and M. K. WHITE (*Jour. Agr. Sci. [England], 17 (1927), No. 1, pp. 118-139, fig. 1*).—An analysis of the records of 48 dairy shows held by the British Dairy Farmers' Association indicates that the percentage of fat in both morning and evening milk decreases until about the fortieth day, when the minimum is reached, after which a steady rise occurs. The yield of milk increases at first and reaches a maximum at about the forty-fifth day after calving. From that time there is a steady decrease. The shorter the time between milkings the smaller is the yield of milk and also the percentage of solids-not-fat, but the greater the percentage of fat. The yield of solids-not-fat increases until about the thirtieth day and then decreases. Based on these data, the British Friesian breed led all others in yield of milk, while the Jersey breed was high in percentage of fat.

Studies on "cream line" formation, F. J. DOAN (*Pennsylvania Sta. Bul. 204 (1926), pp. 21, 22*).—The first sentence of the abstract previously given under this title (E. S. R., 56, p. 171) should read "The temperature of the pasteurization media did not appear to affect the creaming ability unless it was higher than 212° F."

A pure milk supply, A. CUNNINGHAM and T. GIBSON (*Edinb. and East of Scot. Col. Agr. [Pub.] 1, n. ser. (1926), pp. 24*).—This is a comprehensive study of the character and source of bacterial contamination of milk. Suggestions on the production of milk free from contamination and the value to the producer of such milk are made by the authors.

A farm dairy sterilizer, N. S. GOLDING (*Brit. Columbia Dept. Agr., Dairy Circ. 13 (1926), pp. 6, fig. 1*).—This is a description of a simple and economical sterilizer for farm milking utensils with directions for its use. A bacterial analysis made on cans cleaned with this apparatus showed that they were rendered practically sterile by steaming for not less than 3 minutes.

Experiments with dairy products at the Kansas Station (*Kansas Sta. Bien. Rpt. 1925-26, pp. 101-103*).—The results of two experiments are noted.

Ice cream investigations.—Results of comparisons between the butyl alcohol and Mojonnier tests for butterfat in ice cream showed that they checked very closely and could be used interchangeably.

Corn sugar may be used to replace 30 per cent of the cane sugar in an ice cream mix without injuring the body, flavor, or texture. Mixes containing corn sugar freeze slower and the amount of time required for freezing was in direct proportion to the amount of corn sugar present. Overrun was obtained with more difficulty, and the larger the amount of corn sugar present the greater the difficulty.

Bacteriological studies of ice cream.—In continuing the studies of the bacterial content of ice cream (E. S. R., 54, p. 573), considerable light was thrown on the characteristics of the organisms producing "pin point" colonies. These bacteria are thermotolerant but not thermophilic. They develop an agar only in the presence of sugar.

The present status of density of ice cream, G. D. TURNBOW (*Ice Cream Rev., 10 (1927), No. 7, pp. 60-63, figs. 3*).—Efforts to standardize the weight or density of ice cream, as conducted at the University of California, are reported.

Several factors which might have an influence on density were studied. The first of these factors was agitation. Mixes were divided and processed in identical manner, but one mix was agitated severely and the other just enough to prevent cooking flavors from developing. The slow agitation mix developed nearly twice as much viscosity during aging as the mix which was severely agitated.

A more stable viscosity was secured by aging the mix at from 33 to 34° F. than by aging at higher temperatures. Ice cream aged at this temperature developed superior body and texture. Work with varying speeds of the dasher, ranging from 71 to 211 r. p. m., showed a variation in the retention of the initial viscosity of the mix ranging from approximately 74 per cent of the initial viscosity to only 26 per cent.

The percentage of total solids also had an effect upon the density of ice cream, especially upon the parts drawn off the freezer at different times. The higher the percentage of total solids the less difference there was between the weight of the first, second, and fourth cans of ice cream drawn off. A table illustrating three possible standards for ice cream weights are included. The author recommends one of these standards.

Adjustment of composition important, F. J. DOAN (*Butter, Cheese, and Egg Jour., 1927, Feb. (mo. ed.), pp. 23, 24, 26, 27*).—The author describes methods of standardizing mixes for the manufacture of uniform high quality sweetened condensed milk. It has been found that it is almost invariably necessary to add skim milk or to remove cream to adjust the mix, and examples of both procedures are described.

The acidity question, C. D. DAHLE (*Ice Cream Trade Jour.*, 22 (1926), No. 12, pp. 49-51).—The control of acidity in the ice cream mix is described. The flavor of ice cream depends in a large measure upon the acidity of the mix. High acidity also retards the time required to obtain a 100 per cent overrun and makes the freezing time longer. Reducing the acidity of an already low acid mix to a point below 0.15 per cent results in bitter soapy flavors.

The use of "neutralizers" depends for their efficient use upon a knowledge of each and the skill of the operator using them. The use of too much neutralizer results in poor flavor due to the presence of salts formed by the acids and alkalies. An acidity of 0.2 per cent may be considered normal.

VETERINARY MEDICINE

[Progress report on animal diseases in Connecticut] (*Connecticut Storrs Sta. Bul.* 142 (1926), pp. 168, 169, 180).—Reference is made to blood testing and the eradication of infectious abortion as successfully undertaken in the college herd, commencing in March, 1925. The owners of 40 herds, averaging 30 head, adopted the plan employed, which consists in the removal of all reactors, the abortion-free heifers being added, with the result that 15 herds are now free from the infection. The attempt to perfect an abortin for use in diagnosis gave encouraging results.

Brief reference is made to studies of the toxicity of *B. pullorum* in eggs, a detailed account of which by Rettger, Slanetz, and McAlpine has been noted (*E. S. R.*, 56, p. 678). In continuation of control work with blackhead of turkeys 50 young poults were placed in each of three lots. The first lot was kept on the weekly yard rotation plan, the second was kept on the same ground during the entire rearing season but the yard was allowed to rest from about November 15 to the following May, and the third was kept on the same ground all the season, but the ground was occupied constantly from November 15 until the following May by maturing and mature turkeys. The loss in the lot kept on the rotation plan was less than half as great as with the other two, between which there was little difference in the mortality.

A continuation of the study of fowl paralysis by Pappenheimer (*E. S. R.*, 55, p. 73) led to the discovery that this fatal disease occurs in all parts of the United States, the characteristic changes which it produces in the nervous system being found in apparently normal chickens, also in birds which do not have coccidiosis or any intestinal parasites. It was found that the infection may be transmitted to young chicks which do not show the disease until about two months after inoculation.

Report of the veterinarian, A. L. SHEALY (*Florida Sta. Rpt.* 1926, pp. 85-94, figs. 2).—The author reports upon the work of the year with salt sickness in cattle, which led to the conclusion that this is due to a nutritional deficiency.

In observations of some 200 flocks of poultry infested with Manson's eye worm the percentage of infestation varied considerably both in the flocks and in the infested birds, since some individuals had as few as one or two while others had as many as 100. Observations of the life history of the worm by D. A. Sanders are reported upon. Eggs placed in sterile soil with an abundant supply of organic matter hatched under favorable conditions, and within two months attained a length of 1.5 mm. The experiments indicate (1) the elimination of immature, noninfective stages of the parasite, (2) the need of a period of incubation in the soil or water longer than the exposure allowed in this experiment, (3) the existence of an intermediate host, and (4) that adult parasites are not transmitted directly from one bird to another.

Data obtained in a study of leeches in horses are briefly noted.

Diseases of farm animals (*Kansas Sta. Bien. Rpt. 1925-26, pp. 118-123, 124, 126, 127*).—A brief reference is made to the results of post-mortem and laboratory examinations of diseased animals and tissues, followed by abortion disease investigations, an account of which is given in Technical Bulletin 14 (E. S. R., 52, p. 779). In blackleg investigations it was found that the virulence of cultures depends upon the presence of (1) living cells, (2) aggressins produced by these cells, and (3) a lethal substance found in virulent *Clostridium chauveii* cells. Ferric sulfate, ferric chloride, and ferrous sulfate were added to the various media, and it was found that the ferric sulfate greatly increased the virulence of a number of strains in the organism. One strain which had been avirulent since 1921 was stimulated to such a degree that it again killed guinea pigs and calves.

Attempts to produce permanent immunity to hog cholera in natively immune pigs by use of the virus are briefly referred to.

In reporting upon poultry disease investigations a table is given of the results of examinations made of diseased birds sent to the laboratory for diagnosis. Two outbreaks of paratyphoid in chicks were diagnosed, the basis being the isolation of an organism which morphologically resembles *Salmonella schotmulleri*. Work on bacillary white diarrhea consisted of studies of the agglutination test for detection of *S. pullorum* infection carriers, preparation and preservation of test fluids, preservation of blood serum, distribution of bacillary white diarrhea in Kansas, mortality of chicks in bacillary white diarrhea outbreaks, complement fixation for *S. pullorum* infection in adult birds, and the transmission of bacillary white diarrhea in incubators (E. S. R., 55, p. 374). During the biennium 9,440 agglutination tests were made and in addition 300 complement fixation tests to compare the relative efficiency of the agglutination and complement-fixation tests. To date a close correlation of results has been obtained by the two methods. A summary of studies of the mortality in eight outbreaks of bacillary white diarrhea is given in tabular form. The work indicates that losses seldom start before the fourth day after the chicks are hatched and that the heaviest losses occur from the fourth to the tenth day. Losses are seldom observed from the acute type of the disease after the fourteenth day.

Reference is made to a study of the value of bacterins from the different strains of *Pasteurella avicida* and to the development of serological tests demonstrating immunity. In parasitological investigations the large round-worm of poultry (*Ascaridia perspicillum*) was given particular attention. It was found that the thymus glands of parasitized chicks become reduced in size; that the blood-sugar content of growing chicks is reduced during parasitism; that bleeding affects the resistance of the chickens to parasites, repeated bleeding making young chickens more susceptible; and that chicks from 5 to 100 days old became progressively more susceptible to parasitism. Chickens whose diet lacked Vitamin B were much less resistant to parasitism than those whose diet contained it. In studies of the viability of the worm eggs under out-of-door conditions it was found that during the period between July 21 and August 20 all eggs on the surface and those buried 2 and 4 in., respectively, were killed by heat from the sun in unshaded soil, but many of the eggs placed similarly in shaded soil survived. Temperatures of -20° F. were found to be sufficient to kill embryonated eggs when placed on the surface of the soil, but a burial of 4 in. gave sufficient protection to enable large numbers of eggs to survive such freezing.

During the course of studies of the behavior of nematode larvae in the host, larvae of nine nematodes belonging to three families were observed.

Larvae belonging to the family Ascaridae upon hatching from the eggs in the intestine of the host bored through the wall of the intestine and migrated to the liver, lungs, and trachea, and back to the intestine again before settling down to grow to maturity; larvae belonging to the family Heterakidae have a tendency to migrate, but they seldom bore through the wall of the intestine; and larvae of the family Oxyuridae appear not to have the migratory habit. Studies made on filaria nematodes occurring in poll evil and fistulous withers in horses afford strong evidence that a nematode may be the cause of these two important disorders.

Annual administration report of the Civil Veterinary Department in Ajmer-Merwara (British Rajputana) for the year 1924-25, J. H. G. JERROM (*Ajmer-Merwara Civ. Vet. Dept. Ann. Admin. Rpt. 1924-25, pp. 12*).—This is the usual annual report (E. S. R., 52, p. 377).

Annual report of the Civil Veterinary Department, Bihar and Orissa, for the year 1925-26, P. B. RILEY (*Bihar and Orissa Civ. Vet. Dept. Ann. Rpt. 1925-26, pp. [4]+20+XXVI+4, pl. 1*).—This is the usual report (E. S. R., 55, p. 70).

Report on the Civil Veterinary Department, Burma (including the Insein Veterinary School), for the year ended the 31st March, 1926, T. D. STOCK (*Burma Civ. Vet. Dept. Rpt. 1926, pp. [6]+24, pl. 1*).—This is the usual annual report (E. S. R., 54, p. 574).

The transfusion problem, C. A. DOAN (*Physiol. Rev., 7 (1927), No. 1, pp. 1-84*).—This contribution from the Rockefeller Institute for Medical Research is presented in connection with a bibliography of 717 titles.

Further studies of the isolation and cultivation of *Bacterium abortus* (Bang), I. F. HUDDLESON, D. E. HASLEY, and J. P. TORREY (*Jour. Infect. Diseases, 40 (1927), No. 2, pp. 352-368*).—This is a report of work at the Michigan Experiment Station.

The authors find that the growth activity of *B. abortus* is governed by an increased carbon dioxide tension, by the liberation of hydrogen sulfide, and the formation of ammonium magnesium phosphate, the production of the latter two substances being controlled by an abundance of carbon dioxide and the reaction of the culture medium. It is pointed out that there is a biochemical reaction which serves to distinguish *B. abortus* from *Brucella melitensis*, that is, in the formation of ammonium magnesium phosphate and liberation of hydrogen sulfide. *B. abortus* may be measured quantitatively in infective milk with a high degree of accuracy by employing, as a culture medium, gentian violet, beef liver infusion agar, and incubating in an atmosphere containing from 5 to 10 per cent carbon dioxide. In the gravity separation of cream the rising fat globules and body cells carry with them the majority of the abortion bacteria in milk. The culturing of the gravity cream layer of milk is as efficient for determining the presence of *B. abortus* in milk as are guinea-pig inoculation methods. *B. abortus* does not appear to multiply in milk held at ice-box temperatures and decreases in numbers rapidly when held longer than eight days. The number of colonies of *B. abortus* which develop on plated culture medium decreases as the length of time they are held aerobically at 37° C. increases.

Bovine infectious (contagious) abortion of cattle, with a short account of the disease in swine and sheep, C. P. FITCH, W. L. BOYD, and R. E. LUBBEHUSEN (*Minn. Univ. Agr. Ext. Spec. Bul. 28, rev (1925), pp. 33, figs. 12*).—This revision (E. S. R., 42, p. 676) is a practical summary of information.

Human infections with organism of contagious abortion of cattle and hogs, A. C. EVANS (*Jour. Amer. Med. Assoc., 88 (1927), No. 9, pp. 630-632*).—In

this discussion of the subject the author presents abstracts of 20 cases of infection which have been reported from man in this country, and briefly refers to 35 cases of undulant fever in South Africa due to *Brucella melitensis abortus* and to other outbreaks in Italy and a case in Palestine.

Meningitis due to *B. enteritidis* Gaertner, G. STUART and K. S. KRICKORIAN (*Jour. Hyg. [London]*, 25 (1926), No. 2, pp. 160-164, fig. 1; *abs. in Jour. Trop. Med. and Hyg. [London]*, 29 (1926), No. 22, p. 385).—The authors describe a case which they consider unique in that no reference has been found in medical literature to meningitis due to *Bacillus enteritidis*. It is pointed out that only 9 cases of meningitis have been traced to the paratyphoid group of organisms, 7 to *B. paratyphosus* B, 1 to *B. paratyphosus* A, and 1 to a bacillus of undifferentiated type.

Can the cattle tick *Haemaphysalis bispinosa* act as the carrier of piroplasmosis (*Piroplasma bigeminum*)? An experimental enquiry, J. LEGG (*Aust. Jour. Expt. Biol. and Med. Sci.*, 3 (1926), No. 4, pp. 203-216).—According to the author's investigations, the engorgement of *H. bispinosa* in each of the several stages of its life history on an animal recently recovered from piroplasmosis, followed by engorgement on a different susceptible animal in each of the three subsequent stages of its life history, failed to convey the disease. All the susceptible cattle subsequently reacted to inoculation with virulent blood. The experiments indicate that this tick does not act as an intermediate host of bovine piroplasmosis.

On the use of trypanblue in the treatment of the piroplasmoses of ruminants [trans. title], A. DONATIEN and F. LESTOQUARD (*Bul. Soc. Path. Exot.*, 20 (1927), No. 1, pp. 64-77, figs. 10).—The authors find that the action of trypanblue is specific in the treatment of the true piroplasmoses of bovines and ovines and that no other treatment has as effective therapeutic action. The resistance to its action by the *Babesiella* appears to be a generic characteristic.

Some experiences on serum-simultaneous method of inoculation for rinderpest in the field, C. DANDAYUTHA PANI (*Indian Vet. Jour.*, 3 (1927), No. 3, pp. 164-172).—In reporting upon his experiences with the serum-simultaneous method of inoculation for rinderpest, the author points out that, while it produces an immunity in the inoculated animals for a considerably longer time than does the "serum-alone" method, it has a number of disadvantages.

The chemotherapy of surra (*Trypanosoma evansi* infections) of horses and cattle in India, J. T. EDWARDS (*Roy. Soc. Trop. Med. and Hyg. Trans.*, 20 (1926), No. 1-2, pp. 10-73, pl. 1, figs. 9; *abs. in Vet. Rec.*, 7 (1927), No. 3, pp. 56-59, fig. 1).—Considering the result of treatment of surra with Bayer 205, the author discusses the dosage, toxic symptoms, intrathecal injection, initial peripheral sterilization, duration of peripheral sterilization after the administration of single doses, treatment with repeated doses, combined intravenous-intrathecal administration, and prophylactic action. He next discusses the treatment of surra with tartar emetic, including the minimum lethal dose for cattle; treatment of surra in buffaloes; treatment of equine surra; and prophylactic action. Then follows a discussion of the use of tryparsamide for surra, including treatment in buffaloes, cattle, and equines. The treatment of surra with bismuth compounds is next considered, including treatment of surra in cattle and in horses.

It is concluded that outbreaks of surra in cattle, including buffaloes, are easily checked by the administration of injections intravenously of relatively simple trypanocidal agents, such as tartar emetic or bismuth phosphate, single injections usually being sufficient. With equines the results obtained with applications of Bayer 205 surpassed those obtainable by other medicaments.

Intravenous administration of 5 gm. in 10 per cent aqueous solution per 1,000 lbs. body weight is said to be a suitable therapeutic dose.

Livestock diseases (*Florida Sta. Rpt. 1926, pp. 123-125*).—In investigations of livestock diseases in the Everglades in the summer of 1925, A. L. Shealy found sterility in cattle to be the most serious and prevalent disease.

Sheep losses in the feed lots, I. E. NEWSOM (*Colorado Sta. Rpt. 1926, pp. 39, 40*).—In studies of sheep losses in the feed lots much attention was given to the anaerobes that may be present in the carcasses of sheep which have died of various diseases, but particularly those that are presumed to have died from overeating. It was found that sore mouth in lambs was usually present during the last feeding season and in one or more instances caused the loss of a considerable number of animals. Observations indicated that *Actinomyces necrophorus* was present in most of the cases and that the affection might be properly considered a necrobacillosis. Coccidiosis is said to be on the increase and in some instances caused rather serious losses.

Breeding swine for natural resistance to cholera (*Iowa Sta. Rpt. 1926, p. 43*).—Investigations conducted indicate that either the 60 tested first-generation offspring from seven so-called immune sows lacked resistance to hog cholera, or that such resistance is recessive in its heredity.

Experimental investigations of epizootic cerebrospinal meningitis of the horse (Borna disease) [trans. title], W. ZWICK, O. SEIFRIED, and J. WITTE (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 30 (1926), No. 1-2, pp. 42-136, pls. 8, figs. 5*).—An extended account of investigations conducted at the Institute of Veterinary Hygiene and Infectious Diseases at the University of Giessen is given in connection with a review of the literature, a list of 182 references to which is included.

The authors find that the diplostreptococci occurring in the brains of horses and rabbits affected with Borna disease are nonpathogenic and at most play only a secondary part in its etiology, the disease being caused by a filtrable virus. Experiments with both domestic and laboratory animals show that the affection is transmissible to the rabbit through intracerebral, intracocular, corneal, nasal, repeated intravenous, subcutaneous, and intraperitoneal injections and through the feeding of brain emulsion from the horse. It is also transmissible from rabbit to rabbit by intracerebral injection. The symptoms, the course of the disease, and the pathoanatomical and histological findings seen in experimental animals are similar to those of spontaneous Borna disease in the horse. It is pointed out that the virus of this disease is present principally in the central nervous system, not having been found in the blood or, with the exception of the salivary gland, in any of the internal organs.

In experimental work the subcutaneous and intraperitoneal injection of rabbits with infected brain material gave an immunity which protected against intracerebral injections that consistently killed control animals.

Range paralysis of poultry, H. J. STAFSETH and E. P. JOHNSON (*Michigan Sta. Quart. Bul., 9 (1927), No. 3, pp. 105-109*).—This affection of poultry appeared in Michigan in the fall of 1921 with considerable frequency and has since increased in prevalence until it is now the most serious ailment affecting birds of from 4 to 14 months of age. While it has been found that leg weakness may be a symptom of a number of diseases, including tuberculosis, sarcomatosis, bacillary white diarrhea, fowl cholera, worm infestations, nutritional disturbances, botulism, and coccidiosis, the authors became convinced that a certain pathogenic agent must be responsible for the very prevalent disease in poultry which occurs in young stock in late summer, fall, and early winter. Their investigations led to the discovery that duodenal coccidiosis infection is prob-

ably the most important cause of this condition in fowls. They found that the coccidia may localize rather deeply in the mucous membrane of the duodenum and produce this condition. Five of twelve birds infected by feeding incubated or sporulated coccidia in bran mash were affected. The lesions, diagnosis, treatment, prevention, and care of infected flocks are briefly considered.

Cultural and antigenic studies on *Salmonella gallinarum* and *Salmonella pullorum*, H. G. MAY and K. GOODNER (*Jour. Bact.*, 13 (1927), No. 2, pp. 129-146).—In this contribution from the Rhode Island Experiment Station the details are given, largely in tabular form, of investigations conducted in connection with those previously noted (*E. S. R.*, 55, p. 275).

The authors' study of the carbohydrate fermentation of 52 strains of *S. pullorum* and 31 strains of *S. gallinarum* shows that the members of each group agree very closely in the production of acid from these substances. It is pointed out that *S. pullorum* usually produces gas from fermentable carbohydrates while *S. gallinarum* never produces gas. The titration of antigens from these strains against antisera from 8 representative strains of *S. pullorum*, 5 representative strains of *S. gallinarum*, and 1 strain of *Eberthella typhosa* has been found to reveal no definite antigenic differences between the two groups of avian pathogens nor to reveal any subgroups with the exception of a slight differentiation within *S. gallinarum*. The authors regard both *pullorum* and *gallinarum* as belonging to the genus *Salmonella*, placed in the second edition of the manual of the Society of American Bacteriologists (*E. S. R.*, 56, p. 326). A method for the rapid identification of these two species consists in passing suspected avian pathogens (Gram-negative rods) through glucose, dulcitol, lactose, and sucrose.

The chicken mite (*Dermanyssus avium*) and its control [trans. title], J. KÖHNLEIN (*Arch. Wiss. u. Prakt. Tierheilk.*, 53 (1925), No. 2, pp. 144-180, figs. 10).—This is an extended account of studies of *D. avium* in connection with a list of references to literature. An account of this pest, by H. P. Wood, has been noted (*E. S. R.*, 37, p. 859).

Preliminary note on the transmission of the eye worm of Australian poultry, J. W. FIELDING (*Aust. Jour. Expt. Biol. and Med. Sci.*, 3 (1926), No. 4, pp. 225-232, pl. 1).—The author's experiments here reported are considered to present indisputable evidence that the cockroach, *Leucophaea surinamensis* L., is a responsible agent for the transmission of eye worms of fowls and ducks. The cockroach apparently ingests the young larvae from the droppings and from the ground, the larvae passing through the wall of the alimentary tract, on the outside of which they encapsulate. In the capsules development takes place, and on attaining the stage of infectivity, they leave the capsules, and wander about in the body cavities, having been recovered from both the thoracic and abdominal cavities as well as from the legs. The infected cockroaches are in their turn taken up by the poultry, and, apparently, do not pass farther than the crops before the worms which have attained the infective stage escape from the intermediate host; they then pass up the esophagus to the mouth and eventually through the nasolachrymal duct to their destination.

The control of intestinal parasites, C. D. CARPENTER (*Poultry Sci.*, 6 (1926-27), No. 2, pp. 79-86).—A practical account.

Studies on the *Ascaris lumbricoides*, H. M. MARTIN (*Nebraska Sta. Research Bul.* 37 (1926), pp. 78, figs. 3).—This is a summary of the knowledge based upon a review of the literature in connection with a bibliography of 110 titles, and a report on investigation personally conducted. The author presents the details of 13 experiments on the life history of *A. lumbricoides* and 14 experiments on other phases of the subject. The data have been sum-

marized by the author as follows: It has been observed that the uteri from pig *Ascaris* as small as 125 mm. in length may contain eggs which will develop to the infectious stage when incubated at the proper temperature. Adult male *Ascaris* may attain a length of 310 mm. and females a length of 490 mm. Eggs subjected to a temperature of 31 to 34.5° C. in the presence of moisture and oxygen may develop to the vermiform stage in 10 days. Segmentation of the eggs does not take place if they are subjected to a temperature of -5 to 10°. Eggs placed at a temperature of from -5 to 10° in a dry condition were found to be viable after two years. Eggs kept at this temperature in a moist condition remained viable for over four years, at which time they were still capable of developing to the vermiform stage and producing *Ascaris pneumonia* in the cavia.

Hatching of *Ascaris* eggs occurs chiefly in the small intestine, and may occur in the alimentary tract of a guinea pig as early as two hours after ingestion. Hatching of the eggs does not seem to take place when they are introduced beneath the skin of pigs. Investigations show that the larvae migrate through the circulation from the intestine to the lungs by way of the liver and heart, thus confirming data presented by Stewart (E. S. R., 45, p. 160) and by Ransom and Foster (E. S. R., 43, p. 275). Evidence has been obtained which shows conclusively that *Ascaris* larvae, after having completed their vasculopulmonary circuit in pigs, will settle down and develop to maturity in the small intestine of this animal as early as 49 days after the ingestion of infectious eggs.

Pigs may become infested with intestinal *Ascaris* as a result of ingesting tissue which is infected with *Ascaris* larvae. Contact with rabbits which had been fed *Ascaris* eggs produced *Ascaris pneumonia* in normal rabbits, thus indicating a possibility that rodents may act as intermediate hosts, although it is quite obvious that this method of infection is by no means common in nature.

Pathologic changes may be observed in almost any organ in the body as a result of migrating *Ascaris* larvae. Intrauterine infection in swine with *Ascaris* appears to be very uncommon.

It is apparent that the *Ascaris* of man and swine are morphologically and biologically indistinguishable, but physiologically are distinct species; that is, adult *Ascaris* will not occur in the small intestines of swine from the ingestion of human *Ascaris* eggs, and vice versa. *Ascaris* infected pigs do not react allergically to the same extent that worm-infested horses do. It is also certain that a negative reaction is by no means an indication that the pig was not infested with *Ascaris* at some time during its life. It appears that the resistance acquired by pigs against *Ascaris* infection is due to an age factor and not to an immunity, at least not an immunity comparable to the one in microbial infections.

Epidemiological studies on respiratory infections of the rabbit.—IX, The spread of *Bacterium lepi-septicum* infection at a rabbit farm in New City, N. Y., L. T. WEBSTER (*Jour. Expt. Med.*, 45 (1927), No. 3, pp. 529-551, figs. 13).—In an epidemic among thoroughbred rabbits on a farm in New City, N. Y., studied over a period of 2 years, 50 to 75 per cent of the total mortality was due to *B. lepi-septicum* infection.

AGRICULTURAL ENGINEERING

[Agricultural engineering studies at the Colorado Station] (*Colorado Sta. Rpt.* 1926, pp. 41-45).—The progress results of studies by E. B. House of sub-grade soils of Colorado, made in cooperation with the U. S. D. A. Bureau of

Public Roads, indicate that cracks in concrete pavement are less where there is a longitudinal center joint, where the pavement is thicker at the edges than at the center, and when a dowel is used. Where the grade is low the larger number of cracks are transverse to the center line of the road, and where the grade line is high they are parallel to the center line.

In a continuation of the study of humidifying air in buildings, G. A. Cumings found that two humidifiers which operate on the top of radiators and use absorbent material to increase the evaporation surface are of little value in buildings. In no case was the relative humidity of the air raised more than 2 per cent in a room under normal conditions.

Studies on fire protection by carbon dioxide gas by Cumings showed that this gas may be used efficiently and economically to extinguish small fires.

[Agricultural engineering studies at the Iowa Station] (*Iowa Sta. Rpt. 1926, pp. 9, 10*).—The progress results of studies of the air requirements of poultry conducted by the agricultural engineering section in cooperation with the poultry, chemistry, and veterinary physiology sections are briefly presented. A battery of 10 pens of approximately 37.5 sq. ft. of floor space each was used. Ten birds were placed in each pen and the pens closed. Each pen received a definite amount of air, varying by pens from $\frac{3}{8}$ to $1\frac{1}{2}$ cu. ft. per minute. No correlation could be found between air supply and egg production, fertility, or hatchability. While the moisture conditions, especially in the pens receiving the smaller amounts of air, would be considered very bad, the hens appeared contented and maintained egg production equal to those receiving a greater amount of air and slightly greater than similar hens kept on the poultry farm under normal conditions. Much less of the mash feed was consumed in the test pens than under normal conditions.

Tests of an airplane type of wheel for the generation of electricity by wind power showed that this type of wheel 10 ft. in diameter gives less power than the ordinary type of wheel 14 ft. in diameter. The airplane type seemed much more reliable and less likely to be damaged in wind storms. It was found that the summer months form the questionable period in the output of the plant due to lack of wind.

In an investigation of bituminous concrete, 3-in. creosote wood block, cork brick, concrete, rubber blocks, and 2-in. homemade wood blocks as dairy barn floor materials, the concrete and rubber blocks showed the least wear.

Report of the committee on the development of ground-water supplies, G. W. PUTNAM ET AL. (*U. S. Pub. Health Serv., Pub. Health Bul. 160 (1926), pp. 43-55, 135-138*).—This report was presented at the sixth annual conference of State sanitary engineers held at Louisville, Ky., in April, 1925. It considers the sanitary defects affecting the safety of water obtained from various types of ground water supplies and the safeguards which should be employed to remedy them.

Examples given of towns in which epidemics have occurred due to the various defects indicate that there are many sanitary defects in connection with ground water supplies which have in the past caused the intermittent infection of otherwise safe supplies. In many instances difficulty in adequately safeguarding a ground water supply amply justifies the continuous disinfection of the water as insurance against intermittent slight contamination. A code of principles on sanitary control in the development of ground water supplies is included.

Small water powers, F. J. TAYLOR (*Estate Mag., 25 (1925), Nos. 7, pp. 509-514 figs. 4; 8, pp. 596-604, figs. 9*).—Information is given on the design of small water power plants especially adapted for farm conditions.

Concrete, plain and reinforced.—Vol. 1, *Theory and design of concrete and reinforced structures*, F. W. TAYLOR, S. E. THOMPSON, and E. SMULSKI (*New York: John Wiley & Sons; London: Chapman & Hall, 1925, vol. 1, 4. ed., pp. XIV+969, pls. 7, figs. 327*).—This is the fourth edition of this book (E. S. R., 37, p. 590). It contains chapters on materials and methods for making concrete; reinforcement; tests of reinforced concrete; theory of reinforced concrete; reinforced concrete design; design of flat slab structures; concrete and reinforced concrete columns; foundations and footings; piles; building construction; wall bearing construction; basement walls; roof construction; stairways, fire exits, and elevator shafts; steel window sash; structural plans for buildings; architectural treatment of exterior and interior of reinforced concrete buildings (prepared by H. C. Robbins); concrete in construction of theaters and auditoriums; reinforced concrete in different types of buildings; reinforced concrete chimneys; retaining walls; and tables and diagrams.

Water gain and allied phenomena in concrete work, H. J. GILKEY (*Engin. News-Rec.*, 98 (1927), No. 6, pp. 242-244, figs. 3).—The results of studies conducted at the University of Colorado are briefly reported which showed that the phenomenon of gaining water is a natural one, occurring in dry concrete mixtures as well as in wet ones. It results from an effort of the solids to sink to the lowest possible position. After the concrete has been poured and working has ceased, this settling will continue until the mass starts to stiffen and the displaced water will rise. It is considered likely, therefore, that in attempting to control the workability of the mixture by the insertion of a workability clause, such as the designation of the slump or the flow, such designation should apply to the concrete in the forms instead of to that at the mixer.

Sampling and testing of highway materials, W. H. BARTON, JR., and L. H. DOANE (*New York and London: McGraw-Hill Book Co., 1925, pp. IX+355, figs. 83*).—This book contains chapters on laboratory practice; sampling; Portland cement, Portland cement concrete, and paving brick; aggregates; miscellaneous materials; bituminous materials; specifications; curves, diagrams, and tables; and subgrade soils.

Tests of Kansas road materials, C. H. SCHOLER and H. ALLEN (*Kans. Engin. Expt. Sta. Bul.* 15 (1925), pp. 68, figs. 6).—A summary of the results secured on natural road building materials tested in Kansas (E. S. R., 50, p. 484).

Public Roads [February, 1927], (*U. S. Dept. Agr., Public Roads*, 7 (1927), No. 12, pp. 233-252+[2], figs. 20).—This number of this periodical contains the status of Federal-aid highway construction as of January 31, 1927, together with the following articles: Fill Settlement in Peat Marshes, by V. R. Burton; Determination of Consistency of Soils by Means of Penetration Tests, by C. Terzaghi; California Road Survey Demonstrates the Economic Possibilities of Subgrade Studies, by C. A. Hogentogler; Design of a Constant Temperature Moist Closet, by W. F. Purrington; Effect of Highway Slash on Infestation by Western Pine Beetle Studied (see page 860); and The Action of Calcium Chloride on Cements.

Cast iron in its relation to the automotive industry, E. J. LOWRY (*Jour. Soc. Automotive Engin.*, 20 (1927), No. 2, pp. 277-290, figs. 13).—Studies are reported which tend to prove that true hardness is not measurable by any known test, that the present hardness test is not a function of machinability or of wear, and that combined carbon bears little relation to any of these three factors. The governing features seem to be the forms of carbon, the structure of the iron, and the quality of the materials used. The method used in determining quality of material was that of dilatation. This test

showed that the expansion of the casting is related to the expansion of the material used.

Applications of X-rays in the automotive industry, G. L. CLARK, R. H. ABORN, and E. W. BRUGMANN (*Jour. Soc. Automotive Engin.*, 20 (1927), No. 2, pp. 291-304, figs. 22).—Studies conducted at the Massachusetts Institute of Technology are reported which included a résumé of X-ray science and of experimental results regarding practical applications to the examination of automotive materials. Special attention is devoted to the detection of imperfections in castings, the development of improved casting technique, the substitution of castings for forgings, and the X-ray examination of valves and other parts.

The rôle of metallic colloids in the suppression of detonation, H. L. OLIN, C. D. READ, and A. W. GOOS (*Indus. and Engin. Chem.*, 18 (1926), No. 12, pp. 1316-1318, figs. 4).—Experiments conducted at the University of Iowa are reported in which gasoline was tested with different compounds. Experiments with straight gasoline treated with tetraethyl lead in different forms showed that the superiority of the fuels used was due to the presence of undecomposed ethyl rather than to the colloidal metal present. Further experiments with nickel carbonyl indicated that free metallic particles suspended in the combustion zone of the cylinder do not have a measurable effect in suppressing detonation.

Ultraviolet spectroscopy of engine-fuel flames, G. L. CLARK and A. L. HENNE (*Jour. Soc. Automotive Engin.*, 20 (1927), No. 2, pp. 264-269, figs. 2).—Studies conducted at the Massachusetts Institute of Technology are reported in which details are given of the method of control of the engine so that quantitative and reproducible measurements of detonation and comparisons with spectra can be made. Typical data are presented with photographs of the free-burning flames of hydrogen, carbon monoxide, methane, gasoline in a blowtorch, and the like. The outstanding result obtained was that during detonation the first quarter spectrum extends far into the ultra-violet and that of the second quarter a somewhat less distance, the third and fourth quarters being characterized by very little radiation energy. During normal explosion or when knock suppressers, irrespective of their chemical nature, are used in the engine under detonating conditions the spectra of all four quarters have the same length and essentially the same intensity. Lead emission lines from tetraethyl lead appear only in the first quarter. This is taken to indicate that the action of an antiknock material occurs throughout the mixture rapidly, probably by thermal decomposition ahead of the explosion wave. The ultra-violet spectra show that all substances which act as knock suppressers have precisely the same effect, in that in their presence there is no emission in the far ultra-violet, such as occurs in detonation, and the energy liberated is distributed throughout the whole stroke instead of largely in the first quarter.

Flow of heat in pistons, H. A. HUEBOTTER and G. A. YOUNG (*Purdue Univ., Engin. Expt. Sta. Bul.* 25 (1925), pp. 119, figs. 67).—Studies are reported, the purpose of which was to establish the optimum distribution of metal in the trunk type of piston for thermal conductivity from the head to the cylinder wall.

The results showed that the head of uniform section is the best conductor of heat, and that the short barrel of tapered section is the best dissipator of heat. A head section thick at the circumference will assist in the dissipation of heat, and for this reason a large fillet is recommended at the junction of the head and the barrel. The addition of metal to the head was found to lower the maximum temperature more than the same volume of metal applied

to the barrel. The barrel should be as thick as the head section at the head end and as thin as practicable at the open end.

Ribs, when properly designed, were found to improve the conductivity more than an equal quantity of metal added to either the head or the barrel. The proportions of the head, the barrel, and the ribs are mutually dependent for best performance. The triangular rib, extending from the center of the head to midway the length of the barrel, is the most effective. A large number of thin ribs were found to be superior to a few ribs of the same total thickness, since this arrangement gives better heat distribution over the head and the barrel.

Between 60 and 85 per cent of the total heat was found to be dissipated from the ring belt in the usual type of piston. The conventional ring belt is about 60 per cent as effective as the piston skirt in dissipating heat with the same temperature difference. It was found that the ring belt should be as short as possible, and that a broad bearing land within the ring belt will improve the heat emission.

The results showed further that piston rings which make good thermal contact with the piston should be used for maximum cooling, and that a gray iron piston head section should be designed for conductivity rather than for strength. Gray iron should be fine grained and homogeneous for thermal conductivity, and low density, low coefficient of expansion, and high coefficient of conductivity should characterize the piston material.

Colony houses for poultry, J. G. HALPIN, J. B. HAYES, and J. SWENEHART (*Wis. Agr. Col. Ext. Circ. 208 (1926), pp. 8, figs. 3*).—Practical information on the planning and construction of colony houses for poultry adapted to Wisconsin conditions is presented, together with working drawings and bills of material.

Dairy-stable ventilation, F. L. FAIRBANKS and A. M. GOODMAN (*N. Y. Agr. Col. (Cornell) Ext. Bul. 151 (1926), pp. 35, figs. 26*).—Practical information on the planning and construction of ventilation systems for dairy stables under the climatic conditions prevailing in the State of New York is presented, together with diagrammatic illustrations and working drawings. Descriptions are given of different systems of dairy stable ventilation, including especially the King and Rutherford and modifications thereof.

RURAL ECONOMICS AND SOCIOLOGY

[Investigations in agricultural economics at the Connecticut Storrs Station, 1926] (*Connecticut Storrs Sta. Bul. 142 (1926), pp. 172-174, fig. 1*).—In addition to the studies previously noted (*E. S. R.*, 54, p. 483; 55, pp. 286, 684), a survey of the Connecticut commercial apple industry shows 600 commercial growers with 200,000 bearing and 90,000 nonbearing trees. Data are given as to the chief varieties of trees, distribution of jobbers' supplies, source of retailers' supplies, and growers' market for apples.

[Investigations in agricultural economics at the Florida Station, 1926], C. V. NOBLE (*Florida Sta. Rpt. 1926, pp. 95, 96*).—A study made of the 1925 Irish potato crop on 294 farms showed that the average labor incomes—gross receipts less 7 per cent on investment and all farm expenses—besides house and farm products for home use, were \$32 for farmers having 15 acres or less in potatoes and \$149, \$629, \$223, \$656, and \$710, respectively, for farmers having from 16 through 29 acres, 30 through 39, 40 through 49, 50 through 69, and 70 acres and over of potatoes.

[Investigations in agricultural economics and farm management at the Iowa Station, 1926] (*Iowa Sta. Rpt. 1926*, pp. 6-8).—The results are given of work not previously noted (*E. S. R.*, 55, pp. 187, 686).

Growth of mortgage indebtedness on Iowa farms.—The total mortgage indebtedness in 11 townships in 6 counties increased from \$453,000 on 7,300 acres in 1915 to \$1,385,000 on 12,400 acres in 1923, and then decreased to \$1,194,000 on 11,800 acres in 1925, the percentage of land mortgaged being 32, 57, and 57 in the respective years. The number of foreclosures varied from 6 in 1919 to 105 in 1925. The losses of mortgaged land through reversions to mortgagee and voluntary settlement were more numerous than those through foreclosures.

Iowa County cost route.—The first year's work on the cost route in Iowa County shows that on farms with tractors the horses worked approximately 50 per cent more hours during the year than on nontractor farms, the average cost per hour of horse labor being 12.1 cts. on tractor farms and 15.9 cts. on nontractor farms. The use of 2-row cultivators in corn production was found to economize labor and increase man capacity.

[Investigations in agricultural economics at the Kansas Station, 1925-1926] (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 18-29).—The results of investigations not previously noted are reported.

Studies in farm organization and cost of production.—The results of a 5-year study on cost of production in McPherson and Jackson Counties are summarized. Tables are given showing the hours of man and horse labor per acre and acres covered in a 10-hour day in different operations with different sizes and types of equipment in raising wheat in McPherson County and corn in Jackson County. The standard feed requirements for a 1,200-lb. horse working 700 hours in McPherson County and a 1,200- to 1,400-lb. horse working 1,000 hours in Jackson County are included.

The marketing of Kansas wheat.—A tabulation and classification of data obtained by the station for 1922 and 1923 and by the State Board of Agriculture for 1924 for from 251 to 643 farms show that from approximately 10 to 12 per cent of the wheat crop is being marketed earlier than it would be if some farmers were able to obtain credit from local banks.

Data assembled on the cost of operating country elevators for 1920-21, 1921-22, and 1922-23 show that (1) in ordinary years margins and expenses are fairly closely adjusted to each other and permit an average profit of 2 cts. per bushel, although probably one-third of the elevators earn no profits; (2) fixed operating costs, of which salaries and wages constitute about 75 per cent, largely determine what the local buying margin must be; and (3) a knowledge of the milling qualities of wheat and attention to seasonal price trends are important elements in the sales ability of a manager.

Shrinkage and damage in farm storage.—A study was made of all the wheat harvested with combined harvesters on 5 farms near Stafford, Kans., to determine the extent and causes of heating in the bin, the temperatures reached under different conditions, and the extent of the damage as shown by milling and baking tests. Wheat with more than 14 to 14.5 per cent moisture is likely to heat, although wheat with as much as 15 per cent moisture did not heat in protected barn bins. Green wheat with 16 to 17 per cent moisture showed signs of heating and began to cake at the end of 5 days, although the temperature of the wheat was only 86° F., and samples taken showed no inferior baking qualities. Samples taken after 52 days showed a decrease of about 25 per cent in the loaf volume of bread. Samples from heating bins before heating had progressed far showed an increase in loaf volume and no evidence of injury to texture and color. Wheat with 16 to 17 per cent moisture, because of

green berries, caked badly after 10 days' storage and developed extremely high temperatures. Wheat with 14.2 per cent moisture stored with wheat having 16 per cent moisture showed some damage. Wheat containing from 12 to 13.5 per cent moisture remained at a temperature of 95° or above for 5 days without damage.

The economics of the poultry industry on Kansas farms.—A study was made to determine the effect of the size of flocks upon other factors influencing production, the cost of maintaining general farm flocks, changes in the average production for farms in the State, changes in regions of high and low production, distribution of poultry on farms by counties and regions of high or low numbers per farm, and the proportion of total production consumed on the farm.

Flocks of approximately 125 hens were found preferable on average farms, if high production per hen was desired. Feeding 70 lbs. of grain and over per hen gave no better financial results than feeding from 40 to 50 lbs. per hen. Interest charges varied from 7 to 9 cts. per hen, building charges 9 to 12 cts., and expenses \$1.50 to \$1.80 per hen, the overhead being from 3 to 4 per cent. More than two-thirds of the meat produced was sold. The poultry and eggs averaged 43 per cent of the livestock and livestock products used on the farm, and the value of the portion so used was usually greater than the charges for labor, interest, use of buildings, etc.

The marketing of Kansas livestock and livestock products.—Data were obtained by a questionnaire regarding organization, volume of business, and methods of cooperative livestock selling organizations. Of 98 organizations reporting, 53 had livestock shipping as their principal business, the principal business of most of the others being grain. Of 97 organizations reporting, 75 handled livestock on a commission basis, 8 bought outright, and 14 gave patrons the option of either method. The hundredweight was the basis most commonly used in computing commissions. More than one-half of the organizations used a sinking or insurance fund to cover losses due to crippling or killing in transit. Less than one-third used commercial insurance.

An economic study of the cattle feeding enterprise in Iowa, J. A. HOPKINS, JR. (Iowa Sta. Bul. 242 (1927), pp. 46, figs. 12).—This bulletin is divided into 3 parts, as follows: (1) A description of the general development of the beef enterprise in Iowa and the State's place in the beef production of the United States; (2) a study of the factors determining the efficiency and profitableness of fattening cattle; and (3) a condensed statement of the results of a study of cattle prices and the demand for beef.

Records and estimates are given on the physical and financial costs of gains, profits, and similar factors on about 550 lots of feeding cattle in Pottawattamie County during the period 1918-1923. The average cost per pound put on in the lots studied was 16.8 cts. Analysis was made by multiple correlation, using the following factors: The rate of gain per head per day in pounds; cost per pound of gain in cents; grade as expressed as the percentage which the price paid for the feeders was of the general average feeder price in Chicago; finish at sale, the price received expressed as a percentage of the prevailing price of 1,200 to 1,500 lb. steers in Chicago; pounds of crude carbohydrate equivalent in the ration per day; pounds of crude protein per day; pounds of fiber in the ration per day; length of feeding period in days; hours of labor per head per month; number of cattle in the herd; price of corn in cents per bushel; ratio of price of cattle to price of corn; margin received per 100 lbs.; and profit per head.

The price of corn was found to be the largest single influence on the cost per pound of gain, a change from 80 cts. to \$1 per bushel increasing the cost per pound nearly 3 cts. A change from 1:15 to 1:14 in the cattle-corn ratio reduced the profit about \$2.40 per head. An added margin—difference in price per pound of fattened steers and feeders—of \$1 per 100 lbs. on cattle weighing 775 lbs. when purchased was associated with an increased profit of about \$1.25 per head. An additional pound of crude fiber per day in the feed decreased the gain about 1/30 lb. per day. Increasing the herd from 1 to 2 carloads saved 8 hours' labor per month per car, decreased the rate of gain about 1/10 lb. per day per head, and increased the cost of gain about 0.6 ct. per pound. Within reasonable limits, the average cost per pound of gain increased 0.3 ct. for each additional month fed. An increase of 1/2 lb. per day over the average in the rate of gain resulted in a decrease of about 2.3 cts. in the average cost of gain. Larger rates of gain per day were usually associated with lower costs per pound and higher profits.

A statistical study of the prices and production of beef cattle, J. A. HOPKINS, JR. (*Iowa Sta. Research Bul. 101 (1926), pp. 337-396, figs. 26*).—The principal purpose of this study was to discover how far the cattle producer can depend on the prices of cattle and of related products, and how to interpret them as a guide to production for his own and for the social advantage. The methods used are essentially those of Persons for business conditions.⁴

From 1868 to 1896 the Chicago price of cattle declined 4 cts. per 100 lbs. per year, but the buying power increased at the rate of about 0.5 per cent of the average value per year. From 1896 to 1914 the price of 1,200 to 1,500 lb. steers increased on an average of about 21.5 cts. per 100 lbs. per year, and the buying power increased about 1.1 per cent per year. For the period prior to 1895 the typical seasonal price curve rose from December to the late spring, the peak being at 104.5 per cent in April, May, and June, and the minimum 94.8 per cent in November. After 1895, when corn finishing became much more common, the high point in the prices of 1,200 to 1,500 lb. steers was normally reached in August and September, and the lowest point in February. Much of the seasonal variation, however, was due to variation in the quality of the stock coming on the market at different seasons. From 1866 to 1924 there were 5 major cycles in prices, but they were irregular both as to length and in amplitude, and each seemed to be due to different and unusual forces and conditions.

A study was made of the secular trend, seasonal fluctuations, and cyclical fluctuations in the prices of beef hams, beef carcasses, beef cattle receipts, corn prices, prices of feeder cattle, the feeder margin, hog prices, the prices of 10 sensitive commodities compiled and used by the Harvard Economic Service, and the prices of 12 industrial stocks—the Dow-Jones series—and the correlation of such prices with cattle prices.

The correlation of beef carcass prices with cattle prices showed a strong relationship both with no lag and with a 1-month lag for carcasses. The prices of beef hams lagged 1 to 3 months. Cattle receipts gave a negative correlation, which was decidedly higher when the receipts were correlated with prices at a time 7 months later. The degree of correlation between corn and cattle prices steadily increased as the lag of cattle prices was increased up to 6 months. The size of the coefficients of correlation in the case of feeder and fat cattle prices suggests that fat cattle prices have a greater influence on feeders than feeders on fat cattle prices in following months. The correlation

⁴ Persons, W. M. *Indices of Business Conditions* (pp. 5-107) and *Index of General Business Conditions* (pp. 111-205). *Rev. Econ. Statist.*, 1 (1919).

coefficients of feeder margins and cattle prices were all positive and were greatest with a 6 to 7 months lag. Hog prices correlated with cattle prices of preceding months gave significant positive coefficients, the correlation increasing until the largest coefficient was obtained with a 5-months lag. Movements of cattle prices were similar to those of the 10 sensitive stocks, although the variations in cattle prices corresponding in time to the variations in the stocks were not always the most outstanding. Cattle prices changed as soon as and often 1 or 2 months prior to the changes in the prices of the sensitive stocks. The prices of industrial stocks moved 2 to 4 months in advance of cattle prices.

Land management, N. I. Koslov (*Zemleustroïstvo. Moscow: Gosud. Izdatel., 1923, pp. 65+[2], pls. 4*).—The author presents the changes in land ownership since the revolution, the methods adopted by the Soviet Government to increase the productivity of the land, the new laws pertaining to agriculture, and their advantages over the former system of land utilization.

Prices of farm products received by producers.—I, North Atlantic States (*U. S. Dept. Agr., Statis. Bul. 14 (1927), pp. [2]+121, fig. 1*).—Tables are given for Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania showing the monthly farm prices of their leading farm products usually from 1908 or 1910 through 1925; the December 1 farm price of crops, 1866–1925; January 1 farm values of livestock, 1867–1926; value of farm products per unit, by crop-reporting districts, 1924; wages of hired farm labor, 1866–1926; and the value per acre of farm lands, 1912–1926.

Crops and Markets, [March, 1927] (*U. S. Dept. Agr., Crops and Markets, 4 (1927), No. 3, pp. 81–120, figs. 3*).—The usual tables, charts, notes, and summaries are given for cold storage holdings, cotton, other crops, dairy and poultry products, feedstuffs, fruits, vegetables, grain, hay, livestock and livestock products, prices, seeds, and world agriculture. Special articles are included on the farm stocks of grain and merchantable corn in the United States, 1890–1927; planting intentions on March 1, 1927; and the relation of farmers' planting intentions to the agricultural outlook.

The agricultural outlook for 1927 (*U. S. Dept. Agr., Misc. Circ. 101 (1927), pp. 40; Sup., pp. 2+22*).—This fifth annual report was prepared by the staff of the Bureau of Agricultural Economics, assisted by representatives of other bureaus of this Department and of 25 State colleges of agriculture. It is designed to give information as to the probable conditions which will exist when the 1927 farm products are ready for market. The general situation is discussed and conditions as to each important farm product are considered in some detail. A mimeographed supplement gives the principal sources of information on which the report is based.

Agricultural outlook for Oklahoma, 1927, J. T. SANDERS ET AL. (*Oklahoma Sta. Circ. 66 (1927), pp. 16*).—The general conditions in the State and national and international conditions so far as they affect Oklahoma agricultural conditions are analyzed, with a view to furnishing Oklahoma farmers information as to the most probable future trends of demand and supply for the important agricultural products of the State.

Texas agricultural outlook for 1927, L. P. GABBARD (*Texas Sta. Circ. 45 (1927), pp. 16*).—The national agricultural outlook for 1927 (see above) for the major crops and livestock enterprises is interpreted in terms of Texas agriculture.

Agriculture in Finland (*Suomen Maataloutta Kuvioin ja Kartoin. Finlands Lantbruk i Diagramm och Kartor. L'Agriculture de la Finlande en Diagrammes*

et Cartes. Porvoo (Borgå): Werner Söderström Osakeyhtiö, 1925, pp. 164, figs. 317).—An agricultural atlas in Finnish, Swedish, and French.

Cooperation in agriculture: A selected and annotated reading list, compiled by C. GARDNER (*U. S. Dept. Agr., Misc. Circ. 97 (1927), pp. 76*).—A selected and annotated reading list of works printed in English, with special reference to purchasing, marketing, and credit. A classified list by subjects and countries and a list of periodicals are included.

Co-operative democracy, J. P. WARBASSE (*New York: Macmillan Co., 1927, 2. ed., rev., pp. XIV+331*).—This is the second edition of this work, previously noted (*E. S. R., 50, p. 92*).

Studies in European co-operation, [I], II, C. F. STRICKLAND (*Lahore, Punjab: Govt., 1922 [vol. 1], pp. [7]+166+V; 1925, vol. 2, pp. [5]+182+LXXX+IX*).—Volume 1 is a report of a four months' visit in 1920 to Holland, Belgium, Italy, and England to study European cooperation, and volume 2 is a report of a study made in 1924 in the British Isles, Denmark, Norway, Sweden, and Egypt of land mortgage banks, credit and cooperation, dairying, consolidation of holdings, colonization and small holdings, and adult education. The subjects are discussed and conclusions reached with the requirements of India, and especially Punjab, in mind. Appendixes to volume 2 include a translation of the Punjab 5-feddan law; the Danish law of June 20, 1850, concerning credit associations and loan banks; the by-laws of five Indian mortgage banks; the Agricultural Credits Act of 1923 of England; and the Egyptian law (Law No. 27) regulating agricultural cooperative societies in Egypt.

[Report of the International Country Life Commission] (*Bul. Comn. Internatl. Embell. Vie Rurale, 1926, Nos. 1, pp. 44; 2, pp. 144; 3, pp. XVIII+152*).—Bulletin 1 contains the various reports of the proceedings, the president's address, and the following reports made at the first meeting held at Brussels July 19, 1925: The Use of Electricity in Rural Sections, by Baron Forgeur; Present and Possible Methods for Checking Rural Exodus, by Baron de Cartier d'Yve; Improvement of Country Life in Hungary, by Weis; and The Rural Welfare Movement, by A. Prokes.

Bulletin 2 includes the following papers, reports, and addresses: The Commission for the Improvement of Country Life, by F. Graftiau; Belgian National Commission for the Improvement of Country Life, by J. Giele; The Country Life Movement in the United States, by C. J. Galpin; The Social Activities of the Farm and Village, by D. Sanderson; Rural Life Improvement Activities of the International Institute of Agriculture, by A. Hobson; the Farm Home in the United States of America, by G. E. Frysinger; the Rôle of the Family Life in the Country, by Mrs. Bednarikova-Voprsalova; Improvement of Rural Life in Hungary, by Schandl and Weis; The Rôle of the Social Life in the Country, by J. Voprsal; The Importance of the Home in the Improvement of Country Life, by A. M. DeVuyst; The School and Country Life, by J. Herbé; Rôle the School Played in the Embellishment of Country Life, by V. Smetanka; Training Girls to be Leaders in Rural Life, by St. Nihal Singh; A School for the Preparation of Young Girls for the Improvement of Rural Social Life, by De Vuyst; The Importance of Women's Institutes in the Improvement of Country Life, by Baroness de Crombrughe de Picquendaele; The United Irishwomen; Guild for Rural Clubs in Ireland; Some Social Aspects of Cooperative Marketing in the United States, by F. B. Bomberger; Competition Between Villages in the Province of Brabant (Belgium), by J. Lindemans; The Problem of the Moral Improvement of Mankind, by P. DeVuyst; The Beautifying of Villages in Poland, by E. Janowski; and A Plan for a Manual on Village Life, by J. Lindemans.

Bulletin 3 contains various lists of the program, reports, etc.; reports upon country life work in Holland, the Finish "Martha" Association, the Association of the Societies of Professional Gardeners of Poznan, Poland, and the arrangement of intermediate and primary instruction for girls to overcome the tendency to leave the village; and A Proposed Program for the Formation of a Rural Community of Interest to All Countries, by K. L. Butterfield.

Most of the papers, etc., are printed in both English and French.

Farm population of the United States, L. E. TRUESDELL (*U. S. Bur. of the Census, Census Monog. 6 (1926), pp. XI+536, figs. 17*).—An analysis of the 1920 farm population figures, especially in comparison with urban data, and a study of the main economic factors affecting the farm population. It contains a general survey and chapters and tables on rural and urban population from 1790 to 1920; composition and distribution of farm population; number and distribution of farm, village, and urban population by sex, age, race, nationality, and parentage; and agricultural occupations. A special chapter and tables are given on the composition, characteristics, and occupations of the farm population of Otsego County, N. Y.; Dane County, Wis.; New Madrid and Scott Counties, Mo.; Cass County, N. Dak.; Wake County, N. C.; Ellis County, Tex.; and King County, Wash. This chapter and tables are based on a special tabulation of the census schedules made by the Bureau of Agricultural Economics, U. S. D. A.

Rural social agencies in northern Illinois, M. L. WHITTAKER (*North. Ill. State Teachers Col. Quart., 20 (1925), No. 2, pp. 36, pls. 11*).—A study of the rural social agencies in the 25 northern counties of Illinois was made in cooperation with the U. S. Department of Agriculture. Thirteen typical agencies are described.

Some town-country relations in Union County, Ohio, P. P. DENUNE (*Ohio State Univ. Studies, Sociol. Ser. No. 1 (1924), pp. 30, fig. 1*).—A field study was made during July to September, 1923, of the church, school, lodge, recreation, amusement, social, and economic relations of the town and country population of Union County, Ohio, to discover the underlying attitudes of mind affecting these relationships and the modes of expressing these attitudes. The population of the county was strictly rural, there being only 2 towns with more than 1,000 population besides the county seat, which had a population of 3,633 in 1920.

No social distinctions or cleavage were found to exist between townspeople and farmers. Cooperation and mutual interest existed in such matters as schools, public entertainments, etc. In economic problems and business practices, however, the only tendency away from an individualistic attitude was seen in the development of certain cooperative enterprises among the farmers under the influence of the farm bureau federation.

Methods of conducting family budget enquiries, J. H. RICHARDSON (*Internatl. Labor Off., Geneva, Studies and Rpts., Ser. N, No. 9 (1926), pp. 100*).—This study is one of a series being made by the International Labor Office of the methods adopted in various countries with regard to different kinds of labor statistics. The collection of information is discussed under the heads of selection of the families, duration of inquiry, and methods of securing the budgets; the scope of information under the heads of general conditions, income, and expenditure; and the compilation of results under classification, income, expenditure, and methods of reducing data for different-sized families to terms of a common unit.

Appendixes contain notes on the scope and methods used in obtaining information and compiling results in the more important family budget enquiries

conducted by the government or local administrative authorities in different countries since 1900 and specimens of the forms used in the various inquiries.

Social work a family builder, H. TOWNSEND (*Philadelphia and London: W. B. Saunders Co., 1926, pp. 247*).—A textbook for nurses, dietitians, home demonstration agents, home economists, and special teachers, written to furnish an understanding of the principles of social work in behalf of families and individuals. It consists of chapters on the reason for and backgrounds of social work, social work and social progress, the ancient and modern in present-day practice, origins, and continuities of the family, the immigrant and the American family in a changing world, the family standard of living, the scientific approach to a problem, diagnosis and treatment of a family problem, and family social work under public or private auspices.

A list of topics for discussion, subjects for reports, references, and suggested reading is given for each chapter.

Statistics of hogs, pork, and pork products (*U. S. Dept. Agr., Statis. Bul. 18 (1927), pp. 208*).—Tables are given for the year 1925 with comparable data for earlier years, showing for hogs the number on farms, breeds, changes in numbers, pig surveys, and losses from disease, the receipts, shipments, slaughter, condemnations, weights, and costs at the leading markets of the United States, exports, costs of marketing, farm value by States, monthly prices by States, and prices at the principal markets; and for pork and pork products the production, consumption, receipts, supply, exports and imports, cold-storage holdings, and monthly and weekly prices at principal markets.

Statistics relative to the dairy industry in New York State, 1925 (*N. Y. State Dept. Farms and Markets, Agr. Bul. 192 (1926), pp. 71, figs. 7*).—Statistics as to dairy cattle, milk production, dairy products, bovine tuberculosis eradication, milk plants, etc., are given. The bulletin was prepared in cooperation with the Bureau of Agricultural Economics, U. S. D. A.

First annual report upon the agricultural statistics of Northern Ireland, 1925 (*North. Ireland Agr. Statis. Ann. Rpt., 1 (1925), pp. 78, fig. 1*).—The first detailed annual report upon the agricultural statistics of Northern Ireland. Tables and texts are included covering the revision of the statistics for 1919–1922, division of land during the years 1914–1925, the tillage campaign of 1914–1918, decline in plowed area in 1919–1925, yield of crops, livestock forestry, agricultural holdings, employment in agriculture, and prices of livestock and other agricultural products.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

The farm, E. DAVENPORT (*New York: Macmillan Co., 1927, pp. XIX+462, pls. 16*).—This book is a "discussion of the partnership between the farmer and his farm." The 38 chapters are divided into 3 parts, (1) what nature has provided to make farming possible (pp. 2–225); (2) farm operations (pp. 227–395; and (3) the farm in trust (pp. 397–443).

Horticulture, H. P. STUCKEY and C. D. MATHEWS (*Atlanta, Ga.: Smith, Hammond & Co., 1926, pp. X+717, pl. 1, figs. 224*).—This text is designed primarily for the use of vocational agricultural classes.

Laboratory outlines in plant pathology, H. H. WHETZEL, L. R. HESLER, C. T. GREGORY, and W. H. RANKIN (*Philadelphia and London: W. B. Saunders Co., 1925, 2. ed., rev. and rewritten, pp. 231, fig. 1*).—This second edition (*E. S. R., 36, p. 540*) has been completely revised and rewritten by the senior author.

These outlines, intended primarily for use by persons taking a regular 4-year course at Cornell University, are planned to acquaint students effectively

with the material here presented as the result of experience and testing in actual practice work. Although changes in arrangement and terminology appear, the general character of the outlines remains the same.

Laboratory practice in the methods of control of the diseases studied is reserved for the course following this on the principles of plant-disease control.

Productive poultry husbandry, H. R. LEWIS (*Philadelphia and London: J. B. Lippincott Co., 1926, 6. ed., rev., pp. XXII+584, pls. 2, figs. 240*).—The sixth edition of this book previously noted (*E. S. R., 46, p. 95*).

Training unadjusted boys as farmers, E. P. BRADT (*Sci. Agr., 7 (1927), No. 8, pp. 306-308, figs. 2*).—The article briefly describes the plan of the Boys' Training School at Bowmanville, Ont. Most of the boys in residence are city bred and reared. Boys from 10 to 13 years old spend practically all of their time in academic school work, and are compelled to spend a certain amount of time in each of the four departments—metal working, motor mechanics, woodworking, and agriculture. Older boys are apprenticed to the department they prefer or for which they show the greatest aptitude, and receive small pay. Boys in the agricultural department during the first year of apprenticeship receive instruction and practice in general farm and barn work, and the second year they may specialize in such courses as poultry, dairying, or gardening.

A forestry program for women's organizations, L. T. CONWAY (*U. S. Dept. Agr., Misc. Circ. 91 (1927), pp. II+14, figs. 5*).—A collection of talks, readings, poems, and quotations.

FOODS—HUMAN NUTRITION

Studies on the refrigeration of meat, I, II (*Aust. Jour. Expt. Biol. and Med. Sci., 3 (1926), Nos. 1, pp. 15-31, pls. 3, fig. 1; 2, pp. 81-88, fig. 1*).—Two papers are presented.

I. Investigations into the refrigeration of beef, G. A. Cook, E. F. J. Love, J. R. Vickery, and W. J. Young.—The "drip" or exudation of protein-containing liquid from cut surfaces after the freezing and thawing of beef was studied by freezing samples at various rates, from a slow freezing of large pieces to an almost instantaneous freezing of thinner slabs with liquid air, the thawing being similarly varied. Drip was estimated by placing uniform samples under light pressure on blotting paper for 2 hours, the result of a blank run on the unfrozen meat being subtracted from the loss in weight due to the drip of the frozen-thawed samples. Total nitrogen was determined on the paper-absorbed drip. Histological examination was made (1) in still frozen sections of the frozen meat and (2) in sections cut from material fixed in 10 per cent formalin and stained in haematoxylin and eosin. Comparative rates of autolysis were studied by incubation at 35° C., followed by precipitation with tannic acid, and determination of nonprecipitable nitrogen.

Long latent periods of freezing and short thawing periods increased drip, nitrogen loss on thawing, histological alteration, and both rate and extent of autolysis. Very rapid freezing, with slow thawing or prolonged storage at 1° so far reduced the drip and other evidence of alteration as to give almost perfect reconstitution. This is probably due to a lessening of the separation of water from the colloids. Mutton showed less ice formation and structural distortion than did beef under the same conditions.

II. The freezing of beef and mutton press juices, J. R. Vickery.—Centrifuged clear juices pressed from beef and mutton about 48 hours after rigor mortis had passed off were frozen in uniform glass cylinders with arrangements to

secure various rates of freezing, temperature changes being followed by means of thermocouples, set in stoppers to prevent evaporation during storage of the frozen juice. The effect of the rate of thawing was also studied, from very rapid to very slow thawing. Determinations before and after freezing and thawing of nitrogen not precipitated by centrifuging showed a fairly complete reconstitution of beef and mutton juices when frozen with latent periods of 3 hours or less, the results being better with slow thawing. The ultramicroscope, however, showed much fewer colloidal particles after freezing and thawing of beef juice, the reduction decreasing with an increase in the rate of freezing. Mutton juice showed little difference in number of particles after freezing and thawing, and variation from 0.3 to 3 hours in freezing time had little effect. These results are tentatively attributed to alterations brought about by freezing in the muscle sarcolemma.

Bacteriology of meat curing (*Iowa Sta. Rpt. 1926, pp. 28, 29*).—This is a brief progress report on a study of the microbiological and physicochemical principles involved in the curing of meat products as determined by curing small chunks of pork under known conditions. "Color, texture, taste and rate of cure have been found to be governed by the bacterial flora, hydrogen ion concentration, other ion effects, temperature of cure, and condition of meat at time of cure." The formation of color during curing was found to be a function not only of the nitrite ions but of the concentration of salt. Nitrites proved effective in a concentration of from 1/10 to 1/20 that of the nitrates generally used, but a desirable color was not produced until the concentration of salt was increased to at least 10 per cent. The presence of calcium and magnesium in the water used in curing had no noticeable effect upon color formation, taste, or texture of the cured product.

Selection and use of bacon, A. M. CHILD (*Minnesota Sta. Bul. 232 (1926), pp. 19, figs. 5*).—This bulletin, which is based largely on experimental work conducted by the author, contains useful information for the housewife on the selection of bacon with regard to quality and comparative costs of different types, the most economical and satisfactory ways of cooking bacon with standards for judging the finished product, and recipes for the use of bacon fat as a shortening agent and of bacon in unusual breakfast and luncheon dishes.

Studies on dietary value of meat (*Iowa Sta. Rpt. 1926, pp. 35, 36*).—In the preliminary experiments reported rats were carried through two and in a few cases three generations on meat and vegetable rations having certain mineral, vitamin, and protein deficiencies and on rations consisting of all meat; meat, liver, and bone; meat and bone; a well-balanced food mixture; and vegetables with milk products.

While admitting that the experiment should be continued through several more generations for the results to be conclusive, the results obtained tend to show: "(1) That a high meat diet is apparently not harmful over the periods of time covered by this experiment. (2) That the dilution of such a diet with carbohydrates (dextrinized) apparently does not help it. (3) That calcium is necessary in liberal quantities, but a meat and bone meal diet needs added vitamins to make it optimum. Liver seems to supply this deficiency. (4) That the addition of meat to a diet, provided enough vitamins and mineral salts are present, speeds up growth and reproduction, and makes for an optimum rearing of young."

Manual for the manufacturer of preserved food—fruits and vegetables, G. RAY (*Manuel du Fabricant de Conservees (Conservees de Fruits—Conservees de Légumes)*). Paris: J. B. Baillière & Sons, 1926, pp. VI+7-376, figs. 168).—Included in this handbook on methods of preserving foods by heat, refrigeration,

dehydration, the addition of antiseptics, and the occlusion of air are various French laws corresponding to the United States Food and Drugs Act.

Canning of non-acid vegetables, O. D. ABBOTT (*Florida Sta. Rpt. 1926, p. 99*).—In attempts to determine the causes of frequent spoilage in nonacid vegetables canned in Florida peas and corn were canned by the hot-pack method for 3 hours in a water bath and at 10 lbs. pressure for 50 minutes.

Thus far the peas canned by either method have spoiled and the corn has not. It is suggested that the difference may be due to the methods of packing the jars. The corn was packed very loosely in the jars which were then filled with hot water. This is thought to make possible rapid penetration of heat to the center of the jars, while in jars packed tightly the temperature in the center may not be high enough to kill the spores.

Some factors that influence jelling, O. D. ABBOTT (*Florida Sta. Rpt. 1926, pp. 98, 99*).—Attempts to prepare a standard jelly from kumquats were unsuccessful, although the pectin content, 1.688 per cent, and the H-ion concentration, pH 2.9, were such as to lead one to expect that good jellies could be made from the fruit. It is suggested that the failure may be due to the predominating acid and salt content.

The vitamin content of some common fruits and vegetables (*Kansas Sta. Bien. Rpt. 1925-26, pp. 128, 129*).—In this preliminary report the results obtained in a study of the vitamin C content of raw and canned pears are summarized as follows:

"The minimum protective amount of raw pear is about 10 gm. daily, although this amount is not sufficient to provide for good growth. Larger amounts gave better growth, while 30 and 35 gm. gave better growth than 5 cc. of tomato juice. The antiscorbutic factor of pear is destroyed in canning by either the 'cold pack' or 'open kettle' method. Storing pears under refrigeration seemed not to affect their antiscorbutic content. The substitution of California for home-grown pears did not affect the growth curve of the experimental animals."

The place of the banana in the diet, W. H. EDDY and M. KELLOGG (*Amer. Jour. Pub. Health, 17 (1927), No. 1, pp. 27-35, figs. 5*).—This paper includes a more detailed report of the study of the vitamin content of the banana, noted in a preliminary report (*E. S. R., 55, p. 293*), and a review of the literature on its nutritive value and digestibility.

The preliminary data on the content of vitamins A and C in the ripe banana are confirmed, and in addition it is stated that bananas baked in the skin retain their antiscorbutic properties better than when baked without the skin, probably on account of the protective action of the skin in the prevention of oxidation. A cure is reported of a case of scurvy in an 8-months-old baby by a banana-milk mixture made by whipping 200 gm. of ripe raw banana into 570 cc. of milk. The mixture was fed in 120 cc. portions every 4 hours with no resulting digestive disturbances.

The vitamin B value of ripe raw bananas is reported to be about that of tomato juice as tested by the method of Sherman and Grose (*E. S. R., 51, p. 461*), from 8 to 10 gm. daily being required. Difficulties in getting the rats to eat enough of the basal diet with the large amount of banana necessary were overcome by subtracting from the basal diet the amount of the carbohydrate furnished by the banana.

No evidence was obtained as to the presence of vitamin D in bananas when substituted for flour in the Sherman-Pappenheimer diet 84 in amounts as high as 15 per cent.

A bibliography of 25 titles is appended.

Malt and malt extract as sources of vitamin B and C [trans. title], L. RANDOIN and R. LECOQ (*Bul. Soc. Chim. Biol., 9 (1927), No. 1, pp. 49-58*,

figs. 7).—Using the basal diets previously described for vitamin C (E. S. R., 50, p. 166) and for vitamin B with rats (E. S. R., 53, p. 265) and with pigeons (E. S. R., 56, p. 393), the authors have found both dried malt and malt extract to be completely lacking in vitamin C and malt extract to contain vitamin B as determined with either rats or pigeons. In the rat experiments the malt extract replaced the sucrose which had comprised 68 per cent of the basal diet, and in the pigeon experiments it replaced the dextrin to the extent of 66 per cent of the diet.

The alleged therapeutic value of the malt extract for human scurvy is attributed to the probability that patients responding favorably to it are really suffering from a deficiency of vitamin B as well as C, and are partially cured through the richness of the extract in vitamin B.

Vitamin B [trans. title], L. SCOTTI-FOGLIENI (*Arch. Ital. Biol.*, 75 (1925), pp. 183-185).—The author heated a suspension of rice bran in water in an autoclave at temperatures of 100, 110, 120, and 134° C., respectively, and then allowed the vapor to pass through a serpentine condenser instead of escaping into the air. This condensate and the liquid obtained by filtering the mixture in the autoclave were tested alone and combined on polyneuritic pigeons. Only slight evidences of curative properties were noted for any of the preparations tested alone, but when combined (distillate and filtrate for each temperature) the curative effect was prompt and marked.

These results are considered to indicate that vitamin B is composed of two substances which are not active separately but only when combined. The nonvolatile fraction gives positive, and the volatile fraction negative, tests with the Folin-Macallum phosphotungstic acid reagent.

The content of antiberiberi vitamin in some vitamin patent foods [trans. title], E. KOMM (*Ztschr. Untersuch. Lebensmitl.*, 52 (1926), No. 4, pp. 303-307, figs. 6).—This report of a study of the vitamin B content of various German proprietary foods is of interest in that the method of testing consisted in feeding pigeons polished rice until a marked fall in body temperature occurred and noting whether the administration of the material being tested was followed by a prompt rise in temperature. Temperature and weight curves are given showing that the temperature response is more rapid than the weight response following the ingestion of materials containing vitamin B.

The newest vitamin, W. P. KENNEDY (*Sci. Prog. [London]*, 21 (1927), No. 84, pp. 659-664).—A review and discussion of the literature on vitamin E.

Practical dietetics with reference to diet in health and disease, A. F. PATTEE (*Mount Vernon, N. Y.: Author*, 1927, 16. ed., pp. XV+1-676, figs. 9).—A revision of the volume previously noted (E. S. R., 55, p. 590).

Preventive medicine and hygiene, M. J. ROSENAU (*New York and London: D. Appleton & Co.*, 1927, 5. ed., pp. XXV+1458, pl. 1, figs. 157).—A revision of the volume previously noted (E. S. R., 46, p. 859).

Special diets made Kosher, S. K. DAVIS (*Western Dietitian*, 2 (1927), No. 6, pp. 17, 20, 21).—This general discussion of the problems involved in preparing special diets conforming to Jewish dietary laws is supplemented by diabetic, gastric hyperacidity, and roughage diets adapted to traditional Passover customs.

The use of high fat diets for constipation, F. H. SMITH (*Jour. Amer. Med. Assoc.*, 88 (1927), No. 9, pp. 628, 629).—This contribution from the department of nutrition, St. Mary's Hospital, Rochester, Minn., describes exceptionally favorable results obtained in obstinate cases of constipation by the use of diets containing a large amount, 225 gm. daily, of fat. It is stated that from 3 to 4 days are required to establish normal bowel habits on the high-fat diet.

Utilization of calcium and phosphorus from fresh, dried, and canned milk (*Kansas Sta. Bien. Rpt. 1925-26, pp. 129, 130*).—Four adults and 5 children (3 girls and 2 boys between 7 and 12 years of age) served as subjects in the calcium metabolism studies which are reported briefly. Simple diets were used in which as large a proportion as possible of the calcium was furnished by milk in amounts less than the optimum level. In the work with children, fresh milk was used during the first, second, and seventh periods of 3 days each; powdered milk during the third and fourth periods; and unsweetened condensed milk during the fifth and sixth periods. In the work with adults fresh milk from the college herd was used during the third and fourth periods, fresh milk from two cows kept in the barn and deprived of sunlight for more than 4 months the seventh and eighth periods, powdered whole milk the first and second, and unsweetened condensed milk the fifth and sixth periods.

In the experiments with children the fresh and dried milk furnished not less than 75 per cent, and the condensed milk not less than 63 per cent, of the total calcium. The retention of the calcium per kilogram was only from 50 to 75 per cent as much on the dried, and less than 50 per cent as much on the condensed milk as on the fresh. With the adults the milk furnished about half the total calcium. In the dried milk periods the retention was much less than in the fresh herd milk periods. Two of the 4 subjects showed poorer utilization and 2 as good on the condensed milk as on the fresh. Two subjects only were on the diet when the fresh milk used came from cows which had been kept away from sunlight. Both showed a lowered utilization than on the other fresh milk and about the same as on the dried milk.

The general trend for phosphorus was about the same as for calcium, although the results were not as conclusive.

A note on the calcium content of the serum of normal adults, I. ROSEN and F. KRASNOW (*Jour. Lab. and Clin. Med., 12 (1926), No. 2, pp. 157, 158*).—Determinations by the Kramer-Tisdall method (*E. S. R., 46, p. 203*) of the calcium content of the blood sera of 50 medical students are reported with minimum, maximum, and average values of 10.7, 13.2, and 11.6 mg. per 100 cc. Attention is called to the fact that the values are definitely higher than the values usually accepted as normal (9 to 11 mg. per 100 cc.). In the present series 91 per cent of the values were between 11 and 12.9, and only 7 per cent less than 11 mg. per. 100 cc.

Coefficient of digestibility and dynamic action of a simple diet in contrasting types of individuals, J. WHITACRE and K. BLUNT (*Jour. Home Econ., 19 (1927), No. 1, pp. 20-27*).—To determine whether variations in food demands of different people of similar body build and apparent activity are attributable to individual differences in the specific dynamic action or digestibility of food for different temperamental types, five graduate students of home economics at the University of Chicago, three belonging to the nervous, vivacious type and two to the calm, phlegmatic type, served as subjects in 6-day metabolism experiments on a simple mixed diet. The senior author served as subject three times and the other four once each. The diet selected was thought to be adequate in all respects and furnished from 2,224 to 2,532 calories per person daily, with a percentage distribution of protein 13, fat 40, and carbohydrate 47 per cent. The data obtained included the coefficient of digestibility of the protein, fat, and carbohydrate, the basal energy metabolism and percentage of increase after meals, and the basal pulse rate and the pulse rate after meals.

The coefficients of digestibility were strikingly similar, showing no correlation with the type of individual. The height of elevation of the oxygen consumption over the basal was not appreciably different for the two types, and the stimulation was even less prolonged in the vivacious than in the placid-type subject.

It is concluded that a lower dynamic action of the food and higher coefficient of digestibility can not account for the easy gain of overweight and placid persons. A list of 17 references to the literature is included.

Nutritional survey, O. D. ABBOTT (*Florida Sta. Rpt.* 1926, p. 98).—A preliminary survey by G. Westover of the nutritional status of 500 rural school children of two counties in Florida has shown that 50 per cent of the children examined were from 5 to 33 per cent under weight, 48 per cent had defective teeth, and 33 per cent enlarged tonsils. Further examination showed conjunctivitis, skin eruptions, anemia, and hookworm to be prevalent.

Increase in stature of American boys in the last fifty years, H. GRAY (*Jour. Amer. Med. Assoc.*, 88 (1927), No. 12, p. 908, fig. 1).—The author has compared his height-age data for private-school boys (E. S. R., 56, p. 394) with similar data reported 50 years ago by Bowditch. The latter data consisted of two series of measurements, one for sons of American-born fathers in various professions and the other for 303 Boston boys of American parentage attending the Private Latin School, the Massachusetts Institute of Technology, and the Public Latin School. The average height of the boys measured by Gray exceeded the first series of Bowditch by 7.9 cm. (3.1 in.) and the second series by 6.5 cm.

A study of the effect of nutrition on mental growth, A. J. SMITH and A. M. FIELD (*Jour. Home Econ.*, 18 (1926), No. 12, pp. 686-690).—This study was conducted in the fourth, fifth, and sixth grades of a public school in Alabama, the subjects comprising 37 girls and 24 boys. The children were divided into two groups according to weight. Those who were 7 per cent or more underweight for height and age by the Baldwin-Wood tables comprised the underweight or experimental group, consisting of 19 girls and 6 boys, and the other 18 boys and 18 girls, the normal or control group. The underweight children were examined by a physician, who found all of the boys and all but 5 of the girls to have some physical defects, but these were not corrected during the period of the experiment, which lasted 5 months. During this time special attention was paid to the dietary habits of the underweight group, school lunches being provided to supplement the home diet. The National Intelligence Tests, Scale A, were given to all of the children, form 1 at the beginning and form 2 at the end of the period. The physical gains were measured by the gains in weight during the period.

Both control and experimental groups of girls exceeded the expected gain in weight, while both groups of boys fell below it. The average gain of the control group was the same as the expected gain, and that of the experimental group exceeded the expected gain. In mental age the greatest gain, 14.1 months, was made by the control boys, followed by a gain of 13.5 months by the control girls. The corresponding gains for the experimental groups were 9.3 and 9.2 months, respectively. The gain in intelligence quotient for the control group, 6.3, was more than twice that of the underweight group.

"While this study was of too short duration and with too few subjects to be conclusive, it would indicate that the assumption that improved nutrition, as measured by gain in weight, will bring about improved mentality is at least not yet proved."

Review of literature on the physiological effects of abnormal temperatures and humidities, R. R. SAYERS and S. J. DAVENPORT (*Pub. Health Rpts.* [U. S.], 42 (1927), No. 14, pp. 933-996, fig. 1).—Included in this extensive literature review is a discussion of the kind of clothing which should be worn to prevent the ill effects of subjection to extremes of temperature, either climatic or industrial. A list of 139 literature references on the general subject of the physiological effects of abnormal atmospheric conditions is appended.

TEXTILES AND CLOTHING

The dyeing of cotton and artificial silk fibres, A. J. HALL (*Chem. Age* [London], 16 (1927), No. 402, pp. 19-21, fig. 1).—Attention is called to peculiarities of the dyeing properties of treated cellulosic fibers, with comment on their importance to the dyeing industry.

The influence of humidity on the elastic properties of cotton.—III, On the breaking load at 20° C., J. C. MANN (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 6 (1927), No. 4, pp. 53-64, figs. 11).—Tests involving six varieties of cotton showed that the strength of single fibers increases with rise in humidity, the increase being of the order 10 to 15 per cent of the breaking load at 44 per cent relative humidity. The effect of humidity is important up to 66 per cent relative humidity but negligible above 66 per cent. The test methods are detailed.

Physical tests to determine the effects of chemical or other treatments on yarns, C. F. GOLDTHWAIT (*Amer. Dyestuff Rptr., Sample Swatch Quart.*, 1927, Jan., pp. 7-14, figs. 19).—The tests described are concerned with the length of a yarn sample, correction for weight of yarn, and elastic properties of yarns.

Processes for rendering woolen goods unshrinkable, A. J. HALL (*Textile Colorist*, 49 (1927), No. 579, pp. 161-164, figs. 5).—Recent investigations on the chlorination of wool are reviewed.

Annual wool review, 1926, J. B. MCPHERSON (*Bul. Natl. Assoc. Wool Manfrs.*, 57 (1927), Extra No. 1, pp. 99-226, pls. 2).—The information recorded is similar in scope to that noted previously (E. S. R., 55, p. 195).

A directory of textile merchandise, including textile brands and trade-marks, compiled by Textile World (*New York: Bragdon, Lord & Nagle Co.*, 1921, 2. ed., pp. 15-630).—This directory supplies a list of trade names, brands, and trade-marks of products of which textile fibers, yarns, or cloth are the principal materials, the kinds of goods to which the names apply, and the first-hand distributors. Brands are also classified according to product. A discussion on Valid Trade Marks and Their Originations, by H. C. Thomson, is included.

The protective value of certain clothing fabrics (*Kansas Sta. Bien. Rpt.* 1925-26, pp. 131, 132).—Samples of white wool, silk, linen, and cotton materials as closely alike as possible in weave were tested for their screening effect against sunburn (1) by the action of direct sunlight on the skin, (2) by the action of ultra-violet light on sensitized paper, (3) by photometric measurements, and (4) by spectrographic analysis.

The results obtained with direct sunlight and spectrographic analysis were identical and indicated a much greater protection with wool and silk than with cotton or linen. This relation was also shown, but to a less marked extent, by the ultra-violet light measurements. The percentage of interspace for the different fabrics was 8.8 for wool, 12 for silk, 5.5 for linen, and 5.3 for cotton.

“The data tend to show that the protection from sunburn afforded the skin by fabrics depends principally upon the percentage of interspace due to weave. The vegetable fibers, cotton and linen, however, transmit some of the rays that burn and hence have a small coefficient of protection. Animal fibers, silk and wool, on the other hand, absorb a portion of the rays, thus having a large coefficient of protection.”

Smoke: A destroyer of family wash, R. A. PHAIR and J. G. LUKASH (*Starchroom Laundry Jour.*, 34 (1927), No. 4, pp. 37-42, figs. 3).—The type of damage described as occurring in cotton fabrics, especially shirts, in “wet

wash" or home washed clothes only in winter, principally during January, February, and March, appeared to be caused by the presence of minute quantities of sulfuric acid in the air. The destruction and acid content of the fabric appeared to increase under conditions of cold and fog. See also a previous report by Allyn (E. S. R., 56, p. 595).

MISCELLANEOUS

The Thirty-ninth Annual Report of the Colorado Agricultural Experiment Station for the Year 1926, C. P. GILLETTE ET AL. (*Colorado Sta. Rpt. 1926*, pp. 46).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1926, a report of the director on the work of the station, and departmental reports. The experimental work reported is for the most part abstracted elsewhere in this issue.

Report of the director [of Connecticut Storrs Station], 1926, W. L. SLATE, JR. (*Connecticut Storrs Sta. Bul. 142 (1926)*, pp. 165-182, figs. 7).—This contains the organization list, a report of the director, and a financial statement for the fiscal year ended June 30, 1926. The experimental work reported is for the most part abstracted elsewhere in this issue.

[Annual Report of Florida Station, 1926], W. NEWELL ET AL. (*Florida Sta. Rpt. 1926*, pp. 125+VI, figs. 10).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1926, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Annual Report [of Iowa Station], 1926, C. F. CURTISS and W. H. STEVENSON (*Iowa Sta. Rpt. 1926*, pp. 63).—This contains a report on the work of the station, including a financial statement for the fiscal year ended June 30, 1926. The experimental work recorded not previously noted is for the most part abstracted elsewhere in this issue.

[Report of Kansas Station, 1925-1926], L. E. CALL (*Kansas Sta. Bien. Rpt. 1925-26*, pp. 162).—This contains the organization list, financial statements for the biennium ended June 30, 1926, and a report of the director summarizing the work and publications of the station. The experimental work recorded not previously noted is for the most part abstracted elsewhere in this issue.

Michigan Agricultural Experiment Station Quarterly Bulletin, [February, 1927], edited by R. S. SHAW and E. B. HILL (*Michigan Sta. Quart. Bul.*, 9 (1927), No. 3, pp. 81-126, figs. 4).—In addition to articles abstracted elsewhere in this issue, this number contains the following: Power Possibilities of Small Streams, by O. E. Robey; Grow Better Potatoes, by H. C. Moore; Preparing and Fertilizing Potato Soils, by F. W. Trull; Methods Recommended for Increasing Oat and Barley Yields, by G. R. Schlubatis; Soil Preparation and Fertilization for Corn, by C. E. Millar; and Position on Ridge Affects Conifers Growth, by A. K. Chittenden and W. Martin.

NOTES

Florida Station.—In continuing the studies on Manson's eye worm of poultry noted on page 874, many insects were examined without finding any laval forms of the parasite, until finally specimens of *Pycnoscelus surinamensis* Linn., a species of cockroach, were examined. Larvae of the eye worm were found to be present in the thoracic and abdominal cavities of some of these roaches. When these larvae were transferred to the eyes of chickens, examinations several days later revealed that the larvae remained in the eyes of the birds and had taken position in the tear sac beneath the nictitating membranes in each bird identical to that in which mature parasites are found. Larvae were also removed from the body of a cockroach and placed one at a time on the roof of the mouth and on the tongue of a chicken, with the result that in a few hours the presence of the parasite was noted in both eyes.

These observations confirm the findings of J. W. Fielding (noted on page 879) that this species of roach is the intermediate host for Manson's eye worm.

Hawaii University.—Dr. Frederick G. Krauss, professor of agronomy and genetics, has been given leave of absence for an extended study of tropical plants, especially the pineapple in the Dutch East Indies and Malaya, and of *Cajanus* in the Himalayan region. He will then proceed to Berlin for the Fifth International Congress of Genetics in September and a year's genetics study in Germany.

Kansas College and Station.—The vacancy occasioned by the resignation of Dr. R. P. White, assistant professor of botany and assistant plant pathologist, as previously noted, has been filled by the appointment of Dr. O. H. Elmer, assistant plant pathologist in the Iowa Station, who entered upon his new duties May 21.

Massachusetts College.—Dr. Robert J. McFall, extension professor of agricultural economics and on leave of absence for work in cooperation with the U. S. Department of Commerce, has resigned effective June 1 to become special agent in the Bureau of Foreign and Domestic Commerce of that department.

Mississippi Station.—The Delta Substation at Stoneville, located on the highest land of the region, was submerged in the recent floods to a depth of from 1.5 to 6.5 ft., but was fortunate in escaping serious damage. The property loss in livestock, buildings, and growing crops for the State as a whole is estimated as in excess of \$250,000,000. It is regarded as doubtful whether more than 30 to 40 per cent of the flooded area can be replanted this season.

A laboratory and office are being fitted up at the main station to accommodate the station home economics department, hitherto located on the campus of the Mississippi State College for Women at Columbus.

Montana College and Station.—H. K. Wilson has been appointed assistant in agronomy in the college and station, succeeding H. N. Watenpaugh, resigned.

Nevada Station.—C. A. Brennen has been appointed range economist, beginning June 1, and will have charge of the Purnell project entitled A Study of the Economics of Cattle Production on Ranch and Range in Nevada.

Clemson College.—Lyman Neel has been appointed extension specialist in poultry husbandry.

INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.," "Conn. State," "Mass.," etc., after entries refer to the publications of the respective State experiment stations; "Alaska," "Guam," "Hawaii," "P.R.," and "V.I." to those of the experiment stations in Alaska, Guam, Hawaii, Porto Rico, and Virgin Islands; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

Abaca disease, eradication, 748.

Abortion—

- acriflavine treatment for, Ga., 278.
- eradication, Conn.Storrs, 874.
- immunization, Ky., 172.
- in cattle, 876.
- in cattle, diagnosis, value of placental examination, 476.
- in cattle, prevention and control, 574.
- in cattle, studies, Wash.Col., 573; Wis., 773.
- in sheep, 876.
- in sheep in Silesia, cause, 777.
- in swine, 876; Ill., 276, 379.
- organism of animals, human infections with, 876.
- studies, Kans., 875.
- tuberculous, in cattle, 476.
- value of living vaccine for, Minn., 174. (See also *Bacillus abortus* and *Bacterium abortum*.)

Abortion-free herds, establishment, Del., 377.

Abrazax grossulariata, notes, 659.

Absorption in different parts of gastrointestinal tract, 192.

Acacia farnesiana, control, Guam, 229.

Acacia, lack of nodule-formation in, 124.

Acacia seedlings, descriptions, 646.

Acalypha flea beetle, notes, 157.

Acanthorhynchus vaccinii, notes, 249.

Accessory food factors. (See Vitamins.)

Accounting, farm. (See Farm accounting.)

Achaea lienardi, notes, 859.

Achres spp., notes, 756.

Acid—

phosphate. (See Superphosphate.)

preservative action in catsup, N.Y. State, 711.

soils, biochemical activities, effect of lime, Conn.Storrs, 624.

Acidophilus milk, preparation, Ill., 392.

Acidosis, trembles, and milk sickness, 572.

Acriflavine treatment for abortion, Ga., 278.

Actia pilipennis, notes, 361.

Actinomyces, cause of sweet potato pox, Del., 348.

Actinomyces—

necrophorus, notes, Colo., 878.

scabies, papers on, 339.

Adams Act, first 20 years under, editorial, 701.

Adelges abietis, studies, N.Y.Cornell, 156.

Accidium grossulariae, notes, 542.

Aegeria—

exitosa. (See Peach borer.)

tipuliformis. (See Currant borer.)

Aegilops and wheat hybrids, morphology and cytology, 633.

Aerological—

code, 1926, U.S.D.A., 617.

survey of United States, U.S.D.A., 507.

Agar slants, exudate from, 573.

Age and area theory, critical review, 221.

Agglutinin absorption, 676.

Aggregates, road. (See Road materials.)

Agricultural—

chemistry. (See Chemistry.)

College and Model Farm in the Ukraine, notes, 499.

Colleges and Universities, survey, 198. colleges curricula, papers on, 587.

colleges, organization list, U.S.D.A., 790.

(See also Arizona, etc.)

colonization policy of Zionist Organization, 790.

(See also Land settlement.)

cooperation—

development and status, 685.

in Europe, studies, 889.

possibilities and limitations, Ky., 789.

reading list, U.S.D.A., 889.

credit in Jugoslavia, 484.

credit, international, 685.

credit, relation to crop insurance, 686.

education—

and improvement in China, British aid to, 97.

in Great Britain, 187.

in South Africa, notes, 198.

pioneers in, passing of, editorial, 601.

Agriculture—Continued.

education—continued.

service of Federal Board for Vocational Education, 487.

vocational, course outlines for, 488.

vocational, value, 389.

(See also Agricultural colleges and Agricultural schools.)

engineering. (See Engineering.)

experiment stations. (See Experiment stations.)

extension, use of motion pictures in, U.S.D.A., 791.

extension work, effectiveness, Wis., 488.

extension work, papers on, 587.

(See also Extension.)

journalism, textbook, 390.

journals, new, 100, 199, 500, 800.

labor, wages, index numbers, Ohio, 183, 285, 581.

legislation, international yearbook, 485.

legislation, 1924, summary, 485.

machinery—

costs, Ohio, 285.

for corn borer control, 179.

for grape leafhopper control, 179.

tests, 80.

map of Union of Socialistic Soviet Republics, 790.

outlook, 1927, Okla., 888; Tex., 888; U.S.D.A., 888.

problems, international aspect, 684.

production and distribution, adjusting, W.Va., 786.

production, cooperation in, 889.

production, index numbers, Ohio, 183, 285, 581.

products, balance of trade in, 789.

products, marketing. (See Marketing.)

products, prices received by producers, U.S.D.A., 888.

progress in typical Maryland community, Md., 786.

research—

and education, Federal aid for, Kans., 584.

at 1926 convention, editorial, 1.

in Australia and New Zealand, 97.

in Bombay, 135.

national problems for cooperation, 101; U.S.D.A., 195.

Ohara Institute for, 500.

pioneers in, passing of, editorial, 601.

school classes, evening, in dairying, 790.

schools, Mexican, 800.

statistics, international yearbook, 790.

statistics of Northern Ireland, 891.

surveying, textbook, 187.

Agriculture—

and meteorology, papers on, 113.

Department of. (See United States Department of Agriculture.)

in Finland, 888.

in Persia, survey, 104.

Agriculture—Continued.

in Washington State, 688, 786.

Maori, 334.

northern limits, 432.

taxation problems, S.Dak., 685.

use of electricity in, 579, 681, 889;

Ill., 280; Ind., 281; Mich., 398;

Wis., 781.

Agronomic experiments, mathematical analysis, 332.

Agronomy, relation to plant physiology, 722.

Air in buildings, humidifying, Colo., 881.

Airplane dusting—

for grasshopper control, 256.

for vegetable pests, 57, 254.

Alaska Stations, notes, 497.

Albumin—

egg, vitamin B in, 491.

formation in plants, rôle of chloroplasts, 814.

Alcohol—

effect on sex ratio in rats, 32.

fumes, effect on sex ratio in mice, 227.

(See also Ethyl and Methyl alcohol.)

Alcohol-benzol mixture v. benzol for motor plows, 80.

Alcoholism, effect on rats, 32.

Alcohols, germicidal activity, relation to chemical constitution, 572.

Alder, red, of Pacific Northwest, U.S.D.A., 46.

Aleurobius farinae in flax seed, 662.

Aleurodes variabilis, notes, 552.

Aleurodes vaporariorum. (See White fly, greenhouse.)

Alfalfa—

alone and in mixtures, tests, Ill., 334.

bacterial wilt and root rot, studies, 147.

breeding, Ariz., 730; Can., 432.

curing studies, Nebr., 735.

cutting test, Kans., 822.

diseases in Manitoba, 541.

effect of sulfur, Mont., 123.

feeding value for wintering cattle, Oreg., 365.

fertilizer experiments, Kans., 822; Nebr., 735; Wis., 715.

germination of old seeds, 39.

hardy, hay yield, Pa., 134.

hay, amount per day for lambs, Kans., 368.

hay, chopped, effect, Wis., 772.

hay, chopping for beef cows, Wis., 762.

hay, digestibility, effect of fiber, N.Mex., 159.

hay, digestion experiments, Ill., 368.

hay, energy value for sheep, Ill., 367.

hay for brood sows, Del., 369.

hay, nutritive value of different cuttings, Wash.Col., 561.

hay v. Rhodes grass hay for cattle, Ariz., 762.

hay v. soy bean hay for dairy cows, Wis., 772.

Alfalfa—Continued.

- hay, yield and quality, factors affecting, Nebr., 734.
 insects affecting, Kans., 856; Nev., 259.
 irrigated, variety tests, Wash.Col., 528.
 irrigation experiments, 55; Kans., 823; Utah, 525.
 leaf anomalies, studies, 629.
 pasture for pigs, Iowa, 266.
 pasture v. Sudan grass pasture for hogs, Nebr., 564.
 pests in Argentina, 659.
 proteins of, 708.
 residual effect on soil, Kans., 811.
 root rot diseases, Kans., 842.
 seed, chalcis fly in, Utah, 553.
 seed germination, factors affecting, 433.
 seed, heating, effect on germination, Colo., 820.
 seed production, Idaho, 231; Utah, 525.
 seed, scarified and unscarified, longevity, Minn., 524.
 seed screenings, feeding value, Idaho, 368.
 seed, source tests, Iowa, 822.
 seed, stored, viability of legume bacteria on, Can., 513.
 seed tests, U.S.D.A., 231.
 seedling experiments, Wis., 732.
 stem nematode, notes, Utah, 540.
 studies, Ill., 335.
 usage for poultry, S.Dak., 669.
 varieties, behavior, Guam, 228.
 varieties, winter hardiness, Ill., 230; Minn., 527.
 variety tests, Ark., 332; Can., 432; Fla., 821; Iowa, 821; Kans., 822; Minn., 524; Mont., 133; Wash.Col., 525.
 weevil, control, Nev., 260.
 weevil, notes, Colo., 854; Wyo., 553.
 white spot, notes, Utah, 540.
 wilt and root rot, Colo., 839.
 winterkilling, causes, Wis., 732.
 with hay grasses, cutting tests, Wis., 732.
 yellow leaf blotch, notes, Utah, 540.
 yellows, cause, Wis., 756.
 yields, effect of precipitation and temperature, 413.
- Algae, nitrogen fixation by, 509.
- Alkali—
 effect on angular leaf spot of cotton, Ariz., 745.
 soils, freezing up phenomenon, 619.
 soils, increasing permeability, 508.
 soils, mapping, 511.
 soils of Siberia and Turkestan, 716.
 soils, origin, 20, 210.
 soils, reclamation, Wash.Col., 576.
 soils, studies, Wyo., 509.
 tolerance of plants, Ariz., 512.
- Alkalies—
 action on clay, 510.
 effect on wool, 697.

Alkaline—

- metabolic products, effect on growth of fungi, 221.
 soils, availability of phosphates, Ariz., 213.
- Allelomorphs, quadruple, affecting eye color in *Habrobracon*, 223.
- Almonds—
 injury from crows, 456.
 variety tests, Miss., 739.
- Alternaria*—
brassicæ nigrescens, notes, Del., 348.
fici, notes, 851.
herculea, studies, 145.
radicina, studies, 545.
solani, cause of potato tuber rot, Me., 246.
 sp., notes, 249, 549, 748.
- Alternaria*—
 core mold of apple, 647.
 leaf spot on watermelon, Fla., 143.
 rot of lemons, Calif., 249.
- Altitude, effect on forage crops, Wyo., 134.
- Aluminum—
 fertilizing value, 323.
 hydroxide and freezing up of alkali soils during reclamation, 619.
 nitride process of nitrogen fixation, 623.
 relation to plant growth in acid soils, 323.
- Amarantus disease in Sumatra, 456.
- Amatidae, data, 358.
- Amblyomma americanum*, cause of typhus-like fever, 277.
- American—
 Association of Cereal Chemists, methods of analysis, 13.
 Chemical Society, fiftieth anniversary, 309.
 Council of Education, report, 587.
 National Livestock Association, proceedings, 69.
 Society of Animal Production, meeting, 98.
 Society of Testing Materials, standards, supplement, 780.
 Soil Survey Association, proceedings, 511.
- Amids, rôle in higher plants, 325.
- Amines in distillate from Kjeldahl-Gunning nitrogen determinations, 111.
- Ammonia—
 action on wool, 496.
 in rain from protected and exposed gage, 212.
- Ammonification in red prairie soils, 21.
- Ammonium—
 nitrate action on acid sand soils, 514.
 sulfate action on acid sand soils, 514.
 sulfate and sodium nitrate, comparison, 23, 623.
 sulfate, effect on soil reaction, 22.
 sulfate, production, 626.
- Amorbia humerosana*—
 notes, Pa., 154.
 studies, Pa., 156.

- Amorbia, life history studies, 858.
 Amphibians and reptiles of Indiana, keys, 754.
 Amylases, chemical studies, 501.
 Anaerobes, tissue-invading, identification, 475.
Anaphe infracta, silk from, tests, 823.
Anaphothrips signipennis, biology and control, 459.
 Anaphylaxis, relation to immunity, 676.
Ancylostoma spp., notes, U.S.D.A., 776.
 Anemia—
 blood regeneration in, 494.
 pernicious, treatment, 294.
 relation to iron in diet, 494.
 relation to vitamin A deficiency, 293.
 Anesthetics, effect on respiration of cereals, 125.
 Angiosperms, chromosome numbers in, list, 816.
Angitia fenestralis, biology, 856.
 Angleton grass, characteristics and habits, Tex., 35.
 Animal—
 breeding principles, treatise, 760.
 chromosomes. (See Chromosomes.)
 diseases—
 in Ajmer-Merwara, 876.
 in Bihar and Orissa, 876.
 in Bombay, 774.
 in British Baluchistan, 571.
 in Burma, 876.
 in Connecticut, Conn.Storrs, 874.
 in Fiji, 277.
 in Kenya Colony, 173.
 in Mauritius, regulation, 277.
 in Northern Ireland, 277.
 in Prussia, 571.
 in Trinidad and Tobago, 277.
 post-mortem and laboratory examinations, Kans., 875.
 recent advances in, 477.
 relation to public health, 775.
 ultra-microscopic, cell inclusions, 676.
 (See also specific diseases.)
 ecology, course in, 250.
 experiments, operative technique, 775.
 fats. (See Fats.)
 feeding experiment, directions, 390.
 fibers. (See Fibers.)
 glue, water-resistant, 802.
 nutrition, potassium in, 465.
 nutrition work, Iowa, 863.
 pest control, relation to conservation, 56.
 pests of economic plants, treatise, 355.
 tissues, histological technique, 675.
 Animals—
 domestic, worm parasites of, 571.
 exports and imports in Northern Ireland, 277.
 laboratory, biometrical measurements, 669.
 ruby eye in, heredity, 428.
 Animals—Continued.
 wild, of Australasia, 853.
 (See also Cattle, Livestock, Mammals, Sheep, etc.)
 Anions, retention by soils, effect of exchangeable bases, 416.
 Anopheles—
 emergence, 62.
 engorged, destruction as malaria control measure, 62.
Anopheles spp., food of, 62.
 (See also Malaria and Mosquitoes.)
 Antagonism between salts in bacterial development, 26.
 Anthocyanin pigments of plants, 813.
 Anthocyanins in grapes, 311.
 (See also Pigmentation and Pigments.)
Anthonomus—
 grandis. (See Boll weevil.)
 musculus, life history and control, 861.
 suturalis, notes, 861.
 Anthracnose. (See specific host plants.)
 Anthrax—
 plants as possible carriers, La., 173.
 prophylaxis, Ark., 378.
 symptomatic. (See Blackleg.)
Anticarsia gemmatilis, notes, 155.
 Antidiphtherine, vaccination of poultry with, 679.
 Antineuritic vitamin. (See Vitamin.)
 Antirachitic. (See Rickets and Vitamin D.)
 Antiscorbutic. (See Scurvy.)
 Antiscorbutic vitamin. (See Vitamin C.)
 Antixerophthalmic vitamin. (See Vitamin A.)
 Ants—
 baits for, Utah, 553.
 natural history, 759.
 wasps, and bees, treatise, 862.
 white. (See Termites.)
Anuraphis—
 roseus. (See Apple aphid, rosy.)
 tulipae in storage warehouses, control, 60.
Apanteles—
 Artonae n.sp., description, 760.
 carpatas, notes, Va., 556.
 diatraeae, notes, 557.
 glomeratus, parasite of *Pieris brassicae*, 661.
 Apatite, dicalcic phosphate from, preparation, 510.
Aphanomyces euteiches, notes, Wis., 747.
Aphelenchus fragariae—
 in strawberry plants, 152.
 notes, 850.
Aphelinus—
 diaspidis, notes, Guam, 251.
 jucondus, feeding habits, 862.
 mali in New South Wales, 362.
 mali introduction into Germany, 856.
Aphidencyrus inquisitor, feeding habits, 862.
 Aphididae—
 of Egypt, 660.
 of Great Britain, 660.

Aphids—

- in cauliflower seed beds, control, N.Y.State, 253.
- survival expectancies, 156.
- woolly, control, Tenn., 154.
- woolly, parasite of, 362.

(See also Apple aphid, woolly.)

Aphis—

- abietina*. (See Spruce aphid.)
- gossypii*. (See Melon aphid.)
- leguminosae*, notes, 751.
- persicae*. (See Peach aphid, green.)
- pomi*. (See Apple aphid.)
- rumicis*. (See Bean aphid.)
- spiraeicola* in Florida, factors affecting, 555.
- spiraeicola*, notes, Fla., 855.

Apiculture. (See Beekeeping.)

Apiomerus pilipes, host of *Trypanosoma cruzi*, 362.*Aplanobacter insidiosum*—

- description, 147.
- notes, Colo., 839.

Apparatus—

- for carbon dioxide determination, 13.
- for depicting fiber cross sections, 193.
- for determining pH value, 503.
- for drying crops in the stack, 180.
- for holding milk at uniform temperature, 474.
- for measuring vascular plugging, 446.
- for recording fluctuating weight of beehive, 662.
- respiration, for small animals, 14.
- vacuum extractor, description, 12.

Appetite, loss of, and vitamin B deficiency, 795.

Apple—

- aphid, rosy, value of oil emulsion sprays for, 253.
- aphid, survival expectancies, 156.
- aphid, woolly, control, Calif., 255.
- aphid, woolly, parasite, introduction into Germany, 856.
- (See also Aphids, woolly.)
- black scab, notes, 747.
- blight resistant varieties, Tenn., 145.
- blight susceptible varieties, Ky., 144.
- blossom weevil, control, 57.
- blossom wilt, notes, 747.
- blotch, control, Tenn., 145.
- blotch in Ohio, studies, 53.
- blotch, pathologic histology, 453.
- capsid bug, control, 660.
- crown gall, studies, Tenn., 145; Wis., 746.
- die-back, control, Del., 348.
- disease, notes, Kans., 842.
- diseases in cold storage, 53, 54.
- diseases in Indiana, 647.
- diseases, notes, 747.
- fire blight, studies, Ill., 241; Pa., 144.
- frog-eye, cause, Pa., 144.
- fruit moth, notes, 659.
- fruit spot, cause, Pa., 144.
- grafts, formation of scion roots, 835.

Apple—Continued.

- industry, commercial, survey, Conn. Storrs, 884.
- leaf miner, biology and control, 758.
- leaf rollers, life history studies, 858.
- leaf scorch, studies, 653.
- leaves, leafhopper injury to, 59.
- measles, susceptibility of varieties, 353.
- mildew, control, 849.
- miner, notes, 659.
- nursery stock canker, notes, 747.
- orchards, establishing, Ind., 237.
- orchards, fertilization, W.Va., 535.
- orchards, sod-nitrate v. cultivation, 536.
- root or collar rot, notes, Ill., 349.
- root rot, notes, 747.
- root stock investigations, 44.

Apples—

Arkansas, cross fertilization of, 836.
 breeding experiments, Ill., 233, 342.
 chemical changes during ripening,
 Iowa, 832.
 cold storage, acidity, Iowa, 849.
 cold storage experiments, 237.
 cold storage, functional diseases, 53,
 54.
 cost of production in Shenandoah Val-
 ley, U.S.D.A., 785.
 crab. (See Crab apple.)
 disease resistant varieties, 549.
 effect of thinning, Utah, 533.
 fertilizer experiments, 43; Ark., 341;
 Del., 341; Ill., 342; Pa., 139.
 fruiting, an exhaustive process, 835.
 fungus flora of, Wash.Col., 540.
 growth and composition, relation to
 leaf area, 836.
 hardiness in, determination, 43.
 hardiness in, dye absorption test for,
 Iowa, 832.
 harvesting, relation to internal brown-
 ing, Utah, 550.
 inoculation method, 849.
 insects affecting, N.Y.State, 251.
 Massachusetts, market outlet for, Mass.,
 689.
 nitrogen and carbohydrate in develop-
 ing fruit, N.Y.Cornell, 344.
 nitrogen fertilizers for, comparison,
 836.
 picking maturity, relation to storage,
 U.S.D.A., 345.
 pollen sterility in, 643.
 pollination studies, 442; Ark., 340.
 pollination tests, Wash.Col., 533.
 propagation on own roots, 140.
 propagation studies, Del., 342.
 propagation studies, correction, Del.,
 741.
 propagation, use of burrknots in, 140.
 respiration rate and response to tem-
 perature, 742.
 scion selection, Vt., 442.
 self-fruitfulness tests, S.C., 532.
 soil management studies, Kans., 833.
 spray injury to, 47.
 spray residues, removal from, 442.
 spraying and dusting experiments, Me.,
 151.
 spraying experiments, 849; Ark., 347.
 stocks for, N.Y.State, 235.
 storage cellar, air-cooled, for, 442.
 storage, development of scab, Me., 151.
 storage studies, Wash.Col., 533.
 stored, effect of fertilizer treatments,
 Pa., 138.
 value of selection of framework
 branches, Pa., 139.
 variety and miscellaneous studies, Vt.,
 442.
 variety tests, Miss., 739.
 York Imperial, fruiting habit, 741.

Apricot trees, distribution of carbohydrates
 in, 536.

Apricots—

Coryneum beijerinckii affecting, 551.
 injury from crows, 456.
 protection from codling moth, 556.

l-Arabinoase, isolation, 409.

Arbutus unedo, root tubercles of, 221.

Archips argyrospila. (See Fruit tree leaf
 roller.)

Archips, life history studies, 858.

Areca nut koleroga, control, 544.

Arginine determination in pure proteins
 and tissues, 710.

Argyresthia conjugella, notes, 659.

Argyrol injection for sinusitis in turkeys,
 478.

Argyroploce variegana, biology, enemies,
 and control, 360.

Arizona—

Station, notes, 300.

Station, report, 797.

University, notes, 196, 300, 798.

Arkansas—

Station, notes, 497, 798.

Station, report, 398.

University, notes, 798.

Armillaria mellea, notes, 748.

Army worm, fall, notes, 155.

Arrow grass as poisonous plant, Wyo., 572.

Arsenical—

compounds, action on Lepidoptera, 856.
 powders, use as larvicide for mosqui-
 toes, 258.

residues, removal from fruits, Colo.,
 442.

sprays for weed control, Colo., 821.

Arsenicals—

effect on respiratory metabolism of
 insects, 553.

use in Germany, 856.

(See also Calcium arsenate and Lead
 arsenate.)

Artona catoxantha, parasite of, 760.

Ascaridae behavior in host, Kans., 876.

Ascaridia—

lineata, notes, 56.

perspicillum, studies, Kans., 875.

Ascaris—

inflexa, notes, 576.

lumbricoïdes, studies, Nebr., 879.

Ascochyta—

asteris, notes, 54.

sp., notes, 748.

trifolii, notes, 541.

Ascochyta blight of canning peas, N.Y.
 State, 241.

Ascogaster carpocapsae, notes, Del., 357.

Ash determination in flour, 14.

Asparagine, rôle in nitrogen transformation
 in plants, 325.

Asparagus—

cutting first year, effect, S.C., 532.

disease resistant varieties, 549.

fertilizer experiments, 833.

Asparagus—Continued.
 nitrate utilization in absence of light, 344.
 quality after cutting, factors affecting, Calif., 235.

Aspergillus—
niger, notes, S.Dak., 649.
oryzae, saccharine cultures, new product of, 325.

Asphondylia opuntiae, studies, 58.

Aspidiotiphagus citrinus—
 notes, Guam, 251.
 on coconut palm, 58.

Aspidiotus—
ancylus. (See Putnam's scale.)
destructor, life history and control, Guam, 251.
destructor, notes, 756.
perniciosus. (See San Jose scale.)

Association of—
 Land-Grant Colleges and Universities—
 convention, place of research in, 1.
 notes, 400.
 proceedings, 587.
 Official Agricultural Chemists, proceedings, 501.
 Southern Agricultural Workers, notes, 399.

Aster—
 diseases, studies, 54.
 wilt, control, Ill., 241.
 wilt, studies, Iowa, 840.
 yellows, insect transmission, 54.
 yellows, notes, Ill., 349.

Asterolecanium pustulans, notes, 552.

Athel trees as windbreaks for citrus orchards, Ariz., 739.

Atite in plants, 220.

Atmospheric moisture. (See Humidity.)

Atriplex—
 absorption of water by, 724.
 tumbleweed seed, effect of heat, 433.

Aulacaspis rosae. (See Rose scale.)

Aularches miliaris, life history, habits, and control, 59.

Automotive industry—
 cast iron in, 882.
 X-rays used in, 883.

Avitaminosis. (See Vitamin deficiency.)

Avocado diseases, control, Fla., 143.

Avocados—
 fertilizer experiments, 645.
 improvement, 532.
 pollination tests, 645.
 stocks for, 645.

Azotobacter distribution in Bavarian soils, 319.

Baby beef. (See Cattle, baby beef.)

Bacillus—
abortus equi, biological and serological study, 175.
abortus equi, notes, Ky., 172.
abortus, production of aggressins, studies, Ark., 377.
 (See also *Bacterium abortum* and *Abortum*.)

Bacillus—Continued.
amylobacter, notes, 847.
carotidae and *B. carotovorus*, comparison, 452.
botulinus distribution in soil, 677.
 (See also *Clostridium botulinum*.)
carotovorus and *B. aroideae*, comparison, 452.
cinerea forms, metabolism, 349.
coli communis, notes, 549.
enteritidis, meningitis due to, 677, 877.
equidistans n.sp., description, 174.
felsineus, notes, 847.
lurvae, studies, Can., 362.
melitensis. (See *Bacterium melitensis*.)
mesentericus, action on cellulose, 297.
mycoides, notes, 549.
pseudooerosis n.sp., description, 174.
radicicola. (See Nodule bacteria.)
rickettsiformis n.sp., description, 174.
subtilis, action on cellulose, 297.
subtilis, notes, 651.
tetani distribution in soil, 677.

Bacon—
 palatability and keeping qualities, effect of salt quantity, Kans., 866.
 selection and use, Minn., 893.

Bacteria—
 acid-fast, studies, Wis., 777.
 agglutination capacity, relation to electrical charge, Pa., 176.
 anaerobic. (See Anaerobes.)
 and leaf variegation, studies, 629.
 and plants not legumes, symbiosis in, 629.
 development, relation to antagonism between salts, 26.
 growth, effects of salt and pH, 350.
 in milk, soil, etc. (See Milk, Soil, etc.)
 lactic acid, physiology, 73.
 morphology and life cycles, Ark., 348.
 obligate thermophilic, from soil, studies, 512.
 on tobacco, 639.
 variation in, 475.

Bacteriology—
 determinative, Bergey's manual, 326.
 of food, textbook, 490.

Bacteriophage—
 lytic for *Salmonella pullorum*, 575.
 nature of, 676.
 of fowl cholera, 575.
 prophylactic and therapeutic possibilities, 475.

Bacteriophagy, treatise, 518.

Bacterium—
abortum—
 infection in cow's udder, nature of, 573.
 isolation and cultivation, 876.
 isolation, whole milk and milk sediment for, 477.
 metabolism, 677.
 porcine type, Ill., 379.

Bacterium—Continued.

abortum—continued.

(See also *Bacillus abortus* and Abortion.)

- alcaligenes*, metabolism, 677.
andropogoni, notes, 48.
bronchisepticum, metabolism, 677.
campestre, notes, 549
casei ϵ and *Mycoderma thöni*, biology, 473.
citri. (See Citrus canker.)
coli. (See *Bacillus coli*.)
erivanense n.sp., notes, 750.
galleriae, notes, 758.
gummisudans, notes, 54.
holci n.sp., description, Iowa, 542.
leptosepticum infection of rabbits, 880.
Wöhnisi n.sp., notes, 750.
lycopersici n.sp., on tomatoes, 549.
maculicolum, notes, 541.
malvacearum, notes, 549, 846.
marginale, notes, 549.
marginatum, notes, 54; S.C., 539.
melitensis, metabolism, 677.
mori, notes, 647, 654.
phaseoli, notes, Pa., 145.
phaseoli sojense, notes, Del., 348.
pisi, notes, 648.
pruni, control, 453.
pullorum, animal feeding experiments, Conn.Storrs, 678.
pullorum in eggs, toxicity, Conn.Storrs, 874.

(See also *Salmonella pullorum*.)

- savastanoi*, notes, 549.
solanacearum, notes, Fla., 143.
tabacum, host plants, 248.
tabacum, notes, 648, 748.
tularensis, hereditary transmission in wood tick, 261.
tumefaciens, effects of X-ray treatments, 629.
tumefaciens, notes, 549, 653.
vignae, notes, 647.
vignae on Lima beans, Del., 348.
viridifaciens, notes, Pa., 145.
viridilividum, notes, 549.
vitians, notes, 549.

Bahia grass, cultural and pasturing studies, Fla., 132.

Bakery by-products, feeding value, Pa., 165.

Bakery infection with *Monilia sitophila*, 391.

Balance, deflection, for use in biochemical laboratories, 312.

Balclutha mbila, transmission of streak disease by, 649.

Balsam—

- fir in Upper Peninsula, Mich., 838.
 fir, tissue anatomy after budworm attack, 355.
 red heart rot, cause, 355.

Bamboo, *Myzocallis* infesting, 555.

Banana—

- bunchy top disease, 354, 851.
 Panama disease, studies, 454.
 thrips rust, 459.

Bananas—

- culture, Hawaii, 743.
 injury from fruit-piercing moths, 756.
 place in the diet, 894.
 ripening, temperature and respiration, 837.
 time of planting and cold storage studies, 44.

Barberry—

- eradication, U.S.D.A., 448.
 eradication campaign, Mont., 544.
 (See also Wheat stem rust.)

Bark beetles, British, 661.

Barley—

- and products, composition and digestibility, 665.
 breeding experiments, Ill., 333.
 chlorophyll defect in, 724.
 cross, inheritance of characters, 630.
 culms, number of nodes in, 230.
 culture experiments, 35.
 effect of fallow, Wyo., 825.
 flour, fat content, 312.
 grades, feeding value, 665.
 growth, effect of climate, 113.
 growth, effect of methyl and ethyl alcohol, 125.
 improvement, Ill., 334; Kans., 822.
 linkage in, 630.
 pollen, preservation, 230.
 pure lines, effect of climatic conditions, 730.
 seeding experiments, 825.
 seeds, frosted, germination, Colo., 820.
 smooth-awned, breeding, 825.
 smuts, control, Wis., 746.
 stripe, control, Wis., 746.
 stripe, notes, 541.
 treatise, 337.
 varieties, Ind., 132.
 varieties, registration, 433.
 variety tests, 35, 825; Ariz., 731; Ark., 332; Ill., 229, 333; Kans., 822; Minn., 524; Mont., 133; Utah, 525; Wash.Col., 525; Wyo., 526.
 with orange lemmas, 329.
 yields, effect of precipitation and temperature, 413.
 yields, increasing, Mich., 899.
 yields on muck lands, Mich., 823.

Barn roof, Gothic, with sprung rafters, 683.

Bartonella bacilliformis, experimental transmission by ticks, 662.

Basic slag. (See Phosphatic slag.)

Basus stigmaterus, notes, 557.

Bean—

- anthracnose in Canada, physiological study, 148.
 aphid, toxicity of plant products to, 358.
 bacterial blight, weed host, 351.
 bacteriosis, effect of planting 2-year-old seed, Colo., 839.
 beetle, Mexican, control, Ky., 157.
 beetle, Mexican, notes, S.C., 553.

Bean—Continued.

- blight, effect of time of planting, N.Y. State, 241.
- chocolate spot, notes, 747.
- disease, notes, 148.
- fusariosis, notes, 545.
- leaf roller, notes, 155.
- leafhopper, control, Fla., 855.
- mosaic, notes, 648.
- seeds soaked in water, injurious factor, 516.
- stem blight, notes, S.C., 539.

Beans—

- canning, diseases of, Wis., 747.
- canning, inoculation experiments, Wis., 734.
- curing, McNaughton system, Mich., 826.
- disease resistant varieties, 549.
- horse. (*See* Horse beans.)
- Lima, bacterial organisms affecting, Pa., 145.
- Lima, characteristic injury from pod borer, 258.
- Lima, spot disease on, Del., 348.

- Patani, varieties as cover crop, Guam, 228.
- production, U.S.D.A., 528.
- string, losses of vitamin B in cooking, Wis., 794.
- variety tests, Ga. Coastal Plain, 531; Minn., 524.
- (*See also* Mung beans, Soy beans, Velvet beans, etc.)

Bearings—

- full and partial journal, characteristics, 682.
- oil flow in, 578.

Beech wood, hemicelluloses of, 10.

Beechnut cake, poisonous, chemical composition, 202.

Beef—

- blood, chemical composition, 463.
- cost of production, Ill., 385.
- extract, protein in, nutritive value, 290.
- press juices, freezing, 892.
- production, S.C., 560.
- production, economic, Ark., 365.
- refrigeration, studies, 466, 892.
- (*See also* Cattle, beef.)

Beekeepers' Association—

- Maryland State, report, 64.
- of Ontario, report, 461.

Beekeepers, International Congress, proceedings, 662.

Beekeeping—

- in Brazil, textbook, 558.
- in Canada, Can., 461.
- in outyards, 64.
- in Victoria, 462.
- treatise, 662, 760.
- use of calcium cyanide in, 558.

Bees—

- amebic disease of, 856.
- care and product, treatise, 862.
- disease in Great Britain, 760.
- diseases in United States, 558.
- fall management, 64.
- foulbrood. (*See* Foulbrood.)
- individual activities, Iowa, 856.
- intestinal bacteria, 362.
- life-sustaining value of various carbohydrates and honeys, 64.
- of Chile, studies, 65.
- papers on, 461.
- queen, controlled mating, 662.
- queen, rearing, 760.
- recording work of, 662.
- selective breeding and wintering, Wyo., 553.
- studies, Kans., 862.
- wasps, and ants, treatise, 862.
- water carriers and nectar carriers, 159. (*See also* Honey.)

Beet—

- mosaic, notes, 541.
- pulp, feeding value, Idaho, 368.
- tops, feeding value, 471.
- webworm, control, Minn., 557.

Beets—

- crown gall affecting, 653.
- field or fodder. (*See* Mangels.)
- sugar. (*See* Sugar beets.)

Beggiatoa mirabilis, permeability in, 324.*Bembecia marginata*. (*See* Raspberry root borer.)

Benzoate, preservative action in catsup, N.Y.State, 711.

Benzol v. alcohol-benzol mixture for motor plows, 80.

Berries. (*See* Fruits, small, and Raspberries, Strawberries, etc.)

Bibliography of—

- apple diseases in cold storage, 53.

 plant protection, 647.
 plants, sterile culture, 816.
 poultry diseases, 478.
 price fixing 424 B. C.—1926 A. D., U.S.D.A., 388.
 quinhydrone electrode, theory, construction, and operation, 111.
 Ransom, B. H., 755.
 soil moisture control, 177.
 soils, carbon-nitrogen ratio in, 210.
 spray plants, stationary, Calif., 283.
 sugar cane borers, 858.
 tachina fly, red-tailed, Miss., 558.
 tuberculosis of Carnivora, 678.
 wireworms injurious to wheat, Idaho, 64.
 Bichloride of mercury. (*See* Corrosive sublimate.)
 Big mud mite, control, 37, 558.
 Binder and knotter troubles, 384.
 Bindweed, control, Kans., 823.
 Biochemistry—
 lectures on, 408.
 progress in, treatise, 309.
 treatise, 309.
 Blocoenose of spruce budworm, 661.
 Bios activity, studies, 110.
 Birch—
 leaf skeletonizer, paper on, 458.
 river, and sweet gum, soil and moisture relations, 346.
 Birds—
 bred in captivity, records, 657.
 distribution in Ecuador, 657.
 in captivity, management, 56.
 migrations, 75.
 nematodes of, 56.
 of British India, 551.
 of the Netherlands, 754.
 of the State, notes, Ark., 356.
 of western Canada, 754.
 protection, directory of officials for, U.S.D.A., 56.

Birds—Continued.

- protection, international congress for study, proceedings, 456.
 reproduction in, physiology of, 67.
 wild plants and seeds for, 754.
Birgus latro on coconut palm, 58.
 Bituminous paving mixtures, researches on, U.S.D.A., 480.
 Black color inheritance in swine, 729.
 Black scale, control, 555.
 Blackberries, hardness, relation to composition, Mo., 644.
 Blackberry diseases, control, U.S.D.A., 54.
 Blackberry mosaic, notes, 647.
 Blackhead of turkeys, control, Conn.Storrs, 874.
 Blackleg—
 in sheep, immunization, Mont., 173.
 pathology, 174.
 studies, Kans., 875.
 Blandy Experimental Farm, notes, 799.
 Bleaching, dyeing, printing, and finishing industries, activities, 194.
Blepharospira cambivora, notes, 55.
 Blindness in mice, 129.
Blissus leucopterus. (*See* Chinch bug.)
 Blistar beetles on soy beans, control, 860.
 Blister canker, control, Iowa, 849.
 Blood—
 chemical differences, related to sex, 331.
 cholesterol and lecithin in, 14.
 corpuscles, red, in fowls, effect of sex hormones, 769.
 dried. (*See* Dried blood.)
 groups, undescribed anomaly in, 475.
 nitrogen determination in, microcolorimetric, 504.
 of children, effect of irradiated milk, 593.
 of portal vein, sampling method, 775.
 regeneration in anemia, 494.
 serum, calcium determination in, 313, 896.
 sugar, determination, 112, 505.
 sugar of animals, studies, 225.
 transfusion problem, 876.
 uric acid in, cyclic variations, 193.
 Blueberries—
 propagation, Wash.Col., 534.
 wild, tests, Miss., 739.
 Bluegrass—
 Kentucky, metals in, 804.
 pastures, injury from burning off, 433.
 pastures, pests of, Ky., 57.
 Body fluids, iodine in, determination, 312.
Boehmeria nivea, bast fibers of, 697.
 Boll weevil—
 breeding from infested cotton squares, 158.
 control, Ga.Coastal Plain, 558.
 control methods, Miss., 135.
 control, recommendations for, 158.
 control, tests of insecticides, 158.
 injury, relation to age of bolls, 158.
 life history and habits, S.C., 558.
 notes, S.C., 552.

Boll weevil—Continued.

- problem in Arizona, 259.
- senses of, 558.
- studies, Ark., 355; Fla., 861.
- work of Chemical Warfare Service on, 158.

Bollworm—

- eggs, Tripleps attacking, 555.
- notes, S.C., 553.
- pink, in French West Africa, 756.
- pink, in Mexico, biology, 661.
- pink, notes, 553.

Bombyx mori. (See Silkworms.)

Bonbons, recipes, 590.

Bone—

- composition, 14.
- flour, steamed, feeding value, 872.
- formation, effect of fluorine, Ark., 363.
- inorganic composition, 191.
- meal, effect on growth of heifers, 73.
- meal, feeding, effects on hens, Can., 468.
- meal, feeding value, Mont., 164.
- meal, feeding value for range cattle, Tex., 263.
- meal, fertilizing value, 509.

Books on—

- agricultural journalism, 390.
- agricultural surveying, 187.
- animal breeding principles, 760.
- animal pests of economic plants, 355.
- bacteriology of food, 490.
- bacteriophage, 518.
- barley, 337.
- beekeeping, 662, 760.
- beekeeping in Brazil, 558.
- bees, care and product, 862.
- bees, wasps, and ants, 862.
- biochemistry, 309.
- botanical terms, 722.
- botany, descriptive systematic, methods, 812.
- carinations, culture, outdoor and indoor, 837.
- cats, races, breeding, and diseases, 769.

- marketing principles, 187.
- microchemistry, 201.

Books on—Continued.

milk, condensed, and powder, 75.
 milk utilization, 73.
 mineral raw materials for fertilizers,
 world conditions, 720.
 mules, production, 767.
 national formulary, 275.
 oils, essential, 201.
 palms of British India and Ceylon,
 838.
 pathology, 275, 675.
 pathology, chemical, 275.
 photosynthesis, 424, 626.
 physiology, comparative, 774.
 physiology, nutritional, 289.
 plant growth and soil conditions, 714.
 plant physiology, 423.
 plants and man, 123.
 plants, flowering, effective use, 646.
 plants, life of, 626.
 potash, industrial development, 213.
 potato diseases, 50.
 poultry husbandry, 892.
 proteins, chemistry of, applications, 9.
 protozoology, 657.
 protozoology, human, 675.
 quilts, patchwork, history, 397.
 rabbits, raising for fur, 168.
 refrigeration principles, 783.
 research work procedure, 489.
 resins, natural and synthetic, chemis-
 try of, 107.
 road materials, sampling and testing,
 882.
 roof coverings, manufacture and appli-
 cation, 78.
 rural life, 187.
 rural social resources, 487.
 science teaching, 488.
 sedimentation, 619.
 shrubs and flowering trees, 443.
 shrubs and trees of California gardens,
 treatise, 346.
 sisal culture in German East Africa,
 828.
 sociology, rural, 489.
 soil characteristics, 617.
 soil conditions and plant growth, 714.
 spiders, British, 362.
 statistics, elements, 690.
 stresses, statically indeterminate, 780.
 surveying principles and practice, 76.
 tariff and cattle industry, 486.
 tariff on wool, 485.
 teaching of science and the science
 teacher, 488.
 textile fabrics, finishing, 596.
 textiles, 93.
 textiles and clothing, 790.
 timber and underwood industries, treatise,
 487.
 trees, 240.
 trees and shrubs, 443.
 trees and shrubs of California gardens,
 346.
 trees of Great Britain, 646.

Books on—Continued.

vegetables, culture, 833.
 water works practice, 280.
 wheat flour, chemistry of, 108.
 wood, chemistry of, 107.
 wool, tariff on, 485.
 yarns and fabrics, testing, 496.
 Bordeaux mixture—
 effect on transpiration in plants, Kans.,
 813.
 for potatoes, Minn., 547.
 v. copper lime dust, N.Y. Cornell, 351.
 Borna diseases of horses, 878.
 Borrellina, new group of ultramicroscopic
 parasites, 554.
 Botanical—
 microtechnique, manual, 626.
 survey of portions of South Africa, 748.
 Botany—
 Chinese economic, studies, 390.
 descriptive systematic, methods, trea-
 tise, 812.
 dictionary of, 722.
 Botrytis—
cinerea conidia, germination, 748.
cinerea in Alaska, 243.
cinerea, notes, 54.
parasitica, notes, 748.
 sp., notes, Pa., 50.
 spp. causing distinct onion neck-rots,
 450.
 spp., notes, 747.
 Bots in horses, control, U.S.D.A., 259.
 Boys—
 American, increase in stature in last
 fifty years, 897.
 4-H club work, U.S.D.A., 84, 691.
 private school, growth standards, 394.
 training as farmers, 892.
 Bracon—
carpocapsae, notes, Del., 357.
gibbosus, notes, Va., 556.
 Braconidae, new species, and synonymical
 notes, 662.
 Brambles, hardness, relation to composi-
 tion, Mo., 644.
 Bran prices and index, Ohio, 285.
 (See also Rice bran, Wheat bran, etc.)
Braula coeca, paper on, 64.
 Breadfruit v. corn meal for cows, 568.
 Breads, fat content, 312.
 (See also Flour.)
 Breeding. (See Animal breeding, Plant
 breeding, and specific plants and animals.)
Bremia lactucae, notes, 748.
 Bridge floors, concrete v. timber for,
 U.S.D.A., 177.
 British Goat Society yearbook, 71.
 Broomcorn—
 bacterial disease, 47.
 culture in New Mexico, 35.
 variety tests, Can., 432.
 Brown rot diseases, notes, 747.
 Brown-tail moth in Nova Scotia, control,
 458.

- Brucella*—
abortus and *B. melitensis-paramelitensis*, differentiation, 776.
abortus infection in man, 174.
melitensis abortus, notes, 877.
- Brückner cycle in United States, U.S.D.A., 712.
- Brussels sprouts—
 black rot, control, N.Y.State, 242.
 seed beds, corrosive sublimate treatment for, N.Y.State, 846.
- Bryophyllum calycinum*—
 isolated piece, regeneration, 324.
 tumor formation in, 541.
- Bucculatrix canadensisella*, paper on, 458.
- Buckwheat, ground whole, feeding value, Pa., 169.
- Bud moth, eye-spotted, biology, enemies, and control, 360.
- Bud worm, green, biology, enemies, and control, 360.
- Budgets, family—
 making, 489.
 methods of conducting inquiries, 890.
- Buds, accessory, studies, 326.
- Buffer solutions, new set, 503.
- Building—
 code requirements, recommended, 780.
 materials, sampling and testing, 882.
- Bulb fly, lesser, in Oregon, 259.
- Bulbs—
 American, behavior in forcing house, U.S.D.A., 743.
 Dutch flowering, heteroploidy and somatic variation in, 634.
 in storage, aphids infesting, 60.
 rotting diseases, 446.
- Bull snake as enemy of rodents, 56.
- Bumblebees, rearing in artificial nests, 759.
- Bunt. (*See* Wheat smut, stinking.)
- Buprestidae of North America, 661.
- Bureau of Entomology, directory of field activities, U.S.D.A., 553.
- Burlap, value against frosts, 239.
- Busseola fusca*, control, 858.
- Busses, use on rural highways, U.S.D.A., 384.
- Butter—
 adulterated, detection, miscibility tests in, 205.
 analysis, 506.
 bacteria in, effect on quality, 674.
 Canadian creamery, manufacture, 673.
 carbonation of, 74.
 deterioration, peroxidase as factor, 274, 612.
 effect of ground soy beans and cottonseed meal on, S.Dak., 671.
 effect on hemoglobin production, 495.
 fat. (*See* Milk fat.)
 freight rates, Ohio, 285.
 keeping quality, factors affecting, 274.
 making, neutralization of cream for, 474.
 making, starters for, Ark., 377.
 print, shrinkage, 674.
- Butter—Continued.
 printing, effect, Ill., 376.
 quality, effect of care of churn, 74.
 quality, effect of cream quality, Ill., 273.
 quality, factors affecting, S.Dak., 570.
 quality, relation to bacteria, 674.
 sampling and testing methods, Vt., 570.
 sorting, rapid method for, 615.
 sweet cream, keeping quality, 474.
 synthetic, bacteria in, proteolytic action, 610.
 vitamin A in, effect of different feeds, 472.
- Buttermilk—
 fat lost in, Ill., 273.
 feeding value for chicks, Can., 469.
 semisolid, feeding value, Wis., 765.
 v. meat meal for laying hens, Minn., 567.
- Cabbage—
 black rot, control, N.Y.State, 242.
 breeding experiments, Del., 342.
 disease resistant varieties, 549.
 diseases, U.S.D.A., 749.
 diseases in Indiana, 649.
 Iacope, tests, Iowa, 841.
 injury from copper, Del., 324.
 leaf spot, notes, 145.
 maggot, control, 63.
 proteins of, 709.
 seed beds, corrosive sublimate treatment for, N.Y.State, 846.
 self-pollination, effect, Pa., 139.
 soluble calcium and phosphorus in, 108.
 variety tests, Can., 432.
 yellows in seedlings, factors affecting, 448.
 yellows, notes, Kans., 842.
 yellows-resistant types, Wis., 740.
- Cacao curing, 45.
- Cacao meal, palatability and feeding value, 472.
- Cacao pests, life history and habits, 757.
- Cacao, tests, 532.
- Cacao witch-broom disease, notes, 843.
- Cacoccia*—
fumiferana, studies, 460.
 spp., notes, 58.
- Cactus, tree, growth and permeability of century-old cells, 516.
- Cactuses, ancestral lines, 46.
 (*See also* *Opuntia*.)
- Cadelle, summary, U.S.D.A., 259.
- Calcification processes, studying, use of rabbit for, 593.
- Calcium—
 absorption in intestines, 192.
 arsenate v. sodium fluosilicate for boll-weevil control, 158.
 arsenate-lime-sulfur spray, 107.
 assimilation, dietary factors affecting, 464.
 carbonate, effect on availability of phosphate, 624.
 carbonate, effect on soil reaction, 22.

Calcium—Continued.

- chloride action on cements, U.S.D.A., 882.
- chloride, effect on concrete, 77.
- consumption of children, Ohio, 493.
- cyanamide, composting with soil, effect, 321.
- cyanamide, production, 626.
- cyanide as pest control, 358.
- cyanide as soil fumigant for wire-worms, 157.
- cyanide, use in bee culture, 558.
- deficient diets, value of egg yolk in, 293.
- determination in bone, 14.
- equilibrium in milking cows, effect of sunlight, 464.
- exchangeable, availability in soils, 416.
- excretion, effect of potassium intake, 465.
- fixation from burnt limes, limestone, and dolomite incorporations in soil, 214.
- hydroxide, effect on sulfate losses from soils, 214.
- in blood of birds, changes in during reproductive cycle, 67.
- in blood serum, determination, 313, 896.
- in milk, utilization, Kans., 896.
- losses from limed soils, 721.
- losses from soil, factors affecting, 213.
- metabolism, effect of fresh and heated milk, 292.
- metabolism in rats, 293.
- metabolism with hydrochloric acid milk, 393.
- oxalate monohydrate and trihydrate in plants, 628.
- silicates, synthetic, as source of lime, 215, 625.
- soluble, in cabbage, 108.
- (See also Lime.)
- Calendra oryza.* (See Rice weevil.)
- Califorange, preparation and antiscorbutic properties, 296.
- California—
 - Forest Experiment Station, notes, 198.
 - Station, notes, 196, 699.
 - University, notes, 196, 699.
- Calliptamus italicus*, control, 256.
- Calluna vulgaris*, development of mycorrhiza in, 726.
- Calocoris fulvomaculatus*, notes, 58.
- Calotermes* spp., notes, 462.
- Calves—
 - dairy, raising, 672.
 - fattening, Ariz., 560.
 - feeding experiments, Kans., 871.
 - growth, effect of sunlight, Kans., 871.
 - lungs, protein in, nutritive value, 290.
 - rations for, Wash.Col., 569; Wis., 772.
 - self-feeders for, S.Dak., 671.
 - steer, feeding experiments, Ohio, 261.
 - vitamin A requirement, 169.
 - vitamin B requirement, Pa., 168.

- Camarosporium abietis* n.sp., notes, 753.
- Camel specialist, report, 678.
- Camphor thrips, notes, Fla., 152.
- Campoplex* spp., notes, Va., 556.
- Campsomeris annulata*, notes, U.S.D.A., 860.
- Canadian Seed Growers' Association, report, 738.
- Canaries, sex-linkage and other genetical phenomena, 818.
- Cancer, nature of, genetic studies, 225.
- Candy making, recipes, 590.
- Cane. (See Sugar cane.)
- Canning—
 - non-acid vegetables, Fla., 894.
 - of foods, theory and practice, 413.
- Cantaloupes. (See Muskmelons.)
- Capon production, 769.
- Carbohydrate—
 - consumption of children, Ohio, 493.
 - metabolism, studies, 87.
 - splitting in plants, mechanism, 425.
- Carbohydrates—
 - effect on calcium and phosphorus absorption, 192.
 - growth response to, 25.
 - in corn crosses, inheritance, Iowa, 519.
 - in corn, inheritance, 29.
 - in corn, variations, S. Dak., 627.
 - in developing flower and fruit of apple, N.Y.Cornell, 344.
- Carbon—
 - assimilation by green plants, 424.
 - deposition in internal-combustion engine, 78.
 - deposits from typical automobile oils, 579.
 - dioxide assimilation, 628.
 - dioxide determination, apparatus for, 13.
 - dioxide, effect on dairy products, 74.
 - dioxide, effect on pH of soils, Wis., 715.
 - dioxide fertilization, 41.
 - dioxide gas, fire protection by, Colo., 881.
 - dioxide, rôle in crop rotation, Colo., 810.
 - disulfide, discovery of insecticidal property, 554.
 - monoxide and hydrogen mixtures, synthetic motor fuel, 576.
 - tetrachloride damage to liver, factors affecting, 572.
 - transformations in cellulose decomposition, 421.
- Carbonate determination in bone, 14.
- Carbonates, concentration in Minnesota soils, 210.
- Carnations—
 - culture, outdoor and indoor, treatise, 837.
 - notes, Ill., 234.
- Carpellody in corn, 29.
- Carpocapsa pomonella.* (See Coddling moth.)

- Carrot—
 black rot, studies, 545.
 decay, cause, 350.
 Rhizoctonia crown rot, notes, Kans., 842.
 rust fly, control, 63.
 weevil, notes, Iowa, 855.
- Carrots—
 culture experiments, Can., 433.
 proteins of, 709.
 storage, relation to black rot, 545.
 variety tests, Can., 432.
- Casein, phosphorus nucleus of, 709.
- Castor—
 beans in central Asia, 433.
 cake, decomposition, 420.
- Castration, effect on horn development in Merino sheep, 663.
- Catalase activity—
 and rice germination, 725.
 determination in plant tissue, 814.
- Catalpa plantations, cuttings in, Pa., 142.
- Catarrh, chronic nasal, in horses, autogenous vaccines for, 777.
- Cats—
 races, breeding, and diseases, treatise, 769.
 relation to human skin disease, U.S.D.A., 776.
- Catsup, preservative action of ingredients, N.Y.State, 711.
- Cattle—
 age and quality of offspring, 729.
 baby beef, feeding and grazing experiment, Tenn., 163.
 baby beef, feeding experiments, Kans., 364.
 baby beef, stanchion-feeding v. group-feeding, Ohio, 262.
 beef, buying and feeding, 863.
 beef, feeding experiments, Ill., 262; Iowa, 863; Kans., 863; Wis., 762.
 (See also Calves, Cows, and Steers.)
 beef, feeding in California, 863.
 beef, prices and production, Iowa, 887.
 beef, production in Kansas, U.S.D.A., 288.
 Bhagnari breed, description, 763.
 breeding herd, maintenance, Ill., 366.
 breeds and types in Dutch East Indies, 70.
 British Dairy Shorthorn, development, 817.
 cost of production, Ill., 285.
 dairy—
 effect of self-feeding, Ill., 375.
 feeding, 271.
 feeding demonstrations, 568.
 feeding experiments, Ark., 375; Can., 772; Ill., 271; Kans., 870; S.Dak., 671; Wis., 771.
 feeds for, Kans., 871.
 fly repellents for, Kans., 871.
 improvement, Ind., 272.
 mineral supplements for, Ariz., 771.
- Cattle—Continued.
 dairy—continued.
 protein requirements, Vt., 568.
 surface area estimation, use, Mo., 161.
 (See also Cows.)
 disease, obscure hemorrhagic, Nev., 278.
 diseases, notes, Utah, 571.
 (See also specific diseases.)
 effect of winter rations on gains, U.S.D.A., 163.
 feeding and dairy control, congress for, proceedings, 770.
 feeding enterprise, economic study, Iowa, 886.
 feeding experiments, Ariz., 762; Kans., 364; Minn., 559.
 feeding experiments, application of biometry to, 863.
 (See also Cattle, beef, and dairy, Calves, Cows, and Steers.)
 Guernsey and Holstein, persistency of lactation in, Ill., 375.
 heat production, effect of air temperature, 161.
 Holstein, variations in color patterns, 223.
 industry and tariff, treatise, 486.
 industry survey in sand hills, Nebr., 582.
 lice, control, 156.
 mineral deficiency in rations, Minn., 366.
 pasture values and methods for, Kans., 865.
 plague. (See Rinderpest.)
 poisoning. (See Livestock poisoning, Plants, poisonous, and specific plants.)
 purebred v. scrub, N.Dak., 559.
 shipping to Britain from Canada, 70.
 Shorthorn, German bred, morphological studies, 763.
 statistics of New Mexico, 70.
 sterility in, problem, Mich., 398.
 types in different countries, 763.
 (See also Calves, Cows, Heifers, and Steers.)
- Cauliflower—
 bacterial rot, 351.
 bacteriosis, notes, 541.
 black rot, control, N.Y.State, 242.
 bud, nitrogenous constituents, 9.
 leaf spot, notes, 145.
 seed beds, aphid control in, N.Y.State, 253, 254.
 seed beds, corrosive sublimate treatment for, N.Y.State, 846.
- Cecal abligation in fowls, 176.
- Celery—
 changes in during storage, 439.
 culture experiments, Mont., 138.
 damping-off, control, Fla., 143.
 disease resistant varieties, 549.
 varieties, systematic study, 439.

- Cell division—
activity, release of, 814.
studies, 727.
- Cellomass, digestibility, N.Mex., 159.
- Cells—
and tissues, physical chemistry of, 108.
plant and animal, chondriomes in, 427.
(See also Plant cell.)
- Cellulose—
and wood, chemistry of, treatise, 107.
chemical nature, 123.
decomposition by soil fungi, 421.
decomposition in soil, 211, 808.
digestibility, 261.
effect of bacteria on, 297.
sausage casings, 291.
technical research in, 193.
- Cement—
action of calcium chloride on, U.S.D.A., 882.
high alumina, description and uses, 77.
Portland, action of sulfates on, 281.
(See also Concrete.)
- Cenangium abietis* on western yellow pine, 355.
- Centeter cinerea*, notes, U.S.D.A., 860.
- Centipedes, garden, notes, Calif., 256.
- Cephalosporium*—
asteris, notes, 541.
malorum n.sp., description, 849.
sacchari, notes, Del., 348.
spp. on mushrooms, 847.
- Cephenomyia trompe*, life history, 759.
- Cerambycid larvae, North American, classification and biology, 361.
- Cercospora*—
cruenta, notes, 351.
gossypina, notes, 351.
nicotianae, notes, 452, 648.
sp., notes, Fla., 143.
- Cereal—
disease susceptibility, 648.
diseases in Manitoba, 541.
(See also specific hosts.)
pollen, preservation, 230.
smut, stinking, relation to soil character, 648.
(See also Smut and specific host plants.)
straw, physiological and chemical aspects, N.Y.State, 212.
- Cereals—
chromosome numbers, 127.
fat content, 312.
inheritance studies in, Wash.Col., 543.
quality, relation to seeding practices, 33.
rickets-producing effect, 92.
starch in, genesis, 325.
varieties, registration, 433.
(See also Grain and specific grains.)
- Ceuthorrhynchus pleurostigma*, control, 63.
- Chaetocampa crotonella* n.sp., description, 257.
- Chaetocampa*, new genus, erection, 257.
- Chaetodacus tryoni*, summary, 361.
- Chalcid flies, new, 65.
- Chalcid fly in alfalfa seed, Utah, 553.
- Chalcidoid parasites, new coccid-inhabiting, descriptions, 362.
- Changa. (See Mole cricket.)
- Char filtration, factors affecting, 806.
- Charcoals, adsorbent, studies, 110.
- Cheese—
American, effect on hemoglobin production, 495.
American, pasteurization of curd for, Wis., 773.
cottage, manufacture, Ill., 376; Mich., 275; Nebr., 674.
freight rates, Ohio, 285.
microscopic appearance, 275.
parings, feeding value, Wis., 765.
pimento, defect of, 674.
processed, manufacture and legislation relating to project, 773.
skipper in cured meats, U.S.D.A., 859.
stinker, studies, Wis., 773.
varieties, vitamin A in, 794.
- Chemical—
analysis, methods of American Association of Cereal Chemists, 13.
analysis, treatise, 110.
analysis, volumetric, 804.
products, international trade in, 626.
synonyms and trade names, appendix, 309.
- Chemistry—
and home economics, 801.
applied, progress in, 309.
colloid. (See Colloid chemistry.)
dairy, manual, 310.
food, textbook, 201.
for agricultural students, textbook, 588.
in America, half-century of, treatise, 309.
organic, textbook, 309.
quantitative agricultural, laboratory manual, 408.
surface, introduction, treatise, 501.
- Chenopodium murale*, relation to sugar beet curly top, 51.
- Chermes on silver fir, control, 360.
- Cherries—
cold storage behavior, 141.
Coryneum beijerinckii affecting, 551.
dwarfing, shriveling, and dropping, N.Y.State, 850.
identification of nursery stock, 837.
sour immature, dropping, 536.
sour, response to fertilizers and pruning, N.Y.State, 742.
stocks for, N.Y.State, 235.
- Cherry—
aphid, black, Wis., 755.
blossom wilt, notes, 747.
die-back, notes, 747.
fruit fly, life history and control, N.Y.State, 252, 259.
leaf scorch, notes, 747.
leaf spot, control, Kans., 833; Tenn., 145; Wis., 746.

Cherry—Continued.

- leaf spot, notes, 647.
- stocks behavior in nursery, 44.
- trees, crown gall affecting, 653.
- trees, disbudding experiments, Kans., 833.
- trees, pollination studies, Wis., 740.

Chestnut—

- black canker, control, 55.
- blight in Europe, 55.
- blight in Ontario, 355.
- blight situation, silvicultural aspects, 355.
- canker reported in Belgium, 456.

Chick—

- embryos, development, effect of injections, Conn.Storrs, 869.
- embryos, studies, 462.
- soma, chromosomes of, 816.

Chicken—

- liver, effect on hemoglobin production, 495.
- mite, control, 879.

Chickens—

- breeding, for diarrhea resistance, Ill., 276.
- broiler production, Ariz., 768; Pa., 168.
- caponizing, directions for, 769.
- composition of gains, Ill., 270.
- nutritional requirements, 768.
- spermatozoa production by, effect of feeds, 167.
- standard breeds and varieties, U.S.D.A., 470, 669.
- White Leghorn, growth of skeleton, 669.
- (See also Chicks, Fowls, Hens, Poultry, and Pullets.)

Chicks—

- brooding and pullet development, 670.
- care and management, N.J., 870.
- corn as feed for, deficiency, 767.
- early growth rates, effect of ultra-violet light, 868.
- feed costs in brooding and rearing, Can., 469.
- feeding, Can., 468, 469.
- grit requirements, 166; Ohio, 167.
- growth behind window glass and glass substitute, 868.
- growth rate, effect of minerals, Wis., 767.
- hatching and raising, 671.
- milk for, value, Iowa, 869.
- nutrient requirements, Nebr., 767.
- ration and method of feeding, N.J., 768.
- rickets in, 869.
- starvation period, Can., 468.

Chigger, tree-toad, life history and biology, 760.

Children—

- development and parental education, 588.
- diabetic diets for, 92, 93.
- growth, effects of supplementary lunches, 693.

Children—Continued.

- health in, clinical signs, 90.
- mental growth, effect of nutrition, 897.
- mineral consumption, Ohio, 493.
- rural school, nutritional survey, Fla., 897.
- undernourished, metabolism, 395.
- underweight, tuberculosis survey, 495. (See also Boys, Girls, and Infants.)

Chilo loftini, notes, 155.*Chilocorus schiodtii*, notes, 756.

Chinch bug—

- injury to sorghum varieties, Kans., 822.
- on St. Augustine grass, control, Fla., 555.

Chinese—

- cabbage leaf spot, notes, 145.
- diet, adequacy, 793.

Chionaspis citri, notes, 552.

Chlorination of wool, 596.

Chlorine—

- determination in foods, 14.
- excretion, effect of potassium intake, 465.
- in rain and snow, U.S.D.A., 321.
- in tobacco, effect, 437.
- ions, selective absorption, 724.

Chlorophyll and carotin pigments in corn, inheritance, 30.

Chloroplasts, rôle in albumin formation in plants, 814.

Chlorosis of barley, 724.

Choanephora cucurbitarum on *Amarantus*, 456.

Chocolate—

- as source of protein in diet, 491.
- milk, preparation, Pa., 171.

Chokecherries, notes, S.Dak., 532.

Cholesterol—

- in blood, determination, 14.
- irradiated, antirachitic value, 202.
- irradiated, fractionation, 203.
- polymerization, 10.

Choline in yeast, 9.

Chondriomes in animal and plant cells, 427.

Chromatin and cytoplasm, comparative morphology, 516.

Chromosome Y, genetic factors in, 27.

Chromosomes—

- behavior in *Oenothera*, 727.
- behavior in triploid wheat hybrids, 633.
- behavior in wheat and rye hybrids, 634.
- distances and coincidence, standard errors of, 126.
- homologous, maturation divisions relation to segregation, 327.
- in chick soma, determination, 816.
- morphology in several species, 27.
- mutations in *Datura*, effect of radium, 727.
- number in angiosperms, list, 816.
- number in crop plants, 327.
- number in *Trifolium* species, 28.
- of *Drosophila*, crossing-over in, 816.
- of rodents, 727.
- plant, number and size, 127.

- Chrysomphalus ficus* (aonidium). (See Florida red scale.)
- Chrysopa* sp., notes, 257.
- Churn, care of, effect on butter produced, 74.
- Cicadas of New Jersey, key, 59.
- Cicadula seannotata* (See Leafhopper, six-spotted.)
- Cider, making—
and preservation, Mich., 711.
pasteurization in, 413.
- Cinnabar moth, notes, 659.
- Citricola scale, control, 555.
- Citrus—
aphid, control methods, 60.
aphid, life history notes, Fla., 855.
aphid outbreak, factors affecting, 555.
black spot on dried orange peel from China, 851.
blight, studies, Fla., 839.
canker, notes, 549, 748.
canker, soil inoculated with, effect on citrus seedlings, Fla., 839.
culture, variety and root stock experiments, 45.
diseases and control, treatise, 751.
diseases, notes, 748.
(See also Lemon, Orange, etc.)
flavors, use of fatty oils in, 310.
fruits, coloring, Fla., 814.
fruits, culture in Florida, economic aspects, U.S.D.A., 583.
fruits, effect of arsenical sprays, 751.
(See also Lemons, Oranges, etc.)
industry in South Africa, 645.
insects, control, Fla., 659.
insects, control, handbook, 555.
melanose, perfect stage of fungus, 152.
nursery stock, scalding, Ariz., 745.
pests in Rhodesia, 57.
scab, cause, 851.
scaly bark, studies, Fla., 839.
seedlings, absorption of ions by, Calif., 219.
trees, distribution of roots, Ariz., 738.
trees, fertilizer experiments, 45.
trees, improvement by bud selection, 45.
trees, oil sprays for, 254.
- Cladosporium*—
citri, notes, 851.
sp., notes, 549.
- Clay—
action of alkalies on, 510.
determination, Robinson method, 511.
separation into fractions, 510.
soils, acid, formation of hardpan in, 717.
soils, permeability, 618.
suspensions, effect of electrolytes, 416.
- Clay-lime complex, base exchange capacity, 808.
- Clemson College, notes, 900.
- Climographs and biotic regions of Oklahoma, 616.

- Climate—
of British Columbia, 16.
of North Queensland, adaptation of the white man to, 393.
significance for agricultural entomology, 856.
- Climates of California, 207.
- Climatic factors, effect of local influences, U.S.D.A., 712.
- Climatological data. (See Meteorological observations.)
- Climatology and meteorology of Pinheiro, 207.
(See also Meteorology.)
- Closterium acerosum*, rate of reproduction, factors affecting, 517.
- Clostridium*—
botulinum, notes, 589.
botulinum type C food poisoning, anti-toxin for, Ill., 276.
(See also *Bacillus botulinus*.)
butyricum, notes, 674.
chauvei, notes, Kans., 875.
hemolyticus bovis n.sp., description, Nev., 278.
thermocellum end-products, effect of molecular complexity, 109.
- Cloth, action of atmosphere on, 194.
- Clothing—
and textiles, textbook, 790.
choice, care, and cost, treatise, 397.
fabrics, protective value, Kans., 898.
selection and construction, score cards for judging, U.S.D.A., 597.
- Clover—
alsike, seed and hay yields, Ill., 230.
and grass mixtures, comparisons, Can., 432.
breeding experiments, Can., 432.
crimson, proteins of, 708.
diseases in Manitoba, 541.
effect of sulfur, Mont., 123.
energy value for sheep, Ill., 367.
failure, causes, Ky., 750.
fertilizer experiments, Iowa, 811; Ky., 132.
foreign, subject to disease, Ohio, 148.
hay, antirachitic properties, 464.
inoculation experiments, Wis., 734.
leaf curculio, egg studies, 458.
red, anthracnose and mildew susceptibility, 48.
red, anthracnose, cause of clover failure, U.S.D.A., 244.
red, anthracnose resistance, Va., 528.
red, germination of old seeds, 39.
red, hard seeds and broken seedlings in, 826.
red, hay yields, Va., 528.
red, in Wales, insects affecting, 57.
red, proteins of, 708.
red, seed and hay yields, Ill., 231.
red, seed production, Ill., 336.
red, seed, stored, viability of legume bacteria on, Can., 513.
red, seed tests, U.S.D.A., 231.

- Clover—Continued.
 red, variety tests, Can., 432.
 root borer, life history notes, 458.
 root borer, studies, U.S.D.A., 158.
 root rot, studies, 48.
 seed, distinguishing, 337.
 seed, source tests, Iowa, 822.
 seeding experiments, Ind., 132.
 sweet. (*See Sweet clover.*)
 Tifton bur, variety tests, Ga.Coastal Plain, 523.
 varieties, resistance to low temperatures, 735.
 white, variety tests, Can., 432.
 Wood, root-nodule bacteria, 734.
 yields, effect of precipitation and temperature, 413.
- Club work. (*See Boys' and Girls'.*)
- Cnidocampa flavescens.* (*See Oriental moth.*)
- Cobalt in Kentucky bluegrass, 804.
- Coccidae, biology and classification, 858.
- Coccidiosis—
 and bacillary white diarrhea in chicks, 679.
 in feeder cattle, 678.
 in poultry, Wis., 774.
 notes, Colo., 878.
- Coccids—
 of Baden, 856.
 of Soledad, list, 858.
- Coccus hesperidum*, notes, 552.
- Cockchafer, gray-back, notes, 358.
- Cockerels, purebred, effect on hatchability of eggs, Minn., 567.
- Cockroach, Surinam, control, 256.
- Cockroaches of Coachella Valley, California, 251.
- Cocoa—
 as source of protein in diet, 491.
 meal, effect on dairy cattle, Vl., 569.
- Coconut—
 bud rot, control, 751.
 bud rot, eradication, 748.
 bud rot, studies, Fla., 840.
 diseases in British Guiana, 842.
 meal, feeding value, Guam, 265.
 oil and palm kernel oil mixtures, examination, 615.
 palm diseases, 541.
 palm pests, 58, 458.
 red ring disease, 454.
 scale, life history and control work, Guam, 251.
 scale, notes, 756.
- Codling moth—
 affecting cherries, 258.
 bionomics and control, Del., 356.
 control, 258, 660, 758; Colo., 855.
 in Arkansas Valley, 858.
 life history and control, 556.
 life history notes, 61.
 life history studies, Ark., 356; N.Y. State, 252.
 oil spray for, 61.
- Cod-liver oil—
 action of light, 110.
 and butter fat, comparative amounts of vitamins, 490.
 antirachitic properties, variation in, 478, 869.
 effect of ultra-violet irradiation, 503.
 feeding, effect on eggshells, Can., 469.
 feeding, effect on flavor in poultry meat, 670.
 growth-promoting property, 592.
 in diet of mother, effect on vitamin D in milk, 796.
 routine administration, value, 495.
 value for chicks, Minn., 566.
- Coffee—
 berry beetle borer in Dutch East Indies, 856.
 berry borer in Uganda, summary, 362.
 black rot or koleroga, control, 455.
 diseases in Kenya, 455.
 fertilizer experiments, P.R., 345.
 insects affecting, 553.
 insects affecting in Trinidad and Tobago, 659.
 root disease, notes, 851.
 wilt, notes, 843.
- Coleoptera in syllabus of insect biology, 860.
- Coleosporium*—
solidaginis, notes, 54.
tussilaginis, notes, 542.
- Colleges. (*See Agricultural colleges.*)
- Colletotrichum*—
biologicum n.sp., description, 124.
coffeanum, strains, 629.
falcatum, notes, 51.
glocosporioides, notes, 455.
gossypii, notes, 750.
lindemuthianum in Canada, physiological study, 148.
 sp., notes, Fla., 143.
 spp., cultural characteristics, 148.
trifolii cause of clover failure, U.S.D.A., 244.
- Collodion sack method for study of water-soluble constituents of soil, 408.
- Colloid—
 and capillary chemistry, treatise, 201.
 symposium, monograph, 408.
- Colloidal—
 behavior of soils and fertility, 808.
 chemistry, laboratory manual, 501.
 chemistry, new conceptions, treatise, 501.
 soil material, electro dialysis and exchangeable bases, 115.
 soil material, properties, U.S.D.A., 208.
 sulfur as spray material, 47.
- Colloids—
 in soil, nature of, 208.
 metallic, rôle in suppression of detonation, 883.
 soil, base exchange in, 416.
 soil, electrokinetic behavior, relation to base exchange capacity, 415.

- Colloids—Continued.
 soil, relation to plant nutrition, 723.
 soil, studies, 18.
- Color—
 black, inheritance in swine, 729.
 food, development of industry in United States, 590.
 inheritance, black, in swine, 729.
 inheritance in a poultry cross, Kans., 817.
 inheritance in Dachshunds, 129.
 inheritance in goats, 224.
 inheritance in horses, 728.
 inheritance in pigeons, 818.
 inheritance in potatoes, 338, 429.
 inheritance in sheep, 818.
 of aleurone and endosperm in corn, factors for, 519.
 problems in woollen and worsted industries, 95.
 reactions of vitamin A, 10, 410.
- Colorado Station—
 notes, 196.
 report, 899.
- Colorimeter—
 correction curves for sugar, 204.
 new, for small amounts of liquid, 504.
- Colostrum production, 473.
- Colts—
 rations for, Ill., 371.
 soy bean hay for, Ill., 270.
- Combines—
 harvesting and threshing tests, Wis., 778.
 on wheat farms, cost of using U.S.D.A., 785.
 operation tests, 282.
- Community organization, textbook, 187.
 (See also Rural community.)

Feijoas, pollination, 646.

Females, immature, offspring from, Ill., 224.

Fence posts, preservation, Ark., 382.

Fern mite, studies, 65.

Ferments. (*See Enzymes.*)

Fertility in sheep, 668.

Fertilizer—

- experiments, 719, 720; Fla., 811; Iowa, 811.

(*See also special crops.*)

handbook, American, 625.

law, Mo., 322.

mixtures, ternary, geometrical calculation, 119.

spreaders, tests, 80.

Fertilizers—

absorption by Ceylon soils, 419.

analyses, Me., 625.

application on seed and seedling, 212.

composition and prices, N.Y.State, 722.

effect on pH in soil, 419.

effect on plant cell sap, Mich., 318.

effect on potash content of soil, 622.

effect on quality of winter wheat, 639.

for pastures, N.Y.Cornell, 334.

inspection and analyses, Conn.State,

423; Ind., 514; Ky., 216; Mass.,

514; Mo., 322; N.H., 323; N.J.,

514; Tex., 216; Vt., 423.

inspection and analyses in Maryland, 216.

inspection and analyses in New York, 216.

international trade in, 626.

1926 yearbook, 423.

phosphatic, availability on acid and non-acid soils, 121.

treatise, 720.

Festuca ovina, studies, 736.

Feterita, smut resistance in, 246.

Fiber—

cross sections, depicting, 193.

crude. (*See Cellulose.*)

Fibers—

plant, molecular structure, 297.

technical research in, 193.

textile, bacterial decomposition, 297.

Field crops—

breeding work, 630.

in the Ukraine, varietal diversity, 432.

work in British Guiana, 35.

work in England, Northumberland Co., 334.

work in Kenya, 823.

work in Uganda, 823.

(*See also Crops, Forage crops, Root crops, etc.*)

Field—

experiments, arrangement, 332.

experiments, artificial plats for, 227.

experiments, new methods with check plats, 131.

experiments, with cotton, technique, 635.

observations, technique, 113.

plat variability, determinations, 432.

Figs—

fruit fall of, 851.

variety tests, Miss., 739.

Fir—

silver, in Great Britain, relation to chermes, 360.

white, yield, stand, and volume tables, Calif., 240.

Fire blight—

cankers, studies, Ill., 349.

studies, Wis., 746.

Fires—

extinguishing with carbon dioxide gas, Colo., 881.

farm, cause and prevention, 81.

farm, method of study, 283.

forest. (*See Forest fires.*)

Fish—

crushed, decomposition, 420.

guano, decomposition, 420.

liver, effect on hemoglobin production, 495.

meal, feeding value, 766; S.C., 268.

meal, Swedish, composition and feeding value, 666.

meals, studies, 22.

oil as adhesive in lead arsenate sprays, U.S.D.A., 658.

refrigeration and preservation, 413.

Fistulina hepatica in oaks, 753.

Fistulous withers in horses, notes, Kans., 876.

Flax—

and cereal mixture, tests, Wis., 733.

and oats mixtures, tests, Minn., 524.

and wheat mixtures, tests, Minn., 524; Mont., 133.

hemp, and jute yearbook, 297.

pasm disease, 49.

plant, botanical study, 631.

plant characters, effect of fertilizers, 827.

plant, distribution of nitrogen in, 697. production, Wis., 733.

rust, control, Minn., 245.

rust, notes, 847.

seed, infestation by mites, 662.

straw, pulping, chemistry, 698.

variety tests, Minn., 524; Wash.Col., 525.

wilt resistance in, nature, N.Dak., 847. yarns behavior under repeated impacts 94.

Flea bites, reaction to, 660.

Fleas, transmission of plague by, 63.

Flies—

attacking cattle in Dutch East Indies, 461.

Flies—Continued.

- breeding in manure, control, 557.
- house. (*See* House flies.)
- on cultivated mushrooms, control, Pa., 154.
- repellents for cattle, Kans., 871.
- white. (*See* White fly.)

Flood and gravel control, Utah, 576.

Flora of South Africa, treatise, 837.
(*See also* Plants and Vegetation.)

Florida—

- red scale, control, Fla., 855.
- Station, notes, 96, 900.
- Station, report, 195, 899.

Flour—

- ash determination in, 14.
- chemistry of, treatise, 108.
- diastatic activity, control, 204.
- experimental baking test, standardizing, 86.
- fat content, 312.
- fineness, effect on composition and baking quality, U.S.D.A., 390.

- cost of production, Ill., 284.

Milk—Continued.

- dry, fat in, susceptibility to oxidation, 611.
 effect of heat, 291.
 effect on hemoglobin production, 495.
 energy value, related to composition, Ill., 490.
 evaporated, vitamin B in, 190.
 fat and cod-liver oil, comparative amounts of vitamins, 490.
 fat in, Babcock test for, Okla., 171.
 fat in margarine, determination, 615.
 fat, loss from incomplete churning, Ill., 273.
 fat percentage, effect of fat in ration, 672.
 fat percentage, effect of temperature, 170.
 fat percentage, methods of determining, N.Y.State, 773.
 fat production, inheritance of, studies, 272.
 fat, rate of secretion, 473.
 fat secretion, physiology of, 772.
 forms, for growing chickens, comparison, 470.
 fresh and preserved, calcium and phosphorus from, utilization, Kans., 896.
 handling and manufacture of dairy products, treatise, 73.
 heat sterility, relation to bacteria, Wis., 773.
 human, antirachitic properties, 91.
 human, antirachitic properties, effect of irradiation of mother, 295, 593.
 human, production and handling, 292.
 irradiated, effect on blood, 593.
 malted, fat determination in, 412.
 market, improvement, Mich., 376.
 pasteurization, inefficient, causes, Ill., 272.
 pasteurization, studies, 473.
 pasteurization with agitator flash pasteurizers, 474.
 peptic digestion, 292.
 powder, keeping quality, 474.
 powder, keeping quality, effect of clarification, 611.
 powder, treatise, 75.
 production and butterfat percentage from related animals, 170.
 production, effect of gluten feed, 472.
 production, effect of surplus feed, 770.
 production, effect of tethering, 471.
 production, high-grade, essentials, Vt., 570.
 production, indexes for persistency, 170.
 production, inheritance of, studies, 272.
 production, nutrients required in India, 672.
 production, swedes v. silage for, 671.
 ropy, organisms causing, 73.
 secretion, effect of edestin, Ill., 376.
 secretion, experimental disturbances in, 272.

Milk—Continued.

- secretion, physiological factors, 473.
 separated, cell contents of different portions, N.Y.State, 274.
 sickness and acidosis, 572.
 skimmed. (See Skim milk.)
 sweetened condensed, rancidity in, 611.
 sweetened condensed, tallowness in, 612.
 titratable acidity and pH of, effect of heating, 611.
 total solids in, effect of temperature, Ill., 375.
 value for chicks, Iowa, 869.
 vitamin A destruction in by ultra-violet light, 88.
 vitamin B potency, effect of vitamin in ration, Pa., 169.
 yield and quality, effect of stage of lactation and breed, 872.
- Milking—
 machines, care of, Conn.Storrs, 870.
 utensils, sterilizer for, 873.
- Milkweed—
 economic possibilities, Iowa, 832.
 flagellate infection of, 250.
- Milkweeds in Maryland, flagellate infection, 54.
- Millepedes, control, Pa., 154.
- Millet, variety tests, Ga.Coastal Plain, 523.
- Milo kernel smut, control, Kans., 842.
- Milo, smut resistance in, 246.
- Mimorista flavidissimalis*, studies, 58.
- Mineral—
 deficiency in cattle, Minn., 366.
 metabolism of dairy cows, 73; Kans., 870.
 metabolism of horses fed bran exclusively, 72.
 metabolism of lactating animals, effect of ultra-violet light, 73.
 mixtures for pigs, Ky., 164.
 raw materials for fertilizers, world conditions, treatise, 720.
 requirements of range cattle, 263.
 supplements, effect on rats, Iowa, 863.
 supplements for dairy cattle, 872; Wis., 771.
 supplements for pigs, 866; Iowa, 266, 267.
- Minnesota—
 Crookston Substation, report, 598.
 Morris Substation, report, 598.
 University, notes, 196, 798.
- Miris dolabratus*. (See Meadow plant-bug.)
- Mirostroma juglandis*, notes, 647.
- Mississippi Station—
 notes, 900.
 Raymond Branch, report, 797.
 South Branch, report, 797.
- Missouri University, notes, 96, 196, 600.
- Mites—
 infestation of flaxseed by, 662.
 on cultivated mushrooms, control, Pa., 154.
- Mitogenetic rays, 517.

- Mocis repanda*, notes, 552.
 Moist closet, constant temperature, design, U.S.D.A., 882.
 Moisture equivalent of soils, 208, 510.
 Molasses, availability of iron in, 494.
 Mole cricket, Porto Rican, control on golf courses, 359.
Moneilema crassa, studies, 58.
Monilia sitophila, bakery infection with, 391.
 Monkeys, menstrual cycle in, 819.
Monochaetia cryptomeriae n.sp., description, 748.
 Monocotyledons, morphological study, 812.
 Monomolybdophosphotungstic acid, rapid preparation, 12.
 Monophlebinae, classification, 858.
 Montana—
 College, notes, 196, 700, 900.
 Station, notes, 700, 900.
 Station, report, 195.
 Moor Culture Association, Swedish, work of, 824.
 Morning-glory—
 Japanese, deformed leaves in, inheritance, 521.
 wild, control, Utah, 525; Wash.Col., 525.
 Morphogenesis—
 in animals, 331.
 materials for physiology of, 662.
 Mortar strength, effect of grading sand, U.S.D.A., 177.
 Mosaic—
 and related diseases, 648.
 cross-inoculation studies, 48.
 disease viruses, studies, Iowa, 840.
 diseases, studies, 349.
 (See also *specific host plants*.)
 Mosquito larvae, effects of changes of pH value, 461.
 Mosquitoes—
 anopheline, of Japan, revision, 557.
 control work in New Jersey, N.J., 62.
 of British Columbia, control, 557.
 powdered larvicides for, 258.
 (See also *Anopheles and Malaria*.)
 Mosses, genetic studies, 127.
 Moths injurious to fruit, 859.
 Motion pictures—
 of Department of Agriculture, list of films, U.S.D.A., 791.
 use in extension work, U.S.D.A., 791.
 Motor—
 fuels, detonation specifications for, 781.
 fuels, flames of, ultra-violet spectroscopy, 681.
 fuels, petroleum, detonation characteristics, 780.
 truck impact tests, U.S.D.A., 681.
 vehicle revenues, collection and disposition, U.S.D.A., 681.
 Mountain lions in Arizona, habits, 656.
 Muck land, varieties of general crops for, Mich., 823.
 Mulberry bacterial blight in Britain, 654.
 Mules, production, treatise, 767.
 Mung bean disease in Philippines, studies, 351.
 Mung beans, varieties as cover crop, Guam, 228.
 Muriate of potash. (See *Potassium chloride*.)
Musca domestica. (See *House flies*.)
 Muscle, striated and smooth, effect on hemoglobin production, 494.
 Mushroom species, mica ink-cap, notes, N.Y.State, 140.
 Mushrooms—
 cultivated, control of pests, Pa., 154.
 fungus parasite of, Pa., 144.
 in England, diseases of, 847.
 Muskmelon—
 diseases, notes, Del., 348.
 mildew, control, Guam, 245.
 Muskmelons—
 culture in California, Calif., 236.
 disease resistant varieties, 549.
 fertilizer experiments, Ill., 343.
 harvesting and marketing, Colo., 583.
 Mutations—
 in *Habrobracon*, origin, 223.
 in mice, symbols for, 728.
 in sweet potatoes, 328.
 Mutton press juices, freezing, 892.
Mycoderma—
 thöni and *Bacterium casei* ϵ , biology, 473.
 vini, notes, 206.
Mycogone perniciosa—
 notes, Pa., 144.
 on mushrooms, 847.
 Mycorrhiza—
 plants, nutrition, 726.
 tree, studies, 753.
Myrosporium corticola on apple and pear, 353.
Myzaphis abietina, notes, 659.
Myzocallis—
 kahawaluakolani, notes, 256.
 taiwanus n.sp., description, 555.
Myzus—
 cerasi. (See *Cherry aphid, black*.)
 chelidonii, notes, 58.
 houghtonensis. (See *Gooseberry witch-broom aphid*.)
 persicae. (See *Peach aphid, green*.)
 Naphthalene fumigation of greenhouses, 256.
 Narcissus—
 bulb fly, notes, Mich., 361.
 bulbs, disease of, 852.
 bulbs, *Tylenchus dipsaci* on, 456.
 National—
 Agricultural College Student Council, organization, 198.
 Formulary, 275.
 Livestock and Meat Board, report, 466.
 Nebraska University, notes, 197.
Nectria—
 galligena, notes, 747.
 rubi, notes, 354.

- Negro extension work, 1914-1924, U.S.D.A., 85.
- Nematoda families and genera, synopsis, 754.
- Nematode—
larvae behavior in host, Kans., 875.
stem and bulb, present status in America, 54.
- Nematodes—
control, Fla., 152.
in eyes of horses, 678.
of birds, 56.
- Nematus ribesii*—
gynandromorph of, 662.
notes, 659.
- Nephelodes*—
emmedonia, notes, 758.
minians. (See Cutworm, bronzed.)
- Nephelometer, errors in use, 504.
- Neutralizers and starters, Ark., 376.
- Nevada Station, notes, 900.
- Nevada Station, report, 299.
- New Hampshire Station, notes, 498.
- New Mexico College, notes, 197, 498.
- New Mexico Station, notes, 197, 498.
- New York State—
College of Agriculture, research activities, 698.
College of Home Economics, report, 588.
Station, notes, 97, 197, 498.
Station, report, 299.
- Nickel in Kentucky bluegrass, 804.
- Nicotiana*—
deformis n.sp., notes, 429.
rustica, nicotine content, factors affecting, Pa., 134.
tabacum, inheritance in, 631.
- Nicotiana*—
interspecific hybridization in, 632.
pseudo-fertility in, 31.
- Nicotianas* in Argentina, 37.
- Nicotinic acid in yeast, 9.
- Nightshade family as host for *Synchytrium endobioticum*, 651.
- Nile flood and world weather, 807.
- Nitrate—
absorption by oats and cotton, 213.
industry, Chilean, 120.
losses from limed soils, 721.
nitrogen determination, modified method, 805.
of ammonia. (See Ammonium nitrate.)
of soda. (See Sodium nitrate.)
reducing properties of plants, 220.
- Nitrates—
Chilean, production, 626.
distribution in Swedish soils, 120.
excessive production, control, Colo., 810.
formation in volcanic soils, 120.
in rain from protected and exposed gage, 212.
in soil, relation to sweet clover, 210.
losses from soil, factors affecting, 214.
- Nitrates—Continued.
production, 319, 621.
production, effect of sweet clover handling, Ill., 622.
reduction in protein synthesis, 25.
- Nitrification—
effect of sunlight, 21.
effect of temperature and moisture, 720.
- Nitrogen—
and cultivated plants, 119.
compounds in rain and snow, 120; U.S.D.A., 321.
determination in blood, microcolorimetric, 504.
determination, modified method, 805.
distribution in cauliflower, 9.
distribution in flax, 697.
endogenous, of molting hens, 165.
fixation and distribution in soils, Wash.Col., 508.
fixation as aluminum nitride, 623.
fixation by nodule bacteria, tests, 635.
fixation, electric arc process, phenomena in, 623.
fixation, newer developments, 623.
fixation studies at Pusa, 509.
growth response to, 25.
in developing flower and fruit of apple, N.Y.Cornell, 344.
in grain, factors affecting, Wash.Col., 509.
in leaves of crops, daily variation, Kans., 813.
in mixtures of white flour and animal foods, biological value, 188.
in soil, effect on wheat, Idaho, 339.
lime. (See Calcium cyanamide.)
loss from manure, effect of sulfur, 509.
metabolism, effect of fresh and heated milk, 292.
nonprotein, in blood, 193.
requirements of orchard trees, Ohio, 195.
transformations in cellulose decomposition, 421.
urinary, as indication of protein intake, 692.
- Nodule—
bacteria in soil, effect of supplementing with artificial cultures, 21.
bacteria, longevity, 35.
bacteria, nitrogen fixation by, tests, 635.
bacteria of Leguminosae, Wis., 526.
bacteria, viability outside of the plant, 123.
formation, lack of in subfamily of Leguminosae, 124.
(See also Legumes, inoculation.)
- North Dakota—
biological survey, U.S.D.A., 656.
Station, notes, 498.
- Northeastern Forest Experiment Station, notes, 97.
- Notolophus posticus*, life history notes, 61.
- Nubbin, chromosomal constitution, 727.

Nursery—

inspection to eliminate variety mixtures, 344.

stock identification, 837.

Nut trees in Illinois, insects affecting, 555.

Nutrient media. (See Culture media.)

Nutrition—

and health, 588.

animal. (See Animal nutrition.)

effect on mental growth, 897.

experiments, synthetic diets for, 693.

laboratory, report, 791.

plant. (See Plant nutrition.)

Nyssus sp. injurious in Queensland, 757.

Nyssus gallinae. (See Chicken mite.)

Oak mildew in Russia, 551.

Oaks—

growth, relation to acorn weight, 444.

hollowness and stag-headedness in, 753.

insects affecting, 555.

Oat—

and pea mixtures, tests, Ill., 334.

and pea silage. (See Silage.)

and vetch mixtures, tests, Ill., 334.

feed, feeding value, Iowa, 266.

flour, fat content, 312.

hulls, furfural manufacture from, 313.

hybrids, rust resistance of, Iowa, 841.

loose smut, infection and susceptibility, 448.

nematodes, notes, 541.

smut, control, 147, 350; Kans., 842.

smut infection, factors affecting, 651.

smut, loose, life history and control, 543.

smut resistant strains, Kans., 822.

smut, stinking, control in Uruguay, 543.

smuts, physiologic races, 650.

stem rust, physiological specialization, Minn., 447.

straw, effect on soil fertility, 119.

straw, energy value for sheep, Ill., 367.

yields, increasing, Mich., 899.

Oatmeal proteins, dietetic value, 391.

Oats—

and flax mixtures, tests, Minn., 524.

breeding experiments, Ark., 332; Ill., 333; Wash.Col., 525.

carbon dioxide output, effect of anesthetics, 125.

correlated inheritance of characters, W.Va., 519.

cost of production, Ill., 385.

cultural and planting tests, Kans., 822.

culture experiments, 35.

dwarfing in, Minn., 222.

effect of fallow, Wyo., 825.

false wild forms in, 429.

false wild, origin, 27.

feeding value, Ill., 370; Iowa, 266.

fertilizer experiments, Ga.Coastal Plain, 523; Iowa, 811; Miss., 731; S.C., 525; Tenn., 531.

Fulghum, value, Tenn., 436.

improvement, Kans., 822.

Oats—Continued.

prices and index, Ohio, 285.

pure lines, effect of climatic conditions, 730.

rate of absorption of sodium nitrate, 213.

recovery power after injury, 63.

seed, injury from smut disinfection, 147.

seeding experiments, 825; Tenn., 531; Wis., 732.

seeds, frosted, germination, Colo., 820.

varieties, Ind., 132.

varieties and strains, registration, 433.

varieties, yields, Ill., 230.

variety tests, 35, 825; Ariz., 731; Ark., 332; Fla., 821; Ga.Coastal Plain, 523; Ill., 333; Iowa, 821; Kans., 822; Minn., 524; Mont., 133; Tenn., 530; Wash.Col., 525; Wyo., 526.

wild, control, Mont., 133.

winter, breeding for the South, 636.

yields, effect of weather, 207, 413.

yields on muck lands, Mich., 823.

yields, trend in, U.S.D.A., 685.

Ochromoigenia ormioides, notes, U.S.D.A., 860.

Oedemagena tarandi, life history, 759.

Oenothera—

hybrids, studies, 31.

old-gold flower color in, inheritance, 521.

pollen mother cells, meiosis in, 521.

Renner's studies on genetics of, 31.

third linkage group in, 130.

Oenothera—

lamarckiana, brittle races of, 521.

lamarckiana, chromosome behavior in, 727.

muricata, meiosis in anthers, 428.

nanella-brevistylis, segregation, 330.

Oestrous cycle—

and menstrual cycle, differences, 226.

effect of thyroid feeding, 465.

in albino mice, 663.

Office of Experiment Stations, notes, 198, 799.

Ohio—

State University, notes, 600.

Station, bimonthly bulletin, 195, 299.

Oidium lactis growth, effects of salt and pH, 350.

Oil—

and color chemistry, monograph, 507.

burners for domestic use, U.S.D.A., 598.

meal. (See Linseed meal.)

palm diseases, 541.

palms, African, germination of seeds, 45.

palms, growth and correlation in, 45.

sprays, notes, 458.

sprays, tests, 254.

sprays, use on citrus trees, 254.

Oils—

automobile, carbon deposits from, 579.

chemistry of, new aspects, 801.

essential, treatise, 201.

Oils—Continued.

- lightwood, oxidation and hydrolysis, 801.
- lubricating, emulsions, insecticidal value, 60.
- lubricating value, 577.
- of sweet clover seed, 502.
- textile, for dyeing and finishing of cotton, 93.
- (See also Fats, Corn oil, Cottonseed oil, Olive oil, etc.)

Okra seed composition, 502.

Oleomargarine. (See Margarine.)

Oligosita xiphidii n.sp., description, 760.

Olive—

- floral anomalies in, 629.
- oil, Tunisian, composition, 710.

Olives—

- curing, cause of floaters in, 206.
- effect of pruning, Ariz., 739.
- fumigation with calcium cyanide, 659.
- scale insect affecting, 555.

Olla abdominalis sobrina, notes, 257.*Onchocerca volvulus* development in *Simulium damnosum*, 62.*Oncopeltus fasciatus*, notes, 250.

Onion—

- Botrytis neck rots, notes, 450.
- bulb rot, cause, 450.
- diseases, notes, 747.
- diseases, resistance to, 450; Wis., 745.
- maggot, control, 63.
- pink root, causal organism, studies, 246.
- smut, control, 451, 847.
- thrips control in greenhouses, 256.
- white rot in Europe and America, 351.

Onions—

- Spanish types, notes, Utah, 533.
- wild, eradication, Tenn., 439.
- yields, Colo., 831.

Ontogeny, physiological, 462.

Oogenesis in white mice, 127.

Oospora—

- mall* n.sp., description, 849.
- scabics*. (See Potato scab.)

Operating statement for business, making, analysis, and use, 790.

Ophideris fullonica, notes, 756.*Ophiobolus*—

- cariceti* in western Canada, 350.
- graminis* growth, effect of soil reaction, 243.
- graminis*, notes, 448; Kans., 841.

Opuntia insects of United States, 58.

Orange—

- center rot, notes, 748.
- juice, concentrated, vitamin C in, 296.
- juice, irradiated, antirachitic value, 91.
- peel, dried, black spot on, 851.
- pulp, dried, digestibility by ruminants, Calif., 261.
- trees, cincturing and root pruning tests, 645.

Oranges—

- bud mutation in, 45.
- effect of arsenical sprays, 751.
- Satsuma, propagation, Fla., 832.
- variety and root stock experiments, 45.
- Washington Navel, cool storage, 851.
- Washington Navel, strains, Ariz., 739.

Orchard—

- cover crops, hardy, 344.
- grass, correlations in, 816.
- management, studies, Iowa, 833.
- soils, bacterial activities in, 512.

Orchards—

- fertilizer experiments, Wash.Col., 533.
- irrigation, U.S.D.A., 834.
- judging, score cards for, 790.
- planting and thinning distances, Calif., 534.
- rabbit and mouse control in, Mo., 355.
- soil management studies, Mont., 138; Pa., 139.
- (See also Fruits, Apples, Peaches, etc.)

Orchid—

- seedlings, culture, Ill., 344.
- seedlings from crosses, Ill., 235.
- seeds, symbiotic germination, 24.
- seeds, symbiotic germination, 24.

Oregon—

- College, notes, 97.
- Station, notes, 97.

Organic matter—

- changes in two soil zones, 721.
- in heavy alkaline soils, 718.
- in soil, function, 621.
- in soil, origin and nature, 620.
- maintenance in soils, Wash.Col., 508.

Orgilus obscuratus, notes, 361.*Orygia antiqua*, notes, 659.

Oriental—

- moth, papers on, 253.
- peach moth. (See Peach moth.)

Ornamental plants, shrubs, and trees. (See Plants, Shrubs, and Trees.)

Ornithology, advancement in, 56.

Orobanche hederæ, anatomy and attachment to host, 427.

Oroya fever, etiology, 662.

Oryzaephilus surinamensis. (See Grain beetle, saw-toothed.)*Oscinella frit* injury to oats, studies, 63.

Ova, migration from one horn of uterus to other in rats, 68.

Ovarian hormone administration, subcutaneous v. intraperitoneal, 729.

Overall shrinkage, 595.

Ovoferrin, availability of iron in, 494.

Ovulation—

- in rabbits, 331.
- time of in menstrual cycle of monkey, 227.

Ox blood, protein in, nutritive value, 290.

Ox palates, protein in, nutritive value, 290.

Oxen, yoking, new system, 480.

Oxyuridae behavior in host, Kans., 876.

- Oysters—
 canned, antirachitic value, Wis., 794.
 nutritional value, 793.
- Ozonium root rot, studies, U.S.D.A., 145.
- Paddy. (See Rice.)
- Paint and varnish industries, volatile solvents used in, 507.
- Paints and varnishes, analysis, 313.
- Palm—
 bud rot in south India, operations against, 751.
 coconut. (See Coconut.)
 kernel oil and coconut oil mixtures, examination, 615.
- Palms—
 of British India and Ceylon, treatise, 838.
 of Florida, descriptions, Fla., 538.
 oil. (See Oil palms.)
- Pandemis, life history studies, 858.
Pandemis limatata, notes, Pa., 154.
- Papayas, vitamins in, 87.
- Paper—
 making materials, technical research in, 193.
 mulch, effect on pineapple culture, 537.
 mulch, effects on Hawaiian soils, 209.
 pulp, digestibility, 261; N.Mex., 159.
 pulp from waste Kauri wood, 647.
- Para B-suipestifer group, variation in, 475.
- Paradevescovina, new genus, erection, 462.
- Paradichlorobenzene as soil fumigant, Calif., 255.
- Paraheliotropism, physiology, 326.

 in pigs, 678.
 range, of poultry, Mich., 878.
 tick, in Australia, 476.
- Parasite of sheep muscle, studies, Wyo., 574.
- Parasites—
 and hosts, cellular interaction, 452.
 and parasitic diseases of goats, 678.
 and predators of sugar cane borers, 858.
 animal, identification, 675.
 animal, of man, clinic and therapy, 775.
 animal, of man, natural history, 775.
 animal, of man, X-ray diagnosis, 173.
 animal, precipitin reactions of extracts, 173.
 chalcid, feeding habits, 862.
 ecology, 57.
 fungus, of plants, 843.
 in poultry, 175.
 intestinal, control, 879.
 intestinal, of poultry, removal, 575.
 metazoan, of poultry in Australia, 778.
 new coccid-inhabiting chalcidoid, descriptions, 362.
 new, from Syrphidae, 760.
 of Japanese beetle, summary, U.S.D.A., 860.
 rearing, type of cage for, 854.
 sensitizing powers, 776.
 ultramicroscopic, studies, 554.
- Parasitism, physiology of, 843.
Paratettia teanus, parthenogenesis in, 31.
 Paratyphoid? and Hymenoptera, 362.
 Paratyphoid in chicks, Kans., 875.
 Parsnips, proteins of, 709.
Paspalum dilatatum, spacing experiments, Guam, 228.
- Pasteurella*—
avicida, bacterins from, Kans., 875.
muricida n.sp., notes, 656.
- Pasteurization. (See Milk and Cream.)
- Pasture—
 grasses, studies, Kans., 865.
 plants, characteristics of roots, 824.
 plants of East Africa, 334.
 tests for cattle, Minn., 559.
- Pastures—
 fertilizer experiments, Conn.Storrs, 821; Fla., 821; Ind., 132.
 grazing studies, Colo., 820.
 irrigated, studies, Kans., 865.
 permanent, studies, Wash.Col., 824.
 studies, N.Y.Cornell, 334; S.C., 525.
 (See also Grasses and Grasslands.)
- Pathology—
 chemical, treatise, 275.
 textbook, 275, 675.
- Paving mixtures, bituminous, researches on, U.S.D.A., 480.
- Pea—
 and oat mixtures, tests, Ill., 334.
 aphid in California, 257.
 aphids, parasitic control, Wis., 756.
 blight, notes, Wis., 747.
 mosaic, notes, 349.
 moth, notes, 659.
 pollen, preservation, 230.
 root rot and blight, 351.
 root rot, notes, Wis., 747.
 seeds, ashing methods, 13.
 (See also Peas.)
- Peach—
 aphid, green, notes, N.Y.State, 253.
 bacterial leaf spot, studies, Del., 348.
 bacterial spot, control, 453; Ill., 241.
 bacterial spot, notes, 647.
 borer, control, 360.
 borer, control with paradichlorobenzene, 460.
 borer, lesser, in South Dakota, S.Dak., 659.
 borer, western, control, Calif., 255.
 brown-pocket heart rot, studies, 152.
 brown-rot fungus, studies, 453.
 brown-rot mummies, longevity, Md., 748.
 cottony scale, summary, N.Y.State, 257.
 leaf curl, control, Ill., 349.
 leaf curl, notes, Utah, 540.
 moth, oriental—
 in Canada, 458.
 in Ohio, 859.
 life history studies, Pa., 153.
 on apples, Del., 356.
 paper on, 253.
 studies, 359.
 summary, U.S.D.A., 258.

Peach—Continued.

- orchards, establishing, Miss., 44.
- shot hole, control, 453.
- trees, summer pruning, Ill., 234.
- trees worked on Marianna plum, results, 141.
- yellows, insect carriers, possibility, Del., 348.

Peaches—

- breeding experiments, Ill., 233, 343.
- Coryneum beijerinckii* affecting, 551.
- disease resistant varieties, 549.
- dusting v. spraying, Miss., 739.
- Elberta, growth of fruit, 237.
- fertilizer experiments, Ark., 341; S.C., 532.
- harvested immaturely, effect, Wash.Col., 533.
- identification of nursery stock, 837.
- pectic constituents, relation to softening of fruit, Md., 644.
- spray injury to, 47.
- varieties, productivity and bud hardness, Ind., 141.
- variety tests, Ga.Coastal Plain, 531; Miss., 739.
- winter injury to, Utah, 533.

Peanut—

- cake, decomposition, 420.
- cake, fertilizing value, 509.
- meal, composition and use as diabetic food, 92.
- oil feed, feeding value, S.C., 268.
- rosette, notes, 748.
- rosette, studies, 751.

Peanuts—

- breeding experiments, Fla., 821.
- fertilizer experiments, Fla., 821; Ga. Coastal Plain, 523.
- hogging down, S.C., 565.
- production in Gambia, 736.
- variety tests, Ark., 332; Fla., 821; S.C., 525.

Pear—

- black scab, notes, 747.
- blight cankers, control, 453.
- blight resistant varieties, Tenn., 145.
- canker, notes, 747.
- canker, unusual form, 654.
- fire blight, studies, Ill., 241.
- fruit rot, notes, 747.
- midge, control, 661.
- midge, parasites of, establishment in New Zealand, 661.
- psylla, control, 458.
- root aphid, control, Calif., 255.
- root rot, notes, 748.
- rot, notes, 541.
- scab, notes, 747.
- scab, studies, 849.
- stocks, crown gall affecting, 653.
- trees, young, effect of tying down limbs, 141.

Pears—

- breeding experiments, S.Dak., 641.
- fertilizer experiments, 43.

Pears—Continued.

- identification of nursery stock, 837.
- pollen sterility in, 643.
- pollination tests, Wash.Col., 533.
- spray injury to, 47.
- spray residues, removal from, 442.
- vitamin C in, Kans., 894.

Peas—

- canning, Ascochyta blight of, N.Y.State, 241.
- canning, breeding experiments, Wis., 739.
- canning, improvement, Wis., 236.
- canning, losses in Ontario, cause, 351.
- canning, variety tests, S.Dak., 641.
- dusting by airplane, 57.
- irrigation experiments, Utah, 525.
- seeding experiments, 825; Wis., 732.
- uses in the diet, 291, 589.
- variety tests, Ga.Coastal Plain, 523, 531.
- yield, effect of weather, 207.

Peat—

- bibliography of, U.S.D.A., 421.
- deposits in New England, profiles, 212.
- lands, problems in selection, U.S.D.A., 212.
- marshes, fill settlement in, U.S.D.A., 882.
- soil, analysis of crops as index of fertility, 120.
- soil types, fertilization and yield on, 824.

Pecan—

- diseases, control, Fla., 852.
- insects, notes, Fla., 855.
- scab, studies, Fla., 839.

Pecans—

- culture experiments, Kans., 833.
- fertilizer experiments, Fla., 832.
- fruit-bud differentiation and flower development, 142.
- growth curve, Fla., 832.
- varieties, Ariz., 739.
- varieties, food and timber value, Iowa, 833.
- variety tests, Miss., 739.

Pectates, insoluble, studies, 613.

Pectic acid, studies, 613.

Pectin—

- acetyl groups in, 311.
- ash-free, methods of obtaining, 10.
- rôle in jelly making, Del., 392.
- sols, viscosity, 310.

Pectinase of *Sclerotinia cinerea*, 516.*Pectinophora gossypiella*. (See Bollworm, pink.)

Pediculus. (See Lice.)

Pegomyia brassicae. (See Cabbage maggot.)

Pellagra, etiology, 296.

Penicillium—

- expansum*, toxic substances produced by, 243.
- luteum*, heterothallism in, 727.
- roqueforti* strains, factors affecting growth, 172.
- spp., notes, 249.

Pennsylvania—

College, notes, 97, 197, 499, 798.

Station, notes, 97, 197, 499, 798.

Station, report, 195.

Pentalonia nigronervosa, notes, 354.

Pentose determination, 312.

Pepper—

detection of added pepper shells in, 506.

seed-borne diseases, fungicides for, Fla., 840.

Peppermint rust, studies, 547.

Peppers, effect of various lengths of day, 640.

Peridermium—*pini*, notes, 542.*strobi*. (See White pine blister rust.)Permeability in *Beggiatoa mirabilis*, 324.

Peronea, life history studies, 858.

Peroxidase, effect on keeping quality of butter, 612.

Peroxidation and antirachitic vitamin, relation, 109.

Persimmon—

host and reservoir for destructive insects, S.C., 553.

wood, utilization, U.S.D.A., 46.

Persimmons, variety tests, Miss., 739.

Pestalozzia guepini vaccinii, notes, 249.

Petroleum oil for sprays, 254.

Petunia mosaic, notes, 647.

Phaciocephalus cubanus n.sp., description, 858.*Phanerotoma tibialis*, notes, Del., 357.*Pharbitis nil*, deformed leaves in, inheritance, 521.

Pharbitis seeds, ripening processes in, 627.

Pharmacopoeia, German, 775.

Pheasants of Japan, monograph, 552.

Phenacoccus hirsutus in Egypt, 460.

Phenacomys, revision of genus, U.S.D.A., 55.

Phenological—

observations, coordination in, 114.

observations in Italy, 16.

observations, value in agriculture, 114. Service, German, report, 207.

Phenols, germicidal activity, relation to chemical constitution, 572.

Phloeothrips oleae on olives, fumigation, 659.*Phlyctaena linicola*, notes, 49.

Phoma—

bismarckii n.sp., description, 849.*citricarpa*, notes, 851.*fuliginea* n.sp., description, 849.*lavandulae*, notes, 748.

spp., notes, 748.

subcircinata, notes, 148.

Phomopsis—

pseudotsugae in Great Britain, 55.

sp., notes, 249.

Phorbia cepetorum. (See Onion maggot.)

Phoresie, new case of, 760.

Phosphate—

colloidal, properties, 321.

determination in bone, 14.

Phosphate—Continued.

losses by leaching from N.Welsh soils, 721.

rock, as supplement to manure, N.Dak., 422.

rock, availability, 121.

rock, availability, relation to fineness, 624.

rock, effect on soil reactions, 22.

Phosphates—

availability in alkaline soils, Ariz., 213.

effect on crop yield, 623.

international trade in, 626.

Phosphatic slag, effect on lime status of soils, 121.

Phosphoric acid—

for citrus fruits, sources, Fla., 832.

in phosphates, physiological value, 121.

manufacture, volatilization methods, 624.

of calcareous soils, determination, 20. requirements of soils, 710.

use as fertilizer, 422.

Phosphorus—

absorption in intestines, 192.

assimilation from phytin by oats, 624.

excretion, effect of potassium intake, 465.

fertilizing value, Ill., 234.

in milk, utilization, Kans., 896.

in proteins, determination, 504.

in soil solutions, effect of lime and phosphates, 213.

in tomato seed and pulp, 834.

intake of children, Ohio, 493.

metabolism, effect of fresh and heated milk, 292.

metabolism, effect of testes, 664.

nucleus of casein, 709.

rôle in agriculture, 422.

soluble, in cabbage, 108.

water-soluble, field test for, Mich., 321.

Photosynthesis—

daily course in plants, 325.

first sugar of, 425.

sugar as product, 627.

treatise, 424, 626.

water content as a factor, 126.

Phototropism, studies, 325.

Phragmidium rubi-idaei, notes, 748.*Phthorimaea operculella*. (See Potato tuber moth.)*Phyllobius* spp., early stages, 64.*Phyllosticta*—*antirrhini*, notes, 648.*grossulariae*, notes, 748.*phaseolina*, notes, 148.*solitaria* infection, histology of tissues, 453.*ulmicola*, notes, 647.*Phylloxera vastatrix*. (See Grape phylloxera.)

Physalis and cucurbit mosaic intertransmissible, 49.

Physiology—

comparative, textbook, 774.

nutritional, treatise, 289.

Physiology—Continued.

- of taste, 491.
- plant, textbook, 423.
- tropical, studies, 393.
- Physopella vitis*, notes, 249.
- Phythiacystis citrophthora*, notes, 748.
- Phytin, phosphorus in, assimilation by crops, 624.
- Phytomonas hyacinthi*, notes, 541.
- Phytonomus posticus*. (See Alfalfa weevil.)
- Phytophaga destructor*. (See Hessian fly.)
- Phytophthora*—
 - faberi*, notes, 852.
 - infestans*, oospore-like bodies in cultures, 146.
 - (See also Potato blight, late.)
 - nicotianae*, notes, 52.
 - palmivora*, notes, 751.
 - sp. affecting tomatoes, Fla., 143.
 - syringae*, description, 456.

Phytophthora tuber rot of seed potatoes, 547.

Phytoptus vitis, winter treatment, 850.

Phytosterols—

- of corn oil, 310.
- of rice bran fat, 310.
- of wheat germ oil, 310.
- Pickle brine, effect of scum, 206.
- Pickle fermentation, 413.
- Pieris brassicae* and parasite, 661.

Pig—

- breeders' annual for 1926, 766.
- houses and equipment, 684.
- houses, sunlight movable, for Kentucky, 782.
- snouts, protein in, nutritive value, 290.
- Pigeon peas—
 - insects affecting, Fla., 152.
 - varieties as cover crop, Guam, 228.
- Pigeons—
 - color breeding in plumage, 818.
 - crosses in, inheritance of plumage, 128.
 - polyneuritic, nitrogen metabolism, 795.
 - sensitization to foreign proteins, 475.

Pigmentation, animal, morphogenetics, 428.

Pigments—

- in corn, genetic linkage between, 30.
- paints, and varnishes, analysis, 313.
- (See also Anthocyanin and Color inheritance.)

Pigs—

- cost of production, Ill., 284.
- crossbred, studies, Ill., 370.
- crossbreds v. purebreds, Iowa, 265.
- development as animals of economic importance, 668.
- diseases, studies, Ill., 379.
- experiments, Ill., 370.
- fattening experiments, Wash.Col., 566.
- fattening on rye, Mont., 269.
- fattening, protein supplements for, S.C., 268.
- feeding and fattening, 71.
- feeding experiments, Ariz., 764; Ark., 369; Can., 765; Del., 369; Fla., 164, 864; Guam, 265; Ill., 264, 667; Ind., 566; Iowa, 266, 267, 864; Kans.,

Pigs—Continued.

- feeding experiments—continued.
 - 864; Mont., 164; Nebr., 564; Pa., 165; S.C., 565; S.Dak., 565, 667; Wis., 765.
 - (See also Sows, brood.)
 - gains as affected by worm treatment, Ky., 164.
 - hernia in, Wis., 129.
 - Improved Landschwein, litter size, 467.
 - inbreeding v. outbreeding, Iowa, 864.
 - marketing in England and Wales, 387.
 - mineral supplements for, 866; Ky., 164.
 - nutritive requirements, Kans., 864.
 - pasture values and methods for, Kans., 865.
 - prices, factors affecting, U.S.D.A., 184.
 - prices, fluctuations in, Kans., 688.
 - production, English methods, 766.
 - protein supplements, Del., 369.
 - raising, equipment for, 81.
 - seasonal sex-ratio in, 71.
 - shipping, feeding and handling, 761.
 - spring, feeding methods, Kans., 865.
 - statistics, U.S.D.A., 891.
 - suckling, development and maintenance, 467.
 - type test, Ill., 264.
 - (See also Sows and Swine.)
- Pimento cheese, defect of, 674.

Pimpla—

- nucun*, bionomics, cage for study, 854.
- ♂♂, notes, 361.

Pine—

- beetle, western, control problem, 861.
- beetle, western, effect of highway slash on infestation, U.S.D.A., 860.
- blister rust. (See White pine blister rust.)
- geometrid in Bavaria, 856.
- germination, 347.
- loblolly, primer, U.S.D.A., 538.
- oil, western yellow, toxicity to *Lenzites sepiaria*, 655.
- Scotch and Austrian, root studies, 744.
- Scotch, pollen fall in Copenhagen, 347.
- seed, red and white, season for sowing, 538.
- shoot moth, European, outbreak, 458.
- shoot moth, European, parasites of, 361.
- shoots, growth, effect of weather, 207.
- transplants, effect of spacing and root pruning, 538.
- western yellow, self pruning, 355.
- (See also White pine.)

Pineapple—

- bran, feeding value, 69.
- brown spot, notes, 748.
- chlorosis, notes, 354.

Pineapples—

- culture, effect of paper mulch, 537.
- effect of paper mulch, 209.
- insects and pests affecting, 459.
- Pink bollworm. (See Bollworm, pink.)
- Piophilus casei* in cured meats, U.S.D.A., 859.

Pipe joints, threaded, strength tests, 479.
 Piroplasmoses of ruminants, action of trypanblue, 877.
 Piroplasmosis, bovine, relation to *Haemaphysalis vispina*, 877.
 (See also Texas fever.)
 Pisé de terre, use in building construction, 479.
Pissodes dubius, notes, 427.
 Plague fleas, studies, 63.

Plant—

breeding, Ariz., 730.
 breeding in Bombay, 135.
 breeding in Porto Rico, 532.
 breeding in Scotland, 334.
 cell sap, relation to fertilizers, Mich., 318.
 cell wall, structure and development, 697.
 (See also Cells.)
 chromosomes. (See Chromosomes.)
 cuticle, structure, distribution, and function, 216.
 diseases—
 and pests, comparison of control methods, 349.
 and pests in Denmark, 541.
 and plant protection, 46.
 control, Kans., 349.
 due to smut fungi, 843.
 epidemic, 747.
 factors in study of, 747.
 in England and Wales, 242.
 in India, 445.
 in Indiana, 647.
 in Philippines, 748.
 relation to environment, 647.
 relation to soil temperature, Wis., 445.
 relation to soil temperature, equipment for study, 350.
 seed-borne, control, 242.
 (See also Fungi and different host plants.)
 extracts, insecticidal properties, 358.
 fibers, molecular structure, 297.
 growth—
 and light, studies, 325.
 and soil conditions, treatise, 714.
 and solar radiation, 114.
 effect of aluminum, 323.
 effect of bacteria, 220.
 effect of silicon, 323.
 inhibiting and stimulating substances, 124.
 physiology of, 423.
 rate, effect on structure, 423.
 rate, nature of, 626.
 relation to light, 217.
 relation to solar radiation study, 807.
 relation to temperature, 807.
 hosts and parasites, cellular interaction, 452.
 immunity and resistance, studies, 242.
 inspection. (See Nursery inspection.)

Plant—Continued.

materials, nitrogen determination in, 805.
 nutrition, relation to soil colloids, 723.
 nutrition, relation to soil solution, 723.
 nutrition, studies, Kans., 811.
 organs, negatively geotropic, distribution of geotropic sensitivity, 326.
 pathology, 444.
 pathology, laboratory outlines, 891.
 photometer, description, 723.
 physiology in 1925, review of German literature, 414.
 physiology, relation to agronomy, 722.
 physiology, textbook, 423.
 pigmentation. (See Anthocyanin, Pigments, and Pigmentation.)
 propagation, hardwood cuttings, 834.
 protection, bibliography, 647.
 protoplasm, protein properties, 723.
 regeneration, theory, 425, 426.
 successions, relation to soil reactions, 317.
 tissue, catalase activity determination, 814.
 tissue fluids, extraction, 723.
 tissue, isoelectric point for, 424.
 tissues, ashing methods, 13.
 tissues, storage, salt absorption by, 219.
 tissues, vascular, interference of water flow through, 446.
 tumors, effects of X-ray treatments, 629.

Plantain disease, notes, 843.

Plants—

alkali tolerance, Ariz., 512.
 and man, treatise, 123.
 and soils, moisture relationships, 209.
 aquatic, sign of death in, 326.
 as indicators of ground water, 679.
 calcifugous, pH and permeability in, 814.
 composition, Wash.Col., 508.
 cultivated, origin, 33.
 desert. (See Desert.)
 disease resistance to, 450.
 effect of cyanogen compounds, 125.
 effect of daily length of light period, 640.
 effect of light, 813.
 etiolated, effect of brief light exposure, 424.
 fiber. (See Fiber.)
 flowering, effective use, treatise, 646.
 fungus parasites of, 843.
 horticultural, physiology of reproduction, Mo., 440.
 house, requirements for culture, Mich., 743.
 imported, U.S.D.A., 326.
 injurious in Hawaii, 357.
 insect attraction to, 558.
 life of, 626.
 metabolism in, intermediate products, 515.

Plants—Continued.

- nitrate reducing properties, 220.
 not legumes, bacterial symbiosis in, 629.
 oleiferous, composition of seeds, relation to geographical factors, 34.
 ornamental, variety tests, Minn., 531.
 ornamental, winter injury in 1925-26, Iowa, 833.
 permeability. (*See* Permeability.)
 photosynthesis. (*See* Photosynthesis.)
 poisonous, on ranges, Utah, 571.
 poisonous, studies, 572; Wyo., 572.
 (*See also* Livestock poisoning and specific plants.)
 pollination. (*See* Pollination.)
 protein synthesis by, 25.
 rainfall interception by, 414.
 regeneration theory, 324.
 respiration. (*See* Respiration.)
 response to light and temperature, Wis., 725.
 rôle of amids in, 325.
 rôle of asparagine in nitrogen transformations, 325.
 rôle of cane sugar in, 425.
 sex in, change of, 815.
 sodium chloride tolerance, 724.
 sterile culture, 816.
 structure, relation to growth rate, 423.
 sun scald injuries in, 643.
 transpiration. (*See* Transpiration.)
 twining movement in darkness, 518.
 utilization of manure by, 320.
 utilization of water by, 317.
 woody. (*See* Woody.)
 (*See also* Flora and Vegetation.)
- Plasma—
 membrane, studies, 324.
 swelling and growth, 814.
 ultrafilter theory, 324.
- Platygaster* sp., notes, 661.
Plectridium pectinovorum, notes, 847.
Pleosphaeria semeniperda n.sp., notes, 844.
Pleosphaerulina briostana, studies, 649.
Pleospora graminea, notes, 541.
Plesiocoris rugicollis, control, 660.
 Pleuropneumonia in cattle imported into Japan, 174, 175.
Pleurotus ostreatus resistance to sodium fluoride and zinc chloride, 853.
- Plowing—
 electric, 384.
 tests with monopolin and benzol, 80.
- Plows and plowing, 80, 282.
 Plows, draft, notes, Ill., 280.
 Plows, yoking oxen to, 480.
- Plum—
 aphid and brown rot control, 555.
 brown rot, notes, 647.
 die-back, notes, 747.
 diseases, notes, 747.
 roots, Marianna, as peach stock, 141.
 silver leaf, notes, 747.
 trees, blossoming period, factors affecting, 42.

Plum—Continued.

- trees, crown gall affecting, 653.
 withertip, notes, 747.
- Plumage, white, inheritance in pigeons, 128.
- Plums—
 identification of nursery stock, 837.
 varieties, identification, 443.
 variety, notes, S.Dak., 532.
 variety tests, Miss., 739.
- Pluripotenz, use of term, 126.
Plusia spp., notes, 659.
- Plutella maculipennis*, parasite of, 856.
Podisus spinosus, notes, Va., 556.
Podosporiella verticillata, notes, 844.
 Poison baits for crows, 456.
 Poisonous plants. (*See* Plants, poisonous.)
 Poll evil, notes, Kans., 876.
- Pollen—
 abortion in chromosomal types of *Datura*, 127.
 abortive, percentage in plants, 815.
 collection and utilization by bees, N.Y. Cornell, 260.
 dimorphism in corn, 329.
 longevity, 427.
 morphology, index to plant relations, 427.
 mother cells of *Oenothera*, meiosis in, 521.
 tube growth in vitro, effect of temperature, 815.
 tube growth, rôle of salts in, 26.
- Pollination in orchards, 756.
 (*See also* specific plants.)
- Polychrosis viteana*. (*See* Grape berry moth.)
Polydrusus cervinus, early stages, 64.
 Polyembryony, false, in corn, 30.
 Polyneuritis, test of indolinones for, 92.
 Polyploidy, recent experiments, 27.
 Polyporaceae in Bulgaria, 630.
- Polyporus*—
adustus as wound parasite of apple trees, 849.
hispidus, notes, 654.
rubidus n.sp., notes, 851.
schweinitzii resistance to sodium fluoride and zinc chloride, 853.
- Polystictus*—
 spp. resistance to sodium fluoride and zinc chloride, 853.
versicolor on apple wood, 248.
- Polythrincium trifolii*, life history, 749.
- Pomace flies, white-eyed, pigmented facets in, 223.
- Pomelo. (*See* Grapefruit.)
Popillia japonica. (*See* Japanese beetle.)
 Poplar canker, description, 250.
- Poria incrassata*—
 affecting Douglas fir, 250.
 resistance to sodium fluoride and zinc chloride, 853.
- Pork—
 and pork products, statistics, U.S.D.A., 891.
 cost of production, Ill., 385.

Pork—Continued.

- cracklings, protein in, nutritive value, 290.
- production on Wyoming corn, Wyo., 269.
- soft, effect of oil in soy beans, Ill., 370.
- soft, studies, Ark., 369.

Portheria dispar. (See Gipsy moth.)

Porto Rico Station, report, 598.

Potash—

- content of soil, effect of lime and fertilizers, 622.
- determination in mixed fertilizers, 504.
- effect on cotton bolls and foliage, 323.
- effect on purity of sugar cane juice, 524.
- effect on soil reactions, 22.
- effect on yield and quality of grapes, 644.

The first section of the document discusses the political and economic conditions of the United States in the early 1860s. It highlights the growing tensions between the North and the South, particularly regarding the issue of slavery. The text describes how the Southern states, feeling that their interests were being threatened by Northern policies, began to secede from the Union. This led to the formation of the Confederate States of America, which was a direct challenge to the authority of the United States government.

The second section of the document details the military and diplomatic actions taken by the Union in response to the secession. It covers the initial battles, such as the Battle of Fort Sumter, and the subsequent efforts to maintain the integrity of the Union. The text also discusses the international relations of the United States during this period, as the country sought to gain support from other nations against the Confederacy.

The third section of the document focuses on the social and economic impact of the Civil War. It examines how the war affected the lives of ordinary citizens, particularly in the South, where the economy was in a state of collapse. The text also discusses the role of the federal government in managing the war effort and the challenges it faced in terms of resources and logistics.

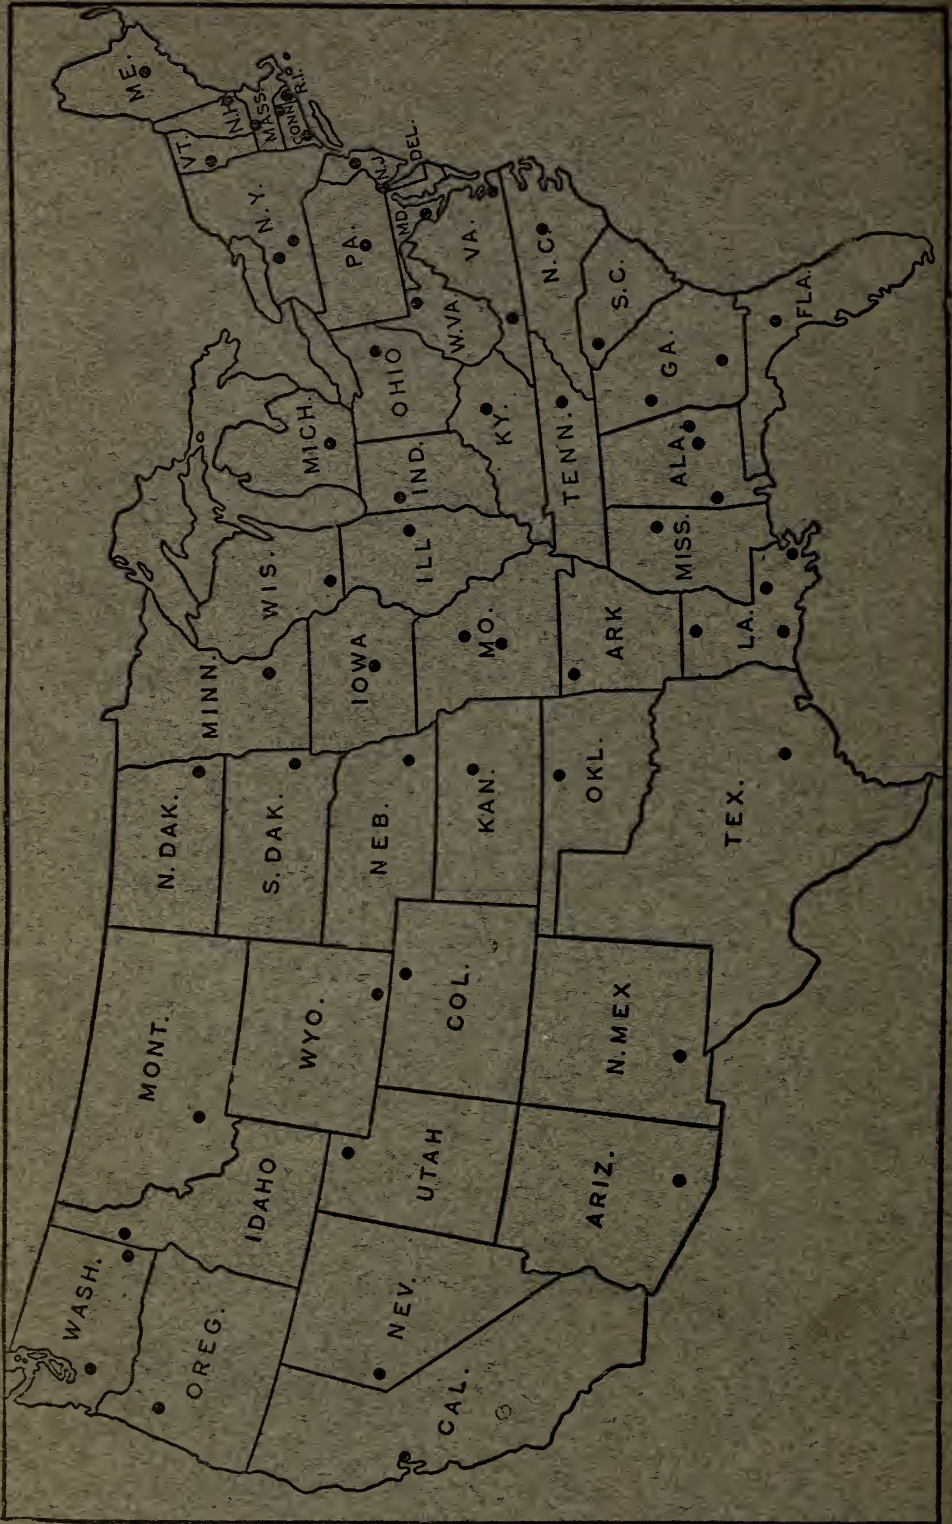

The fourth section of the document discusses the political and economic conditions of the United States in the early 1860s. It highlights the growing tensions between the North and the South, particularly regarding the issue of slavery. The text describes how the Southern states, feeling that their interests were being threatened by Northern policies, began to secede from the Union. This led to the formation of the Confederate States of America, which was a direct challenge to the authority of the United States government.

The fifth section of the document details the military and diplomatic actions taken by the Union in response to the secession. It covers the initial battles, such as the Battle of Fort Sumter, and the subsequent efforts to maintain the integrity of the Union. The text also discusses the international relations of the United States during this period, as the country sought to gain support from other nations against the Confederacy.

The sixth section of the document focuses on the social and economic impact of the Civil War. It examines how the war affected the lives of ordinary citizens, particularly in the South, where the economy was in a state of collapse. The text also discusses the role of the federal government in managing the war effort and the challenges it faced in terms of resources and logistics.
